Variability in Disposition Rates and Mean Days of Hospitalization
for the 100 Most Common Diagnostic Codes in U.S. Army Health
Services Command Facilities

David A. McFarling, COL MC

"Statistical monitoring and feedback are the cornerstone of any continuous quality improvement effort, as they make it possible to engage everyone in an ongoing examination of performance." (Caper, 1991)

Significant variations in the utilization of health services occur between geographical areas with similar demographic characteristics. Although these variations were recognized more than fifty years ago (Wennberg, 1990), they received little serious attention until the work of Wennberg and Gittelsohn and others in the early 1970's and during the 1980's (1,2,4,13,16, 17,18).

Recent work by Chassin, Brook and others (4,5) demonstrates convincingly that at least some of the observed variability results from inconsistent and inappropriate utilization of health services. In turn, inconsistent and inappropriate utilization of services has played a significant role in the calamitous rise in health care costs and, equally importantly, such misutilization of health services must inevitably lead to poorer clinical outcomes.

Most studies of geographical variability in health care utilization have used techniques that are known collectively as "small area analysis" or SAA. Paul-Shaheen and coworkers (12)

have extensively reviewed SAA studies reported in the medical and the health policy research literature. This study used SAA-like techniques to analyze the utilization patterns in 37 of the 39 medical facilities within the U.S. Army Health Services Command (HSC). The goal of this study was to determine the range of variability among the most common diagnostic codes so that this information could eventually be incorporated into HSC's overall program of Total Quality Management (TQM).

METHODS

STUDY POPULATION. The U.S. Army Health Services Command is the operational medical major command responsible for all Army medical treatment facilities (MTF) in the continental United States (CONUS), Hawaii, Panama, and Puerto Rico. HSC is responsible for comprehensive health care for more than 3 million eligible beneficiaries. HSC operates thirty-nine hospitals ranging in size from Walter Reed Army Medical Center in Washington, D.C. (754 beds) to Weed Army Hospital at Fort Irwin, California (13 beds). HSC hospitals are spread throughout the United States with facilities in every geographical area.

The HSC is organized into regions corresponding to each of the eight Army Medical Centers (MEDCENS). (Note: In 1989, the year of the study data, Letterman Army Medical Center (LAMC) was the regional medical center for the lower half of the West Coast.

LAMC has subsequently been downsized and is no longer a MEDCEN.) For each region, the MEDCEN serves as the referral facility or tertiary care center for that region's smaller hospitals (called Medical Activities or MEDDACs). Each MEDCEN has a full range of medical specialists and offers comprehensive medical services. Each MEDCEN also provides graduate medical education (GME) programs including internships, residencies, and fellowships. Unlike the MEDCENS, the MEDDACs do not necessarily offer a full range of specialty and subspecialty services. The services offered at the MEDDACs largely depend of the mix of physicians assigned to the staff and other factors such as available medical equipment and ancillary support. Some of the larger MEDDACs have active residency programs in Family Practice but do not otherwise offer GME training.

Medical services which cannot be provided at the MEDDAC are provided either through referral to the regional MEDCEN or through local community practitioners. In the latter case, these services are paid for by the Civilian Health and Medical Program for the Uniformed Services (CHAMPUS). Since CHAMPUS has both a \$150 deductible and a 20% copayment once the deductible is exceeded, Army beneficiaries have a strong financial incentive to obtain their care in the Army medical facility when possible.

DATA SOURCES. The period chosen for analysis is calendar year 1989 (CY89). Calendar year 1989 is the most recent complete calendar year in which the clinical data are unaffected by the

rapid mobilization and deployment of medical assets in support of Operation Desert Shield and Operation Desert Storm.

Small Area Analysis typically addresses variability in three major areas: disposition rates, bed day utilization, and costs. Due to the mechanisms through which military facilities are funded, cost information cannot be obtained for specific individual diagnoses or procedures. Therefore, this study considered only disposition rates and bed day utilization.

The U.S. Army Patient Administration Systems and Biostatistics Activity (PASBA) maintains statistical records for all Army facilities. The U.S. Army Health Care Studies and Clinical Investigation Activity (HCSCIA) maintains a comprehensive statistical database which includes all CHAMPUS utilization data (including detailed expenditures) for all federal facilities since 1988.

The PASBA provided a list of the 100 most common diagnoses, based on ICD-9-CM code, for HSC during CY89. All codes were based on the primary diagnoses, that is the first diagnosis listed on the medical narrative summary sheet. For each diagnostic code, PASBA provided the number of dispositions and the mean days of hospitalization at each of 37 HSC facilities. The Fort Irwin and Fort Drum MEDDAC data were not included due to extremely small size and atypical mission of these facilities. The most common diagnostic code was V300 "single infant born in hospital" with

30,509 dispositions during calendar year 1989. The least common was 5920 "calculus of kidney" with 733 dispositions.

DATA ANALYSIS. The disposition rates per 10,000 population in each facility's catchment area were calculated by dividing the number of dispositions for each diagnosis by the reported population of Army beneficiaries in the catchment area and multiplying by 10,000. The catchment area includes all persons living within a 40 mile radius of the facility. The total of all catchment areas does not equal the total number of HSC beneficiaries for reasons discussed in the next paragraph. The average number of bed days for each diagnosis was entered into the study directly from the PASBA data. HCSCIA provided comparable CHAMPUS data on numbers of dispositions and bed days. The overall disposition and bed day rates were calculated for both direct care data only and for direct care data combined with CHAMPUS data.

The crude disposition rates and mean bed days for both direct care and the combination of direct care and CHAMPUS were adjusted using the indirect standardization method (Fleiss, 1981). The overall beneficiary population of HSC was used as the standard population. The data was standardized for age, sex, and active duty versus non-active duty status. The eight demographic groups used for data adjustment were:

Males, 0-17 years

Females, 0-17 years

Active duty males, 18-44 years
Active duty females, 18-44 years
Non-active duty males, 18-44 years
Non-active duty females, 18-44 years
Males, 45 years and older
Females, 45 years and older

Non-active duty males and females in the 18-44 years old range included dependents of active duty, retired personnel, and dependents of retired personnel. Over the age of 45, the numbers of active duty males and females are so small as to have no statistical significance when analyzed separately. Therefore, beneficiaries over 45 years old were not divided into active duty and non-active duty groups.

The HSC divides its facilities by size and by mission into four peer groups: Medical Centers, Large MEDDACs, Medium MEDDACs, and Small MEDDACs. The facilities comprising each peer group tend to be located in similar demographic areas (e.g. MEDCENS in larger metropolitan areas and small MEDDACs in more rural settings) and have similar population demographics. Each MEDCEN provides graduate medical education programs and serves as a referral center for its region. Therefore, MEDCEN practice patterns should be considerably different from those of smaller facilities. For the MEDDACs, the practice patterns may differ depending on additional factors such as size, staffing and population served. Demographic adjustments were made as

described. To try to adjust as much as possible for the effects of size, staffing, and mission the three MEDDAC peer groups were analyzed separately.

The MEDCEN peer group presented a problem in that unlike the rest of the members of that group, Letterman Army Medical Center (LAMC) did not offer OB/GYN care in 1989. Due to the overall high occurrence of OB/GYN diagnoses in HSC, this had a significant potential to distort the findings. Therefore, the data for disposition rates and mean bed days were recalculated deleting LAMC from the calculations for all OB/GYN related diagnoses. Since this recalculation made no significant difference in the overall peer group results, no adjustments for LAMC OB/GYN data were made in the final analysis.

For each set of rates, an average, standard deviation and coefficient of variation were calculated. The coefficient of variation (standard deviation divided by the mean) is a convenient measure of "spread" of the values for one set of data (e.g. disposition rates for a particular diagnostic code) compared to the "spread" of values for another data set. A wide range of variability produces a high coefficient of variation and a narrow range a small coefficient of variation. Within each peer group, the diagnostic codes were ranked from the greatest coefficient of variation to the least.

Ranking the diagnostic codes in descending order of

coefficient of variation for disposition rates and for mean bed days produced a numerical estimate of variability in each factor. To produce a single composite measure of variability, the two rankings--variability of disposition rate and of bed days--were summed and the resulting rank order used as a "composite index of variation." The lowest sum represents the most overall combined inconsistency and the highest the least. When ties in the ranking sums occurred, these were broken on the basis of the difference between the ranking for dispositions and the ranking for days. Smaller differences were taken to represent more consistent variability or non-variability and these diagnoses were placed ahead of those diagnoses with the same overall sum but with larger differences between the component rank scores.

For each of the summary tables, the consistency of the variability rankings between peer groups was determined by calculating a Kendall Coefficient of Concordance (Siegel, 1956). The same process was used to determine consistency in rankings across each of the four data sets. For comparisons across peer groups, the Coefficient of Concordance ranged from .51 to .63 and all "p" values were less than 0.001. The rankings across the four data sets produced coefficients of concordance between .53 and .88 and all "p" values were less than 0.001.

RESULTS

The Appendix, Sections B through J, contains the data on the

variability in disposition rates, bed days, and a composite measure of the two combined. This data is arrayed in a variety of ways (e.g. by facility, by peer group, by source of data, etc.). There is no generally recognized absolute degree of variability that is considered "acceptable" or "unacceptable" using this methodology (See DISCUSSION).

Table 1, Section A, contains the demographic data for the 37 HSC facilities in 1989. Table 2, Section A, shows the overall disposition rates per 10,000 population and Tables 3-9 show the overall disposition rates for each of the population subsets.

The individual facility disposition rates and average bed days by diagnosis are found in Section B, Tables 1-32. These tables also show the highest rate, lowest rate and the high-to-low ratio for each diagnosis. In cases where the low rate was zero, no ratio was calculated.

Tables 1-32 in Section C show the mean, the standard deviation, and the coefficient of variation for the disposition rates and bed days for each diagnostic code within a given peer group. In each table, the diagnostic codes are arranged in order of descending coefficient of variation. Therefore, the diagnostic codes toward the top of the list are those that show the most variability and those toward the bottom the least.

Section D contains the composite index of variability

rankings by peer group. The composite index of variation is the sum of the rankings for variability in disposition rate and for variability in bed days. The lowest sums represent those codes with the most overall variability.

Section E lists the average rates for dispositions and for bed days across the four peer groups. The codes are arranged in order of variability as previously determined using the coefficient of variation. Section F shows the comparative variability rankings across peer groups for disposition rates and for bed days separately.

Section G shows the composite index of variability rankings across the peer groups. Table 5, Section G shows how the overall composite index of variability rankings compare using the four different data sets.

Section H lists the diagnostic codes in order of overall composite index of variability rankings by data set (i.e. direct care, crude and adjusted, and combined CHAMPUS and direct care, crude and adjusted).

Tables 1-5, Section I, show a comparison of the rankings for disposition rates by data source (i.e., direct care crude, direct care adjusted, combined direct care and CHAMPUS crude, combined direct care and CHAMPUS adjusted). Tables 1-5, Section J, show a comparison of average length of stay rankings by data source.

DISCUSSION

The purpose of studying utilization rates such as those detailed in this report is to provide data which can be used to improve clinical quality and to reduce unnecessary resource utilization by identifying unusual patterns of variation. If the all medical care was delivered in a reasonably consistent manner from practitioner to practitioner, there would be little justification for such studies. However, every study of utilization patterns performed to date has shown just the opposite. For many types of care there are inconsistencies which cannot be explained on the basis of the characteristics of the population served (4,5,6,10,11,15,16,17,18). These inconsistencies contribute to both the high cost and to the uncertain clinical benefits of many current medical practices.

This study uses SAA-like techniques which are similar to previous studies. However, this study has several unique features. First, none of the previous studies deal with a large number of facilities within a single multifacility health care system covering all geographical regions of the United States. Second, none deal with care in the Military Health Services System (MHSS). The MHSS is unique in several respects. The MHSS has a dual role in health care, the maintenance of readiness to provide medical support for the troops in war and the provision of peacetime health care. Further, MHSS beneficiaries have the option of receiving care at military treatment facilities or at

civilian facilities through the Civilian Health and Medical Program for the Uniformed Services (CHAMPUS). At the moment, the choice of one or the other type of care is largely unconstrained.

Third and lastly, none of the previous studies of geographical variations in utilization rates specifically targeted the most common types of care within a health care system. Most of the previous studies have concentrated on a relatively small number of diagnoses and procedures selected on the basis of prior information about inconsistent practices or other issues such as high costs. In this study, frequency of occurrence was the only basis for selection of the diagnoses to be studied. One disadvantage of this approach is that the 100 most frequent diagnostic codes probably do not include many of the most variable diagnoses. On the other hand, if quality improvements in the system are to have a genuine impact on care, then they should logically be directed at the most frequent types of care. Analyzing the variability of a rare diagnosis or procedure might have little impact on the system as a whole.

The data appear to show that of the 100 most common diagnostic codes in HSC, some codes show great inconsistency in disposition rates or bed days or both and other codes that show very little variability in either. In order to accept this as a legitimate observation the likely accuracy of the data and the variation introduced by other factors such as population

demographics must be considered.

Several factors somewhat limit the precision of the data used for this study. First, the base population served by each facility is not entirely clear. Army facilities treat not only Army active duty and retired personnel and their dependents, but also often treat U.S. Navy and U.S. Air Force active duty and retired personnel and their dependents. The reported population in each facility's catchment area does not include non-Army beneficiaries. Another problem arises in that the catchment area population figures are based on enrollment in the Defense Eligibility Enrollment Reporting System (DEERS). At least 20-30% of the addresses in the DEERS records are incorrect.* Finally, the catchment areas extend only to a 40 mile radius from the facility. For a variety of reasons, many patients who live more than 40 miles from a medical facility will nonetheless travel to the facility for care. The number of such persons in any given facility's general geographical area, but beyond the 40 mile radius that determines the catchment area, is uncertain. Even if the true size of the potential eligible beneficiary population for most facilities is not precisely known, the errors should be more or less equally distributed throughout the system so that the results may not be significantly biased.

Another difficult problem presented by the data is the use of ICD-9-CM codes as the data source (Jencks, 1992). The ICD-9-

*U.S. Army Health Care Studies and Clinical Investigation Activity, Unpublished Data.

CM codes are often vague and may vary widely in the number of diagnoses that are included in any given code. Furthermore, to completely capture the data on a specific clinical diagnosis may require combining several related (or sometimes seemingly unrelated) codes. In this study, V670 Follow-up Exam, Following Surgery, was among the most variable of the diagnostic codes. Much of this variability clearly results from a hodgepodge of dissimilar clinical cases being encompassed in this code or from this code being inappropriately selected by the coding clerk or both. In such cases, little useful information can be obtained without further study of individual medical charts.

A related area of concern for quality management is how the diagnostic codes relate to procedures performed. The IDC-9-CM codes used were only the first code listed on the chart summaries. Therefore, in most cases, there is no information about what procedures were or were not performed during that admission. For example, Code 4741 Hypertrophy of Tonsils and Adenoids is relatively specific (i.e., denotes a single, uniform diagnosis) and shows a high degree of variability. Since this diagnosis is a frequent reason for admission for tonsillectomy, it may indicate a high degree of variation in the rates of tonsillectomies across the system. This will require confirmation through additional studies linking ICD-9-CM codes to procedures.

Finally, simple coding errors produce another possible

source of variation. Random coding errors due to typographical errors or misinterpretation of the narrative summary diagnoses should produce little or no effect on the overall results. On the other hand, coding errors caused by poorly dictated narrative summaries, consistent anomalous terminology by a practitioner, or misinterpretations by records clerks may not be randomly distributed and could potentially alter the results. The problems with using the ICD-9-CM codes are not unique to this study (Jencks, 1992) and will continue until a more specific and useable system is devised.

Another consideration in determining the significance of the observed variability is the source of the data. The Military Health Care System actually consists of two parallel systems, the "direct care" system comprised of the military treatment facilities and the CHAMPUS system. The decision to include CHAMPUS data in the analysis has both advantages and disadvantages. The direct care data reflects the behavior of providers who work in HSC facilities. The CHAMPUS data reflects the behavior of civilian community practitioners. Neither group necessarily follows the standards of the other so that mixing the data introduces an additional element of uncertainty.

On the other hand, there are advantages to using the CHAMPUS data. Not all facilities have the full complement of specialists necessary to offer comprehensive medical services. Therefore, some of the variability noted in the direct care data could

result from the provider mix at the facilities. Including the CHAMPUS utilization data from the corresponding facility catchment area partially compensates for this since patients unable to obtain care at the military treatment facility due to unavailability of a particular type of specialist often use the CHAMPUS system. The addition of CHAMPUS data to direct care data had only a slight effect on any of the variability rankings. In some cases this probably reflects the relatively small number of CHAMPUS admissions. In others, it suggests that some diagnoses and procedures are managed as inconsistently in the civilian community as in the direct care system. In any case, the degree of variability shown by those diagnoses at the top of the lists cannot be explained solely by citing variations in provider staffing since if this were so, factoring in the CHAMPUS data should have eliminated much of that variability.

Finally, in a system composed of widely differing treatment facilities covering widespread demographic areas, some of the variability observed might be expected to be due to the demographics of the population served. In addition, the realities of military life require that active duty patients sometimes be managed differently than non-active duty patients. Important factors that enter into the management of active duty patients include barracks living and the requirement for vigorous physical activity. The data was adjusted age, sex, and active duty versus non-active duty status. None of the demographic

adjustments had any significant effects on the variability rankings.

Assuming that the reliability and validity of the data are acceptable after recognizing the various confounding factors, the next question is what does the data actually measure? This study used disposition rates and mean bed days as measures of variability. Disposition rates reflect not only the community prevalence of a illness, injury or other condition, but also the local criteria for hospitalization. In previous studies, disposition rates have been generally more variable for conditions where there is greater practitioner discretion (14). Likewise, in this study many of the most variable diagnoses seem to represent areas where providers have considerable latitude in management, particularly with respect to admission for inpatient care. On the other hand, the diagnoses showing the least variation in disposition rates characteristically have a relatively limited number of provider options. For example, the admission rates for "acute appendicitis" and "pyelonephritis" show little variability, indicating a very high degree of consistency.

In some cases the variability in disposition rates found in this study reflects unique situations unrelated to general clinical practices. For example, the variability in 0449 HTLV-III/LAV is clearly related to other considerations. Patients infected with HIV are usually treated in the limited number of

medical centers where major HIV related research projects are underway. Clearly, this skews the natural distribution of patients and causes an artificially high degree of variability across regions.

Mean bed days reflect provider behavior once the patient is hospitalized. However, variation in mean bed days is not entirely independent of the variation in utilization rates. In all peer groups, there is a modest but significant correlation between the two measures using the Spearman Rank Order Coefficient (Siegel, 1956). This suggests that where there is uncertainty about the optimal management of a condition or inconsistency due to other factors, then this may be reflected in both the admission rates and in the mean bed days.

Since there seemed to be a relationship between variability in disposition rates and variability in bed days, a composite index of variation combining rankings of the variability in disposition rates and mean bed days was used to provide an additional perspective. For some purposes, this composite index may be preferable and for others it may be more important to concentrate on a single measure such as bed days.

The very high correlation between the rank order of variability across all four data sets (crude and adjusted direct care; crude and adjusted direct care combined with CHAMPUS) suggests that where there are no other confounding factors, the

high rankings for those diagnostic codes consistently at the top of all lists reflect genuine inconsistency which cannot be accounted for by underlying population characteristics or, in most cases, by staffing mix.

The data does not suggest any specific reason for this observed inconsistency. Subtle differences in system structure and specific policies with respect to certain kinds of care account for some of the variability. Staffing differences may affect utilization rates more in areas where CHAMPUS support is less readily available in the surrounding community or in cases where patients might not wish to use CHAMPUS due to the expense and non-urgent nature of the care. For example, the utilization rates for elective cosmetic surgery vary dramatically depending on the availability of military plastic surgeons. If cosmetic procedures are not available in the direct care facility, patients may opt not to undergo an expensive elective procedure which is only partially covered by CHAMPUS. The example of the effect of AIDS treatment programs and their effect on the distribution of patients has already been mentioned.

The final, and to health care providers least palatable, possibility is that practitioners are managing similar patients in much different ways. This may be due to the lack of consistent scientific information on which to base their practices or to other considerations such as personal biases, recent good or bad results, financial considerations, etc. (14)

How can a health care system use the results of this and similar studies to improve quality? First, these studies identify possible problem areas for further evaluation. As mentioned in the "Results" section, there is no standard absolute "acceptable" degree of variability. A single measure of variation such as a given value of the coefficient of variation or a particular numerical ranking might be arbitrarily used as a cutoff point, but there is little or no objective basis for picking one point as opposed to another. Alternately, and perhaps more appropriately, quality improvement groups can simply target a general range (e.g. the top quarter of a variability ranking list) and pick from the diagnostic codes in that group those that appear to need more detailed study. Which table or tables to use--direct care data, combined data, disposition rates only, bed days and disposition rates combined, etc.--depends on how the information is to be used. For example, if a project was undertaken to establish consistent admission criteria, then the disposition rates would be of primary importance. Second, the data from this study can be used as a "baseline" rate against which to compare the future results of quality improvement initiatives.

To effectively use this data for quality improvement, each of the possible sources of unexplained variation in practice patterns must be considered separately and the appropriate corrective action taken. One such source of variation is the data validity. This relates to the quality, accuracy and

precision of the recorded data rather than the actual provision of care. Inaccurate data is a major problem for all health care systems. Part of the problem is related to inadequate or inaccurate documentation of care and part is inherent in the use of the ICD-9-CM system. Improvements in the ICD-9-CM (now IDC-10-CM) coding system are likely to occur only over a long period of time. In the interim, practitioners need to evaluate how what they put in the chart is translated to diagnostic codes and whether or not those codes accurately reflect the care delivered.

Another source of apparent variability in practice patterns are externally imposed factors such as the availability and the distribution of specialists and research protocols, outbreaks of disease which may be limited to one area (e.g. food poisoning or heat stroke), or contingencies such as support provided to field training. These factors may produce variability in practice patterns unrelated to individual provider behavior. Many of these are management issues and subject to the vagaries of personnel, funding, etc.

The last source of variability, genuinely inconsistent provider behavior, is the major area where there are immediate opportunities for quality improvement. Where wide variations in actual clinical practices for the same or similar conditions exist, it is highly unlikely that all providers are practicing in an equally effective manner or using resources wisely. Wide variation in utilization of health services must include a

considerable degree of inappropriate utilization of health services.

Inappropriate utilization can occur in the form of overutilization, underutilization, and misutilization. Overutilization, particularly of high technology diagnostic procedures, is both costly and contributes to the maldistribution of care by diverting resources that could be more effectively utilized. Underutilization leads to the failure to detect and treat illnesses in the early stages resulting in poorer clinical outcomes. Misutilization, defined as the use of inappropriate or ineffective clinical practices, results in suboptimal clinical outcomes if not outright harm.

The recognition of variability in health services utilization due to clinical practice differences is only a preliminary step. Where two rates differ and no reason other than provider behavior can be identified, either or both rates may reflect suboptimal care. Further research is critically needed to determine what genuinely constitutes optimal or appropriate care, particularly in common conditions with broad provider discretion for care.

Where inconsistent and inappropriate clinical practices do occur, the question still remains as to the best way to correct the problem. Quality problems can be "systemic" or

"extrasystemic" (9). In the context of this study, a systemic cause for variability would be that practitioners are uncertain of the correct management for a problem and must choose among a wide variety of options without adequate information. An extrasystemic problem would be that one or only a few persons are practicing in a manner contrary to well-established and generally accepted practice. This concept can be applied equally well when one views each hospital as a "provider" within a multifacility (multifacility) system.

Successful total quality management programs address both extrasystemic and systemic issues. The data from this and similar studies can pinpoint possible extrasystemic problems (i.e., those unique to individual institutions or practitioners) by identifying institutions which are clearly outliers for certain types of care. Such cases can then be individually investigated in sufficient detail to allow corrective action to be taken where necessary. Systemic problems (i.e., those that are widespread throughout a system and not the result of isolated cases) can be approached through more generalized interventions such as carefully selected clinical practice guidelines.

Clinical practice guidelines remain controversial. Used properly, guidelines can in theory result in more effective and consistent clinical practices. Unfortunately, attempts to implement guidelines often meet intense resistance. Practitioners resent any potential loss of autonomy and fear

the use of guidelines as tools for supporting malpractice litigation. Data on unaccountable variations in utilization rates provide powerful tools to argue that guidelines and other attempts at rational standardization of care are genuinely needed. Conversely, data showing little or no variation in practice patterns across a system suggests that that particular type of care is delivered in a consistent manner. However, it is well to remember that increased consistency in either disposition rates or in the use of bed days does not, by itself, necessarily indicate improved quality of care. In addition to studies like this that evaluate patterns of resource utilization, studies that correlate these patterns to specific clinical outcomes and to the cost-effectiveness of care are critically needed.

NOTE: THE MORTALITY RATE IS THE NUMBER OF DEATHS PER 100 PERSON-YEAR. THE 95% CONFIDENCE INTERVAL IS SHOWN IN PARENTHESES.

REPRODUCTION: VARIATION IN NUMBER OF PREGNANCY
 LOSS: IN NUMBER OF PREGNANCIES PER 100
 DELIVERY RATE: NUMBER OF DELIVERIES PER 100

TABLE 11. VARIABILITY, RATES BY PEAK INJURY, LARGE HEADING, AVERAGE LENGTH OF STUDY GROUP, SELECT CASES INDICATED RATES

Table with 6 columns: ICD-9 code, Description, S.D., CHIEF VAR, AVG, and CHIEF VAR. The table lists various medical conditions such as 'OTH PLASTIC SURG, COSMETIC IMP', 'CONGESTIVE HEART FAILURE', 'SYNOVITIS/TENOSYNOVITIS', etc., with corresponding numerical values in each column.
