## ABSTRACT

The Haystack pointing system can direct an antenna at selected points of an orbit. The point selected may be the intersection of the orbit with a fixed right ascension half plane, a fixed longitude half plane, or a fixed declination cone; in addition a horizon-to-horizon scan along the orbit may be generated. The primary use for this facility is in connection with radar or communication experiments with a West Ford dipole belt. The Belt program in the pointing system, given a set of orbital parameters and the selected schedule, generates the celestial coordinates and their rates of change for use by other programs in the system in producing antenna angles, range, and doppler.

## I. INTRODUCTION

The Belt Celestial Computation Program (BELTP) was written for the Univac 490 as part of the pointing system for the Haystack radar antenna operated by Lincoln Laboratory. Written in SPURT assembly language, the program calculates pointing information in celestial coordinates for a selected point of a belt in orbit around the earth, such as the West Ford dipole belt. Basically, the program performs the calculations necessary to convert mean orbital elements which are valid as of a certain day to instantaneous elements valid as of the time of computation; from these it then determines celestial coordinates and their first time derivatives of a point on the orbiting belt according to the "schedule" (mode of operation) of the program. The schedule selects the point on the belt by keeping one coordinate fixed.

BELTP is divided into three main sections: the controller, the four schedules, and the utility routines. The controller is further divided into an initialization section and a working section. When the initialization section is entered with L(SYSTAT1) set to -0, the operator types in the parameters on the on-line typewriter. When the initialization section is entered with L(SYSTAT1) set to +0, the operator may examine the previous input values and, optionally, either use them again or change them.

Each of the four schedules is divided into two distinct subprograms. The initialization section, which is entered only once during initialization or reinitialization, calculates the values that are to be constant during the tracking, given the initial input values. When the working section of a schedule is entered, a calculation is made for the right ascension, declination, and range for the time contained in W(CELTIME). All routines save and restore all registers with the exception of B7.

Errors will fall into two general classifications: the belt is untrackable because of the physical limitations of the radar scan, or inconsistent parameters have been specified. If an error occurs, control will be transferred to the location following the return jump to BELTP and the A-register will contain a code indicating the nature and probable location of the error. A normal exit will transfer control to two locations after the return jump.
