REVISION

This publication, 90 19 60B, is a revision of the Xerox 530 Computer Reference Manual, 90 19 60A. It incorporates Publication Revision Package, 90 19 60A-2(4/73). The major change to the manual is the addition of Appendix B, "Instruction Timing". Other changes are indicated by a vertical line in the margin of the affected page.

Xerox 530 Computer System

1. XEROX 530 COMPUTER SYSTEM

INTRODUCTION

This high-speed low-cost system is an integrated combination of sophisticated hardware technology (i.e., large- and medium-scale integrated circuits), advanced microprogramming techniques, and field-proven existing software. The Xerox 530 has advantages that are usually found only in large computing systems. It is well suited for a multiusage environment, both real-time and general-purpose applications.

A basic system includes a central processor, main memory, and an independent input/output processor. The basic system may be expanded easily to accommodate the user's requirements (see "Standard and Optional Features"). The CPU's basic instruction repertoire may be increased to include the optional floating-point and field-addressing instructions. Main memory may be expanded by adding more memory modules. Input/output capability may be increased by adding a second input/output processor and additional device controllers and peripheral devices. A large complement of peripheral devices is available for cost effective input/output.

Concurrent multiprogramming capability permits the user to operate one or more fully protected, real-time programs in the foreground while concurrently operating a general-purpose program in the background. Overhead in switching from one task to another is minimized because both hardware and software are specifically designed for rapid context switching. A hardware register permits the software to generate reentrant code efficiently. Therefore, routines common to several programs, whether in foreground or background, need to be stored in memory only once.

The comprehensive field-proven programming package (assemblers, compilers, mathematical and utility routines, and applications) utilizes advanced features in the hardware. These programming systems are easy-to-use programming tools that increase productivity and allow user programs to be written more quickly at lower cost.

Existing Sigma 2 or 3 computer programs may be run on a Xerox 530 computer system. The compatibility of the modular software eliminates reprogramming or requires only minimal upgrading.

Optional field addressing instructions enable efficient operation upon any group of from 1 to 16 contiguous bits in memory without regard to word boundaries. Effectively used, the system provides a bit and byte manipulating capability, a general pushdown stack facility, and the ability to effectively operate on logical structures such as tables and strings. General register instruction capability puts the result of executing one of a prescribed set of arithmetic and logical instructions (see Chapter 3) into a designated general register rather than into the accumulator. This mode of operation permits efficiencies in both code generation and execution times.

To enhance computations using scientific notations, optional floating-point hardware is available.

Xerox 530 systems provide significant reliability, maintainability, and availability improvements over other small- or medium-size computer systems. A remote assistance terminal connection with special software permits remote assistance as an integral part of maintenance.

GENERAL CHARACTERISTICS

The Xerox 530 computer system functions efficiently in a variety of computing environments and applications. Its operating characteristics and features are outlined below:

- Both word and byte organization of memory.
- Memory expandable from 8K words to 64K words in increments of 8K words.
- General-purpose registers to control program operations (all are available to the program). They provide
 - Hardware index registers for preindexing (base address), postindexing, or both (double indexing).
 - Hardware register for subroutine linkages.
 - Double precision accumulator.
 - Program address register.
 - Temporary storage register.
- Rapid context switching to preserve computer environment when switching from one program to another, including automatic status preservation at interrupt.
- Up to two independent Input/Output Processors (IOPs) for high-volume data I/O operations.
 - Up to 28 fully automatic I/O channels operating concurrently with one another.
 - I/O data chaining, for scatter-read and gatherwrite operations.

- Up to two direct memory adapters (optional), each having a maximum information transfer rate of approximately 625,000 words per second.
- Direct input/output of a full word (in parallel) without the use of an I/O channel (optional).
- A real-time priority interrupt system that features
 - Ten internal interrupt levels and up to 30 external interrupt levels. All external and most internal levels can be individually armed, enabled, and triggered by program control.
 - Automatic identification and fast response time.
 - Machine fault register which collects fault status enabling program retrieval.
 - Power Monitor for automatic shutdown in event of power failure and resumption of processing when power returns.
 - System protection that includes both memory write protection and operation protection for foreground programs.
 - Two real-time clocks (one with a choice of resolution) for independent time bases.
- An extensive repertoire that includes these classes of instructions:
 - Memory reference.
 - Conditional branch.
 - Copy (register-to-register).
 - Direct control.
 - Multiply/Divide.
 - Double precision, operations on 32-bit operands.
 - General register capability, which places the result of executing one of a prescribed set of arithmetic and logical instructions into a designated general register rather than in the accumulator.
 - Floating-point (optional).
 - Field addressing (optional), which permits operation on any group of from 1 to 16 contiguous bits in memory without regard to word boundaries, providing bit and byte manipulation, general pushdown stack capability, and ability to operate on logical structures such as tables and strings.

- Instruction characteristics include
 - Only one word of storage required for most instructions.
 - Two levels of indexing and one level of indirect addressing may be invoked individually or simultaneously.
 - Relative addressing (forward and backward).
 - Use of index register 2(B) as a base address register.
 - Direct reference of up to 1024 addresses; 256 addresses beginning with location zero, 256 addresses beginning with the base address, 256 addresses beginning with the current instruction location (relative forward), and 256 addresses backward from the current instruction (relative backward).
- Comprehensive, modular software that expands in capability and speed as the system grows, with no reprogramming required. Existing, field-proven Sigma 2 or 3 computer programs may be run on a Xerox 530 system.
 - Basic Control Monitor (BCM) Operating System for smaller systems including Symbol and Basic FORTRAN.
 - Real-Time Batch Monitor (RBM) Operating System including Extended Symbol, Basic FORTRAN IV, ANS FORTRAN IV, RPG, and SORT.
 - General loading programs.
 - Utility routines.
 - Mathematical routines.
 - General Debug for symbolic program troubleshooting.
 - Concordance program for documentation.
 - System Generation program for creating installation master.
- Standard and special-purpose peripheral equipment including
 - Rapid Access Data (RAD) files: capacities of .75, 1.5, or 3.0 million bytes per storage unit; transfer rate of 188,000 bytes per second; average access time of 17 milliseconds.
 - Magnetic tape units: IBM compatible; 7-track units operating at 37.5 inches per second with transfer rates up to 20,800 bytes per second; 9-track units operating at 75 inches per second with transfer rates up to 60,000 bytes per second.

 Card equipment: reading speeds up to 200 or 400 cards per minute; punching speeds up to 100 cards per minute.

l

- Line printers: fully buffered with speeds from 310 to 1100 lines per minute; up to 132 print positions and up to 91 characters.
- Keyboard/printers: ten characters per second; also available with paper tape reader (20 characters per second) and punch (10 characters per second).
- Paper tape equipment: readers with speeds up to 300 characters per second; punches with speeds up to 120 characters per second.
- Graph plotters: digital incremental, providing drift-free plotting in two axes in up to 300 steps per second at speeds from 30 millimeters to three inches per second.
- Data communications equipment: complete line of character-oriented and message-oriented equipment to connect remote user terminals to the computer system via common carrier lines and local terminals directly.
- Removable disk storage: capacities from 24.5million to 196.6 million bytes; transfer rate of 312,000 bytes per second; average access time of 87.5 milliseconds; one- or two-byte data paths; device pooling.
- Multiprocessing equipment: exchange of critical control and data signals between CPUs and between IOPs on a real-time basis; sharing of I/O devices attached to IOPs; concurrent control of external (DIO) devices.

REAL-TIME AND MULTIUSAGE FEATURES

Real-time applications are characterized by a need for (1) hardware that provides quick response to an external environment, (2) sufficient speed to keep up with the real-time process itself, and (3) input/output flexibility to handle a wide variety of data types at varying speeds.

Multiusage applications, in the context of this computer system, are defined as the combination of foreground (real-time) and background processing techniques into one system. One of the most difficult general computing problems is the real-time application with its severe requirements for extreme speed and capacity. Since the computer system design is on a real-time base, it is well qualified for a mixture of applications in a multiusage environment. Many hardware features that are valuable for real-time applications are equally useful in background processing, but in different ways. The major features that make this system suitable for multiusage applications are described in the following paragraphs. <u>Multilevel</u>, Priority Interrupt System. In a multiusage environment, many elements operate simultaneously and asynchronously. Thus, an efficient priority interrupt system is essential. The source of each interrupt is automatically identified and responded to according to its priority. For further flexibility, each level can be individually disarmed (to discontinue input acceptance) and disabled (to defer responses). Use of the disarm/disable feature makes programmed dynamic reassignment of priorities quick and easy, even while a real-time process is in progress.

Programs that deal with interrupt signals from special equipment often require checkout before the equipment is actually available. To permit simulating this special equipment, any external interrupt level can be "triggered" by the CPU through execution of a single instruction. This capability is also useful in establishing a modified hierarchy of responses. For example, in responding to a high priority interrupt after the urgent processing is completed, it may be desirable to assign a lower priority to the remaining portion so that the interrupt system is free to respond to other critical stimuli. The interrupt routine can accomplish this by "triggering" a lower priority level, which processes the remaining data only after other interrupts have been handled.

READ DIRECT and WRITE DIRECT instructions (described in Chapter 3) allow the program to acknowledge an I/O interrupt condition, read the status of interrupts, and control the individual levels of the priority interrupt system.

Nonstop Operation. When connected to special devices (on a ready/resume basis), the computer maybe excessively delayed if the specific device does not respond quickly. A built-in watchdog timer assures that the computer cannot be delayed for an excessive length of time.

<u>Real-Time Clocks.</u> Many real-time functions must be timed to occur at specific instants. Other timing information is also needed; for example, elapsed time since a given event, or the current time of day. The computer system provides two real-time clocks, one with varying degrees of resolution, to meet these needs. These clocks also facilitate handling separate time bases and relative time priorities.

Rapid Context Switching. When responding to a new set of interrupt-initiated circumstances, a computer system must preserve the current operating environment for continuance later, while setting up the new environment. This changing of environments must be done quickly, with a minimum of "overhead" time costs. In this computer system, relevant information about the current environment (instruction address, status indicators, etc.) is retained in a 32-bit program status doubleword (PSD). When an interrupt occurs, the current PSD is automatically stored at an arbitrary location in memory; and the interrupt-servicing routine begins, following the location into which the PSD is stored. At the end of the interrupt-servicing routine, the PSD is restored and the interrupt level cleared. Memory Protection. Both foreground (real-time) and background programs can be run concurrently in this computer system, since a real-time program is protected against destruction or alteration by an unchecked background program. The protect feature prevents accessing protected areas of memory for specified combinations of reading, writing, and instruction acquisition. The feature guarantees that protected memory cannot be written into by a program residing in unprotected memory. This feature also prevents background programs from executing instructions that could change the I/O system or the protection system. The protection pattern can be changed very quickly.

Input/Output. Because of the wide range of capacities and speeds, the computer system simultaneously satisfies the needs of many different application areas economically, both in terms of equipment and programming.

STANDARD AND OPTIONAL FEATURES

The basic Xerox 530 system has the following standard features:

- A CPU that includes
 - Main memory of 8K words.
 - Extended arithmetic unit (including multiply/ divide).
 - Processor control panel.
 - Two real-time clocks.
 - Memory protection feature.
 - Interrupt master including 16 levels of interrupt priority.
 - Power Monitor.
- Input/Output Processor (IOP) with 16 channels.
- Remote assistance terminal connection.

The system may also include the following optional features:

- Memory in 8K increments to a maximum of 64K.
- Floating-point arithmetic instructions.
- Field addressing instructions.
- Up to 24 external interrupt levels (two optional groups of 12).
- External interface (Direct I/O).
- An additional input/output processor with 12 channels.

- Four ASR, KSR Teletype models available (keyboard/ printer required as operator's console).
- Up to two Direct Memory Attachments.

INFORMATION NOMENCLATURE AND FORMATS

The binary digit, or bit, is the most basic unit of digital information. Depending upon the context, a bit may be described by its binary value (0 or 1), status (off or on), condition (false or true), or other dichotomous attributes. A group of bits that are functionally related is commonly referred to as a "field". Except for fields that are used as operands for field addressing instructions, all fields have fixed formats and parameters (length, boundaries, and positional notations). The parameters of operands (containing from 1 to 16 bits) for field address instructions, described in Chapter 3, are defined by the software. Common "fixed" fields are bits, bytes, words, and doublewords.

The parameters of a fixed word, as illustrated, are 16 contiguous bits, a unique position (0 through 15) for each bit, and word boundaries that occur between bit 15 of one word and bit 0 of the next word.

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 1

The format of a data word for fixed point arithmetic operation is

Bit position 0 contains a sign bit which is 0 if the integer is positive or a 1 if the integer is negative. Bit positions 1–15 represent the value of the integer. Bit position 1 is the most significant bit; bit position 15 is the least significant bit. The binary point is assumed to be on the right boundary.

Negative numbers are expressed in the two's complement.

For logical operations, a word is considered to be 16 bits without sign.

The format for a typical one-word instruction is

Bit positions 0-3 contain the operation code (OP). The operation code and format for each instruction are described in Chapters 3 or 4.

Bit positions 4–7 (R, I,X, S) comprise an address–control field. Refer to "Effective Address Computation" for further details.

Bit positions 8–15 contain a displacement value. Refer to "Effective Address Computation" and Chapters 3 or 4 for further details. When the parameters of a byte (eight contiguous bits) are fixed, a byte is either the most significant half of a word (byte 0) or the least significant half of a word (byte 1). Bit positions within a byte are designated as 0 through 7. Byte boundaries occur between bit 7 of one byte and bit 0 of the next byte. Byte boundaries between bytes of different words coincide with the word boundaries.

		B	yte	0					B	yt	e	1		
0	1	2	3 4	5	6	7	0	1	2	3	4	5	6	7

The parameters of a doubleword are always fixed. The individual bits are numbered 0 through 31.

The first 16 bits (0-15) comprise the most significant word and the second 16 bits (16-31) comprise the least significant word. Doubleword boundaries occur between bit 31 of one doubleword and bit 0 of the next doubleword. The general format of a doubleword is

						-			cai										as			<u> </u>									
0	1	2	3	14	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

A doubleword is always referred to by the address of the most significant word. As part of a Program Status Doubleword, an I/O Control Doubleword, a Field Descriptor required for field addressing instructions, or as part of doubleword operands, the most significant word of a doubleword may have either an even or odd address.

Field Addressing, General Register, and Multiple Register instructions, as described in Chapter 3, are two-word instruction sequences which have the following format:

		1			(2			F	ະບ	nc	ti	or	1	
	C	DF)	R			E I	D							
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

For these instructions, the first word is always a READ DIRECT (Mode 0) instruction. As such, the recommended coding for the first word is as illustrated. The format and coding of the second word is similar to that described above for the typical one-word instruction.

A two-word instruction sequence is also used to exit from an interrupt-servicing routine. The format is similar to that illustrated above, except the first word is coded as a WRITE DIRECT (Mode 0).

The specific format (and recommended coding, when applicable) for each instruction is shown in Chapter 3.

Hexadecimal digits (each equivalent to four bits) are commonly used when referring to binary information. Thus, a four-bit field (e.g., operation code) may be expressed as one hexadecimal character, a byte may be expressed as a string of two hexadecimal digits, a word as a string of four hexadecimal digits, and a doubleword as a string of eight hexadecimal digits. The 16 configurations of four bits and corresponding decimal and hexadecimal digits are shown below.

Binary	Decimal	Hexadecimal
0000	0	0
0001	1	1
0010	2	2
0011	3	3
0100	4	4
0101	5	5
0110	6	6
0111	7	7
1000	8	8
1001	9	9
1010	10	А
1011	11	В
1100	12	С
1101	13	D
1110	14	E
1111	15	F

Note that within this manual (except for format diagrams) a hexadecimal number is displayed as a string of hexadecimal digits enclosed by single quotes and preceded by the letter "X". For example, the binary number 01011010 is expressed in hexadecimal notation as X'5A'.

Although hexadecimal notation is generally used to denote address and data values, decimal notation (where it is more meaningful or customary) may be used. Decimal/hexadecimal conversions are performed by assembler systems.

2. SYSTEM ORGANIZATION

A Xerox 530 computer system, as illustrated in Figure 1, may be comprised of standard and optional units. A functional description of the main memory, central processor unit (CPU), interrupt system, fault system, and interconnecting buses is given in this chapter. The input/ output processors (IOPs) and related input/output instructions are described in Chapter 4. The processor control panel (PCP) and related operating procedures are described in Chapter 5.

BUSES

The various units of the computer system are interconnected by three buses. The "memory" bus connects the Memory Control to all memory modules. The "unit memory" bus is used by all units that require direct access to memory with the exception of the CPU, which connects directly to memory control logic. The "internal Direct I/O (DIO)" bus provides control interconnections between the CPU, interrupt system, external DIO Interface, IOPs, and Direct Memory Adaptors.

MAIN MEMORY

The memory system, which operates synchronously with the other central system components, is composed of magnetic core memory modules (CMM). The storage capacity of each memory module is 8K words, with each word consisting of 16 data bits plus two parity bits (one parity bit for each byte of the word). The memory capacity ranges from a minimum of 8K words to a maximum of 64K words, in 8K word increments.

When the memory system is 64K words, the memory is "wraparound" or circular, where the next location after 64K-1 is location 0. If a system has less than 64K words, any attempt to address a nonexistent location for either a fetch or store operation results in a machine fault interrupt.

The main memory may be accessed via one of four (maximum) access paths to the unit memory bus and by the CPU. Each access path of the unit memory bus is used by an IOP or a Direct Memory Adapter. Memory is addressed identically by all units (including the CPU) and only one memory access may take place during any instant of time. If two or more accesses to memory are attempted simultaneously, the conflict is resolved in accordance with the following priority: Direct Memory Adapter-2 (highest priority), IOP-2, IOP-1, Direct Memory Adapter-1, CPU (lowest priority).

CENTRAL PROCESSING UNIT

The central processing unit (CPU) is the primary controlling element for most system functions. Control intercommunications between the CPU, the interrupt system, external DIO adapter, IOPs, and Direct Memory Adapters are accomplished via the internal DIO bus.

Basically, the CPU consists of registers, an arithmetic logic unit, and a microprogrammed control unit (see Figure 2).

GENERAL REGISTERS

These eight registers are used for various purposes by a program. The address, designation, and function of each general register are as follows:

Address	Designation	Function
0	Z	Zero-Source
1	Р	Program Address
2	L	Link Address
3	Т	Temporary storage
4	х	Index 1 (post-index)
5	В	Index 2 (pre-index or base)
6	E	Extended accumulator
7	А	Accumulator

The general registers are addressable by General Register instructions, COPY instructions, READ DIRECT (Mode 0) instructions, and WRITE DIRECT (Mode 0) instructions, as described in Chapter 3.

PROTECTION SYSTEM REGISTERS

These 16 registers and a protect violation interrupt level comprise a protection system that guarantees the integrity of a master- or executive-mode (foreground) program while another (background) program is concurrently being executed. The protection system provides both operation protection and memory write protection. Each bit in these 16 registers (or words) is associated with a specific block of 256 consecutive locations in main memory. Bit 0 of protection register 0 is associated with main memory locations X'0000' through X'00FF', bit 1 of protection register 0 is

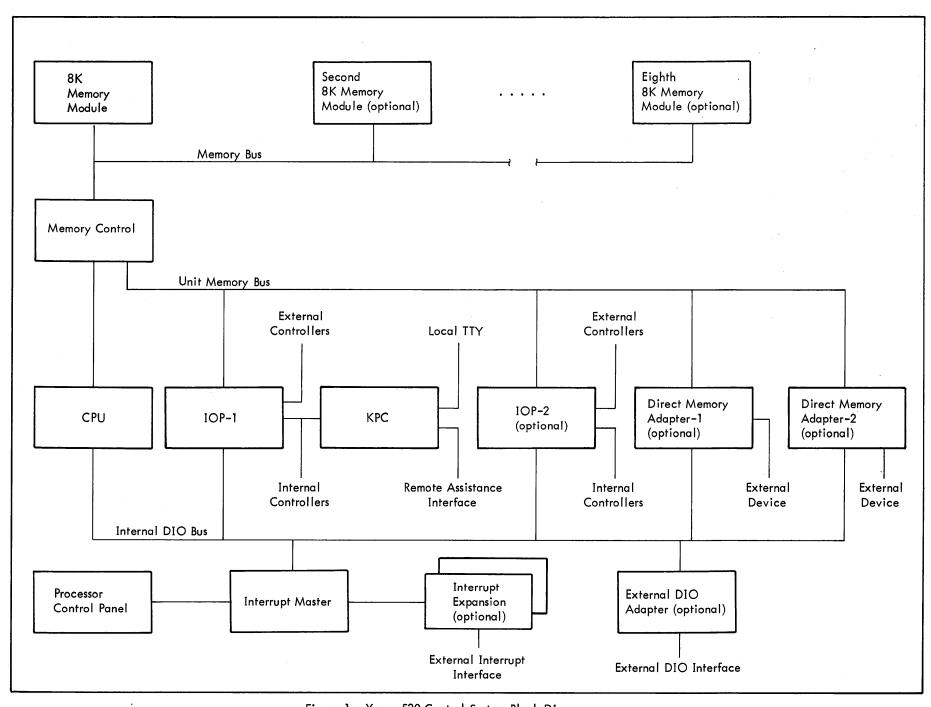

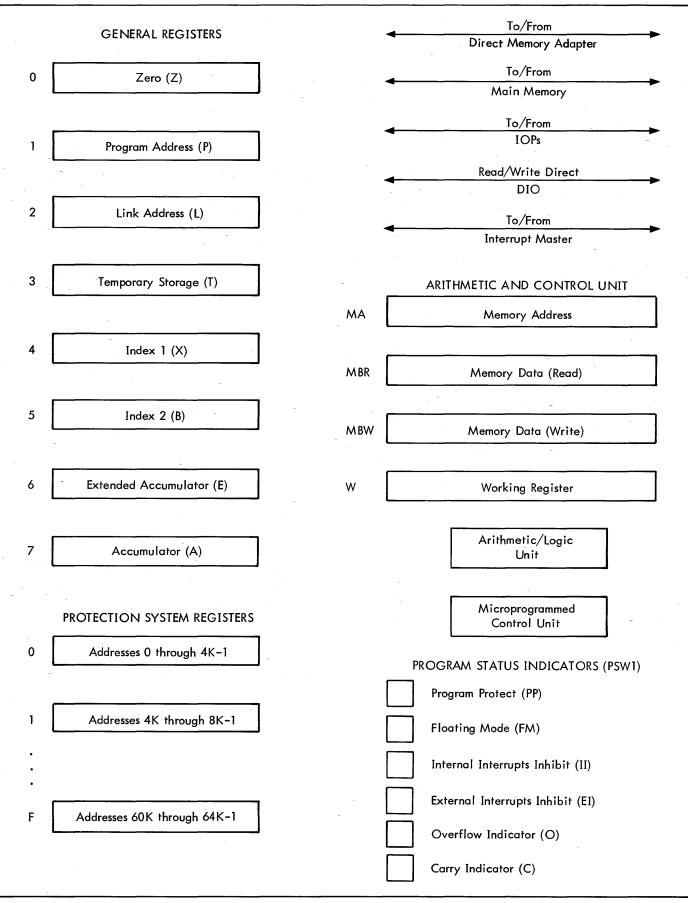

Figure 1. Xerox 530 Central System Block Diagram

7

associated with main memory locations X'0100' through X'01FF', and bit 15 of protection register X'F' is associated with main memory locations X'FF00' through X'FFFF'. A protect bit of "0" designates an unprotected memory block and a protect bit of "1" designates a protected block.

Each of the protection system registers can be loaded individually by executing a WRITE DIRECT (Mode 0) instruction having a function value of X'8r', where r is a hexadecimal digit that designates the protection register that is to be loaded with the contents of the accumulator (A register). Thus, the protect bits for 16 memory blocks (40% words of main memory) can be set up by executing a single instruction.

Operation of the protection system is under control of the key-operated switch on the processor control panel (see Chapter 5). If the protection system is enabled, the following rules apply:

- Privileged READ DIRECT and WRITE DIRECT instructions can be executed only if they are accessed from protected memory. If a privileged instruction is accessed from unprotected memory, the instruction is not executed; instead, the protect violation interrupt level is triggered. Note that two-word instruction sequences for Field Addressing, General Register, and Multiple Register instructions, as well as the SET FLOATING MODE instruction, are not privileged.
- 2. An instruction accessed from unprotected memory can be immediately followed by an instruction accessed from protected memory only in response to an interrupt condition. If an instruction is accessed from protected memory and the immediately preceding instruction was accessed from unprotected memory, the instruction is not executed (unless it is in response to an interrupt condition); instead, the protect violation interrupt level is triggered. This rule applies to branching from unprotected memory to protected memory as well as to executing an instruction in protected memory as the next instruction in normal sequence after an instruction in unprotected memory.
- 3. A STORE ACCUMULATOR (STA) or an INCREMENT MEMORY (IM) instruction can be used to alter protected memory only if the instruction is accessed from protected memory. If an attempt is made to alter protected memory with an instruction accessed from unprotected memory, the operation is not performed; instead, the protect violation interrupt level is triggered.

ARITHMETIC AND CONTROL UNIT

The arithmetic and control unit contains the necessary registers and control logic to access general registers or main memory, to modify instruction addresses, to perform arithmetic and logical operations, to provide indications of computational results, and to preserve interrupt status information. Basically, the arithmetic and control unit consists of registers, program status indicators, and a bussed arithmetic/ logic unit with control provided by a microprogrammed control unit built around a read-only memory.

The MA (Memory Address), MBR (Memory Buffer Read), and MBW (Memory Buffer Write) registers are used to access main memory and provide temporary storage for information read out or written into main memory. The W (Working) register is an internal register and is not programmable; however, its contents may be displayed by the indicators on the processor control panel. The contents of the W register are used when generating effective addresses or effective instructions.

PROGRAM STATUS DOUBLEWORD

Critical control conditions of the CPU are defined by the Program Status Doubleword (PSD). When stored in main memory, the first (most significant) word of a PSD may occupy a location with an even address or an odd address and the second word must occupy the next contiguous location. The format of a PSD, as stored in memory, is as follows:

0	0 PMII000C Program Address
0 1 2 2	4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

The first word of a PSD contains the following six status bits:

Bit Position	Status Bit Designation	Function
8	PP	Protected Program
9	FM	Floating Mode
10	II	Internal Interrupt Inhibit
11	EI	External Interrupt Inhibit
14	0	Overflow
15	С	Carry

Other bit positions are unassigned and must contain a zero. The second word of a PSD contains a program address. The first word of the current PSD is contained within an internal register (PSW); the second word of the current PSD is contained within general register 1 (P). The contents of the first word of the current PSD may be displayed by indicators on the Processor Control Panel.

If the Protected Program (PP) bit is a 1, the current program is located in an area of main memory that is protected; otherwise, the PP bit is a 0.

If the Floating Mode (FM) bit is a 1, the CPU is conditioned to perform Floating Point instructions (optional).

The Internal and External Interrupt inhibit bits determine whether a program interruption can occur. If an interrupt inhibit bit is a 0, the respective set of interrupt levels are allowed to interrupt the program being executed. Conversely; if an interrupt inhibit bit is a 1, the respective set of interrupt levels are inhibited from interrupting the program. Inhibiting interrupt levels also removes them from the interrupt system priority chain, allowing a lower-priority interrupt level to interrupt the program. Note, however, that the first six standard interrupt levels cannot be inhibited; and, that the six integral (external) interrupt levels within the standard group may be controlled with the Internal Interrupt inhibit bit.

The Overflow and Carry bits reflect the results of various operations. For arithmetic operations, the Overflow bit is set to a 1 if an overflow occurred and the Carry bit is set to a 1 if a carry occurred from the most significant (sign) position of the adder. Also, on a subtract operation, the Carry bit is set to a 1 if a "borrow" occurred from the sign position of the adder. For nonarithmetic operations (i.e., I/O operations), the Overflow and Carry bits may reflect status information relevant to the operation. When applicable, the significance of the Overflow and Carry bits are described under each instruction.

When an interrupt occurs, the current PSD is automatically stored in main memory and another PSD is loaded into the PSW and P registers to become the active PSD. The first PSD remains inactive in main memory until it is restored into the PSW and P registers (normally, when exiting from an interrupt-servicing routine).

INTERRUPT SYSTEM

Physically, the modular interrupt system is composed of one standard group of 16 interrupt levels and one or two optional groups, each with 12 external interrupt levels (see Table 1). Thus, a minimum interrupt system has 16 interrupt levels, an intermediate system has 28 levels, and a maximum system has 40 interrupt levels.

Each interrupt level has a unique priority, as listed in column 2, Table 1; a unique memory location, as listed in column 1; and, an assignment, as listed in column 6. Other operational and control characteristics are described in subsequent paragraphs.

STANDARD GROUP

The 16 interrupt levels that comprise the standard group are divided into two functional groups: internal and integral (or external). The functional assignments of each interrupt level is described below. <u>Power-On/Power-Off</u>. These two interrupt levels (memory locations X'100' and X'101') are essential to the power monitor feature. Whenever an imminent power failure is sensed, the power-off interrupt level is triggered and a "power-off" routine is entered that typically stores (saves) volatile information (e.g., registers, program status doublewords, etc.) in main memory, halts all I/O operations, and ends with the CPU in a waiting state. When the power returns to a safe limit, the power-on interrupt level is triggered and a "power-on" routine is entered that typically restores information from main memory and prepares the system to resume processing.

These two interrupt levels operate automatically and continuously. They cannot be inhibited by the Internal Interrupt (II) bit of the Program Status Doubleword. Also, they are not addressable; hence, they cannot be controlled by a WRITE DIRECT instruction or interrogated with a READ DIRECT instruction.

If the power-on and power-off routines are both executed within two milliseconds, the power monitor feature is able to preserve the system, even under the most adverse condition (i.e., a power failure occurs immediately after the power assumed a normal value). This time constraint is imposed because of the following reasons:

- 1. The relative priority of the two interrupt levels precludes the power-off routine from becoming active until the power-on routine is completed (system is restored to a predictable state).
- 2. The primary power will remain at a safe limit for two milliseconds after an imminent power failure has been detected.

Note that when the power-on interrupt is active, the program protect feature is disabled (status of PSD 8, the PP bit, is ignored); and the program may execute instructions from any portion of memory.

Counter 2/Counter 1 (Real-Time Clocks). These two standard interrupt levels may be triggered by pulses from internal or external sources. Counter 1 has a constant frequency of 500 Hz; counter 2 may be set, at installation time, to any of four frequencies - the commerical line frequency, 2kHz, 8kHz, or a user-supplied external signal. When a clock pulse is received by one of the counter interrupt levels (and the level is armed and enabled), the value in the dedicated interrupt location is incremented by 1, and the level is cleared and re-armed. If the value in the dedicated interrupt location is zero after being incremented, the corresponding counter-equals-zero interrupt level is then triggered. All other interrupt levels (including the counterequals-zero interrupt levels) are processed by interruptservicing routines and are designated as "normal" interrupt levels. The counter interrupt levels are addressable (group code X'0') and their status can be read with a READ DIRECT (Mode 1) instruction. They can be armed, disarmed, enabled, disabled, or triggered. Since a counter interrupt level never goes to the active state in normal operations,

Dedi Inter Loca	•	Priority	Read Status Register	Set Active Register	Write Direct Register			PSD Inhibit	Read/Write
Dec.	Hex.	Level	Bit	Bit	Bit	Assignment	Availability	Bit	Group Code

Table 1. Interrupt System

^{tt}Connected and used as an external interrupt level.

the level must not be programmed into that state. These two levels can not be inhibited by the II bit of the Program Status Doubleword. Counter 2 has the third highest priority and counter 1 has the fourth highest priority within the interrupt system. Machine Fault. This interrupt level is triggered whenever the Fault Register is nonzero, signifying that an abnormal condition has been detected and the correct PCP switches are enabled (see "Fault System"). The status of the machine fault interrupt level may be read into bit position 0 of the A register by executing a READ DIRECT (Mode 1) instruction. This interrupt level cannot be controlled with a WRITE DIRECT (Mode 1) instruction nor can it be inhibited by the Internal Interrupt bit of the Program Status Doubleword.

<u>Protection Violation.</u> This sixth highest priority interrupt level is part of the protection system. This interrupt level is triggered if the protection system is enabled when a protection violation is encountered. The status of the interrupt level is read into bit position 1 of the A register whenever a READ DIRECT (Mode 1) instruction is executed. This interrupt level cannot be controlled with a WRITE DIRECT (Mode 1) instruction nor can it be inhibited by the Internal Interrupt control bit of the Program Status Doubleword.

Input/Output. The input/output interrupt level accepts interrupt signals from standard I/O systems. An I/O interrupt-servicing routine must contain an ACKNOWLEDGE I/O INTERRUPT (AIO) instruction, described in Chapter 4, that identifies the source and cause of an I/O interrupt. The I/O interrupt level is addressed with a group code of X'0'. The state of the interrupt level may be read into bit 6 of the A register by executing a READ DIRECT (Mode 1) instruction. The interrupt level may be controlled by a WRITE DIRECT (Mode 1) instruction and bit 6 of the A register. The interrupt level may be inhibited by the Internal Interrupt bit of the Program Status Doubleword.

<u>Control Panel</u>. The control panel interrupt level may be activated by either the INTERRUPT switch on the processor control panel or by a special control sequence on the operator's keyboard (see Chapter 5). The interrupt level can be triggered by the computer operator to initiate a specific routine. The control panel interrupt level is addressed with a group code of X'0'. The state of this interrupt level may be read into bit position 7 of the A register by executing a READ DIRECT (Mode 1) instruction. The interrupt level may be controlled with a WRITE DIRECT (Mode 1) instruction and bit 7 of the A register. The interrupt level may be inhibited by the Internal Interrupt bit of the Program Status Doubleword.

<u>Counter-Equals-Zero.</u> As described under "Counter 2/ Counter 1" above, a counter-equals-zero interrupt level is triggered whenever the corresponding counter (memory location) is incremented to the value of zero as a result of a count pulse. Triggering a counter-equals-zero interrupt level does not affect the counting process. The counter-equals-zero interrupt levels may be addressed with a group code of X'0'. The state of counter two-equals-zero may be read into bit position 10 of the A register and the state of counter one-equals-zero may be read into bit position 11 of the A register when a READ DIRECT (Mode 1) instruction is executed. Both interrupt levels may be controlled with a WRITE DIRECT (Mode 1) instruction and both interrupt levels may be inhibited by the Internal Interrupt bit of the Program Status Doubleword.

Integral Interrupt Levels. There are six integral interrupt levels within the standard group that may be used by the customer as external interrupts. The interrupt levels are addressed with a group code of X'0'. The state of each interrupt level may be read with a READ DIRECT instruction and controlled with a WRITE DIRECT instruction. The interrupt levels may be inhibited by the Internal Interrupt bit of the Program Status Doubleword.

Note: Care must be exercised in assigning integral five and integral six interrupt levels since foreground tasks connected to these interrupts can not utilize certain RBM or BCM monitor services (e.g., requests for monitor input/output services can not be made from these interrupt levels).

OPTIONAL INTERRUPT GROUPS

Each optional interrupt group consists of 12 external interrupt levels. All 24 optional interrupt levels may be inhibited by the External Interrupt bit of the Program Status Doubleword. The first 16 optional interrupt levels are addressed with a group code of X'5' while the last eight optional interrupt levels are addressed with a group code of X'6'. All optional interrupt levels may be read with a READ DIRECT (Mode 1) instruction and controlled with a WRITE DIRECT (Mode 1) instruction.

INTERRUPT LEVEL STATES

Each interrupt level is controlled on an individual basis by three flip-flops. Two of the flip-flops define four mutually exclusive states: disarmed, armed, waiting, and active. The third flip-flop enables or disables the level. The various states and the condition causing changes in state (see Figure 3) are described in the following paragraphs:

<u>Disarmed.</u> When an interrupt level is in the disarmed state, no signal to that interrupt level is admitted; that is, no record is retained of the signal nor is any program interrupt caused by it at any time.

<u>Armed.</u> When an interrupt level is in the armed state (IP flip-flop is on), it is capable of accepting and remembering an interrupt signal. The receipt of such a signal advances the interrupt level to the waiting state (IS flip-flop is turned on).

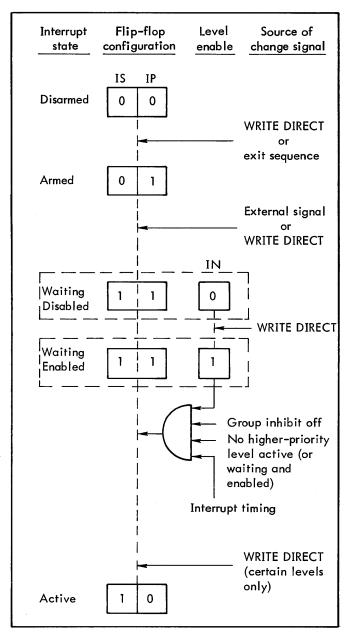

Figure 3. Interrupt Level Operation

<u>Waiting.</u> When an interrupt level in the armed state receives an interrupt signal, it advances to the waiting state, and remains in the waiting state until it is allowed to advance to the active state. (IP and IS flip-flops are both on in the waiting state.)

If the level-enable flip-flop (IN) is off, the interrupt level can undergo all state changes except that of moving from the waiting to the active state. Furthermore, if this flipflop is off, the interrupt level is completely removed from the chain that determines the priority of access to the CPU. Thus, an interrupt level in the waiting state with its level-enable in the off condition does not prevent an enabled, uninhibited interrupt level of lower priority from moving to the active state.

- When an interrupt level is in the waiting state, the following conditions must all exist simultaneously before the level advances to the active state:
 - The level is enabled (i.e., its level enable flip-flop, IN, is a 1).
 - 2. The group inhibit (if applicable) is off (i.e., the appropriate inhibit is a 0).
- 3. No higher-priority interrupt level is in the active state (or is in the enabled, waiting state with its inhibit off).
- 4. The CPU is in an interruptible phase of operation.

Active. When a normal interrupt level (any interrupt level except Counter 2 or Counter 1) meets all of the conditions necessary to permit it to move from the waiting state to the active state, it is permitted to do so by being acknowledged by the computer, which then automatically stores the current PSD at the location specified by the contents of the location associated with the level. The first instruction of the interrupt-servicing routine is then taken from the location following the stored PSD. A new interrupt cannot occur until after the execution of this first instruction.

A normal interrupt level remains in the active state until it is removed from the active state by a specific configuration of the WRITE DIRECT (WD) instruction, followed by an LDX instruction (an "exit sequence"), or if the same active level is armed or disarmed via an appropriate WD instruction. An interrupt-servicing routine can itself be interrupted (whenever a higher-priority interrupt level meets all of the conditions for becoming active) and then continued (after the higher-priority interrupt level is removed from the active state). However, an interrupt-servicing routine cannot be interrupted by a lower-priority interrupt level as long as its interrupt level remains in the active state. Normally, the interrupt-servicing routine returns its interrupt level to the armed state and transfers program control back to the point of interrupt by means of an interrupt routine exit sequence (see "Interrupt Routine Entry and Exit").

READING INTERRUPT LEVELS

Except for the first two interrupt levels (power on and power off), the state of all interrupt levels may be read into the A register by executing a READ DIRECT (Mode 1) instruction. The format of a typical READ DIRECT (Mode 1) instruction is as follows:

-	1	R	I	х	s	C	Dis	pl	ac	:e	me	ən	t		 1			0	c	0	de		0)	T	G	oup	
	0 1 2 3	4	5	6	7	8	9	10	nt	12	13	14	15	0	Τ	2	3	4	5	6	7	8	9	10	nti	2 13	14 15	, †

The effective instruction (shown enclosed within broken lines) is generated from the original instruction in the same manner as an effective address; i.e., the displacement value is modified as specified by the "RIXS" bits. The recommended method for producing the appropriate configuration of the effective instruction is to indirectly address a memory location that contains the appropriate bit configuration.

Bits 0-3 of the effective instruction must be coded as X'1' to specify the interrupt control mode. (See READ DIRECT instruction, Chapter 3, for other control modes.)

Bits 4 and 8-11 must be coded as zeros.

Bits 5, 6, and 7 (the "code" field) may be coded to one of three values to specify a read operation to be performed (read one of the three flip-flops associated with each interrupt level).

Code Field Bits 5 6 7	Read Function
001	Set to a 1 the accumulator bits correspond- ing to each interrupt level that is in the Armed or Waiting state. Read IP flip-flops.)
010	Set to a 1 the accumulator bits correspond- ing to each interrupt level that is in the Waiting (or Active) state. (Read IS flip-flops.)
100	Set to a 1 the accumulator bits correspond- ing to each interrupt level that is Enabled. (Read IN flip-flops.)

The A register bit format for the READ DIRECT (Mode 1) instruction is shown in column 3 of Table 1. For READ DIRECT group code X'0', bit 5 is unused and is indeterminate, and bit 4 is set to 1 if the TRACE toggle switch is in the up (on) position or set to 0 if the TRACE switch is in the down (off) position. An uninstalled interrupt level will respond with a 0 to any of the three read operations.

Bits 12-15 specify which group of interrupt levels is to be interrogated.

Group Field Value	Interrupt Group Interrogated
X'0'	Standard group. Note that the first two interrupt levels (power on and power off) cannot be interrogated with a READ DIRECT instruction.
X'5'	The first 16 (optional) external inter– rupt levels.
X'6'	The last 8 (optional) external inter- rupt levels.

INTERRUPT SYSTEM CONTROL

The interrupt system may be controlled in the following ways:

- If the Internal Interrupt (II) bit of the Program Status Doubleword (PSD) is set to a 1, all interrupt levels within the standard group, except the first six – power on, power off, counter 2, counter 1, machine fault, and protection violation (see Table 1), are inhibited.
- 2. If the External Interrupt (EI) bit of the PSD is set to a 1, all optional interrupt levels are inhibited.
- 3. Except for the first six interrupt levels, each interrupt level (on an individual basis as specified by assigned bits of the A register) may be set to the Active state by executing a WRITE DIRECT (Mode 1) instruction, described below.
- 4. Except for the power on, power off, machine fault, and protection violation interrupt levels, each interrupt level (on an individual basis as specified by assigned bits of the A register) may be armed, disarmed, enabled, disabled, or triggered by executing a WRITE DIRECT (Mode 1) instruction, described below.

The format of a typical WRITE DIRECT (Mode 1) instruction for controlling the interrupt system is as follows:

ſ			0		F	ł	[x	s		Die	spl	a	ce	m	en	it			1		0	c		de			0		G	rou	ıр	F
7	0	1	2	3	4	5	5	6	7	8	9	10	11	12	13	14	15	0	T	2	3	4	5	6	-7'	8	9	10	11	12	13 14	15	1

The effective instruction (enclosed within broken lines) is generated in the same manner as an effective address; i.e., the displacement value of the original instruction is modified by the "RIXS" bits.

The recommended method for producing the appropriate configuration of the WRITE DIRECT effective instruction is to indirectly address a memory location that contains the appropriate bit configuration.

Bits 0-3 of the effective instruction must be coded as X'1' to specify the interrupt control mode. (See "WRITE DIRECT" instruction, Chapter 3, for other control modes.)

Bits 4 and 8-11 must be coded as zeros.

Bits 5, 6, and 7 (the "code" field) may be coded to any one of eight values to specify a function that is to be performed on a group of interrupt levels which is designated by the value of the "group" field (bits 12–15).

Individual interrupt levels within the designated group are further designated by the contents of the A register. The value of the "code" field and associated functions are as follows:

Code Field Bits 5 6 7	Write Function	Group Value
000	A code field (bits 5-7) of 000 will cause each interrupt level corresponding to the 1's in the accumulator to be set to the Active state if that interrupt level was previously in either the Armed or Waiting state. This operation is not	X'0'
	affected by the state of the level en- able flip-flops or the group inhibits. Any levels in the Disarmed state and those levels corresponding to the 0's in	X'5'
	the accumulator are not affected. If the selected interrupt level is already Active, it will be set to the Disarmed state. The Set Active operation causes	X'6'
	the selected level to enter the Active	The relation

		gi

The required values for the "group" field and the designated interrupt groups are as follows:

Group Value	Selected Interrupt Group
X'0'	Standard group. Note, as shown in Table 1, that the power on, power off, machine fault, and protection violation interrupt levels cannot be controlled by a WRITE DIRECT instruction.
X'5'	The first 16 (optional) external interrupt levels.
X'6'	The last 8 (optional) external interrupt levels.

The relationship between the individual bits of the A register and the individual interrupt levels for the WRITE DIRECT instruction is shown in columns 4 and 5 of Table 1. Note that all bits of the A register are not assigned within groups X'0' and X'6'.

INTERRUPT ROUTINE ENTRY AND EXIT

When a normal interrupt level (not counter 2 or counter 1) becomes active, the computer automatically saves the Program Status Doubleword (which contains the protected program indicator, the floating mode bit, internal and external inhibit bits, overflow and carry bits, and the program address). The status information is stored in the location whose address is contained in the dedicated interrupt location. If the FM bit is set, the Scratchpad Floating Accumulator is stored into the Memory Floating Accumulator (three locations identified by the address in memory location 1).

The current value in the program address (P) register is stored in the location following the status information. The significance of the stored program address depends upon the particular interrupt level as follows:

- For the machine fault error or the protect violation, the stored program address is the address of the instruction that was being executed at the time the interrupt condition occurred.
- For all other normal interrupt levels, the stored program address is the address of the next instruction in sequence after the instruction whose execution was just completed at the time the interrupt condition occurred.

After the program address is stored, the next instruction to be executed is then taken from the location following the stored program address. The first instruction of the interruptservicing routine is always executed before another interrupt can occur. Thus, the interrupt-servicing routine may inhibit all other normal interrupt levels so that the routine itself will not be interrupted while in process.

At the end of an interrupt-servicing routine, an exit sequence restores the program status and Scratchpad Floating Accumulator that existed when the interrupt level became active. An exit sequence is a two-word instruction sequence comprised of a WRITE DIRECT (Mode 0) instruction with an effective address of X'00D8' followed immediately by a LOAD INDEX (LDX) instruction with an effective address equal to the address value in the interrupt location for the routine (no interrupt is processed by the CPU between these two instructions). Execution of LDX in an interrupt routine exit sequence does not affect the contents of index register 1 (X).

COUNTER INTERRUPT PROCESSING

The counter interrupt levels are not associated with interruptservicing as such. Instead, an active counter interrupt level is serviced by accessing the contents of the memory location assigned to the interrupt level, incrementing the value in the memory location by 1, and restoring the new value in the same memory location. The processing of an active counter interrupt level does not affect the overflow indicator or the carry indicator. Thus, the on-going program is not affected by a counter clock pulse (other than by the time required for processing) unless the result in the assigned memory location is all 0's after being incremented; in that case, the corresponding counter-equals-zero interrupt level is triggered.

CPU INTERRUPT RECOGNITION

If all other conditions are met and an interrupt level is waiting and enabled, the CPU will recognize and process an interrupt following the completion of any instruction, except between the storing of the PSD and the execution of the next instruction upon entering a normal interrupt subroutine.

Note: Two-word instruction sequences, as required for field addressing, multiple register operations, and general register operations, as well as for exiting from an interrupt-servicing routine, are not completed until the second word of the sequence is executed. Hence, the CPU does not process any interrupts during a two-word instruction sequence.

FAULT SYSTEM

The fault system continuously monitors operations, especially data transfers, within the entire computer system in order to detect abnormal conditions. By executing a READ DIRECT (Mode 1) instruction with an effective address of X'1040' (normally, as part of an MFI subroutine), 16 bits of fault status information (as described below) are copied into the A register and the fault register is reset. By evaluating the fault information, the CPU may perform either a fault logging operation or a fault recovery procedure.

The relatively high priority of the MFI level within the interrupt system permits a fault condition to be reported and processed expeditiously. Note that the MFI level may be interrogated with a READ DIRECT (Mode 1) instruction but cannot be controlled with a WRITE DIRECT instruction or inhibited by the Internal Interrupt inhibit bit of the Program Status Doubleword.

FAULT INFORMATION FORMATS

The general format for the 16 bits of fault information which may be copied into the A register or displayed on the processor control panel is as follows:

	U	Ini	it				A 200			υl					1
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

The "unit" field identifies the source(s) of fault information (see Table 2); the "mode" field permits the various faults which may be detected within each unit to be classified into one of four modes; and the "fault status" field indicates specific faults. In case a memory fault is detected, the fault status field also includes the three most significant bits of memory address associated with the attempted memory access. The mode and fault status information is dependent upon the unit (see Tables 3, 4, and 5).

Table 2. Unit Field (Fault Information)

Bit Position 0 1 2 3 4 5			
000000	No faults.		
1	CPU.		
01	Reserved for special systems.		
0 - 1	IOP-2.		
0 1	IOP-1.		
0 1 -	Interrupt Master or External DIO system.		
0 – – – 1 Direct Memory Adapter.			
Notes: 1. If the unit field indicates a CPU fault (bit 0 is a 1) in combination with one			

Table 2. Unit Field (Fault Information) (cont.)

Notes: (cont.)		or more other unit indicators (bits 1-5), then the mode and fault status information (bits 6-15) is valid only for the CPU. The READ DIRECT instruction (effective address X'1040') that returned this word of fault infor- mation will reset the CPU unit fault indicator (bit 0) to 0, reset the CPU mode and fault status information (bits 6-15), and allow the mode and fault status information from the other units to occupy the fault regis- ter. A second READ DIRECT in- struction should be issued within the Machine Fault Interrupt (MFI) subroutine in order to avoid a second MFI, and in order to process the remaining fault information. (See Note 2.)
	2.	If the unit field indicates a combina- tion of two or more unit indicators (bits 1-5) and the CPU indicator is zero (bit 0 is a 0), then the unit field is valid in pointing to the units that re- ported faults simultaneously, but the mode and fault status information (bits 6-15) is not valid (the information is merged). The READ DIRECT instruction which returned this word of fault infor- mation will reset the entire fault register.

1000 - 0 1 -	Unimplemented instruc tion (class A).			
1000 - 0 1	Unimplemented in- struction (class B).			
	Mode 0			
00	Reserved.			
Notes: 1. If more than one mode of faults exists simultaneously, the CPU Fault Register				

Table 3. Mode and Fault Status Values (CPU Faults) (cont.)

<u>Notes:</u> (cont.)	will report only the highest priority fault mode. The fault modes have the following priority: Mode 1 (highest), Mode 3, Mode 2, Mode 0. In addition, Mode 2 faults are divided into two groups which are mutually exclusive for reporting purposes. The first group consists of two faults: fan not normal and DIO data-in parity error. The second group of Mode 2 faults consists of five faults that may be detected within the microprogrammed operations. The first group of Mode 2 faults have priority over the second group.

2. Within a particular mode, more than one fault may be reported simultaneously.

00 1 -	NIO address parity error.
00 1	NIO data parity error (not reported for data-in parity error).

Table 5. Mode and Fault Status Values (IM and DIO Faults)

Bit Positions 6789101112131415	Description					
0000000100	A pseudo-fault gener- ated whenever the TRACE switch is on and the INTERRUPT switch is activated.					
0000000010	A DIO parity error oc- curred during a WRITE DIRECT instruction to the Interrupt Master. No attempt is made to abort the WRITE DIRECT.					
0000000000	Data parity error oc- curred during an external WRITE DIRECT instruc- tion. No attempt is made to abort the WRITE DIRECT.					
Note: Faults that are detected in the Interrupt Master (IM) or in DIO operations are as listed above. The first two faults are associated with IM operations and the last fault is asso- ciated with DIO operations.						

EFFECTIVE ADDRESS COMPUTATION

The CPU forms the effective address of a memory reference instruction in three basic steps as follows:

 If the R bit (bit 4 of the instruction word) and the S bit (bit 7 of the instruction word) are both 0's, the reference address is equal to the value in the displacement field of the instruction. (This is referred to as "nonrelative" addressing.)

2. If the R bit is a O and the S bit is a 1, the reference address is equal to the value in the displacement field in the instruction plus the 16-bit value (base address) in index register 2. (This is referred to as "preindexing", or "base-relative" addressing.)

3. If the R bit is a 1, the reference address is equal to the 16-bit value in the internal W register (address of the current instruction before it is incremented to the address of the next instruction) plus the value in the low-order nine bits of the instruction, interpreted as a 9-bit two's complement integer. (This is referred to as "self-relative" addressing.)

Step 2 (determine direct address)

- 1. If the I bit (bit 5 of the instruction word) is 0, the direct address is equal to the value of the reference address (as determined in step 1).
- 2. If the I bit is a 1, the reference address is treated as an indirect address; the direct address is the 16-bit value in the location whose address is equal to the reference address. In effect, the indirect address is replaced by the direct address value.

Step 3 (determine effective address)

- 1. If the X bit (bit 6 of the instruction word) is a 0, the effective address is equal to the value of the direct address (as determined by step 2).
- If the X bit is a 1, the effective address is equal to the value of the direct address plus the 16-bit value in index register 1. Note that indexing with X is applied after indirect addressing. (This is referred to as "post-indexing".)

The effective address for an instruction, therefore, is the final 16-bit address value developed for that instruction, starting with the displacement value in the instruction itself. The main memory location whose address equals the effective address value is referred to as the "effective location". Similarly, the contents of the effective location are referred to as the "effective word".

The process of effective address computation is summarized in Table 6. The symbols used in Table 6 are defined as follows:

- R Bit 4 of the instruction.
- I Bit 5 of the instruction.
- X Bit 6 of the instruction.

- S Bit 7 of the instruction.
- D Bits 8-15 of the instruction (Displacement).
- SD Sign extended displacement value.
- (D) Contents of location D.
- (X) Contents of index register 1 (general register 4).
- (B) Contents of index register 2 (general register 5).
- (W) Contents of the internal W register (the address of the current instruction).

Table 6. Effective Address Computation

R	Ι	Х	S	Effective Address
0	0	0	0	D
0	0	0	1	D + (B)
0	0	1	0	D + (X)
0	0	1	1	D + (X) + (B)
0	1	0	0	(D)
0	1	0	1	(D + (B))
0	1	1	0	(D) + (X)
0	1	1	1	(D + (B)) + (X)
1	0	0		(W) + SD
1	0	1		(W) + SD + (X)
1	1	0		((W) + SD)
1	1	1		((W) + SD) + (X)

EFFECTIVE INSTRUCTIONS

An effective instruction is generated in the same manner as an effective address. In the case of effective instructions, the final 16-bit value (or portions thereof) is used to modify or augment the operation code of a given instruction, namely, a READ DIRECT or a WRITE DIRECT instruction that is used separately or as part of a two-word instruction sequence, as described in Chapter 3.

3. INSTRUCTION REPERTOIRE

This chapter describes all CPU instructions, except I/O instructions, which are described in Chapter 4. When applicable, the following information is provided for each instruction:

- 1. Mnemonic the code used by assemblers to produce the instruction's basic operation code.
- 2. Instruction name the instruction's descriptive title.
- 3. Parenthetical note an indication of whether the instruction is optional and/or privileged.
- Format a one- or two-word diagram showing the various subfields of the instruction. The contents of subfields may be represented with descriptive words, symbols, abbreviations, or specific hexadecimal or binary values.

When the configuration of an effective instruction can be ascertained readily from the configuration of the original instruction (i.e., when the "RIXS" bits of the original instruction are coded with zeros, the last eight bits of the effective instruction are equal to the last eight bits of the original instruction, and the leading eight bits of the effective instruction are zeros), the diagram (enclosed with solid border lines) illustrates the format of the instruction as stored in memory or as printed out during a listing.

When the configuration of an effective instruction does not correlate directly with that stored in memory, that portion of the effective instruction which is generated by modifying the contents of the displacement field is enclosed within broken border lines and appears immediately to the right of the original instruction. These portions of the effective instruction are available to the computer via internal registers and are not stored in memory or available for printouts.

Two-word instructions that specify Field Addressing, General Register, and Multiple Register operations must occupy two contiguous memory locations. The diagrams for these instructions show the first instruction word directly above the second instruction word. The address of the first word may be either even or odd.

- 5. Verbal description an explanation of the function or operation performed by the instruction.
- 6. Affected a symbolic listing of registers, storage areas, and indicators that can be affected by the instruction.
 - <u>Note:</u> The instruction address portion of the program status doubleword (P register) is considered affected only if a branch condition can occur as a result of the instruction execution.

7. Timing - see Appendix B.

The following symbols are commonly used in the descriptions:

- A Accumulator (general register 7).
- B Index 2 (general register 5).
- C Carry indicator (PSD bit 15).
- D Displacement (bits 8-15 of instruction).
- E Extended accumulator (general register 6).
- EI External interrupt inhibit (PSD bit 11).
- EL Effective location.
- EW Effective word, or (EL).
- FM Floating Mode bit (PSD bit 9).
- (W) Contents of the internal W register (address of the current instruction).
- II Internal interrupt inhibit (PSD bit 10).
- O Overflow indicator (PSD bit 14).
- P Program address register, next instruction address, (general register 1).
- PP Protected program indicator (PSD bit 8).
- SD Sign extended displacement value.
- T Temporary storage (general register 3).
- X Index 1 (general register 4).
- Z General Register 0.

Other symbols and abbreviations, normally applicable to a limited number of instructions, are defined within the descriptions of those instructions.

MEMORY REFERENCE INSTRUCTIONS

LDA LOAD REGISTER A

			8		R		х				-					
1	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LOAD REGISTER A is a one-word nonfloating-point instruction that loads the effective word into the A register (general register 7).

This format is also used by FLOATING LOAD (see "Floating-Point Instructions").

Affected: (A)

STORE REGISTER A is a one-word nonfloating-point instruction that stores the contents of the A register (general register 7) into the effective location.

This format is also used by FLOATING STORE (see "Floating-Point Instructions").

Affected: (EL)

LOAD INDEX

LOAD INDEX is a one-word instruction that loads the effective word into Index 1 (general register 4). This instruction is not affected by the Floating Mode bit (PSD 9).

Affected: (X)

ADD ADD

ADD is a one-word nonfloating-point instruction that adds the effective word to the contents of the A register and then loads the result into the A register.

The Overflow and Carry indicators are set or reset to reflect the result of the addition as follows:

- O C Significance
- The signs of the two operands are equal but the sign of the result is different.
- A carry occurred from the sign bit position of the adder.
- 0 0 Neither of the above conditions occurred.

This format is also used by FLOATING ADD (see "Floating-Point Instructions").

Affected: (A), O, C

SUBTRACT is a one-word nonfloating-poing instruction that forms the one's complement of the effective word, increments by 1, adds this value to the contents of the A register, and then loads the result into the A register.

The Overflow and Carry indicators are set or reset to reflect the result of the subtraction as follows:

- O C Significance
- The sign of the result in the A register is equal equal to the sign of the effective word, but the sign of the original operand in the A register was different.
- 1 A carry occurred from the sign bit position of the adder, either during incrementing the one's complement or in adding the value to the A register: the magnitude of the 16-bit word in the effective location is equal to or less than the magnitude of the 16-bit word in the A register.
- 0 0 Neither of the above conditions occurred.

This format is also used by FLOATING SUBTRACT (see "Floating-Point Instructions").

Affected: (A), O, C

AND LOGICAL AND

LOGICAL AND is a one-word instruction (not affected by the FM bit) that forms the logical product of the effective word and the contents of the A register, and loads this product into the A register. The logical product contains a 1 in each bit position for which there is a corresponding 1 in both the A register and the effective word; the logical product contains a 0 in each bit position for which there is a 0 in the corresponding bit position of either operand.

Affected: (A)

IM INCREMENT MEMORY

INCREMENT MEMORY is a one-word instruction (not affected by the FM bit) that adds 1 to the effective word and then stores the result in the effective location. The Overflow and Carry indicators are set or reset to reflect the result of the incrementing as follows:

- O C Significance
- The resulting value of the effective word is X'8000' (32, 768).
- The resulting value of the effective word is X'0000'.
- 0 0 Neither of the above conditions occurred.

Affected: (EL), O, C

SHIFT (General)

This general format may be used to specify any of nine oneword SHIFT instructions. The displacement value is modified as specified by the "RIXS" bits to generate the effective instruction. SHIFT instructions are not affected by the Floating Mode bit.

Bits 0 through 6 of the effective instruction must be coded as zeros. Bits 7 through 10 specify one of the following nine shift instructions which are described separately:

78910	Shift instruction specified	Mnemonic
1000	Normalize shift	
0000	Shift Arithmetic Right Single	SARS
0001	Shift Arithmetic Left Single	SALS
0010	Shift Circular Right Single	SCRS
0011	Shift Circular Left Single	SCLS
0100	Shift Arithmetic Right Double	SARD
0101	Shift Arithmetic Left Double	SALD
0110	Shift Circular Right Double	SCRD
0111	Shift Circular Left Double	SCLD

Bits 11 through 15 are used only by the nonnormalized shift instructions (when bit 7 is a 0). These bits contain the "count", a value of 0 through 31, which specifies the number of bit positions of the shift operation.

The NORMALIZE SHIFT instruction must be generated by coding the "RIXS" bits of the original shift instruction with a nonzero value so that bit 7 of the effective instruction is a 1. All other bits of the effective instruction must be 0.

If the initial contents of the Extended Accumulator (E) and the Accumulator (A) are both zero, the instruction exits without changing any register.

If the initial contents of either E or A are not zero, the instruction performs a double-register arithmetic left shift on E and A (bits shifted out of bit position 0 of A shift into bit position 15 of E). The double-register shifting continues until bit positions 0 and 1 of E are different. The contents of the temporary storage register, T (general register 3), are decremented by one for each left shift performed. At the completion of the NORMALIZE SHIFT instruction, the Carry indicator is reset and the Overflow indicator is set if the contents of the T register overflowed (i.e., was decremented past negative full scale during the normalize operation). If the T register has not overflowed, the Overflow indicator is reset.

Affected: (T), (E), (A), O, C

SARS SHIFT ARITHMETIC RIGHT SINGLE

		2			()		0	0	0		C	ou	ni	
0	1	2	3	4	5	6	7	18	9	10	11	12	13	14	15

A SHIFT ARITHMETIC RIGHT SINGLE instruction causes the contents of the A register to be shifted right as many bit positions as specified by the "count" field. The sign position (bit 0) is copied into vacated bit positions on the left. Bits shifted out of bit position 15 are lost. Both Overflow and Carry indicators are reset to zero.

Note: Although the effective instruction may be generated by using other values in bit positions 4 through 15 of the original instruction, the recommended coding is as illustrated above.

Affected: (A), O, C

SARD SHIFT ARITHMETIC RIGHT DOUBLE

A SHIFT ARITHMETIC RIGHT DOUBLE instruction causes the contents of the E and A registers to be shifted right as many bit positions as specified by the "count" field. The two registers are treated as a single 32-bit register. The sign position (bit 0) of the E register is copied into vacated bit

positions on the left of the E register. Bits shifted out of bit position 15 of the E register are copied into bit position 0 of the A register. Bits shifted out of bit position 15 of the A register are lost. Both Overflow and Carry indicators are reset to zero.

<u>Note:</u> Although the effective instruction may be generated by using other values in bit positions 4 through 15 of the original instruction, the recommended coding is as illustrated above.

Affected: (E), (A), O, C

SALS SHIFT ARITHMETIC LEFT SINGLE

		2				0)	0	0	1		С	ວບ	nt	
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

A SHIFT ARITHMETIC LEFT SINGLE instruction causes the contents of the A register to be shifted left as many bit positions as specified by the "count" field. Zeros are copied into the vacated bit positions on the right. Bits shifted out of the sign position (bit 0) are lost.

The Overflow and Carry indicators are set or reset to reflect the result of the shift as follows:

- O C Significance
- 1 The sign bit was changed.
- An odd number of "1" bits were shifted out of the sign bit position.
- 0 0 Neither of the above conditions occurred.
- <u>Note:</u> Although the effective instruction may be generated by using other values in bit positions 4 through 15 of the original instruction, the recommended coding is as illustrated above.

Affected: (A), O, C

SALD SHIFT ARITHMETIC LEFT DOUBLE

			2				0		1	0	1		C	οu	nt	,	
•	0	1	2	3	14	5	6	7	8	9	10	11	12	13	14	15	

A SHIFT ARITHMETIC LEFT DOUBLE instruction causes the contents of the E and A registers to be shifted left as many bit positions as specified by the "count" field. The two registers are treated as a single 32-bit register. Vacated bit positions on the right of A register are filled with zeros. Bits shifted out of bit position 0 of the A register are copied into bit position 15 of the E register. Bits shifted out of bit position 0 of the E register are lost. The Overflow and Carry indicators are set or reset to reflect the result of the shift as follows:

- O C Significance
- 1 The sign bit was changed.
- An odd number of "1" bits were shifted out of the sign bit position.
- 0 0 Neither of the above conditions occurred.
- <u>Note:</u> Although the effective instruction may be generated by using other values in bit positions 4 through 15 of the original instruction, the recommended coding is as illustrated above.

Affected: (E), (A), O, C

SCRS SHIFT CIRCULAR RIGHT SINGLE

2	0	01	0	Count
0 1 2	4 5 6 7	8 9	10	11 12 13 14 15

A SHIFT CIRCULAR RIGHT SINGLE instruction causes the contents of the A register to be shifted right as many bit positions as specified by the "count" field. Bits shifted out of bit position 15 are copied into bit position 0. Both Over-flow and Carry indicators are reset to zero.

Note: Although the effective instruction may be generated by using other values in bit positions 4 through 15 of the original instruction, the recommended coding is as illustrated above.

Affected: (A), O, C

SCRD SHIFT CIRCULAR RIGHT DOUBLE

A SHIFT CIRCULAR RIGHT DOUBLE instruction causes the contents of the E and A registers to be shifted right as many bit positions as specified by the "count" field. The two registers are treated as a single 32-bit register. Bits are shifted out of bit position 15 of the E register into bit position 0 of the A register and from bit position 15 of the A register into bit position 0 of the E register. Both Overflow and Carry indicators are reset to zero.

Note: Although the effective instruction may be generated by using other values in bit positions 4 though 15 of the original instruction, the recommended coding is as illustrated above.

Affected: (E), (A), O, C,

2 0 0 1 1 Count

A SHIFT CIRCULAR LEFT SINGLE instruction causes the contents of the A register to be shifted left as many bit positions as specified by the "count" field. Bits shifted out of the sign position (bit 0) are copied into bit position 15.

- O C Significance
- 0 0 An even number of "1" bits were shifted out of the sign bit position.
- 0 1 An odd number of "1" bits were shifted out of the sign bit position.
- Note: Although the effective instruction may be generated by using other values in bit positions 4 through 15 of the original instruction, the recommended coding is as illustrated above.
- Affected: (A), O,C

SCLD SHIFT CIRCULAR LEFT DOUBLE

Γ		2			(0		1	1	1		С	ου	n	ł
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

A SHIFT CIRCULAR LEFT DOUBLE instruction causes the contents of the E and A registers to be shifted left as many bit positions as specified by the "count" field. The two registers are treated as a single 32-bit register. Bits are shifted from bit position 0 of the A register into bit position 15 of the E register and from bit position 0 of the E register.

- <u>O</u><u>C</u><u>Significance</u>
- 0 0 An even number of "1" bits were shifted out of the sign bit position.
- 0 1 An odd number of "1" bits were shifted out of the sign bit position.

<u>Note:</u> Although the effective instruction may be generated by using other values in bit positions 4 through 15 of the original instruction, the recommended coding is as illustrated above.

Affected: (E), (A), O, C

COMPARE

D RIX S Displacement

COMPARE is a one-word nonfloating-point instruction that algebraically compares the contents of the A register and the effective word, with both operands treated as signed quantities. The Overflow and Carry indicators are set or reset to reflect the result of the comparison as follows:

- O C Result of Comparison
- 0 0 The operand in the A register is algebraically less than the effective word.

- O C Result of Comparison
- 1 0 The operand in the A register is algebraically greater than the effective word.
- 1 1 The operand in the A register is equal to the effective word.

This format is also used by FLOATING COMPARE (see "Floating-Point Instructions").

Affected: O, C

B BRANCH

Γ	4	4		R	I	х				•					
0	1	2	3	14	5	6	7	8	9	10	11	12	13	14	15

BRANCH (a one-word instruction, not affected by FM bit) loads the effective address into the Program Address register (general register 1). Thus, unconditionally, the next instruction is accessed from the location pointed to by the effective address of the BRANCH instruction. (Conditional branch instructions are described below.)

This instruction also resets the Floating Mode (FM) bit (PSD 9) to a zero.

Affected: (P), FM

CONDITIONAL BRANCH INSTRUCTIONS

The eight conditional branch instructions specify conditional, relative branching. Each conditional branch instruction performs a test to determine whether the branch condition is "true".

If the branch condition is true, the instruction acts as a BRANCH instruction coded for self-relative addressing with neither indirect addressing nor indexing. (The conditional branch instructions automatically invoke self-relative addressing.) Thus, if the branch condition is true, the next instruction is accessed from the location pointed to by the effective address of the conditional branch instruction.

If the branch condition is not true, the instruction acts as a "no operation" instruction and the next instruction is accessed from the next location in ascending sequence after the conditional branch instruction.

Each conditional branch instruction is a one-word instruction not affected by the FM bit.

The branch condition is true only if bit 0 of the accumulator (general register 7) is 1.

Affected: (P)

 $6 0 1 0 \pm \text{Displacement}$

The branch condition is true only if the accumulator (general register 7) contains the value X'0000'.

Affected: (P)

BEN BRANCH IF EXTENDED ACCUMULATOR NEGATIVE

		6		1						•					it
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15.

The branch condition is true only if bit 0 of the extended accumulator (general register 6) is 1.

Affected: (P)

BNO BRANCH IF NO OVERFLOW

The branch condition is true only if the Overflow indicator is reset (0). The Overflow indicator is not affected.

Affected: (P)

BNC BRANCH IF NO CARRY

The branch condition is true only if the Carry indicator is reset (0). The Carry indicator is not affected.

Affected: (P)

BIX BRANCH ON INCREMENTING INDEX

BIX adds 1 to the current value in Index 1 (general register 4) and loads the result into Index 1. The branch condition is true only if the result in Index 1 is a nonzero value.

Affected: (X), (P)

BXNO BRANCH ON INCREMENTING INDEX AND NO OVERFLOW

	(5		1					Di						
0	1	2	3	4	5	6	7	8	9	10	ш	12	13	14	15

If the Overflow indicator is set (1), no operation is performed and the computer executes the next instruction in sequence. However, if the Overflow indicator is reset (0), BXNO adds 1 to the current value in Index 1 (general register 4) and loads the result into Index 1; the branch condition is true only if the result in Index 1 is a nonzero value. The Overflow indicator is not affected by this instruction.

Affected: (X), (P)

BXNC BRANCH ON INCREMENTING INDEX AND NO CARRY

		(5		1	0											
ľ	0	T	2	3	4	5	6	7	Т	8	9	10	11	12	13	14	15

If the Carry indicator is set (1), no operation is performed and the computer executes the next instruction in sequence. However, if the Carry indicator is reset (0), BXNC adds 1 to the current value in Index 1 and loads the result into Index 1; the branch condition is true only if the result in Index 1 is a nonzero value. The Carry indicator is not affected.

Affected: (X), (P)

COPY INSTRUCTIONS

A one-word copy instruction specifies operations between any two general registers. The format of a copy instruction is

	7	7	_	0	P	A Ç	A I	C D	1	DR	I S	SR
0	1	2	3	4	5	6	7	8	9	10 11	112	13 14 15

- Bit(s) Function
- 0-3 Bit positions 0-3 are coded as X'7', to specify the copy instruction.
- 4-5 Bit positions 4-5 specify which of four operations(OP) is to be performed. The operations are
 - 4 5 Operation
 - 0 0 Logical AND
 - 0 1 Logical inclusive OR Carry indicators
 - 1 0 Logical exclusive OR not affected.
 - Arithmetic add (Overflow and Carry indicators set as described for the instruction ADD.)

Overflow and

- 6 Bit position 6 specifies whether the current value
 (AC) of the Carry indicator is to be added to the result. If this bit is a 1, the Carry indicator is added to the low-order bit position of the result. If this bit is a 0, the Carry indicator is ignored.
- 7 Bit position 7 specifies whether the value X'0001'
 (AI) is to be added to the result. If this bit is a 1, a 1 is added to the low-order bit position of the result. If bits 6 and 7 are both 1's, the value X'0001' is added to the result (regardless of the current value of the Carry indicator).
- 8 Bit position 8 specifies whether the destination (CD) register (specified by bits 9-11) is to be cleared before the operation called for by bits 4-7 is performed. If bit 8 is a 1, the destination register is initially cleared. If bit 8 is 0, the initial contents of the destination register remain unchanged until the result is loaded into the destination register.
- 9-11 Bit positions 9-11 specify the general register that
 (DR) is to contain the result of the instruction. The
 Overflow and Carry indicators may be affected.
- 12 Bit position 12 specifies whether the source regis-(IS) ter operand (the value in the register specified by bits 13-15) is to be used as it appears in the source register, or is to be inverted (one's complemented) before the operation is performed. If bit 12 is a 1, the inverse of the value in the source register is to be used as the source register operand; however, the value in the source register is not changed. If bit 12 is a 0, the value in the source register is used as the source register operand.
- 13-15 Bit positions 13-15 specify the general register
 (SR) that contains the value to be used (normally or inverted) as the source register operand. A value of 0 in this field designates the value X'0000' as the contents of the source register.

The general registers are identified as follows:

Address	Designation	Function
0	Z	Zero
1	Р	Program address
2	L	Link address
3	Т	Temporary storage
4	х	Index 1
5	В	Index 2 (base address)
6	E	Extended accumulator
7	А	Accumulator

When execution of the copy instruction begins, the P register has already been incremented and contains the address of the next instruction.

Copy instructions are not affected by the Floating Mode bit.

Affected: (DR), O, C

Examples:

Instruction	Effect
X'74F0'	Clear the accumulator (general regis- ter 7) to all zeros.
X'74FF'	Invert (form the one's complement of) the contents of the accumulator.
X'7DFF'	Negate (form the two's complement of) the contents of the accumulator.
X'7C78'	Subtract 1 from the contents of the accumulator.
X'7D7B'	Subtract the contents of the T register from the contents of the accumulator.
X'75A1'	Copy the contents of the P register plus 1 into the L register.

The basic assembly language recognizes the following command mnemonics and generates the appropriate settings for bit positions 0-8 of the copy instruction. The settings for bit positions 9-15 are derived from the argument field of the symbolic line in which the command mnemonic appears. The source register operand is the contents of the source register if the IS bit is 0, or is the inverse (one's complement) of the contents of the source register if the IS bit is 1.

RCPY REGISTER COPY

			7				4		1		D۴	2	I S		SR	
1	0	Т	2	3	4	5	6	7	8	9	10	11	12	13	14	15

RCPY copies the source register operand into the destination register. The Overflow and Carry indicators are not affected.

RADD REGISTER ADD

RADD adds the source register operand to the contents of the destination register and loads the result into the destination register. The Overflow and Carry indicators are set as described for the instruction ADD, based on the register operands and the final result.

ROR logically inclusive ORs the source register operand with the contents of the destination register and loads the result into the destination register. If the corresponding bits in the source register operand and the destination register are both 0, a 0 remains in the corresponding bit position of the destination register; otherwise, the corresponding bit position of the destination register is set to 1. The Overflow and Carry indicators are not affected.

REOR REGISTER EXCLUSIVE OR

		;	7			8	B		0			-	2	I I		
1	0	1	2	3	4	5	6	7	18	9	10	11	12	13	14	15

REOR logically exclusive ORs the source register operand with the contents of the destination register and loads the result into the destination register. If the corresponding bits of the source register operand and the destination register are different, the corresponding bit position of the destination register is set to 1; otherwise, the corresponding bit position of the destination register is reset to 0. The Overflow and Carry indicators are not affected.

RAND REGISTER AND

	;	7			(0		0	1	D۴	2	I S	5	SR		
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	

RAND logically ANDs the source register operand with the contents of the destination register and loads the result into the destination register. If the corresponding bits of the source register operand and the destination register are both 1, a 1 remains in the destination register; otherwise, the corresponding bit position of the destination register is reset to 0. The Overflow and Carry indicators are not affected.

RCPYI REGISTER COPY AND INCREMENT

7			DR	I S	
0 1 2 3	4 5 6 7	8	9 10 11	12	13 14 15

RCPYI copies the source register operand into the destination register and then adds 1 to the new contents of the destination register. The Overflow and Carry indicators are not affected.

RADDI REGISTER ADD AND INCREMENT

	2	7			0)		0	1			5				
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	

RADDI adds the source register operand to the contents of the destination register, increments the result by 1, and loads the final result into the destination register. The Overflow and Carry indicators are set, as described for the instruction ADD, based on the register operands and the final result.

RORI REGISTER OR AND INCREMENT

	7	7			5	;		0			13	SR
0	1	2	3	4	5	6	7	8	9	10 11	12	13 14 15

RORI logically ORs the source register operand with the contents of the destination register, increments the result by 1, and loads the final result into the destination register. The Overflow and Carry indicators are not affected.

REORI REGISTER EXCLUSIVE OR AND INCREMENT

	7	7				9				DF	1	5	L		
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

REORI logically exclusive ORs the source register operand with the contents of the destination register, increments the result by 1, and loads the final result into the destination register. The Overflow and Carry indicators are not affected.

RANDI REGISTER AND AND INCREMENT

RANDI logically ANDs the source register operand with the contents of the destination register, increments the result by 1, and loads the final result into the destination register. The Overflow and Carry indicators are not affected.

RCPYC REGISTER COPY AND CARRY

	7	7				6				DF		•			
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

RCPYC copies the source register operand into the destination register and then adds the current value of the Carry indicator to the result in the destination register. The Overflow and Carry indicators are not affected.

RADDC REGISTER ADD AND CARRY

RADDC adds the source register operand to the contents of the destination register, adds the current value of the Carry indicator to the result and loads the final result into the destination register. The Overflow and Carry indicators are set, as described for the instruction ADD, based on the register operands and the final result.

7	,			6	5		0		DR	2	I S		SR	
0 1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

RORC logically inclusive ORs the source register operand with the contents of the destination register, adds the current value of the Carry indicator to the result, and loads the final result into the destination register. The Overflow and Carry indicators are not affected.

REORC REGISTER EXCLUSIVE OR AND CARRY

		;	7			,	4		0				Э	1		1
ľ	0	1	2	3	4	5	6	7	18	9	10	11	12	13	14	15

REORC logically exclusive ORs the source register operand with the contents of the destination register, adds the current value of the Carry indicator to the result, and loads the final result into the destination register. The Overflow and Carry indicators are not affected.

	7	7			2	2		0		DF	٢	I S		SR	
0	1	2	3	14	5	6	7	8	9	10	11	12	13	14	15

RANDC logically ANDs the source register operand with the contents of the destination register, adds the current value of the Carry indicator to the result and loads the final result into the destination register. The Overflow and Carry indicators are not affected.

RCLA REGISTER CLEAR AND ADD

		7	7			C	2				DR		I S		SR	
1	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

RCLA clears the destination register, adds the source register operand to the cleared destination register, and loads the final result into the destination register. The Overflow and Carry indicators are reset to 0.

RCLAI REGISTER CLEAR, ADD, AND INCREMENT

		7	7			0)		1		DR		I S	5	SR	
1	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

RCLAI clears the destination register, adds the source register operand to the cleared destination register, increments the result by 1, and loads the final result into the destination register. The Overflow and Carry indicators are set, as described for the instruction ADD, based on the contents of the source register operand and the final result.

RCLAC REGISTER CLEAR, ADD AND CARRY

	7	7				E				DR		-	E .		
0	1	2	3	14	5	6	7	8	9	10	11	12	13	14	15

RCLAC clears the destination register, adds the source register operand to the cleared destination register, adds the current value of the Carry indicator to the result, and loads the final result into the destination register. The Overflow and Carry indicators are set, as described for the instruction ADD, based on the contents of the source register operand and the final result.

MUL MULTIPLY

MULTIPLY is a one-word nonfloating-point instruction that multiplies the effective word by the contents of the A register (treating both words as signed integers), loads the 16 high-order bits of the doubleword product into the extended accumulator (general register 6), and loads the 16 low-order bits into the A register (general register 7). Neither overflow nor carry can occur; however, the Carry indicator is set equal to the sign of the doubleword product.

This format is also used by FLOATING MULTIPLY (see "Floating-Point Instructions").

Affected: (E), (A), C

DIV DIVIDE

DIVIDE is a one-word nonfloating-point instruction that divides the doubleword contained within the extended accumulator (general register 6) and the accumulator (general register 7) by the effective word (treating both words as a signed integer).

If the absolute value of the quotient is equal to or greater than 32,768 (2¹⁵), the Overflow indicator is set to 1 and the instruction is terminated with the contents of the extended accumulator and the accumulator unchanged from their previous values, and the Carry indicator is set equal to the sign of the dividend.

If the absolute value of the quotient is less than 32,768, the Overflow indicator is reset to 0, the integer quotient is loaded into the accumulator (general register 7), the integer remainder is loaded into the extended accumulator, and the Carry indicator is set equal to the sign of the remainder. (The sign of the remainder is the same as the sign of the dividend.)

This format is also used by FLOATING DIVIDE (see "Floating-Point Instructions").

Affected: (E), (A), O, C

The format of a typical WRITE DIRECT instruction is

			- "									Γ'				Γ.								-	-	-		ţ
l à	Ы	т	$ _{\vee}$	c	5										_			C			ti							L
	ĸ	I	^	P	יוטן	splo	C	er	ne	in	Г	1	VIC	ba	e			Г	U	10		or	1					Į.
0 1 2 3	4	5	6	7	8 9	2 10	11	12	13	14	15	<u>ہ</u>		2	3	1	5	7	71	8	9	10	11	12	13	14	15	t

The "mode" and "function" fields for the effective instruction are generated in the same manner as described under "Effective Address Computation" in Chapter 2. As listed in Table 7, each of the 16 different values of the mode field designates a different portion of the computer system that is to perform a control or nonarithmetic operation as specified by the value of the accompanying function field. The number of different operations that can be specified within each mode (or for each portion of the computer system) varies for each mode. The WRITE DIRECT instruction, as the READ DIRECT instruction, generates a set of control or nonarithmetic instructions that may be comprised of 16 subsets of instructions (one subset of instructions for each mode or for each portion of the computer system). The subset of instructions for WRITE DIRECT (Mode 0) operations is described within subsequent paragraphs. The subsets of instructions for other modes of operations (Mode 1 through Mode F) are appropriately referenced.

WRITE DIRECT (MODE 0) INSTRUCTIONS

The format and recommended coding for a typical WRITE DIRECT (Mode 0) instruction is as follows:

	0)			С)			F	un	ci	ic	'n		
Ļ	1	2	3	4	5	6	7	8	9	10	π	12	13	14	15

The WRITE DIRECT (Mode 0) instruction is unique in that if the "RIXS" bits are coded as zeros, the "function" may be encoded directly into the original instruction. Otherwise, the "RIXS" bits and the "displacement" field of the original instruction must be coded with appropriate values, which will result in an effective instruction as shown below.

Mo	de	Portions of Computer System	
Value	Title	Designated	General Control or Nonarithmetic Operation Performed
0	Internal Computer Control	CPU and/or IOP	 Copy contents of the A register into a specified general register or I/O channel register. Copy contents of bit position 0 of specified general register or I/O channel reg-
			ister into the Overflow indicator and then reset bit position 0 of the same register to 0.
			3. Copy contents of the A register into one of the 16 protection registers.
			 Load program status information from the A register into the first word of the Program Status Doubleword.
			5. Prepare IOP-1 or IOP-2 to operate as directed by a subsequent diagnostic program.
			6. Set the Wait flip-flop to a 1 and cause the CPU to stop computations.
			7. Prepare the CPU to exit from an interrupt-servicing routine.
			8. Set or reset the External Interrupt (EI) and/or the Internal Interrupt (II) program status indicators.
1	Interrupt Control	Interrupt system	As described in Chapter 2, under "Interrupt System".
2 thru E	Direct Control	DIO system using stan- dard Xerox computer products	Exchange control information and data as required to perform an I/O operation. Note that each mode value is assigned to a different DIO system. (Refer to the Xerox Com- puter Systems/Interface Design Manual, 90 09 73, for further details.)
F	Direct Control	Specially designed equipment	Exchange control information and data as required to perform an I/O operation. (Refer to the Xerox Computer Systems/Interface Design Manual, 90 09 73, for further details.)

Table 7. WRITE DIRECT Mode Values and General Functions Performed

The function field may have any one of 256 different values; however, as described subsequently, not all values of the function field are assigned as part of an effective instruction (see Appendix C).

<u>Note:</u> Attempting to use a function value that is not assigned results in an "unimplemented instruction" fault.

For explanation purposes, the function values associated with WRITE DIRECT (Mode 0) instructions are divided into four functional groups, which are also readily differentiated by the values of the first two bits of the function field (bits 8 and 9), as described below.

Function field

bit positions	- Control or nongrithmetic
89	operation performed

0 0 All function values within this group (except X'00') are assigned. Each value designates a specific general register or an I/O channel register that is to be loaded with the contents of the A register.

The format and recommended coding for a WRITE DIRECT instruction to perform the above described operation is as follows:

	()			()		0	Ū			_	R		
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

The "DR" field is coded with the address of the general or I/O channel register that is to be the destination register for the load operation.

Affected: (DR)

0 1 All function values within this group (except X'40') are assigned. Each value designates a specific general register or an I/O channel register whose bit position 0 content is to be copied into the Overflow indicator and then reset to a 0.

The format and recommended coding for a WRITE DIRECT instruction to perform the above described operation is as follows:

The "SR" field is coded with the address of the general or I/O channel register that is to be the source register from which bit position 0 is to be copied.

Affected: O and bit 0 of source register.

Function field bit positions

89

0

1

 Control or nonarithmetic operation performed

Within this group of function values (X'80'-X'BF') only the first 16 function values (X'80'-X'8F') are assigned. Each of the assigned values permits one of the 16 protection registers to be loaded with the contents of the A register.

The format and recommended coding for a WRITE DIRECT instruction to load a protection register is as follows:

		(C			()				8			Ρ	R	
1	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

The protection register, as specified by the value of the "PR" field is loaded with the contents of the A register.

Affected: (protection register)

1

1

Within this group of function values (X'C0'-X'FF'), only the function values described below are assigned.

The format and recommended coding for a WRITE DIRECT instruction to load the program status indicators of the first word of the Program Status Doubleword from the A register is as follows:

	()			()			(С			(C	
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Bit positions 8-11, 14, and 15 of the PSD are loaded with the contents of corresponding bit positions of the A register. If this instruction causes the Protected Program bit (PSD 8) to change from a 1 to a 0, the next instruction is in protected memory, and the protection feature is operative. A protection violation interrupt occurs when the next instruction is accessed.

Affected: Program Status Indicators

The format and recommended coding for a WRITE DIRECT instruction to prepare IOP-1 to operate as directed by a subsequent diagnostic program is as follows:

The format and recommended coding for a WRITE DIRECT instruction to prepare IOP-2 to operate as directed by a subsequent diagnostic program is as follows:

i		()			()			(С				3		
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	·

Function field bit positions

89

1 1

operation performed The format and recommended coding for a WRITE DIRECT instruction to

Control or nonarithmetic

for a WRITE DIRECT instruction to set the Wait flip-flop and cause the CPU to stop communication is as follows:

The Wait flip-flop may be reset to a 0 by any interrupt activation (including counter interrupts) or by moving the COMPUTE switch to the IDLE position.

Affected: Wait flip-flop

A WRITE DIRECT instruction is also used as the first word of a two-word instruction sequence for exiting from an interrupt-servicing routine. The format and recommended coding for the two-word instruction sequence is as follows:

0	0	D	8
с	RIXS	Displa	cement
0 1 2 3	4 5 6 7	8 9 10 11	12 13 14 15

The first instruction word sets the exit condition by inhibiting all normal interrupt levels. The second instruction word, whose effective address must be equal to the address in the interrupt location for the desired interrupt-servicing routine, performs the following:

- Loads the Program Status Doubleword from the first two words of the interrupt routine (bits 0-7, 12, and 13 of the effective doubleword are ignored).
- 2. If the FM bit of the new PSD is set, the SFA is loaded from the Memory Floating Accumulator.

Function field	
bit positions	

<u>8</u>	<u>9</u>
1	l
(co	ont.)

Control or nonarithmetic operation performed

3. Arms the highest-priority active interrupt level.

- 4. Resets the exit condition.
- Affected: PP, FM, II, EI, O, C, (P), SFA, highest-priority interrupt level

The format and recommended codings for setting and resetting the External and Internal interrupt control bits of the Program Status Doubleword and the significance of each are as follows:

Reset the External Interrupt bit to 0.

Reset the Internal Interrupt bit to 0.

Reset both the External and Internal Interrupt bits to 0.

Set the External Interrupt bit to 1.

Set the Internal Interrupt bit to 1.

Set both the External and Internal Interrupt bits to 1.

RD READ DIRECT (partially privileged, partially optional)

The format of a typical READ DIRECT instruction is

1		_	_		1	т	Т			-					-		-				T	-		+	-		-	_		٦
	1		1		R	1	ιþ	K	S	1	Dis	spl	a	ce	m	er	nt	٨	٨c	de	e İ			F	ur	nct	io	n		
	0	1	2	3	4	5	+	6	7	8	9	10	П	12	13	14	15	0	'n	2	зŤ	T :	5 6	7	8	<u>9</u> 1	0 ī	1112	13 I	4 15

The "mode" and "function" fields for the effective instruction are generated in the same manner as described under "Effective Address Computation", in Chapter 2. As listed in Table 8, each of the 16 different values of the mode field designates a different portion of the computer system that is to perform a control or nonarithmetic operation as specified by the value of the accompanying function field. The number of different operations that can be specified within each mode (or for each portion of the computer system) varies for each mode. Thus, the READ DIRECT instruction generates a set of control or nonarithmetic instructions that may be comprised of 16 subsets of instructions (one subset of instructions for each mode or for each portion of the computer system). The subset of instructions for READ DIRECT (Mode 0) operations is described within subsequent paragraphs. The subsets of instructions for the other modes of operations (Mode 1 through Mode F) are appropriately referenced.

Table 8. READ DIRECT Mode Values and General Functions Performed

N	Node	Portions of Computer System	
Value	Title	Designated	General Control or Nonarithmetic Operations Performed
0	Internal Computer Control	CPU and/or IOP	 Copy contents of specified general register or I/O channel register into the A register. I/O operations via an IOP, as described in Chapter 4. Copy contents of DATA switches into the A register. Condition the CPU to perform a. Field Addressing instructions. b. General Register instructions. c. Doubleword instructions. d. Multiple-Register instructions. e. Floating-Point instructions.
			 Copy the first word of the Program Status Doubleword into the A register and then conditionally alter the program status indicators.
1	Interrupt Control	Interrupt System	As described in Chapter 2, under "Interrupt System".
2 thru E	Direct Control	DIO system using stan- dard Xerox computer products	Exchange control information and data as required to perform an I/O operation. Note that each mode value is assigned to a different DIO system. (Refer to the Xerox Computer Systems/Interface Design Manual, 90 09 73, for further details.)
F	Direct Control	Specially designed equipment	Exchange control information and data as required to perform an I/O operation. (Refer to the Xerox Computer Systems/Interface Design Manual, 90 09 73, for further details.)

READ DIRECT (MODE 0) INSTRUCTIONS

The format and recommended coding of a typical READ DIRECT (Mode 0) instruction is as follows:

		1			(0				Fu	no	cti	or	n	
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

The READ DIRECT (Mode 0) instruction is unique in that if the "RIXS" bits are coded as zeros, the "function" may be encoded directly into the original instruction. Otherwise, the "RIXS" bits and the "displacement" field of the original instruction must be coded with appropriate values, which will result in an effective instruction as shown below.

Γ		1		F	ł	I	x	s	T	Di	sp	la	се	m	en	t		0)			6)	1		Ē	U	nc	tic	n.		
0	1	2	3	1.		5	6	7	ta	9	10	11	1 12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30 3	1

The function field may have any one of 256 different values; however, as described below, not all values of the function field are assigned as part of an effective instruction (see Appendix C).

<u>Note</u>: Attempting to use a function value that is not assigned results in an "unimplemented instruction" fault.

For explanation purposes, the function values associated with a READ DIRECT (Mode 0) instruction are divided into four functional groups, which are also readily differentiated by the values of the first two bits of the function field (bits 8 and 9), as described below.

Function field bit positions

15	Control or nonarithmetic
-	operation performed

<u>8</u> <u>9</u>

0 0

All values within this group (except X'00') are assigned. Each value designates a specific general register or an I/O channel register whose contents are copied into the A register.

The format and recommended coding for a READ DIRECT instruction to perform the above described operation is as follows:

The "SR" field is coded with the address of the general or I/O channel register that is to be the source register for the copy operation.

Affected: (A)

Except for function values X'41', X'42', X'44', X'48', X'50', and X'60', which

Function field

bit positions
<u>8</u>9

1 0

1 1

Control or nonarithmetic operation performed

0 1 (cont.)

are interpreted as I/O instructions, all function values within this group (X'40'-X'7F') are unassigned. The I/O instructions are described in Chapter 4.

Function values within this group (X'80'-X'BF') are assigned as follows:

1. Function value X'80' causes the contents of the DATA switches to be copied into the A register.

The format and recommended coding for a READ DIRECT instruction to perform the above described operation is as follows:

1	0	8	0
0 1 0 0	1 6 1 7	0 0 10 11	12 12 14 16

Affected: (A)

- Excluding function values X'80', X'81', and X'87', the function values associated with field addressing instructions are X'N0', X'N1', X'N7', X'N8', X'N9', and X'NF', where "N" may have a hexadecimal value of 8, 9, A, or B. See "Field Addressing Instructions" for further details.
- Function values X'8A'-X'8E' are associated with general register operations, other than the A register. See "General Register Instructions" for further details.
- Function values X'92'-X'96', X'9A'-X'9D', X'A2'-X'A4', X'AA', X'AB', and X'B2' are associated with LOAD/ STORE MULTIPLE and doubleword instructions as described under "Multiple-Register Instructions".
- 5. Function value X'9E' causes the Floating Mode control bit (PSD9) to be set to a 1. See "Floating-Point Instructions" for further details.
- The following function values are unassigned: X'81'-X'87', X'A5', X'A6', X'AC'-X'AE', X'B3'-X'B6', and X'BA'-X'BE'.

Within this group of function values (X'C0'-X'FF'), all values except the nine described below are unassigned. Each of

1.

0

Function field

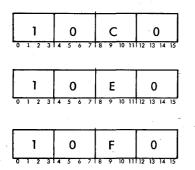

bit positions

 $\frac{8}{1}$ $\frac{9}{1}$

(cont.)

Control or nonarithmetic operation performed

the assigned values may be encoded into the original READ DIRECT instruction, as illustrated; their format and recommended coding, and the operations performed are as follows:

Each of the three READ DIRECT instructions causes the first word of the program Status Doubleword to be copied into the A register.

-	_									-							
-			I			0)			E	-			4			
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	

Copy first word of PSD into A register; then reset the External Interrupt (EI) bit, PSD 11, to zero.

		1		-	C)			E				8		
ب	1	2	3	4	5	6	7	8	0	10	11	12	13	14	15

Copy the first word of PSD into A register; then reset the Internal Interrupt (II) bit, PSD 10, to zero.

-		1			C)			E			-	C	2	
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Copy the first word of PSD into A register; then reset the EI and II bits (PSD 10 and 11) to zeros.

Copy first word of PSD into A register; then set the EI bit to 1.

1	0	F	8			
0 1 2 3	4 5 6 7	8 9 10 11	12 13 14 15			

Copy first word of PSD into A register; then set the II bit to 1. Function field bit positions

> 8<u>9</u> 11 (cont.)

Control or nonarithmetic

operation performed

Copy first word of PSD into A register; then set the EI and II bits to 1's.

Note that bit positions within the first word of the Program Status Doubleword that do not contain program status indicators are copied into the A register as zeros.

GENERAL REGISTER INSTRUCTIONS

All general register instructions, as listed below, are provided as part of the standard repertoire of instructions.

Instruction Name	Mnemonic
Load Word	LW
Store Word	STW
Add Word	AW
Subtract Word	SW
Logical And	AND
Compare Word	CW

		1	ł			0				0.	C	0	1	G	FR	
		8	3		R	I	х	s	Displaceme							
1	0	1	2	3	14	5	6	7	8	.9	10	п	12	13	14	15

LOAD WORD is a two-word instruction sequence that loads the effective word (specified by the effective address of the second instruction word) into register L, T, X, B, or E (specified by the GR field of the first instruction word).

No interrupts are processed by the CPU between these two instruction words.

The GR field must be coded with a value of 010 through 110 and is interpreted as follows:

<u>GR Code</u>	Significance							
010	General Register 2 (L)							
011	General Register 3 (T).							
100	General Register 4 (X)							

GR Code

Significance

101 General Register 5 (B).

110 General Register 6 (E).

Affected: (L, T, X, B, or E)

STW STORE WORD

	1				()		10)	Q	0	1	G	;R	
	•		R	I	х	s	D	is	pl	a	ce	m	er	et.	
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

STORE WORD is a two-word instruction sequence that stores the contents of register L, T, X, B, or E (specified by the GR field of the first instruction word) into the effective location (specified by the effective address of the second instruction word).

No interrupts are processed by the CPU between these two instruction words.

The GR field must be coded with a value of 010 through 110 and is interpreted as follows:

GR Code	Significance
010	General Register 2 (L).
011	General Register 3 (T).
100	General Register 4 (X).
101	General Register 5 (B).
110	General Register 6 (E).

Affected: (EL)

AW ADD WORD

1		()		10	001	GR
А	R	I	х	S	Dis	place	ment
0 1 2 2	4	5	6	7	9 0	10 11 12	12 14 15

ADD WORD is a two-word instruction sequence that adds the effective word (specified by the effective address of the second instruction word) to the contents of register L, T, X, B, or E (specified by the GR field of the first instruction word) and then loads the result into the specified register. The Overflow and Carry indicators are set as described below.

O C Significance

1

- The signs of the two operands are equal but the sign of the result is different.
- A carry occurred from the sign bit position of the adder.

0 0 No overflow or carry occurred.

No interrupts are processed by the CPU between these two instruction words.

The GR field must be coded with a value of 010 through 110 and is interpreted as follows:

GR Code	Significance
010	General Register 2 (L).
011	General Register 3 (T).
100	General Register 4 (X).
101	General Register 5 (B).
110	General Register 6 (E).

Affected: (L, T, X, B, or E), O, C

SW SUBTRACT WORD

		1			()		1	10 001					GR			
		B		R	I	х	S	D)is	ijΡ	a	ce	m	en	t		
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15		

SUBTRACT WORD is a two-word instruction sequence that forms the one's complement of the effective word (specified | by the effective address of the second instruction word), increments by 1, adds this value to the contents of register | L, T, X, B, or E (specified by the GR field of the first instruction word), and then loads the result into the specified register. The Overflow and Carry indicators are set as described below.

- O C Significance
- The sign of the result in the register is equal to the sign of the effective word but the sign of the original operand in the register was different.
 - A carry occurred from the sign bit position of the adder, either during incrementing the one's complement or in adding the value to the specified register: the 16-bit magnitude in the effective location is equal to or less than the 16-bit magnitude in the specified register.

0 0 No overflow or carry occurred.

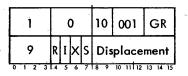

No interrupts are processed by the CPU between these two instruction words.

The GR field must be coded with a value of 010 through 110 and is interpreted as follows:

GR Code	Significance
010	General Register 2 (L).
011	General Register 3 (T).
100	General Register 4 (X).
101	General Register 5 (B).
110	General Register 6 (E).

Affected: (L, T, X, B, or E), O, C

AND LOGICAL AND

LOGICAL AND, as a two-word instruction sequence, forms the logical product between the effective word (specified by the effective address of the second word) and the contents of register L, T, X, B, or E (specified by the GR field). The logical product is loaded into the specified register.

No interrupts are processed by the CPU between these two instruction words.

The GR field must be coded with a value of 010 through 110 and is interpreted as follows:

GR Code	Significance
010	General Register 2 (L).
011	General Register 3 (T).
100	General Register 4 (X).
101	General Register 5 (B).
110	General Register 6 (E).

Affected: (L, T, X, B, or E)

CW COMPARE WORD

1	(0-	10	001	GR					
D	RI	хs	Displacement							
0 1 2 3	4 5	6 7	8 9	10 11 12	13 14 15					

COMPARE WORD is a two-word instruction sequence that algebraically compares the contents of register L, T, X, B, or E (specified by the GR field) and the effective word (specified by the second instruction word). Both operands are treated as signed quantities.

The Overflow and Carry indicators are set or reset according to the result of the comparison as follows:

O C Significance

1

- 0 0 The operand in the specified register is algebraically less than the effective word.
 - 0 The operand in the specified register is algebraically greater than the effective word.
- 1 1 The operand in the specified register is equal to the effective word.

No interrupts are processed by the CPU between these two instruction words.

The GR field must be coded with a value of 010 through 110 and is interpreted as follows:

GR Code	Significance
010	General Register 2 (L).
011	General Register 3 (T).

GR Code	Significance
100	General Register 4 (X).
101	General Register 5 (B).
110	General Register 6 (E).

Affected: O, C

MULTIPLE-REGISTER INSTRUCTIONS

All nonfloating-point multiple-register instructions, as listed below, are included with the standard repertoire of instructions.

Instruction Name	Mnemonic
Load Multiple	LDM
Load Double	LDD
Store Multiple	STM
Store Double	STD
Double Add	DAD
Double Subtract	SDB
Compare Double	CPD

LDM LOAD MULTIPLE

1		. (0		1	10 ××× y						уу				
8	R	I	х	s	D)is	pl	a	ce	me	en	t				
0 1 2 3	1	5	6	7	8	9	10	11	12	13	14	15				

LOAD MULTIPLE is a two-word instruction sequence that loads two or more consecutive registers with a corresponding number of effective words from consecutive memory locations. The function field of the first instruction word specifies the number of registers to be loaded (value of X field), and the address of the first register (value of Y field). (The X and Y fields must be coded with values of 010 through 110.) The effective address of the second instruction word points to the first effective word in memory.

No interrupts are processed by the CPU between these two instruction words.

Affected: (specified registers)

LDD LOAD DOUBLE

1	0	10 010 110
8	RIXS	Displacement
0 1 2 3	4 5 6 7	8 9 10 11 12 13 14 15

LOAD DOUBLE is a LOAD MULTIPLE instruction in which the X field is coded with a value of 2 (specifying the number of registers to be loaded) and the Y field is coded with a value of 6 (specifying the extended accumulator as the first register to be loaded). The effective address of the second instruction word points to the first effective word in memory.

No interrupts are processed by the CPU between these two instruction words.

Affected: (E), (A)

STM STORE MULTIPLE

1	0	10	ххх	ууу			
E	RIXS	Dis	place	ment			
0 1 2 3	4 5 6 7	8 9	10 11 12	13 14 15			

STORE MULTIPLE is a two-word instruction sequence that stores the contents of specified registers into specified effective locations. The function field of the first instruction word specifies the number of registers to be stored (value of X field), and the address of the first register (value of Y field). (The X and Y fields must be coded with values of 010 through 110.) The effective address of the second instruction word points to the first word of the effective location.

No interrupts are processed by the CPU between these two instruction words.

Affected: (specified effective locations)

STD STORE DOUBLE

	1	I			(0		10	C	0	1	0	110			
	1			R	I	х	S	Displaceme							t	
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	

STORE DOUBLE is a STORE MULTIPLE instruction in which the X field is coded with a value of 2 (specifying the number of registers) and the Y field is coded with a value of 6 (specifying the extended accumulator as the first register). The effective address of the second instruction word points to the first of two effective locations in which the contents of the E and A registers will be stored as a doubleword. No interrupts are processed by the CPU between these two instruction words.

Affected: (two specified effective locations)

DAD DOUBLE ADD

	1				(0		10 010 110						
	A	٩		R	I	х	s	Dis	place	ment				
0	1	2	3	14	5	6	7	8 9	10 11 12	13 14 15				

DOUBLE ADD is a two-word instruction sequence that adds the contents of the effective locations (as specified by the effective address of the second instruction word) to the contents of the extended accumulator and accumulator (E and A registers), as specified by the function field of the first instruction word, and then loads the result into the extended accumulator.

The Overflow and Carry indicators may be set as follows:

- O C Significance
- The signs of the two operands are equal but the sign of the result is different.
- A carry occurred from the sign bit position of the adder.
- 0 0 No overflow or carry occurred.

No interrupts are processed by the CPU between these two instruction words.

Affected: (E), (A), O, C

DSB DOUBLE SUBTRACT

	. 1				(D		1	0	0	10)	110			
	E	3		R	I	x	s	D)is	β	a	ce	me	en	t	
0	0 1 2 3				5	6	7	8	9	10	11	12	13	14	15	

DOUBLE SUBTRACT is a two-word instruction sequence that forms the one's complement of the effective doubleword (as specified by the effective address of the second instruction word), increments by 1, adds this value to the contents of the extended accumulator and accumulator (as specified by the function field of the first instruction word), and then loads the result into the extended accumulator and accumulator. The Overflow and Carry indicators may be set as follows:

O C Significance

- The sign of the result in the extended accumulator is equal to the sign of the effective doubleword but the sign of the original operand in the extended accumulator was different.
 - I A carry occurred from the sign bit position of the adder, either during incrementing the one's complement or in adding the value to the extended accumulator and accumulator: the 32bit magnitude of the effective doubleword is equal to or less than the 32-bit magnitude in the extended accumulator and accumulator.

No interrupts are processed by the CPU between these two instruction words.

Affected: (E), (A), O, C

CPD COMPARE DOUBLE

1	0	10	010	0 110				
D	RIXS	Dis	place	ment				
0 1 2 3	4 5 6 7	8 9	10 11 12	13 14 15				

COMPARE DOUBLE is a two-word instruction sequence that algebraically compares the 32 bits of the extended accumulator and accumulator (E and A registers) and the effective doubleword. The function field of the first instruction word specifies the number of general registers involved (the value of the X field must be 2), and the address of the first register (the value of the Y field must be 6). The effective address of the second instruction word points to the effective doubleword. Both operands are treated as signed quantities.

The Overflow and Carry indicators are set or reset according to the result of the comparison as follows:

- O C Result of Comparison
 - 0 The 32-bit operand in the extended accumulator and accumulator is algebraically less than the effective doubleword.
 - 0 The 32-bit operand in the extended accumulator and accumulator is algebraically greater than the effective doubleword.
 - 1 The 32-bit operand in the extended accumulator and accumulator is equal to the effective doubleword.

No interrupts are processed by the CPU between these two instruction words.

Affected: O, C

0

1

1

FLOATING-POINT INSTRUCTIONS

The floating-point feature consists of the hardware implementation of seven optional floating-point instructions:

Instruction Name	Mnemonic
Floating Load	FLD
Floating Store	FST
Floating Add	FAD
Floating Subtract	FSB
Floating Multiply	FMP
Floating Divide	FDV
Floating Compare	FCP

Each of these floating-point instructions is evoked by executing the corresponding fixed-point instruction (LOAD, STORE, ADD, SUBTRACT, MULTIPLY, DIVIDE, or COMPARE) with the Floating Mode (FM) bit in the Program Status Doubleword (PSD) set to a 1 (see "Floating-Point Mode Control").

All floating-point instructions operate on the Scratchpad Floating Accumulator (SFA) described below and a specified three-word floating operand contained within three contiguous memory locations. (See "Floating-Point Numbers" for other characteristics of floating-point operands.) The effective address of the floating-point instruction, which may be generated using any mode of effective address computation available to memory reference type of instructions, points to the first location containing the floating operand. Except for FLOATING STORE and FLOATING COMPARE instructions, the results of all floating-point instructions replace the original contents of the SFA and the floating operand in main memory is not affected. For FLOATING STORE instructions, the contents of the SFA is stored into the floating operand. For FLOATING COM-PARE instructions, neither the contents of SFA nor the floating operand is modified.

FLOATING-POINT NUMBERS

An extended precision floating-point number consists of the three consecutive 16-bit words with the following format:

First word:

s		I	Ma	DS.	0	f`	ma	an	tis	sso	Ľ				
0	1	2	3	4	5	6	7	8	9	10	111	12	13	14	15

Second word:

Third word:

The first two words contain a signed two's complement mantissa with the binary point following bit 0 of the first word. The third word contains a signed two's complement integer binary exponent. A floating-point number (N) has the following formal definition:

1. A nonzero floating-point number has the value

 $N = (mantissa)(2^X)$

where X represents the binary exponent.

- A positive floating-point number with a mantissa of zero and a binary exponent of zero is called a "true" zero. All floating-point operations that produce a zero result will always produce a "true" zero.
- 3. A positive nonzero floating-point number is normalized if and only if the mantissa is contained in the interval

 $1/2 \le \text{mantissa} < 1$

- 4. A negative floating-point number is formed by taking the two's complement of the mantissa of its positive representation. The binary exponent portion of a negative floating-point number is identical to the binary exponent portion of its positive representation.
- 5. A negative floating-point number is normalized if and only if the floating-point number formed by taking the two's complement of the mantissa is a normalized positive floating-point number.

By this definition, a floating-point number of the form

First word:

Second word:

Third word: Binary Exponent = X

is not normalized because the two's complement of the mantissa is not a normalized positive number. Since all floatingpoint arithmetic instructions produce a result that is either a true zero or a normalized floating-point number, whenever a number of the form shown above might be generated, it is converted by the hardware into a floating-point number of the form

First word:

Second word:

Third word: Binary Exponent = Y

where the binary exponent \boldsymbol{Y} is one greater than the binary exponent \boldsymbol{X} .

Table 9 contains examples of floating-point numbers.

Table	9.	Floating-Point	Numbers

	Extended F	Precision Floating-Point	Number
	Ma	antissa	Exponent
$= (1/2) \times 2^{1}$ $= - (1/2) \times 2^{1}$ $= - (1/2) \times 2^{1}$ $= - (5/8) \times 2^{4}$ $= - (5/8) \times 2^{4}$ $= - (5/8) \times 2^{7}$ $= - (25/32) \times 2^{7}$ $= - (25/32) \times 2^{7}$ $= -2^{-31} \times 2^{32767} \approx 10^{9864}$	First Word	Second Word	Third Word
0 (called true zero)	×'0000'	×'0000'	×'0000'
$+1 = (1/2) \times 2^{1}$	×'4000'	×'0000'	X'0001'
$-1 = -(1/2) \times 2^{1}$	X'C000'	×'0000'	X'0001'
$+10 = (5/8) \times 2^4$	X'5000'	×'0000'	X'0004'
$-10 = -(5/8) \times 2^4$	X'B000'	×'0000'	X'0004'
$+100 = (25/32) \times 2^7$	X'6400'	×'0000'	X'0007'
$-100 = -(25/32) \times 2^7$	X'9C00'	×'0000'	X'0007'
$(1-2^{-31}) \times 2^{32767} \approx 10^{9864}$	X '7FFF'	X'FFFF'	X'7FFF'
$(1-2^{-31}) \times 2^{-32768} \approx 10^{-9864}$	X'7FFF'	X'FFFF'	X'8000'

EXPONENT UNDERFLOW AND OVERFLOW

Exponent underflow occurs during any floating-point arithmetic operation whenever an arithmetic operation results in a binary exponent that is a larger negative number than can be properly represented in two's complement form in 16 bits including the sign. Whenever exponent underflow occurs during the operation of a floating-point instruction, the result of that instruction will be a true zero.

Exponent overflow occurs during any floating-point arithmetic operation whenever an arithmetic operation results in a binary exponent that is a larger positive number than can be properly represented in 16 bits including the sign. An attempt to divide by zero during a floating-point divide operation will also cause exponent overflow. Whenever exponent overflow occurs during the operation of a floatingpoint instruction, the result of that instruction will be the largest possible normalized floating-point number with the same sign as the correct result of the instruction would have had if exponent overflow had not occurred. If the correct result of the floating-point instruction would have been positive and exponent overflow occurs, the hexadecimal result of the instruction will be

first word:	X'7FFF'
second word:	X'FFFF'
third word:	X'7FFF'

If the correct result of the floating-point instruction would have been negative and exponent overflow occurs, the hexadecimal result of the instruction will be

first word:	X'8000'
second word:	X'0001'
third word:	X'7FFF'

The Overflow (O) indicator is set or reset at the conclusion of each arithmetic floating-point instruction to indicate whether exponent overflow or underflow occurred during that instruction as follows:

- O Result of Instruction
- 0 Neither exponent overflow nor exponent underflow occurred.
- Exponent overflow or exponent underflow occurred.

FLOATING-POINT MODE CONTROL

Hardware-implemented floating-point operations are automatically invoked whenever bit 9 (FM) of the Program Status Doubleword is set to a 1. The LOAD, STORE, ADD, SUB-TRACT, MULTIPLY, DIVIDE, and COMPARE instructions are automatically modified into FLOATING LOAD, FLOATING STORE, FLOATING ADD, FLOATING SUB-TRACT, FLOATING MULTIPLY, FLOATING DIVIDE, and FLOATING COMPARE, respectively. All other instructions are not affected by the state of FM.

The FM bit is set to a 1 whenever any of the following operations are performed:

1. By executing a SET FLOATING MODE (SFM) instruction. The format and required coding of the SFM instruction is as follows:

			1			C)		-	9			E			
1	0	_ ł	2	3	4	5	6	7	8	9	10	11	12	13	14	15

The SFM instruction is a nonprivileged READ DIRECT (Mode 0) instruction that can be executed from either protected or unprotected memory. The "RIXS" bits of the instruction must all be coded as zeros.

If an attempt is made to set FM when the floating-point option is not installed, bit 9 of the PSD remains a zero and machine fault interrupt is triggered.

- If bit 9 of the A register (general register 7) is a 1, it will be copied into the FM position whenever the privileged WRITE DIRECT instruction with a final effective address of X'00C0' is executed. This WD instruction can only be executed from protected memory.
- 3. If the FM bit was a 1 at the time it was stored (saved) by an interrupt entry procedure, the FM bit will be restored as a 1 when exiting the interrupt routine (a WRITE DIRECT instruction with a final effective address of X'00D8' followed immediately with a LOAD INDEX (LDX) instruction). Bit 9 of the effective word for the LDX instruction contains the FM bit that was saved.

Hardware-implemented floating-point operations are automatically inhibited whenever the FM bit of the PSD is reset. The FM bit is reset to 0 by any of the following conditions or operations:

- Whenever a general CPU reset signal is generated (occurs when primary power is initially applied to the system and when the RESET switch on the Processor Control Panel is raised).
- 2. By executing an unconditional BRANCH(B) instruction from either protected or unprotected memory.
- If bit 9 of the A register (general register 7) is a zero, it will be copied into the FM position whenever the privileged WRITE DIRECT instruction with a final effective address of X'00C0' is executed. This WD instruction can only be executed from protected memory.

4. When an interrupt level moves from the waiting state to the active state as the result of the occurrence of an interrupt that alters the normal sequence of instructions, the state of the FM bit will be saved with the rest of the current PSD at the memory location specified by the contents of the interrupt location. After saving the previous state of the FM bit, the FM bit is reset.

The status of the FM bit (as well as other program status indicators) can be read under program control by privileged READ DIRECT (Mode 0) instructions that copy the first word of the Program Status Doubleword into the A register.

SCRATCHPAD FLOATING ACCUMULATOR

A Scratchpad Floating Accumulator (SFA), consisting of three 16-bit high-speed registers, is used in conjunction with all hardware floating-point instructions. The contents of the SFA can be modified and read only by executing hardware floating-point instructions. For all hardware floating-point instructions, the SFA contains one of the initial arguments prior to execution of the instruction. At the conclusion of all arithmetic floating-point instructions, the initial argument in SFA is replaced by the result of the floating-point instruction.

Whenever an operation occurs that causes the FM bit of the PSD to be reset, the contents of SFA is automatically saved in memory by storing it in three contiguous memory locations (called Memory Floating Accumulator). This automatic transfer will occur regardless of how the FM bit is reset (including interrupt entry) except that no transfers will occur when the general CPU reset signal occurs. The address of the first location of the Memory Floating Accumulator is specified by the contents of memory location 1.

Note: If the program is operating under Basic Control Monitor (BCM) or Real-Time Batch Monitor (RBM), the Memory Floating Accumulator is the first three locations in the user's temporary stack in memory.

Whenever an operation occurs that causes the FM bit of the PSD to be set, the contents of the Memory Floating Accumulator replaces the previous contents of SFA. This automatic transfer will occur regardless of how the FM bit is set, including interrupt exit where the interrupted program being restored was operating with the FM bit set.

The contents of SFA will also be transferred automatically to the Memory Floating Accumulator when the FM bit is set and the COMPUTE switch on the Processor Control Panel (PCP) is switched from RUN or STEP to IDLE.

When the COMPUTE switch is switched from IDLE to RUN or STEP and the FM bit is set, the contents of the Memory Floating Accumulator replaces the previous contents of SFA prior to an instruction execution. The availability of the contents of SFA in memory when the CPU is in an IDLE state facilitates testing and debugging floating-point operations from the PCP.

FLD FLOATING LOAD (optional)

If FM is set, the execution of the following instruction will result in a floating-point load operation:

The effective address of the instruction is the address of the first word of the floating operand. FLD loads the floating operand into SFA. The first word of the floating operand also replaces the previous contents of the A register (general register 7).

Affected: SFA, (A)

FST FLOATING STORE (optional)

If FM is set, the execution of the following instruction will result in a floating-point store operation:

The effective address of the instruction is the address of the first word of the floating operand. FST replaces the floating operand with the contents of SFA. The first word of SFA also replaces the previous contents of the A register (general register 7).

Affected: Floating operand, (A).

FAD FLOATING ADD (optional)

If FM is set, the execution of the following instruction will result in a floating-point add operation:

	/	4		R	I	х	s	Displacement
0	1	2	3	4	5	6	7	8 9 10 11 12 13 14 15

The effective address of the instruction is the address of the first word of the floating operand. FAD adds the floating operand to the contents of the SFA and then loads the result into SFA. The first word of the result also replaces the previous contents of the A register (general register 7).

Prior to the FAD, SFA and the floating operand must both contain either a normalized nonzero number or a true zero. The result in SFA after FAD is always either a normalized nonzero number or a true zero. The result is unpredictable if, prior to the FAD, either SFA or the floating operand contains a floating-point number that is neither a normalized nonzero number nor a true zero. There is one exception to the previous statement; if the floating operand contains a true zero and SFA contains neither a normalized nonzero number nor a true zero, FAD will replace the contents of SFA with either the properly normalized nonzero number or a true zero. During the operation of FAD no guard digits are used. If prealignment shifting of one of the arguments is required, none of the bits shifted off the right end of the mantissa are preserved. If postnormalization of the result is required, zeros will be shifted into the right end of the mantissa.

If exponent underflow occurs, the Overflow indicator is set to 1 and the result stored in SFA is a true zero. If exponent overflow occurs, the Overflow indicator is set to 1 and the result stored in SFA is the largest possible normalized floating-point number with the same sign as the correct result of the instruction would have had if exponent overflow had not occurred. If neither exponent underflow nor overflow occurs, the Overflow indicator is set to 0.

Affected: SFA, (A), O

FSB FLOATING SUBTRACT (optional)

If FM is set, the execution of the following instruction will result in a floating-point subtract operation:

The effective address of the instruction is the address of the floating operand. FSB subtracts the floating operand from the contents of SFA and then loads the results into SFA. The first word of the result also replaces the previous contents of the A register (general register 7).

Prior to the FSB, SFA and the floating operand must both contain either a normalized nonzero number or a true zero. The result in SFA after FSB is always either a normalized nonzero number or a true zero. The result is unpredictable if, prior to the FSB, either SFA or the floating operand contains a floating-point number that is neither a normalized nonzero number nor a true zero.

During the operation of FSB no guard digits are used. If prealignment shifting of one of the arguments is required, none of the bits shifted off the right end of the mantissa are preserved. If postnormalization of the result is required, zeros will be shifted into the right end of the mantissa.

If exponent underflow occurs, the Overflow indicator is set to 1 and the result stored in SFA is a true zero. If exponent overflow occurs, the Overflow indicator is set to 1 and the result stored in SFA is the largest possible normalized floating-point number with the same sign as the correct result of the instruction would have had if exponent overflow had not occurred. If neither exponent underflow nor overflow occurs, the Overflow indicator is set to 0.

Affected: SFA, (A), O

If FM is set, the execution of the following instruction will result in a floating-point multiply operation:

	3	}		R	I	Х				-					
0	1	2	3	14	5	6	7	8	9	10	11	12	13	14	15

.

The effective address of the instruction is the address of the first word of the floating operand. FMP multiplies the floating operand by the contents of SFA and then loads the result into SFA. The first word of the result also replaces the previous contents of the A register (general register 7).

Prior to the FMP, SFA and the floating operand must both contain either a normalized nonzero number or a true zero. The result in SFA after FMP is always either a normalized nonzero number or a true zero. The result is unpredictable if, prior to the FMP, either SFA or the floating operand contains a floating-point number that is neither a normalized nonzero number nor a true zero.

All the bits of the mantissa of the normalized product will be significant. One additional bit of the product will be generated so that if a one-place postnormalization shift is required, a significant bit can be shifted into the right end of the mantissa rather than a zero.

If exponent underflow occurs, the Overflow indicator is set to 1 and the result stored in SFA is a true zero. If exponent overflow occurs, the Overflow indicator is set to 1 and the result stored in SFA is the largest possible normalized floatingpoint number with the same sign as the correct result of the instruction would have had if exponent overflow had not occurred. If neither exponent underflow nor overflow occurs, the Overflow indicator is set to 0.

Affected: SFA, (A), O

FDV FLOATING DIVIDE (optional)

If FM is set, the execution of the following instruction will result in a floating-point divide operation:

5 R I X S Displacement

The effective address of the instruction is the address of the first word of the floating operand. FDV divides the contents of SFA by the floating operand and then loads the result into SFA. The first word of the result also replaces the previous contents of the A register (general register 7).

Prior to the FDV, SFA and the floating operand must both contain either a normalized nonzero number or a true zero. The result in SFA after FDV is always either a normalized nonzero number or a true zero. The result is unpredictable if, prior to the FDV, either SFA or the floating operand contains a floating-point number that is neither a normalized nonzero number nor a true zero.

If exponent underflow occurs, the Overflow indicator is set to 1 and the result stored in SFA is a true zero. If the floating operand is zero or if exponent overflow occurs, the Overflow indicator is set to 1 and the result stored in SFA is the largest possible normalized floating-point number with the same sign that the correct result of the instruction would have had if exponent overflow had not occurred. If neither exponent underflow nor overflow occurs, the Overflow indicator is set to 0.

Affected: SFA, (A), O

FCP FLOATING COMPARE (optional)

If FM is set, the execution of the following instruction will result in a floating-point compare operation:

	C)				Х									- 1	
0	1	2	3	14	5	6	7	8	9	10	11	12	13	14	15	

The effective address of the instruction is the address of the first word of the floating operand. FCP compares the floating operand to the contents of SFA. The result of the comparison is used to set and reset the Overflow and Carry indicators as follows:

- O C Result of Comparison
- 0 0 The contents of SFA is less than the floating operand.
- 1 0 The contents of SFA is greater than the floating operand.
- 1 1 The contents of SFA is equal to the floating operand.

The contents of the A register (general register 7) are not affected by the execution of FCP. The result of FCP will be unpredictable if either SFA or the floating operand contains a floating-point number that is neither a normalized nonzero number nor a true zero.

Affected: O, C

FIELD ADDRESSING INSTRUCTIONS

All of the following field addressing instructions are optional:

Instruction Name	Mnemonic
Load Logical Field	LLF
Load Arithmetic Field	LAF
Store Field	STF

Instruction Name	Mnemonic
Store Zero Field	SZF
Store Ones Field	SOF
Compare Logical Field	CLF
Compare Arithmetic Field	CAF
Sense Left Bit of Field	SLF

Field addressing instructions facilitate specifying and operating upon fields of information (1 through 16 contiguous bits) within memory without restriction in regard to byte or word boundaries (i.e., a specified field of 16 bits may occupy bit positions 9 through 15 of memory location "n" and bit positions 0 through 8 of memory location "n + 1"). The ability to perform bit and byte manipulations as well as push-down stack operations permit field addressing instructions to operate efficiently upon component elements (fields) of three types of logical structures.

- Tables Field addressing instructions facilitate the creation of table structures (collections of different sized fields) that make efficient use of memory and allow direct access to any element within those tables. Table structures utilized by field addressing instructions can be modified without requiring the modification of the code that references those tables.
- Strings Field addressing instructions efficiently operate on strings of identically sized elements. Loop termination control, without the use of any of the general registers, is provided for strings of up to and including 256 elements. Byte string operations are an example of such a string.
- 3. Push-Down Stacks Field addressing instructions allow the creation of any number of push-down stacks in memory. Various modes of field addressing instructions allow pushing new elements into any stack, pulling the top element from any stack, accessing words within a stack that are a known number of word locations away from the current top-of-stack and also detecting when the last available space within a stack has been used.

A typical field addressing instruction consists of two contiguous instruction words. The first instruction word is a nonprivileged READ DIRECT (Mode 0) instruction with the following format:

		1			()				R				s×	`_
0	r	2	3	4	5	6	7	8	9	10	n	12	13	14	15

The SX field of the function value must be coded as either 000, 001, or 111. The SX field specifies one of three self-indexing modes as follows:

Function Value of READ DIRECT	Self-Indexing Mode
0000000010 RX 000	No Self-Indexing
000000010 RX 001	Self-Incrementing
000000010 RX 111	Self-Decrementing

Self-incrementing and self-decrementing are described further below.

For all three self-indexing modes, the RX field causes identical action and must be coded to some three-bit value (other than 000). The RX field specifies one of two registerindexing modes as follows:

RX Field	Register-Indexing Mode
001	No Register Indexing
010 011 100 101 110 111	Register Indexing

Register indexing is described further below.

The second instruction word has the format of a single-word referencing instruction.

	С									sp					
0	ĩ	2	3	4	5	6	7	8	9	10	н	12	13	14	15

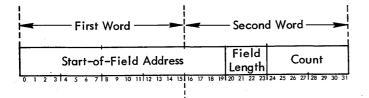

The operation code (OP) field indicates the specific field manipulation operation that is to be performed: Load Logical Field, Load Arithmetic Field, Store Field, Store Zero Field, Store Ones Field, Compare Logical Field, Compare Arithmetic Field, and Sense Left Bit of Field.

The effective address of the second instruction word is the address of the first word of a two-word "field descriptor" in main memory. This effective address may be generated using any mode (described under "Effective Address Computation"), thereby allowing, for example, indexing into a table of field descriptors.

No interrupts are processed by the CPU between these two instruction words.

FIELD DESCRIPTOR

The two-word field descriptor may start on any word boundary and has the following format:

START-OF-FIELD ADDRESS

If no self-indexing is specified (SX field of the first instruction word is coded 000) and if no register indexing is specified (RX field is coded 001), the first 20 bits (all 16 bits of word 1 and the first 4 bits of word 2) of the field descriptor (unmodified) become the effective start-of-field address. Otherwise, these 20 bits are modified as specified by the field addressing instruction to generate the effective startof-field address. The final result of any and all address modification is the bit-address of the first (leftmost) bit of the effective field (the field actually operated on by the field addressing instruction). The first 16 bits of the effective start-of-field address point to the word containing the first bit of the effective field and the next 4 bits specify the bit position occupied by that bit within that word.

FIELD LENGTH

This 4-bit field is contiguous to the start-of-field address and specifies the length (number of bits) of the effective field. The value in this field is one less than the number of bits in the field (i.e., 0000 indicates a 1-bit field, 0001 indicates a 2-bit field, ..., 1111 indicates a 16-bit field.

COUNT

This 8-bit field is used in conjunction with self-incrementing and self-decrementing to provide loop termination control when operating on a string of identically sized elements or to provide a "stack-full" indication for push-down stack operations.

SELF-INCREMENTING OF THE START-OF-FIELD ADDRESS

If self-incrementing is specified (SX field of the first instruction word is coded with 001), the start-of-field address in the field descriptor is incremented by the number of bits in the field (field length plus one), the count field in the field descriptor is incremented by one and then the field descriptor as modified by these two addition operations replaces the original field descriptor in memory. The addition of one to the count field (bits 24-31) is performed modulo 256 so that the field length field (bits 20-23) as restored to memory is always unmodified from the original field length. This new incremented start-of-field address is either the effective start-of-field address or is used as the basis for register indexing as described subsequently.

The self-incrementing operation is illustrated in Figure 4.

For all field addressing instructions, except COMPARE LOGICAL FIELD and COMPARE ARITHMETIC FIELD, the Overflow indicator (O) is set or reset depending on whether overflow occurred when incrementing the count field (assuming the count field to be an eight-bit positive integer). The Overflow indicator is set if the incremented count restored to memory is equal to all zeros and is reset otherwise. For COMPARE LOGICAL FIELD and COMPARE ARITHME-TIC FIELD, the Overflow indicator is used to indicate the results of a comparison and is not affected by the contents of the incremented count field.

Self-incrementing is useful as part of the inner loop when operating sequentially on every element in a string of elements of identical size. If prior to the field addressing instruction, the field descriptor points at the last element processed, then a field addressing instruction with selfincrementing will modify the field descriptor to point at the next element in the string as part of the effective start-offield address computation. In this case, the count field can be used to provide loop termination control. If prior to starting to process a string of identical sized elements, the count field in the initial descriptor contains a number equal to 256 minus the number of elements in the string, then, when the string is processed using field addressing instructions with self-incrementing, the Overflow indicator will be set by the field addressing instruction that processes the last element.

Self-incrementing is also used for operating on push-down stacks. If a push-down stack consists of a sequential string of identical sized elements with the current top-of-stack element having an address larger than the address of the other elements within the stack, then self-incrementing is used for pushing a new element into the stack. If prior to a field addressing instruction, the field descriptor points at the current top-of-stack element, then a Store Field instruction with self-incrementing will push a new element into the stack and leave the field descriptor pointing to that new element as the current top-of-stack. In this case the count field can be used to indicate that the stack is full. If the initial descriptor that is set up when the push-down stack is empty contains a number in the count field equal to 256 minus the maximum allowable size of the push-down stack, then the Overflow indicator will be set following the field addressing instruction that pushed a new element into the last available space in the stack.

If self-incrementing is specified and no register indexing is specified (RX field of the first instruction word is coded with 001), then the effective start-of-field address is equal to the incremented start-of-field address in the field descriptor as restored to memory.

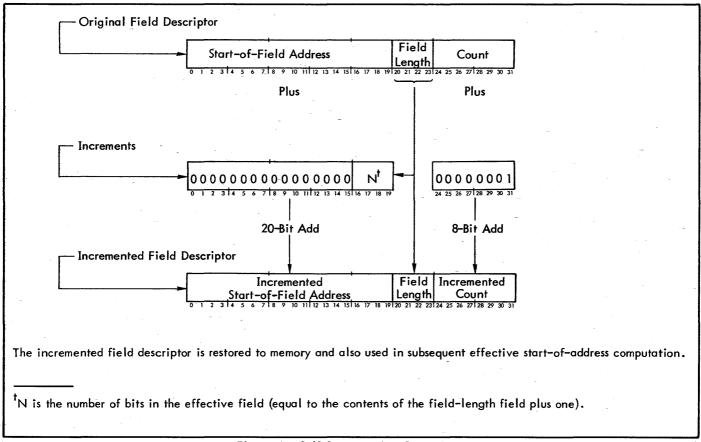

Figure 4. Self-Incrementing Operation

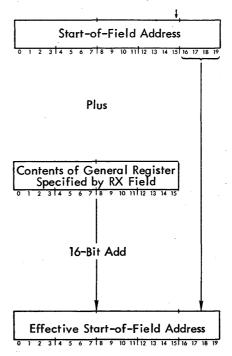

REGISTER INDEXING OF THE START-OF-FIELD ADDRESS

Register indexing can be invoked in conjunction with any of the self-indexing modes. Register indexing adds the contents of one of the general registers to the word address portion (bits 0-15) of the start-of-field address contained in the field descriptor in memory. If either self-decrementing or no self-indexing is specified, the field descriptor in memory at the time register indexing is performed will be identical to the original field descriptor in memory. If selfincrementing is specified, the field descriptor in memory at the time register indexing is performed will be the incremented result of the self-incrementing operation. The RX field of the first instruction word specifies whether register indexing is to be invoked and if so, which general register is to be used.

RX Field	General Register
001	No register indexing
010	Ĺ
011	т
100	X
101	B
110	E
111	Α

If register indexing is specified, the operation performed on the start-of-field address currently contained in the field descriptor in memory is illustrated by the following diagram:

Start-of-field address from current contents of field descriptor in memory (after self-incrementing)

Register indexing can only affect the word address portion of the effective start-of-field address. The result of the register indexing addition is the effective start-of-field address; however, the field descriptor in memory is not modified as a result of register-incrementing. Note this important distinction between self-incrementing and register indexing. Whenever self-incrementing is performed, the result replaces the original field descriptor in memory whereas the results of register-indexing never affects the field descriptor in memory.

As an example of the use of register indexing, consider a table made up of "n" sequential 16-bit words in memory. Each word contains a collection of software status associated with a particular I/O device. The I/O devices are arbitrarily numbered sequentially from "0" to "n-1" for a system with "n" devices. The first word of the table contains software status information associated with device number "0", the second word contains software status information associated with device number "1", etc. The format of each word in the table is identical; the same specific piece of status information for each device appears in the same bit positions in each word of the table. Given such a table structure, a set of field descriptors would exist (one for each different piece of status information in the table). These field descriptors would all have a start-offield address indicating the left bit of the appropriate field in the table entry for device "0". This same set of descriptors would then be used to locate the appropriate status information for any device. This would be accomplished by loading one of the general registers 2 through 7 with the device number of the device of interest. Then, a field addressing instruction would be executed pointing at the field descriptor for the desired piece of status information for device "0" and invoking register indexing using the register containing the device number.

Register indexing can also be used to reference elements contained within a push-down stack provided that the elements within the push-down stack are all 16-bit words. A word that is known to be "n" words below the current topof-stack word can be accessed by loading one of the general registers 2 through 7 with a number equal to "-n". Then, a field addressing instruction would be executed with a field descriptor which points to the current top-of-stack word and invoking register-indexing using the register containing the value "-n".

OTHER CHARACTERISTICS OF FIELD ADDRESSING INSTRUCTIONS

Information presented thus far has been associated with the identification of the effective field (generating an effective start-of-field address). This section briefly describes the operation performed on the effective field by the various field addressing instructions.

The eight field addressing instructions fall logically into four categories: load, store, compare, and sense. In all of the following descriptions, the A register refers to general register 7.

There are two load instructions, LOAD LOGICAL FIELD and LOAD ARITHMETIC FIELD. LOAD LOGICAL FIELD loads the effective field into the right-hand end of the A register (i.e., the rightmost bit of the effective field replaces bit 15 of A) and loads zeros into the remainder of the A register. LOAD ARITHMETIC FIELD loads the effective field into the right hand end of the A register and replaces the remainder of the bits in the A register with the leftmost bit of the effective field. LOAD ARITHMETIC FIELD treats the field to be a signed quantity and, therefore, loading the remainder of the bits in the A register with the leftmost bit of the field is really sign extension.

As an example of the two load operations, consider a fivebit effective field with a binary configuration of

Effective Field 1 1 0 0 1

The final result in the A register for each of the load instructions is as follows:

Result of LOAD LOGICAL FIELD

0000000000011001 2 3 4 5 6 7 8 9 10 11 12 13 14 1

A Register

Result of LOAD ARITHMETIC FIELD

1																A Register
6	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	

However, if the five-bit effective field has a binary configuration of

0 1 0 0 **Effective Field** 1

Then the result in the A register of each of the load instructions is as follows:

Result of LOAD LOGICAL FIELD

Result of LOAD ARITHMETIC FIELD

2 3 4 5 6 7 8 9 10 11 12 13 14

A Register

If the field length is 16 bits, the results of LOAD LOGICAL FIELD and LOAD ARITHMETIC FIELD are identical regardless of the binary configuration of the field.

There are three store instructions, STORE FIELD, STORE ZERO FIELD, and STORE ONES FIELD. STORE FIELD replaces the effective field in memory by the "n" rightmost bits of the A register where "n" is equal to the number of bits in the effective field. For example, if the contents of the field length field specifies a field length of three, then STORE FIELD replaces the effective field in memory by the contents of bits 13-15 of the A register. The contents of the A register is not affected by a STORE FIELD instruction. STORE ZERO FIELD replaces every bit of the effective field in memory with zeros. STORE ONES FIELD replaces every bit of the effective field with ones. For all store instructions, no other bits in the memory word or words containing the effective field are modified except those bits which are part of the effective field.

If the contents of the field length field in the field descriptor specifies a field length of one bit, STORE ZERO FIELD and STORE ONES FIELD perform the function of clearing or setting a particular bit in memory.

There are two compare instructions, COMPARE LOGICAL FIELD, and COMPARE ARITHMETIC FIELD. COMPARE LOGICAL FIELD forms a 16-bit word containing the effective field at the right-hand end and zeros in all other bit positions and then compares this word with the contents of the A register. The Overflow and Carry indicators are set or reset as in the fixed-point compare instruction to indicate the result of the comparison. COMPARE ARITHME-TIC FIELD is the same as COMPARE LOGICAL FIELD except that the 16-bit word compared to the contents of the A register is formed by sign extending the leftmost bit of the effective field into all other bit positions rather than zeros. Neither compare instruction modifies the contents of the A register.

There is one sense instruction called SENSE LEFT BIT OF FIELD. This instruction loads the leftmost bit of the effective field into the Carry indicator (C) without modifying either the effective field or the A register. If the contents of the field length field in the field descriptor specifies a field length of one bit, SENSE LEFT BIT OF FIELD performs the function of testing the state of a particular bit in memory.

SELF-DECREMENTING OF THE START-OF-FIELD ADDRESS

Self-decrementing has no effect on the effective start-offield address calculation for the current field addressing instruction. Self-decrementing is essentially the converse operation to self-incrementing. However, where selfincrementing modifies the field descriptor in memory and affects the effective start-of-field address calculation, selfdecrementing is performed after the operation on the effective field is complete and, therefore, only modifies the field descriptor in memory. Self-decrementing will, however, affect the effective start-of-field address of any subsequent field instructions using the same field descriptor. Selfincrementing and self-decrementing cannot both be invoked in the same field addressing instruction.

If self-decrementing is specified (SX field of first instruction word is coded with 111), then, after all operations involving the effective field are completed, the start-of-field address in the field descriptor in memory is decremented by the number of bits in the field, the count field in the field descriptor is decremented by one, and then the field descriptor as modified by these two subtraction operations replaces the original field descriptor in memory.

The subtraction of one from the count field (bits 24-31) is performed modulo 256 so that the field length (bits 20-23) as restored to memory is always unmodified from the original field length.

The self-decrementing operation is illustrated in Figure 5.

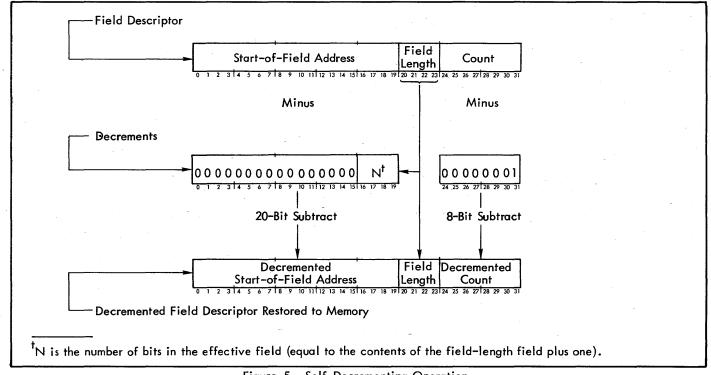

Figure 5. Self-Decrementing Operation

For all field addressing instructions, except COMPARE LOGICAL FIELD and COMPARE ARITHMETIC FIELD, the Overflow indicator (O) is set or reset depending on whether overflow occurred when decrementing the count field (assuming the count field to be an eight-bit positive integer). The Overflow indicator is set if the decremented count restored to memory is equal to all ones and is reset otherwise. For COMPARE LOGICAL FIELD and COMPARE ARITHME-TIC FIELD, the Overflow indicator is used to indicate the results of a comparison and is not affected by the contents of the decremented count field.

If self-decrementing and register-indexing are both specified, the register indexing operation is performed on the original field descriptor as part of the effective start-offield address calculation as described under "Register Indexing of the Start-of-Field Address". Then the resultant effective start-of-field address is used to find the effective field and the operation is performed as described under "Other Characteristics of Field Addressing Instructions". After all operations involving the effective field are completed, the self-decrementing takes place. The original field descriptor from memory is used for selfdecrementing as described above.

Self-decrementing is used for operating on push-down stacks of the type previously described under "Self-Incrementing of the Start-of-Field Address". If, prior to a field addressing instruction, the field descriptor points at the current top-of-stack element, then a load field instruction with self-decrementing will pull the current top-ofstack element off of the stack and load it into the A register and then decrement the field descriptor so that it is pointing to the next element down in the stack as the current top-of-stack.

LLF LOAD LOGICAL FIELD (optional)

1	0	10 RX SX
8	RIXS	Displacement
0 1 2 3	4 5 6 7	8 9 10 11 12 13 14 15

LOAD LOGICAL FIELD is a two-word instruction sequence that loads the effective field into the right-hand end of the A register (general register 7). The rightmost bit of the effective field replaces bit 15 of the A register, etc. If the number of bits in the effective field is less than 16, then zeros replace the remainder of bits in the A register.

The effective address of the second instruction word is the address of the first word of a 32-bit field descriptor. The contents of the field descriptor in conjunction with the contents of the RX and SX fields of the first instruction word are used to locate the effective field. The contents of the SX field may also cause the field descriptor in memory to be modified.

If self-incrementing is specified and the incremented count field that replaces the original count field in the field descriptor in memory contains all zeros, the Overflow (O) indicator is set. If self-decrementing is specified and the decremented count field that replaces the original count field in the field descriptor in memory contains all ones, the Overflow indicator is set. If neither of the above two conditions occurs, the Overflow indicator will be reset as a result of the LOAD LOGICAL FIELD instruction.

No interrupts are processed by the CPU between these two instruction words.

Affected: (A), O, Field descriptor if self-incrementing or self-decrementing is specified.

LAF LOAD ARITHMETIC FIELD (optional)

	1			(C		1	0	- 1	۲ ×	(s>	(
	9		R	I	x	s	C	Dis	β	a	ce	me	en	t
0	1 2	3	14	5	6	7	8	9	10	11	12	13	14	15

LOAD ARITHMETIC FIELD is a two-word instruction sequence that loads the effective field into the right-hand end of the A register (general register 7). The rightmost bit of the effective field replaces bit 15 of the A register, etc. If the number of bits in the effective field is less than 16, the leftmost bit of the effective field replaces the remainder of bits in the A register (sign extension).

The effective address of the second instruction word is the address of the first word of a 32-bit field descriptor. The contents of the field descriptor in conjunction with the contents of the RX and SX fields of the first instruction are used to locate the effective field. The contents of the SX field may also cause the field descriptor in memory to be modified.

If self-incrementing is specified and the incremented count field that replaces the original count field in the field descriptor in memory contains all zeros, the Overflow (O) indicator is set. If self-decrementing is specified and the decremented count field that replaces the original count field in the field descriptor in memory contains all ones, the Overflow indicator is set. If neither of the above two conditions occurs, the Overflow indicator will be reset as a result of the LOAD ARITHMETIC FIELD instruction.

No interrupts are processed by the CPU between these two instruction words.

Affected: (A), O, Field descriptor if self-incrementing or self-decrementing is specified.

STF STORE FIELD (optional)

1	0	10	RX	sx
А	RIXS		•	
0 1 2 3	4 5 6 7	8 9	10 11 12	13 14 15

STORE FIELD is a two-word instruction sequence that replaces the effective field in memory with "n" rightmost bits of the contents of the A register (general register 7), where "n" is equal to the number of bits in the field. Bit 15 of the A register replaces the rightmost bit of the effective field, etc. The contents of the A register are unchanged by the STORE FIELD instruction. No other bits in the memory word or words containing the effective field are modified except those bits that are part of the effective field.

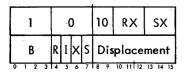

The effective address of the second instruction word is the address of the first word of a 32-bit field descriptor. The contents of the field descriptor in conjunction with the contents of the RX and SX fields of the first instruction are used to locate the effective field. The contents of the SX field may also cause the field descriptor in memory to be modified.

If self-incrementing is specified and the incremented count field that replaces the original count field in the field descriptor in memory contains all zeros, the Overflow (O) indicator is set. If self-decrementing is specified and the decremented count field that replaces the original count field in the field descriptor in memory contains all ones, the Overflow indicator is set. If neither of the above two conditions occurs, the Overflow indicator will be reset as a result of the STORE FIELD Instruction.

No interrupts are processed by the CPU between these two instruction words.

Affected: Effective field, O, Field descriptor if selfincrementing or self-decrementing is specified.

SZF STORE ZERO FIELD (optional)

STORE ZERO FIELD is a two-word instruction sequence that replaces every bit of the effective field in memory with a zero. No other bits in the memory word or words containing the effective field are modified except those bits that are part of the effective field.

The effective address of the second instruction is the address of the first word of a 32-bit field descriptor. The contents of the field descriptor in conjunction with the contents of the RX and SX fields of the first instruction are used to locate the effective field. The contents of the SX field may also cause the field descriptor in memory to be modified.

If self-incrementing is specified and the incremented count field that replaces the original count field in the field descriptor in memory contains all zeros, the Overflow (O) indicator is set. If self-decrementing is specified and the decremented count field that replaces the original count field in the field descriptor in memory contains all ones, the Overflow indicator is set. If neither of the above two conditions occurs, the Overflow indicator will be reset as a result of the STORE ZERO FIELD instruction.

No interrupts are processed by the CPU between these two instruction words.

Affected: Effective field, O, Field descriptor if selfincrementing or self-decrementing is specified.

1	0					RX	sx				
C	R	I	x	s	Displacement						
0 1 2	3 4	5	6	7	89	10 11 12	13 14 15				

STORE ONES FIELD is a two-word instruction sequence that replaces every bit of the effective field in memory with a one. No other bits in the memory word or words containing the effective field are modified except those bits that are part of the effective field.

The effective address of the second instruction is the address of the first word of a 32-bit field descriptor. The contents of the field descriptor in conjunction with the contents of the RX and SX fields of the first instruction are used to locate the effective field. The contents of the SX field may also cause the field descriptor in memory to be modified.

If self-incrementing is specified and the incremented count field that replaces the original count field in the field descriptor in memory contains all zeros, the Overflow (O) indicator is set. If self-decrementing is specified and the decremented count field that replaces the original count field in the field descriptor in memory contains all ones, the Overflow indicator is set. If neither of the above two conditions occurs, the Overflow indicator will be reset as a result of the STORE ONES FIELD instruction.

No interrupts are processed by the CPU between these two instruction words.

Affected: Effective field, O, Field descriptor if selfincrementing or self-decrementing is specified.

CLF COMPARE LOGICAL FIELD (optional)

1	0	10 RX SX						
5	RIXS	Displacement						
0 1 2 3	4 5 6 7	8 9 10 11 12 13 14 15						

COMPARE LOGICAL FIELD is a two-word instruction sequence that forms a 16-bit word made up of the contents of the effective field in the right-hand end and zeros in all other bit positions. COMPARE LOGICAL FIELD then algebraically compares the contents of this word containing the logical field with the contents of the A register (general register 7).

The effective address of the second instruction is the address of the first word of a 32-bit field descriptor. The contents of the field descriptor in conjunction with the contents of the RX and SX fields of the first instruction are used to locate the effective field. The contents of the SX field may also cause the field descriptor in memory to be modified.

The Overflow (O) and Carry (C) indicators are set or reset according to the result of the comparison as follows:

- O C Result of Comparison
- 0 0 The contents of the A register are algebraically less than the contents of the word containing the logical field.
- 1 0 The contents of the A register are algebraically greater than the contents of the word containing the logical field.
- 1 1 The contents of the A register are equal to the contents of the word containing the logical field.

No interrupts are processed by the CPU between these two instruction words.

Affected: O, C, Field descriptor if self-incrementing or self-decrementing is specified.

CAF COMPARE ARITHMETIC FIELD (optional)

	1	I			(0		10	RX	s	X
	(2		R	I	x	s		plac		
0	ĩ	2	3	4	5	6	7	89	10 11 1	2 13	4 15

COMPARE ARITHMETIC FIELD is a two-word instruction sequence that forms a 16-bit word made up of the contents of the effective field in the right-hand end and all other bit positions equal to the leftmost bit of the effective field. COMPARE ARITHMETIC FIELD then algebraically compares the contents of this word containing the sign-extended field with the contents of the A register (general register 7).

The effective address of the second instruction is the address of the first word of a 32-bit field descriptor. The contents of the field descriptor in conjunction with the contents of the RX and SX fields of the first instruction are used to locate the effective field. The contents of the SX field may also cause the field descriptor in memory to be modified. The Overflow (O) and Carry (C) indicators are set or reset according to the results of the comparison as follows:

O C Result of Comparison

1

1

- 0 0 The contents of the A register are algebraically less than the contents of the word containing the sign-extended field.
 - 0 The contents of the A register are algebraically greater than the contents of the word containing the sign-extended field.
 - The contents of the A register are equal to the contents of the word containing the signextended field.

No interrupts are processed by the CPU between these two instruction words.

Affected: O, C, Field descriptor if self-incrementing or self-decrementing is specified.

SLF SENSE LEFT BIT OF FIELD (optional)

	1	1			(D		1	0	F	٢X			s>	\langle
	1	F		R	I	х	s	S Displacement							t
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SENSE LEFT BIT OF FIELD is a two-word instruction sequence that sets or resets the Carry (C) indicator based on whether the leftmost bit of the effective field is a one or a zero. Neither the effective field nor the A register (general register 7) is modified by this instruction.

The effective address of the second instruction is the address of the first word of a 32-bit field descriptor. The contents of the field descriptor in conjunction with the contents of the RX and SX fields of the first instruction are used to locate the effective field. The contents of the SX field may also cause the field descriptor in memory to be modified.

If self-incrementing is specified and the incremented count field that replaces the original count field in the field descriptor in memory contains all zeros, the Overflow (O) indicator is set. If self-decrementing is specified and the decremented count field that replaces the original count field in the field descriptor in memory contains all ones, the Overflow indicator is set. If neither of the above conditions occurs, the Overflow indicator will be reset as a result of the SENSE LEFT BIT OF FIELD instruction.

No interrupts are processed by the CPU between these two instruction words.

Affected: O, C, Field descriptor if self-incrementing or self-decrementing is specified.

4. INPUT/OUTPUT SYSTEMS

This chapter contains information pertaining to byteoriented input/output processors (IOPs) and to external direct input/output (DIO) systems.

IOP SYSTEMS

The computer system may have one or two input/output processors: IOP-1 (standard) with 16 channels, and IOP-2 (optional) with 12 channels. The maximum transfer rate of an IOP is 640,000 bytes per second for controllers connected to the internal interface and 504,000 bytes per second for controllers connected to the external interface using the optional two-byte interface feature.

The CPU initiates an I/O operation by selecting a device and IOP channel (see "Device Numbers") and executing an I/O instruction (see "SIO Instruction"). The IOP assumes control of the I/O operation and performs it automatically in accordance with prestored control parameters contained within a pair of channel registers (see "I/O Control Doubleword") and main memory (see "I/O Tables"). Data chaining is automatic under control of these parameters.

While the I/O operation is being performed, the CPU is free to execute instructions or perform other operations. Any IOP event that requires CPU intervention is reported either as an I/O interrupt or as a machine fault interrupt. An interrupt-servicing routine entered as a result of an I/O interrupt must contain an AIO instruction (see "I/O Instructions"). An interrupt-servicing routine entered as a result of a machine fault interrupt must contain a READ DIRECT (Mode 1) instruction (see "Fault System").

At the end of each IOP operation, the IOP automatically provides information regarding the I/O operation (see "Operational Status Byte").

Although the time-consuming details of a byte-oriented I/O operation are assumed by an IOP, the CPU retains "master" control at all times. When necessary, the CPU may determine the progress of any I/O operation or the status of any I/O device without affecting the I/O operation. The CPU may also stop any I/O operation or reset the entire I/O system (see "I/O Instructions" and "Device Status Byte").

DEVICE NUMBER

Each device within an IOP system is assigned an eight-bit device number at installation time. This number is manually selected by physical means, based on the equipment configuration for the specific installation. The device number of a given device, when loaded into bit positions 8-15 of the accumulator, is used as an I/O address by I/O instructions. It determines which I/O channel register pair is used to govern the data transmission to and from the device. Table 10 illustrates the relationship between device numbers and channel register pairs.

Table 10.	IOP Channel Register and Channel–Device–
	Controller Numbers (Hexadecimal)

Contents o	of Bits 8–15	Channel I	Register
Single Device Controllers ^t	Single or Multiple Device Controllers	Word Address	Byte Count
IOP-1 (First or Only IOP)		а -	
00 01 02 03 04 05 06 07 08 07 08 07 08 09 0A 09 0A 0B 0C 0D 0E 0F	8X 9X AX BX CX ^{tt} DX ^{tt} EX ^{tt} FX ^{tt}	08 0A 0C 0E 10 12 14 16 18 1A 1C 1E 20 22 24 26	09 0B 0F 11 13 15 17 19 1B 1D 1F 21 23 25 27
IOP-2 (Sec- ond IOP) 10 11 12 13 14 15 16 17 18 19 1A 18	CX ^{††} DX ^{††} EX ^{††} FX ^{††}	28 2A 2C 2E 30 32 34 36 38 3A 3C 3E	29 2B 2D 2F 31 33 35 37 39 38 3D 3F

^tAll other device numbers in the range of X'00'-X'7F' are unassigned and not used.

^{tt} If the system contains only IOP-1, these four groups of device numbers are assigned to IOP-1. If the system contains IOP-1 and IOP-2, these device numbers are assigned to IOP-2 only.

Device numbers are generally of two types: single-unit device numbers that are assigned to devices whose controllers permit only that device to be governed by the associated channel register pair (for example, a card reader or card punch); or multiunit device numbers that are assigned to devices whose controller permits more than one device to be governed by the associated channel register pair (for example, magnetic tape units). The two types of device numbers are illustrated below:

Single-	unit device number	м	Multiunit device number						
000	Device Number] []	D	с		D			
8 10	11 15	8	9	11	12	15			

For single-unit device numbers, bits 8-10 are coded as zeros and bits 11-15 identify the device. For multiunit device numbers, bit 8 is coded as a 1, bits 9-11 specify the device controller, and bits 12-15 identify the individual device to be used with that controller.

Note: As shown in Table 10, both single-unit and multiunit device numbers are associated with the first eight channels of IOP-1 and the first four channels of IOP-2. Each of these channels may accommodate devices of either the single-unit or multiunit types, but not both. The last eight channels of each IOP may each accommodate only one device of the single-unit type.

I/O CONTROL DOUBLEWORD (IOCD)

Each I/O channel has a pair of I/O channel registers associated with it. The first IOCD for each I/O operation must be copied into the appropriate I/O channel registers by the CPU prior to initiating the I/O operation. The address of each I/O channel register is listed in columns 3 and 4 in Table 10. Subsequent IOCDs required to complete the I/O operation as a result of data chaining are fetched automatically by the IOP from the current I/O table in memory after all data transfers for that I/O table have been completed. During an I/O operation, the I/O channel registers contain the current I/O Control Doubleword, which has the following format:

Word Address	E CI Byte Count
	16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

The even-numbered register contains a word address that points to a memory location that is part of an I/O table (described below). The odd-numbered register contains three flag bits and a byte count. The first flag bit (E) is an error flag that is set to a 1 if a memory fault (memory parity, address parity, or nonexistent memory error - see "Fault System") is detected during a memory access for either input or output operations, or if any parity error is detected on bytes received from a device. The next two flag bits, called data chaining (DC) and interrupt (I) flags, specify action to be taken by the IOP system when the data transmission, as specified by the byte count of the current IODC, is completed. If the DC flag is 0 when the byte count is reduced to zero, the device is told (via a "count done" signal) that the I/O operation is over and that it should neither send nor receive more data but should terminate its operation. At the conclusion of an I/O operation,

when all data has been transmitted and all checking associated with the data record has been performed, the device transmits an Operational Status Byte which is loaded into the even-numbered I/O channel register containing "channel end" and/or "unusual end". The device controller may generate an "unusual end" signal in place of or in conjunction with the "channel end" signal. The action caused is the same as for "channel end", except that the Operational Status Byte will contain different information. "Unusual end" may occur at any time during an I/O operation, and causes termination of all I/O operations for the device controller involved; the data chaining flag is ignored.

During normal operations, if the DC flag is set to a 1 when the byte count reaches zero, the IOP system automatically fetches the next IOCD from a doubleword location in the current I/O table and loads it into the I/O channel registers in place of the previous IOCD. Data transmission continues using the new IOCD and a new I/O table.

Note: The Operational Status Byte is loaded into the evennumbered I/O channel register only if the I/O operation has been either completed or terminated, as signaled by "channel end" or "unusual end".

If the interrupt (I) flag is set to a 1, the IOP system will instruct the device controller to generate an interrupt request if

- 1. The byte count reaches zero.
- The I/O operation has been abnormally terminated by 2. the IOP or device controller ("unusual end").
- The I/O operation has been normally completed ("channel 3. end"),

The I/O interrupt servicing routine includes an AIO instruction to determine which device controller (with the highest priority) is interrupting and the reason for the interrupt (see "Device Interrupt").

Data chaining must be specified

- When the amount of data required to complete the I/O 1. operation exceeds the amount that can be specified by the current IOCD. The byte count field of the first IOCD may specify one order byte and up to 8191 data bytes. The byte count field of each subsequent IOCD relating to the same I/O operation may specify up to 8192 data bytes.
 - Note: A maximum byte count is specified when the initial value of the byte count field is zero. The byte count field configuration goes from all zeros to all ones after the first byte is transferred into or out of the current I/O table.
- When the amount of data required to complete an I/O2. operation cannot be contained in one I/O table because the available memory is comprised of fragments (isolated regions of unused memory locations), none large enough to contain all of the required data bytes and/or control information (see "I/O Tables").

OPERATIONAL STATUS BYTE

At the conclusion of the I/O operation, the device transmits the operational status byte to the CPU, which loads the status byte into bit positions 0-7 of the even-numbered I/O channel register associated with the device and loads zeros into the remainder of the register. (The loading of the operational status byte occurs even if channel end is signaled in the middle of an I/O table transmission.) The operational status byte contains five flags, as shown in the following diagram.

TICCU000

Bit Function

1[†]

- 0^t The transmission error (TE) flag is set to 1 if the device or the device controller has detected any errors during the operation. This includes such errors as parity check on magnetic tape, the parity check at the end of a RAD sector, and memory parity error on an output operation.
 - The incorrect length (IL)flag indicates whether (1) or not (0) the input or output record contained the number of bytes specified by the controlling IOCD's byte count. Incorrect length may or may not be considered an error, depending on the type of operation performed. For example, during a card read operation, if a byte count of 80 is specified, then the length is correct, because only 80 bytes can be read from the card in the EBCDIC format. If, however, a count of 75 bytes is specified, the card reader will receive a count done signal before it reaches the end of the card, which causes the incorrect length flag to be set to 1. Similarly, if the reader detects the end of the card before it reaches a count done signal, the incorrect length flag is set to 1.
- 2^t The chaining modifier (CM) flag is set to 1 by some devices to indicate that a special condition has been encountered. For example, the unbuffered card punch requires the output image to be transmitted 12 times, once for each row. After the 12th row is punched, the punch controller sets the chaining modifier flag to 1 to indicate that the last transmission has been received and that no further transmissions are required for the current card. The chaining modifier may be used in different ways by other devices.
- 3 The channel end (CE) flag is set to lat the conclusion of every error free I/O operation to indicate that all data involved in the operation have been transmitted and all checking associated with the data has been performed.

Bit Function

4

The unusual end (UE) flag is set to 1 if the operation terminated because of some unusual condition. The unusual condition may or may not be an erroneous or faulty condition; in any event, it is not a normal termination. For example, a magnetic tape Read operation that encountered an end-of-file record instead of a data record would produce an unusual end condition. A faulty operation such as a card jam in the middle of a card-reading operation would also produce unusual end. If the UE flag is set, the state of the CE flag is not specified.

5-7 These bits are always loaded as zeros.

I/O TABLES

All I/O operations are performed to and from an I/O table. The IOCD controlling the first I/O table must be loaded into the I/O channel registers by the CPU. A specific configuration of the WRITE DIRECT instruction is used to transfer the initial IOCD from the accumulator to the I/O channel registers (see "WRITE DIRECT (Mode 0)" instructions).

Each I/O table contains a data section and/or control information for an I/O operation controlled by an IOP. The type and number of I/O tables required for an operation is dependent upon the type of operation and the number of data bytes to be transferred. An I/O table (see Figure 6) may have an order byte, a data section, and a next I/O Control Doubleword. All parts of an I/O table must be contained within contiguous memory locations and may occupy any region of memory except dedicated memory locations (e.g., memory locations assigned to or reserved for interrupt levels).

The six types of I/O tables that may be formed by using the order byte, data section, and next IOCD either individually or in combination with one another are described in Table 11.

ORDER BYTE

This part of an I/O table is required only in the first I/O table for an I/O operation. The eight bits that comprise the order byte contain control information for the device controller and I/O device (see "Device Orders"). In a multi-I/O table operation, the order byte from the first I/O table prevails for the entire operation. For some control operations (e.g., stop), the order byte constitutes the I/O table. For a data transfer operation, the order byte is followed immediately by a data section. If the data section contains an odd number of bytes, the order byte occupies the first byte of the first word of the first I/O table. If the data section contains an even number of bytes, the order byte occupies the second byte of the first word of the first I/O table and the first byte of the first word of the first I/O table and the first byte of the first word is ignored.

^TThese functions are not necessarily implemented in all peripheral device controllers. Refer to peripheral device reference manuals for more complete information.

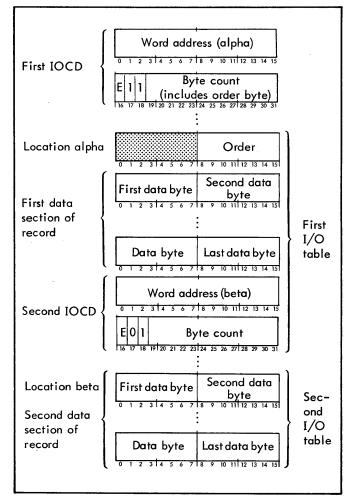

Figure 6. I/O Control Doublewords and I/O Tables

DATA SECTION

This part of an I/O table is required for all operations involving data transfers into or out of main memory. The data section will be the second part of the first I/O table and the first or only part of subsequent I/O tables relating to the same I/O operation. If additional data is required, the data section will be followed immediately by the next I/O Control Doubleword. As part of the first I/O table, the data section may contain up to 8191 data bytes. As part of subsequent I/O tables, the data section may contain up to 8192 data bytes. For output operations, the data section contains information that has been pre-stored by the CPU in preparation of a forthcoming output operation. For input operations, the data section will contain the information after the input operation has been performed. Thus, data transfers into or out of main memory via IOP operations are accomplished into or out of data sections of I/O tables.

NEXT IOCD

This part of an I/O table is required only if data chaining is specified by the current IOCD. The four bytes that comprise the next IOCD are not included in the byte count value. When present, the next IOCD is always the last part of an I/O table. The next IOCD is automatically copied by the IOP into the appropriate I/O channel registers when the byte count of the associated IOCD reaches zero. After being copied into the I/O channel registers, the next IOCD becomes the current IOCD and assumes all associated functions.

Table 11. I/O Tables

Order Byte	Data Section	Next IOCD	Description
1	0	0	I/O table is comprised of an order byte only and may be stored in any available mem- ory location. In the associated IOCD, data chaining is not specified and the byte count value is 1. This form of I/O table is used for operations in which no data is transferred (e.g., Stop of Control orders as described under "Device Orders").
1	0	1	I/O table is comprised of an order byte and the next IOCD. In the associated IOCD, data chaining is specified and the byte count value is 1 (the four bytes con- taining the next IOCD are not included in the byte count). No data transfers will take place. This form of I/O table permits utilizing a five-byte memory fragment as the first I/O table of a multitable I/O operation.
1]	0	I/O table is comprised of an order byte and a data section. In the associated IOCD, data chaining is not specified and the byte count value must reflect the order byte and the number of data bytes to be transferred. Maximum number of data bytes may be 8191. This form of I/O table is used when all data bytes for the I/O operation are contained in this I/O table. The size of the I/O table is as specified by the byte count of the associated IOCD.

Table 11. I/O Tables (cont.)

Order Byte	Data Section	Next IOCD	Description
I	1	1	I/O table is comprised of an order byte, a data section, and the next IOCD. In the associated IOCD, data chaining is specified and the byte count value must reflect the order byte and the number of data bytes to be transferred. Maximum number of data bytes is 8191. Byte count does not include the four bytes containing the next IOCD. This form of I/O table is used as the first I/O table in a multitable I/O operation. The size of the I/O table is four bytes more than specified by the byte count of the associated IOCD.
0	1	1	I/O table is comprised of a data section and the next IOCD. In the associated IOCD, data chaining is specified and the byte count value reflects only the number of data bytes to be transferred. Maximum number of data bytes may be 8192. Byte count does not include the four bytes containing the next IOCD. This form of I/O table is used as an intermediate (not the first or last) I/O table in a multitable I/O operation. The size of the I/O table is four bytes more than specified by the byte count of the associated IOCD.
0	1	0	I/O table is comprised of a data section only. In the associated IOCD, data chaining is not specified and the byte count value reflects only the number of data bytes to be transferred. Maximum number of data bytes may be 8192. This form of I/O table is used as the last I/O table of a multitable I/O operation. The size of the I/O table is as specified by the byte count of the associated IOCD.

DEVICE ORDERS

When a device is started for an I/O operation, it first requests an order from the IOP system to determine what operation is to be performed. An order byte, which has been prestored in the first word of the first I/O table in anticipation of this I/O operation, is transmitted to the device under control of the I/O channel to which the device is attached. The orders that may be accepted by a device are Write, Read, Read Backward, Control, Sense, and Stop. The code format for each order is shown below. Bit positions marked "M" specify unique modifications that depend on the device to which the order is sent.

	Bit position of device order byte										
Order	0	1	2	3	4	5	6	7			
Write	м	м	м	м	м	м	0	1			
Read	м	м	м	м	м	м	1	0			
Read Backward	м	м	м	м	1	1	0	0			
Control	м	м	м	м	м	м	1	1			
Sense	м	м	м	м	0	1	0	0			
Stop	I	0	0	0	0	0	0	0			

The device orders operate in the following manner:

1. <u>Write</u>. The Write order causes the device controller to initiate an output operation. The controller makes output requests to the IOP system and data bytes are transmitted from memory, under control of the IOCD, to the device. The output operation normally continues until no further data chaining is to take place and the byte count of the last IOCD is reduced to zero. At this time, the IOP signals count done and the device generates channel end. Channel end occurs when the device has received all information associated with the output operation, has generated all checking information, and (if possible) has performed post-write checking. It is possible for some devices to generate channel end before count done is received.

- 2. <u>Read.</u> The Read order causes the device to initiate an input operation. Bytes are transmitted by the devices, then stored in memory under control of the IOCD. The input operation continues until the device generates channel end or until the byte count is reduced to zero and count done is signaled to the device. In either case, the operation is eventually terminated by a channel end signal when all checking has been performed on the input record.
- 3. <u>Read Backward</u>. The Read Backward order can be executed only by certain peripheral devices. The Read Backward order causes the device that can execute it to start operation in a backward direction and to transmit bytes; however, the record appears in memory in reverse sequence from the way it was originally written.
- 4. <u>Control</u>. The Control order is used to initiate special operations by the device. For some operations, the Control order itself may be sufficient to specify the entire operation to be performed. With magnetic tape operations, for example, the Control order initiates such operations as rewind, backspace record, back-space file, space record, etc. These orders can all be specified by the modifier (M)bits of the Control order.

If, however, the controller requires additional information for a particular operation, it is provided by the same IOCD that controls the transmission of the Control order. When all data necessary for the operation have been transmitted (and, in some cases when the operation itself is complete), the device controller signals channel end.

- 5. <u>Sense</u>. The Sense order causes the device to transmit one or more bytes of information describing its current operational status. These bytes are stored in memory under control of the IOCD. The type of status information that may be transmitted is a function of each individual device.
- 6. Stop. The Stop order (interpreted by some devices) causes a device to terminate its operation immediately. The I modifier bit (in position 0 of the Stop order) indicates that the device is to trigger the I/O interrupt level at the time it receives the Stop order. Bit positions 1, 2, and 3 of the Stop order are ignored.

DEVICE INTERRUPTS

All device controllers (and in the case of multiunit devices, the devices themselves) can generate a device interrupt. Each device remembers that it has generated an interrupt so that when the instruction ACKNOWLEDGE I/O INTERRUPT (AIO) is executed, the device with the highest priority identifies itself to the program. Device interrupts are generated by the device at the time of data chaining or at unusual end or channel end if the interrupt (I) flag in the controlling IOCD is set to 1. The interrupt flag is inspected by the I/O system at channel end time, unusual end time, and at data chaining time.

In addition to these normal times for interrupts, some devices can accept a Control order (or even a Read or Write order) that directs the device to interrupt after the transmission operation is completed. This type of interrupt generally occurs at channel end (that time during the operation of the device when all mechanical motion associated with a previously initiated operation has been completed). For example, a magnetic tape unit can be directed (with a Control order) to rewind and to interrupt when the rewind is complete. The order is accepted and channel end is generated immediately after the rewind operation begins. The device remembers the necessity to interrupt and, when the load point is encountered, the tape stops and channel end occurs; at this time the device generates an interrupt (and holds the interrupt-pending status until it is acknowledged). In this case, the magnetic tape control unit may be busy controlling the operation of another device for a read or write function. The pending device interrupt is a status condition that can be read by I/O instructions.

I/O INSTRUCTIONS

The CPU initiates and controls I/O operations using six instructions.

- Start Input/Output (SIO)
- Test Input/Output (TIO)
- Test Device (TDV)
- Halt Input/Output (HIO)
- Acknowledge I/O Interrupt (AIO)
- Reset Input/Output.

These instructions are coded as internal control functions of the READ DIRECT instruction. All instructions except AIO and Reset Input/Output require a device number in bit positions 8-15 of the accumulator when the instruction is executed.

To permit IOPs to operate at optimum data transfer rates, short program loops that repetitively execute I/O instructions should be avoided.

SIO Start Input/Output

SIO is used to initiate an input or output operation with the device selected by the device number contained in bit positions 8–15 of the accumulator. If a device recognizes the number, it returns its device status byte into bit positions 0–7 of the accumulator (see "Device Status Byte"); otherwise, zeros are returned to these positions.

The Overflow and Carry indicators are set or reset, according to the result of the instruction, as follows:

- O C Significance
- 0 0 I/O address recognized and SIO accepted.
- 0 1 I/O address recognized but SIO not accepted.
- 1 0 Controller "busy" with device other than one addressed and unable to send status.
- 1 1 I/O address not recognized.

Affected: (A)₀₋₇, O, C Timing: See Appendix B

TIO Test Input/Output

TIO causes the device whose device number is in bit positions 8-15 of the accumulator to make the same responses it would make to an SIO instruction, except that the device is not started nor is its state altered. If a device recognizes the device number, it returns its device status byte to bit positions 0–7 of the accumulator (see "Device Status Byte"); otherwise, zeros are returned to these positions.

The Overflow and Carry indicators are set or reset, according to the result of the instruction, as follows:

- O C Significance
- 0 0 I/O address recognized and SIO can be accepted.
- 0 1 I/O address recognized but SIO cannot be accepted.
- 1 0 Controller "busy" with device other than one addressed and unable to send status.
- 1 1 I/O address not recognized.

Affected: (A)₀₋₇,O,C

Timing: See Appendix B

TDV Test Device

-	1	ĺ	-		()				4			. 4	1		
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	L

TDV is used to obtain specific information about the device whose device number is contained in bit positions 8-15 of the accumulator. The device state is not altered. If a device recognizes the device number, it returns its device status byte to bit positions 0-7 of the accumulator (see "Device Status Byte"); otherwise, zeros are returned to these positions.

The Overflow and Carry indicators are set or reset, according to the result of the instruction, as follows:

- O C Significance
- 0 0 I/O address recognized.
- 0 1 I/O address recognized and controller is in a test mode.
- 1 0 Controller "busy" with device other than one addressed and unable to send status.
- 1 1 I/O address not recognized.

Affected: (A)₀₋₇,O,C

Timing: See Appendix B

HIO	Halt	Input/Output	

		1			()			4	ļ			8	3		
0	1	2	3	4	5	6	7	8	9	10	н	12	13	14	15	t

HIO causes the device whose device number is in bit positions 8-15 of the accumulator to stop its current operation immediately. The HIO instruction may cause the device to terminate improperly. In the case of magnetic tape units, for example, the device is forced to stop whether it has reached an interrecord gap or not. A pending interrupt within the device will be reset. If a device recognizes the device number, it returns its device status byte to bit positions 0-7 of the accumulator (see "Device Status Byte"); otherwise, zeros are returned to these positions. The Overflow and Carry indicators are set or reset, according to the result of the instruction, as follows:

O C Significance

- 0 0 I/O address recognized and the device controller is not "busy".
- 0 1 I/O address recognized and the device controller was "busy" at the time of the halt.
- 1 0 HIO not accepted. Controller "busy" with device other than one addressed and unable to send status.
- 1 1 I/O address not recognized.

Affected: (A)₀₋₇, O, C Timing: See Appendix B

AIO Acknowledge I/O Interrupt

AIO is used to acknowledge an interrupt generated by an I/O device. It causes the highest-priority interrupting device to identify itself and return not only status, but also its device number. If any devices have interrupts pending, the highest-priority device clears its pending interrupt and returns its status (which is loaded into bit positions 0-7 of the accumulator) and its device number (which is loaded into bit positions 8-15) (see "Device Status Byte"); if no interrupt is recognized, zeros are returned into bit positions 0-7 of the accumulator.

The Overflow and Carry indicators are set or reset, according to the result of the instruction, as follows:

- O C Significance
- 0 0 Normal interrupt recognition.
- 0 1 Unusual interrupt recognition or controller in test mode.
- 1 0 Invalid code.
- 1 1 No interrupt recognition.

Affected: (A),O,C

Timing: See Appendix B

Reset Input/Output

Reset Input/Output causes all units connected to the internal DIO bus to be initialized (e.g., Direct Memory Adapters, External DIO, IOPs, and the interrupt system.

<u>Note:</u> The integrity of the I/O channels cannot be assured to be the same after executing a Reset Input/ Output instruction.

DEVICE STATUS BYTE

As the result of executing an I/O instruction, if there is a device whose number corresponds to the number in the accumulator, its Device Status Byte is loaded into bit positions 0–7 of the accumulator. (The device number in bits 8–15 is not altered.)

The AIO instruction does not require the device number, since one of its functions is to obtain the number of the device that triggered the I/O interrupt level.

The overflow and carry indicators are set to record the nature of the response to all I/O instructions. The I/O status loaded into the accumulator by the I/O instructions is summarized in Table 12.

For the instructions SIO, TIO, and HIO the status indicators have the following meaning:

<u>Device Interrupt Pending</u>. Bit 0 indicates whether (if it is a 1) or not (if it is a 0) the device has generated an interrupt signal that has not yet been acknowledged. A new I/O operation cannot be initiated on this device until the pending interrupt signal has been acknowledged by means of an AIO instruction.

<u>Device Condition</u>.[†] Bits 1 and 2 describe which of four possible conditions the device is currently in. The device conditions are

- 00 Device ready. The device can accept and act upon an SIO instruction if no device interrupt is pending.
- 01 Device not operational. A nonoperational device does not accept an SIO instruction. It requires operator intervention before any action can be taken with regard to its operation.

^tFor single-unit device controllers, bits 1-2 and 5-6 are identical. Some devices only differentiate between the "ready" and "busy" states rather than identifying four distinct states. 10 Device unavailable.

11 Device busy. The device has accepted an SIO instruction and has not yet concluded the operation.

<u>Device Mode.</u> Bit 3, the mode status indicator, is a 1 if the operator has cleared the device for operation and has actuated the START switch, placing the device in the "automatic" mode. If the mode status indicator is a 0, the device is in the "manual" mode and requires operator intervention before it can operate. A ready device in the "manual" mode can accept an SIO instruction even though it cannot begin to operate until it is placed in the "automatic" mode. Some devices are "permanently" in the automatic mode.

<u>Unusual End Termination</u>. Bit 4 is set to 1 if the previous operation on this device resulted in an unusual end; otherwise, bit 4 is reset to 0.

<u>Device Contoller Condition.</u> Bits 5 and 6 describe which of four possible conditions the device controller is currently in. These conditions are identical in meaning to the device conditions. The controller need not be in the same condition as the device in the case of a multiunit device controller. The device controller conditions are

- 00 Device controller ready. If the controller is ready and the device is ready, an SIO instruction can be accepted.
- 01 Device controller not operational.
- 10 Device controller unavailable.
- 11 Device controller busy. The controller and the device connected to it (or one of the devices connected to it) have accepted an SIO instruction and the I/O operation thus initiated has not terminated.

Note that in addition to the Device Status Byte in position 0-7, the instruction AIO also causes the device number to be loaded into bit positions 8-15 of the accumulator.

			· · · · · · · · · · · · · · · · · · ·

Table 12. Device Status Byte

EXTERNAL DIO

With the optional External DIO, the READ DIRECT and WRITE DIRECT instructions are used to communicate with special system devices. WRITE DIRECT is used to transmit a control signal, along with 16 data bits, to a device. Similarly, READ DIRECT is used to transmit a control signal and then accept 16 data bits from the external unit. Both instructions can be used to obtain a two-bit status response from the device.

When the External DIO feature is installed, the WRITE DIRECT instruction can set up the 16 control lines plus

the 16 data lines; these remain stable until an acknowledgment signal is received from the device. A delay by the device in responding to WRITE DIRECT does not have any adverse effect on the operation of the byteoriented IOP system.

The READ DIRECT instruction operates in a similar fashion. The 16 control lines are held stable and the device responds with its acknowledge signal and 16 data bits. Xerox publication 90 09 73 (Interface Design Manual) describes the External DIO in detail.

5. OPERATOR CONTROLS

PROCESSOR CONTROL PANEL

The processor control panel (PCP), illustrated in Figure 7, contains switches and indicators that permit operating and maintenance personnel to control and monitor the computer system. Each switch and/or switch position is identified with functional and/or operational information. The DATA indicators are labeled with positional information; all other indicators are backlighted and identified functionally.

PCP switches are described in Table 13. PCP indicators are described in Table 14.

BASIC OPERATING PROCEDURES

INITIALIZATION (POWER ON AND NORMAL LOAD)

- 1. Set all toggle switches located above DATA indicators to the down position.
- 2. Set the PCP MODE SELECT switch to the NORMAL position.
- 3. Turn the Keylock switch to the PCP ENABLED position.

- 4. After the power-on sequence is completed (signified by the POWER ON indicator), proceed to next step.
- 5. Prepare input device.
- 6. Set DATA switch 7 (0 = IOP-1; 1 = IOP-2).
- 7. Set DATA switches 8-15 to value of device number.
- 8. Momentarily lift RESET switch.
- 9. Momentarily lift LOAD switch.
- Place RUN switch in the up position (self-locking). As a result of the above procedures, a micrologic test of the basic CPU functions will be executed and the first record will be loaded from the input device to location X'0000' through X'003F' and the WAIT indicator will be backlighted.
- 11. Place RUN switch in the down position and then return to the up position. The record that has been loaded, as described in the preceding steps, will now be executed.
- 12. The Keylock switch may be turned to the PROTECTON position if subsequent operator interventions are required only for PCP interrupts. All switches other than DISPLAY SELECT and INTERRUPT are disabled.

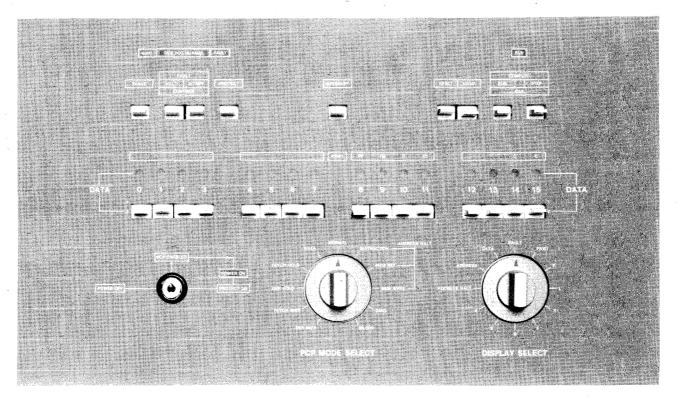

Figure 7. Processor Control Panel

Table 13. PCP Switches

Name (Type)	Position	Function
(Keylock)	POWER OFF	Removes ac power from the computer system.
	PCP ENABLED	Permits ac power to be applied to the computer system. When this switch is initially moved from the POWER OFF to the PCP ENABLED position, an auto- matic power-on sequence is started and the POWER ON indicator is lighted. When the keylock switch is in this position, all switches on the PCP are enabled.
	PROTECT ON	Disables all PCP switches except the INTERRUPT and the DISPLAY SELECT. This position is normally used when the CPU is executing a program that re- quires a minimal amount of attention and service from the computer operator.
PCP MODE SELECT	NORMAL	Allows the CPU to operate in a normal manner as determined by the other control switches and programmed controls.
(Rotary) This switch is	INSTRUCTION ADDRESS HALT	Allows an address match to cause an Idle condition only if the access is one of the instruction itself.
effective only when the PCP is enabled.	MEMORY REFERENCE ADDRESS HALT	Allows any address match to cause an Idle condition.
	MEMORY WRITE ADDRESS HALT	Allows an address match to cause an Idle condition only if a write access is attempted.
•	DIAG	Modifies the load and run operation such that a predetermined machine lan- guage test routine is transferred from read-only-memory to the first 256 main memory locations and executed from main memory. The normal load and run operation does not occur.
	MLOOP	In conjunction with the run function, permits continuous execution of the CPU micrologic test.
	ENTER DATA	Enables the operator to store the contents of the DATA indicators into the register selected by the DISPLAY switch by activating the STEP or RUN switch.
	FETCH/HOLD	Allows the contents of the memory location specified by the address register to be read into the data register when the STEP or RUN switch is activated. The address register is not incremented as a result of this operation.
• •	DEPOSIT/HOLD	Allows the contents of the DATA switches to be stored in the location speci- fied by the memory address register and in the data register when the RUN or STEP switch is activated. The address register is not incremented by this operation.
	FETCH/ INCREMENT	The same as FETCH/HOLD except the address register is incremented.
- - -	DEPOSIT/ INCREMENT	The same as DEPOSIT/HOLD except the address register is incremented.

Table 13. PCP Switches (cont.)

Name (Type)	Position	Function
DISPLAY SELECT	PSW1	Allows the contents of the first word of the program status word to be displayed and modified. Bits 0 through 7 are always zero.
(Rotary)	Р	Allows the contents of the P register (general register 1) to be displayed and modified.
This switch is always effective.	L	Allows the contents of the L register (general register 2) to be displayed and modified.
	Т	Allows the contents of the T register (general register 3) to be displayed and modified.
	X	Allows the contents of the X register (general register 4) to be displayed and modified.
	В	Allows the contents of the B register (general register 5) to be displayed and modified.
	E	Allows the contents of the E register (general register 6) to be displayed and modified.
	A	Allows the contents of the A register (general register 7) to be displayed and modified.
	ADDRESS HALT	Allows the contents of the address halt register to be displayed and modified. The address halt register is used in conjunction with the three address halt modes as selected by the PCP MODE SELECT switch (INSTRUCTION ADDRESS HALT, MEMORY ADDRESS HALT, and MEMORY WRITE ADDRESS HALT). The contents of the address halt register must be modified appropriately by the operator prior to entering the RUN mode with the PCP MODE SELECT switch in one of the three ADDRESS HALT positions. Otherwise, the results of the operation are indeterminate.
* * .		<u>Note:</u> The address halt register is also used to contain the top-of-memory address in memory scan operations.
	DATA	Allows the contents of the data register to be displayed. This register con- tains the contents of the memory location pointed to by the contents of the address register.
	ADDRESS	Allows the contents of specific memory locations to be displayed and modified.
-	FAULT	Allows the contents of the fault register to be displayed only. The fault regis- ter can not be modified via the PCP.
DATA 0 through DATA 15		Each of these 16 general-purpose switches may be set to the 1 or 0 position to represent data or control information during load, register modification, mem- ory display, memory modification, address halt, and memory scan operations.
TRACE (Locking Toggle)	up	If PCP is enabled, this switch provides a continuous trigger of the PCP inter- rupt level, which, if this level is armed and enabled, will cause an interrupt to occur at every interruptible point of each instruction executed (interrupt routines can not be traced).
-		Note: If the INTERRUPT switch is raised while the TRACE switch is up, the machine fault interrupt will be triggered and the fault register will uniquely identify this "pseudo-fault" combination of events.

Table 13.	PCP	Switches ((cont.))
-----------	-----	------------	---------	---

Name (Type)	Position	Function
TRACE (cont.)	down	Allows INTERRUPT switch to function normally when PCP is enabled.
HALT	up -	Causes the CPU to halt if a fault condition is encountered.
(Locking Toggle)	down	If the HALT and INTRPT switches are both down, any fault condition will be ignored.
INTRPT	up	Causes the CPU to enter an interrupt service routine if a fault condition is encountered (overrides HALT switch).
(Locking Toggle	down	If the HALT and INTRPT switches are both down, any fault condition will be ignored.
PROTECT	up	Enables memory protect feature if PCP is enabled.
(Locking Toggle)	down	Disables memory protect feature if PCP is enabled.
INTERRUPT	up	A manual means for generating PCP interrupt (see also TRACE).
(MOMENTARY Toggle)	down	None.
RESET (Momentary	υp	Causes the CPU system, including the I/O, to be manually reset by the operator.
Toggle)	down	None.
LOAD	up	Permits the operator to initiate the load operation (input data from I/O device
(Momentary Toggle)	down	None.
RUN (Locking Toggle)	up	If the PCP MODE SELECT switch is in the NORMAL position, the CPU enter the compute mode of operation whereby instructions are executed in a con- tinuous manner under program control.
	down	If the RUN and STEP switches are down at the same time, the CPU is in the Idle mode.
STEP (Momentary Toggle)	up	If the PCP MODE SELECT switch is in the NORMAL position, the CPU enter the compute mode and executes a single instruction. This switch is disabled if the RUN switch is in the up position.
	down	If the STEP and RUN switches are both down, the CPU is in the Idle mode.

Table 14. PCP Indicators

Name	Significance (when lighted)
WAIT	Indicates that the CPU is in the Wait state.
DCV NOT NORMAL	Indicates that a power supply has been set to the LOW MARGIN condition.
FAULT	Indicates a fault has occurred. The type of fault may be determined by displaying the fault register.
RUN	The CPU is busy executing instructions in a continuous manner.
DATA 0 through DATA 15	When the CPU is in the Idle state, these 16 indicators display the contents of registers selected by the DISPLAY SELECT switch. When the CPU is in the Run state, these indi- cators will display either the contents of the CPU W register or the fault register.
	Each indicator is labeled with a positional notation that corresponds to the bit position of a word. DATA indicators 8, 9, 10, 11, 14, and 15 are also functionally marked (above each mentioned position) to reflect the significance of the bits when displaying the first word of the program status doubleword (PSW1).

The Keylock switch in the PROTECT ON position forces the following PCP switches into the state listed below:

RESET	DISABLED
LOAD	DISABLED
TRACE	DISABLED
COMPUTE	RUN
FAULT	INTERRUPT
PROTECT	ON
PCP MODE SELECT	NORMAL

- 13. If the loading operation failed,
 - a. Check for obvious peripheral failures (e.g., card jam, runaway tape, etc.).
 - b. If a peripheral failure is not immediately observed, set the DISPLAY SELECT switch to the FAULT position and, if the display indicates a machine fault, record the machine environment immediately for use by maintenance personnel.

REGISTER MODIFICATION

- 1. Set PCP to Idle state (the Keylock switch is in the PCP ENABLED position and the RUN and STEP switches are both in the down position).
- 2. Rotate the DISPLAY SELECT switch to select the appropriate register. The current contents of the select register is displayed in the DATA indicators.
- 3. Rotate the PCP MODE SELECT switch to the ENTER DATA position.

- 4. Set the individual DATA switches to the desired configuration.
- 5. Momentarily lift the STEP switch. The DATA indicators now display the same bit configuration as the DATA switches.
- Note: The contents of the fault register may be selected and displayed at any time. However, the contents can not be modified by the operator via the PCP.

ENTER LOOP

If the RUN switch is used instead of the STEP switch in step 5 of "Register Modification", the enter data function is cycled continuously.

MEMORY DISPLAY

- 1. Set PCP to Idle mode (the Keylock switch is in the PCP ENABLED position and the RUN and STEP switches are both in the down position).
- 2. Set the PCP MODE SELECT switch to the ENTER DATA position.
- 3. Set the DATA switches to the address of the first memory location to be displayed.
- 4. Set the DISPLAY SELECT switch to the ADDRESS position.
- 5. Momentarily lift STEP switch.

- Set the DISPLAY SELECT switch to the DATA position. 6.
- Set the PCP MODE SELECT switch to the FETCH/HOLD 7. position (if a single location access is desired) or to the FETCH/INCREMENT position (if a series of sequential accesses is desired).
- Momentarily lift the STEP switch. The DATA indica-8. tors now display the contents of the desired memory location. If the PCP MODE SELECT switch is in the FETCH/INCREMENT position, the contents of the next sequential memory location will be displayed each time the STEP switch is momentarily lifted.
 - **MEMORY MODIFICATION (SINGLE)**
- Set PCP to Idle mode (Keylock switch is in the PCP 1. ENABLED position, and the RUN and STEP switches are both in the down position).
- 2. Set PCP MODE SELECT switch to the ENTER DATA position.
- Set address of location to be modified in DATA 3. switches.
- 4. Set DISPLAY SELECT switch to ADDRESS position.
- Mementarily lift STEP switch. 5.
- Set PCP MODE SELECT switch to DEPOSIT/HOLD 6. position.
- 7. Set desired data configuration in DATA switches.
- 8. Momentarily lift STEP switch.

MEMORY MODIFICATION (MULTIPLE SEQUENTIAL LOCATIONS)

- Set PCP to Idle mode (Keylock switch is in the PCP 1. ENABLED position and the RUN and STEP switches are both in the down position).
- 2. Set PCP MODE SELECT switch to the ENTER DATA position.
- 3. Set DATA switches with address of first location to be modified.
- Set DISPLAY SELECT switch to ADDRESS position. 4.
- Momentarily lift STEP switch. 5.
- Set PCP MODE SELECT switch to DEPOSIT/INCREMENT 6. position.

- 7. Set DATA switches with desired data.
- Momentarily lift STEP switch. 8.
- 9. Repeat steps 7 and 8 until all memory locations are modified.

ADDRESS HALT

- 1. Set PCP to Idle state (Keylock switch must be in the PCP ENABLED position, the RUN switch must be down, and the STEP switch must be down).
- 2. Set the DISPLAY SELECT switch to the ADDRESS HALT position.
- Set PCP MODE SELECT switch to the ENTER DATA 3. position.
- Set DATA switches to the desired stop address. 4.
- 5. Momentarily lift the STEP switch.
- Set the PCP MODE SELECT switch to one of the fol-6. lowing positions:
 - INSTRUCTION a.
 - h. MEMORY REFERENCE
- ADDRESS HALT
- MEMORY WRITE c.
- 7. Set the RUN switch in the up position. Program execution is performed until a match occurs. The RUN indicator is turned off. To continue, place the RUN switch in the down position and then return it to the up position.
 - Note: The "Address Halt" mode may be used during load operations by performing this step after step 6 and before step 7 as described under "Initialization".

MEMORY SCAN

- 1. To cycle on a single location, follow the procedures listed under "Memory Display" or "Memory Modification", as desired, but use the RUN switch instead of the STEP switch.
- 2. To cycle on all or some portion of memory other than a single location, enter a top-of-memory (or top-oftest area) into the ADDRESS HALT register first; then perform the procedures listed for "Memory Display" or "Memory Modification (Sequential)" but use the RUN switch instead of the STEP switch.

STANDARD SYMBOLS AND CODES

The symbol and code standards described in this publication are applicable to all Xerox computer products, both hardware and software. They may be expanded or altered from time to time to meet changing requirements.

The symbols listed here include two types: graphic symbols and control characters. Graphic symbols are displayable and printable; control characters are not. Hybrids are SP, the symbol for a blank space; and DEL, the delete code, which is not considered a control command.

Three types of code are shown: (1) the 8-bit Xerox Standard Computer Code, i.e., the Extended Binary-Coded-Decimal Interchange Code (EBCDIC); (2) the 7-bit American National Standard Code for Information Interchange (ANSCII); and (3) the Xerox standard card code.

STANDARD CHARACTER SETS

1. EBCDIC

57-character set: uppercase letters, numerals, space, and & - / . < > () + 1 \$ * : ; , % # @ ' =

63-character set: same as above plus ¢! _ ?

89-character set: same as 63-character set plus lowercase letters

2. ANSCII

64-character set: uppercase letters, numerals, space, and ! " \$ % & ' () * + , -. / \ ; : = < > ? @ _ []

95-character set: same as above plus lowercase letters and $\{ \}$

CONTROL CODES

In addition to the standard character sets listed above, the symbol repertoire includes 37 control codes and the hybrid code DEL (hybrid code SP is considered part of all character sets). These are listed in the table titled Standard Symbol-Code Correspondences.

SPECIAL CODE PROPERTIES

The following two properties of all standard codes will be retained for future standard code extensions:

- 1. All control codes, and only the control codes, have their two high-order bits equal to "00". DEL is not considered a control code.
- No two graphic EBCDIC codes have their seven loworder bits equal.

STANDARD 8-BIT COMPUTER CODES (EBCDIC)

4

NOTES:

- The characters ^ \ { } [] are ANSCII characters that do not appear in any of the EBCDIC-based character sets, though they are shown in the EBCDIC table.
- 2 The characters ≠ | ¬ appear in the 63- and 89-character EBCDIC sets but not in either of the ANSCII-based sets. However, Xerox software translates the characters c into ANSCII characters as follows:

EBCDIC	=	ANSCII
¢		` (6-0)
I		(7-12)
-		~ (7-14)

- 3 The EBCDIC control codes in columns 0 and 1 and their binary representation are exactly the same as those in the ANSCII table, except for two interchanges: LF/NL with NAK, and HT with ENQ.
- 4 Characters enclosed in heavy lines are included only in the standard 63- and 89-character EBCDIC sets.
- 5 These characters are included only in the standard 89-character EBCDIC set.

STANDARD 7-BIT COMMUNICATION CODES (ANSCII)¹

5

NOTES:

- 1 Most significant bit, added for 8-bit format, is either 0 or even parity.
- 2 Columns 0-1 are control codes.
- 3 Columns 2-5 correspond to the 64-character ANSCII set. Columns 2-7 correspond to the 95-character ANSCII set.
- 4 On many current teletypes, the symbol

^	is	† (5–14)
_	is	(5-15)
~	is	ESC or ALTMODE control (7-14)

and none of the symbols appearing in columns 6-7 are provided. Except for the three symbol differences noted above, therefore, such teletypes provide all the characters in the 64-character ANSCII set. (The Xerox 7015 Remote Keyboard Printer provides the 64-character ANSCII set also, but prints ^ as Λ .)

5 On the Xerox 7670 Remote Batch Terminal, the symbol

!	is	1	(2-1)
[is	¢	(5-11)
]	is	!	(5-13)
^	is	-	(5-14)

and none of the symbols appearing in columns 6–7 are provided. Except for the four symbol differences noted above, therefore, this terminal provides all the characters in the 64-character ANSCII set.

Hexadecimal fractions may be converted to decimal fractions as follows:

Express the hexadecimal fraction as an integer times 1. 16⁻ⁿ, where n is the number of significant hexadecimal places to the right of the hexadecimal point.

0. CA9BF3₁₆ = CA9 BF3₁₆ ×
$$16^{-6}$$

Find the decimal equivalent of the hexadecimal integer

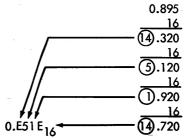

$$CA9 BF3_{16} = 13 278 195_{10}$$

Multiply the decimal equivalent by 16⁻ⁿ

$$13 278 195
 x 596 046 448 x 10-16
 0.791 442 09610$$

cimal fractions may be converted to hexadecimal fractions successively multiplying the decimal fraction by 16₁₀. er each multiplication, the integer portion is removed to n a hexadecimal fraction by building to the right of the adecimal point. However, since decimal arithmetic is d in this conversion, the integer portion of each product st be converted to hexadecimal numbers.

imple: Convert 0.895₁₀ to its hexadecimal equivalent

APPENDIX B. INSTRUCTION TIMING

INSTRUCTION TIMES

The instruction times for the Xerox 530 instructions are calculated by adding the preparation time and the instruction execution time. These times are shown in Table B-1. For those instructions where a range of numbers is shown for the preparation time, the preparation time is a function of the specific effective address mode as shown in note (1) to Table B-1. All of the times shown in the table are accurate within ±0.1%, assume no input/output or memory interference, and assume that all instructions and operands are in the same 8K memory module.

Table B-1. In	nstruction	Preparation	and Execu	tion Times	(in µsecs.)

-

Notes: (cont.)

- (i) Assumes IOP is not busy. If IOP is busy, CPU must wait until the end of the current IOP service cycle.
- (1) Assumes external device controller. FSL is Function Strobe Leading Acknowledge.
- (15) Assumes standard interrupts. Add 2.88 µsec for first group of 12 interrupt levels. Add 5.76 µsec for second group of 12 optional interrupt levels.
- (14) FSA is Function Strobe Acknowledge from external device.
- (v) Assumes standard interrupts. Add 1.92 µsec for first group of 12 optional interrupt levels. Add 3.94 µsec for second group of optional interrupt levels. Also assumes not reentering floating point mode.
- J is the number of prealignment shifts required. K is the number of postnormalization shifts required.
- (b) FMP and FDV instruction execution times are typical times based on a random distribution of ones and zeros in the operands.
- Time shown is for 16-bit field starting on bit 0. For a 16-bit field starting on some other bit position, use the "other fields - contained within two words" execution times.
- Time shown is for 8-bit field starting on bit 0 or 8. For an 8-bit field starting on some other bit position, use the appropriate "other fields" execution times, depending on whether the 8-bit field is contained within one memory word or two memory words.
- Time shown is for 4-bit field starting on bit 0, 4, 8, or 12. For a 4-bit field starting on some other bit position, use the appropriate "other fields" execution times, depending on whether the 4-bit field is contained within one memory word or two memory words.
- Add 0.32 µsec if register indexing is specified by the RX field in the instruction. Add 3.52 µsec if selfincrementing is specified by the SX field in the instruction. Add 4.16 if self-decrementing is specified by the SX field in the instruction. See the description of "Field Addressing Instructions" in Chapter 3.

APPENDIX C. READ/WRITE (MODE 0) INSTRUCTIONS

This appendix is comprised of eight tables. Tables C-1 through C-4 show the 256 different function values for a READ DIRECT (Mode 0) instruction. Tables C-5 through C-8 show the 256 different function values for a WRITE DIRECT (Mode 0) instruction. Each table consists of 64 function values (assigned and unassigned). Unassigned function values are reserved and must not be used. Attempting to use an unassigned function value results in a Machine Fault Interrupt.

Table C-1.	READ DIRECT	(Mode 0)	Instruction.	Function	Values	X'00'-X'3F'

	В	FA RX=6 SX=0	FA RX=6 SX=1	LDM or STM X=6 Y=2					FA RX=6 SX=7	FA RX=7 SX=0	FA RX=7 SX=1						FA RX=7 SX=7

Note: Except for function values X'80' (copy contents of DATA switches into A register) and X'9E' (SFM; Set Floating Mode), which are one-word instructions, each of the other assigned function values within this group is the first word of a two-word instruction sequence. These function values are identified and described with the following symbols and mnemonics:

- CPD A doubleword compare instruction.
- DAD A doubleword add instruction.
- DSB A doubleword subtract instruction.
- FA A field addressing instruction.
- GR A general register instruction. The accompanying value (2-6) indicates the general register that is used as the accumulator.
- LDD A doubleword load instruction.
- LDM A multiple register (other than doubleword) load instruction.
- RX For field addressing instructions, RX=1 signifies no indexing register, RX=2 through RX=7 signify the indexing register.
- STD A doubleword store instruction.
- STM A multiple register (other than doubleword) store instruction.
- SX For field addressing instructions, SX=0 signifies no self-indexing, SX=1 signifies self-incrementing, SX=7 signifies self-decrementing.
- X For multiple register and doubleword instructions, the X value signifies the number of registers.
- Y For multiple register and doubleword instructions, the Y value signifies the first register.
