CALCULATIONS OF SHIPBOARD HEAT EXCHANGERS.

Reference textbook.

A. S. Tsygankov.

Page 2.

In the book is generalized and systematized the calculated
material, accumulated in the process of designing the heat
exchangers. The book is a reference textbook of practical nature and
does not contain theoretical linings/calculations and substantiation.
The systematization of the given material allows with the minimum
expenditure of time sufficient to full-valued produce the necessary
linings/calculations and calculations.

The book is intended for the technical-engineering workers
(designers and builder-heat technicians) can also serve as textbook
for the students of ship-building and energy call and students of
technical schools.

Page 3.

Preface.

Heat exchangers are the composite/compound equipment component
of the power plants, which have extensive application in the
industry, and also on the vessels of civil/civilian and serviceman of
fleets.

The creation of the ideal and reliable equipment, which
corresponds to the contemporary level of development of technology,
requires the thorough study of occurring in the apparatuses processes
and technology of their production on the basis of experimental
investigations and production experiment.

In the past postwar years is carried out the series/row of
scientific research and experimental works on heat engineering, which
contributed to accumulation of considerable experience according to
the design, to production and testing of heat exchangers and served
as basis for writing of this book.

This edition of the book differs from the publication 1948 [1] of
the more detailed treatment of the questions, connected with the heat

transfer, hydraulic resistance and structural strength of heat exchangers.

FOOTNOTE 1. A. S. Tsygankov. Calculations of shipboard heat exchangers. Sudpromgiz, 1948. ENDFOOTNOTE.

The obsolete calculation formulas are replaced here by modern ones. During the treatment/processing of the book is taken into consideration also the majority of observations and wishes of the reviewers and readers.

Page 4.

For the purpose of warning/prevention of the errors and for the savings of time with the execution of calculations in the book are given typical examples of the thermal designs of the most widely used apparatuses and examples of the calculations of hydraulic resistances for different working media, which take place in their cavities.

In the book is given the single procedure of calculation of different tube plates and are given examples of the calculation of the strength of the basic parts of apparatuses.

The section of applications/appendices is renovated and

supplemented by new tabulated data of the physical parameters of the working media of heat exchangers.

A. Tsygankov.

Page 5.

Chapter I.

THERMAL DESIGNS.

§1. Pressures and rarefaction/evacuation.

By the pressure is understood the force, which acts per unit of
surface. Working standard of pressure is called technical atmosphere,
i.e., the pressure, produced by force in 1 kg to 1 cm² of surface.

In the rarefaction/evacuation, or the vacuum, is understood the
difference between the pressure of the external atmosphere and the
absolute pressure in the place of measurement, while by the
overpressure - a difference between the absolute and atmospheric
pressures. Absolute pressure is expressed in the absolute
atmospheres, and vacuum - in the millimeters of mercury or water
column, and also in the percentages.

Normal barometric pressure, or physical atmosphere:

B=760 mm Hg   =1.033 kg/cm².

The technical atmosphere:

$P = 1$ at $= 1$ kg/cm^2 = 735.6 mm Hg with 0°C;

p = 737.4 mm Hg with 15°C;

p ~ 10 m H$_2$O with 4°C.

Absolute, either real, pressure:

$$p_a = p_b + p \}$$
$$p_a = p_b - p_h \}$$. (1)

where p_b - atmospheric, or barometric, pressure, mm Hg;

p - overpressure (reading manometer), mm Hg.

p_h - vacuum, or rarefaction/evacuation (reading vacuum gauge), mm Hg.

Page 6.

Pressure at any point within the liquid:

$$p = p_0 + \gamma z \ \text{kg/m}^2, \qquad (2)$$

where p_0 - pressure above the surface of liquid, kg/m^2;

γ - the specific gravity/weight of liquid, kg/m^3;

z - submersion depth of point under the surface of liquid, m.

The force of pressure of liquid on the flat/plane vertical wall:

$$P = (p_0 + \gamma z_{ct}) F \ \text{kg}, \qquad (3)$$

where z_{ct} - height/altitude, equal to the submersion depth of the geometric center of wall, m;

F - area of wall, m^2.

The force of pressure of liquid on the inclined wall:

$$P = (p_0 + \gamma z_{ct}) F \cos \alpha \ \text{kg}, \qquad (4)$$

where α - angle of component with the normal to the wall.

During the determination of force of pressure on the curved

surface of wall into formula (4) instead of $F \cos \alpha$ is substituted

the projection of surface, perpendicular to force direction

The pressure of vapor or gas (characteristic equation):

$$p = \frac{RT}{v} \ \text{kg/m}^2,\qquad\qquad (5)$$

where R - gas constant, kg-m/kg   °K: for the saturated water vapor

R=47.05, for air R=29.27;

T=273.2+t°C - absolute temperature, °K;

v - specific volume, m³/kg.

Absolute condenser backpressure:

$$\left.\begin{array}{l} p_{\kappa} = b - h \ \text{мм рт. ст.}^{(1)} \\[4pt] p_{\kappa} = \frac{b-h}{735,6} \ ama^{(2)} \\[4pt] p_{\kappa} = \left(1 - \frac{p_h}{100}\right) 735,6 \ \text{мм рт. ст.}^{①} \end{array}\right\}\qquad (6)$$

Key: (1). mm Hg. (2). atm(abs.).

where b - reading barometer, mm Hg;

h - reading vacuum gauge, mm Hg;

p_h - vacuum in the capacitor/condenser, c/c.

Rarefaction/evacuation in the capacitor/condenser:

$$p_h = \frac{735,6 - p_\varkappa}{735,6} \, 100, \, \%. \qquad (7)$$

where $p_\varkappa$ - the same as in formula (6).

Page 7.

The pressure of mixture in the capacitor/condenser:

$$p_{cm} = p_n + p_\varepsilon \quad \text{mm Hg} \qquad (8)$$

where p_n - partial pressure of vapor, mm Hg:

p_ε - partial air pressure, mm Hg.

Partial pressure of vapor can be determined according to tables 1 and 2 for the water vapor (see applications/appendices) in depending on the temperature of mixture.

Partial pressure of vapor in the air-steam mixture:

$$p_n = \frac{p_{cm}}{1 + 0.622 \, \frac{G}{D}} \quad \text{mm Hg} \qquad (9)$$

Partial air pressure in the air-steam mixture:

$$p_\bullet = \frac{p_{c\kappa}}{1+1.61\,\dfrac{D}{G}} \quad \text{мм} \ \text{Hg} \tag{10}$$

Here $p_{c\kappa}$ - pressure of mixture in capacitor/condenser, mm Hg;

D - quantity of that entering capacitor/condenser of vapor, kg/h;

G - quantity of air, kg/h.

Critical pressure of vapor (atm(abs.)):

$$\left.\begin{array}{l}{}^{(1)}\text{насыщенного} \quad p_{\kappa p} = 0.577\,p_\bullet \\ {}^{(2)}\text{перегретого} \quad\ p_{\kappa p} = 0.574\,p_\bullet\end{array}\right\}, \tag{11}$$

Key: (1). saturated. (2). overheated.

where p_0 - initial pressure of vapor, atm(abs.).

Water vapor pressure - see applications/appendices, Table 1 and 2.

Selection of design pressures.

The pressure of cooling water in the branch pipes of pumps for the capacitors/condensers, the oil coolers, the coolants of condensate and other similar to them apparatuses and the pressure of the preheated feed outboard water in the preheaters for the vaporizers/evaporators is accepted from the conditions of overcoming the losses of head in the system of this conduit/manifold, in the established/installed on it apparatuses and the accessories, and also in depending on final counterpressure.

Usually the calculated water pressure p is:

1) for the capacitors/condensers and the oil coolers 8-25 m H_2O;

2) for the vaporizers/evaporators 15-40 m water column.

Page 8.

Vapor pressure p of the heating for feed heaters of first stage usually is approximately 1.5-2.5 atm(abs.), since in essence for preheating water in the preheaters is utilized the exhaust steam from the auxiliary mechanisms of a machine-boiler installation.

Vapor pressure p of the heating for feed heaters of the second and third steps/stages is 5 atm(abs.) and it is above. For this

purpose is utilized the exhaust steam from the group of the auxiliary
mechanisms, which work to the increased counterpressure, or the
vapors from main turbines.

Vapor pressure p of the heating in oil heaters usually is
accepted on 3-5 atm(abs.) higher than pressure of petroleum and in
the majority of the cases is 20-25 atm(abs.).

For some types of injectors the pressure of petroleum can reach
40 atm(abs.). In this case, and also at the pressures of petroleum,
which exceed pressure of vapor it is expedient to apply oil heaters
with the dual tube plates or sectional oil heaters which work on the
high parameters of vapor.

Pressure p of that heating (primary) vapor in the
vaporizers/evaporators is recommended the accepting of:

1) for the vacuum evaporators 1.5-2.5 atm(abs.) (usually as
heating steam is utilized the exhaust steam from the auxiliary
mechanisms);

2) for the vaporizers/evaporators, which work under the positive
pressure, 3-5 atm(abs.) (is applied also the mastered or throttled
live steam).

During the pollutics/contamination of the heating coils the vapor pressure of the heating for the purpose of the maintenance of productivity, can be increased to 8 atm(abs.).

Pressure p_2 of the secondary steam in the vaporizers/evaporators, as a rule, is accepted:

	(1) ama
(2) Для вакуумных одноступенчатых	0,5—0,8
(3) Для вакуумных циркуляционных	0,3—0,7
(4) Для вакуумных двухступенчатых:	
(4a) в первой ступени	0,6—0,8
(4b) во второй ступени	0,2—0,4
(5) Для атмосферных, а также для испарителей с давлением выше атмосферы	1,0—2,0

Key: (1). atm(abs.). (2). For vacuum single-stage ones. (3). For vacuum circulation ones. (4). For vacuum two-stage ones. (4a). in first stage. (4b). in the second step/stage. (5). For atmospheric ones, and also for vaporizers/evaporators with pressure higher than atmosphere.

Vapor pressure p of the heating for the atmospheric and vacuum deaerators is received as 1.2-2.0 atm(abs.) (usually is utilized the exhaust steam).

Operating pressure in the housings of deaerators is accepted:

1) in vacuum 0.1-0.9 atm(abs.);

2) in atmospheric 1.1-1.4 atm(abs.).

Vapor pressure p of working in the steam-air ejectors is usually received as 10 atm(abs.) and it is above.

Page 9.

Vacuum in the capacitors/condensers depends on a number of factors (principal of them are temperature and quantity of cooling water) and is usually within the limits:

1) for the shipboard turbine plants from $p_h = 95\%$ with $t_1 = 15°C$ to $p_h = 90\%$ with $t_1 = 30°C$;

2) for stationary installations $p_h = 96 - 97,5\%$ with $t_1 = 10-15°C$ or during the cooling by river water in the unlimited quantity;

3) for installation with steam engines vacuum p_h in essence is limited by the sizes/dimensions of low-pressure cylinder and it usually composes 85-87c/c.

Absolute condenser backpressure near the place of air exhaust

(to avoid the overexperditure of energy to the exhaust device/equipment and an increase in its dimension) must be not less than 25 mm Hg:

$$p_{\kappa}' = p_{\kappa} - \Delta p,$$

where p_{κ} - absolute condenser backpressure, mm Hg:

Δp - steam resistance of capacitor/condenser, mm Hg.

§2. Temperatures and their difference.

Temperature characterizes the degree of the warmth of body. Temperature is measured in the degrees according to international thermometric scale, according to which temperature of the fusion of ice at the normal atmospheric pressure is designated through $0^\circ C$, while the boiling point of water - through $100^\circ C$. The temperature, measured according to the international scale, is designated by letter t, and its scale - $^\circ C$.

Temperaure counted off from the absolute of zero temperatures, is called the absolute temperature:

$$T = 273,2 + t,\ ^\circ K, \qquad\qquad (12)$$

where t - temperature, $^\circ C$.

Mean temperature of the heat-transfer agent:

$$t_{cp} = 0,5\,(t_1 + t_2)\ ^\circ C, \qquad\qquad (13)$$

where t_1 - initial temperature of heat-transfer agent, °C;

t_2 - final temperature of heat-transfer agent, °C.

Mean temperature of the mixture:

$$t_{cm} = \frac{G_1 c_1 t_1 + G_2 c_2 t_2 + \dots}{G_1 c_1 + G_2 c_2 + \dots} \, °C, \qquad (14)$$

where G_1, G_2 - weights of the components, entering the mixture, kg;

c_1, c_2 - average/mean heat capacities of components, kcal/kg°C;

t_1, t_2 - temperature of components, °C.

Page 10.

Mean temperature of the wall, which divides two heat-transfer agents:

$$t_{cт}^{cp} = 0.5 \left(\frac{t_1 + t_2}{2} + \frac{t_1' + t_2'}{2} \right) °C, \qquad (15)$$

where t_1, t_1' - initial temperatures of heat-transfer agents, °C;

t_2, t_2' - final temperatures of heat-transfer agents, °C.

Mean temperature cf the surface of the wall:

$$t \approx 0.5\,(t_{cp} + t_{ct}^{cp})\,^{o}C, \qquad (16)$$

where t_{cp} - mean temperature of heat-transfer agent, ^{o}C;

t_{ct}^{cp} - mean temperature cf wall, ^{o}C.

Formulas (15) and (16) it is possible tc use alsc for determining approximate value of the temperature of the surface of wall with small differences in the temperatures cf heat-transfer agents.

Temperature of the surface of single-layer wall [1]:

1) internal

$$t_{ct_1} = \frac{a_1 t_1 + A t_2}{a_1 + A}\,^{o}C, \qquad (17)$$

$$t_{ct_2} = t_{ct_2} + q\,\frac{s}{\lambda}\,^{o}C; \qquad (18)$$

2) external

$$t_{ct_1} = \frac{t_1 + a_2 B t_2}{1 + a_2 B}\,^{o}C, \qquad (19)$$

$$t_{ct_2} = t_{ct_1} - q\,\frac{s}{\lambda}\,^{o}C, \qquad (20)$$

where t_1 - temperature cf medium from inside cf wall, ^{o}C;

t_2 - temperature cf medium frcm the face cf wall, ^{o}C;

α_1 - heat-transfer coefficient of medium from inside of wall, kcal/m²h   °C;

α_2 - heat-transfer coefficient of medium from the face of wall, kcal/m²h   °C;

q - quantity of heat, transferred of 1 m² of the surface of wall, kcal/m²h;

s - wall thickness, m;

λ - coefficient of the thermal conductivity of wall, kcal/m-hour °C;

A and B - values, determined according to the formulas:

$$A = \frac{1}{\frac{s}{\lambda} + \frac{1}{\alpha_2}}; \quad B = \frac{1}{\alpha_1} + \frac{s}{\lambda}.$$

FOOTNOTE ¹. For calculating the temperatures of the surface of wall the heat-transfer coefficients of medium α_1 and α_2 in the first calculation are received tentatively according by this on page 74, and then, according to the determination of their values, in that produced the calculation again is done the refined calculation of

these temperatures. ENDFCCINCIE.

Page 11.

The temperatures of the surface of walls t_{cr1} and t_{cr2} can be determined graphically (Fig. 1) as follows.

On the x axis plot/deposit value s/λ, and on both sides from it the cuts, equal to $1/\alpha_1$ and $1/\alpha_2$ from ends/leads of which are established the perpendiculars.

At a distance of t_1 and t_2 from the axis/axle x-об and in parallel to it draw a line of temperatures, which intersect with the perpendiculars at points a and c. Straight line, which connects these points, intersects the surface of wall at points c and d and gives unknown temperatures t_{cr1} and t_{cr3}.

Mean temperature of the boundary layer:

$$t_{rp} = 0{,}5 \, (t_{cp} + t_{cr}) \, ^{\circ}C. \qquad (21)$$

where t_{cp} - mean temperature of medium, $^{\circ}C$;

t_{cr} - temperature of wall, determined according to formulas (17)-(20) or by graphic method, $^{\circ}C$.

By formulas (15) - (21) used during the calculation of heat transfer and hydraulic resistance.

During the derivation of calculation formulas on heat exchange and hydraulic resistance from conducted experiments the individual authors applied the different methods of calculating the determining temperature in order to consider the effect of heat flux. Some of them as the determining temperature accepted the temperature of wall $t_{ст}$. determined according to formulas (17)-(20), others - mean temperature of medium $t_{ср}$. determined according to formula (13), the third - different combinations, the fourth - mean temperature of boundary layer $t_{гр}$. determined according to formula (21) and, etc.

Using calculation formulas on heat exchange and hydraulic resistance, it is necessary the determining temperature to calculate by that method which was used with the derivation of calculation formula.
Fig. 1.   Fig. 2.

Fig. 1. Graph/curve of determination of temperature of surface of
wall.

Key: (1). Medium.

Fig. 2. Graph/curve of determination of temperature of surface of
two-layered wall.

Page 12.

    Temperature of the surface of two-layered wall (Fig. 2):

    1) the external surface of the first layer of the wall

$$t_{cr_1} = \frac{\left(a_1 C + \frac{a_1}{a_2} D\right) t_1 + D t_2}{a_1 C + \frac{a_1}{a_2} D + D} \,^{\circ}C; \qquad (22)$$

2) the external surface of the second layer of the wall

$$t_{cr_2} = \frac{a_1 D t_1 + (a_2 D + a_1 a_2 C) t_2}{(a_1 + a_2) D + a_1 a_2 C} \,^{\circ}C; \qquad (23)$$

3) on the boundary between the layers of the walls

$$t'_{cr} = t_{cr_1} - q \frac{s_1}{\lambda_1} = t_{cr_2} + q \frac{s_2}{\lambda_2} \,^{\circ}C. \qquad (24)$$

Here a_1 - heat-transfer coefficient of the first layer, kcal/m²h °C;

a_2 - heat-transfer coefficient of the second layer, kcal/m²h °C;

t_1 - temperature of medium from the side of the first layer, °C;

t_2 - temperature of medium from the side of the second layer, °C;

s_1 - the wall thickness of the first layer, m;

s_2 - the wall thickness of the second layer, m;

λ_1 - coefficient cr the thermal conductivity of the first layer cf wall, kcal/m-hour   C;

λ_2 - coefficient cf the thermal conductivity of the seccnd layer cf wall, kcal/m-hour   °C;

q - quantity cf heat, transferred cf 1 m² cf the surface of wall, kcal/m²h:

C and D - value, they are determined acccrding tc the fcrmulas:

$$C = \frac{\lambda_1}{s_1} + \frac{\lambda_2}{s_2}; \quad D = \frac{\lambda_1}{s_1}\frac{\lambda_2}{s_2}.$$

The temperature of tne air, driven cut frcm the capacitor/condenser, is accepted:

1) according to data of tke experiments

$$t_n = t_1 + 4 + 0.1\,(t_2 - t_1)\ °C; \tag{25}$$

2) according to the data cf the practice

$$t_n = t_1 + (3 \div 5)\ °C, \tag{26}$$

where t_1 - temperature cf coclirg water upon the entrance intc the capacitor/condenser, °C;

t_2 - temperature of cooling water on leaving from the capacitor/condenser, °C.

Calculations according to formulas (25) and (26) give close results.

Page 13.

The temperature of the superheated steam which at the saturation pressure is condensed as the saturated steam:

$$t_{ns} = t_n + 0,0001515\, a_n\, (t_n - t_s)\; °C, \qquad (27)$$

where t_s - saturation temperature, which corresponds to condenser backpressure, °C;

a_s - heat-transfer coefficient of water, kcal/m²h ·°C;

t_s - temperature of cooling water upon the entrance into the capacitor/condenser, °C.

Formula (27) is applied during the determination of the cooling surface of capacitor/condenser, if it is necessary to lower the temperature of the superheated steam before its condensation.

The temperature of the saturated water vapor tentatively can be

determined according to the following approximated formulas:

$$t_{\text{n}} \approx 100\sqrt[4]{p_{\text{n}}} \ °C \ \text{при} \ p_{\text{n}} = 1{,}0-25 \ ama; \quad (28)$$

$$t_{\text{n}} \approx 100\sqrt[3]{p_{\text{n}}} \ °C \ \text{при} \ p_{\text{n}} = 0{,}1-1{,}0 \ amu; \quad (29)$$

$$t_{\text{n}} \approx 145\sqrt{p_{\text{n}}} \ °C \ \text{при} \ p_{\text{n}} = 0{,}03-0{,}1 \ ama, \quad (30)$$

Key: (1). with. (2). atm (abs.).

where p_{n} - pressure of saturated steam, atm (abs.).

The temperature of water vapors - see appendices table 1 and 2.

Difference in the temperatures.

By a difference in the temperatures is understood the heat drop between the final and initial temperatures, while by the average/mean difference - an heat drop between mean temperatures of heat-transfer agents.

Quantity of heat, transferred through the surface during the heat exchange, proportional to an average/mean difference in temperatures.

With a uniform and small temperature drop along the length of surface of heating or cooling) an average/mean difference in the

temperatures will be aritnmetical, which is changed on the straight
line from the initial tc final difference.

With the more interse heat exchange and large differences in the
temperatures, which usually is cbserved in the heat exchangers, a
temperature drop along the length cf surface is uneven; in this case
an average/mean difference in the temperatures will be logarithmic,
which is changed on the curve from the initial tc a finite difference
in the temperatures cf heat-transfer agents.

Page 14.

If relation $\dfrac{t_2 - t_1}{t_2 - t_1} < 2,$ tnen a difference in the temperatures
between the average/mean logarithmic and arithmetic mean does not
exceed 4o/o. In this case it is possible tc use fcrmulas (32) and
(33) arithmetic mean differences in the temperatures.

The value of an average/mean difference in the temperatures
depends not only on the values cf the initial and final temperatures
of heat-transfer agents, but alsc cn the direction of the motion of
their flow.

The schematics cf the direction of the action of heat-transfer
agents, which are usually encountered during the calculation cf an

average/mean difference in the temperatures in the apparatuses, are given in Fig. 3.

A difference in the temperatures of the heat-transfer agents

$$\delta t = t_2 - t_1 \; ^\circ C,$$ (31)

where t_2 - the greatest temperature of heat-transfer agent, $^\circ C$;

t_1 - the minimum temperature of heat-transfer agent, $^\circ C$.

Arithmetic mean difference in the temperatures:

1) for the unidirectional flow

$$\delta t = 0{,}5\,[(t_1 - t_1') + (t_2 - t_2')]\ {}^\circ C; \qquad (32)$$

2) for the countercurrent

$$\delta t = 0{,}5\,[(t_1 - t_2') + (t_2 - t_1')]\ {}^\circ C, \qquad (33)$$

where t_1, t'_1 – initial temperatures of heat-transfer agents, ${}^\circ C$;

t_2, t'_2 – the final temperatures of heat-transfer agents, ${}^\circ C$.

The diagram of a change in the temperatures of heat-transfer agents and arithmetic mean difference in the temperatures in the dependence on the direction of coolant flows is depicted in Fig. 4. Lines AB and CD show a change in the temperatures over surface of F with the countercurrent, lines AB and C'D' – with the unidirectional flow.
Fig. 3.   Fig. 4.

Fig. 3. Schematics of direction of motion of heat-transfer agents.

Key: (1). Unidirectional flow. (2). Countercurrent. (3).
Crosscurrent. (4). Displaced current.

Fig. 4. Diagrams of change aritnmetic mean difference in
temperatures.

Page 15.

Average/mean logaritnmic difference in the temperatures:

1) for the unidirectional flow

$$\Delta t = \frac{(t_1 - t_1') - (t_2 - t_2')}{2.3 \lg \frac{t_1 - t_1'}{t_2 - t_2'}} \, {}^\circ C. \tag{34}$$

The diagram of a change in the temperatures over surface of F with the unidirectional flow is depicted in Fig. 5;

2). for the countercurrent

$$\Delta t = \frac{(t_1 - t_2') - (t_2 - t_1')}{2.3 \lg \frac{t_1 - t_2'}{t_2 - t_1'}} \, {}^\circ C. \tag{35}$$

The diagram of a change in the temperatures over surface of F with the countercurrent is given in Fig. 6;

3) for mixed and crosscurrent:

$$\Delta t = \frac{(t_1 - t_2') - \left(t_2 - \frac{t_1' + t_2'}{2}\right)}{2.3 \lg \frac{t_1 - t_2'}{t_2 - \frac{t_1' + t_2'}{2}}} \, {}^\circ C. \tag{36}$$

The diagram of a change in the temperatures over surface of F with the mixed current is represented in Fig. 7;

4) for the case when temperature of one of the heat-transfer agents (for example, condensable vapor) is permanent, the difference between the unidirectional flow and the countercurrent disappears and

the formula cf an average/mean logarithmic difference in the
temperatures takes the following form:

$$\Delta t = \frac{t_2 - t_1}{2.3 \lg \frac{t - t_1}{t - t_2}} \, °C. \qquad (37)$$
Fig. 5.   Fig. 6.

Fig. 5. Diagram of change in temperatures with unidirectional flow.

Fig. 6. Diagram of change in temperatures with countercurrent.

Page 16.

The diagram of a change in the temperatures over surface of F during the heat exchange when one of the heat-transfer agents has permanent temperature, is given in Fig. 8:

5) for single-flow capacitors/condensers with crosscurrent of water and steam according to experimental data:

$$\Delta t = \frac{t'_2 - t'_1}{2.3 \lg \left[\dfrac{1}{1 - 2.3 \dfrac{t'_2 - t'_1}{t_1 - t_2} \lg \dfrac{t_1 - t'_1}{t_2 - t'_1}} \right]} \; °C. \qquad (38)$$

6) for the capacitors/condensers of two-flowing ones and more:

$$\Delta t = \frac{(t_2 - t_1') - (t_1 - t_2')}{2.3 \lg \dfrac{t_2 - t_1}{t_1 - t_2'}} \ ^\circ C/ \tag{39}$$

Here t - permanent temperature of heat-transfer agent, $^\circ$C;

t_1, t'_1 - initial temperatures of heat-transfer agents, $^\circ$C;

t_2, t'_2 - the final temperatures of heat-transfer agents, $^\circ$C.

In formulas (38) and (39) as the initial temperature of vapor t_1 is accepted saturation temperature of vapor which corresponds to absolute condenser backpressure, and for the final - saturation temperature of vapor t_2, which corresponds to absolute condenser backpressure about the place of air exhaust.
Fig. 7.
Fig. 8.

Fig. 7. Diagram of change in temperatures with mixed current.

Fig. 8. Diagram of change in temperatures during heat exchange when one of heat-transfer agents has permanent temperature.

Page 17.

If heat-transfer agent is the superheated steam and if the temperature of the walls of the tubes lower than temperature of its saturation, then in formula (34) of an average/mean logarithmic difference in the temperatures is substituted the temperature of saturation, and not superheated steam, which corresponds to its pressure.

For the apparatuses with the more complicated crossed and mixed current the calculation of average/mean differences in the

temperatures becomes complicated by mathematical calculations. In
this case their calculation can be produced according to formula (35)
with the subsequent multiplication of result for correction factor
ε, determined on the graphs/curves of Fig. 9-12, given for different
flow charts of heat-transfer agents.

On these graphs/curves the value of coefficient ε is given as
the function of two dimensionless quantities $\varepsilon = f(P,R)$, equal to:

$$P = \frac{t_2' - t_1'}{t_1 - t_1'}; \qquad R = \frac{t_1 - t_2}{t_2' - t_1'}.$$
Fig. 9. Values of correction factor $\varepsilon=f(P,R)$ for determining the average/mean logarithmic difference in the temperatures in the compound circuit of the motion of liquids.
Fig. 10. Values of correction factor $\varepsilon=f(P,R)$ for determining average/mean logarithmic difference in temperatures in compound circuit of motion of liquid.

Page 18.

The relationship/ratio of average/mean differences in the temperatures in the two-stage evaporator with the equal heating

surfaces in each step/stage

$$\frac{\Delta t_1}{\Delta t_2} = \frac{Q_1}{k_1} : \frac{Q_2}{k_2},\qquad(40)$$

where Δt_1 - an average/mean difference in the temperatures in first
stage, ^{o}C;

Δt_2 - average/mean difference in the temperatures in the second
step/stage, ^{o}C;

Q_1 - rate of heat transmission in first stage of
vaporizer/evaporator, kcal/h;

Q_2 - rate of heat transmission in second step/stage, kcal/h;

k_1 - coefficient of heat transfer in first stage, kcal/m^2h
^{o}C;

k_2 - coefficient of heat transfer in second stage, kcal/m^2h
^{o}C.
Fig. 11. Values of correction factor $\varepsilon = f(P,R)$ for determining the average/mean logarithmic difference in the temperatures in the compound circuit of the motion of liquid.
Fig. 12. Values of correction factor $\varepsilon = f(P,R)$ for determining average/mean logarithmic difference in temperatures in compound circuit of motion of liquid.

Page 19.

Selection of calculated temperatures.

The temperature of the outboard water: 1) the initial calculated

temperature t_1 of the cooling or preheated outboard water is equal to approximately/exemplarily 15-20°C;

2) the final calculated temperature t_2 of the cooling outboard water:

In the oil coolers ...   20-25°C.

In the capacitors/condensers ...   23-32°C.

Increase in the temperature Δt of cooling water in the capacitors/condensers:

Two-pass and more than ... 8-11°C.

Single-pass ...   6-8°C.

For the capacitors/condensers, which work with p>0.1 atm (abs.), Δt=13-17°C.

The final calculated temperature t_2 of the preheated outboard water in the preheaters of vaporizers/evaporators is usually received as 60-90°C; in the preheaters of the circulation vaporizers/evaporators:

At a pressure in housing of the vaporizer/evaporator 0.7 atm(abs.) ...   104-106°C.

At a pressure in the housing of the vaporizer/evaporator 0.3 atm(abs.) ...   85°C.

Temperature of feed water. The initial temperature of feed water in the preheaters is usually the temperature of the condensate, which enters from the capacitor/condenser, taking into account its increase in steam-jet airs ejector, mixers and other apparatuses, if they are established/installed on the way from capacitor/condenser to the preheater, or the temperature of condensate in by heat box.

Initial calculated temperature t_1 of feed water usually lies/rests within limits of 36-50°C.

Final temperature t_2 of feed water in the preheaters is selected in depending on the thermal circuit of installation and number of steps/stages of preheaters in it, and also on the construction/design of boiler, and usually it is accepted:

° C
(1) При одноступенчатом подогреве . . . .   95—115
(2) При двухступенчатом подогреве . . . . :   120—170
(3) При трехступенчатом подогреве . . . .   170—220

Key: (1). With the single-stage of preheating. (2). With two-stage preheating. (3). During three-stage preheating.

Temperature t of the neated water in the atmospheric deaeraters is received as 102-104°C, and in the vacuum ones - corresponding to the boiling point with this working pressure in the housing of deaerator.

Page 20.

The temperature of heating steam: 1) for the vaporizers/evaporators minimum temperature t of the saturation higher than temperature of the secondary steam on 15-20°C, but maximum (with the superheated steam) is not higher than 200-230°C;

2) for the deaeraters (with the mastered superheated steam) t=180-230°C;

3) for feed heaters and preheaters of the circulation vaporizers/evaporators, which work on the exhaust steam, t≤230°C;

4) for the preheaters of usual evaporative installations (vacuum or working under the pressure) preheating water is conducted by the secondary steam of vaporizers/evaporators or by condensate of heating steam.

The temperature of the petroleum: 1) the initial calculated temperature t_1 of petroleum in heaters of fuel/propellant is received as 10-15°C;

2) the final calculated temperature t_2 of petroleum usually is taken within limits of 90-95°C;

The temperature of oil: 1) the initial temperature t_1 of oil upon the entrance in oil coolers usually is approximately 55-60°C;

2) final temperature t_2 of oil, which emerges from the oil cooler:

For the lubrication of the bearings of shafting, turbines, reducer, etc. ...   45-55°C.

For the lubrication of the teeth of reducer and automatic

control ...   35-45°C.

The selection of the calculated temperatures of oil is conducted in the dependence on the viscosity of oil used: the less the viscosity of oil, the is accepted below the temperature of lubrication and vice versa.

A difference in the temperatures Δt between the initial temperature of the heating (cooling) medium and the final temperature of heated (cooled) medium must comprise not less than 8-10°C.

A difference in the temperatures in the capacitor/condenser between the condensable vapor and the cooling water on leaving on the average comprises:

	°C
(1) Для стационарных турбин	4,5—6,5
(2) Для поршневых паровых машин	8,5—11
(3) Для корабельных турбоустановок средней мощ-ности (18—35 тыс. л. с.)	22—28
(4) Для корабельных турбоустановок большой мощ-ности (50—65 тыс. л. с.)	8,5—11
(5) Для коммерческих судов с паровыми турбинами	6,5—8,5
(6) Для коммерческих судов с паровыми машинами	14—16,5

Key: (1). For the stationary turbines. (2). For piston steam machines. (3). For ship turboinstallations of average/mean power (18-35 thousand hp). (4). For ship turboinstallations of large power (50-65 thousand hp). (5). For commercial vessels with steam turbines. (6). For commercial vessels with steam engines.

A difference in the temperatures Δt between the primary and secondary steam of vaporizers/evaporators it is expedient to assign within limits of 20-30°C.

A difference in the temperatures Δt between the temperature of the entrance of water into the circulation vaporizer/evaporator and the temperature of the output of brine from the vaporizer/evaporator is received as 12-15°C.

Page 21.

Difference in the temperatures Δt between the temperature of condensation and the temperature of condensate on leaving from the capacitor/condenser:

In the regenerative capacitors/condensers ...   1°C.

In the nonregenerative capacitors/condensers ...   4°C.

A difference in the temperatures between the temperature of the condensable vapor and the temperature of air, i.e., the possible value of supercooling condensate in the condensers of the type O-V for guaranteeing the regeneration

$$\Delta t = t_s - t_a + 3°C,$$

where t_s - condensation temperature of vapor, °C;

$t_в$ - temperature of the air, driven out from the capacitor/condenser, °C.

§3. Volumes and weights.

By the specific volume of substance is understood the ratio of the volume, occupied by substance, to its weight. Unit the measurement of specific volumes - m^3/kg or cm^3/g.

The value, reciprocal to specific volume, it is the specific gravity/weight of substance and is designated by letter γ. Dimensionality of specific gravity/weight - kg/m^3 or g/cm^3.

The mass of unit volume is called density and is designated by letter ρ.

The specific volume of the medium:

$$v = \frac{V}{G} = \frac{1}{\gamma} \; m^3/kg, \qquad (41)$$

where V - volume, occupied by medium, the m^3;

G - weight of medium, kg;

γ - the specific gravity/weight of medium, kg/m^3.

The specific volume of vapors and gases (characteristic equation):

$$v = \frac{RT}{p} \ \text{m}^3/\text{kg},\qquad (42)$$

where T - absolute temperature, $^\circ$K;

p - pressure of vapor or gas, kg/m^2;

R - gas constant, kg-m/kg $^\circ$K.

The specific volume of the superheated steam:

$$v_n = \frac{47,05\,T}{p} - 0,016 \ \text{m}^3/\text{kg},\qquad (43)$$

where T - absolute temperature of vapor, $^\circ$K;

p - pressure of superheated steam, kg/m^2.

Page 22.

Specific volume of wet steam:

$$v_x = x v_s \ m^3/kg, \qquad (44)$$

where x - a degree of dryness of steam; pair;

v_s - the specific volume of dry saturated steam, m^3/kg.

The specific volume of the mixture:

$$v_{cm} = \frac{G_1 v_1 + G_2 v_2 + \dots}{G_1 + G_2 + \dots} \ m^3/kg, \qquad (45)$$

where G_1, G_2 - weights of the components, entering the mixture, kg;

v_1, v_2 - the specific volumes of the components, entering mixture, m^3/kg.

The volume of mixture in the capacitor/condenser (according to the law of Dalton):

$$V_{cm} = V_n + V_s \ m^3, \qquad (46)$$

where V_n - volume, occupied by vapcr, m^3;

V_a - volume, occupied by air, m^3.

The volume of the air, exhausted frcm the capacitor/condenser:

$$V_a = \frac{29.27 (273 + t_a) G_a}{\rho_a} \; m^3/h \qquad (47)$$

where t_a - temperature cf air, ^oC;

G_a - weight of the exhausted air, kg/h;

ρ_a - partial air pressure, kg/m^2.

The volume cf dry air in depending cn the temperature:

$$V_t = V_o \left(1 + \frac{1}{273} t \right) \; m^3, \qquad (48)$$

where V_0 - a volume of dry air at temperature cf 0^oC and barcmetric pressure 760 mm Hg, m^3;

t - temperature cf air, ^oC.

The volume of water in the deaeratirg tank fcr the shipbcard

installations is selected from the conditions for a 3-4-minute water
supply and is determined

$$V = \frac{W v}{15 \div 20} \, \text{м}^3,$$ (49)

where W - a quantity of deaerated water (productivity), t/h;

     v - the specific volume of the deaerated water, m³/t.

Page 23.

     The specific weight of the humid air

$$\gamma_{\text{вл}} = \gamma_{\text{сух}} - 0,176 \frac{\varphi h_s}{T} \, \text{кг/м}^3,$$ (50)

where $\gamma_{\text{сух}}$ - the specific weight of dry air (it is found through tables
5 of applications/appendices), of кg/m³; h_s - water vapor
pressure upon the complete saturation of air, mm, Hg;

     T - absolute temperature of humid air, °K;

     φ - relative air humidity:

$$\varphi = \frac{h_n}{h_s} 100 = \frac{d}{d_s} 100\%,$$

where h_n - partial water vapor pressure mm Hg;

     d - moisture content of air with this temperature and upon

this saturation:

$$d = 622 \frac{h_n}{B - h_n} \text{ g/kg dry air,}$$

d_s - a moisture content of air with this temperature and upon complete saturation, the g/kg;

B - barometric pressure of atmospheric air as the gas mixture:

$$B = h_c + h_n \text{ mm Hg,}$$

where h_c - partial pressure of dry air, mm Hg.

The weight of the humid air

$$G_{вл} = G_{сух} + G_n \text{ кг,} \qquad (51)$$

where $G_{сух} = \frac{B - h_n}{2,153\,T}$ - weight of dry air, kg;

$G_n = \frac{h_n}{3,461\,T}$ - weight of water vapors, kg.

Here B - barometric pressure of atmospheric air, mm Hg;

h_n - partial water vapor pressure of the atmosphere, mm Hg;

T - absolute temperature of air, °K;

number 2.153 - the gas constant of dry air in the measurement of pressure in kg/m²;

number 3.461 - gas constant water vapors in the measurement of pressure in kg/m².

Page 24.

The specific gravity/weight of oil-products with different temperatures

$$\gamma_t = \gamma_{20} - \beta(t - 20) \quad t/m^3, \qquad (52)$$

where γ_{20} - the specific gravity/weight of oil-product with 20°C, t/m³;

β - temperature correction for 1°C (it is determined on Tables 1):

t - temperature of oil-product, °C.

The graph/diagram of the dependence of the specific gravity/weight of different oil-products on the temperature is given in Fig. 13.

Specific volumes and weights of water vapors, air and liquids - see applications/appendices, Table 1-14.

The enthalpy (enthalpy) of the humid air:

$$i_{в.л} = 0{,}24t + (0{,}46t + 595)d10^{-3} \text{ kcal/kg dry air,} \quad (53)$$

where 0.24t - enthalpy of dry air, kcal/kg:

$0.46td10^{-3}$ - heat of superheat of the water vapors, which contain in the air, kcal/kg the dry air:

$5959d10^{-3}$ - heat of vaporization with 0°C, kcal/kg dry air.
Fig. 13. Graph/diagram of the dependence of the specific gravity/weight of oil-products on the temperature. M12 - petroleum residue the sailor; M120 - petroleum residue naval; M40 - petroleum residue furnace; UT and T - lubricating oils.

Key: (1). t/m³.

Table 1. Values of temperature correction β.

(1) Удельный вес при $t = 20°$ C	β
0,90	0,000633
0,91	0,000620
0,92	0,000607
0,93	0,000594
0,94	0,000581
0,95	0,000567
0,96	0,000554
0,97	0,000541

Key: (1). Specific gravity/weight with.

§ 4. Heat capacities.

Heat capacity, or weight specific heat, is called a quantity of heat, necessary for the heating 1 kg substances on 1°C. With an increase in the temperature the heat capacity increases (for mercury it decreases).

Page 25.

The heat capacity of imperfect gases depends not only on temperature, but also on the pressure, and it is subdivided into the heat capacity at constant pressure c_p and the heat capacity at a constant volume c_v.

Is distinguished heat capacity weight, volumetric and molar in depending on that, to what quantitative unit it is related.

Weight heat capacity c, c_p or c_v is measured in kcal/kg °C; volumetric c_{ob} — in kcal/m³ °C and molar μc — in kcal/mole °C.

The heat capacity of the water:

$$c = 0.9983 - 0.005184 t\, 10^{-2} + 0.006912\, t^2\, 10^{-4} \text{ kcal/kg} \quad °C. \quad (54)$$

where t - temperature of water, °C.

Thermal capacity of water vapor:

$$c_p = c_{p_0} + 0.5311 \frac{p}{p_{кр}} \left(\frac{T_{кр}}{T}\right)^{3.5} + 1.1991 \left(\frac{p}{p_{кр}}\right)^3 \left(\frac{T_{кр}}{T}\right)^{18} \text{ kcal/kg} \qquad °C, \quad (55)$$

where $c_{p_0} = 0.3613 + 0.0001736I + \frac{9.0}{T}$, - heat capacity with p=0;

p - absolute pressure, кg/м²;

$p_{кр}$ = 225.05•10⁴ - critical pressure, кg/м²;

$T_{кр}$ = 273.2+374=647.2 - critical temperature, °K;

T - absolute temperature, °K.

The heat capacity of overheated water vapor in depending on temperature and pressure of steam - see applications/appendices, Fig. 1.

The heat capacity of the oil-products:

$$c_p = (0.403 + 0.00081t) \frac{1}{\sqrt{\gamma_{15}}} \text{ kcal/kg} \qquad °C, \qquad (56)$$

where t - temperature of oil-products, °C;

γ_{15} - the specific gravity/weight of oil-products with 15°C, t/m³.

The graph/diagram of the dependence of the heat capacity of oil-products on the temperature and the specific gravity/weight is represented in Fig. 14.

Heat capacity of the air:

$$c_p = 0.2404 + 0.0000843 t \text{ kcal/kg} \quad °C, \quad (57)$$

where t - temperature of air, °C.
Fig. 14. Graph/curve of a change of the heat capacity of oil-products in the dependence on the temperature and the specific gravity/weight.

Key: (1). kcal/kg.

Page 26.

The graph/curve of a change in the heat capacity of the air, calculated according to formula (57), in the dependence on the temperature is given in Fig. 15, and in the dependence on the temperature and the pressure - 16.

The heat capacity of the humid air:

$$c_z = 0,242 + 0,47 d \, 10^{-3}$$

kcal/kg dry air   °C,   (58)

where d - a moisture content of air, g/kg.

The heat capacity cf the mixture:

$$c = \frac{G_1 t_1 c_1 + G_2 t_2 c_2 + \ldots}{G_1 t_1 + G_2 t_2 + \ldots}$$

kcal/kg $^\circ$C, (59)

where G_1, G_2 - weights cf blending agents kg;

   t_1, t_2, temperature cf the blending agents, $^\circ$C;

   c_1, c_2 - heat capacity of the blending agents, kcal/kg $^\circ$C.

The expression cf the dependence between the molar heat capacity:

$$\mu c_p = \mu c_v + \mu A R = \mu c_v + 1,985, \qquad (60)$$

where $\mu AR=1.985$ - the gas constant of 1 moles in the thermal units.

Translation/conversion cf molar heat capacity μc into weight c:

$$c = \frac{(\mu c)}{\mu}. \qquad (61)$$
Fig. 15.   Fig. 16.

Fig. 15. Graph/curve of change of heat capacity of the air in dependence on temperature.

Key: (1). kcal/kg.
Fig. 16. Graph/curve of change of heat capacity of the air in dependence on temperature and pressure.

Key: (1). kcal/kg. (2). atm (abs.).

Page 27.

The translation/conversion of the weight heat capacity c into

volumetric c_{o6}:

$$c_{o6} = c\gamma. \tag{62}$$

The value of heat capacities for different bodies are given in appendices (Table 4-14 and Fig. 1-3).

§ 5. Coefficients of thermal conductivity.

The coefficient of thermal conductivity indicates the ability of substance to carry out heat. The value of this coefficient determines a quantity of heat which is passed per unit time through the unit of the surface of wall with a temperature drop on 1°C per the unit of length, and it is measured in kcal/m-hour   °C.

The coefficient of the thermal conductivity of water in depending on temperature is shown graphically in Fig. 17 and Table 6 of applications/appendices.

The coefficient of the thermal conductivity of the water vapor:

$$\lambda = \frac{0.00578 \, c_v \sqrt{T}}{1 + \frac{321}{T}} \text{ кcal/m-hour} \quad °C, \tag{63}$$

where c_v - thermal capacity of water vapor at a constant volume, equal to

$$c_v = 0.259 + 0.000111 T \text{ кcal/kg} \quad {}^\circ C,$$

T - absolute temperature, ${}^\circ K$.

The coefficient of the thermal conductivity of water and water vapor in depending on temperature and pressure is represented curves in Fig. 18.
Fig. 17.

Fig. 18.

Fig. 17. Coefficient of thermal conductivity cf water in depending on temperature.

Fig. 18. Coefficient of thermal conductivity cf water and water vapor in depending cn temperature and pressure.

Key: (1). kcal/m-hour. (2). Saturation curve. (3). kg/cm².

Page 28.

The coefficient of thermal conductivity for the overheated water vapor in depending on temperature and pressure - see applications/appendices, Fig. 2.

The coefficient of the thermal conductivity of the air:

$$\lambda = \frac{0.00167\,(1 + 0.000194T)\,\sqrt{T}}{1 + \frac{117}{T}} \quad \text{kcal/m-hour} \quad ^{\circ}\text{C}, \qquad (64)$$

where T - absolute temperature, $^{\circ}$K.

The curve of the dependence of the coefficient of the thermal conductivity of air on the temperature is given in Fig. 19, and 20 are depicted the curves of the coefficient of the thermal conductivity of different gases at pressure 760 mm Hg and different temperatures.

The coefficient of the thermal conductivity of oil in the range of temperatures of 20-100°C for the approximate computations can be accepted

$$\lambda = 0.10 \div 0.11 \quad \text{kcal/m-hour} \quad ^{\circ}\text{C.} \qquad (65)$$

The coefficient of the thermal conductivity of oil-products can be determined according to the empirical formula

$$\lambda = \frac{0.101}{\gamma_{15}}\,(1 - 0.00054t) \quad \text{kcal/m-hour} \quad ^{\circ}\text{C}, \qquad (66)$$

where γ_{15} - is specific weight of oil-products at temperature of 15°C, t/m^3;

t - mean temperature, $^{\circ}$C.
Fig. 19.

Key: (1). kcal/m-hour.

Page 29.

This formula is applied to the oil-products with the specific

gravity/weight, equal to 0.78-0.95 t/m³, in the range of temperatures of 0-200°C.

Fig. 21 depicts the coefficients of the thermal conductivity of different brands of oils in depending on the temperatures, calculated according to formula (66).

It should be noted that in the literary sources occur and other formulas of the definition of the coefficients of the thermal conductivity of oil-products, which give contradictory results, in consequence of which formula (66), and also existing up to now formulas, which differ from formula (66), it is possible to examine only as those approximated.

Fig. 22 gives the curves or the coefficients of the thermal conductivity of different metals in the dependence on the temperature. The value of the coefficients of thermal conductivity for different bodies - see applications/appendices, Table 4-12.

Key: (1). kcal/m-hour.

§ 6. Viscosities/ductilities/toughness.

Viscosity/ductility/toughness characterizes the value of the molecular cohesion/coupling of particles and depends on the force of the internal friction, which appears between two layers of liquid during their motion.

Viscosity/ductility/toughness is determined by the speed of the displacement/movement of layers and by the properties of liquid. The viscosity of liquids with an increase in the temperature decreases, and with the pressure increase insignificantly it increases; however, at high pressures - 100 atm(ats.) and more - viscosity change becomes perceptible.

Page 30.

The unit of absolute viscosity represents the force (tangent), necessary for the mutual displacement at a rate of 1 cm/s of two layers of liquid in area 1 cm² each, located at a distance 1 cm one relative to another, and it is expressed in the poises.

The ratio of absolute viscosity to the density at the same temperature is called kinematic viscosity.

In the system of practical units is dynamic, or absolute, viscosity is expressed in kg•s/m², and kinematic - in m²/s. Viscosity in the Engler degrees is ratio of the time of the discharge 200 cm³ of product to the time of the discharge of the same volume of water from Engler's instrument with 20°C and is designated °E.

The dynamic viscosity of the water:

$$\mu_p = \frac{0.0178}{1 + 0.0337t + 0.000221t^2} \ poises,\qquad (67)$$

where t - temperature of water, °C.

The dynamic viscosity of water in depending on temperature is represented curve in Fig. 23.

The dynamic viscosity of gases and water vapor

$$\mu \cdot 10^6 = \frac{2.766T}{821 + t}\sqrt{\frac{T}{273}} \ kg\bullet s/m^2,\qquad (68)$$

where t - temperature of gas or vapor, °C;

T - absolute temperature of gas or vapor, °K.

For the overheated water vapor dynamic viscosity in depending on

temperature and pressure is represented curves - see

applications/appendices, Fig. 3.

Dynamic viscosity of the air:

$$\mu \, 10^6 = 1{,}712 \sqrt{1 + 0{,}003665\,t}\,(1 + 0{,}0008\,t)^2 \ \text{kg} \cdot \text{s}/\text{m}^2, \quad (69)$$

t - temperature of air, °C.

Fig. 24 and 25 give the respectively curved of the dynamic and

kinematic viscosity of air in the dependence on the temperature and

the pressure.

The dynamic viscosity of air, water vapor, oxygen, nitrogen, and

also the kinematic viscosity of flue gases in depending on

temperature are represented in Fig. 26.
Fig. 23. Dynamic viscosity cf water in depending cn temperature.

Page 32.

The effect of pressure on the viscosity of gases to p=10 atm (abs.) can be disregarded/neglected.

The kinematic viscosity of the mixture of gases in the engineering is computed according to the formula:

$$\nu_{CM} = \frac{100}{\frac{v_1}{\nu_1} + \frac{v_2}{\nu_2} + \frac{v_3}{\nu_3} + \ldots} \quad m^2/s,$$

where ν_1, ν_2, ν_3 - kinematic viscosity of separate components, m^2/s;

v_1, v_2, v_3 - volumetric contents of separate blending agents, o/o.

The dynamic viscosity of the oil-products:

$$\lg \mu_p = -3 + \frac{0.211}{0.968 - \gamma}$$

poises,   (70)

where γ - specific gravity/weight of oil-product at appropriate temperature, g/cm^3.

For the most commonly used lubricating oils and the petroleum residue Fig. 27 depicts their kinematic viscosities and viscosity in the Engler degrees in depending on the temperatures, obtained according to the data of tests.

For determining the viscosity of oil-product at prescribed/assigned temperature it is possible to use the following approximation formula of recalculation:

$$°E_t = \frac{°E_{50} 50^n}{t^n} \quad \text{or} \quad \nu_t = \frac{\nu_{50} 50^n}{t^n}, \qquad (71)$$

where $°E_{50}$ - viscosity ($°E$) or kinematic viscosity v_{50} at 50°C, indicated in the standards for the oil-products;

t - temperature at which it is necessary to determine viscosity, by °C;

n - exponent, it is selected on Tables 2.

Formula (71) is applied in the range of temperatures from 30 to 150°C for the viscosity of oil-products, which does not exceed 16°E, but in the range of temperatures from 40 to 110°C - for the viscosity of oil-products more 16°E.

Key: (1). Kinematic viscosity coefficient. (2). Viscosity in Engler

degrees.

Page 34.

Transfer equations from some ones of viscosity to others:

1) from the dynamic viscosity, expressed in poises μ_p, to the

dynamic viscosity μ, expressed in working standards:

$$1 \text{ poise} = 1 \text{ dynes. s.}/cm^2 = 1/98.1 \text{ kg}°s/m^2; \qquad (72)$$

2) from the dynamic viscosity, expressed in the poises, μ_p to

kinematic viscosity

$$1 \text{ poise} = \gamma/962.36 \ m^2/s; \qquad (73)$$

3) from the dynamic viscosity μ to the kinematic ν:

$$\nu = \frac{\mu}{\rho} = \frac{\mu g}{\gamma} \quad \text{m}^2/\text{s}; \tag{74}$$

4) from kinematic viscosity ν to the dynamic μ:

$$\mu = \nu\rho = \nu\frac{\gamma}{g} \quad \text{kg} \bullet \text{s}/\text{m}^2; \tag{75}$$

5) from the viscosity, expressed in the Engler degrees ($^{\circ}$E), tc the dynamic viscosity μ:

$$\mu \cdot 10^6 = \left(0{,}746\,^{\circ}\text{E} - \frac{0{,}643}{^{\circ}\text{E}}\right)\gamma \quad \text{kg} \bullet \text{s}/\text{m}^2; \tag{76}$$

6) from the viscosity, expressed in the Engler degrees ($^{\circ}$E), tc kinematic viscosity ν:

$$\nu \cdot 10^6 = \left(7{,}31\,^{\circ}\text{E} - \frac{6{,}31}{^{\circ}\text{E}}\right) \quad \text{m}^2/\text{s}. \tag{77}$$

Here ρ - density, kg$\bullet$s/m^4;

γ - specific gravity/weight, kg/m^3;

g - acceleration cf gravity m/s^2.

The graph/curve of the recalculation of viscosity from the Engler degrees into the dynamic and kinematic viscosity in depending on the specific gravity/weight of liquid γ (t/m^3) is represented in Fig. 28.

The values of the coefficients of viscosity for different media are given in appendices (Table 4-12).

§ 7. Speeds.

Under the average speed of the motion of medium or flow is understood the path, passed by the moving medium for the time unit. The speed, at which occurs the transition of stream-line conditions into the turbulent with the constant/invariable viscosity and the given diameter of duct, is called critical speed.

Unit speed measurement of flow - m/s.

The determination of turbulent and stream-line conditions see § 22.

The speed of medium according to the equation of the continuity:

$$v = \frac{G}{\gamma F} \text{ m/s},\qquad(78)$$

where G - expenditure/consumption of medium, kg/s;

γ - the specific gravity/weight of medium, kg/m³;

P - sectional area of opening/aperture, m².

Discharge velocity through the opening/aperture:

$$v = \varphi \sqrt{2gH \frac{\gamma_1}{\gamma_2}} \ \text{m/s},\qquad(79)$$

where φ - velocity coefficient (see § 25);

g - acceleration of gravity of m/s²;

H - velocity head, m;

γ_1 - the specific gravity/weight of medium under standard conditions, kg/m³;

γ_2 - the specific gravity/weight of medium at its mean temperature, kg/m³.

Page 36.

The speed of mixture in the section:

$$v_{cm} = \frac{G_1 v_1 + G_2 v_2 + \ldots}{G_1 + G_2 + \ldots} \text{ m/s},\qquad(80)$$

where G_1, G_2 - weights of the components, entering the mixture, kg;

v_1, v_2 - speed of the components, entering the mixture, m/s.

The critical speed of the water:

$$v_{\kappa p} = \frac{p}{Bd} \text{ m/s},\qquad(81)$$

where p - Poisson ratio of viscosity to the density:

$$p = \frac{1}{1 + 0,0337 t_1 + 0,000221 t_1^2};$$

B=43.79 - constant;

d - inner diameter, m;

t_1 - initial temperature of water, °C.

Discharge velocity of steam behind the nozzle:

$$v = 91.53 \varphi \sqrt{h} \ \text{m/s,} \qquad (82)$$

where φ - velocity coefficient (see § 25);

h - adiabatic drop/jump in the heat:

$$h = i_0 - i_d \ \text{kcal/kg;}$$

i_0 - enthalpy of steam with nozzle entry, kcal/kg;

i_d - enthalpy of steam on leaving from the nozzle, kcal/kg.

The critical speed or discharge of steam (gas):

$$v_{кр} = \sqrt{2 g p_1 v_1 \frac{k}{k+1}} \ \text{m/s,} \qquad (83)$$

where g - acceleration of gravity m/s²; p_1 - a pressure of vapor or gas, kg/m²;

v_1 - the specific volume of vapor or gas, m³/kg;

k - adiabatic index: k=1.4 - for the air and the diatomic gases; k=1.3 - for the superheated steam; k=1.135 - for the dry saturated steam; k=1.035+0.1x - for wet steam;

x - degree of dryness of steam.

Speed of sound in the gases:

$$v = \sqrt{gkp_1 v_1} \quad \text{m/s,} \qquad (84)$$

where g, k, p_1 and v_1 - the same as in formula (83).

Page 37.

The average speed of liquid in the cylindrical housing with the transverse bulkheads:

$$v_{cp} = \frac{Lv_1 + (N-1)Av_2}{L + (N-1)A} \quad \text{m/s,} \qquad (85)$$

where L - distance between centers of input and exhaust ducts, m;

v_1 - speed of the liquid above the partition/baffle, m/s;

. v_2 - speed of the liquid between the partitions/baffles in the central series/row, m/s;

N - number of partitions/baffles;

N-1 - number of gaps/intervals between the partitions/baffles (input and exit sections are not considered);

$A = \frac{s}{6f}$ - average/mean length of the gaps/intervals between the partitions/baffles, equal to distance between centers of gravity of the areas of the segments (cut off by partitions/baffles), confined by chord s, m;

f - area of the segment above the partition/baffle, m².

The speed of the condensed steam in the capacitor/condenser:

$$v = \frac{G v_n}{3600 LD \left(1 - \frac{d_n}{t} \sqrt{n_{rp}}\right)} \quad m/s, \tag{86}$$

where G - a quantity of condensed steam, kg/h;

v_n - specific volume of steam, m³/kg;

L - length of steam housing, m;

D - outside diameter of the arrangement/position of the beam of tubes, m;

$d_{\scriptscriptstyle H}$ - outside diameter of tubes, mm;

t - space of the laying out of tubes, mm;

$\eta_{\scriptscriptstyle Tp}$ - solidity/loading factor of the tube plate, see formula (175).

The maximal allowable speeds of steam in the upper series/row of the tubes of capacitor/condenser. The values of allowable speeds of steam upon the entrance into the capacitor/condenser in depending on vacuum in the capacitor/condenser are given in Fig. 29 and Table 3.
Fig. 29. Dependence of the maximum permissible speed of steam upon the entrance into the capacitor/condenser on the vacuum.

Key: (1). m/s. (2). atm(abs.).

Page 38.

In the contemporary shipboard capacitors/condensers are accepted the higher speeds, which reach by 80-100 m/s with the vacuum 0.08 atm(abs.).

The speed of steam in the central gangway of capacitor/condenser is usually received as v=3-5 m/s. In the remaining parts of the capacitor/condenser it is necessary to attain the identical speeds, on the basis of the requirement to prevent the possibility of forming air pockets (stagnant places).

Speed of steam which carries along the drops of the water:

$$v > \sqrt{2.2gd\frac{\gamma_\text{B}}{\gamma_\text{n}}} \text{ m/s},\tag{87}$$

where g - acceleration of gravity m/s^2;

   d - diameter of spherical drop, m;

   γ_B - the specific gravity/weight of water, kg/m^3;

   γ_n - specific gravity/weight of steam, kg/m^3.

The values of the speeds at which steam it carries along drops, in depending on the diameter of drop and pressure of steam p, are given in Table 4.

Table 3. Values of speeds steam upon the entrance into the capacitor/condenser.

Key: (1). atm(abs.). (2). Speed at which steam carries along drops, m/s.

Page 39.

Selection of rated speeds.

The speeds of steam v in the branch pipes of heat exchangers usually are accepted:

For the saturated steam ...   30-50 m/s.

For the superheated steam ...   50-75 m/s.

For the capacitors/condensers ...   100-150 m/s.

The speed of liquids in the branch pipes of heat exchangers can be accepted in the dependence on the speed in the conduit/manifold and permissible hydraulic resistances in the apparatus; therefore it can be within the limits of 0.4-2.5 m/s.

For the main capacitors/condensers it can be accepted also in the dependence on the expenditure of cooling water, speed of vessel and construction/design of circulation branch pipes and can reach 2.5-7.5 m/s.

Speed of the preheated water in the tubes of preheaters 1-2.5

m/s.

Speed of cooling water in the tubes of capacitors/condensers
1.8-2.4 m/s.

Usually average speeds v accept:

for the single-pass capacitors/condensers with the self-flow
system of cooling water ...   1.25-2.0 m/s.

For the single-pass capacitors/condensers during the supplying
of cooling water by the pump ...   3.0 m/s.

For the capacitors/condensers of the two-pass and with a large
number courses ...   2.4 m/s.

The velocity of cooling water in the oil-cooking pipes in
0.4-1.0 m/s

The speeds of water and especially marine water are limited to
the usually indicated limits, on the basis of the conditions of
preventing the phenomena of corrosion and erosion which considerably
more intensely flow/occur/last at the higher speeds and destructively
they act not only to the blacks, but also to the nonferrous metals.

Speed of petroleum in the tubes of fuel heater v=0.5-1.2 m/s.

Speed of oil in the intertube space of oil coolers v=0.4-0.8 m/s.

The exit velocity of condensate from the apparatuses is assigned in depending on diversion conditions for condensate, local resistances and the like and usually are accepted v=0.4-1.0 m/s.

Speed of air-steam mixture in branch pipes v~~15 m/s.

§ 8. Expenditures and quantities.

Under the expenditure is understood the amount of liquid, which takes place per unit time through the "clear opening of its flow".

Page 40.

Fluid flow rate is determined from the fundamental flow equation - so-called equation of continuity, continuity or continuity of the motion of jet. The measurement of expenditures and quantities is made in the units of weight (t/h, kg/h), volumetric ones (m³/h, l/s) and thermal (kcal/h).

For the gases and the vapors, i.e., elastic liquid, volumetric flow rate is not characteristic value as a result of the possibility
of their expansion or compression, and in this case it is necessary
to use the weight flow rate, which are a constant value for all
sections.

The flow equation:

$$Q = v_1 f_1 = v_2 f_2 = \text{const.} \qquad (88)$$

where v_1, v_2 - speeds of flow, m/s;

f_1, f_2 - sectional area of flow, m^2.

The expenditure of liquid or gaseous substance according to the
equation of the continuity:

$$G = \frac{uF}{v} \text{ kg/s,} \qquad (89)$$

where u - speed of medium, m/s;

F - sectional area, m^2;

v - the specific volume of medium, m^3/kg.

Flow of the cooling water:

$$W = \frac{Q}{c(t_2 - t_1)} \text{ kg/h,} \qquad (90)$$

where Q - the quantity of heat, transferred to water, kcal/h;

c—the heat capacity of water, kcal/kg, °C;

t_1 - initial temperature of water, °C;

t_2 - the final temperature of water, °C.

Expenditure is vapor:

$$G = \frac{Q\eta}{i-q} \text{ kg/h,} \qquad (91)$$

where Q - a quantity of heat, kcal/h;

$\eta = 1.02$ - coefficient, which considers the heat losses;

i - enthalpy of steam, kcal/kg;

q - enthalpy of liquid, kcal/kg.

Page 41.

Heat consumption can be determined according to one of the following expressions

$$
\left.\begin{array}{l}
Q = Dc\,(t_2 - t_1)\,\text{ккал/час} \\[4pt]
Q = D\,(i - q)\,\text{ккал/час} \\[4pt]
Q = \dfrac{\lambda}{s}\,F\,(t_2 - t_1)\,\text{ккал/час} \\[4pt]
Q = kF\Delta t\,\text{ккал/час}
\end{array}\right\} \qquad (92)
$$

Key: (1). kcal/h.

where D - a quantity of heated substance, kg/h;

c - heat capacity of substance with mean temperature, kcal/kg $^\circ C$;

t_1 - initial temperature, $^\circ$C;

t_2 - final temperature, $^\circ$C;

i - enthalpy of steam, kcal/kg;

q - enthalpy of liquid, kcal/kg;

λ - coefficient of the thermal conductivity of wall, kcal/m-hour $^\circ$C;

s - wall thickness, m;

F - surface of heating or cooling, m²;

k - coefficient of heat transfer, kcal/m²h   °C;

Δt - average/mean logarithmic difference in the temperatures, °C.

A quantity is steam, that is formed by the spontaneous evaporation:

$$G = W \frac{q_1 - q_2}{r} = Wc \frac{t_1 - t_2}{r} \quad kg/h, \qquad (93)$$

where W - amount of liquid, which enters the apparatus, kg/h,

q_1 - enthalpy of the liquid, which enters the apparatus, kcal/kg;

q_2 - enthalpy of liquid, which corresponds to pressure of steam in the housing of apparatus, kcal/kg;

r - heat of vaporization, kcal/kg;

c - heat capacity cr liquid with mean temperature, kcal/kg °C;

t_1 - temperature cf the liquid, which enters the apparatus, °C;

t_2 - temperature cf liquid, which corresponds to pressure of steam in the housing cf apparatus, °C.

Graph/curve for determining a quantity cf steam, generatrix by spontaneous evaporatior frcm 1 m³ cf hot water (having saturation temperature), in depending on lowering in the pressure above the surface of evaporaticn, is giver in Fig. 30.
Fig. 30. Graph/curve of the determination of a quantity of steam, the forming with the incidence/drop pressure above the surface of hot water.

Key: (1). The quantity of steam that is isolated to 1 m³ of hot water, kg/m³. (2). Pressure or steam 1 atm(abs.). (3). atm(abs.). (4).Water pressure, atm (abs.).

Page 42.

The expenditure cf water for the vaporizer/evaporator

$$W = \frac{DS_p}{S_p - S_0} \text{ kg/h,} \qquad (94)$$

where D - productivity of vaporizer/evaporator, kg/h;

S_p - salinity of brine in the housing cf vaporizer/evaporator, °B (Brandt);

S_0 - salinity of the water, which enters the vaporizer/evaporator, °B.

The additional expenditure cf feed water for vaporizer/evaporator with the supply by its blowoff water from the boiler:

$$W = \frac{D(S_p - S_z) - D_{np}(S_p - S_{np})}{S_p - S_0} \text{ kg/h} \qquad (95)$$

where D, S_p, S_0 - the same as in formula (94);

S_1 - salinity of the distillate of vaporizer/evaporator, °B;

D_{np} - quantity of blowoff boiler water, kg/h;

S_{np} - salinity of blowoff boiler water, °B.

A quantity of circulating water in the circulation vaporizers/evaporators can be determined according to the formula

$$W = \frac{Dr}{24c(t_1 - t_2)} \quad t/h \quad (96)$$

where D - productivity of vaporizer/evaporator, tons/day;

r - heat of vaporization at the appropriate pressure in the vaporizer/evaporator, kcal/kg;

c - heat capacity of the entering water evaporator, kcal/kg of °C;

t_1 - temperatures of the entrance of water into the vaporizer/evaporator from the preheater, °C;

t_2 - temperature of the output of brine from the

vaporizer/evaporator, °C.

Consumption curves of water for the circulation
vaporizer/evaporator of different productivity in depending on a
difference in the temperatures of water with the entrance into the
vaporizer/evaporator and the output from it (for the operating
pressure in the vaporizer/evaporator p=0.3 atm(abs.)) are given in
Fig. 31.

From Fig. 31 it is evident that the consumption of the
circulating water grows/rises with a decrease of a difference in the
temperatures and an increase in the productivity of
vaporizer/evaporator.
Fig. 31. Curves of the dependence of the consumption of water on the productivity of circulation vaporizer/evaporator and difference in the temperatures of water with the entrance and the output from it.

Key: (1). Quantity of circulating of water t/h. (2). productivity. (3). tons/day. (4). Difference in temperatures.

Page 43.

A quantity of air-blast brine from the vaporizer/evaporator:

$$W_p = W - D = D \frac{S_n}{S_p - S_o} \quad \text{кg/h,} \qquad (97)$$

where W, D, S_p, S_o - the same as in formula (94);

Concentration of brine in the housing cf the vaporizer/evaporator:

$$S_p = \frac{WS_0 - DS_1}{W_p} \ {}^\circ E, \qquad (98)$$

where W, S_0, D - the same as in formula (94):

S_1 - salinity of the distillate cr vaporizer/evaporator, ${}^\circ B$;

W_p - quantity of air-blast brine from vaporizer/evaporator, kg/h.

The time, which corresponds to the achievement of the concentration of brine accepted in the housing cf the vaporizer/evaporator:

$$t = \frac{S_p - S_0}{S_0} \frac{V_1}{V_2} \ hcur, \qquad (99)$$

where S_p, S_0 - the same as in formula (94);

V_1 - volume, occupied by water in the housing of vaporizer/evaporator to the datum level, the m^3;

V_2 - volume of the water, which evaporates during one hour, m^3/h.

The curves of the coefficient of the purging of
vaporizer/evaporator in depending on the salinity of feed marine
water and brine in the housing of vaporizer/evaporator are
represented in Fig. 32.
Fig. 32. Coefficient of the purging of vaporizer/evaporator in depending on the salinity of feed marine water and brine.

Key: (1). Coefficient of the purging of vaporizer/evaporator. (2). Coefficient of purging. (3). Salinity of seawater, °B. (4). Salinity of brine, °B. (5). Salinity of water S_0, °B.

Page 44.

The quantity of oxygen, introduced by the deaerated water into the deaerator:

$$G_{\kappa} = a_{\kappa} W 10^{-3} \ kg/h, \qquad (100)$$

where a_{κ} - content of dissolved oxygen in the water, determined on the curve of Fig. 33, in depending on the temperature of water at the

barometric air pressure 760 mm Hg, saturated by water vapor, the mg/ℓ:

W - quantity of deaerated water, t/h.

After the admission into the deaerator of the mixture, which consists of the condensate or different condensates and additions of feed water, quantity of oxygen, introduced by water mixture, it is determined from the formula

$$G_{\kappa} = (a'_{\kappa} W' + a''_{\kappa} W'' + \ldots) 10^{-3} \quad \text{кg/h,} \qquad (101)$$

where $a'_{\kappa}, a''_{\kappa}$ - content of dissolved oxygen in the water, determined on Fig. 33 for each component, mg/ℓ;

W', W" - a quantity of deaerated water, t/h.

The quantity of dissolved gases of air, introduced by the deaerated water into the deaerator:

$$G_{r} = a_{r} W 10^{-3} \quad \text{кg/h,} \qquad (102)$$

where a_{r} - content of the dissolved gases of air in the water, determined on the curve of Fig. 33 in depending on the temperature of

water at the barometric air pressure 760 mm Hg, saturated by water

vapor, mg/ℓ:

W - quantity of deaerated water, t/h.
Fig. 33. Oxygen content and air in the water at a barometric pressure 760 mm Hg in depending cr the temperature of water.

Key: (1). the content of gases, mg/l. (2). Air. (3). Oxygen.

Page 45.

A quantity of gases, introduced by water mixture, is determined analogously with a quantity cf cxygen [see formula (101)].

A quantity of vapcr (steam-gas mixture), driven out from the deaerator, if we disregard/neglect an insignificant residual/remanent quantity cf dissolved cases in the deaerated water, is found by the formula

$$G_{\text{cм}} = G_{\text{r}}\left(1 + 0{,}622\,\frac{p_{\text{в}}}{p_{\text{r}}}\right)\ \text{кг/h},\qquad (103)$$

where $p_{\text{п}}$ - partial pressure of the vapor [see formula (8)] in the deaerator, atm(abs.);

$p_{\text{г}}$ - partial gas pressure above the surface of water in the deaerator, determined according to the formula

$$p_{\text{г}} = \frac{p_{\text{п}} a_{\text{г}}}{a_{\text{п}}} \quad \text{atm (abs.)}, \tag{104}$$

where $a_{\text{п}}$, $a_{\text{г}}$ - contents of dissolved oxygen and dissolved gases of air in the water the mg/l [see formulas (100) and (102)];

$p_{\text{п}}$ - partial oxygen pressure above the surface of water in the deaerator, determined according to the formula

$$p_{\text{п}} = \frac{p_0 a_p}{k a_0} \quad \text{atm (abs.)}, \tag{105}$$

p_0 - physical atmosphere, equal to 1.033 atm(abs.);

a_p - calculated (final) oxygen content in the deaerated water, the mg/l; for the shipboard deaerators usually is accepted $a_p = 0.03$ mg/l;

$k = 2-3$ - ratio of equilibrium oxygen pressure in the vapor to partial, necessary for guaranteeing the prescribed/assigned (final) oxygen

content in the deaerated water;

a_0 - constant of the weight solubility of oxygen or solubility of oxygen in the water at its pressure above the water 760 mm Hg, mg/l: it is determined on the curve of Fig. 34 in depending on temperature.

Values $a_\text{в}$, a_r, a_0, $p_\text{в}$ and p_r, entering formules (103)-(105), independent of pressure in the deaerator, they are accepted or are calculated at a pressure of the physical atmosphere how is achieved the retention/preservation/maintaining constant value P_r due to an increase in value p_n, i.e. due to the increase in the vapor, which ensures intensity and high quality of deaeration.

From formula (103) it follows that independent of pressure in the deaerator a quantity of vapor always must be connected with the partial pressure of non-condensable gases P_r, and consequently, with their consumption.

Page 46.

By a small change in the values of gas constants of the vapor and of the non-condensable gases, entering formula (103) in the form of the permanent relation, equal to 0.622, with a change of the pressure in the deaerator it is possible to disregard.

A quantity is of vapor that contains in the vapor:

$$G_n = G_{cm} - G_r \quad kg/h.$$ (106)

The effect of the value of vapor on the depth of the deoxygenation of water is shown in Fig. 35, and 36 are given the curves, which show the oxygen content in the water in depending on its underheating to the boiling point.
Fig. 34. Weight solubility of oxygen in depending on temperature at its pressure above the water, equal to 760 mm Hg.

Key: (1). mg/l.
Fig. 35.
Fig. 36.

Fig. 35.

Effect of the value of vapor on the depth of the deoxygenation of water.

Fig. 36. Oxygen content in water in depending on its underheating to boiling point.

Key: (1). Oxygen content, cm³/2. (2). underheating.

Page 47.

As can be seen from Fig. 35, the value of vapor with respect to the consumption of heating steam for obtaining qualitative deaerated water, it composes altogether only 1.5-2c/o. However, since they are possible: 1) the disturbance/breakdown of the conformity of feed of vapor with the water supply, which unavoidably with the manual control leads to the systematic underheatings and the "breakthroughs" of oxygen into the feed water and, therefore, to an overall increase in the oxygen content in it; 2) the incidence/impingement of gases into the deaerator not only with the deaerated water, but also heating with those condensing by vapor even 3) gas permeation into the deaerator through the leakages/looseresses of apparatuses and conduits/manifolds, that for guaranteeing the qualitative deaeration the value of vapor expedient to support in the limits of 4-6 kg/t of the deaerated water, which composes 3.5-5o/o of the consumption of heating steam.

The expenditure of working vapor for steam-air ejector can be

determined according to of the curves of Fig. 37, refined according to the data of practice, in depending on the degree of rarefaction/evacuation in the capacitor/condenser and on the size/dimension of ejector.

Curve 1 gives relation $G_n : G_s$ (flow rate of working vapor in kg/h to a quantity of air, driven out from the capacitor/condenser in kg/h) for one- and two-stage ejectors of small sizes/dimensions with the consumption of working vapor to 60 kg/h; curve 2 - for two- and three-stage ejectors with the consumption of working vapor from 60 to 100 kg/h; curve 3 - for the same ejectors with the consumption of working vapor from 100 to 300 kg/n and curve 4 - for the large ejectors with the consumption of working vapor is more than 300 kg/h.

The distributions of the total consumption of working vapor according to the steps/stages is expedient to determine of the conditions of the identical initial vapor pressure of working of each step/stage, identical minimum sections of nozzle, but taking into account the pressure in the chamber of mixing. In this case tentatively it is possible to accept the consumption of working vapor on the steps/stages equal ones, since virtually, as a result of different pressures after the nozzle, they will differ little.

The quantity of air entering the Condenser:

1) for high-pressure turbines

$$G_{\text{в}} = \frac{G_n}{2000} + 1.36 \quad \text{kg/h} \qquad (107)$$

2) for medium-and low-pressure turbines

$$G_{\text{в}} = 1.5 \left(\frac{G_n}{2000} + 1.36 \right) \quad \text{kg/h} \qquad (108)$$

3) for piston engines

$$G_{\text{в}} = 2 \left(\frac{G_n}{2000} + 1.36 \right) \quad \text{kg/h} \qquad (109)$$
Fig. 37. Expenditure of working vapor for steam-air ejector in depending on rarefaction/evacuation and quantity of air.

Key: (1). Rarefaction/evacuation mm Hg. (2). ratio.

116

where G_n - quantity of condensed vapor in capacitor/condenser, kg/h.

A quantity of air in the capacitor/condenser with the varying load:

$$G_s = \frac{1}{2000}(0,33G_n + 0,67G_{ns}) \ \kappa_{\mathcal{J}}/h, \qquad (110)$$

where G_n - quantity of condensed vapor at rated load of capacitor/condenser, kg/h;

G_{nx} - quantity of condensed vapor with this load of capacitor/condenser, kg/h.

Quantity of air-steam mixture, driven out from the capacitor/condenser:

$$G_{cm} = G_{s}\left(1 + 0.622\frac{p_n}{p_s}\right) \text{ кг/ч.} \qquad (111)$$

A quantity of vapor that contains in the air-steam mixture:

$$G_s = \frac{G_{cm}}{1 + 1.61\frac{p_s}{p_n}} \quad \text{кг/ч,} \qquad (112)$$

where G_s - quantity of air, driven out from the capacitor/condenser, kg/h;

p_s - partial air pressure, mm Hg;

p_n - partial pressure of vapor, mm Hg.

A quantity of air, which is contained in the air-steam mixture, is determined from formula (106).

A quantity of moisture, which evaporates during moistening of the air:

$$W = G_{\text{в}}(d_{\text{к}} - d_{\text{н}}) 10^{-3} \quad \text{kg/h,} \qquad (113)$$

where $G_{\text{в}}$ - quantity of moistered air, kg/h;

$d_{\text{н}}, d_{\text{к}}$ - initial and final moisture content of air, g/kg.

Quantity of emitted heat. During the calculation of the heat losses into the surrounding space by the heated surfaces of apparatuses one should consider both the heat loss by convection and by emission.

Page 49.

The first of these losses can be determined according to formula (92), the second - according to formulas (114) or (115).

The total quantity of given up by wall heat into the surrounding space is determined by the sum of these losses.

A quantity of heat, emitted by hot body into the surrounding space, calculated according to the Stefan-Boltzmann formula:

$$Q_{xyч} = C\left[\left(\frac{T_{cт}}{100}\right)^4 - \left(\frac{T_{oкp}}{100}\right)^4\right] \text{ kcal/m}^2\text{h} \qquad (114)$$

or according to the formula

$$Q_{xyч} = \alpha_{xyч}(t_{cт} - t_{oкp}) \text{ kcal/m}^2\text{h}, \qquad (115)$$

where $T_{cт} = 273,2 + t_{cт}$ - absolute temperature of the wall, heat-radiating, °K;

$T_{oкp} = 273,2 + t_{oкp}$ - absolute temperature of the surrounding space, which obtains heat, °K;

C - radiation factor, depending on surface condition, the kcal/m²h (°K)⁴. (Values of value C they are given in Table 14);

$\alpha_{xyч}$ - radiation coefficient from the wall in the surrounding space [see formula (160)].

§9. Coefficients of heat transfer and heat emission.

The heat transfer in the heat exchangers is conducted

simultaneously by the metncd of the thermal conductivity (transition of energy within the body frcm its one particle it is direct to another) and by the metncd cf convection (transition of energy in the form of heat together with the single material particles, which contain this heat).

The convective heat exchange can occur bcth with the free and with the constrained mction cf liquid. The action of liquid, caused cn a difference in the densities of the heated and cold particles, is called free. Constrained mction is created by the external exciting forces - pumps, compressors, fars, agitators.

During the heat exchange distinguish the phenomena the heat emissions and heat transfer. Heat emission is characterized by the coefficient, which measures a quantity of heat which is transferred from the heating body tc the wall cr from the wall to the heating body. Heat transfer is characterized by the ccefficient, which measures a quantity cf heat which is transferred from the heating body to that heated. Thus, ccefficient of heat transfer or heat emission is called the quantity cr heat, transferred by the unit of surface for the time unit with a difference ir the temperatures of media in 1°C.

Page 50.

In the metric system the coefficients of heat transfer or heat emission are measured in the kcal/m²h °C.

The equivalent thermal units, mechanical and electrical energy are expressed by the following dependences:

$$1\ \kappa\kappa a \lambda^{(1)} = 427\ \kappa_{2\kappa}^{(2)};$$
$$1\ \lambda.^{(3)}c. = 632,3\ \kappa\kappa a \lambda/yac^{(4)};$$
$$1\ \kappa_{6}m^{(5)} = 860\ \kappa\kappa a \lambda/yac^{(6)}.$$

Key: (1). kcal. (2). kg.-m. (3). hp. (4). kcal/h. (5). kW.

The coefficient of heat transfer depends on many factors. Thus, for instance, in the capacitors/condensers it depends:

1) from the side of water on the rate of motion, temperature of water and degree of contamination of the tubes;

2) from the side of steam from the content of air in a steam, steam load on the cooling surface, the formation/educations of water film on the tubes, the location of the cooling tubes and depth of the cooling beam.

In depending on these factors the coefficient of heat transfer

can change in relation 1:3.

Similarity criteria.

For determining the coefficients of heat transfer is been
commonly used the law of similitude, which consists in the
combination of theoretical and experimental methods.

The application/appendix of the law of similitude to the study
of heat transfer made it possible to establish/install the dependence
between some dimensionless quantities - similarity criteria. Most
commonly used are the following similarity criteria.

Reynolds number characterizes the relation of the forces of
inertia and viscous forces in the fluid flow and is expressed by the
dependence

$$Re = \frac{vd}{\nu} = \frac{vd\gamma}{\mu g}. \qquad (116)$$

Nusselt's criterion characterizes the intensity of heat exchange
for the boundary liquid - wall and is expressed by the dependence

$$Nu = \frac{\alpha d}{\lambda}. \qquad (117)$$

Peclet's criterion characterizes heat fluxes during the
convective heat exchange and is expressed by the dependence

$$Pe = 3600 \frac{vd}{a} = 3600 \frac{vd c \gamma}{\lambda}. \qquad (118)$$

Page 51.

Prandtl number characterizes the physical properties of liquid and is expressed by the dependence

$$Pr = \frac{Pe}{Re} = \frac{3600\nu}{a} = \frac{3600\mu g c}{\lambda}. \qquad (119)$$

Grashof's criterion characterizes interaction of lifts and viscous forces and is expressed by the dependence

$$Gr = \frac{g l^3 \Delta t}{\nu^2}. \qquad (120)$$

Here α - heat-transfer coefficient, kcal/m²h   °C;

d, l - linear dimension, diameter of duct or length, m;

λ - coefficient of thermal conductivity, kcal/m-hour   °C;

v - rate of motion of liquid or gas, m/s;

μ - coefficient of dynamic viscosity, kg·s/m²;

ν - kinematic viscosity coefficient, m²/s;

c - heat capacity (at a constant pressure), kcal/kg°C;

g - acceleration of gravity m/s²;

γ - specific gravity/weight, kg/m³;

a=λ/cγ - coefficient of thermal diffusivity (characterizes the rate of temperature balance in the unevenly heated fluid flow or gas), m²/h;

β - coefficient of linear expansion of liquid or gas, 1/°C;

Δt - difference in the temperatures, °C.

Over-all heat-transfer coefficients from the heating medium to that heated through the wall.

1. Through single-layer flat/plane wall

$$k = \frac{1}{\frac{1}{\alpha_1} + \frac{s}{\lambda} + \frac{1}{\alpha_2}} \quad kcal/m^2h \; °C, \qquad (121)$$

where α_1 - heat-transfer coefficient from heating medium to wall, kcal/m²h °C;

s - wall thickness, m;

λ - coefficient of heat conductivity of material of wall, kcal/m-

hour °C:

α_2 - heat-transfer coefficient from wall to heated medium, kcal/m²h °C.

2. Through multilayer flat/plane wall

$$k = \frac{1}{\frac{1}{\alpha_1} + \frac{s_1}{\lambda_1} + \frac{s_2}{\lambda_2} + \ldots + \frac{s_n}{\lambda_n} + \frac{1}{\alpha_2}} \ \text{kcal/m}^2\text{h °C,} \quad (122)$$

where $s_1 + s_n$ - thickness of walls (layers), m;

$\lambda_1 + \lambda_n$ - coefficient of thermal conductivity of material of walls (layers), kcal/m- hour °C.

Page 52.

3. Through single-layer cylindrical wall

$$k = \frac{1}{\frac{1}{\alpha_1} + \frac{s}{\lambda} + \frac{1}{\alpha_2} \frac{2d_1}{d_1 + d_2}} \ \text{kcal/m}^2\text{h °C} \quad (123)$$

4. Through the multilayer cylindrical wall

$$k = \cfrac{1}{\left(\cfrac{1}{a_1 d_i} + \cfrac{1}{2\lambda_1} \ln \cfrac{d_1}{d_i} + \cfrac{1}{2\lambda_2} \ln \cfrac{d_2}{d_1} + \dots + \cfrac{1}{2\lambda_n} \ln \cfrac{d_n}{d_{n-1}} + \cfrac{1}{a_2 d_a}\right) d_i},$$

$$\text{kcal/m}^2\text{h} \ ^{\circ}\text{C}, \qquad\qquad (124)$$

where d_i - cylinder bore, m;

i_1, d_2 - outer diameters or cylinder and layers, m;

d_a - outer diameter of latter/last n layer, m;

ln - natural logarithm.

If the wall thickness of cylinder is insignificant in comparison with the inner diameter and the thickness of the layer (insulation/isolation) and comprises less than 1/20 diameters, then in this case the coefficient of heat transfer can be calculated as for the flat/plane wall.

5. Through finned wall:

1) for unit of smooth surface

$$k = \cfrac{1}{\cfrac{1}{a_1} + \cfrac{s}{\lambda} + \cfrac{1}{a_2} \cfrac{F_1}{F_2}} \ \text{kcal/m}^2\text{h} \ ^{\circ}\text{C}; \qquad (125)$$

2) for unit of finned surface

$$k = \frac{1}{\frac{1}{\alpha_1}\frac{F_2}{F_1} + \frac{s}{\lambda}\frac{F_2}{F_1} + \frac{1}{\alpha_2}} \quad \text{κcal/m}^2\text{h } ^\circ\text{C,} \quad (126)$$

where $\frac{F_1}{F_2}$ - ratio of smooth surface to that finned;

$\frac{F_2}{F_1}$ - ratio of finned surface to smooth.

Fig. 38 depicts the finned wall with a thickness of s, the coefficient of thermal conductivity of which is equal to λ. One side of this wall with finneds of the same material. From hair side the surface is equal to F_1, while with that finned - F_2; the latter is comprised from the surface of edges/fins and surface of wall itself between the edges/fins.
Fig. 38. Coefficient of heat transfer through the finned wall.

Page 53.

Particular coefficients of heat transfer.

The simplified determination of the coefficients of heat transfer from the vapor to the water for the capacitors/condensers can be recommended according to the following approximation formula resulting data which answer the character of the curves Fig. 39; this formula gives, however, somewhat the higher values

$$k = 942 \sqrt{v} \sqrt[4]{t_{cp} + 17,8} \quad \text{kcal/m}^2\text{h } ^\circ\text{C,} \qquad (127)$$

where v - a rate of water in tubes, m/s;

t_{cp} - mean temperature of water, $^\circ$C.

The curves of the coefficient of heat transfer for the brass
tubes with a diameter of 19 mm are given in Fig. 39. The values of
coefficient of k of heat transfer are given maximum, attained in the
virtually pure/clean capacitors/condensers of good
construction/design with certain supply.
Fig. 39. Coefficient of heat transfer from the vapor to the water depending on the rate and temperature of cooling water for brass tubes with a diameter of 19 mm.

Key: (1). To (over the external surface) kcal/m²h °C. (2). Mean temperature of cooling water. (3). m/s.

Page 54.

For the tubes with a diameter of 16 mm k it increases by 2o/o. For the tubes with a diameter of 25 mm k it decreases by 3o/c. For

the German silver tubes k it descends to 10c/c and for the steel
tubes - by 17-20o/o.

These coefficients cf heat transfer are determined for the
capacitors/condensers, designed with Δt taking into account the
effect of steam resistance.

For obtaining the average/mean value of coefficient cf k' the
obtained coefficient k in formula (127) cr in Fig. 39 should be
multiplied by 0.8-0.85 to account for the effect of surface
contaminations and inconstancy of other factors, noted on page 50.

The coefficient of heat transfer for the capacitors/condensers
according to the data cf VTI is determined by the formula

$$k = 3500 \left(\frac{1,1v}{\sqrt[4]{d_n}} \right)^x \left[1 - \frac{0,42\sqrt{a}}{1000} (35 - t_s)^2 \right] \Phi_z \Phi_s .$$

<div align="center">kcal/m²h   °C,   (128)</div>

where $x = 0,12a (1 + 0,15) t_s$;

a=0.8-0.85 - the coefficient, which considers surface contamination
cf the cooling;

v - rate of water in the tubes, m/s;

$d_{\text{в}}$ - inner diameter of tube, mm;

$t_{\text{в}}$ - temperature of cooling water in the capacitor/condenser, °C;

Φ_z - factor, which considers the effect of a number of courses of water in the capacitor/condenser,

$$\Phi_z = 1 + \frac{z-2}{10}\left(1 + \frac{t_{\text{в}}}{35}\right);$$

z - number of courses of water in the capacitor/condenser;

$\Phi_{\text{в}}$ - factor, which considers the effect of the steam load of capacitor/condenser U [see formula (161)]: $\Phi_{\text{в}} = 1$ for the nominal steam load or changing within the limits from $U_{\text{ном}}$ to $U_{\text{гр}} = \delta_{\text{гр}} U_{\text{ном}}$, where $\delta_{\text{гр}} = 0.9 - 0.012 t_{\text{в}}$; $\Phi_{\text{в}} = \delta(2 - \delta)$ for $U < U_{\text{гр}}$, where $\delta = \dfrac{U}{U_{\text{гр}}}$.

The coefficient of heat transfer for the capacitors/condensers of steam engines:

$$k_{\text{o}} = 0.8k \; \text{кcal/m}^2\text{h} \; °C,$$

where k - the coefficient of heat transfer, determined in formula (127) or in of the curves of Fig. 39;

number 0.8 - the coefficient, which considers the presence in capacitor/condenser of oil, introduced with the vapor in the dustlike state.

Page 55.

The coefficient of heat transfer for the vaporizers/evaporators and the distillers (from the vapor to the boiling brine of marine water) is determined on of the curves of Fig. 40 in depending on the temperature of primary (heating) and secondary steam.

During the practical calculations of vaporizers/evaporators should be considered the degree of surface contamination of heat exchange, the effect of air and the nonuniformity of the distribution of heat-transfer agent, which make the coefficient worse of heat transfer against that theoretically calculated. This effect is considered by the correction factor β, which is introduced in the form of factor to the coefficient of heat transfer, found in of the curves of Fig. 40. The value of correction factor β is accepted within the limits from 0.8 to 0.9 in depending on the salinity of marine water and brine in the housing of vaporizer/evaporator. The larger salinity of water and brine answers the smaller value of coefficient and vice versa.

The coefficient of heat transfer from the vapor to the petroleum residue depending on the rate and mean temperature of petroleum residue is determined on the graph/curve Fig. 41.

The curves of graph/curve are constructed according to the data of tests for the course of the admiralty fuel oil M12 in the steel tubes with a diameter of 17/13 mm.
Fig. 40. Coefficient of heat transfer for the vaporizers/evaporators in depending on a difference in the temperatures (between the temperature of the saturation cf primary and secondary steam) and the temperature of the evaporation cf water.

Key: (1). Vaporization temperature. (2). To kcal/m²h °C.

Page 56.

The coefficient of heat transfer from the vapor to petroleum residue M 20 and M 40 can be with sufficient precision/accuracy determined by the dependence:

$$k_{\text{м}} = z_1 k \text{ кcal/m}^2 \text{h } °C, \tag{129}$$

where ε_1 - the correction factor, which considers a change in the brand of petroleum residue and taken: $\varepsilon_1 = 0.93$ - for petroleum residue M 20, $\varepsilon_1 = 0.87$ - for petroleum residue M 40;

k - coefficient of heat transfer from the vapor to petroleum residue M 12, determined in the graph/curve Fig. 41.

The coefficient of heat transfer from the vapor to the petroleum residue, which takes place in the tubes with established/installed in them retarders, can be determined the dependence

$$k_p = \varepsilon_2 k_u \quad \text{kcal/m}^2\text{h }^\circ\text{C}, \qquad (130)$$

where ε_2 - correction coefficient, which considers the effect of retarders in depending on rate and mean temperature of petroleum residue, determined in the graph/curve Fig. 42;

k_u - coefficient of heat transfer from the vapor to the petroleum residue of this brand, determined on formula (129) and graph/curve of Fig. 41.

As retarders were applied the flat/plane steel strips with a thickness of 1 mm and the spirals, convoluted from the same bands with different space of twisting.

Tests showed that with viscous motion of petroleum residue in the tube, which usually occurs in the fuel heaters, the decrease of the space (from 300 to 50 mm) or spiral retarders or the replacement by their flat/plane ones does not exert a substantial influence on an increase in the coefficient of heat transfer.

The coefficient of heat transfer from the vapor to oil in depending on rate and mean temperature of oil is determined on the graph/curve Fig. 43.
Fig. 41. Coefficient of heat transfer from the vapor to the petroleum residue in depending on its rate and mean temperature.

Key: (1). To the kcal/m²h °C. (2). Mean temperature. (3). m/s.

Page 57.
Fig. 42. Correction factor, which considers effect of retarders established/installed in tubes.

Fig. 43. Coefficient of heat transfer from vapor to oil in depending on its rate of mean temperature.

Key: (1). Mean temperature. (2). kcal/m²h °C. (3). m/s.

Page 58.

The curves of graph/curve are constructed according to the data of tests for the course of oils of brands T and UT in the copper tubes with a diameter of 10/8 mm.

Tentative limits of the values of the coefficients of heat transfer k (kcal/m^2h °C) in the shipboard heat exchangers:

from one gas to the next ... 25-40

from the gas to the water ... 50-100

from one water to the next ... 1000-2000

from the condensable vapor to the water ... 2500-3500

from the condensable vapor to the air ... 80-140

from the condensable vapor to oil ... 100-350

from the condensable vapor to the petroleum residue ... 100-400.

General/common/total heat-transfer coefficients.

Heat-transfer coefficient during the free convection (free motion) of liquid, gas (vapor) in the large volume is determined from the formula of M. A. Mikheev

$$\alpha = c \frac{\lambda}{d} (GrPr)^n \quad \text{кcal/m}^2\text{h °C,} \qquad (131)$$

where λ - coefficient of the thermal conductivity of medium, kcal/m-hour °C;

d - determining size/dimension (diameter), m;

Gr - Grashof's criterion;

Pr - Prandtl number;

c, n - coefficients.

The values of coefficients of c and n are given in Table 5.

Formula (131) is applied for any drop ones and gaseous liquids, for the vertical and horizontal ducts (wires), the horizontal plates/slabs and the spheres of any size/dimension. In this case, if the exothermal surface of plate/slab is turned upwards, then the obtained from formula (131) value of coefficient increases by 30o/c, but if the exothermal surface is turned downward, then value decreases by 30o/o.

As the determining size/dimension is accepted the diameter, and for the plates/slabs - smaller side of plate/slab.

Table 5. Values of coefficients of c and n.

Режим движения (1)	(GrPr)	c	n
Ламинарный (2)	$1 \cdot 10^{-3} \div 5 \cdot 10^2$	1,180	1/8
Переходный (3)	$5 \cdot 10^2 \div 2 \cdot 10^7$	0,546	1/4
Турбулентный (4)	$2 \cdot 10^7 \div 1 \cdot 10^{10}$	0,135	1/3

Key: (1). State of motion. (2). Laminar. (3). Transient. (4). Turbulent.

Page 59.

As the determining temperature is accepted mean temperature of boundary layer, determined according to formula (16).

The coefficient of heat transfer with forced viscous motion of liquid, gas (vapor) in the duct is determined from the formula of I. T. Alad'yev

$$a = 0,74 \frac{\lambda}{d} Re^{0,2} (GrPr)^{0,1} Pr^{0,2} \text{ kcal/m}^2\text{h } {}^\circ C, \qquad (132)$$

where λ - coefficient of the thermal conductivity of medium, kcal/m-hour °C;

d - diameter of duct, m;

Re - Reynolds number;

Pr - Prandtl number;

Gr - Grashof's criterion.

Formula (132) is applied for the horizontal and stand pipes, and also for ducts and channels of any section: in this case instead of the diameter of ducts is substituted the equivalent diameter of section.

In the vertical position of ducts and with the coincidence of the directions of the free and constrained action the coefficient of the heat emission in 15c/o than lower calculated according to formula (132), while in opposite direction - in 15o/c is above.

As the determining size/dimension is accepted the diameter of duct or the equivalent diameter of section, while for the determining temperature - temperature of boundary layer.

If the length of duct $l < 50$ d, then the obtained value according to the formula must be multiplied by correction factor ε_l (Table 6).

Heat-transfer coefficient with the forced turbulent motion of liquid, gas (vapor) in the duct, and also with the longitudinal washing of the bank of tubes is determined from the formula

$$\alpha = 0{,}023 \frac{\lambda}{d} Re^{0.8} Pr^{0.4} \quad \text{kcal/m}^2\text{h } ^\circ\text{C}, \qquad (133)$$

where the designations the same as in formula (132).

Formula (133) is applied to the drop and elastic liquids for ducts and channels of any section, and also for the longitudinal external washing of the banks of tubes with $Re > 1 \cdot 10^4$ and $Pr = 0.7-2500$, also, at temperature of the wall lower than boiling point of liquid, and also for the superheated steam by pressure to 100 atm(abs.) with $Re \leqslant 2 \cdot 10^6$.

Table 6. Values of coefficients

l/d	1	2	5	10	15	20	30	40	50
ε_1	1,9	1,7	1,44	1,28	1,18	1,13	1,05	1,02	1,0

Page 60.

As the determining size/dimension is accepted the equivalent diameter of duct and for the determining temperature - mean arithmetic temperature of liquid.

With $\frac{l}{d} < 50$ the obtained value for α must be multiplied by correction factor ε_1 (Table 7).

Formula (133) is valid also for ring cross-section $d_1/d_2 = 0.1-1.0$ in the case of heat exchange with the external (larger) surface.

For the ring cross-section and the heat exchange with the internal surface the formula takes the form

$$a = 0,023 \frac{\lambda}{d_1} \left(\frac{d_2}{d_1} \right)^{0.45} Re^{0.8} Pr^{0.4} \; \kappa cal/m^2 h \; ^{\circ}C, \qquad (134)$$

where d_1 - an outside diameter of core tube;

d_2 - inner diameter of body tube.

Heat-transfer coefficient during the transient mode/conditions. Motion is unstable. Reynolds number is within the limits of Re from 2200 to 10000.

In this case of formula (132) and (133) the heat emissions for the laminar and turbulent mode/conditions are not applied, but their extrapolation is not admitted.

Table 7. Values of coefficients ε_l

Re \ l/d	1	2	5	10	15	20	30	40	50
$1 \cdot 10^4$	1,65	1,50	1,34	1,28	1,17	1,13	1,07	1,03	1,0
$2 \cdot 10^4$	1,51	1,40	1,27	1,18	1,13	1,10	1,05	1,02	1,0
$5 \cdot 10^4$	1,34	1,27	1,18	1,13	1,10	1,08	1,04	1,02	1,0
$1 \cdot 10^6$	1,28	1,22	1,15	1,10	1,08	1,06	1,03	1,02	1,0
$1 \cdot 10^8$	1,14	1,11	1,08	1,05	1,04	1,03	1,02	1,01	1,0

Page 61.

For determining the heat-transfer coefficient during the

transient mode/conditions it should be used the following dependence:

$$a = Nu \frac{\lambda}{d} \ \ kcal/m^2h \ ^\circ C, \qquad (135)$$

where Nu - Nusselt's criterion, determined in depending on criteria

Re, Pr and products $GrPr^3$ on the graph/curve Fig. 44 or according to

formula (136);

λ - coefficient of the thermal conductivity of medium at mean

temperature, kcal/m-hour $^\circ C$;

d - diameter of duct, m.
Fig. 44. Graph/curve of heat emission during the transient mode/conditions.

Page 62.

Approximate value of Nusselt's criterion Nu for the transient mode/conditions through the graph/curve Fig. 44 is located in a

following manner:

1) on the ordinate at value $Re_{\kappa p}=10^4$ is plotted/deposited the value of Prandtl number Pr, calculated at mean temperature of medium (point A);

2) on the ordinate at value $Re_{\kappa p}=2200$ is plotted/deposited the value of the product of criteria Gr Pr³, calculated at mean temperature of boundary layer (point B);

3) points A and B are connected by the straight line $\overline{AB}$;

4) on the axis/axle of abscissas is plotted/deposited the value of criterion Re for the transient mode/conditions (point C), and from point C is set up ordinate before the intersection with the straight line $\overline{AB}$ (point D);

5) by the value of ordinate CD is determined the unknown value of Nusselt's criterion Nu during transition mode/conditions.

Approximate value of Nusselt's criterion Nu during the transient mode/conditions can be also determined according to the formula

$$Nu = (Nu_{\tau} - Nu_{\pi})\frac{Re - 2200}{7800} + Nu_{\pi}. \qquad (136)$$

where Nu_{τ} - Nusselt's criterion, calculated for $Re_{\kappa p}=10^4$ according to

formula (133);

Nu_s - Nusselt's criterion, calculated for $Re_{\kappa p} = 2200$ according to formula (132).

The coefficient of heat transfer during the transverse flow around duct by liquid and gas (vapor) is determined from the formulas of V. I. Gomelauri:

For the liquids

$$a = c \frac{\lambda}{d} Re^n Pr^{0.4} \ \kappa cal/m^2 h \ ^\circ C. \qquad (137)$$

For the gases

$$a = c \frac{\lambda}{d} Re^n \ \kappa cal/m^2 h \ ^\circ C, \qquad (138)$$

where c and n - the coefficients, which depend on the value of criterion Re (Table 8).

Table 8. Value of coefficients cr c and n.

(1) Критерий Рейнольдса Re	(2) Коэффициент c для жидкости	(3) Коэффициент c для газа (пара)	n

5000÷100 000	0,226	0,197	0,60

Key: (1). Reynolds number. (2). Coefficient c for liquid. (3). Coefficient c for gas (vapor).

Page 63.

Remaining designations the same as in the preceding/previous formulas.

Formulas (137) and (138) are applied for the drop ones and the the elastic liquids with the washing of single ducts.

As the determining size/dimension is accepted the diameter of streamline tube, while for the determining temperature - mean temperature of liquid.

The rate of flow is determined in the narrowest section cf channel.

Heat-transfer ccefficient during the transverse flcw arcund the bank of tubes of gas (air) is determined on S. V. Litvinov's formula:

$$\alpha = c \epsilon \frac{\lambda}{d} Re^n \cdot \kappa cal/m^2 h \; ^\circ C, \qquad (139)$$

where the values cf coefficients cf c, ϵ and n depend on the schematic cf run of pipes in the beam, a number cf series/rcws and distance S_1 between the axes/axles of ducts in the series/row.

The values of ccefficients of c, ϵ and n are given in Table 9; remaining designations the same as in the preceding/previous formulas.

The schematics cf run cf pipes in the beams are given in Fig. 45.

Formula (139) is applied for the air and the flue gases.

The rate of flow relates tc the narrowest section in the beam (series/row).

Page 64.

As the determining size/dimension is accepted the diameter of duct, while for the determining temperature - mean temperature of flow.

The heat-transfer coefficient with the cross flow of air, calculated according to formula (139), is valid only for the cases when angle ψ, comprised by direction of flow and by axis/axle of duct, called angle of attack, is equal to 90°. At angle ψ, different from 90°, the value of heat-transfer coefficient, found from formula (139), should be multiplied by coefficient ε, obtained from the graph/curve Fig. 46.

Heat-transfer coefficient in bent tube is determined from the formula, derived on the basis of experimental data:

$$\alpha_{изг} = \left(1 + 1.77 \frac{d}{R}\right) \alpha \; к
кал/м^2 \cdot час \, °C, \qquad (140)$$

Key: (1). kcal/m²h.

where α - heat-transfer coefficient for straight/direct ducts, kcal/m²h °C:

d - diameter of duct, mm;

R - radius cf curvature of duct, mm.

Heat-transfer coefficient in bent tube cther conditions being equal will be more than in the straight line. This increase cccurs due to the disturbance/breakdcwn of the laminarity of the flcw in the rotation, which creates the ccnditicns cf mcre intense heat exchange. With an increase in the radius cf curvature cf duct the coefficient of heat transfer decreases.
Fig. 45. Schematics of run of pipes in the beams: a) corridor; b) checkered.

Fig. 46. Dependence of heat emission of duct on angle of attack ψ.

Page 65.

Particular heat-transfer coefficients.

Heat-transfer coefficient α for the water: 1) for the water, which takes place in tube or channel of any section with laminar flow, α is determined from formula (132):

2) for the water, which takes place in the tube with turbulent flow,

$$\alpha = A v^{0,8} d^{-0,2} \; \text{ккал/м}^2\text{-час} \; {}^\circ C, \qquad (141)$$

Key: (1).   kcal/m²h.

where $A = (1190 + 21.5\, t_{cp} - 0.015\, t^2_{cp})$:

v - speed of water, m/s;

d - diameter of tube, m;

t_{cp} - mean temperature of water, °C.

Values A, $v^{0.8}$, $d^{-0.2}$ are given in tables 10, 11 and 12.

Table 10. Values A.

t_{cp} °C	0	10	20	30	40	50	60

Page 66.

Fig. 47 gives the nomogram for determining the heat-transfer coefficient for the water, calculated according to formula (141).

Nomogram makes it possible to determine heat-transfer coefficient for different mean temperatures of water and different diameters of tubes in the dependence on the speed of water in the tubes. The determination of heat-transfer coefficient in the nomogram is shown by the arrows/pointers:

3) for the water, which flows around about the tubes during the free convection (free action), α are determined from formula (131);

4) for the water, which flows around about the tubes at low speeds,

$$\alpha = 0.5 \frac{\lambda}{d} Re^{0.6} Pr^{0.3} \ \textit{ккал/м}^2\textit{-час} \ °C; \qquad (142)$$

Key: (1). kcal/m²h.

where λ, d, Re and Pr - the same as in the designation of similarity criteria.
Fig. 47. Nomogram for determining the heat-transfer coefficient from the wall to the water and from the water to the wall.

Key: (1). kcal/m²h. (2). m/s.

Page 67.

5) for the water during the transverse flow around tube α it is

determined from formula (137);

6) for the water, which flows around about the tubes lengthwise with the turbulent motion, α is determined from formula (133);

7) for the boiling water

$$a = 22 p^{0.58} \Delta t^{2.33} \ \kappa\kappa\alpha\pi)_{M^2 \cdot \text{час}} \ ^\circ C, \qquad (143)$$

Key: (1). kcal/m²h.

where p - pressure in container, atm(abs.);

Δt - difference in the temperatures between the surface of wall and the boiling water, °C.

Fig. 48 gives the curve of heat-transfer coefficient α for the boiling water in the dependence on a difference in temperatures $t_{ct} - t_{o}$ (between the wall and the water) at the atmospheric pressure of the boiling liquid. Curve consists of two sections, which are shared with the point of the critical temperature head (by difference in the temperatures), equal to about 25°C).
Fig. 48. Heat-transfer coefficient for the boiling water in depending on a difference in the temperatures between the wall and the boiling water.

Key: (1). kcal/m²h.

Page 68.

The solid line of curve is located in limits of 5-25°C of the temperature head; it is calculated according to formula (143) for the atmospheric pressure.

Laws governing the heat-transfer coefficient, located in other limits of the temperature head, are different. An increase in the temperature head higher than critical leads to a sharp reduction in the heat-transfer coefficient for the boiling water.

Heat-transfer coefficient α for the oil-products: 1) for the oil-products, petroleum residue and oil, which take place in the tubes with viscous motion,

$$\alpha = 13.2 \frac{\lambda}{d} Pe^{0.23} \left(\frac{l}{d}\right)^{-0.5} \text{ккал}^{(1)}/\text{м}^2\text{-час} \,°C, \qquad (144)$$

Key: (1). kcal/m²h.

where λ - coefficient of the thermal conductivity of oil-product, kcal/m·h °C;

d - diameter of tube, m;

l - length of tube, m;

Pe - Peclet's criterion.

The motion of oil-products usually occurs with laminar flow;

2) for oil, which flows around about the tubes across,

$$\alpha = 550 \sqrt{\frac{v}{l - d_{\text{н}}}} (1 + 0.006 t_{\text{ср}}) \text{ккал}^{(1)}/\text{м}^2\text{-час} \,°C, \qquad (145)$$

Key: (1). kcal/m²h.

where v - speed of oil, m/s;

   t - space of tubes, mm;

 $d_{\scriptscriptstyle H}$ - outside diameter cf tubes, mm;

t_{cp} - mean temperature cf cil, °C.

Fig. 49 gives curves of heat-transfer ccefficients for the oil
coclers, calculated acccrding tc formula (145) in the dependence on
the speed and mean temperature oils also of the space of tubes. With
the space of tubes 21 mm the heat-transfer coefficient increases by
9c/o, while with the space 20 mm - to 22c/o;

3) for the oil-prcducts, preheated in the cistern by coils (heat
emission with the free acticn),

$$\alpha = 1.57 \sqrt[4]{\frac{t_{cr}-t}{v d_{\scriptscriptstyle H}}} \; \text{ккал/м}^2\text{-час °C;} \qquad (146)$$

Key: (1). kcal/m²h.

4) for the oil-prcducts, which take place along stand pipe,

$$\alpha = 2.61 \sqrt[3]{\frac{t_{cr}-t}{v}} \; \text{ккал/м}^2\text{-час °C;} \qquad (147)$$

Key: (1). kcal/m²h.

Page 69.

　　5) for the oil-products, which take place along horizontal duct,

$$\alpha = 1.91 \sqrt[4]{\frac{t_{ct} - t}{\nu d_{H}}} \quad \text{ккал} / \text{м}^2\text{-час} \ ^\circ\text{C}, \qquad (148)$$

Key: (1). the kcal/m²h.

where t_{ct} - temperature of wall, determined according to formula (19), °C;

　　t - temperature of oil-products, °C;

　ν - kinematic viscosity coefficient, m²/s;

　d_{H} - outside diameter of coil, m.

　　Heat-transfer coefficient for the condensing water vapor: 1) for the vertical wall or the stand pipe

$$\alpha_{H} = A \sqrt[4]{\frac{r}{H(t_s - t_{ct})}} \quad \text{ккал} / \text{м}^2\text{-час} \ ^\circ\text{C}, \qquad (149)$$

Key: (1). kcal/m²h.

where $A = 0.943 \sqrt[4]{\frac{\gamma^2 \lambda^3}{\mu}}$ depends on temperature t_{rp}, of determined according to formula (16) or (21);

r - heat of vaporization, кcal/kg;

H - height of wall cr duct, m;

t_s - temperature of the condensable vapcr, °C.
Fig. 49. Heat-transfer coefficient for the oil coolers in depending on speed and mean temperature of oil, which takes place between the tubes with a diameter of 16 mm and with space 22 mm.

Key: (1). kcal/m²h. (2). Mean temperature of oil. (3). m/s.

Page 70.

t_{cT} - temperature of wall, determined according to formulas (17)-(19), °C;

γ - the specific gravity/weight of condensate, kg/m³;

λ - coefficient of thermal conductivity, kcal/m-h °C;

μ - viscosity of condensate, kg·s/m².

Values A are given in Table 13;

2) for the inclined wall

$$\alpha_{\beta} = \alpha_{\text{в}} \sqrt[4]{\sin\beta} \quad \kappa\kappa\alpha\lambda/\text{м}^2\text{-час }°C, \qquad (150)$$

Key: (1).   kcal/m²h.

where $\alpha_{\text{в}}$ - heat-transfer coefficient from the condensable vapor to
the vertical wall or tube, the kcal/m²- h °C;

β - angle of the slope of wall to the horizontal plane;

3) for the horizontal duct

$$\alpha_{\text{т}} = 0.77 A \sqrt[4]{\frac{r}{d_{\text{н}}(t_s - t_{\text{ст}})}} \quad \kappa\kappa\alpha\lambda/\text{м}^2\text{-час }°C, \qquad (151)$$

Key: (1). kcal/m²h.

where $d_{\text{н}}$ - outside diameter of duct, m;

A, r, t_s and $t_{\text{ст}}$ - the same as in formula (149);

4) for the beam of the horizontal ducts (arranged/located by one

under another so that the condensate of upper duct it flows on lower)

$$z_n = a_r \sqrt[4]{\frac{1}{n}} \quad \text{ккал}/\text{м}^2\text{-час} \ ^\circ C, \qquad (152)$$

Key: (1). kcal/m²•h.

where z_r - heat-transfer coefficient for the upper duct;

n - number of ducts, arranged/located on the vertical line under each other.

Fig. 50 gives the nomogram for determining the heat-transfer coefficient from the condensable vapor to the wall for the vertical and horizontal location of walls, calculated according to formulas (149) and (151).

Table 13. Values A.

t_{rp}	A	t_{rp}	A	t_{rp}	A	t_{rp}	A	t_{rp}	A	t_{rp}	A	t_{rp}	A
0	1147	30	1495	60	1795	90	2075	120	2330	150	2570	180	2775
10	1270	40	1600	70	1890	100	2160	130	2415	160	2640	190	2835
20	1387	50	1700	80	1985	110	2245	140	2495	170	2710	200	2890

Page 71.

On the nomogram the value α is determined in depending on the product cf the height/altitude cf wall cr team of tubes to a difference in the temperatures of the condensable vapor and wall and on the temperature of boundary layer t_{rp}, cf determined acccrding to formula (16) or (21);

5) for the condensable vapcr within the horizontal ducts and the coils

$$\alpha = (3400 + 100 v_0) \sqrt[3]{\frac{1.21}{l}} \; \textit{ккал/м}^2\textit{-час} \; °C,$$

Key: (1). kcal/m²h.

where v_0 - speed of steam with entrance intc the duct, m/s;

l - length of duct cr ccil, m;

6) for the condensable vapor within the stand pipes α are determined from formula (149).

Heat-transfer coefficient for the condensable moving/driving vapor, which contains air, is determined from empirical formula VTI

$$\alpha = \frac{A(v_\gamma)^{n_1} t^{0.167}}{\Delta t^{0.167}} \quad \text{ккал/м}^2\text{-час} \ ^\circ C, \qquad (153)$$

Key: (1). kcal/m²•h.

where v_γ - the mass flow rate of air-steam mixture in the wide section of channel, kg/м²s.
Fig. 50. Nomogram for determining the heat-transfer coefficient from the condensable vapor to the wall.

Key: (1). for the horizontal location, 10^3 kcal/m²•h°C. (2). for vertical run, 10^3 kcal/m²•h°C. (3). or.

Page 72.

A, n - values, which depend on the content of air in vapor $\varepsilon = \dfrac{G_s}{G_n}$ and the temperature of mixture t_{cm}, to equal temperature of steam t_n, determined on the curves of the graph/curve Fig. 51 and 52;

Δt - the temperature head (difference in the temperatures of

mixture and the walls of duct), °C.

Formula (153) is obtained according to experimental data for the horizontal beam of the brass ducts with a outside diameter of 19 mm and by space between them of 26 mm at $t_n = 30 \div 80°C$; $\Delta t \doteq 3 \div 15°C$; $\overline{v}_1 = 0.1 \div 3.0$ kg/m$_2$s and $\varepsilon = 0 \div 0.3$ kg/kg.

Heat-transfer coefficient for the overheated (not condensing) vapor is determined from formula (133).

It is necessary to keep in mind that, if the temperature of the wall lower than temperature of saturation, then the condensation of the superheated steam flows/occurs/lasts then good as saturated.

Therefore heat-transfer coefficient for the superheated steam is defined:

1) according to formula (149) as for the condensable vapor, if the temperature of the wall lower than temperature of saturation of steam;

2) according to formula (133) as for the overheated (not condensing) steam (or gases), if the temperature of the wall higher than temperature of saturation.

During the determination of heat-transfer coefficient for the condensing superheated steam should be allowed its temperature of saturation at the appropriate pressure, but not the temperature of overheating.
Fig. 51. Value of value A in depending on the content of air in steam and the temperature of air-steam mixture.

Key: (1). kg/kg.

Page 73.

Heat-transfer coefficient for any gas and air: 1) for the gas and the air, which takes place in duct or channel of any section with viscous motion, heat-transfer coefficient is determined from formula (132);

2) for the gas and the air, which takes place in the duct or which flows around about the it lengthwise during turbulent motion, heat-transfer coefficient is determined from formula (133);

3) for the gas and the air with the transverse of the flow around the bank of tubes heat-transfer coefficient is determined from formula (139);

4) for the air (free convection or at the speed of motion is not more than 0.5 m/s) with the vertical run of the flat/plane or cylindrical walls

$$\alpha = 2.2 \sqrt[4]{t_{\text{ст}} - t_{\text{в}}} \quad \text{ккал}/\text{м}^2\text{-час} \, ^\circ\text{C};$$ (154)

Key: (1). kcal/m²•h°C.

5) for the air during the horizontal location of the flat/plane wall, turned by the heat-transmitting surface upward [condition for air circulation as for the formula (154)]

$$\alpha = 2.8 \sqrt[4]{t_{\text{ст}} - t_{\text{в}}} \quad \text{ккал}/\text{м}^2\text{-час} \, ^\circ\text{C};$$ (155)

Key: (1). cal/m²•h°C.
Fig. 52. Value of value n in depending on the content of air steam and the temperature of air-steam mixture.

Key: (1). kg/kg.

Page 74.

6) for the air during the horizontal location of the flat/plane wall, turned by the heat-transmitting surface down [condition for air circulation as for the formula (154)]

$$a = 1,13 \sqrt[4]{t_{ст} - t_в} \; ккал/м^2\text{-}час \; °C; \qquad (156)$$

Key: (1). kcal/m²•h°C.

7) for the air during the horizontal location of the cylindrical

walls [condition for air circulation as for the formula (154)]

$$a = 1,02 \sqrt[4]{\frac{t_{cr} - t_{\scriptscriptstyle B}}{d_{\scriptscriptstyle H}}} \; \kappa\kappa a\lambda/m^2\text{-}uac \; ^\circ C, \qquad (157)$$

Key: (1). kcal/m²•h°C.

where t_{cr} - temperature of wall, °C;

$t_{\scriptscriptstyle B}$ - temperature of surrounding air, °C;

$d_{\scriptscriptstyle H}$ - outside diameter of duct, m;

8) for the environment (air) from the surface of the walls of apparatuses and pipes in the closed location at temperature of heat-transfer agent from 0 to 150°C

$$a \approx 8,4 + 0,06 (t_{cr} - t_{\scriptscriptstyle B}) \; \kappa\kappa a\lambda/m^2\text{-}uac \; ^\circ C. \qquad (158)$$

Key: (1). kcal/m²•h°C.

In this formula is considered the convection and emission with 4.6 kcal/m²•h (°K)⁴.

Heat-transfer coefficient for the humid air

$$a_{\scriptscriptstyle BM} = \xi a_{cyx} \; \kappa\kappa a\lambda/m^2\text{-}uac \; ^\circ C, \qquad (159)$$

Key: (1). kcal/m²•h°C.

where a_{cyx} - heat-transfer coefficient for the dry air, kcal/m²•h°C;

ϵ - coefficient of moisture removal, determined in the formula

$$\xi = 1 + \frac{d10^{-3}}{t_{cp} - t_{cr}} \frac{r - i_{вл}}{c_в};$$

where d - a moisture content of air, g/kg;

t_{cp} - mean temperature of air, °C;

t_{cr} - temperature of the surface of wall, °C;

r - heat of vaporization with t_{cp}, kcal/kg;

$i_{вл} \approx t_{cr}$ - enthalpy of moisture on the surface of wall, kcal/kg;

$c_в$ - average/mean heat capacity of the air, kcal/kg°C.

Tentative limits of the values of heat-transfer coefficients α in kcal/m²•h°C:

During heating and cooling air ... 10-150.

During heating and cooling of superheated steam ... 20-100.

During heating and cooling pertroleum products ... 150-600.

During heating and cooling water ... 200-10000.

During boiling of water ... 500-45000.

During the condensation of water vapors ... 4000-15000.

Page 75.

Radiation coefficient.

Heat transfer can be accomplished/realized also by a method of emission. With the heat transfer from the wall to the surrounding space simultaneously with the convection always has the place and the emission whose intensity depends on the degree of the warmth of the surface of wall.

The radiation/emission of heat by the surface of wall depends on a difference in the temperatures of the wall and the environment and on surface condition of wall, considered by radiation factor. A quantity of heat, emitted by the unit of surface for the time unit with a difference in the temperatures between the emitted surface and the environment in 1°C, is called radiation coefficient.

Radiation coefficient from the wall into the environment is determined from to the formula

$$\alpha_{\text{луч}} = C \frac{\left(\frac{T_{\text{ст}}}{100}\right)^4 - \left(\frac{T_{\text{окр}}}{100}\right)^4}{t_{\text{ст}} - t_{\text{окр}}} \quad \text{ккал/м}^2\text{-час} \, ^\circ C, \qquad (160)$$

Key: (1). kcal/m²•h°C.

where $T_{\text{ст}} = 273.2 + t_{\text{ст}}$ - absolute temperature of the wall, heat-radiating, °K;

$T_{\text{окр}} = 273.2 + t_{\text{окр}}$ - ambient temperature, °K;

$t_{\text{ст}}$ - temperature of wall, °C;

$t_{\text{окр}}$ - ambient temperature, °C;

C - radiation factor, the kcal/m²h(°K)⁴, depending on surface condition.

The values of value C are given in Table 14.

Table 14. Values of the coefficient radiation C.

Page 76.

§ 10. Thermal loads, stresses/voltages and efficiencies.

Under the thermal loads and the stresses/voltages is implied the quantity of heat, per unit of surface (heating or cooling) or unit volume of apparatus.

Thermal loads and stresses/voltages can be expressed in the units the measurement: thermal (kcal/m²•h; kcal/m³•h), weight kg/m²-hour; kg/m³-hour) and volumetric (m³/m²- hour; m³/m³-hour).

Steam load of the condenser:

$$U = \frac{G}{F} \ кг/.м^2\text{-}час, \qquad (161)$$

Key: (1). kg/m²-hour.

where G - a quantity of condensed vapor in capacitor/condenser, kg/h;

F - cooling surface of capacitor/condenser, m².

The permissible values of the steam load of capacitors/condensers in depending on vacuum are represented in Table 15.

The multiplicity of cooling - these are the ratio of a quantity of cooling water to a quantity of condensed vapor or, otherwise, the expenditure of cooling water per 1 kg of the condensed vapor.

The multiplicity of cooling can be expressed by the formula

$$m = \frac{W}{G} \; \textit{кг воды/кг пара,} \qquad (162)$$

Key: (1). water/kg steam.

where W - a quantity of cooling water, kg/h;

G - quantity of condensed vapor, kg/h; or

$$m = \frac{i_2 - i_{\text{н}}}{c(t_2 - t_1)} \; \textit{кг воды/кг пара,} \qquad (163)$$

Key: (1). water/kg steam,

where i_2 - enthalpy of steam upon the entrance, kcal/kg:

$i_{\text{н}}$ - enthalpy of condensate, kcal/kg:

c - heat capacity of cooling water, kcal/kg°C;

t_1 - temperature of cooling water upon the entrance, °C;

t_2 - temperature of cooling water on leaving °C.

Table 15. Permissible values of steam load.

(1) Вакуум в конденсаторе, %	90	90—93	94—95	96—97
(2) Паровая нагрузка, кг/.м²-час	150—200	110—150	60—90	50—70

Key: (1). Vacuum in the capacitor/condenser, c/o. (2). Steam load, kg/m²·h.   Page 77.

The graph/curve of a change in the expenditure of cooling water for 1 kg of the condensed vapor in the dependence on the vacuum in the capacitor/condenser and temperatures of cooling water upon the entrance is shown in Fig. 53.

The permissible values of the multiplicity of cooling m in the capacitors/condensers can oscillate in the limits from 30-40 to 60-70, but sometimes in the single-pass capacitors/condensers they can reach 120, which draws an undesirable increase in productivity and power of circulating pump.

Stress/voltage of vaporization surface:

$$R_{\text{и}} = \frac{D \circ}{F_{\text{и}}} \; \text{м}^3/\text{м}^2\text{-час}, \quad (164)$$

Key: (1). m³/m²-hour.

where D - productivity of vaporizer/evaporator, kg/h;

v - the specific volume of secondary steam, m³/kg;

$F_{\text{м}}$ - surface of the vaporization surface, m².

The value of the stress/voltage of vaporization surface in the vaporizers/evaporators usually is within the limits of 1500-2500 m³/m²-hour and with lowering in the pressure of the secondary steam (to 0.15 atm (abs.)) can reach 6000 m³/m²•h.

Stress/voltage of the heating surface:

$$R_{\text{м}} = \frac{D}{F_{\text{м}}} \quad \text{кг}/\text{м}^2\text{-час}, \qquad (165)$$

Key: (1). kg/m²-hour.

where D - productivity of vaporizer/evaporator, kg/h;

$F_{\text{н}}$ - surface of heating, m².

The value of the stress/voltage of the heating surface in the vaporizers/evaporators usually lies/rests within limits of 80-110 kg/m²-hour and sometimes can reach 150 kg/m²-hour, and with the reliable separators - to 200 kg/m²-hour.

Stress/voltage of the steam volume:

$$R_{\text{в}} = \frac{Dv}{V} \quad \text{м}^3/\text{м}^3\text{-час}, \qquad (166)$$

Key: (1). a m^3/m^3-hour.

where D - productivity cf vaporizer/evaporator, kg/h;

v - the specific volume cf secondary steam, m^3/kg;

V - volume of steam space, m^3.
Fig. 53. Multiplicity of cooling in depending on vacuum and temperature of circulation water.

Key: (1). Vacuum.

Page 78.

The value of the stress/voltage of steam volume for the secondary steam of vaporizers/evaporators can reach:

1) for the vaporizers/evaporators of atmospheric pressure

$R'_s = 3000$ m³/m³-hour;

2) for the vaporizers/evaporators, which work with the pressures, different from atmospheric

$$R_s = fR'_s \text{ м}^3/\text{м}^3\text{-час,}$$

Key: (1). m³/m³-hour.

where f - a coefficient of the pressure whose values are given in Table 16;

3) for the vaporizers/evaporators, which have the sufficiently effective built-in separators or the supplementary separating devices/equipment:

$$R_v = (1,2 \div 1,4) f R'_v \quad \text{м}^3/\text{м}^3\text{-час.} \quad (1)$$

Key: (1). m³/m³•-hour.

The efficiency of heat exchangers η is equal to the ratio of a quantity of heat Q_2, obtained in the apparatus, to a quantity of heat Q_1, which is spent in the process of the work of apparatus, and it is expressed in general form by the formula

$$\eta = \frac{Q_2}{Q_1}. \qquad (167)$$

Efficiency of the apparatuses, which work without a change in the state of aggregation (coolants of water, oil, air, water-to-water preheaters, etc.):

$$\eta = \frac{G_2 c_2 (t'_2 - t_2)}{G_1 c_1 (t'_1 - t_1)}. \qquad (168)$$

Efficiency of the apparatuses, which work with a change in state of aggregation of one of the heat-transfer agents (steam preheaters of water, oil, air, fuel/propellant, capacitors/condensers, etc.):

$$\eta = \frac{G_2 c_2 (t'_2 - t_2)}{D_1 (i_1 - c_1 t_1)}. \qquad (169)$$

Efficiency of the apparatuses, which work with total variation in the state of aggregation of one heat-transfer agent and partial change in the state of aggregation of another heat-transfer agent (vaporizers/evaporators, distillers, distillers, etc.):

$$\eta = \frac{D_2(i_2 - c_2 t_2) - \epsilon D_2 c_2 (t_2' - t_2)}{D_1(i_1 - c_1 t_1)}.$$ (170)

Efficiency of the apparatuses, which work with a change in state of aggregation of both heat-transfer agents (evaporators, etc.):

$$\eta = \frac{D_2(i_2 - c_2 t_2)}{D_1(i_1 - c_1 t_1)}.$$ (171)

Table 16. Values of the coefficients of pressure f.

p, ama [1]	16	4,0	2,0	1,0	0,8	0,7	0,6	0,5
f	0,8	0,87	0,915	1,00	1,15	1,25	1,4	1,6

Key: (1). atm (abs.).

Page 79.

Here G_1 - quantity of cooling (or heating) medium, kg/h;

G_2 - quantity of heated (or cooled) medium, kg/h;

D_1 - quantity of heating condensing steam, kg/h;

D_2 - quantity of the secondary steam, kg/h;

в - coefficient of the purging of the heated medium;

c_1 - heat capacity of the cooling (or heating) medium, kcal/kg °C;

c_2 - heat capacity of the cooled (or heated) medium, kcal/kg °C;

i_1 - enthalpy of heating condensing steam, kcal/kg;

i_2 - enthalpy of the secondary steam, kcal/kg;

t_1 - initial temperature of the cooling (or the final temperature of that heating) medium, °C;

t'_1 - the final temperature of the cooling (or the initial temperature of that heating) medium, °C;

t_2 - initial temperature of the heated (or the final temperature of that cooled) medium, °C;

t'_2 - the final temperature of the heated (or the initial temperature of that cooled) medium, °C.

Usually the efficiency of apparatuses for simplification in the calculations take as the equal to the following values which insignificantly differ from those calculated:

for the heat exchangers, which have thermal insulation ... η 0.97-0.98.

For the apparatuses, which do not have thermal insulation ...

η
C.93-0.95.

The efficiency of apparatuses for convenience in the
calculations very frequently replace by the coefficient, which
considers the heat loss by the apparatus into the environment, which
also is designated through η.   This coefficient is the value,
reciprocal efficiency and takes as the equal to:

For the apparatuses, which have thermal insulation ...
η
1.03-1.02.

For the apparatuses, which do not have thermal insulation ...
η
1.07-1.05.

§ 11. Determination of some structural elements/cells of apparatuses.

With the execution of thermal designs usually it is necessary to
define or to select some structural elements/cells of apparatuses,
as, for instance : the space of the laying out of tubes, a number of
tubes and their length, diameter of the tube plate and surface,
formed by tubes and, etc. which have an effect both on the thermal
design and on the construction/design of apparatus.

Page 80.

Are given below the most necessary formulas and initial data by choice and determination of some structural elements/cells.

The diameter of the branch pipe:

$$d = \sqrt{\frac{4F}{\pi}} = \sqrt{\frac{Dv}{2825u}} \; \text{м},\qquad (172)$$

where d — an inner diameter of branch pipe, м;

P — sectional area of branch pipe, м²;

D — expenditure of the medium through branch pipe, kg/h;

v — the specific volume of medium, м³/kg;

u — speed of medium, м/s.

Equivalent (hydraulic) diameter in general form is expressed by the formula

$$d_y = \frac{4F}{\omega} \; \text{м},\qquad (173)$$

where F — a cross-sectional area of channel, м²;

ω — wetted perimeter of channel, м.

Equivalent diameter for some forms of channel is given in Table 17.

Table 17. Equivalent diameters $d_э$.

(1) Форма канала	(2) Эквивалентный диаметр $d_э$
(3) Круглая труба диаметром d	d
(4) Квадрат со стороной a	a
(5) Прямоугольник со сторонами a и b:	
(6) теплообмен через все стороны	$\dfrac{2ab}{a+b}$
(7) теплообмен через две противоположные стороны a	$2b$
(8) теплообмен через одну сторону a	$4b$
(9) Кольцевое сечение (труба d в трубе D):	
(10) теплообмен через внутреннюю и внешнюю поверхности	$D - d$
(11) теплообмен только через внешнюю поверхность	$\dfrac{D^2 - d^2}{D}$
(12) теплообмен только через внутреннюю поверхность	$\dfrac{D^2 - d^2}{d}$
(13) Межтрубное пространство (диаметр корпуса D, диаметр трубок d и число трубок n):	
(14) теплообмен через трубный пучок	$\dfrac{D^2 - nd^2}{nd}$

Key: (1). Form of channel. (2). Equivalent diameter. (3). Circular
duct with a diameter of d. (4). Square with side a. (5). Rectangle
with sides a and b. (6). heat exchange through all sides. (7). heat
exchange through two offosite sides a. (8). heat exchange through one
side a. (9). Ring cross-section (duct d in duct D). (10). heat
exchange through internal and external surfaces. (11). heat exchange
only through external surface. (12). heat exchange only through
internal surface. (13). Intertube space (diameter of housing D,
diameter of tubes d and number of fellings n). (14). heat exchange

through tube bank.

Page 81.

Space t of the laying out of the tubes:

1) minimum space with the laying out on the triangle of the tubes with a outside diameter of $d_н$ (Fig. 54):

$$t = 1,33d_н;$$

2) for the capacitors/condensers with the laying out on the triangle of the tubes with a diameter of $d_н = 16$ мм:

$$t = d_н + 9 \div 10 \text{ мм};$$

3) for the capacitors/condensers with the laying out of the tubes with a diameter of $d_н = 16$ мм on a radius or the rays/beams:

$$t = d_н + 16 \text{ мм};$$

4) for the small capacitors/condensers with low steam resistance, with rolled tubes $d_н = 16$ мм during the laying out of their space on the triangle

$$t = d_н + 5 \div 6 \text{ мм};$$

5) for the preheaters of water, oil coolers and other apparatuses, which have the tubes with a diameter of $d_н = 16$ мм during the laying out of their space on the triangle

$$t = d_н + 5 \div 6 \text{ мм};$$

6) for the petroleum heaters and other apparatuses, which have

the tubes with a diameter of $d_{_H} = 17$ мм   during the laying out of their space on the triangle

$$t = d_{_H} + 5 \div 6 \ \text{мм}.$$

The area of the tube plate, necessary for the location of one tube on the triangle,

$$f = 0,866 t^2 \ \text{мм}^2, \tag{174}$$

where t - a space of the laying cut of tubes, мм.

The solidity/loading factor of the tube plate:

$$\eta_{\text{тр}} = 1,1 \ \frac{t^2 n}{D^2}, \tag{175}$$

where t - a space of the laying cut of tubes, мм;

n - number of tubes, placed on the tube plate;

D - diameter of the socket/seat of tubes, мм.
Fig. 54. Laying out of tubes on the triangle.

Page 82.

The coefficient of filling of tube plate η_{mp} is equal to:

For the single-pass capacitors/condensers ... 0.75-0.82.

For the two-pass ones and more than ... 0.72-0.78.

For the capacitors/condensers of the type C-V ... 0.58-0.65.

A number of cooling tubes in the capacitor/condenser:

$$n = \frac{Wz}{2825 d^2 \omega},$$ (176)

where W - a quantity of cooling water, m³/h;

z - number of courses of the water;

d - inner diameter of tubes, m;

v - speed of water in tubes, m/s.

The length of tubes (distance between the tube panels):

$$L = \frac{F}{\pi d n z} \; \textit{м}, \qquad (177)$$

where F - a surface of heating or of cooling, m²;

d - outside diameter of tube, m;

n - number of tubes in the course;

z - number of courses.

The surface of heating or cooling:

$$F = \frac{Q}{k \Delta t} \; \textit{м}^2, \qquad (178)$$

where Q - a quantity of introduced or abstracted/removed heat, kcal/h;

k - coefficient of heat transfer, kcal/m²·h°C;

Δt - average/mean logarithmic difference in the temperatures (or a difference in the temperatures), °C.

Furthermore, surface F can be determined according to sizes/dimensions and number of tubes of heating or cooling:

$$F = \pi d l n \ \text{м}^2,\qquad (179)$$

where d - an outside diameter of tubes, m;

l - effective length of tubes, m;

n - total number of tubes in the apparatus.

The area of the smallest section of the nozzle:

$$F_{min} = \frac{G}{m\sqrt{\frac{p_0}{v_0}}},\qquad (180)$$

where G - an expenditure of steam through the nozzle,   kg/s;

m=199 - for the saturated steam and m=209 - for the superheated steam;

p_0 - pressure of steam in front of the nozzle, kg/cm^2;

v_0 - specific volume of steam before nozzle, m^3/kg.

Page 83.

The diameter of the smallest section of the nozzle:

$$d_{min} = m' \sqrt{\frac{G}{\sqrt{\frac{p_0}{v_0}}}} \quad \text{мм,} \qquad (181)$$

where $m' = 1.32$ - for the saturated steam and $m' = 1.3$ - for the superheated steam;

G, p_0, v_0 - the same as in formula (180).

The nozzle exit diameter:

$$d_e = 2{,}015 \sqrt{\frac{Gv_1}{\sqrt{h_0}}} \quad \text{мм,} \qquad (182)$$

where G - an expenditure of steam through nozzle, kg/h;

v_1 - specific volume of steam on leaving from nozzle, m^3/kg;

h_0 - adiabatic drop/jump is steam in nozzle, kcal/kg.

The initial diameter of the diffuser/exit cone:

$$D = 1{,}92 \sqrt{G_c v_n} \sqrt[4]{\frac{0{,}25 + u}{0{,}25 h_0}} \quad \text{мм,} \qquad (183)$$

where G_c - expenditure of compressed steam, kg/h;

v_n - the specific volume of sucked in vapor, m^3/h;

$u = \dfrac{G_n}{G}$ - coefficient of the injection;

$G_n = G_c - G$ - expenditure of sucked in vapor, kg/h;

h_0, G - the same as in formula (182).

Surface of zinc protectors/treads. For the protection equipment from the contact corrosion, which appears as a result of the use/application in the apparatuses of the heterogeneous materials, which work under the corrosive conditions, in the chambers/cameras of apparatuses are established zinc protectors/treads.

The working surface of protector/tread is determined in depending on the sum of all surfaces, which are contacted with corrosive environment, and the radius of action of protector/tread.

The radius of action of protector/tread in the chamber/camera of apparatus is spread not more than on 1-1.5 m, but in the beam of tubes - to the length, equal to ten diameters; therefore during the calculation of the shielded surface, besides the surfaces of

covers/caps and tube plates, suculd be ccnsidered alsc the surface of
tubes, formed by their ends/leads, at the length, equal to their ten
diameters.

Page 84.

The working surface of the protector/tread

$$S = \pi R^2 \eta \ c.M^2,\qquad\qquad (184)$$

where R - the radius of action cf protector/tread, m; R=1.0-1.5 - fcr
the chambers/cameras of the apparatuses; R=8-10 to the diameters of
conduit/manifold, but nct mcre than 2 m with the diameter of
conduit/manifold D=200 mm and nct more than 2.5-3 m with D>200 mm;

η - ratio of the area cf protector/tread and area of the shielded
construction/design, which undergoes contact ccrrosion under
conditions of marine water, equal to:

for the chambers/cameras cf apparatuses, fcrmed by the surfaces
cf covers/caps, cf tube plates and by the ends/leads cf the tubes ...
with 1/400-1/500.

For the ducts with bronze and brass fittings ... 1/200-1/500.

For the steel branch pipes and the housings of apparatuses with

bronze and brass accessories ... 1/200-1/300.

Calculation of the safety valves of containers. Capacity is the valve:

a) for the vapor or the gas

$$G = 225 \mu dh \sqrt{p\gamma} \ \kappa\imath/uac; \quad (1)$$ (185)

Key: (1). kg/h.

b) for the liquids

$$G = 500 \mu dh \sqrt{p\gamma} \ \kappa\imath/uac, \quad (1)$$ (186)

Key: (1). kg/h.

where $\mu=0.85$ - a discharge coefficient;

d - diameter of valve (without the account to the area, occupied by the edges/fins of guides), cm;

$h \leq d/4$ - valve lift, cm;

p - the design pressure of the medium before the valve, kg/cm^2;

γ - the specific gravity/weight of medium, kg/m^3.

The calculation of electrical heating elements can be produced according to to the formula

$$Q = 0,86 I V n = 0,86 I^2 R n = \alpha F \Delta t n = \alpha \pi d l \Delta t n \text{ ккал/час, (187)}$$

Key: (1). kcal/h.

where Q - the calorific requirement, kcal/h;

   I - current strength, a;

   V - voltage, v;

   n - number of in parallel working conductors;

   R - resistance of conductor, ohm;

   α - heat-transfer coefficient from the surface of conductor to the heated medium, the $kcal/m^2-h°C$;

   F - surface of conductor, m^2;

   Δt - difference in the temperatures between the surface of conductor and the heated medium, °C;

   d - diameter of conductor, m;

   l - length of conductor, m.

Page 85.

Chapter II.

EXAMPLES OF THERMAL DESIGNS.

§ 12. Calculation of auxiliary capacitor/condenser.

Initial data for the calculation.

A quantity is steam that enters capacitor/condenser, G_1=2700 kg/h.

Quantity of condensate G_2=1640 kg/h.

Enthalpy of steam i_1=650 kcal/kg.

Enthalpy of condensate q_2=133.4 kcal/kg.

Vacuum in capacitor/condenser V_{aa}=85%.

Quantity of cooling water D=150 m/h.

Temperature of cooling water upon entrance $t_1 = 18°C$.

We accept.

Tubes brass with a diameter of $d_v/d_s = 16/14$ мм.

Number of courses of cooling water in tubes z=2.

Course of computation.

1. Absolute condenser backpressure

$$p_{\text{к}} = 1 - \frac{V_{\text{вн}}}{100} = 1 - \frac{85}{100} = 0.15 \; ama.$$

Key: (1). atm(abs.).

2. Condensation temperature of steam when $p_{\text{к}}$ (on tables 1-3 of applications/appendices)

$$t_s = 53.6°C.$$

3. Temperature of condensate, abstracted/removed from capacitor/condenser,

$$t_{\text{к}} = t_s - 4 = 53.6 - 4 = 49.6°C.$$

4. Quantity of heat, transferred by vapor and by condensate to cooling water,

$$Q = G_1(i_1 - t_{\text{к}}) + G_2(q_s - t_{\text{к}}) = 2700(650 - 49.6) + \\ + 1640(133.4 - 49.6) = 175.7 \cdot 10^4 \; ккал/час.$$

Key: (1). kcal/h.

Page 86.

5. Temperature of cooling water, on leaving from condenser

$$t_2 = t_1 + \frac{Q}{Dc_p} = 18 + \frac{175.7 \cdot 10^4}{150 \cdot 10^3 \cdot 0.94} = 30.4^\circ \text{C},$$

where $c_p = 0.94$ kcal/kg of $^\circ$C - heat capacity of cooling (marine) water.

6. Average/mean logarithmic difference in temperatures of vapor and water

$$\Delta t = \frac{t_2 - t_1}{2.3 \lg \frac{t_s - t_1}{t_s - t_2}} = \frac{30.4 - 18}{2.3 \lg \frac{53.6 - 18}{53.6 - 30.4}} = 29^\circ \text{C}.$$

7. Mean temperature of cooling water

$$t_{cp} = 0.5(t_1 + t_2) = 0.5(18 + 30.4) = 24.2^\circ \text{C}.$$

8. Speed of cooling water in tubes we accept v=1.6 m/s.

9. Coefficient of heat transfer for capacitors/condensers in depending on speed and mean temperature of water (on graph/curve Fig. 39) $k_0 = 3040$ kcal/m²-hour $^\circ$C.

10. Calculated coefficient of heat transfer

$$k = \varphi_1 \varphi_2 k_0 = 1.02 \cdot 0.85 \cdot 3040 = 2640 \text{ kcal/m}^2\text{h}   ^\circ\text{C},$$

where $\phi_1 = 1.02$ - coefficient for tubes with a diameter of $d_\text{H} = 16\,\text{мм}$;

$\phi_2 = 0.85$ - coefficient, which considers pollution/contamination of tubes.

11. Coefficient of heat transfer for capacitor/condenser in formula VTI

$$k = 3500 \left(\frac{1.1 v}{\sqrt[4]{d_\text{H}}} \right)^x \left[1 - \frac{0.42 \sqrt{\phi_2}}{1000} (35 - t_1)^2 \right] \Phi_z \Phi_\delta =$$

$$3500 \left(\frac{1.1 \cdot 1.6}{\sqrt[4]{16}} \right)^{0.378} \left[1 - \frac{0.42 \sqrt{0.85}}{1000} (35 - 18)^2 \right] 1 \cdot 1 =$$

$$2940 \; \overset{(1)}{ккал/м^2 \text{-} час} \, °C,$$

Key: (1). kcal/m²h.

where x - an exponent, equal to

$$x = 0.12 \phi_2 (1 + 0.15 t_1) = 0.12 \cdot 0.85 (1 + 0.15 \cdot 18) = 0.378;$$

Φ_z - the factor, which considers the effect of a number of courses of water in the capacitor/condenser,

$$\Phi_z = 1 + \frac{z - 2}{10} \left(1 + \frac{t_1}{35} \right) = 1 + \frac{2 - 2}{10} \left(1 + \frac{18}{35} \right) = 1;$$

Φ_δ - the factor, which considers the effect of steam load on capacitor/condenser $\Phi_\delta = 1$ for the nominal steam load.

Page 87.

12. Necessary cooling surface of condenser

$$F = \frac{Q}{\Delta t k} = \frac{175,7 \cdot 10^4}{29 \cdot 2640} = 22,9 \ м^2.$$

We accept F=23.1 м².

13. Quantity cooling of tubes in capacitor/condenser

$$n = \frac{Dз}{2825 d_в^2 v_1} = \frac{150 \cdot 2}{2825 \cdot 0,014^2 \cdot 1,6 \cdot 1,0} = 340,$$

where γ=1.0 t/м³ - specific gravity/weight of cooling water.

14. Effective length of tubes (distance between tube plates)

$$l = \frac{F}{\pi d_н n} = \frac{23,1}{3,14 \cdot 0,016 \cdot 340} = 1,35 \ м.$$

15. Space of laying out of tubes on triangle

$$t = d_н + 10 = 16 + 10 = 26 \ мм.$$

16. Solidity/loading factor of pipe panel (from conditions of positioning/arranging of tubes and partitions/baffles in cover/cap for two ducts of water)

$$\eta_{тр} = 0,73.$$

17. Diameter of socket/seat of tubes (inner diameter of housing)

$$D_з = t \sqrt{\frac{1,1 \cdot n}{\eta_{тр}}} = 0,026 \sqrt{\frac{1,1 \cdot 340}{0,73}} = 0,592 \ м.$$

18. Quantity of air, driven out from capacitor/condenser

$$G_в = 1,5 \left(\frac{G_1 + G_2}{2000} + 1,36 \right) = 1,5 \left(\frac{2700 + 1640}{2000} + 1,36 \right) = 5,25 \ kg/h.$$

§ 13. Calculation of deaerator.

Initial data for the calculation.

Productivity on the deaerated water D=70   m/h.

Pressure in deaerator $p_2 = 1.2$ atm

Pressure of that heating of steam $p_1 = 1.8$ atm

Temperature of that heating of steam $t_1 = 180°C$.

Temperature of the mixture of water, which enters the deaerator, which consists of 80c/o of condensate and 20c/o of additional water, $t_2 = 40°C$.

Oxygen content in deaerated water $a_n < 0.03$ mg/l.

Page 88.

We accept.

Coefficient of the use of a body in deaerator $\eta = 0.97$.

Content of dissolved oxygen in the condensate, taking into account possible rhodes of air $a_x = 1.0$ mg/l.

We determine (on Tables 1-3 of applications/appendices).

Enthalpy of water in deaerator $q_1 = 104.4$ kcal/kg.

Enthalpy of that heating or steam $i_1 = 676.1$ kcal/kg.

Temperature of water in deaerator $t_1 = 104.3°$ C.

Enthalpy of the mixture of water, which enters the deaerator, $q_2 = 40$ kcal/kg.

The specific volume of water in deaerator $v = 1.047$ m³/t.

Course of computation.

1. Quantity of heating steam, required for heating of water in deaerator

$$G = \frac{D(q_1 - q_2)}{i_1 - q_2} = \frac{70(104.4 - 40)}{676.1 - 40} = 7.0 \text{ t/h}.$$

2. Quantity of mixture of water, which enters deaerator

$$W'_{cm} = D - G = 70 - 7 = 63 \text{ т/ч}.$$

3. Quantity of additional water, which enters deaerator,

$$W_{\text{д}} = 0.2 \, W_{cm} = 0.2 \cdot 63 = 12.6 \text{ т/ч}.$$

4. Quantity of condensate, which enters deaerator

$$W'_{\text{к}} = W'_{cm} - W_{\text{д}} = 63 - 12.6 = 50.4 \text{ т/ч}.$$

5. Content of dissolved oxygen in additional water at 40°C and pressure 760 mm Hg (on curve for oxygen, Fig. 33)

$$a_{\text{д}} = 6.5 \text{ mg/l}.$$

6. Content of dissolved oxygen in displace water, which enters deaerator,

$$a_{\text{кcm}} = \frac{a_{\text{к}} W_{\text{к}} + a_{\text{д}} W_{\text{д}}}{W_{cm}} = \frac{1.0 \cdot 50.4 + 6.5 \cdot 12.6}{63} = 2.1 \text{ mg/l}.$$

7. Content of dissolved gases of air in additional water at 40°C and pressure 760 mm Hg (on curve for air, Fig. 33)

$$a'_{\text{г}} = 17.2 \text{ mg/l}.$$

8. Content of dissolved gases of air in condensate

$$a_{\text{r}}^{\cdot} = \frac{a_{\text{r}}^{\cdot} \, a_{\text{к}}}{a_{\text{а}}} = \frac{17,2 \cdot 1,0}{6,5} = 2,65 \text{ мg/l.}$$

Page 89.

9. Content of dissolved gases of air in the mixture of water, which enters the deaerator,

$$a_{\text{гсм}} = \frac{a_{\text{r}}^{\cdot} W_{\text{к}} + a_{\text{r}}^{\cdot} W_{\text{а}}}{W_{\text{см}}} = \frac{2,65 \cdot 50,4 + 17,2 \cdot 12,6}{63} = 5,57 \text{ мg/l.}$$

10. Quantity of dissolved gases of air, introduced by water into deaerator,

$$G_{\text{r}} = (a_{\text{r}}^{\cdot} W_{\text{а}} + a_{\text{r}}^{\cdot} W_{\text{к}}) 10^{-3} = (17,2 \cdot 12,6 + 2,65 \cdot 50,4) 10^{-3} = 0,35 \text{ kg/h.}$$

11. Ratio of equilibrium oxygen pressure in vapor to partial according to indications to formula (105), k=3.

12. Constant of weight solubility of oxygen in water at its pressure above water $p_0 = 760$ мм Hg and boiling point of water, equal to about 100°C (on curve of Fig. 34)

$$a_0 = 24.5 \text{ mg/l.}$$

13. Partial oxygen pressure above surface of water in deaerator (retaining by its equal at pressure by $p_0 = 760$ mm Hg from condition of guaranteeing intensity of deaeration)

$$p_\text{к} = \frac{p_0 a_p}{k a_0} = \frac{1.033 \cdot 0.03}{3 \cdot 24.5} = 0.000422 \text{ atm}$$

14. Partial pressure of gass of air above surface of water in deaerator

$$p_\text{г} = \frac{p_\text{к} a_\text{гсм}}{a_\text{ксм}} = \frac{0.000422 \cdot 5.57}{2.1} = 0.00112 \text{ atm}$$

15. Partial pressure of steam in deaerator

$$p_\text{п} = p_\text{а} - p_\text{г} = 1.2 - 0.00112 \approx 1.199 \text{ atm}$$

16. Quantity of vapor (steam-gas mixture), driven out from deaerator,

$$G_\text{см} = G_\text{г} \left(1 + 0.622 \frac{p_\text{п}}{p_\text{г}}\right) = 0.35 \left(1 + 0.622 \frac{1.199}{0.00112}\right) = 234 \text{ kg/h.}$$

17. Total expenditure of steam for deaerator

$$G_\text{п} = (G + G_\text{см}) \frac{1}{\gamma_1} = (7.0 + 0.234) \frac{1}{0.97} \approx 7.5 \text{ m/h.}$$

18. Necessary volume of deaerated water in deaerating tank

$$V = \frac{Dv}{15 \div 20} = \frac{70 \cdot 1.047}{18.3} = 4 \text{ м}^3.$$

Page 90.

§ 14. Calculation of the preheater of water.

Initial data for the calculation.

Productivity of heater $D=55$ of m/h.

Temperature of water upon the entrance into preheater $t_1=40\,^{\circ}C$.

Temperature of water on leaving from preheater $t_2=110\,^{\circ}C$.

Pressure of feed water $p_s=36$ kg/cm^2.

Vapor pressure of heating $p_n=1.8$ atm

Temperature of that heating of steam $t_3=220\,^{\circ}C$.

We accept.

Coefficient of utilization of heat $\eta=0.98$.

Tubes brass V-shaped with a diameter of $d_w/d_s=16/13$ мм.

Number of courses in the tubes of preheater z=6.

We determine (on tables 1-3 of applications/appendices).

Enthalpy of that heating of steam i=695.2 kcal/kg.

Temperature of the saturation of heating of steam $t_s = 116,3°$ C.

Enthalpy of liquid when t_s, equal to q=116.6 kcal/kg.

Heat capacity of feed water when t'_{cp}, equal to c~~1 kcal/kg °C.

Course of computation.

1. Quantity of heat, necessary for preheating water,

$$Q = Dc\,(t_2 - t_1) = 55\,000\cdot 1\,(110 - 40) = 385\cdot 10^4 \text{ kcal/h.}$$

2. Expenditure of steam for preheating of water

$$G = \frac{Q}{(i - q)\,\eta} = \frac{385\cdot 10^4}{(695,2 - 116,6)\,0,98} = 6800 \text{ кg/h.}$$

3. Mean temperature of water in preheater
$$t'_{cp} = 0,5\,(t_1 + t_2) = 0,5\,(40 + 110) = 75°\,\text{C.}$$

4. On tables 6 cf applications/appendices when t'_{cp} we determine:

1) specific gravity/weight cf water $\gamma_{B} = 0.974$ $m/м^3$;

2) the dynamic viscosity of water $\mu_{B} = 38.66 \cdot 10^{-6}$ $kg \bullet s/m^2$;

3) the speed of water in the tubes we preliminarily accept $v_{B} = 1.7$ m/s.

5) Number of tubes in one course

$$n = \frac{D}{2825 d_{B}^2 v_{B} \gamma_{B}} = \frac{55}{2825 \cdot 0.013^2 \cdot 1.7 \cdot 0.974} \approx 70.$$

Page 90.

6. Reynolds number for water

$$Re = \frac{v_{B} d_{B} \gamma_{B}}{\mu_{B} g} = \frac{1.7 \cdot 0.013 \cdot 974}{38.66 \cdot 10^{-6} \cdot 9.81} = 56\,800.$$

7. Heat-transfer coefficient from wall to water, which takes place in tubes with turbulent action,

$$\alpha_{B} = A v_{B}^{0.8} d_{B}^{-0.2} = 2548 \cdot 1.53 \cdot 2.385 = 9350 \text{ kcal/m}^2 \text{-} h \quad °C,$$

where A=2048 (Table 10) depending on t'_{cp}; $v_{B}^{0.8} = 1.7^{0.8} = 1.53$ (Table 11); $d_{B}^{-0.2} = 0.013^{-2} = 2.385$ (Table 12).

8. Mean temperature of condensable steam and water

$$t_{cp}'' = 0,5\,(t_s + t_{cp}') = 0,5\,(116,3 + 75) = 95,7^\circ C. \cdot$$

9. Temperature riding-corps from the side of steam

$$t_{cт} = 0,5\,(t_s + t_{cp}'') = 0,5\,(116,3 + 95,7) = 106^\circ C.$$

10. Coefficient of heat transfer from steam to stand pipe

$$a_n = A_1 \sqrt[4]{\frac{i-q}{H(t_s - t_{cт})}} = 2210 \sqrt[4]{\frac{695,2 - 116,6}{1,8\,(116,3 - 106)}} =$$
$$= 5260\ ккал,\, м^2\text{-}час\,^\circ C,$$
(1)

Key: (1). kcal/m²-h.

where $A_1 = 2210$ (Table 13) depending on $t_{cт}$; $H = 1,8\ м$ - medium altitude of the V-shape of tube (assumed tentatively);

11. Average/mean logarithmic difference in the temperatures of vapor and water in the preheater

$$\Delta t = \frac{t_2 - t_1}{2,3\lg\frac{t_s - t_1}{t_s - t_2}} = \frac{110 - 40}{2,3\lg\frac{116,3 - 40}{116,3 - 110}} = 28,1^\circ C.$$

12. Coefficient of heat transfer from vapor to water

$$k = \frac{1}{\frac{1}{a_n}\cdot\frac{2d_н}{d_в + d_н} + \frac{d_н - d_в}{2\lambda} + \frac{1}{a_n}} =$$
$$\frac{1}{\frac{1}{9350}\cdot\frac{2\cdot0,016}{0,013 + 0,016} + \frac{0,016 - 0,013}{2\cdot90} + \frac{1}{5260}} = 3080\ ккал/м^2\text{-}час\,^\circ C,$$
(1)

Key: (1). the kcal/m²h.

where $\lambda = 90$ kcal/m- hour   °C - coefficient of the thermal
conductivity of brass wall of tube.

Page 92.

13. Coefficient of heat transfer from vapor to water in
depending on speed and mean temperature of water can be also
determined according to curve of Fig. 39. For brass tubes $d_{\text{в}} = 16$ мм we
have

$$k = 1{,}02 \cdot k_{\text{э}} = 1{,}02 \cdot 3640 = 3700 \text{ кcal/m}^2 - h \quad °C.$$

14. Necessary surface of heating preheater

$$F = \frac{Q}{\Delta t k} = \frac{385 \cdot 10^4}{28{,}1 \cdot 3700} = 37{,}1 \text{ м}^2.$$

15. Real surface is accepted

$$F_{\text{д}} = 38 \text{ м}^2.$$

16. Average/mean length of semi-V-shaped tube

$$l = \frac{F_{\text{д}}}{\pi \cdot d_{\text{в}} n z} = \frac{38}{3{,}14 \cdot 0{,}016 \cdot 70 \cdot 6} = 1{,}8 \text{ м}.$$

If $l \neq H = 1.8$ m, then in the presence of the small disagreement one
should change $F_{\text{д}}$, but if disagreement is considerable, then should be
the obtained value for l to substitute for approximate of that
accepted for H and produced repeated calculation, after beginning it
from determination z_{m}.

17. Space of the location of the tubes

$$t = d_\text{H} + 6 = 16 + 6 = 22 \text{ мм.}$$

18. Inner diameter of housing (from conditions for location of bundles of V-shaped tubes, divided in cover/cap by partitions/baffles, that ensure six courses of water) is accepted

$$D_\text{в} = 550 \text{ мм.}$$

§ 15. Calculation of steam cooler.

Initial data for the calculation.

The productivity of steam cooler D=4000 kg/h

temperature of steam upon the entrance into steam cooler $t_1 = 320°C$.

Temperature is of steam on leaving their steam cooler $t_2 = 220°C$.

Pressure of steam $p_1 = 8$ atm

Quantity of cooling feed water G=50000 kg/h.

Temperature of water upon the entrance into steam cooler $t_2 = 125°C$.

Pressure of cooling water $p_2 = 56$ atm

Page 93.

We accept.

Heat availability factor $\eta = 0,97.$

Tubes steel V-shaped with a diameter of $d_н/d_в = 17/13$ мм.

Number of courses cf steam in tubes $z_1 = 2.$

Number of courses cf water in the housing cf steam cocler $z_2 = 2.$

We determine (on Tables 1-3 of applications/appendices).

Enthalpy of steam   upcn the entrance $i_1 = 740$ kcal/kg.

Enthalpy of steam on leaving $i_2 = 688.7$ kcal/kg.

Course of computation.

1. Quantity of heat, transferred by water vapor,

$$Q = D(i_1 - i_2) = 4000(740 - 688.7) = 205\,000 \text{ kcal/h.}$$

2. Mean temperature of overheated steam

$$t_n = 0.5(t_1 + t_2) = 0.5(320 + 220) = 270° \text{ C.}$$

3. On Tables 3 and Fig. 1-3 of applications/appendices when t_n we determine:

1) specific heat of steam $c_p = 0.51$ kcal/kg   °C;

2) specific gravity/weight of steam $\gamma_n = 3.22$ kg/m³;

3). the coefficient of thermal conductivity $\lambda_n = 0.037$ kcal/m-hour °C;

4) dynamic viscosity is steam $\mu_n = 1.93 \cdot 10^{-6}$ kg·s/m².

4. Number of tubes in course (after accepting tentatively speed of steam in them about 50 m/s) we accept n=53.

5. Average speed of steam in tubes of steam cooler

$$v_n = \frac{D}{2825 d_g^2 n \gamma_n} = \frac{4000}{2825 \cdot 0.013^2 \cdot 53 \cdot 3.22} = 49 \text{ m/s.}$$

6. Criterion of Reynolds for steam.

$$Re = \frac{v_n d_n \gamma_n}{\mu_n g} = \frac{49 \cdot 0,013 \cdot 3,72}{1,93 \cdot 10^{-6} \cdot 9,81} = 108\,500.$$

7. Prandtl number for steam

$$Pr = \frac{3600 \cdot \mu_n g c_p}{\lambda_n} = \frac{3600 \cdot 1,93 \cdot 10^{-6} \cdot 9,81 \cdot 0,51}{0,037} = 0,942.$$

8. Heat-transfer coefficient from superheated steam to wall with Re>1•10⁴ and Pr=0.7-2500:

$$\alpha_n = 0,023 \frac{\lambda_n}{d_n} Re^{0,8} Pr^{0,4} = 0,023 \frac{0,037}{0,013} 108\,500^{0,8} \cdot 0,942^{0,4} =$$

$$= 685 \text{ cal/m}^2\text{h} \quad °C.$$

Page 94.

9. Temperature of cooling water on leaving

$$t_4 = t_3 + \frac{Q}{Gc_n} = 125 + \frac{205000}{50000 \cdot 1,017} \approx 129° C,$$

where $c_n = 1,017$ kcal/kg °C - heat capacity of water with t=127°C (Table 6 of applications/appendices).

10. Mean temperature of cooling water

$$t_n = 0,5(t_3 + t_4) = 0,5(125 + 129) = 127° C.$$

11. On Table 6 of applications/appendices when t_n we determine:

1) coefficient of thermal conductivity of water $\lambda_n = 0,59$

kcal/m-hour   °C;

2) specific gravity/weight of water $\gamma_{_s} = 937,3$ kg/m³;

3) dynamic viscosity of water $\mu_{_s} = 22,2 \cdot 10^{-6}$ kg·s/m².

12. Inner diameter of housing of steam cooler (from conditions for location of beam of V-shaped tubes of that divided in cover/cap with partition/baffle, which ensures two courses of steam in tubes) we accept

$$D_{_\text{к}} = 0,28 \text{ м.}$$

13. Area for passage of water in intertube space of steam cooler

$$f = \frac{0,785\,(D_{_\text{к}}^{2} - d_{_\text{н}}^{2}\,nz_{1})}{z_{2}} = \frac{0,785\,(0,28^{2} - 0,017^{2} \cdot 53 \cdot 2)}{2} = 0,01875 \text{ м}^{2}.$$

14. They are equivalent heat-transmitting diameter of intertube space

$$d_{_\text{э}} = \frac{4f}{\pi d_{_\text{н}}n} = \frac{4 \cdot 0,01875}{3,14 \cdot 0,017 \cdot 53} = 0,0265 \text{ м.}$$

15. Average speed tauds in steam cooler

$$v_{_\text{в}} = \frac{G}{3600 \cdot f \cdot \gamma_{_\text{в}}} = \frac{50000}{3600 \cdot 0,01875 \cdot 937,3} = 0,79 \text{ м/s.}$$

16. Reynolds number for water

$$Re_{_\text{в}} = \frac{v_{_\text{в}} d_{_\text{э}} \gamma_{_\text{в}}}{\mu_{_\text{в}} g} = \frac{0,79 \cdot 0,0265 \cdot 937,3}{22,2 \cdot 10^{-6} \cdot 9,81} = 90\,000.$$

17. Prandtl number for water

$$Pr_\bullet = \frac{3600\mu_\bullet g r_\bullet}{\lambda_\bullet} = \frac{3600 \cdot 22,2 \cdot 10^{-6} \cdot 9,81 \cdot 1,017}{0,59} = 1,35.$$

Page 95.

18. Heat-transfer coefficient from wall to water with longitudinal washing of ducts for $Re>1 \cdot 10^4$ and Pr=0.7-2500:

$$\alpha_\bullet = 0,023 \frac{\lambda_\bullet}{d_\bullet} Re^{0,8} Pr^{0,4} = 0,023 \frac{0,59}{0,0265} \, 90\,000^{0,8} \cdot 1,35^{0,4} =$$

5350 kcal/m²h   °C.

19. Heat-transfer coefficient from steam to water

$$k = \frac{1}{\frac{1}{\alpha_n} \cdot \frac{2d_n}{d_n + d_\bullet} + \frac{d_n - d_\bullet}{2\lambda} + \frac{1}{\alpha_\bullet}} = \frac{1}{\frac{1}{685} \cdot \frac{2 \cdot 0,017}{0,017 + 0,013} + \frac{0,017 - 0,013}{2 \cdot 50} + \frac{1}{5350}} =$$

530 kcal/m²h cf °C,

where λ=50 kcal/m- hour   °C - thermal conductivity of wall of steel tube.

20. Average/mean logarithmic difference in temperatures for countercurrent

$$\Delta t = \frac{(t_1 - t_4) - (t_2 - t_3)}{2,3 \lg \frac{t_1 - t_4}{t_2 - t_3}} = \frac{(320 - 129) - (220 - 125)}{2,3 \lg \frac{320 - 129}{220 - 125}} = 137,7 \text{ C.}$$

21. Necessary surface of heating steam cooler

$$F = \frac{Q}{\Delta t k} = \frac{205\,000}{137,7 \cdot 530} = 2,8 \text{ м}^2.$$

22. Real surface taking into account pollution/contamination

$$F_1 = 1,07 F = 1,07 \cdot 2,8 = 3,0 \; \text{м}^2.$$

23. Average/mean length or semi-V-shaped tubes

$$l = \frac{F_1}{\pi d_w n z_2} = \frac{3,0}{3,14 \cdot 0,017 \cdot 53 \cdot 2} = 0,53 \; \text{м}.$$

§ 16. Calculation of the coolant of water.

Initial data for the calculation.

Quantity of the water-cooled $w_1 = 24$ m/h.

Pressure of the water-cooled $P_1 = 2$ kg/cm².

Temperature of the water-cooled upon the entrance into coolant $t_1 = 85°C$.

Temperature of cooled water or leaving from from cooler $t_2 = 75°C$.

Quantity of the cooling (marine) water $W_2 = 18$ m/h.

Pressure of the cooling (marine) water $p_2 = 3$ kg/cm².

Temperature of the cooling (marine) water upon the entrance into coolant $t_3 = 22°C$.

Page 96.

We accept.

Tubes German silver with a diameter of $d_w/d_e = 10/8$ мм.

Number of courses cf cooling water in tubes z=1.

Course of computation.

1. Mean temperature of water-cooled in coolant
$$t'_{cp} = 0.5(t_1 + t_2) = 0.5(85 + 75) = 80^{\circ}\text{C}.$$

2. On Table 6 of applications/appendices when t'_{cp} we determine:

1) heat capacity cf water $c'_p = 1.007$ kcal/kg °C;

2) specific gravity/weight cf water $\gamma_1 = 971.8$ kg/m³;

3) kinematic viscosity of water $\nu_1 = 0.366 \cdot 10^{-6}$ m²/s;

4) coefficient of thermal diffusivity cf water $\alpha_1 = 5.9 \cdot 10^{-4}$ m²/h °C;

5) coefficient of thermal conductivity of water $\lambda_1 = 0.58$ kcal/m-hour °C.

3. Quantity of heat, given up to cooling water,

$$Q = W_1 c_p' (t_1 - t_2) = 24\,000 \cdot 1{,}007\,(85 - 75) = 242\,000 \text{ kcal/h.}$$

4. Temperature of cooling water on leaving

$$t_4 = t_3 + \frac{Q}{W_2 c_p''} = 22 + \frac{242000}{18000 \cdot 0{,}94} = 36{,}4° C,$$

where $c_p'' = 0{,}94$ kcal/kg °C - heat capacity of cooling (marine) water.

5. Mean temperature of cooling water

$$t_{cp}'' = 0{,}5\,(t_3 + t_4) = 0{,}5\,(22 + 36{,}4) = 29{,}2° C.$$

6. Average/mean logarithmic difference in temperatures for countercurrent

$$\Delta t = \frac{(t_1 - t_4) - (t_2 - t_3)}{2{,}3 \lg \frac{t_1 - t_4}{t_2 - t_3}} = \frac{(85 - 36{,}4) - (75 - 22)}{2{,}3 \lg \frac{85 - 36{,}4}{75 - 22}} = 51{,}8° \text{ C.}$$

7. Speed of cooling water in tubes we accept $v_2 = 0{,}8$ m/s.

8. Number of cooling tubes

$$n = \frac{W_3}{2825 d_B^2 v_2 \gamma_2} = \frac{18}{2825 \cdot 0{,}008^2 \cdot 0{,}8 \cdot 1{,}025} = 121,$$

where $\gamma_2 = 1{,}025$ t/m³ - specific gravity/weight of cooling water.

Page 97.

9. Reynolds number for cooling water

$$Re = \frac{v \cdot d_s}{v_2} = \frac{0.8 \cdot 0.008}{0.8 \cdot 10^{-6}} = 8000,$$

where $v_2 = 0.8 \cdot 10^{-6}$ m²/s - kinematic viscosity of cooling water when $t_{cp}' = 29.2°C$ (it is determined according to Table 6 of applications/appendices).

With $2200 < Re = 8000 < 10000$ the action is unstable.

10. Prandtl number for cooling water will comprise [1]

$$Pr = \frac{3600 \, v_2}{a_2} = \frac{3600 \cdot 0.8 \cdot 10^{-6}}{5.3 \cdot 10^{-4}} = 5.4,$$

where $a_2 = 5.3 \cdot 10^{-4}$ m²/h - coefficient of thermal diffusivity of water when t_{cp}' (it is determined according to Table 6 of applications/appendices).

FOOTNOTE [1]. For a more precise calculation the value of criteria Gr and Pr, entering product $GrPr^3$, it is necessary to determine them at temperature of boundary layer. ENDFOOTNOTE.

11. Grashof's criterion for cooling water will comprise [2]

$$Gr = \frac{g d_s^3 \beta \Delta t}{v_2^2} = \frac{9.81 \cdot 0.008^3 \cdot 3 \cdot 10^{-4} \cdot 14.4}{(0.8 \cdot 10^{-6})^2} = 3.4 \cdot 10^4,$$

where g=9.81 m/s^2 - acceleration of gravity; β=3•10^{-4} 1/^{o}C - coefficient of expansion of water when t''_{cp} (it is determined according to Table 6 of appendices); $\delta t = t_4 - t_3 = 36.4 - 22 = 14.4^{o}$C - difference in temperatures of cooling water.

FOOTNOTE 2. Then. ENDFOOTNOTE.

Product of the criteria
$$GrPr^3 = 3.4 \cdot 10^4 \cdot 5.4^3 = 5.32 \cdot 10^6.$$

12. On graph/curve Fig. 44 in depending on GrPr^3 and Pr with Re=8000 for transient mode/conditions we determine Nu=56.

13. Heat-transfer coefficient from wall to cooling water

$$a_2 = \frac{Nu\,\lambda_2}{d_s} = \frac{56 \cdot 0.53}{0.008} = 3710 \text{kcal/m}^2\text{h} \qquad ^{o}C,$$

where λ_2=0.53 - coefficient of thermal conductivity of cooling water when $t''_{cp} = 29.2^{o}$C.

14. Space of location of cooling tubes
$$t = 1.35 d_s = 1.35 \cdot 10 = 13.5 \text{ мм}.$$

Page 98.

15. Inner diameter of housing of coolant from conditions for

location of beam of tubes is taken $D_{\kappa}=0.17$ м.

16. Speed of water-cooled in intertube space with longitudinal washing of beam of tubes

$$v_1 = \frac{W_1}{2825\,(D_{\kappa}^2 - d_{\text{м}}^2 n)\,T_1} = \frac{24}{2825\,(0.17^2 - 0.01^2 \cdot 121)\,0.9718} = 0.52 \text{ м/s.}$$

17. Equivalent heat-transmitting diameter of intertube space

$$d_{\text{s}} = \frac{D_{\kappa}^2 - d_{\text{м}}^2 n}{d_{\text{м}} n} = \frac{0.17^2 - 0.01^2 \cdot 121}{0.01 \cdot 121} = 0.014 \text{ м.}$$

18. Reynolds number for water-cooled

$$\text{Re}_1 = \frac{v_1 d_2}{v_1} = \frac{0.52 \cdot 0.014}{0.366 \cdot 10^{-6}} = 19\,900.$$

19. Prandtl number for water-cooled

$$\text{Pr}_1 = \frac{3600\,\gamma_1}{a_1} = \frac{3600 \cdot 0.366 \cdot 10^{-6}}{5.9 \cdot 10^{-4}} = 2.23.$$

20. Heat-transfer coefficient from water-cooled to wall with turbulent flow for longitudinal washing of beam of ducts

$$a_1 = 0.023\,\frac{\lambda_1}{d_{\text{s}}}\,\text{Re}^{0.8}\text{Pr}^{0.4} = 0.023\,\frac{0.58}{0.014}\,19\,900^{0.8} \cdot 2.23^{0.4} =$$

3600 kcal/м²h   °C.

21. Coefficient of heat transfer from water-cooled to that cooling

$$k_0 = \cfrac{1}{\cfrac{1}{a_1} + \cfrac{d_\text{н} - d_\text{в}}{2\lambda} + \cfrac{1}{a_2} \cdot \cfrac{2d_\text{н}}{d_\text{н} + d_\text{в}}} =$$

$$= \cfrac{1}{\cfrac{1}{3600} + \cfrac{0,01 - 0,008}{2 \cdot 25} + \cfrac{1}{3710} \cdot \cfrac{2 \cdot 0,001}{0,01 + 0,008}} = 1620 \ \textit{ккал/м}^2\textit{-час °C},$$

(1)

Key: (1).   kcal/m² - h.

where λ=25 kcal/m- hour   °C - coefficient of the thermal conductivity of German silver tube.

22. Coefficient, which considers pollution/contamination of tubes, is accepted ϕ=0.8.

23. Calculated coefficient of heat transfer from one water to the next

$$k = \phi k_0 = 0,8 \cdot 1620 = 1300 \quad \text{kcal/m}^2 - h \quad \text{°C}.$$

Page 99.

24. Necessary cooling surface of coolant

$$F = \frac{Q}{\Delta t k} = \frac{242\,000}{51,8 \cdot 1300} = 3,6 \ \textit{м}^2.$$

25. Effective length of tubes (or distance between tube plates)

$$l = \frac{F}{\pi \cdot d_\text{в} n} = \frac{3,6}{3,14 \cdot 0,01 \cdot 121} \approx 0,95 \ \textit{м}.$$

We accept $l = 1.0$ m.

§ 17. Calculation of fuel heater.

Initial data for the calculation.

Productivity of preheater $D = 5$ m/h.

Temperature of petroleum residue upon the entrance in preheater $t_1 = 15°C$.

Temperature of petroleum residue on leaving from preheater $t_2 = 95°C$.

Brand of the petroleum residue: the sailor M20.

Pressure of that heating of steam $P = 29$ atm

We accept.

Heat availability factor $\eta = 0{,}98$.

Tubes of steel V-shaped with a diameter of $d_н/d_в = 17/13$ мм.

Thickness of flat/plane retarders , established/installed in the straight/direct part of the tubes, $\delta = 1.0$ mm.

Number of courses of petroleum residue in the tubes of preheater $z = 6$.

We determine (on Tables 1-3 of applications/appendices).

Temperature of heating steam $t_n = 230.9°$C.

Enthalpy of heating steam $i_n = 669.5$ kcal/kg.

Enthalpy of the condensate of that heating of steam $q = 237.5$ kcal/kg.

Course of computation.

1. Mean temperature of petroleum residue in preheater
$$t_{cp} = 0.5\,(t_1 + t_2) = 0.5\,(15 + 95) = 55°\text{C}.$$

2. efficient weight of petroleum residue M20 with t_1 on graph/curve Fig. 13
$$\gamma_{15} = 0.947 \ m/u^3.$$

3. Average/mean heat capacity of petroleum residue with t_{cp}

$$c_p = (0,403 + 0,00081 t_{cp}) \frac{1}{\sqrt{\gamma_{15}}} = (0,403 + 0,00081 \cdot 55) \frac{1}{\sqrt{0,947}} =$$

$$0,461 \text{kcal/kg} \quad {}^{\circ}\text{C}.$$

Page 100.

4. Quantity of heat, necessary for preheating petroleum residue,

$$Q = Dc_p(t_2 - t_1) = 5000 \cdot 0,461 (95 - 15) = 1,85 \cdot 10^5 \text{kcal/kg}.$$

5. Expenditure of heating of steam for preheater

$$G = \frac{Q}{(i_n - q)\eta} = \frac{1,85 \cdot 10^5}{(669,5 - 237,5) \, 0,98} = 437 \text{kg/h}.$$

6. Average/mean logarithmic difference in temperatures

$$\Delta t_{cp} = \frac{t_2 - t_1}{2,3 \lg \frac{t_n - t_1}{t_n - t_2}} = \frac{95 - 15}{2,3 \lg \frac{230,9 - 15}{230,9 - 95}} = 174^{\circ}\text{C}.$$

7. Number of tubes in one course (on preliminarily taken speed of petroleum residue 0.8 m/s) n=15.

8. Area for passage of petroleum residue in tubes with presence of retarders

$$f = (0,785 d_e^2 - \delta d_e) n =$$
$$= (0,785 \cdot 0,013^2 - 0,001 \cdot 0,013) \, 15 = 0,0018 \, \text{m}^2.$$

9. Specific weight of petroleum residue when t_{cp} we determine on graph/curve Fig. 13 or according to formula

$$\gamma_{cp} = \gamma_{20} - 0,000567\,(t_{cp} - 20) =$$
$$= 0,941 - 0,000567\,(55 - 20) = 0,922 \; m/м^3,$$

where $\gamma_{20} = 0,941 \; m/м^3$ - specific gravity/weight of petroleum residue with t=20°C.

10. Speed of petroleum residue, which takes place in tubes,

$$v = \frac{D}{3600/\gamma_{cp}} = \frac{5}{3600 \cdot 0,0018 \cdot 0,922} = 0,83 \; м/s.$$

11. Coefficient of heat transfer from vapor to admiralty fuel oil M12 in depending on his speed and mean temperature, in reference to external surface of tubes, we determine on graph/curve Fig. 41

$$k_0 = 175 \; kcal/м^2 - h \quad °C.$$

12. Correction factor, which calculates brand of petroleum residue M20 on the basis of data to formula (129), $\varepsilon_1 = 0,93$.

13. Correction factor, which calculates use/application of retarders on the basis of graph/curve Fig. 42 $\varepsilon_2 = 1,42$.

14. Calculated coefficient of heat transfer from vapor to

petroleum residue M20

$$k = c_1 c_2 k_0 = 0.93 \cdot 1.42 \cdot 1.75 = 232 \ \text{кcal/m}^2 - h \quad °C.$$

Page 101.

15. Necessary surface of heating preheater, referred to outside diameter of tubes

$$F = \frac{Q}{\Delta t k} = \frac{1.85 \cdot 10^6}{174 \cdot 232} = 4.57 \ m^2.$$

16. Actual heating surface taking into account possible pollution/contamination

$$F_\phi = 1.1 \cdot F = 1.1 \cdot 4.57 \approx 5.0 \ m^2.$$

17. Average/mean length of semi-V-shaped tube

$$l \approx \frac{F_\phi}{\pi \cdot d_\text{n} n z} = \frac{5}{3.14 \cdot 0.017 \cdot 15 \cdot 6} = 1.03 \ m.$$

18. Space of location of pipes.

$$t = d_\text{n} + 6 = 17 + 6 = 23 \ мм.$$

19. Inner diameter of housing (from conditions for location of beams of V-shaped tubes, divided in cover/cap by partitions/baffles, ensuring 6 courses of petroleum residue) is accepted $D_\text{в} = 283 \ мм.$

§ 18. Calculation of the preheater of oil.

Initial data for the calculation.

Productivity of preheater D=2000 kg/h.

Temperature of oil upon the entrance into preheater $t_1 = 15°C$.

Temperature of oil on leaving from preheater $t_2 = 70°C$.

Brand of oil: turbine UT.

Vapor pressure of heating $p_n = 29$ atm

We accept.

Heat availability factor $\eta = 0.98$.

tube copper V-shaped with a diameter of $d_н/d_в = 10/8$ мм.

Number of courses of oil in the tubes of preheater z=4.

Let us determine (on Tables 1-3 of applications/appendices).

Temperature of heating of steam $t_n = 230.9°C$.

Enthalpy of that heating of steam i=669.5 kcal/kg.

Enthalpy of the condensate of heating of steam when p_s, equal to $q=237.5$ kcal/kg.

Course of computation.

1. Mean temperature of oil in heater.
$$t_{cp} = 0,5\,(t_1 + t_2) = 0,5\,(15 + 70) = 42,5°\,\text{C}.$$

Page 102.

2. Specific gravity/weight of oil OT with t_1 on graph/curve Fig. 13

$$\gamma_{15} = 0,902 \ m/\text{м}^3.$$

3. Average/mean heat capacity of oil with

$$c_p = (0,403 + 0,00081\,t_{cp})\,\frac{1}{\sqrt{\gamma_{15}}} = (0,403 + 0,00081 \cdot 42,5)\,\frac{1}{\sqrt{0,902}} =$$

0,428 kcal/kg   °C.

4. Quantity of heat, necessary for heating of oil,

$$Q = Dc_p\,(t_2 - t_1) = 2000 \cdot 0,428\,(70 - 15) = 47\,200 \ \text{kg/h}.$$

5. Expenditure of heating of steam for preheater

$$G = \frac{Q}{(i - q)\,\eta} = \frac{47200}{(669,5 - 237,5)\,0,98} = 112 \ \text{kg/h}.$$

6. Average/mean logaritnmic difference in temperatures

$$\Delta t = \frac{t_2 - t_1}{2.3 \lg \frac{t_n - t_1}{t_n - t_2}} = \frac{70 - 15}{2.3 \lg \frac{230.9 - 15}{230.9 - 70}} = 187° C.$$

7. Number of tubes in one course (on preliminarily taken speed of oil 1.5 m s) we accept n=8.

8. Area for passage of oil in tubes

$$f = 0.785 d_e^2 n = 0.785 \cdot 0.008^2 \cdot 8 = 0.000402 \ м^2.$$

9. Specific gravity/weight of oil when t_{cp} is determined on graph/curve Fig. 13

$$\gamma_{cp} = 0.836 \ m/м^3.$$

10. Speed of oil, which takes place in tubes,

$$v = \frac{D}{3600 f \gamma_{cp}} = \frac{2}{3600 \cdot 0.000402 \cdot 0.836} = 1.5 \ м/s.$$

11. Coefficient of heat transfer from vapor to oil in depending on its speed and mean temperature, in reference to external surface of tubes, is determined on graph/curve Fig. 43

$$k = 263 \ kcal/м^2 - h \ °C.$$

12. Necessary surface of heating preheater, in reference to

cutside diameter of tubes,

$$F = \frac{Q}{\Delta t k} = \frac{47200}{187 \cdot 263} = 0,96 \ \text{м}^2.$$

Page 103.

13. Actual surface of heating preheater taking into account possible pollution/contamination

$$F_\phi = 1,04 \cdot F = 1,04 \cdot 0,96 = 1,0 \ \text{м}^2.$$

14. Average/mean length of semi-V-shaped tube

$$l = \frac{F_\phi}{\pi \cdot d_н n z} = \frac{1,0}{3,14 \cdot 0,01 \cdot 8 \cdot 4} \approx 1,0 \ \text{м}.$$

15. Space of location of tubes

$$t = 1,3 d_н = 1,3 \cdot 10 = 13 \ \text{мм}.$$

16. Inner diameter of housing (from conditions for location of beams of V-shaped tubes, divided in cover/cap by partitions/baffles, ensuring four courses of oil) we accept $D_к = 100 \ \text{мм}.$

§ 19. Calculation of oil cooler.

Initial data for the calculation.

Productivity of oil cooler D = 16 m/h.

Temperature of oil upon the entrance into oil cooler $t_1 = 55^\circ$C.

Temperature of oil on leaving from oil cooler $t_2 = 37^\circ$C.

Brand of oil: Turbine T.

Oil pressure in the oil cooler $p_1 = 3$ kg/cm^2.

Quantity of that cooling water (marine) $G = 50$ m/h.

Temperature of cooling water upon entrance $t_3 = 15^\circ$C.

Pressure of cooling water $p_2 = 2$ kg/cm^2.

We accept.

Tubes German silver of straight lines with a diameter of $d_n d_s = 10/8$ мм.

Number of courses of cooling water in tubes $z = 2$.

Intertube space is divided by segmental partitions/baffles.

Heat capacity of cooling (marine) water $c_s = 0.94$ kcal/kg $^\circ$C.

The specific gravity/weight of cooling (marine) water

$\gamma_e = 1,025 \, m/\mu^3$.

Course of computation.

1. Mean temperature of oil in oil cooler

$$t'_{cp} = 0,5(t_1 + t_2) = 0,5(55 + 37) = 46° \, C.$$

2. Specific gravity/weight of oil when t'_{cp} on graph/curve Fig. 13 $\gamma_m = 879$ kg/m³.

Page 104.

3. Average/mean heat capacity of oil with t'_{cp}

$$c_p = (0,403 + 0,00081 \, t'_{cp}) \frac{1}{\sqrt{\gamma_{15}}} = (0,403 + 0,00081 \cdot 46) \frac{1}{\sqrt{0,9}} =$$

0,462 kcal/kg   °C,

where γ_{15}=0.9 t/m³ - specific gravity/weight of oil with t=15°C on graph/curve Fig. 13.

4. Quantity of heat, given up by oil to water,

$$Q = Dc_p(t_1 - t_2) = 16\,000 \cdot 0{,}462(55-37) = 132\,000 \text{ kcal/h.}$$

5. Temperature of cooling water on leaving from oil cooler

$$t_4 = t_3 + \frac{Q}{Gc_m} = 15 + \frac{132000}{50000 \cdot 0{,}94} = 17{,}8^\circ \text{C.}$$

6. Mean temperature of cooling water

$$t'_{cp} = 0{,}5(t_3 + t_4) = 0{,}5(15 + 17{,}8) = 16{,}4^\circ \text{C.}$$

7. Average/mean logarithmic difference in temperatures between oil and water according to formula (36) for crosscurrent   .

$$\Delta t = \frac{(t_1 - t_4) - (t_2 - t'_{cp})}{2{,}3 \lg \dfrac{t_1 - t_4}{t_2 - t'_{cp}}} = \frac{(55-17{,}8) - (37-16{,}4)}{2{,}3 \lg \dfrac{55-17{,}8}{37-16{,}4}} = 28^\circ \text{C.}$$

8. Speed of cooling water in tubes we preliminarily accept $v'_s = 0{,}7$ m/s.

9. Number of cooling tubes in oil cooler in preliminary determination.

$$n' = \frac{Gz}{2325\,d_s^2 v'_s \gamma_s} = \frac{50 \cdot 2}{2825 \cdot 0{,}008^2 \cdot 0{,}7 \cdot 1{,}025} = 771.$$

10. Space of location of tubes on triangle

$$t = 1{,}35 d_s = 1{,}35 \cdot 10 = 13{,}5 \text{ мм.}$$

11. Inner diameter of housing (from conditions for location of beam of tubes, divided in cover/cap by partition/baffle, which ensures two courses of water in tubes) we accept $D_k = 435$ мм.

12. Number of cooling tubes, placed in oil cooler, n=778.

Page 105.

13. Speed of cooling water in tubes

$$v_{\text{в}} = \frac{G_{\text{в}}}{2825 \cdot d_{\text{в}}^2 \pi \gamma_{\text{в}}} = \frac{50 \cdot 2}{2825 \cdot 0,008^2 \cdot 778 \cdot 1,025} = 0,693 \ \text{м/s}.$$

14. Kinematic viscosity of water with $t'_{ср}$ on Table 6 of appendices

$$v_{\text{в}} = 1,11 \cdot 10^{-6} \ \text{м}^2/s.$$

15. Criterion of Reynolds for water

$$\text{Re} = \frac{v_{\text{в}} d_{\text{в}}}{v_{\text{в}}} = \frac{0,693 \cdot 0,008}{1,11 \cdot 10^{-6}} = 5000.$$

With 2200<Re=5000<10000 the action is unstable.

16. Prandtl number for water will comprise [1]

$$\text{Pr} = \frac{3600 \cdot v_{\text{в}}}{a_{\text{в}}} = \frac{3600 \cdot 1,11 \cdot 10^{-6}}{5,03 \cdot 10^{-4}} = 7,93,$$

where $a_{\text{в}} = 5,03 \cdot 10^{-4}$ м²/h — coefficient of thermal diffusivity of water with $t'_{ср} = 16,4°C$, determined in Table 6 of applications/appendices.

FOOTNOTE [1]. See footnote to § 16. ENDFOOTNOTE.

17.
Grashof's criterion for the water [2]

$$Gr = \frac{g d_{\text{в}}^3 \beta \delta t}{\nu_{\text{в}}^2} = \frac{9,81 \cdot 0,008^3 \cdot 1,14 \cdot 10^{-4} \cdot 2,8}{(1,11 \cdot 10^{-6})^2} = 1330,$$

where $\beta = 1.14 \cdot 10^{-4}$ 1/°C - coefficient of the expansion of water in Table 6 of applications/appendices when $t_{\text{cp}}'' = 16,4°C$; $g = 9.81$ m/s² - acceleration of gravity $\delta t = \tau_{\text{в}} - \tau_3 = 17.8 - 15 = 2.8°C$ - difference in the temperatures of water.

FOOTNOTE [2]. Then. ENDFOOTNOTE.

18. Product of criteria

$$GrPr^3 = 1330 \cdot 7,93^3 = 6,65 \cdot 10^5.$$

19. On graph/curve Fig. 44 in depending on GrPr³ and Pr with Re=5000 for transient mode/conditions we determine Nu=38.5.

20. Heat-transfer coefficient from wall to water

$$a_{\text{в}} = \frac{Nu \lambda_{\text{в}}}{d_{\text{в}}} = \frac{38,5 \cdot 0,507}{0,008} = 2440 \text{ kcal/m}^2 \cdot h \quad °C,$$

where $\lambda_{\text{в}} = 0,507$ kcal/m- hour   °C - thermal conductivity of water when on tables 6 of applications/appendices.

Page 106.

21. From conditions of laying out of tubes and location of partitions/baffles in housing of oil cooler we accept:

$n_1 = 12$ - number of gaps/intervals (sections) between partitions/baffles;

$h = 0.094$ m - distance between partitions/baffles;

$m = 18$ - number of series/rows of tubes, arranged/located between shear/sections of partitions/baffles;

$m_3 = 492$ - number of clearances between tubes in series/rows, streamlined with cross flow;

$y_0 = 0.0153$ m - average distance between housing and wing tubes;

$\phi = 116°$ - central angle of segment, formed by groove in partition/baffle;

$h_1 = 126$ - number of tubes, arranged/located in segmental groove of partition/baffle.

22. Clearance between tubes

$$y = t - d_{\text{H}} = 13,5 - 10 = 3,5 \; \text{мм} = 0,0035 \; \text{м}.$$

23. Average/mean area of section for passage of oil between partitions/baffles

$$f_1 = \left(2y_0 + \frac{3m_0}{2m} y\right) h = \left(2 \cdot 0,0153 + \frac{3 \cdot 492}{2 \cdot 18} 0,0035\right) 0,094 =$$
$$= 0,0164 \; \text{м}^2,$$

24. Sectional area for passage of oil above partitions/baffles

$$f_2 = \frac{D_{\text{H}}^2}{8} \left(\frac{\varphi \pi}{180} - \sin \varphi\right) - \frac{\pi d_{\text{H}}^2}{4} n_2 =$$
$$= \frac{0,435^2}{8} \left(\frac{116 \cdot 3,14}{180} - \sin 116\right) - \frac{3,14 \cdot 0,01^2}{4} 126 = 0,0164 \; \text{м}^2.$$

25. Average speed of oil between partitions/baffles and above them, since $f_1 = f_2$,

$$v_{\text{H}} = \frac{Q}{3600 \cdot f_1 \gamma_{\text{H}}} = \frac{16}{3600 \cdot 0,0164 \cdot 0,879} = 0,307 \; \text{м/сек}. \quad (1)$$

Key: (1). m/s.

26. Average speed of oil in oil cooler with transverse segmental partitions/baffles

$$v_{\text{cp}} = \frac{Lv_{\text{H}} + (N-1) Av_{\text{H}}}{L + (N-1) A} = \frac{1,04 \cdot 0,307 + (11-1) 2,32 \cdot 0,307}{1,04 + (11-1) 2,32} = 0,308 \; \text{м/сек}. \quad (1)$$

Key: (1). a/s.

Page 107.

Here L=1.04 m - distance between the inlets and oil outlet;

N=11 - number of partitions/baffles;

f - area of the segment above the partition/baffle:

$$f = f_3 + \frac{\pi d_n^2}{4} n_2 = 0.0164 + \frac{3.14 \cdot 0.01^2}{4} 126 = 0.0265 \text{ м}^2;$$

$$A = \frac{S}{6f} = \frac{0.369}{6 \cdot 0.0265} = 2.32 \text{ м},$$

where S - a chord length;

$$S = D_n \sin \frac{\varphi}{2} = 0.435 \cdot \sin \frac{116}{2} = 0.369 \text{ м}.$$

27. Heat-transfer coefficient from oil to wall of tube

$$\alpha_n = 550 \sqrt{\frac{v_{cp}}{t - d_n}} (1 + 0.006 t'_{cp}) =$$

$$= 550 \sqrt{\frac{0.03}{13.5 - 10}} (1 + 0.006 \cdot 46) = 208 \text{ ккал}/\text{м}^2 \cdot \text{час} °C.$$

Key: (1). the kcal/m²h   °C.

28. Coefficient of thermal conductivity of German silver tubes (on tables 38) λ=25 kcal/m- hour   °C.

29. Coefficient of heat transfer from oil to cooling water

$$k = \cfrac{1}{\dfrac{1}{a_{\text{м}}} + \dfrac{d_{\text{н}} - d_{\text{в}}}{2\lambda} + \dfrac{1}{a_{\text{в}}} \cdot \dfrac{2d_{\text{н}}}{d_{\text{н}} + d_{\text{в}}}} =$$

$$= \cfrac{1}{\dfrac{1}{208} + \dfrac{0.01 - 0.008}{2 \cdot 25} + \dfrac{1}{2440} \cdot \dfrac{2 \cdot 0.01}{0.01 + 0.008}} = 188 \ \textit{ккал}/\textit{м}^2 \cdot \textit{час} \ °C. \qquad (1)$$

Key: (1). the kcal/m²h   °C.

30. Necessary cooling surface of oil cooler

$$F = \frac{Q}{\Delta t k} = \frac{132000}{28 \cdot 188} = 25.1 \ \textit{м}^2.$$

31. Distance between tube plates or effective length of tubes

$$l = n_1 h + N\delta = 12 \cdot 0.094 + 11 \cdot 0.003 = 1.163 \ \textit{м},$$

where with $\delta = 0.003$ m - thickness of partitions/baffles.

32. Complete cooling surface of oil cooler

$$F_1 = \pi d_{\text{н}} l n = 3.14 \cdot 0.01 \cdot 1.163 \cdot 778 = 28.6 \ \textit{м}^2.$$

Page 108.

§20. Calculation of air preheater.

Initial data for the calculation.

Productivity of preheater at temperature t=15°C: $G_{\text{в}}$ =5000 m³/h.

Temperature of the air, which enters the preheater, $t_1 = -25°C$.

Temperature of the air, which emerges from the preheater, $t_2 = +15°C$.

Vapor pressure of heating $p_n = 5$ atm (abs.).

We accept.

Heat availability factor $\eta = 0.98$.

Tubes brass of diameters $t_n/d_n = 10/8$ mm.

Number of courses in tubes $z = 1$.

Space of tubes in the width of beam $s_1 = 15$ mm.

Space of tubes in the depth of beam $s_2 = 12.5$ mm.

We determine (on Table 1-3 of applications/appendices).

Temperature of heating steam $t_s = 151.1°C$.

Heat of vaporization $r = 504.2$ кcal/kg.

Course of computation.

1. Mean temperature of air

$$t_{cp} = 0.5(t_1 + t_2) = 0.5(-25 + 15) = -5°C.$$

2. On table 5 of applications/appendices when t_{cp} we determine:

1) kinematic viscosity of air $\nu = 12.9 \cdot 10^{-6}$ m/s;

2) coefficient of thermal conductivity $\lambda = 2.02 \cdot 10^{-2}$ kcal/m h°C;

3) heat capacity of the air $c_p = 0.241$ kcal/kg of °C;

4) specific gravity/weight of air $\gamma = 1.280$ kg m³;

5) specific gravity/weight of air with t=15°C: $\gamma_{15} = 1.185$ kg/m³.

3. Weight quantity of air, passing through heater.

$$G'_{\text{в}} = G_{\text{в}}\gamma_{15} = 5000 \cdot 1.185 = 5930 \; \text{кг/час.}^{(1)}$$

Key: (1). kg/h.

4. Volume of air with

$$G'_{\text{в}} = \frac{G'_{\text{в}}}{\gamma} = \frac{5930}{1.280} = 4650 \; \text{м}^3 \text{/час.}^{(1)}$$

Key: (1). m³/h.

5. Quantity of heat, required for heating of air,

$$Q = G'_s c_p (t_2 - t_1) = 5930 \cdot 0,241 (15 + 25) = 57\,200 \text{ } \textit{ккал/час.}^{(l)}$$

of Key: (1). kcal/h.

Page 109.

6. Expenditure pair for preheating of air

$$G_s = \frac{Q}{r_1} = \frac{57\,200}{504,2 \cdot 0,98} = 116 \text{ } \textit{кг/час.}^{(l)}$$

Key: (1). kg/h.

7. Temperature head between vapor and air

$$\Delta t = t_s - t_{cp} = 151,1 + 5 = 156,1°C.$$

8. We preliminarily accept following structural/design sizes/dimensions of preheater, being guided by fulfilled draft:

number of series/rows of tubes in depth of team:

with even quantity of tubes ... $m_1 = 3$

with odd quantity of tubes ... $m_2 = 2$

number of tubes in even series/row ... $n_1 = 30$

number of tubes in odd series/row ... $n_2 = 29$

Distance between tube plates ... l=0.68 m

distance from wall of housing to wing tube ... δ=0.003 m.

9. Dimensions of section of housing for passage of air in width of beam

$$b = (n_1 - 1)s_1 + d_n + 2\delta = (30 - 1)0,015 + 0,01 +$$
$$+ 2 \cdot 0,003 = 0,45 \text{ м}.$$

10. Clear area for passage of air

$$f = \left(b - \frac{m_1 n_1 + m_2 n_2}{m_1 + m_2} d_n\right) l = \left(0,45 - \frac{3 \cdot 30 + 2 \cdot 29}{3 + 2} 0,01\right) 0,68 =$$
$$= 0,1049 \text{ м}^2.$$

11. Average/mean air speed in preheater

$$v = \frac{G_n^\circ}{3600 f} = \frac{4650}{3600 \cdot 0,1049} = 12,3 \text{ м/сек.}^{(1)}$$

Key: (1). m/s.

12. Reynolds number for air

$$\text{Re} = \frac{v d_n}{v} = \frac{12,3 \cdot 0,01}{12,9 \cdot 10^{-6}} = 9550.$$

Page 110.

13. Heat-transfer coefficient from wall to air for transverse

flow around tubes of staggered arrangement will be determined
according to to formula

$$a = c \cdot \frac{\lambda}{d_{\text{H}}} \, \text{Re}^{n} = 1{,}15 \cdot 0{,}223 \, \frac{2{,}02 \cdot 10^{-2}}{0{,}01} \, 9550^{0{,}6} = 127 \, \text{ккал/м}^2\text{-час} \, ^{\circ}C.$$

by Key: (1). kcal/m²h °C.

where c - a coefficient (cn Table 9) when $\frac{s_1}{d_{\text{H}}} = \frac{15}{10} = 1{,}5$:

$$c = 1 + 0{,}1 \frac{s_1}{d_{\text{H}}} = 1 + 0{,}1 \frac{15}{10} = 1{,}15;$$

• - coefficient in Table 9 as average/mean for five series:

$$\epsilon = \frac{n' + n'' + 3n'''}{5} = \frac{0{,}15 + 0{,}20 + 3 \cdot 0{,}255}{5} = 0{,}223;$$

n=0.6 - an exponent on Table 9.

14. Coefficient of heat transfer from vapor to air

$$k \approx a = 127 \, \text{ккал/м}^2\text{-час} \, ^{\circ}C.$$

Key: (1). kcal/m²h °C.

15. Necessary surface of heating preheater

$$F = \frac{Q}{\Delta t k} = \frac{59100}{156{,}1 \cdot 127} \approx 3{,}0 \, \text{м}^2.$$

16. Accepted surface according to preliminary sizes/dimensions

$$F_{\phi} = (m_1 n_1 + m_2 n_2) \pi d_{\text{H}} l = (30 \cdot 3 + 29 \cdot 2) 3{,}14 \cdot 0{,}01 \cdot 0{,}68 = 3{,}16 \, \text{м}^2.$$

In the case of disagreement it is more than to -5-+10o/c between
the necessary surface and surface, accepted according to preliminary
sizes/dimensions, should be changed the sizes/dimensions accepted and
again produced calculation.

During the setting up of air preheaters in the special compartments from which the fans supply air into the operating locations, the heat availability factor is accepted η =1.0.

§21. Calculation of the coolant or air.

Initial data for the calculation.

Productivity of coolant at temperature t=15°C, G_s =3000 m^3/h.

Temperature of the air, which enters the coolant, t_1=27°C.

Temperature of the air, which emerges from coolant t_2=18°C.

Temperature of the brine, which enters in coolant, t_3=7.5°C.

Temperature of the brine, which emerges from the coolant, t_4=10.5°C.

We accept.

Tubes brass with a diameter of $d_н/d_в$ = 16/14 $мм$.

Number of courses of brine in tubes z=2.

Space of tubes in the width of beam s_1=22 mm.

Space of tubes in the depth of beam s_2=20 mm.

Heat capacity of brine c_p' =0.93 kcal/kg   °C.

The specific gravity/weight of brine γ_p =1.025 т/м³.

Page 111.

Course of computation.

1. Mean temperature of air
$$t_{cp}' = 0.5\,(t_1 + t_2) = 0.5\,(27 + 18) = 22.5°\text{C}.$$

2. On Table 5 of layings when t_{cp}' we determine:

1) heat capacity of the air c_p =0.242 kcal/kg°C;

2) coefficient of thermal conductivity λ=2.18•10⁻² kcal/m•h°C;

3) kinematic viscosity ν =15.93•10⁻⁶ m²/s.

4) specific gravity/weight γ =1.155 kg/m³;

5) specific gravity/weight with t=15°C, equal to γ_{15} =1.185 kg/m³.

3. Weight quantity of air, passing through coolant,

$$G'_e = G_e \gamma_{15} = 3000 \cdot 1,185 = 3560 \; \overset{(1)}{\kappa\text{г/час}}.$$

Key: (1). kg/h.

4. Volume of air with t'_{cp}

$$G''_e = \frac{G'_e}{\gamma} = \frac{3560}{1,155} = 3080 \; \overset{(1)}{\text{м}^3/\text{час}}.$$

Key: (1). m³/h.

5. Quantity of heat, abstracted/removed by brine,

$$Q = G'_e c_p (t_1 - t_2) = 3560 \cdot 0,242 \,(27 - 18) = 7800 \; \overset{(1)}{\text{ккал/час}}.$$

Key: (1). kcal/h.

6. Mean temperature of brine

$$t''_{cp} = 0,5 (t_3 + t_4) = 0,5 (7,5 + 10,5) = 9° \, C.$$

7. Quantity of brine, required for cooling of air,

$$W_p = \frac{Q}{c_p (t_4 - t_3)} = \frac{7800}{0,93 \,(10,5 - 7,5)} = 2800 \; \overset{(1)}{\text{кг/час}}.$$

Key: (1). kg/h.

8. We preliminarily accept following structural/design sizes/dimensions of coolant, being guided by fulfilled draft:

number of series/rows of tubes in depth of beam ... m=16.

Number of tubes in the width of beam ... n=18.

Distance between the tube plates ... l=0.485 m.

Distance from the wall of housing to farthest tube with 6=0.009 m.

9. Size/dimension of section of housing for passage of air in width of beam

$$b = (n-1)s_1 + d_s + 2\delta = (18-1)\,0.022 + 0.016 + 2 \cdot 0.009 =$$
$$= 0.408 \; \text{м}.$$

10. Clear area for passage of air

$$f = (b - nd_s)\,l = (0.408 - 18 \cdot 0.016)\,0.485 = 0.0582 \; \text{м}^2.$$

Page 112.

11. Average/mean air speed in coolant

$$v_s = \frac{G_s''}{3600f} = \frac{3080}{3600 \cdot 0.0582} = 14.6 \; \overset{(')}{\text{м/сек}}.$$

Key: (1). m/s.

12. Reynolds number for air

$$\text{Re} = \frac{v_{\scriptscriptstyle B} d_{\scriptscriptstyle H}}{\nu} = \frac{14{,}6 \cdot 0{,}016}{15{,}93 \cdot 10^{-6}} = 14700.$$

13. Heat-transfer coefficient from wall to air for transverse flow around tubes of staggered arrangement will be determined according to to formula

$$\alpha_{\scriptscriptstyle B} = c\varepsilon \frac{\lambda}{d_{\scriptscriptstyle H}} \text{Re}^{\scriptscriptstyle n} = 1{,}1375 \cdot 0{,}245 \frac{2{,}18 \cdot 10^{-2}}{0{,}016} 14700^{0{,}6} =$$
$$= 123 \ \overset{(1)}{\text{ккал}/\text{м}^2 \cdot \text{час} \, °C},$$

by Key: (1).   kcal/m²h °C.

where coefficient c in Table 9 when $\frac{s_1}{d_{\scriptscriptstyle H}} = \frac{22}{16} = 1{,}375$:

$$c = 1 + 0{,}1 \frac{s_1}{d_{\scriptscriptstyle H}} = 1 + 0{,}1 \frac{22}{16} = 1{,}1375;$$

ε — coefficient in Table 9 as average for 16 series/rows:

$$\varepsilon = \frac{0{,}15 + 0{,}20 + 14 \cdot 0{,}255}{16} = 0{,}245;$$

n=0.6 — index of degree on Table 9.

14. Mean temperature of wall of tube

$$t_{\scriptscriptstyle c\text{т}} = 0{,}5 \left(t'_{\scriptscriptstyle c\text{p}} + t''_{\scriptscriptstyle c\text{p}} \right) = 0{,}5 \left(22{,}5 + 9 \right) = 15{,}75° \, C.$$

15. Temperature of boundary layer from the side of brine

$$t_{\scriptscriptstyle r\text{p}} = 0{,}5 \left(t_{\scriptscriptstyle c\text{т}} + t''_{\scriptscriptstyle c\text{p}} \right) = 0{,}5 \left(15{,}75 + 9 \right) \approx 12{,}3° \, C.$$

16. Rate of brine in tubes

$$v_{\scriptscriptstyle p} = \frac{W_{\scriptscriptstyle p} z}{2825 d_{\scriptscriptstyle B}^2 \gamma_{\scriptscriptstyle p} nm} = \frac{2{,}8 \cdot 2}{2825 \cdot 0{,}014^2 \cdot 1{,}025 \cdot 18 \cdot 16} = 0{,}0342 \ \overset{(1)}{\text{м}/\text{сек}}.$$

Key: (1). m/s.

17. Reynolds number for brine

$$Re = \frac{v_p d_e}{v_p} = \frac{0.0142 \cdot 0.014}{1.23 \cdot 10^{-6}} = 390,$$

where $v_p = 1.23 \cdot 10^{-6}$ at $t_{rp} = 12.3°C$ (on Table 6 of applications/appendices).

Page 113.

18. Prandtl number for brine

$$Pr = \frac{3600 \cdot v_p}{a} = \frac{3600 \cdot 1.23 \cdot 10^{-6}}{5.15 \cdot 10^{-4}} = 8.6,$$

where $a = 5.15 \cdot 10^{-4}$ m²/h - coefficient of thermal diffusivity of brine when t_{rp} (on Table 6 appendices).

19. Grashof's criterion for brine

$$Gr = \frac{g d_e^3 \beta \Delta t}{v_p^2} = \frac{9.81 \cdot 0.014^3 \cdot 1.16 \cdot 10^{-4} \cdot 3}{(1.23 \cdot 10^{-6})^2} = 6250.$$

where $\beta = +1.16 \cdot 10^{-4}$ 1/°C - coefficient of expansion of water when t_{rp} (on Table 6 of applications/appendices): $\Delta t = t_4 - t_3 = 10.5 - 7.5 = 3°C$ - difference in temperatures of brine.

20. product $GrPr = 6250 \cdot 8.6 = 5.35 \cdot 10^4$.

21. Heat-transfer coefficient from wall to brine for laminar

flow of brine in tubes

$$a_p = 0.74 \frac{\lambda_p}{d_a} \mathrm{Re}^{0.2} (GrPr)^{0.1} Pr^{0.2} = 0.74 \frac{0.5}{0.014} 390^{0.2} \cdot 53\,500^{0.1} \cdot 8.6^{0.2} =$$

$$= 397 \ \text{ккал/м}^2\text{-час} ^{\circ}C,$$

Key: (1). the kcal/m²-h°C.

where λ_p =0.5 a kcal/m-hour °C - thermal conductivity of brine when t_{rp} according to the data of table 6 applications/appendices.

22. Ratio of length of tubes to diameter

$$\frac{l}{d_a} = \frac{0.485}{0.014} = 34.6.$$

23. Correcting coefficient ε on table 6: ε =1.036.

24. Heat-transfer coefficient from wall to brine with consideration correction factor

$$a_p' = \varepsilon a_p = 1.036 \cdot 397 = 412 \ \text{ккал/м}^2\text{-час} ^{\circ}C.$$

Key: (1). kcal/m²-h°C.

25. Coefficient of thermal conductivity of brass tubes λ=90 kcal/m-h°C.

26. Coefficient of heat transfer from air to brine

$$k = \cfrac{1}{\cfrac{1}{a_a} + \cfrac{d_n - d_a}{2\lambda} + \cfrac{1}{a_p'} \cfrac{2d_n}{d_n + d_a}} =$$

$$= \cfrac{1}{\cfrac{1}{123} + \cfrac{0.016 - 0.014}{2 \cdot 90} + \cfrac{1}{412} \cdot \cfrac{2 \cdot 0.016}{0.016 + 0.014}} \approx 93 \ \text{ккал/м}^2\text{-час} ^{\circ}C.$$

Key: (1). kcal/m²-h°C.

Page 114.

27. Average/mean logarithmic difference in temperatures for
crosscurrent of air and brine

$$\Delta t = \frac{(t_1 - t_4) - (t_2 - t'_{cp})}{2,3 \lg \dfrac{t_1 - t_4}{t_2 - t'_{cp}}} = \frac{(27 - 10,5) - (18 - 9)}{2,3 \lg \dfrac{27 - 10,5}{18 - 9}} = 12,35^\circ C.$$

28. Necessary cooling surface

$$F = \frac{Q}{\Delta t k} = \frac{7800}{12,35 \cdot 93} = 6,85 \; \text{м}^2.$$

29. Actual cooling surface according to preliminarily taken
sizes/dimensions

$$F_\phi = \pi d_\text{н} l m n = 3,14 \cdot 0,016 \cdot 0,485 \cdot 16 \cdot 18 \approx 7,0 \; \text{м}^2.$$

In the case of cooling external atmospheric air in the
calculation of coolant should be considered the moisture content of
air, and also the permissible (prescribed/assigned) moisture content
of the cooled air.

In this case with the execution of calculation is applied I-d

the diagram of humid air [1].

FOOTNOTE [1]. A. V. Nesterenko, use/application I-d diagram in the calculations of ventilation, Stroyizdat, 1950. ENDFOOTNOTE.

Chapter III.

Calculations of resistances.

§22. Losses of head in the apparatuses.

Losses of head in the apparatuses depend on the presence of
resistances which must overcome the moving/driving mass of liquid on
its path.

These resistances are of two kinds: a) the frictional resistance
of liquid against the walls, which depends on the physical properties
of liquid, its rate, from the quality of surface and sizes/dimensions
of the duct; b) local resistances, which appear as a result of
changing the direction of motion, and also as a result of a change in
the geometric form of fluid flow.

With the course of liquids distinguish character their actions.
In the rectilinear direction the actions and during the sufficiently
coze of the liquid of its particle move rectilinearly and in parallel
to each other. This motion is called flowing, or laminar.

At high rates, even in the case of rectilinear direction, flow, single particles the liquids move disorderly, over the curved lines and in different directions, moreover the particle path they constantly change. This motion is called vortex/eddy, or turbulent.

The diagram of laminar and turbulent fluid flows, which shows the distribution of rates according to the diameter of conduit/manifold, is represented in Fig. 55.
Fig. 55. Diagram of the laminar and turbulent motion of liquid in the duct.

Key: (1). Turbulent motion. (2). Viscous motion. (3). Relative distance from axis/axle to duct.

Page 116.

The criterion by which it is possible to judge about the character of the state of motion of flow, is the value of Reynolds number. The value of Reynolds number, with whom occurs the transition of mode/conditions from laminar to turbulent, is called critical, and the rate of flow, which corresponds to a critical number, is called critical speed.

Reynolds number (or Reynolds's parameter) is expressed by the following formula:

$$Re = \frac{vd}{v} = \frac{vd\gamma}{\mu g},$$
(188)

where v - a rate of medium, m/s; d - diameter of duct, m; ν - kinematic viscosity, m²/s; γ - specific gravity/weight, kg/m³; μ - dynamic viscosity, kg•s/m²; g=9.81 - acceleration of gravity m/s².

With:

Re<2200 - laminar flow; 2200<Re<10000 - wobble; Re>10000 - the turbulent flow;

Thus:

Number 2200 - lower critical Reynolds number.

Number 10000 - upper critical Reynolds number.

Loss to friction in the straight/direct section of the duct

$$\Delta p = \lambda \frac{l}{d} \frac{v^2 \gamma}{2g} \quad \kappa\imath/\mathit{M}^2, \qquad (189)$$

where λ - coefficient of friction drag; l - length of duct, m; d - diameter of duct, m; v - rate of medium, m/s; γ - the specific gravity/weight of medium, kg/m³. g=9.81 - acceleration of gravity m/s².

The local losses:

$$\Delta p = \zeta \frac{v^2 \gamma}{2g} \ \kappa 2/M^2.$$ (190)

where ζ - coefficient of local resistance; v - rate of medium after local obstruction, m/s; γ - the specific gravity/weight of medium, kg/m³; g - acceleration of gravity m/s².

Page 117.

Resistance in the tube system of the apparatus:

$$h = z \left(0.03 k \frac{l}{d} \frac{v^2}{2g} \beta + 1.4 \frac{v^2}{2g} \right) + \frac{v_1^2}{2g} \ \text{м} \ \text{вод. ст.}$$ (191)

Key: (1). water column.

where z - a number of courses of water in the apparatus; l - length of tube, m; d - inner diameter of tube, m; v - the average speed of water in tubes, m/s; g - acceleration of gravity m/s²; β - coefficient, which considers the effect of mean temperature and rate of water (it is accepted on of the curves of Fig. 56); v_1 - velocity of water in branch pipes, m/s.

In formula (191) the first term in the brackets considers losses of head to friction in the tubes; the second term in the brackets considers local losses in the tubes. Losses in the branch pipes of apparatus are considered by the latter/last member of formula.

Fig. 56 gives curves for determining the value of coefficient β in the dependence on mear temperature and rate of water.

With the loads of lower than the calculated resistance in the apparatuses is determined from to the formula

$$h' = h \left(\frac{W'}{W} \right)^{1.8} \text{ м вод. ст.,} \quad (1)$$ (192)

by Key: (1). water column.

where W, W' - consumption of water respectively with calculated and smaller loads, m³/h; h, h' - hydraulic resistance respectively with calculated and smaller loads, m water column.

Hydraulic resistance of capacitor according to the data of VTI:

$$h = z \left(bL v^{1.75} + 0.135 v^{1.5} \right) \text{ м вод. ст.,} \quad (1)$$ (193)

Key: (1). water column.

where z - a number of courses of water in the capacitor; b - coefficient, depending on the inner diameter of tubes and mean temperature of water $t_{cp.}$ determined on Table 18; L - length of tubes, m; v - rate of water in tube, m/s.
Fig. 56. Value of coefficient β in depending on mean temperature and rate of water.

Key: (1). m/s. (2). Coefficient.

Page 118.

With a significant deviation of t_{cp} from 20°C the indicated in Table 18 value b should be multiplied by value $\phi = 1 + 0.007\,(t_{cp} - 20)$.

Resistance in the intertube space of apparatus with the transverse bulkheads:

1) in the passages between the partitions/baffles

$$\Delta p = \frac{4fmv_1^2 \gamma n}{2g} \quad \kappa 2/m^2, \qquad (194)$$

Key: (1). kg/m².

where f - a function of Reynolds number, equal to

$$f = 0,75 \left(\frac{a v_1 \gamma}{\mu g} \right)^{-0,2};$$

m - number of series/rows of tubes, intersected by the flow of the medium; γ - the specific gravity/weight of medium, kg/m³; n - number of gaps/intervals between the partitions/baffles; $\frac{a}{z}$ - distance (clearance) between the series/rows of tubes, m; v_1 - rate of liquid at the edge of partition/baffle, m/s; μ - absolute viscosity at mean temperature of medium, kg·s/m²; g - acceleration of gravity m/s².

2) during the flow through the partitions/baffles

$$\Delta p = \frac{0,0815 u^2 z}{\gamma} \ \kappa z/\textit{м}^2, \qquad (195)$$

Key: (1). kg/m².

where z - a number of partitions/baffles; u - the mass flow rate through partition/baffle, equal to

$$u = v_2 \gamma \ \kappa z/\textit{м}^2\text{-}сек;$$

Key: (1). the kg/m²s.

v_2 - rate of the medium above partition/baffle, m/s.

Fig. 57 schematically depicts heat exchanger with the transverse

bulkheads and flow chart fluid flow in its intertube space.

Resistance in the tubular heat exchangers with the course of medium in the intertube space in parallel to the axis/axle of tubes is defined normally, as for the case of the course of medium on the straight/direct tubes whereby into the formula is substituted equivalent hydraulic diameter.

Resistance in the beam of the ducts, washed by the cross flow of air (gas):

1) in the checkered beams with $\varepsilon = \dfrac{1 - \dfrac{d}{t_2}}{\dfrac{t_1}{d} - 1} < 0,53$

$$\Delta p = 2,8 \, (z+1) \, \mathrm{Re}^{-0,25} \frac{\gamma v^2}{2g} \; \kappa z/м^2 \text{ или } мм \text{ вод. ст.;} \quad (196)$$

Key: (1). kg/m² or mm H₂C.

with $\varepsilon = \dfrac{1 - \dfrac{d}{t_2}}{\dfrac{t_1}{d} - 1} > 0,53$

$$\Delta p = 3,86 \, (z+1) \sqrt{\frac{1 - d/t_2'}{t_1/d - 1}} \; \mathrm{Re}^{-0,25} \frac{\gamma v^2}{2g} \; \kappa z/м^2 \text{ или } мм \text{ вод. ст.;} \quad (197)$$

Key: (1). kg/m² or mm H₂C.

2) in the corridor beams with $\varepsilon = \dfrac{\dfrac{t_2}{d} - 0,8}{\dfrac{t_1}{d} - 1} \leqslant 1$

$$\Delta p = 0,53 \left(\frac{t_2/d - 0,8}{t_1/d - 1} \right)^{2,5} z \, \mathrm{Re}^m \frac{\gamma v^2}{2g} \; \kappa z/м^2 \text{ или } мм \text{ вод. ст.;} \quad (198)$$

Key: (1). kg/m² or mm H₂C.

with $\varepsilon = \dfrac{\dfrac{t_2}{d} - 0,8}{\dfrac{t_1}{d} - 1} > 1$

$$\Delta p = 0.53 \left(\frac{t_2/d - 0.8}{t_1/d - 1} \right)^3 z \, \text{Re}^m \frac{\gamma v^2}{2g} \; \overset{(1)}{\kappa z/м^2} \; \text{или мм вод. ст., (199)}$$

Key: (1). kg/m² or mm H₂C.

where m - an exponent; when $\varepsilon = \frac{t_2}{d} \geqslant 1.24$

$$m = 0.88 \left(\frac{t_1/d - 1}{t_2/d - 1} - 0.1 \right)^{0.138} - 1;$$

when $\varepsilon = \frac{t_2}{d} < 1.24$

$$m = 0.88 \left(\frac{t_2/d}{1.24} \right)^{0.7} \left(\frac{t_1/d - 1}{t_2/d - 1} - 0.1 \right)^{0.138} - 1.$$

Resistance, which considers correction for a change in velocity head in connection with a change in the temperature,

$$\Delta p_t = \frac{2(t'_o - t'_a)}{273 + t_{cp}} \frac{\gamma v^2_{cp}}{2g} \; \overset{(1)}{\kappa z/м^2} \; \text{или мм вод. ст.} \qquad (200)$$

Key: (1). kg/m² or mm H₂C.

Page 122.

Here d - outside diameter of tubes, cm; t_1 - space of tubes in the series/row (in the width of beam), cm; t_2 - space of the tubes between the series/rows (in the depth of beam), cm; t'_2 - diametric space of tubes, cm; z - number of series/rows of tubes in the beam; v - greatest rate in the beam, m/s; v_{cp} - average/mean air speed, m/s; g=9.81 m/s² - acceleration of gravity γ - the specific gravity/weight

of air, kg/m³; $t'_{\rm e}$ - temperature of air upon the entrance, °C; $t''_{\rm e}$ - temperature of air on leaving °C; Re - Reynolds number.

Formulas (196)-(200) are applied with Re from 6000 to 60000 and on spacings between tubes:

1) for the checkered beams

$$0,25 < \frac{1 - \frac{d}{t_2}}{\frac{t_1}{d} - 1} < 2,5;$$

2) for the corridor beams

$$0,2 < \frac{\frac{t_2}{d} - 0,8}{\frac{t_1}{d} - 1} < 6,5.$$

Formulas (196)-(200) are valid for resistances at the angle of attack $\psi = 90°$. With a decrease of the angle of attack of resistance decrease. The values of correction factor $\varepsilon = \frac{\Delta p_\varphi}{\Delta p_{90}}$ are given in Table 19.

Steam resistance of the capacitors:

$$\Delta p = \mu \frac{u^2}{v} \; мм \; \overset{(1)}{\text{рт. ст.}}, \qquad (201)$$

Key: (1). Hg.

where u - velocity of vapor in the capacitor, m/s [see formula (86)]; v - specific volume of vapor, m³/kg; μ - coefficient of steam resistance:

For the nonregenerative capacitors with the laying cut of the tube plate on the triangle ... 0.04.

For the nonregenerative capacitors from the combined by laying out tube plate ... 0.03.

For the regenerative capacitors with the laying out of the tube plate on the triangle ... 0.018.

For the regenerative capacitors from the combined by laying cut tube plate ... 0.012.

Table 19. Values of correction factor ε for the angle of attack.

Page 123.

Maximum permissible resistance of capacitor. Normally the value
of steam resistance of capacitor must not exceed the data, given in
Table 20.

Precise calculation of resistances cannot be fulfilled
virtually. In the critical cases resistance must be determined
experimentally.

Key: (1). Diameter of capacitor D, m. (2). It is more than. (3). Permissible resistance Δp, mm Hg.

§23. Coefficients of friction drag.

Coefficients of friction drag can be determined according to the following formulas.

For the liquids:

1) laminar flow - Reynolds number Re<2200

$$\lambda = \frac{64}{Re};$$ (202)

2) duct with the smooth walls - Reynolds number Re<100000

$$\lambda = \frac{0.3164}{\sqrt[4]{Re}},$$ (203)

where Re - Reynolds number - see formula (188).

The values of coefficient λ, calculated according to formula (203), are given in Table 21.
Table 21. Values of coefficient λ.

Re 10^{-3}	λ	Re 10^{-3}	λ	Re 10^{-3}	λ	Re 10^{-3}	λ	Re 10^{-3}	λ
2	0,0472	10	0,0316	50	0,0212	250	0,0142	700	0,0109
3	0,0427	15	0,0295	60	0,0202	300	0,0135	800	0,0106
4	0,0401	20	0,0266	70	0,0195	350	0,0130	1000	0,0100
5	0,0376	25	0,0252	80	0,0188	400	0,0126	1500	0,0094

Page 124.

Fig. 61 gives ncmcgram for determining the losses of pressure in the dependence on the speed of water and diameter of smooth tubes.

For the oil-products:

$$\lambda = 0,02 + \frac{1,7}{\sqrt{Re}}. \qquad (204)$$
Fig. 61. Nomogram for determining the losses of head in the smooth tubes in depending on the speed of water and diameter of tubes.

Key: (1). water, cm/m. (2). m/s.

Page 125.

For the air:

$$\lambda = 0,0125 + \frac{0.0011}{d},\qquad(205)$$

where d - an inner diameter of tube, mm.

For the water vapor with Re from $0.5 \cdot 10^6$ to $7 \cdot 10^6$ and for liquid with Re>100000

$$\lambda = \frac{1}{\left(1.74 + 2\lg\frac{r}{k}\right)^2},\qquad(206)$$

where r - an inside radius of tube, mm; k=0.064-0.10 - absolute roughness, mm.

For the gases and the water vapor with tubes with the rough walls and Reynolds number Re<500000

$$\lambda = \frac{0.08186}{d^{0.133}}\, Re^{-0.148},\qquad(207)$$

where d - an inner diameter of tube, mm.

For simplicity of calculation we convert formula (207):

$$\lambda = \frac{\lambda_1}{\lambda_2};\quad \lambda_1 = \frac{0.08186}{d^{0.133}};\quad \lambda_2 = Re^{0.148}.$$

The values λ_1 and λ_2, calculated according to the obtained formulas, are given in tables 22 and 23.

Table 22. Values λ_1.

Page 127.

§ 24. Coefficients of local resistances.

1. Values of coefficients of local resistances in intertube space of apparatus without partitions/baffles with course of medium in perpendicular direction to location of tubes can be determined:

1) with turbulent and viscous motion of gas

$$\zeta = 3m \left(\frac{\mu}{a v_p} \right)^{0.2} \tag{209}$$

or

$$\zeta = 3m \left(\frac{1}{Re} \right)^{0.2};$$

2) with turbulent action of liquid

$$\zeta = 4f \frac{l}{d_h}; \qquad (210)$$

3) with viscous action of liquid

$$\zeta = 106 \frac{l}{d_h} \frac{\mu}{v d_h \rho}. \qquad (211)$$

Here m - number of series/rows of tubes, arranged/located perpendicularly to the flow of the medium;

μ - the absolute viscosity of medium, $kg \cdot s/m^2$;

a=t-d - distance (clearance) between the series/rows of tubes, m (here t - space of tubes, m; d - outside diameter of tubes, m);

v - the maximum speed of the medium through the minimum cross section, m/s;

ρ - density of medium, $kg \cdot s^2/m^4$;

Re - Reynolds number [in the formula (188)];

f - coefficient of external friction (according to the data of Table 24);

l - length of the beam of tubes in the direction of flow, m;

d_h - hydraulic diameter, m [according to the formula (173)].

2. Values of coefficients of local resistances for local obstructions of heat exchangers can be accepted on Table 25.

Table 24. Values of the coefficient of external friction f.

Re	f при охлаждении (1)	f при t=const (2)	f при нагревании (3)	Re	f при охлаждении (1)	f при t=const (2)	f при нагревании (3)

Key: (1). during the cooling. (2). with. (3). during heating.

Page 128.

The recommended in Table 25 coefficients of local resistances are referred to the speed of medium in the tubes or between the tubes.
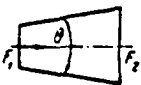

3. Values of coefficients of local resistances for different local obstructions of manifolds can be determined according to tables 26. These coefficients are given for the speed of medium after the local obstruction.

$\frac{F_0}{F_2}$	0,1	0,2	0,3	0,4	0,5	0,6	0,7	0,8	0,9	1,0
E	0,62	0,63	0,64	0,66	0,68	0,71	0,76	0,81	0,89	1,0

Key: (1). Designation and draft. (2). Formulas and table of values of coefficient. (3). Transient divergent cone. (4). Transient convergent cone. (5). Sudden expansion. (6). Sudden contraction. (7). Diaphragm in duct. (8). case of "ideal" compression. (9). Diaphragm upon entrance into duct. (10). case of "inadequate" compression $(F_1 < 20F_0)$ $\zeta = (F_2/EF_0 - 1)^2$ (value E is determined below).

Page 130.

§ 25. Discharge coefficients.

During the discharge the liquids from the openings/apertures of
various forms take the place of the losses, which decrease the real
fluid flow rate, computed from formula (89), and the real discharge
velocity, determined according to formula (78).

These losses depend on the compression of liquid jet, i.e. by
the decrease of section, and by the appearance of friction in the
opening/aperture with the discharge from it of real liquid.

Real expenditure and speed of liquid are calculated taking into
account the losses which are estimated by means of the introduction
to calculation formulas (78) and (89) discharge coefficients in the
form of factors.

By the discharge coefficient they imply:

1. The contraction coefficient ε, equal to the ratio of the
sectional area of jet to the area of the opening/aperture from which
escape/ensues liquid.

2. Velocity coefficient φ, equal to ratio of real discharge
velocity to theoretical taking into account friction in
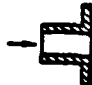

opening/aperture.

3. Coefficient of expenditure μ, equal to product of contraction coefficients and speed.

4. Drag coefficient ς, determined in   § 24.

Page 131.

Table 27. Values of discharge coefficients.

The designations: μ - coefficient of the expenditure; ϕ - velocity coefficient; ζ - drag coefficient; ε - contraction coefficient.

Key: (1). Designation and draft. (2). Values cf coefficients. (3). Opening/aperture in thin wall. (4). Venturi's long nozzle. (5). Nozzle. (6). Borda mouthpiece. (7). Nozzle in form cf compressed jet. (8). Venturi's nozzle at angle. (9). Best angle of taper. (10). Conical nozzle.

Page 132.

The values of discharge coefficients for the various forms of openings/apertures and nozzle are given in Table 27, dependence

in Table

between the coefficients ζ and ϕ *and*, between the coefficients μ, ϕ

and ϵ - in the formulas:

$$\mu = \epsilon \eta; \quad \eta = \sqrt{\frac{1}{1+\zeta}}; \quad \epsilon = \frac{F_1}{F_2}, \qquad (212)$$

where F_1 - an area of contracted section; F_2 - area of

opening/aperture.

The values of coefficients for the *small openings* are close to the

following: $\zeta = 0.06$; $\phi = 0.97$; $\epsilon = 0.64$; $\mu = 0.62$.

Table 29. Dependence between the coefficients ζ and φ.

Chapter IV.

EXAMPLES OF THE CALCULATIONS OF RESISTANCES IN APPARATUSES.

§ 26. Calculation of resistances in the tube part of the apparatuses.

Hydraulic resistance of capacitor.

Initial data for the calculation (from the thermal design).

Expenditure of cooling water $D=150$ t/h.

Speed of cooling water in the tubes with $v_1=1.6$ m/s.

Mean temperature of cooling water $t_{cp}=24.2°C$.

The specific gravity/weight of cooling water $\gamma=1.025$ t/m³.

Number of courses of water in tubes $z=2$.

Length of the tubes between the tube plates $l=1.35$ m.

The thickness of the tube plate is $s=0.02$ m.

Inner diameter of tubes $d_{\text{a}} = 0.014$ m.

Course of computation.

1. Inner diameter of inlets and yield of water is taken $d_1 = 0.15$ m.

2. Speed of cooling water in branch pipes

$$v_{\text{a}} = \frac{D}{2825 d_{11}^2} = \frac{150}{2825 \cdot 0,15^2 \cdot 1,025} = 2,3 \ \text{м/сек.} \quad (1)$$

Key: (1). m/s.

3. Overall length of tubes

$$L = l + 2s = 1,35 + 2 \cdot 0,02 = 1,39 \ \text{м.}$$

4. Value of correction factor β for mean temperature and speed of cooling water (on graph/curve Fig. 56): $\beta = 0.965$.

Page 134.

5. Hydraulic resistance of capacitor

$$h = z\left(0,031\frac{L}{d_\bullet}\frac{v_1^2}{2g}\beta + 1,4\frac{v_1^2}{2g}\right) + \frac{v_2^2}{2g} =$$

$$= 2\left(0,031\frac{1,39}{0,014}\cdot\frac{1,6^2}{2\cdot9,81}0,965 + 1,4\frac{1,6^2}{2\cdot9,81}\right) + \frac{2,3^2}{2\cdot9,81} =$$

$$= 1,41 \text{ м вод. ст.}^{(1)}$$

Key: (1). water column.

Hydraulic resistance of capacitor according to the formula VTI:

$$h = z\left(bLv_1^{1,75} + 0,135v_1^{1,5}\right) =$$

$$= 2\left(0,138\cdot1,39\cdot1,6^{1,75} + 0,135\cdot1,6^{1,5}\right) = 1,48 \text{ м water column },$$

where b=0.138 - the coefficient, depending on the diameter of tubes $d_\bullet$ and mean temperature of cooling water t_{cp} determined on Table 18.

Hydraulic heater resistance of feed water.

Initial data for the calculation (from the thermal design).

Speed of water in the tubes with $v_1 = 1.7$ m/s.

The specific gravity/weight of water $\gamma = 0.974$ t/m^3.

Number of courses of water in tubes z=6.

Average/mean length of tubes in the course of $l = 1.8$ m.

The thickness of the tube plate is s=0.5 m.

Inner diameter of tube d_e =0.013 with m.

Reynolds number Re=56800.

Course of computation.

1. Overall length of tube in course
$$L = l + 2s = 1,8 + 2 \cdot 0,05 = 1,9.$$

2. Coefficient of friction drag for water
$$\lambda = \frac{0,3164}{\sqrt[4]{Re}} = \frac{0,3164}{\sqrt[4]{56\,800}} = 0,0205.$$

3. Losses to friction in straight/direct section of tubes
$$\Delta p_1 = \lambda \frac{zL}{d_e} \frac{v_{11}^2 \gamma}{2g} = 0,0205 \frac{6 \cdot 1,9}{0,013} \cdot \frac{1,7^2 \cdot 974}{2 \cdot 9,81} = 2600 \; \kappa z / \kappa^2. \quad (1)$$

Key: (1). kg/m².

Page 135.

4. Local losses during rotation on 180° in V-shaped tube
$$\Delta p_2 = \zeta_1 \frac{zv_{11}^2 \gamma}{2 \cdot 2g} = 0,5 \frac{6 \cdot 1,7^2 \cdot 974}{2 \cdot 2 \cdot 9,81} = 215 \; kg/m^2,$$

where ζ_1=0.5 - drag coefficient during rotation in V-shaped tube (on
Table 25).

5. Local losses to rotation in chambers/cameras upon transfer of

one beam of tubes in another

$$\Delta p_3 = \zeta_2 \frac{z}{3} \frac{v_1^2 \gamma}{2g} = 2.5 \frac{6}{3} \cdot \frac{1.7^2 \cdot 974}{2 \cdot 9.81} = 717 \; kg/m^2,$$

where $\zeta_2 = 2.5$ - drag coefficient to rotation in chambers/cameras (on Table 25).

6. Local losses in input and downstream chambers

$$\Delta p_4 = \zeta_3 2 \frac{v_1^2 \gamma}{2g} = 1.5 \cdot 2 \cdot \frac{1.7^2 \cdot 974}{2 \cdot 9.81} = 430 \; kg/m^2,$$

where $\zeta_2 = 1.5$ - drag coefficient in input and downstream chambers (on Table 25).

7. Hydraulic heater resistance of feed water

$$h = (\Delta p_1 + \Delta p_2 + \Delta p_3 + \Delta p_4) \cdot 10^{-3} =$$
$$= (2600 + 215 + 717 + 430) \cdot 10^{-3} = 3.962 \; \textit{x water column}.$$

Hydraulic heater resistance of fuel/propellant.

Initial data for the calculation (from the thermal design).

Brand of the petroleum residue: sailor M20.

Speed of petroleum residue in the tubes with retarders v=0.83 m/s.

Mean temperature of petroleum residue $t_{cp}^{*} = 55°C$.

Inner diameter of V-shaped tube $d_4 = 0.013$ with m.

Average/mean length of tubes in the course of $l = 1.03$ m.

Number of courses of petroleum residue in tubes z=6.

The thickness of the tube plate is s=0.035 m.

Course of computation.

1. Overall length of tube in course

$$L = l + 2s = 1.03 + 2 \cdot 0.035 = 1.1 \ \text{м}.$$

Page 136.

2. Losses of head on 1 lin. m in tubes with retarders and chambers/cameras in depending on speed v and mean temperatures t_{cp} of petroleum residue of M2C are determined on graph/curve Fig. 59:

$$\Delta p = 0.21 \ \text{кг/с.м}^2 \cdot \text{м}. \quad ^{(1)}$$

Key: (1). kg/cm²·m.

3. Hydraulic heater resistance of fuel/propellant

$$h = \Delta p L z = 0.21 \cdot 1.1 \cdot 6 = 1.39 \ \text{кг/см}^2.$$

Steam resistance of steam cooler.

Initial data for the calculation (from the thermal design).

The speed is steam in tubes v_n =49 m/s.

Specific gravity/weight is steam γ_n =3.22 kg/m³.

Number of courses of steam in tubes z=2.

Average/mean length or tubes in the course of l=0.53 m.

Inner diameter of V-shaped tube d_n =0.013 m.

The thickness of the tube plate is s=0.025 m.

Number of Reynolds Re=108500.

Course of computation.

1. Overall length of tube in course

$$L = l + 2s = 0,53 + 2 \cdot 0,025 = 0,58 \text{ м.}$$

2. Coefficient of friction drag

$$\lambda = \frac{0,08186}{d_n^{0,133}} Re^{-0,148} = \frac{0,08186}{0,013^{0,133}} \ 108\ 500^{-0,148} = 0,0263.$$

3. Loss to friction in straight/direct section of tubes

$$\Delta p_1 = \lambda \frac{zL}{d_0} \frac{v_n^2 \gamma_n}{2g} = 0,0263 \frac{2 \cdot 0,58}{0,013} \cdot \frac{49^2 \cdot 3,22}{2 \cdot 9,81} = 923 \ kg/m^2.$$

4. Drag coefficient to rotation of steam in tubes (on Table 25) $\varsigma_1 = 0.5.$

5. Local losses during rotation of steam in tubes

$$\Delta p_2 = \varsigma_1 \frac{v_n^2 \gamma_n}{2g} = 0,5 \frac{49^2 \cdot 3,22}{2 \cdot 9,81} = 197 \ kg/m^2.$$

6. Drag coefficient in input and downstream chambers (on Table 25) $\varsigma_1 = 1.5.$

Page 137.

7. Local losses with entrance into chambers/cameras and output of them

$$\Delta p_3 = \varsigma_2 \frac{2v_n^2 \gamma_n}{2g} = 1,5 \frac{2 \cdot 49^2 \cdot 3,22}{2 \cdot 9,81} = 1180 \ kg/m^2.$$

8. Steam resistance or steam cooler

$$\Delta p = (\Delta p_1 + \Delta p_2 + \Delta p_3) 10^{-4} =$$
$$= (923 + 197 + 1180) 10^{-4} = 0,23 \ kg/cm^2.$$

§ 27. Calculation of resistances in the intertube space of apparatuses.

Steam resistance of capacitor.

Initial data for the calculation (from the thermal design).

Quantity of that condensing steam $G_1 = 2700$ kg/h.

Quantity of condensate, which enters the capacitor, $G_2 = 1640$ kg/h.

Enthalpy of condensate $q_2 = 133.4$ kcal/kg.

Condensation temperature of steam $t_s = 53.6°C$.

Inner diameter of the housing of capacitor $D_\kappa = 0.592$ m.

Outside diameter of tubes $d_\text{н} = 0.016$ m.

Space of the location of the tubes with t = 0.026 m.

Distance between the tube plates $l = 1.35$ m.

Solidity/loading factor of tube plate $\eta_\text{тр} = 0.73$.

We determine (on Table 1-3 of applications/appendices).

Heat of vaporization when t_s, equal to r=566.9 kcal/kg.

Specific volume of steam when t_s, equal to v_s =10.2 m³/kg.

Course of computation.

1. Quantity of that is formed from condensate,

$$G_1 = \frac{G_2(q_2 - l_3)}{r} = \frac{1640(133,4 - 53,6)}{566,9} = 230 \; \text{кг/час.}^{(1)}$$

Key: (1). kg/h.

2. Total quantity of steam in capacitor

$$G = G_1 + G_2 = 2700 + 230 = 2930 \; \text{kg/h.}$$

3. Speed of condensable steam in capacitor

$$v = \frac{Gv_s}{3600 D_n l \left(1 - \frac{d_n}{t} \sqrt{\tau_{np}}\right)} =$$

$$= \frac{2930 \cdot 10,2}{3600 \cdot 0,592 \cdot 1,35 \left(1 - \frac{0,016}{0,026} \sqrt{0,73}\right)} = 22 \; m/s.$$

Page 138.

4. Coefficient of steam resistance for nonregenerative capacitors with laying out of tubes in triangle according to given

formula (201) $\mu=0.04$.

5. Steam resistance of capacitor

$$\Delta p = \mu \frac{v^2}{v_s} = 0,04\,\frac{22^2}{10,2} = 1,9\ \text{мм рт. ст.}\ ^{(1)}$$

Key: (1). Hg.

Hydraulic resistance of steam cooler.

Initial data for the calculation (from the thermal design).

Speed of water in steam cooler $v_в = 0.79$ m/s.

Inner diameter of housing $D_в = 0.28$ m.

Area for the passage of water in the intertube space f=0.01875

m.

Number of tubes in course n=53.

Outside diameter of tubes $d_н = 17$ m.

Average/mean length of the beam of semi-V-shaped tubes with

l=0.53 m.

Number of courses of water in housing z=2.

The specific gravity/weight of water $\gamma_{\text{в}}$ =937.3 kg/m³.

Dynamic viscosity of water μ =22.2•10⁻⁶ kg•s/m².

Course of computation.

1. Equivalent hydraulic diameter of one course (half intertube space)

$$d_{\text{э}} = \frac{4f}{\pi(0,5D_{\text{к}} + d_{\text{н}}n) + D_{\text{к}}} = $$
$$= \frac{4 \cdot 0,01875}{3,14(0,5 \cdot 0,28 + 0,017 \cdot 53) + 0,28} = 0,0209 \; \text{м.}$$

2. Reynolds number for water
$$\text{Re} = \frac{v_{\text{в}}d_{\text{э}}\gamma_{\text{в}}}{\mu g} = \frac{0,79 \cdot 0,0209 \cdot 937,3}{22,2 \cdot 10^{-6} \cdot 9,81} = 71\,000.$$

3. Coefficient of friction drag for water

$$\lambda = \frac{0,3164}{\sqrt[4]{\text{Re}}} = \frac{0,3164}{\sqrt[4]{71\,000}} = 0,01935.$$

4. Losses to friction in straight/direct sections of intertube space

$$\Delta p_1 = \lambda \frac{zl}{d_{\text{э}}} \frac{v_{\text{в}}^2 \gamma_{\text{в}}}{2g} = 0,01935 \frac{2 \cdot 0,53}{0,0209} \cdot \frac{0,79^2 \cdot 937,3}{2 \cdot 9,81} = 29,3 \; \text{кg/m².}$$

Page 139.

5. Drag coefficient during rotation on 180° in intertube space

(on Table   25) ς_1=1.5.

   6. Local losses during rotation of flow on 180°

$$\Delta p_2 = \varsigma_1 \frac{v_s^2 \gamma_0}{2g} = 1,5 \frac{0,79^2 \cdot 937,3}{2 \cdot 9,81} = 44,7 \ kg/m^2.$$

   7. Drag coefficient upon entrance into intertube space (on Table   25) ς_2=1.5.

   8. Drag coefficient on leaving from intertube space (on Table 25) ς_3=1.0.

   9. Local entry loss into intertube space and output from it

$$\Delta p_3 = (\varsigma_2 + \varsigma_3) \frac{v_s^2 \gamma_0}{2g} = (1,5 + 1,0) \frac{0,79^2 \cdot 937,3}{2 \cdot 9,81} = 74,5 \ kg/m^2.$$

   10. Hydraulic resistance of steam cooler

$$h = (\Delta p_1 + \Delta p_2 + \Delta p_3) \, 10^{-3} =$$
$$= (29,3 + 44,7 + 74,5) \, 10^{-3} \approx 0,15 \ m \ water \ column.$$

Hydraulic resistance of oil cooler.

Initial data for the calculation (from the thermal design).

   Productivity of oil cooler D=16 t/h.

   The length of the edge (chord) of partition/baffle is s=0.366 m.

   Space of the location of the tubes with t=13.5 mm.

Outside diameter cf tubes $d_{\rm H}$=10 with mm.

Distance between the housing and wing tubes with y_0=15.3 mm.

Number of series/rows cf tubes, intersected by flow, m=18.

Number of gaps/intervals between partitions/baffles n=12.

Distance between the partitions/baffles h=0.094 m.

The average speed cf oil between the partitions/baffles v_1=0.307 m/s.

The average speed cf oil above the partitions/baffles v_2=0.307 m/s.

Kinematic viscosity of oil cf brand T at mean temperature $v=57 \cdot 10^{-6}$ m²/s.

The specific gravity/weight of oil at mean temperature γ=879 kg/m³.

Area of section for the passage of oil above partitions/baffles $f_2 = 0.0164 \ m^2$.

Course of computation.

1. Size/dimension of clear opening for passage of oil at edge of partition/baffle

$$b = s - \frac{s - 2y_n - d_n}{t} d_n =$$
$$= 0,366 - \frac{0,366 - 2 \cdot 0,0153 - 0,01}{0,0135} 0,01 = 0,116 \ m.$$

Page 140.

2. Sectional area for passage of oil at edge of partition/baffle
$$f_1 = bh = 0,116 \cdot 0,094 = 0,0109 \ m^2.$$

3. Speed of oil at edge of partition/baffle
$$v = \frac{D}{3600 f_{1\gamma}} = \frac{16}{3600 \cdot 0,0109 \cdot 0,879} = 0,462 \ m/s.$$

4. Function of Reynolds number
$$f = 0,75 \left[\frac{v(t - d_n)}{\nu} \right]^{-0,2} = 0,75 \left[\frac{0,462(0,0135 - 0,01)}{57 \cdot 10^{-6}} \right]^{-0,2} = 0,384.$$

5. Losses of head of oil in passages between partitions/baffles
$$\Delta p_1 = \frac{4 f m v^2 \gamma n}{2g} = \frac{4 \cdot 0,384 \cdot 18 \cdot 0,462^2 \cdot 879 \cdot 12}{2 \cdot 9,81} = 3200 \ kg/m^2.$$

6. Losses of head of oil during flow through partitions/baffles
$$\Delta p_2 = 0,0815 v_{2\gamma}^2 (n - 1) = 0,0815 \cdot 0,307^2 \cdot 879 (12 - 1) = 74 \ kg/m^2.$$

7. Losses of head of oil with entrance into intertube space and output from it

$$\Delta p_3 = (\zeta_1 + \zeta_2) \frac{v_{1\gamma}^2}{2g} = (1,5 + 1,0) \frac{0,307^2 \cdot 879}{2 \cdot 9,81} = 10,6 \ kg/m^2.$$

$\zeta_1 = 1.5$ - drag coefficient upon entrance into intertube space (on table 25); $\zeta_2 = 1.0$ - drag coefficient on leaving from intertube space (on table 25).

8. Resistance in intertube space (oil cavity) of oil cooler

$$\Delta p = (\Delta p_1 + \Delta p_2 + \Delta p_3) \, 10^{-4} =$$
$$= (3200 + 74 + 10,6) \, 10^{-4} = 0,33 \ kg/cm^2.$$

Aerodynamic drag of air cooler.

Initial data for the calculation (from the thermal design).

Outside diameter of tubes $d_н = 16 \ mm$.

Space of tubes in the series/row (in the width of beam) $t_1 = 22$ mm.

Space of tubes in the depth of beam $t_2 = 20$ mm.

Number of series/rows of tubes in beam $z = 16$.

Average/mean air speed in the coolant $v = 14.6 \ m/s$.

Temperature of air upon entrance $t_1 = 27^\circ C$.

Temperature of air on leaving $t_2 = 18^\circ C$.

Mean temperature in coolant $t_{cp} = 22.5^\circ C$.

The specific gravity/weight of air $\gamma = 1.155$ kg/m³.

Reynolds number Re= 14700.

Page 141.

Course of computation.

1. Diameter pitch of tubes of checkered bundle

$$t = \sqrt{\left(\frac{t_1}{2}\right)^2 + t_2^2} = \sqrt{\left(\frac{22}{2}\right)^2 + 20^2} = 22,9 \ \text{мм}.$$

2. Value

$$\varepsilon = \frac{1 - d_н/t}{t_1/d_н - 1} = \frac{1 - 16/22,9}{22/16 - 1} = 0,8 > 0,53.$$

3. Resistance in checkered bundle of ducts, washed by cross flow of air, when $\varepsilon > 0.53$

$$\Delta p_1 = 3,86 (z + 1) \sqrt{\varepsilon} \, \text{Re}^{-0,25} \frac{v^2 \gamma}{2g} =$$

$$= 3,86 (16 + 1) \sqrt{0,8} \cdot 14700^{-0,25} \cdot \frac{14,6^2 \cdot 1,155}{2 \cdot 9,81} = 66,5 \ \text{мм water column}.$$

4. Resistance, which considers correction for change in velocity head in connection with change in temperature,

$$\Delta p_2 = \frac{2(t_2 - t_1)}{273 + t_{cp}} \frac{v^2 \gamma}{2g} = \frac{2(27 - 18)}{273 + 22.5} \frac{14.6^2 \cdot 1.155}{2 \cdot 9.81} = 0,76 \text{ мм water column}.$$

5. Aerodynamic drag of air cooler

$$\Delta p = \Delta p_1 + \Delta p_2 = 66,5 + 0,76 \approx 67,3 \text{ мм water column}.$$

CHAPTER V.

Materials and their design characteristics.

At present in the practice cf the manufacture cf different
apparatuses and vessels the widest acceptance obtained welding as the
most rational and cheap production method, which ensures good quality
cf production and safe operation.

Therefore all given below data will relate in essence to the
materials, used for the welded apparatuses and the vessels. The types
of welded joints in the ship-building are applied according to the
appropriate standards.

§ 28. Steel.

The materials, used for the apparatuses and the vessels, which
work under the pressure, must contain (according to
controlling-chemical analysis for any steel) not more than 0.30/c C -
during the use/application of an electric welding and net more than

0.35o/o C - during the use/application of other means of welding, or to satisfy the requirements of the corresponding standards.

For manufacturing the shipboard heat exchangers steel is applied mainly in the form of rolled stock, castings and forgings.

The parts of apparatuses and vessels, working medium of which are vapors, condensate, oil, petroleum and air, are fulfilled made of carbon steel, if they do not undergo the straight/direct effect of sea water. For the welded steel housings, the bottoms, the covers/caps and other parts, which work under pressure, is applied sheet steel of brand St. 3, while for the parts of less critical/heavy-duty ones - steel St. 2. The steel cast covers/caps, flanges and other parts are cast made of steel on GOST 977-53. For the steel tube plates, the flanges and other parts in the majority of the cases is applied steel St. 4 and less frequently St. 5. Steel tubes are fulfilled by seamless ones or seamless-rolled of carbon steel on GOST 301-50.

Page 153.

The parts of apparatuses, which require the increased strength or the necessary and sufficient corrosive resistance, and which also undergo the action of high temperatures, are made made of the nickel,

chrome-nickel and other alloy and low-alloy steel.

The fundamental characteristics of different steels, used for
manufacturing the basic parts of heat exchangers and vessels, are
given in Table 29-37 and cn Figs. 62-67.

Temperature effect on the strength is considered, beginning with 230°C, with a reduction/descent in the allowable stress for steel.

Allowable stresses for steel of brand St. 3 in the dependence on the temperature are given in Fig. 62.

For steel St. 2 stresses must be respectively lowered/reduced. For steel St. 4 stresses at temperature more than 300°C cannot be increased in comparison with the stresses/voltages for steel St. 3 Fig. 62.

Page 149.

It is necessary to keep in mind that the allowable stresses (Fig. 62) include the total stresses/voltages which can arise from all loads, which effect on the apparatus, namely: a) the internal pressure; b) impact loads, involving a sudden change in the pressure; c) the weight of apparatus and containing in it working media under operating condition; d) the load, caused by the tossing; e) the local stresses, called by the pick ups and the rings; f) a difference in the temperatures.

Usually in the calculations when selecting of the relationships/ratios of allowable stresses it is customary to assume that

$$R_z = R_d = R_b;$$
$$R_{cm} = 1,8R_z;$$
$$R_{cp} = 0,8R_z,$$

where R_z — permissible tensile stress; R_d — permissible compression stress; R_b — allowable stress or the bend; R_{cp} — permissible shear

stress; R_{cm} — permissible crumpling stress.

The graph of the permissible operating stresses/voltages for different carbon and alloy steels at temperatures more than 350°C is given on Fig. 63.

The graphs of a charge in the impact toughness and limit of the strength of different steels in the dependence on the temperature are given on Fig. 64 and 65.
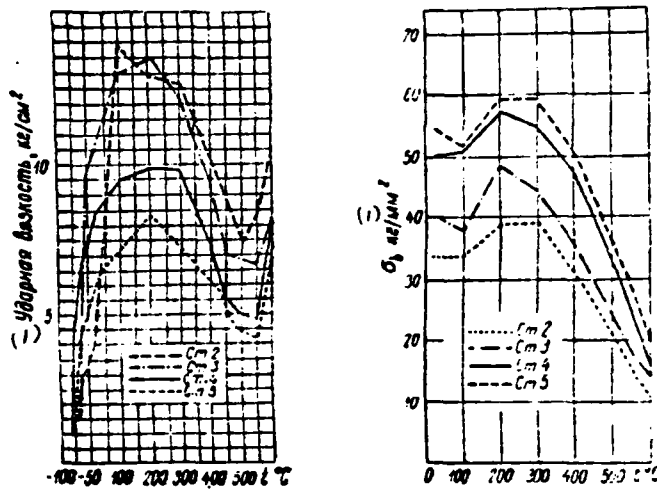

Fig. 64. Changes of the impact toughness of steels in the dependence on the temperature.

Key: (1). Impact toughness, kg/cm².

Fig. 65. Change of limit of strength of steels in dependence on temperature.

Key: (1) kgf/mm².

Page 150.

    With the work of apparatuses or their parts on compression either buckling is considered also the effect of elevated temperatures on the stability of the walls of apparatus or part

itself by the method of reducing/descending ccmputed value of the
yield point and modulus of elasticity of material.

The graph of a change of the yield point in the dependence on
the temperature for the common carbon steel is shown in Fig. 66.

The graph of a change of the modulus of elasticity in the
dependence on the temperature for the common carbon steel is given in
Fig. 67.

Taking into acccurt the effect of ccrrcsicn on the strength cf
apparatus, usually increase thickness walls by value C, taken within
the limits from 1 to 3 mm.

§ 29. Nonferrous metals and alloys.

For manufacturing different parts of apparatuses and vessels are
used extensively nonferrcus metals and their alloys: copper, tin,
aluminum, zinc, bronze, brass, etc.

The parts, working medium cf which it is sea water, and also
parts, which undergo the effect of sea water and air, which contains
moisture, are manufactured frcm the red copper, the bronze, brasses,
etc. For the welded cr scldered parts is applied copper sheet M3 and

M4, rolled brasses and bronze LCo2, LS59-1, L62, L90, BrAMts9-2, etc.; for the castings - copper, bronze and brasses of the predominantly following brands/marks: BrCTs10-2, BrOTs8-4, BrAMts9-2, etc.

Tubes from the nonferrous metal are applied only pulled or seamless-rolled on GOST 494-52 and 617-53, and copper-nickel - on GOST 2203-43.

The basic mechanical properties of nonferrous metals and their alloys with normal and at different temperatures are given respectively in Tables 39 and 40.

Page 153.

The strength of copper with an increase in the temperature considerably is depressed and according to experimental data comprises:

При температуре, °C	20	50	100	150	200	250	285	367	451	556
Прочность, %	100	98	95	91	85	79	75	66	51	33

Allowable stresses for copper and brass in the dependence on the temperature are given into tables 41.

For copper and brassing permissible tensile stresses compose approximately/exemplarily 67o/o of the allowable stress for rolled stock.

Allowable stresses on the bend for annealed copper in the dependence on the temperature are given into tables 42.

For the apparatuses and the parts, which work at temperature more than 250°C, use/application of copper and brasses is not recommended.

The results of the tensile tests of nonferrous metals at different temperatures are given in Table 43.

Page 155.

For manufacturing the separate parts of apparatuses and vessels or for their coating are applied in the limited quantity nonferrous metals as, for example, nickel, aluminum, zinc, tin, lead and so forth, etc. Zinc is applied mainly for the protectors/treads of apparatuses, which undergo destruction under the action of galvanic currents. Aluminum is used for manufacturing of parts sufficiently strong ones and lungs and just as lead, it can be used as the sealing material.

§ 30. Iron casting.

Iron casting has sufficiently limited application in the manufacture of the parts of shipboard heat exchangers.

The cast iron in the majority of the cases are made from gray cast iron as densest and least subjected to action of corrosion, and also possessing good castabilities. Cast iron parts can be used for the apparatuses, which work under the pressure not more than 6 kg/cm^2, also, at temperature of working medium not more than 200°C. The use/application of cast iron parts for the apparatuses, which undergo the effect of sea water, is not allowed/assumed.

The sizes/dimensions of cast iron vessels must not exceed 600 mm in diameter and 400 l on the capacity/capacitance.

The cast cast iron covers/caps, the drains of condensate and other parts of apparatuses and different fittings are made from gray cast iron (on GOST 1412-54) whose basic properties are given into tables 44. A great use in the apparatus construction find cast irons of brands SCh18-36, SCh24-44 and SCh28-48.

Page 156.

A change of the limit cf the strength cf the bend of cast iron in the dependence on the temperature acccrding tc experimental data is given in table 45.

Allowable stress fcr the cast iron:
$$R_s = R_b = 200 \div 250 \ kg/cm^2.$$

For cast iron of average/mean quality the allowable stress on

the bend can be accepted, in depending on the kind of load and surface condition, on Tables 46.

Allowable stress in cast iron on the compression:

$$R_d = 600 \ \kappa g/cm^2.$$

Addition to cast iron wall thickness accept C=7-9 mm, for the centrifugal casting by C=5 mm.

§ 31. Jointing materials (packing).

As the jointing materials in the heat exchangers are applied different packing. When selecting of packing it is considered:

1) the character of the packed medium;

2) operating pressure in the apparatus;

3) operating temperature;

4) the duration of connection to the dismantling;

5) the quality of packing surfaces (smooth, rough);

6) the width of the packing;

7) the thickness of the packing;

8) the force of the tightening of the bolts;

9) the position of the packing;

10) external agency on the packing;

11) the property of sealing material (strength, elasticity, coefficient of friction).

In essence all sealing materials are subdivided into three groups:

1. Nonmetallic pads - rubber, paranite, cardboard, asbestos, etc.

2. Metallic packing, manufactured with pillar from metal or alloy - copper, brass, steel, lead, etc.

3. Submetallic packing, which have metallic mounting/case (brass, copper, lead, zinc) and nonmetallic center (asbestos, rubber), or vice versa.

The most popular include the following sealing materials.

Rubber of the 2nd group, average/mean hardness from 7.5 to 11 kg/cm². It is commonly used as the packing/seal for the smooth flange joints, which are contacted with the cold and hot sea and feed water, the aqueous solutions and the air at temperature from -30 to +60°C

and pressures to 3 kg/cm², and with the cloth packing - to 6 kg/cm².

Heat-resistant rubber of the 4th group of average/mean hardness with the cloth packing is applied for the temperatures to 150°C and the pressure to 10 kg/cm².

Oil-resistant rubber of the 6th group of average/mean hardness is applied for oils and fuel/propellant at temperatures to 60°C and pressures to 3 kg/cm².

Plastic rubber without the harmful impurities is applied for the everyday apparatuses, intended for the preparation of drinking water and food.

Sealing rubber is manufactured any form and any sizes/dimensions in the form of plates, cords or round, square, quadrangular and shaped sections/cuts. The thickness of rubber plates without the packing is from 1 to 40 mm and with the cloth packing from 2 to 15 mm.

Page 158.

Paranite is the most general-purpose and widely used sealing material; it is applied for packing the surfaces, which are contacted

with the cold and hot fresh and sea water, the brine, the acids, the
alkalies, the water saturated and superheated steam, the air and the
flue gases at temperature to 400°C and pressure to 15 kg/cm².
Paranite is manufactured in the form of sheets with size/dimension to
1500 mm and in thickness from 0.3 to 6 mm.

Cardboard is applied for packings/seals of surfaces, which are
contacted with the liquid propellant, the lubricating oils, the air,
the ventilation gases and the drinking water at temperature to 90°C
and pressure to 6 kg/cm²; cardboard impregnated - for the surfaces,
which are contacted with the kerosene and the gasoline at temperature
to 30°C and pressure to 10 kg/cm².

Cardboard asbestos is applied for packing the surfaces, which
are contacted with the hot gases, the gasoline and the kerosene at
temperature to 180°C and pressure to 3 kg/cm².

By fabrics cotton, unbleached linen, by hemp cords with the
greasings by the red lead oxide and different mastics pack the
connections, intended for the low pressures, and the untreated or
slightly machined surfaces.

Copper annealed is applied: brand МЗ for packing the
connections, which are contacted with the saturated and superheated

steam at temperature to 250°C and pressure to 35 kg/cm², brands M1 -
at temperatures to 350°C and pressure to 45 kg/cm², and also for the
Freon, carbonic acid, hot gases, fuel/propellant and oils at
temperature to 200°C and pressure 200 kg/cm².

Iron soft of the type Armco is applied for the saturated and
superheated steam at temperature to 450°C and pressure to 64 kg/cm²
and for other corrode media at temperature to 450°C and pressure to
100 kg/cm².

Aluminum is applied for the media, in which is not dissolved
oxide of aluminum, and at very high and low temperatures and high
pressures.

Lead is applied for packing the connections, which are contacted
with the acids, oils, liquid propellant, gasoline at temperature to
100°C and pressure to 40 kg/cm².

Submetallic and riffled metallic packing are applied in the
dependence on their construction/design for packing the connections,
which are contacted with the gases, the air, the water, the
fuel/propellant by oil, acids and the like at temperatures of
60-250°C and pressure from 5 to 60 kg/cm², and they are established
on smooth surfaces of the connections, which frequently undergo

dismantling.

Tentative widths and thicknesses of packing in depending on their diameter are given in Table 47.

The specific pressures, necessary for the deformation of packing and that maximum permissible, call their flattening, and also specific gravity/weight of the material of packing are given in Table 48.

Page 159.

In order to determine the conditions of nonextrusion of the nonmetallic packing, pressed between the smooth flanges, they use the formula

$$(D_s + b)\, b \sigma_y f > D_s \delta p,$$

where D_s — bore of packing, cm; b - width of packing, cm; δ - thickness of packing, cm; σ_y — the specific pressure on the packing, necessary for the deformation, kg/cm²; p - the design pressure of medium, kg/cm²; f - coefficient of the friction of pad, equal to; f=0.10-0.15 during treatment ∇ of the surface of the flanges; f=0.05-0.08 during treatment $\nabla\nabla$ of the surface of flanges.

composed of temperatures of heat carrier and external surface of
wall.

Page 161.

Recently ever more wide acceptance obtains the new means of the
insulation/isolation of mechanisms, apparatuses and
conduits/manifolds - sc-called FOV - the formed fired vermiculite.

FOV is manufactured in the form of moldings - the rectangular
plates/slabs with the size/dimension 1000x500x30-50 of mm and in the
form of the rectilinear and curvilinear shells with a length of 500
mm, with thickness from 30 to 70 mm and in bore from 30 to 420 mm.
For the diameters more than 130-150 mm to more expediently apply
moldings in the form of the segments which can be established to the
tubes of different diameters; furthermore, segments are transportable
than shells.

The specific weight or the molded plates/slabs - 250 kg/m³, and
shells - 230 kg/m³.

The coefficient of the thermal conductivity λ of articles, in depending on mean temperature t_{cp} is determined from the formula

$\lambda = 0.07 + 0.0002 t_{cp}$

kcal/m•h°C.

Temperature stability of articles to 600°C.

The installation of insulation/isolation by the moldings, which have smaller specific weight, in comparison with Newell and scvelit of the isolated surfaces, is produced without the preheating and requires only the small smearing of welds and joints. Work on the insulation/isolation can be produced independent of the site of installation of the isolated articles.

The use/application of FOV as insulation in the form of moldings makes it possible to considerably reduce the labor consumption of installation works, and to also lower the weight of insulation/isolation.

As facing material for the insulation/isolation in the majority of the cases serve sheets made of galvanized iron with a thickness of 1 mm and sheets from aluminum-maynalium alloy.

Page 162.

Chapter VI.

Calculations of strength.

Heat exchangers, as a rule, work under pressure or in vacuum.
The parts of heat exchangers, which are subjected loads, are designed
in essence for the strength in depending on their material, operating
pressure, temperature and properties of medium.

In this section are given calculation formulas and methods of
determining the strong sizes/dimensions of the basic parts of
different apparatuses and vessels, relied on strength.

The calculation of vessels from the nonferrous metals and the
alloys is produced by the same calculation procedure, as for the
steel vessels, in this case necessary, just as for steel, to consider
all mechanical properties of the material used.

The order of the presentation of material approximately/exemplarily corresponds to the sequence of the produced stress analyses of parts.

§ 33. Calculation of cylindrical walls.

Thin-walled steel cylinders, subjected to internal pressure.

The wall thickness of cylinder or tube

$$s = \frac{pD_s}{230\varphi R_s - p} + C \text{ мм,} \qquad (213)$$

where p - design pressure, кg/см²; takes as the equal to the sum of the operating pressure of medium in the vessel and hydrostatic pressure, if it comprises more than 2.5o/o of the worker; D_s - the cylinder bore, mm; φ - modulus of resistance of weld; it is accepted on Tables 50 in the dependence on the construction/design of weld and welding method; R_s - permissible tensile stress, kg /mm²; it is accepted in the dependence on the temperature of wall on Table 51, and the safety factors - in Table 52. C - addition to the calculated wall thickness, which considers corrosion, tolerances, ovality, etc., mm; C=0.18s with $s_{pacu} > 6$ мм and C=1 мм when $s_{pacu} \leqslant 6$ мм,

(7) Более 400	$\dfrac{\sigma_s^t}{n_\tau};\ \dfrac{\sigma_n^t}{n_n}$	(8) Берется наименьшее значение отношений

The designations: σ_b - the limit of the strength of metal to the elongation at temperature of 20°C, kg /mm²; σ_s^t - yield stress of metal at temperature t, kg /mm²; σ_n^t - creep limit of metal at temperature t, kg /mm²; n_b, n_τ and n_n - safety factors in the relation respectively to the limits of strength, viscosity/yield and creep (they are taken according to Table 52).

Key: (1). Temperature of wall. (2). kg/mm. (3). Note. (4). It is less. (5). From. (6). to. (7). It is more. (8). Is taken small value of relations.

Page 164.

Formula (213) is applied for calculating thick-walled vessels, which refer outside diameter to the internal not more than value 1.5.

During the calculation of the wall thicknesses of the
cylindrical containers, subjected to internal pressure at normal
temperature (cistern and other vessels, which work under conditions,
close to the body constructions/designs), permissible tensile stress
is received as equal to

$$R_s = 0.6\sigma_s, \ \text{kg}/\text{mm}^2 \qquad (214)$$

where σ_s - yield stress of metal with the normal temperature,
kg /mm².

Thin-walled steel cylinders, subjected to ambient pressure.

The wall thickness of cylinder or tube

$$s = \frac{pD}{4R_d}\left(1 + \sqrt{1 + \frac{al}{p(l+D)}}\right) + C \ \text{cm}, \qquad (215)$$

where p - external overpressure, kg/cm²; D - diameter of cylinder in
light/world, cm; R_d -allowable compression stress, kg/cm²; l - length
of cylinder (between the effective rigid attachments), cm; C -
addition, cm; a - factor, obtained experimentally.

Page 165.

For the horizontal cylinders: a=100 - with the longitudinal seam overlapping; a=80 - with the longitudinal seam welded or with the cover plates from both sides.

For the vertical cylinders: a=70 - with the longitudinal seam overlapping; a=50 - with the longitudinal seam welded or with the cover plates from both sides.

Breaking stress in the cylindrical containers. cylindrical containers without rings of rigidity whose breaking stress is lower than the yield point, and the ovality of less than 0.05 D_w rely on stability with respect to the formula

$$p_{\kappa p} = \frac{E}{4(1-\mu^2)}\left(\frac{s}{r}\right)^2 \; kg/cm^2. \qquad (216)$$

Cylindrical containers without rings of rigidity whose breaking stress is higher than the yield point, and ovality less than 0.1 D_w they are designed from the formula

$$p_{\kappa p} = \frac{s}{r}\frac{z_s}{1+\frac{4z_s}{E}\left(\frac{r}{s}\right)^2} \; kg/cm^2 \qquad (217)$$

Here E - modulus of elasticity of material, kg/cm²; s - the wall thickness of vessel (without addition C), cm; r - the mean radius of vessel, cm; μ - Poisson ratio; z_s - yield point of material, kg/cm².

The margin of the stability of the vessel:

$$m = \frac{p_{\kappa p}}{p}.$$

where p - external overpressure of medium, kg/cm²; m⩾4 - for the vertical vessels; m⩾5 - for the horizontal vessels.

Page 166.

Thick-walled steel cylinders, subjected to internal pressure.

If the wall thickness of cylinder exceeds 10o/o of the cylinder

bore, then its calculation is produced according to the formula of

the thick-walled vessels:

$$s = \frac{r}{\varphi}\left(\sqrt{\frac{R_s + p}{R_s - p}} - 1\right) + C \ \textit{cm}, \qquad (218)$$

where r - an inside radius of apparatus, cm; φ - modulus of

resistance of the weld; R_s - permissible tensile stress, kg/cm²; p -

internal overpressure, kg/cm²; C - addition which during the

calculation of the thick-walled cylinders can be placed of the equal

to zero.

If calculation is produced on allowable stress R_s, selected on

the yield point σ_s, then the wall thickness of cylinder will be

determined according to the formula

$$s = r\left(\sqrt{\frac{100\varphi R_s}{100\varphi R_s - \sqrt{3p}}} - 1\right) \ \textit{mm}, \qquad (219)$$

where σ_s - yield point of material, kg /mm².

Remaining designations the same as in formula (218).

Cylindrical wall, included between the rings of rigidity.

If the apparatus, which works under the external overpressure, is equipped with the rings of rigidity, then the cylindrical wall between them works on the bend.

Stress/voltage on the bend in the cylindrical wall between the rings of the rigidity:

$$R_b = \frac{1.5p \sqrt{Ds_1}}{0.643 + \frac{s_1 \sqrt{Ds_1}}{F}} \sqrt{\frac{D^2 s_1^2}{3(1-\mu^2)}} \; kg/cm^2 \qquad (220)$$

where p - external overpressure, kg/cm^2; D - diameter of cylinder in the light/world, cm. s_1 - wall thickness without addition C, cm: for valve apparatuses $s_1 = s-C$, for welded joints $s_1 = \phi(s-C)$; F - cross-sectional area of the ring of rigidity (cm^2) without taking into account addition C; μ - Poisson ratio (Table 38).

Rings of the rigidity of cylindrical wall.

Load on 1 running cm of the length of the circumference of the ring of the rigidity:

$$q = \frac{p \sqrt{Ds_1}}{0.643 + \frac{s_1 \sqrt{Ds_1}}{F}} \; kg/cm. \qquad (221)$$

Page 167.

Critical load on 1 running cm of the circumference of the ring

$$p_{\kappa p} = \frac{3EI}{R} \quad kg/cm \qquad (222)$$

where E - modulus of elasticity, kg/cm^2; I - moment of the inertia of the transverse ring of rigidity, cm^4; R - radius of ring on the neutral line, cm.

Critical load on 1 running cm of the circumference of the ring of rigidity, supported at several points (considering its part as circular arch with the supported ends):

$$p_{\kappa p} = \frac{EI}{R^3}\left(\frac{4\pi^2}{a^2} - 1\right) kg/cm \qquad (223)$$

where a - a central angle between the supports of ring in the portions π

$$\pi = \angle a = 180°.$$

Reserve of resistance to the indentation of the ring:

$$m = \frac{p_{\kappa p}}{q} > 5.$$

Compression stress in the ring over the diametric section/cut:

$$R_d = \frac{qD_{\pi}}{2F} \quad kg/cm^2 \qquad (224)$$

where D_{π} - outside diameter of ring, cm.

If ring is carried cut with the ellipticity, which does not exceed 1o/o of its nominal bore, then the maximum bending moment in the ring can be determined according to Pedctcv's formula:

$$M = 66pl \left(\frac{r}{100} \right)^2 \text{ kq} \cdot \text{cm} \qquad (225)$$

where p — external overpressure, kg/cm^2; l — distance between rings, cm; r — inside radius cf apparatus, cm.

Stress/voltage cn the bend in the ring cf the rigidity:

$$R_b = \frac{M}{W} \text{ kg/cm}^2. \qquad (226)$$

where W — a general/common/total modulus of section of the ring of rigidity and adjacent tc it shell (with a length ~15   cm), cm^3.

Strength bending of the remaining part of the shell can be disregarded/neglected.

Total stress/voltage in the ring of the rigidity:

$$R_{cyм} = R_d + R_b \text{ kg/cm}^2. \qquad (227)$$

Page 168.

Tolerances for the cvality of welded cylinders are given in Table 53.

Table 53. Tolerances for the ovality of welded cylinders (according to the data of practice).

При диаметре цилиндра [1] D, мм	до 200	201—300	301—500	501—1000
[2] Допуск на овальность, % от D	1,5	1,0	0,75	0,5

Key: (1). With the diameter of cylinder. (2). Tolerance for ovality c/c from D.

§ 34. Calculation of the dished bottoms and covers/caps.

Bottoms must have a profile/airfoil of ellipse or curve, close one to the ellipse. The diagram of construction by this curve is given in Fig. 68.

Outside radius of the transfer arc of the bottom

$$r_{\text{и}} = \frac{\sqrt{(0.5D_{\text{н}})^2 + h} \cdot \sqrt{(0.5D_{\text{н}})^2 + h^2} - 0.5D_{\text{н}} + h}{D_{\text{н}}} \text{ мм.} \quad (228)$$

An outside radius of the convex part of the bottom

$$R_{\text{и}} = \frac{(0.5D_{\text{н}})^2 + h^2 - 0.5D_{\text{н}}r_{\text{и}}}{h} \text{ мм,} \quad (229)$$

where $D_{\text{и}}$ - outside diameter of bottom, mm; h - height/altitude of the convex part of the bottom on external surface, mm.
Fig. 68. Diagram of the plotting of curves of the dished bottom.

Page 169.

The dished bottoms whose different types are shown in Figs. 69, 70 and 71, must satisfy also the requirements, indicated in Table 54.
Fig. 69.

Notes: 1. Through hole must be arranged/located centrally.

2. Is not allowed/assumed arrangement of holes on transfer arc of bottom.

3. On cylindrical part is allowed/assumed drilling unit holes.

Key: (1). Height/altitude of the convex part of the bottom over the external surface of h. (2). Inside radius of convex part of bottom. (3). Outside radius of transfer arc of bottom. (4). Distance from edge of hole. (5). to edge of bottom (on projection) a. (6). to edge of another hole (on projection) к. (7). prior to beginning of flanging of through hole. (8). Not less. (8a). and. (9). Not more. (10). Not less than diameter of smaller hole (with unfastened/unstrengthered holes).

Page 170.

The wall thickness of the dished bottom is determined from the formula

$$s = \frac{D_{\text{н}} p y}{200 R_z} + C \text{ мм,} \qquad (230)$$

where $D_{\text{в}}$ - outside diameter of housing, мm; p - design pressure, kg/cm² [see value of p to the formula (213)]; y - form factor of the bottom; values y in depending on the value of relation $\frac{h}{D_{\text{в}}}$ and of character of weakening bottom by holes $\frac{l+d}{D_{\text{н}}}$ are given in Table 55; in the latter/last relation l - a distance from the axis/axle of bottom to the axis/axle of hole, mm; d, d_1, d_2 (Figs 70 and 71) - diameters of holes, mm; is accepted greatest; R_z - permissible tensile stress; it is selected in depending on the temperature of wall according to the data of Table 56; C - addition to the calculated thickness: C=3 мm; for the anechoic bottoms in calculated wall thickness to 17 mm C=2 мm and for the bottoms, manufactured from steel casting, C=5 мm.

0,50	0,75	0,90	1,05	1,20	1,40	1,60	1,75	1,95

Notes: 1. "Anechoic" is called the bottom, which has no holes (cutouts).

2. For intermediate values $\frac{h}{D_м}$ and $\frac{l+h}{D_м}$ form factor is determined by interpolation.

Key: (1). Ratio of the height/altitude of bottom to its diameter. (2). Form factor. (3). bottom anechoic or of that considered as anechoic. (4). bottom with through or other holes with relation. (5). equal.

Page 171.

The wall thickness of the spherical bottom

$$s = \frac{pr}{200\,R_z} + C \text{ мм},$$

where r - an inside radius of sphere, mm; p, R_z and C - the same as in formula (230).

During the calculation of the wall thickness of the bottoms, subject to internal pressure at normal temperature (cistern and other vessels, which work under conditions, close to body constructions/designs), the allowable stress takes as the equal to:

$$R_z = 0.6\sigma_s, \quad \text{kg/cm}^2$$

where σ_s - yield point of material at normal temperature, kg/cm².
Table 56. Values of allowable stresses for calculating the thickness of bottoms and covers/caps, subjected to internal pressure.

(7) От 250 до 400	$\dfrac{\sigma_s^t}{1,25}$	$\dfrac{\sigma_s^t}{1,9}$	$\dfrac{\sigma_s^t}{1,4}$
(8) Более 400	$\dfrac{\sigma_s^t}{1,25}$; $\dfrac{\sigma_n^t}{0,9}$ *	$\dfrac{\sigma_s^t}{1,9}$; $\dfrac{\sigma_n^t}{1,4}$ *	$\dfrac{\sigma_s^t}{1,4}$; $\dfrac{\sigma_n^t}{0,9}$ *

The designations: σ_b - the limit of the strength of metal to the elongation at temperature of 20°C, kg /mm²; σ_s^t - yield stress of metal at temperature t, kg /mm²; σ_n^t - creep limit of metal at temperature t, kg /mm².

Key: (1). Temperature of wall. (2). Allowable stress R_2 kg /mm². (3). for stamped/die-forged bottoms. (4). for cast bottoms. (5). for flat/plane covers/caps.

FOOTNOTE ¹. Is taken small value. ENDFOOTNOTE.

Additional requirements for the dished bottoms.

1) Bottoms are considered as "anechoic" in the following cases:

a) when the maximum size of the unfastened/unstrengthened cutouts it does not exceed 4s with the condition that the distance between the edge of cutout and the edge of bottom (on the projection) comprises less than 0.2 $D_н$;

b) when the maximum size of the completely fastened/strengthened cutouts it does not exceed 8s and the distance between the edge of cutout and the edge of bottom (on the projection) exceeds 0.2 $D_н$;

Page 172.

c) when the maximum size of the completely fastened/strengthened cutouts does not exceed 6s and the distance between the edge of cutout and by the edge of bottom (on the projection) it exceeds 0.1 $D_н$;

2. The stamped edges of through hole reinforcement are not considered.

3. Holes in bottoms can be arranged/located out of zone of transfer arc at a distance not less than s from end of this arc.

4. Hole in center cf flanged bottom outside can be carried out by diameter to 450 mm without special strengthening.

5. Height of cylindrical side cf bottom H must be equal at thickness of bottom: to 10 mm - not less than 25 mm, from 10 to 20 mm - not less than 40 mm, more than 20 mm - according tc thickness cf bottom, but not less than 50 mm.

6. Thickness of cylindrical part of bottom must correspond tc calculated thickness of cylindrical housing cf vessel of the same diameter. In this case the turned edge must comprise not less than 0.9 thickness of bottom.

7. For welded bottoms into denominator cf formula (230) is introduced modulus of resistance of weld ϕ, taken on Table 50.

Cished bottoms, subjected tc ambient pressure.

The wall thickness cf the bottom

$$s = \frac{1.4pD_ny}{200R_d} + C \ \text{мм,} \qquad (231)$$

where R_d - permissible compression stress, kg /mm².

Remaining designations and structural/design requirements are the same as for the bottoms, subjected tc internal pressure.

Breaking stress in the bottoms, which work under the ambient pressure, relies on stability.

For the spherical bottoms

$$p_{\text{кр}} = \frac{2E}{\sqrt{3(1-\mu^2)}} \left(\frac{s}{r}\right)^2 \quad kg/cm^2. \qquad (232)$$

For the hemispheric ends

$$p_{\text{кр}} = \frac{k_1 k_2 \sigma_s}{\frac{r}{s} + \frac{\sigma_s}{k_2 E}\left(\frac{r}{s}\right)^2} \quad kg/cm^2. \qquad (233)$$

Here E - modulus of elasticity of material, kg/cm^2; μ - Poisson ratio; s - the wall thickness of bottom, cm; r - the mean radius of bottom, cm; $k_1 = 1.5$; $k_2 = 40$ - for the stamped/die-forged bottoms from the whole sheet; $k_1 = 1.1$; $k_2 = 20$ - for the stamped/die-forged bottoms from the welded segments; $k_1 = 0.75$; $k_2 = 12$ - for the tapped bottoms of the welded segments; σ_s - yield point of material, kg/cm^2.

Page 173.

The margin of the stability of the bottom

$$m = \frac{p_{\text{кр}}}{p} > 5,$$

where p - external overpressure, kg/cm².

Plate covers/caps, subjected to internal pressure.

The plate covers/caps, subjected to internal pressure (Fig. 72), are designed from the formula

$$\sigma = \frac{3}{\pi(s-C)^2}\left[\frac{0.18P_6(r^2-a^2)}{d^2} + 1.48P_6\lg\frac{r}{a}\right] +$$
$$+ \frac{pR}{2\varphi(s-C)} \; kg/cm^2, \qquad (234)$$

where σ - stress/voltage in the cover/cap, kg/cm²; s - thickness of cover/cap, cm; r - radius of a circle of bolts, cm; C - addition, cm; P_6 - load on all bolts, kg; a - distance from the axis/axle of cover/cap to the line of centers of packing, cm; d - external radius of the flange of cover/cap, cm; p - design pressure, kg/cm²; R - radius of the spherical segment of cover/cap, cm; φ - modulus of resistance of weld.

Allowable stress in the cover/cap is selected on the basis of the safety factors to the elongation; for the limit of strength $n_b = 4$, for the yield point $n_\tau = 1.8$.
Fig. 72. On the calculation of plate covers/caps.

Page 174.

In the plate covers/caps the cutouts in diameter to 50 mm do not require reinforcement with the condition of the sufficient clearance (not less than s) between the edge of cutout and weld, which connects spherical segment to the flange or cover/cap. Holes whose diameter is more than 50 mm are subject to reinforcement.

Conical bottoms, subjected to internal pressure.

1. Vessel is found under internal pressure of vapors or gases. Maximum tensile stress along the generatrix of the cone:

$$R'_s = \frac{pD}{2\varphi'(s - C)\cos\alpha} \quad \text{kg/cm}^2. \qquad (235)$$

Maximum tensile stress on the circular weld of the cone:

$$R'_z = \frac{pD}{4\varphi''(s-C)\cos\alpha} \quad \text{kg/cm}^2. \qquad (236)$$

2. Vessel is filled with liquid to specific maximum altitude. Fig. 73 depicts vessel with a bore of D, conical bottom with a height/altitude of h_2 and central by angle 2α, filled with liquid on the height/altitude of cylindrical part, equal to h_1.

Maximum tensile stress along the generatrix of the cone:

$$R'_z = \frac{\gamma D}{2\varphi'(s-C)\cos\alpha}h_1 \quad \text{kg/cm}^3. \quad (237)$$

Maximum tensile stress on the circular weld of the cone:

with $h_1 < h_2/3$

$$R'_z = \frac{3}{32}\frac{\gamma D}{\varphi'(s-C)\cos\alpha}(h_1 + h_2) \quad \text{kg/cm}^3 \qquad (238)$$

with $h_1 > h_2/3$

$$R'_z = \frac{\gamma D}{12\varphi'(s-C)\cos\alpha}(3h_1 + h_2)^2 \quad \text{kg/cm}^2. \qquad (239)$$

In formulas (235)-(239): p - internal pressure in the vessel, kg/cm²; D - bore of vessel, cm; s - the wall thickness of conical bottom with the addition, cm; C - addition to the corrosion, etc.,

cm; ϕ' - modulus of resistance of weld along the generatrix of the cone; ϕ'' - the modulus of resistance of weld across the generatrix of the cone; α - halves central angle in the degrees; γ - the specific gravity/weight of liquid, kg/cm^2; h_1 - the maximum altitude of liquid in the cylindrical part, cm; h_2 - height/altitude of conical bottom from the apex/vertex to the base/root, *cm.*
Fig. 73. On the calculation of conical bottoms.

Page 175.

3. Vessel is filled with liquid above mirror of which occurs pressure of vapors or gases. In this case the calculation is conducted according to formulas (235) and (236), only instead of p in them is substituted the total pressure of liquid column and pressure in the vessel (kg/cm^2).

§ 35. Calculation of flat/plane walls, covers/caps and bottoms.

Flat/plane walls and covers/caps without the reinforcements.

The thickness of the rectangular wall, attached on the perimeter (Fig. 74),

$$s = 0.53b \sqrt{\frac{p}{R_b\left(1+\frac{b^2}{a^2}\right)}} + C, \, мм, \qquad (240)$$

where p - pressure on the wall, kg/cm^2; b - smaller side of

rectangle, mm; R_b - allowable stress on the bend, kg/cm², equal to $\frac{\sigma_b}{4}$ for steel and $\frac{\sigma_b}{5}$ for the nonferrous alloys; here σ_b - the limit of the strength of material at operating temperature, kg/cm²; a - large side of rectangle, mm; C - addition, mm.
Fig. 74.
Fig. 75.

Fig. 74. On calculation of rectangular wall.

Fig. 75. On calculation of elliptical or oval wall.

Page 176.

The thickness of the elliptical or oval wall, attached on the perimeter (Fig. 75),

$$s = b \sqrt{\frac{1,8p}{R_b\left(1 + \frac{2}{3}\frac{b^2}{a^2} + \frac{b^4}{a^4}\right)}} + C \text{ мм}, \qquad (241)$$

where a - a semimajor axis of ellipse, mm; b - semiminor axis of ellipse, mm.

Remaining designations the same as in formula (240).

Thickness of circular flat/plane covers/caps and bottoms (Fig. (76)

$$s = d\sqrt{\mu \frac{p}{R_b}} + C \text{ см}, \qquad (242)$$

where d - a diameter of cover/cap or bottom, cm; p - maximum operating pressure, kg/cm^2; $\dot{R}_b$ - allowable stress on the bend, kg/cm^2 [see formula (240)]; C - audition to corrosion, cm [see formula (230)]; μ - coefficient, equal to:

For the covers/caps, rigidly connected or the bolts or attached to the flanges of housing (Fig. 76a), and also for flat/plane bottoms, which compose one whole with the housing of apparatus (Fig. 76b) ... 0.162.

For the plates, rigidly attached on their contour/outline ... 0.187.

For the forged (pulled) bottoms, which compose one whole with the housing or welded with it butt (Figs. 76c and d) ... 0.250.

For the covers/caps, which undergo preliminary bend from the tightening of bolts, with the presence of the sealing projection on the cover/cap or the flange of housing (Fig. 76e) ... 0.300.

For the covers/caps, welded all over thickness to the internal surface of housing (Fig. 76f); in this case weld throat it must be not less than 1.25 the thinnest wall thicknesses of housing or bottom ... 0.500.
Fig. 76. On the calculation of the thicknesses of circular flat/plane covers/caps and bottoms.

Page 177.

The thickness of the flat/plane stamped/die-forged bottom with the bent back edges, subjected to internal pressure (Fig. 77),

$$s = \sqrt{\frac{3p}{800\sigma_b}}\left[d - r_i\left(1 + \frac{2r_i}{d}\right)\right]_{\text{мм}},$$

(243)

where p - great design pressure, kg/cm^2; σ_b - limit of the strength of material, kg /mm²; d - bore of bottom, mm; r_i - inside radius of transfer arc from cylindrical part to the flat/plane, mm. Value r_i must be not less than 1/15 d.

Round plate with the hole in the center, attached on the

external and internal contours/cutlines and subjected to bending by the evenly distributed load.

Maximum stress/voltage in the plate:

$$R_{max} = k_1 \frac{qr_n}{s^2} \text{ kg/cm}^2. \qquad (244)$$

Greatest sagging of the plate:

$$f_{max} = k_2 \frac{qr_n^2}{Es^3} \text{ cm.} \qquad (245)$$

Here q - intensity of load, kg/cm²; r_n - outside radius of plate, cm; s - thickness of plate, cm; E - modulus of elasticity of material, kg/cm²; k_1 - dimensionless voltage ratio, it is determined on Fig. 78, in depending on the ratio of an outside radius of plate r_n to a radius of hole r_m; k_2 - a dimensionless coefficient of the sagging/deflection; it is determined on Fig. 79 in depending on ratio r_n and r_m.

Initial data for the plotting of curves of the dimensionless voltage ratios and sagging are the fundamental equations of the theory of the bend of plates:

1) momental equation for the meridian cut;

2) the equation of the angle of the tangent inclination of the elastic line;

3) the equation of elastic line (equation of sagging).
Fig. 77. On the calculation of the flat/plane stamped/die-forged bottoms with the bent back edges.

Page 178.

Flat/plane walls, fastened by spacing or anchor bolts.

Wall thickness during the even distribution of the fastenings

$$s = C\sqrt{p(a^2 + b^2)} \; \text{мм.} \qquad (246)$$

Wall thickness during the nonuniform distribution of the fastenings

$$s = 0.5C(d_1 + d_2)\sqrt{p} \; \text{мм,} \qquad (247)$$

where C - the calculated coefficient, taken on Table 57; p - great design pressure, kg/cm^2; a - distance between spacing or anchor bolts in one series/row (Fig. 80), mm; b - distance between the series/rows of spacing or anchor bolts (Fig. 80), mm; d_1, d_2 - distance between fastenings (Fig. 81), mm.
Fig. 78.

Key: (1). Coefficient of sagging/deflection. (2). Ratio.
Fig. 80.
Fig. 81.

Fig. 80. Evenly distributed fastenings.

Fig. 81. Unevenly distributed fastenings.

Page 179.

Formulas (246) and (247) are derived into the assumptions that the walls made of steel have limit of the strength of material $\sigma_b = 36$ kg /mm². With accomplishing of walls with the large limit of the strength of material their thickness must be reduced by the multiplication of value s on $\sqrt{\frac{36}{\sigma_b}}$.

If the temperature of the medium, which washes wall, is more than 230°C, calculation is conducted taking into account the temperature.

Flat/plane wall, reinforced by stiffening ribs (Fig. 82). A number of transverse and longitudinal edges/fins, and also their

size/dimension and profile/airfoil are selected from the conditions
of allowable stresses in the material of wall and edges/fins. Usually
as the edges/fins are considered angle plates.

Calculation is conducted according to the greatest side of
flat/plane wall.

Let us introduce the following designations: p - design pressure
on the wall, kg/cm^2; a - large side of the rectangle of wall,
included between the edges/fins, cm; b - smaller side of the same
rectangle of wall, cm; h - height of edge/fin, cm; ℓ - length of
edge/fin along the greatest side of wall, cm; B - width of band,
equal to side of rectangle, arranged/located along the length of
edge/fin ℓ, *cm.*

Table 57. Values coefficient C.

(1) Значения C	(2) Условия работы плоских стенок
0,017	(3) Для омываемых горячими газами и водой стенок, в которые ввертываются на резьбе распорные или анкерные болты и расклепываются
0,015	(4) Для таких же стенок, но не омываемых горячими газами
0,0155	(5) Для омываемых горячими газами и водой стенок, в которые ввертываются на резьбе распорные или анкерные болты с наружными гайками или точеными головками.
0,0135	(5) Для таких же стенок, но не омываемых горячими газами
0,014	(6) Для стенок, скрепленных только анкерными трубками
0,013	(7) Для неомываемых горячими газами стенок, имеющих анкеры, снабженные гайками и скрепляющими шайбами, при этом диаметр наружной скрепляющей шайбы равен ²/₅ расстояния между анкерами и толщина шайбы равна ²/₃ толщины стенки
0,012	(8) Для таких же стенок, но диаметр наружной скрепляющей шайбы равен ³/₅ расстояния между анкерами и толщина шайбы равна ⁵/₇ толщины стенок
0,011	(9) Для таких же стенок, но диаметр наружной скрепляющей шайбы равен ⁴/₅ расстояния между анкерами и шайбой, толщина которой равна толщине стенки и которая приклепана к этой стенке

Key: (1). Values. (2). Working conditions of flat walls. (3). For washed by hot gases and water walls, into which are screwed in on thread spacing or anchor bolts and are unriveted. (4). For the same walls, but not washed by hot gases. (5). For washed by hot gases and water walls, into which are screwed in or thread spacing either anchor bolts with external nuts or exact heads. (6). For walls, fastened only by stay tubes. (7). For walls unreached by hot gases, which have anchors, equipped with nuts and fastening washers, in this case diameter of external fastening washer is equal to 2/5 distances between anchors and thickness of washer is equal to 2/3 wall thicknesses. (8). For the same walls, but diameter of external fastening washer is equal to 3/5 distances between anchors and

thickness of washer is equal to 5/6 wall thicknesses. (9). For the same walls, but diameter of external fastening washer is equal to 4/5 distances between anchors and washer whose thickness is equal wall thickness and which is riveted to this wall.

Page 180.

F_1 - cross-sectional area of edge/fin, cm^2; X_1X_1 - centroidal axis of the section/cut of the edge/fin; X_2X_2 - centroidal axis of the section/cut of the band of the flat/plane wall; XX - centroidal axis of section of band and edge/fin; OO - axis/axle of the base/root of the band; I_{x_1} - second moment of area of edge/fin relative to axis/axle X_1X_1, cm^4; it is determined from the tables for the profile/airfoil accepted and the size/dimension of the edge/fin; Z_0 - distance of the apex/vertex of edge/fin from axis/axle X_1X_1, cm; s - thickness of rectangular wall, included between the stiffening ribs, it is determined by formula (240), cm;

Y_1 - distance of axis/axle X_1X_1 from axis/axle OO

$$Y_1 = h + s - Z_0 \ cm;$$

Y_2 - distance of axis/axle X_2X_2 from axis/axle OO

$$Y_2 = 0,5s \ cm;$$

F_2 - cross-sectional area of the band

$$F_2 = Bs \ cm;$$

Z – distance of the neutral axis/axle XX from axis/axle OO

$$Z = \frac{F_1 Y_1 + F_2 Y_2}{F_1 + F_2} \ c_M;$$

a_1 – distance between centers $X_1 X_1$ and XX

$$a_1 = Y_1 - Z \ c_M;$$

a_2 – distance between centers $X_2 X_2$ and XX

$$a_2 = Z - Y_2 \ c_M;$$

Y_3 – distance of the outermost filament from axis/axle XX

$$Y_3 = s + h - Z \ c_M.$$
Fig. 82. On the calculaticn of the flat/plane wall, reinforced by stiffening ribs.

Key: (1). On.

Page 181.

Load, which effects on the edge/fin and the band,

$$Q = lBp \quad \text{kg.} \qquad (248)$$

Greatest bending moment, which effects on the edge/fin and the band,

$$M = \frac{Ql}{12} \quad \text{kg·cm.} \qquad (249)$$

Second moment of area cf band relative to axis/axle $X_2 X_2$

$$I_{x_1} = \frac{Bs^3}{12} \quad \text{cm}^4. \qquad (250)$$

Second moment of area of edge/fin relative to axis/axle XX

$$I_1 = I_{X_1} + a_1^2 F_1 \ \text{cm}^4. \qquad (251)$$

Second moment of area of band relative to axis/axle XX

$$I_2 = I_{X_2} + a_2^2 F_2 \ \text{cm}^4. \qquad (252)$$

Total moment of the inertia of edge/fin and band relative to axis/axle XX

$$I = I_1 + I_2 \ \text{cm}^4. \qquad (253)$$

Stress/voltage, which appears in the edge/fin from the action of moment/torque M,

$$R_s = \frac{M Y_s}{I} \ \text{kg/cm}^2. \qquad \bullet \qquad (254)$$

Stress/voltage, which appears in the band from the action of moment/torque M,

$$R_s = \frac{M Z}{I} \ \text{kg/cm}^2. \qquad (255)$$

Walls and reinforcements of rectangular vessels.

During determining of the dimensions of rectangular vessels they use predominantly the relationships/ratics

$$B = \sqrt{V}; \quad L = \frac{3}{2} B; \quad H = \frac{2}{3} B,$$

where B - the width; L - length; H - height/altitude; V - volume.

The pressure of liquid on the wall of the vessel

$$p = 0.85 \gamma H \quad kg/cm^2 \qquad (256)$$

where γ - the specific gravity/weight of liquid, kg/cm^3; H - height of liquid column, cm.

Page 182.

The wall thickness of the vessel:

$$s = \sqrt{\frac{3pL^2H^2}{8R_b(H^2+L^2)}} + C \; cm,$$ (257)

where L - length of wall, or distance between upright struts, cm;

H - height/altitude of wall, or distance between horizontal stiffeners, cm;

R_b — allowable stress on the bend, kg/cm²;

C - addition to the corrosion, see

The moment of resistance of the upright strut:

$$W = \frac{\gamma LH^3}{16R_b} \; cm^3,$$ (258)

where γ - the specific gravity/weight of liquid, kg/cm³;

L - distance between struts, cm;

H - height of vertical wall, cm;

R_b — allowable stress on the bend of the material of strut, kg/cm².

At the calculated moment of resistance is selected the corresponding section/cut of strut.

Length of horizontal stiffener or distance between connections/communications, which fasten horizontal stiffeners, in the presence of one series/row of horizontal reinforcements on the height/altitude:

$$L = \frac{4}{H} \sqrt{\frac{R_b W}{\gamma}} \; cm. \qquad (259)$$

Length of lower horizontal stiffener or distance between connections/communications, which fasten lower horizontal stiffener, in the presence of two series/rows of horizontal reinforcements on the height/altitude:

$$L_1 = 4 \sqrt{\frac{R_b W}{\gamma \left(H - \frac{h_1 + h_2}{4}\right)\left(h_1 + h_2\right)}} \; cm. \qquad (260)$$

Length of upper horizontal stiffener or distance between connections/communications, which fasten upper stiffener, in the presence of two series/rows of horizontal reinforcements on the height/altitude:

$$L_2 = \frac{4}{H - \frac{h_1 + h_2}{2}} \sqrt{\frac{R_b W}{\gamma}} \; cm. \qquad (261)$$

Page 183.

Here W - moment of resistance of horizontal reinforcements, cm^3;

h$_1$ - distance from the bottom to the lower horizontal element/cell, cm;

h$_2$ - distance from the bottom to the upper horizontal element/cell, cm;

R_b, γ and H - the same as in formula (258).

The distance between the beams/gullies under the bottom of the vessel:

$$l = 1.254s \sqrt{\frac{R_b}{\gamma H}} \ cm, \qquad (262)$$

where s - the wall thickness of bottom without additive C, cm;

R_b, γ and H - the same as in formula (258).

During the calculation of the thicknesses of walls and bottom of welded rectangular vessel the modulus of resistance of weld φ it is possible not to consider under the condition for the arrangement of weld at a distance of 1/4 flight/span between the struts or the beams/gullies where the bending moment has minimum absolute value.

Rectangular chambers/cameras, subjected to internal pressure.

The thickness of wall s of rectangular chamber/camera is determined on the stresses/voltages, which appear in the angle of chamber/camera, and on the stresses/voltages, which appear in the most weakened section/cut of wall (Fig. 83).

For the first case

$$s = \frac{p}{200R} \sqrt{m^3 + l^2} + \sqrt{6M_\bullet \frac{p}{100R}} \quad \text{мм.}$$

(263)

For the second case

$$s = \frac{p}{200R} \frac{l}{\varphi} + \sqrt{\frac{6M_\bullet}{\varphi'} \frac{p}{100R}} \quad \text{мм.} \quad (264)$$
Fig. 83. On the calculation of rectangular chambers/cameras.

Page 184.

Here p - design pressure of medium, kg/cm^2;

R - allowable stress, kg/cm^2 (it is accepted on Tables 56):

M_a — conditional bending moment in the angle of chamber/camera (referred to the unit of length and to the pressure 100 kg/cm^2), determined according to the formula

$$M_a = \frac{1}{3} \frac{m^2 + l^2}{m + l} \text{ } MM^2;$$

M_b — the conditional bending moment in any place of the designed side of chamber/camera (referred to the unit of length and to the pressure 100 kg/cm^2), determined according to the formula

$$M_b = ma - \frac{a^2}{2} - \frac{1}{3} \frac{m^2 + l^2}{m +} \text{ } MM^2.$$

m - half-width in the light/world of the designed side of

chamber/camera, mm;

l — half-width in the light/world of the side, perpendicular to that designed, mm;

a - small distance from the internal surface of side wall to the axis/axle of weakening (hole or weld), mm;

ϕ - coefficient of strength of weld, it is accepted on tables 50;

ϕ' - coefficient of weakening bore surface, equal to

$$\varphi' = \frac{t-d}{t},$$

where t - pitch of holes, mm;

d - diameter of holes, mm.

§36. Calculation of the unfastened/unstrengthened and fastened/strengthened holes.

Unfastened/unstrengthened holes.

Unfastened/unstrengthened are considered: a) hole under the rolling-out and the thread; b) hole packed with access or other

gates; c) the holes, intended for the connection of tubes, branches, bushings and the like on the victuals, if the construction/design of welds does not provide the joint operation of the welded elements/cells with the vessel.

The permissible greatest diameter of unfastened/unstrengthened holes $d_н$ will be determined according to the formula

$$d_н = 8,1 \sqrt[3]{D_в s (1-k)} \ \textit{мм,} \qquad (265)$$

where $D_в$ — bore of housing, mm;

s - the wall thickness of housing, mm;

k - real modulus of resistance of vessel, determined in the formula

$$k = \frac{pD_в}{(200R_s - p)s} < 0,99,$$

where p - design pressure in the housing, kg/cm²;

$\dot{R}_s$ — permissible tensile stress, kgf/mm².

Page 185.

In all cases the greatest diameter of the

unfastened/unstrengthened hole must not exceed

$$d_{u} \leqslant 0.6 D_{o} \quad \text{и} \quad d_{u} \leqslant 200 \, \text{мм}.$$
Key: (1). and.

For the elongated holes value d_{u} must be replaced by the length of the large axis/axle of oval.

In the presence in vessel of the unfastened/unstrengthened holes the hydraulic test must be produced under the pressure, which does not exceed 1.5p, otherwise of hole preliminarily they must be fastened/strengthened.

Fastened/strengthened holes.

The sizes/dimensions of the reinforcements of holes usually are selected from the following relationships/ratios:

$$D > 2d; \quad b > 2s; \quad s \leqslant 2.5 s_{1.}$$

where D - an outside diameter of fastening ring, cm;

d - bore of fastening ring, cm;

b=0.5(D-d) - the width of the fastening ring, cm;

s - thickness of the fastening ring, cm;

s_1 - the wall thickness of housing, ~~see~~ cm

The outside diameter of the fastening ring is determined by the formula:

$$D = \frac{d_1 (s_1 - C - C_1) \varphi}{s} + d \; cm, \qquad (266)$$

where d_1 - a diameter of hole in housing, cm;

C - addition to corrosion, cm;

C_1 - structural/design or production addition, cm;

φ - modulus of resistance of weld.

1. If reinforcement of hole is fastened to rivets, then diameter of reinforcing ring, determined according to formula (266), must be increased to $n\delta$, where n - number of holes under rivets, intersected by critical section/cut of reinforcement, and δ - diameter of rivet holes, cm.

2. If housing of apparatus is carried out unwelded or if with welded housing weld intersects by hole, then in this case into

formula (266) is substituted modulus of resistance of weld $\phi=1$.

3. If to small hole is connected thick-walled branch connection
without fastening finger/pin, then satisfactoriness of reinforcement,
imparted by branch connection to hole, can be checked according to
formula (266), in this case instead of size/dimension of d_1 is
substituted bore of branch connection $d_{вн}$ and for size/dimension of
s_1 - height/altitude of branch connection, equal to 2.5 (s_1-C), cm.

Page 186.

4. If hole has not circular, but elliptical or rectangular form,
then instead of diameter of hole d_1 into formula (266) is substituted
its greatest size/dimension (with exception of case, presented in p.
5) and respectively is determined greatest outside dimension of
reinforcement of hole.

5. If on cylindrical housing is arranged/located elliptical or
rectangular hole whose major axis perpendicular to axis/axle of
cylinder (Fig. 84), then instead of maximum size of hole is
substituted either its width b or half length $l/2$, in depending on
that which of values is more.

§37. Calculation of the riveted seams.

The diameter of rivets is determined on the empirical formulas for the single-sheet welds (overlapping or with one cover plate):

$$d = \sqrt{5s} - 0,4 \ cм, \qquad (267)$$

where s - a thickness of sheets, see

Spacing of the rivets:

1) for the single-row weld (Fig. 85a)

$$t = 2d + 0,8 \ cм;$$

2) for the double-row weld with bussing arrangement of rivets (Fig. 85b)

$$t = 2,6d + 1,0 \ cм;$$

3) for the double-row weld with the staggered arrangement of rivets (Fig. 85c)

$$t = 2,6d + 1,5 \ cм.$$

Distance from the edge of sheet to the center of the rivet:

$$a = 1,5d + 1,6d \ cм.$$

Distance between the rows of rivets with their bussing arrangement:

$$a_1 = 0,8t \ cм.$$

Distance between the rows of rivets with their staggered arrangement:

$$|a_2 = 0,6t \ cм.$$

Coefficient of weakening the sheets:

$$\varphi = \frac{t - d}{t}.$$
Fig. 34. On the calculation of the reinforcements of holes.

Page 187.

The force, which falls on 1 cm of weld length:

$$P = \frac{p_0 D}{2} \; \text{кг/см},\qquad\qquad (268)$$

Key: (1). the kg/cm

where p_0 - high design pressure in the housing, kg/cm²;

D - bore of housing, cm.

The permissible force P must not exceed:

For the single-row welds kg/cm P<500

For the double-row welds with the staggered arrangement of

rivets P=390-950

For the double-row welds with bussing arrangement of rivets
P=390-1000.

Specific sliding resistance:

$$k = \frac{Pt}{0.7h \varkappa l^3} \ \varkappa z \ cm^3. \qquad (269)$$

Key: (1). kg/cm².

Permissible specific sliding resistance for single-row welds

$$k \leqslant 700 \ kg/cm^2.$$
Fig. 85. On the calculation of the riveted seams.

Page 188.

§38. Calculation of tubes.

The wall thickness of the tube

$$s = \frac{p/n}{2 z_b \varphi} + C \ cm,$$ (270)

where p - maximum operating pressure, kg/cm²;

d - bore of tube, cm;

σ_b — limit of the strength of the material of tube, kg/cm^2;

φ - modulus of resistance of weld;

C - addition to the ovality, the corrosion, etc.;

n - safety factor, equal to:

For the liquids........ 4.5.

For vapor............. 5.6.

For superheated steam..... 7.1.

Tubes in wall thickness of less than 1 mm for the shipboard heat exchangers are not applied.

Thicknesses and outside diameters of tubes are accepted on the standards in the dependence on the internal diameters and the pressures.

The recommended tubes for the heat exchangers are shown in Table

58.

The passes of branch connections, welds, branches and the like
for the connection of tubes to the apparatuses take as the equal to
the internal diameters for the fittings, the fittings and the
conduits/manifolds (according to GOST 355-53, Table 59) whose strength
must be selected in depending on conditional pressures according to
GOST 356-52.

Maximum permissible bending deflection of tube $y_{max} = 2$ with mm.

Number of free oscillations/vibrations of the tube:

$$m = \frac{1}{2\pi} \sqrt{\frac{g}{y_0}} \ \textit{кол/сек,} \qquad (273)$$

Key: (1). osc./s.

where y_0 - a maximum bending deflection of tube, cm; $g = 981$ cm/s^2 - acceleration of gravity.

Test hydraulic pressure of the heating and cooling tubes of apparatuses and quite heat exchangers is designated according to GOST 2029-52.

§39. Calculation of bolts and pins.

Complete effort/force, which effects on all bolts from the internal pressure of medium,

$$Q = pF \ \textit{кг}, \qquad (274)$$

cf Key: (1). kg.

where p - the design pressure of medium, kg/cm^2;

F - area, limited by the centerline of packing, cm^2.

Calculated effort for one bolt with the arrangement of bolts in

the circumference (Fig. 86):

$$P_0 = \frac{kQ}{z} \; \text{кг.} \qquad (275)$$

Key: (1). kg.

Calculated effort/force to the most loaded bolt during the arrangement of bolts on the ellipse or rectangle with the relation of the sides of rectangle a/b<1.5 (Fig. 87):

$$P_0 = \frac{kptF}{2\pi r} \; \text{кг.} \qquad (276)$$

Key: (1). kg.

Page 192.

Calculated effort for one bolt during the arrangement of bolts on rectangle with the relation of its sides a/b≥1.5:

$$P_0 = kptr \; \text{кг,} \qquad (277)$$

Key: (1). kg.

where k - the coefficient of the tightening of bolt, which ensures the density of connection with the compression of the packing; k=1.8-2.0 at temperature of medium is less than 300°C; k=2.0-2.5 at temperature of medium is less than 300°C; k=2.0-2.5 at temperature of medium is more than 300°C;

z - number of bolts

$$z = \frac{U}{t},$$

where U - a perimeter cr tne line of the arrangement of bolts, cm:

for the circumference

$$U = \pi D_6;$$

for the rectangle

$$U = 2(a' + b');$$

for the ellipse

$$U = \pi \sqrt{2(a^2 + b^2)};$$

t - distance (space) between the bolts, cm, taken $t = (3.5 - 4\frac{0}{7}) d_0$ - for oils; $t = (4.0-5.0) d_0$ - for tne vapor, the water, the air, the fuel/propellant;

a - large side of rectangle (semi-axis of ellipse) between the centerlines of packing, cm;

a' - the same between the centerlines cf the arrangement of bolts, cm;

b - smaller side cf rectangle (semi-axis of ellipse) between the axial lines of packing, cm;

b' - the same between the centerlines of the arrangement of bolts, cm;

D_6 — diameter of a circle of the arrangement of bolts, cm;

r - small distance from the center of surface to the axis/axle of packing, cm;

d_0 - nominal diameter of the bolt

$$d_\bullet = 1{,}13 \sqrt{\frac{P_n n}{\sigma_\bullet}} + 0{,}5 \; cм, \qquad (278)$$

where $\sigma_\bullet$ — limit of the strength of the material of bolts, kg/cm²;

n - safety factor, taken:

For the precisely executed bolts and the bearing surfaces and the soft jointing material, and also for the cases when it is known that the material of bolts satisfies the technical specifications   5

For the well machined bolts and the surfaces and the soft jointing material 6.5

for the bolts, not not completely which do not satisfy the
conditions, presented with $n = 6.5$ 8

M48	8329	6581	4405	616	486	326

Notes: 1. Table is given for the bolts from the common bolt material St.4 and Steel 20. With the use of other materials the permissible loads and stresses/voltages for the bolts must be changed with respect to a change in the limits of the strength of materials.

2. With increase in temperature allowable stress in bolts and pins must descend in accordance with incidence/drop in limit of strength of material.

3. Sealing bolts in diameter less than 12 mm for shipboard

apparatuses are not applied.

4. Upon consideration of force of tightering of bolts permissible loads and stresses/voltages, indicated in table, must be increased to coefficient or tightening of bolts accepted.

Key: (1). Diameter of bolt d_0. (2). Permissible load in kg with n, equal. (3). Allowable stress in kg/cm² with n, equal.

Page 194.

Calculation of the fillet/shoulder of pin (Fig. 88):

Thickness of the fillet/shoulder of the pin

$$\delta = \frac{P_0}{\pi d_0 R_{cp}} \ cm.$$ (280)

Key: (1). cm.

Diameter of the fillet/shoulder of the pin

$$d_6 = \sqrt{d_0^2 + \frac{1.27 P_0}{R_{cm}}} \ cm.$$ (281)

Key: (1). cm.

Of uniform strength conditions of fillet/shoulder and pin the

sizes/dimensions of fillet/shoulder must not be less

$$\delta > \frac{d_6}{3}; \; d_6 > 1,4d_6.$$

Here $R_{c\varphi}$ — allowable stress in the fillet/shoulder on the shear/section, kg/cm², are accepted $R_{c\varphi} = 0,6 \; R_z;$

R_{cM} — allowable stress in the fillet/shoulder on the warping, kg/cm²; it is received $R_{cM} = 1,8 \; \dot{R}_z;$

R_z — permissible tensile stress, kg/cm².

Remaining designations the same as in the calculation of bolts.

The minimum distances between the bolts for the unscrewing of nuts normal flat/plane open-end wrenches are given in Table 63.

§40. Calculation of flanges.

Thickness of the circular cast flange (Fig. 89)

$$s = \sqrt{\frac{6P_n az}{\pi D_j R_b k}} + C \; cM. \qquad (282)$$

Key: (1). cm.
Fig. 88. On the calculation of the fillet/shoulder of pin.

Table 63. Minimum distances between the bolts.

d_0, м.м	6	8	10	12	14	16	(18)	20	(22)	24	27	30	36	42	48
t_1	26	31	35	42	45	52	60	60	74	71	82	92	106	119	132
t_2	30	35	39	48	52	56	67	67	80	80	89	98	114	130	145
c	12	13	15	18	20	21	25	25	30	30	33	36	41	46	50

The designations: d_0 - nominal diameter of bolt, mm;

t_1 - distance between centers during the removal/taking of the key/wrench upward, mm;

t_2 - distance between centers of bolts during the removal/taking of key/wrench to the side, mm;

c - distance from axis/axle of bolt to the wall, mm.

Page 195.

Thickness of circular welded flange (Fig. 90)

$$s = \beta \sqrt{\frac{P_0 (r_0 - r) t}{R_b (t - d) d}} + 1.2 \ cm. \qquad (283)$$

Key: (1). cm.

Formula (283) should be applied only for mean pressures and diameters, for other cases it is necessary to use formula (282).

Thickness of the rectangular (Fig. 91) or oval flange

$$s = \sqrt{\frac{6 P_0 a}{R_b (t - d) k}} + C \ cm. \qquad (284)$$

Key: (1). cm.

Thickness of the floating flange (Fig. 92)

$$s = 1.225 d_1 \sqrt{\frac{P_i a}{R_b (D - d_f - 2d)}} + C \ cm. \qquad (285)$$

Testing bending stresses in the critical section/cut of flange (Fig. 93) can be produced according to the following formulas.
Fig. 89. On the calculation of the circular cast flange.

Fig. 90. On calculation of circular welded flange.
Fig. 91. On calculation of rectangular flange.

Fig. 92. On calculation of floating flange.
Fig. 93. On calculation of critical section/cut of flange.

Page 196.

Bending stress in section/cut AB on the flange ridge

$$R_b = \frac{3P_0 z \left[r_0 - (r + s_2) \right]}{\pi (r + s_1) s^2} \ \kappa z / c \mathcal{M}^3. \qquad (286)$$

Key: (1). kg/cm².

Bending stress in section/cut AC on the groove of the flange

$$R_b = \frac{3P_0 z \left[2r_0 - (r + s_1 + r_1) \right]}{\pi (r + s_2 + r_1) s_1^2} \ \kappa z / c \mathcal{M}^3. \qquad (287)$$

Key: (1). kg/cm².

Testing flange joint to the density is determined from the formula

$$a = t \sqrt[4]{\frac{p}{s^3}}, \qquad (288)$$

where $\alpha \leqslant 10$ - for steel and bronze;

$\alpha \leqslant 7$ - for cast iron;

Here s - thickness of flange, cm (in the presence of groove in the critical section/cut the calculated thickness of flange must be increased at the depth of groove);

p - the design pressure of medium, kg/cm^2;

a - distance from the center of bolt hole to the wall (flanging or ring) of tube (arm of bend), of cm;

P_0 - calculated effort/force per one bolt, kg;

z - number of bolts;

D_1 - diameter of a circle of coupling flanged tube (critical section/cut), cm;

k - coefficient of the tightening of the bolts (see §39);

r_1 - radius of the outer edge of groove, cm;

s_1 - thickness of flange in the section/cut throughout the groove, cm;

s_2 - thickness of tube in the place of its coupling with the flange, cm;

r_0 - radius of a circle of the centers of bolt holes, cm;

r - inside radius of housing (tube), of cm;

D - outside diameter of flange, cm;

d_1 - diameter of the center line of packing, cm;

d_j — bore of flange, cm;

d - diameter of bolt hole, cm;

C - addition, cm;

t - distance between the bolts (space of bolts), cm;

β=0.43 - coefficient for the flanges, which are not subjected load from the pressure of the packing/seal (flanges with the packing, which pass all over end surface from the action of the tightening of bolts do not test stress/voltage on the bend);

β=0.6 - coefficient for the flanges, loaded on the bend with the action of the sealing pressure (flanges with the packing on the part of the end surface);

$R_0 = \frac{\sigma_b}{n}$ —allowable stress on the bend, kg/cm^2;

where s_b — limit of the strength of material, kg/cm²;

n - safety factor, taken

for the steel and bronze casting.· · · · · · · · 8

Page 197.

The calculation of flanges for rolling-cut, for thread, for rivets or combinations of them is produced according to formula (283) for the welded flanges.

Flanges for the branch connections of heat exchangers are accepted according to GOST to the flanges in the dependence on the internal diameter and the conditional pressure (GOST 355-52 and GOST 356-52).

§41. Calculation of the tube plates.

The tube plates are one of the most critical parts of tubular heat exchangers. Working conditions of the tube plates depend in essence on designation/purpose and construction/design of heat exchangers.

In the practice found use the stated below procedure of calculation of different tube plates, based on the theory of the bend of plates taking into account the basic special features/peculiarities of the design concepts of heat exchangers and working conditions for their.

Let us introduce the following conventional designations:

p - design pressure of medium, kg/cm^2;

s - thickness of the tube plate, cm;

r - calculated parameter of the attachments of the tube plate, cm;

r_1 - radius of a circle of bolt holes, cm;

b - smaller side of the rectangle, limited by the centerline of bolt holes, cm;

b_1 - smaller semi-axis of the ellipse, limited by the centerline of bolt holes, cm;

a - large side of the rectangle, limited by the centerline of bolt holes, cm;

a_1 - semimajor axis of the ellipse, limited by the centerline of bolt holes, cm;

D_1 — diameter of the center line of packing, cm;

$d_н$ — outside diameter of tubes, cm;

n - number of tubes;

t - space of tubes with their laying out on equilateral triangle, cm;

t_1 - space of the arrangement of tubes in the series/row, cm;

t_2 - space between the series/rows of tubes, cm;

d_0 - diameter of connection/communication on the female thread, cm;

z - number of connections/communications;

r_e - radius of a circle of the arrangement of connections/communications;

c_1 - distance between the centerline of bolt holes and extreme series/row of connections/communications, arranged/located along the large side of rectangle or ellipse, cm;

c_2 - distance between the series/rows of connections/communications, arranged/located along the large side of rectangle or ellipse, cm;

c_3 - distance between connections/communications in the series/row, cm;

L - calculated bond length (distance between the planes of framing), cm

Page 198.

Fig. 95. On calculation of circular tube plate, reinforced by connections/communications.

Key: (1). openings. (2). openings for connections/communications.

Page 199.

The thickness of the circular, rectangular and elliptical tube plates, not reinforced and reinforced by connections/communications,

is determined from the formula:

$$s = r \sqrt{\frac{\psi \varphi p}{\rho R_b}} + C \text{ см.} \qquad (289)$$

The calculated parameter of the attachment of tube plate r is selected on Tables 64 in depending on form and method of attachment.

Coefficient ψ, which considers the method of the attachment of the tube plate in depending on its form, is selected on Tables 65 and 66.

Table 64. Value of the calculated parameter r.

Форма и способ закрепления трубной доски (1)	r

Page 201.

The values of coefficient of ϕ are given as average values for the supported and jammed plate.

The coefficient of weakening the tube plate ϕ is determined from the following formulas.

During the laying out of tubes on equilateral triangle

$$\varphi = 1 - 0{,}905 \frac{d_н^2}{t^2}. \tag{290}$$

During-the corridor or checkered laying out of the tubes

$$\varphi = 1 - 0{,}785 \frac{d_н^2}{t_1 t_2}. \tag{291}$$

The values of coefficient ϕ in depending on the diameter of tubes and their space, that have great use/application, are given in Table 67.

Coefficient ε, considering a change of the specific load on the tube plate in the dependence on the diagram of heat exchanger, is determined on Tables 68.

Table 65. Value of coefficient of ψ.

Форма и способ крепления трубной доски (1)	(2) Значение ψ
Для круглой доски, не подкрепленной связями (рис. 94) (3)	0,5
Для круглой доски, подкрепленной анкерными или распорными связями (рис. 95) (4)	0,75
Для прямоугольной доски, не подкрепленной связями, значение ψ выбирается в зависимости от отношения сторон прямоугольника a/b (рис. 96) (5)	(6) По табл. 66
(7) Для эллиптической доски, не подкрепленной связями	$\psi = \dfrac{1,8}{1 + \dfrac{2}{3}\dfrac{b_1^2}{a_1^2} + \dfrac{b_1^4}{a_1^4}}$
Для прямоугольной и эллиптической доски, подкрепленной анкерными или распорными связями, значение ψ выбирается в зависимости от отношения стороны прямоугольника a или полуоси эллипса a_1 к расстоянию c_1 или c_2 (к большей величине), рис. 97 (8)	По табл. 66 (6)

Схема теплообменника и приложение нагрузки (1)	Значение ε (2)
Для трубных досок любой формы с пучком V-образных трубок (рис. 98) или пучком прямых трубок, один конец которых закреплен в неподвижной, а второй — в плавающей трубной доске (рис. 99) при действии нагрузки с любой стороны (3)	$\varepsilon = 1$
Для круглых трубных досок с пучком прямых трубок, один конец которых закреплен в неподвижной, а второй — в подвижной в сальнике трубной доски, скрепленной с крышкой (рис. 100) а) при действии нагрузки со стороны крышек (4)	$\varepsilon = 1$
б) при действии нагрузки со стороны межтрубного пространства	$\varepsilon = 1 - \dfrac{d_w^2 n}{D_f^2}$
Для круглых трубных досок с пучком прямых трубок, закрепленных в двух неподвижных трубных досках (рис. 101) или одной из них, подвижной в сальнике, но не скрепленной с крышкой (рис. 102), при действии нагрузки с любой стороны (5)	$\varepsilon = 1 - \dfrac{d_w^2 n}{D_f^2}$
Для прямоугольных трубных досок с прямыми трубками, закрепленными в двух неподвижных трубных досках (рис. 101), при действии нагрузки с любой стороны (6)	$\varepsilon = 1 - 0{,}785 \dfrac{d_w^2 n}{ab}$
Для эллиптических трубных досок с прямыми трубками, закрепленными в двух неподвижных трубных досках (рис. 101), при действии нагрузки с любой стороны (7)	$\varepsilon = 1 - \dfrac{d_w^2 n}{4 a_1 b_1}$

The designations: a and b - side of the rectangle; a_1 and b_1 -
semi-axis of ellipse, they are accepted to the center line of
packing.

Key: (1). Diagram of heat exchanger and load application. (2). Value.
(3). For tube plates of any form with beam of V-shaped tubes (Fig.
98) or by pencil of straight lines tubes whose one end is attached in
fixed, and by the second - in floating tube plate (Fig. 99) under

effect of load from any side. (4). For circular tube plates with
pencil of straight lines tubes whose one end is attached in fixed,
and by the second - in acoile in gasket tube plate, fastened with
cover/cap (Fig. 100).

a) under the effect of load from the side of covers/caps.

b) under the effect of load from the side of inter-tube space.
(5). For circular tube plates with pencil of straight lines tubes,
attached in two fixed tube plates (Fig. 101) cr one of them, mobile
ones in gasket, but not fastened with cover/cap (Fig. 102) under
effect load from any side. (6). For rectangular tube plates with
straight/direct tubes, attacked in two fixed tube plates (Fig. 101),
under effect of load frcm any side. (7). For elliptical tube plates
with straight/direct tubes, attached in two fixed tube plates (Fig.
101) under effect of load from any side.

Page 203.

For the design pressure of medium p is accepted the larger
pressure of working medium, which effects on cne of the sides of the
tube plate.

For vacuum capacitcrs the design pressure increases by 1 kg/cm²,

which considers the greatest possible vacuum in the
capacitor/condenser.

For the vertical tube racks at their relatively larger
dimensions and weight and low pressures of working media the design
pressure increases by the total weight of tubes, if it comprises more
than 10o/o of the load, created a pressure of medium.

For the circular tube plates, reinforced by anchor or
stays-bolt, design pressure p takes as the equal to the given
specific load p'_2, determined according to formula (296). For the
preliminary determination of the thickness of the tube plate from
formula (289) tentatively it is accepted:

$$p'_2 = (0,5 \div 0,6)p \; \kappa z/c\mu^2. \qquad (292)$$
Key: (1). kg/cm².

Full load from the pressure of working medium on the circular
tube plate

$$Q = 0,785 D_f^2 p \; \kappa z. \qquad (293)$$
by Key: (1). kg.

Page 204.

Load, which falls to the anchor stays, arranged/located on the circular tube plate,

$$P_1 = \frac{\pi p (r_1^2 - r_c^2)^2}{8 \left\{ \left[-2r_c^2 \ln \frac{r_1}{r_c} + \frac{1}{2} \left(1 + \frac{r_c^2}{r_1^2} \right) (r_1^2 - r_c^2) \right] + \frac{8s^3 \varphi L}{3d_0^2 (1 - \mu^2)} \right\}} \text{кг. (294)}$$

Load, which falls to tube plate,

$$P_2 = Q - P_1 \text{ кг.} \qquad (295).$$

Key: (1). kg.

Given specific load on the circular tube plate

$$p_2' = \frac{P_2}{0.785 D_j^2} \text{ кг/см}^2. \qquad (296)$$

Key: (1). kg/cm².

Load, which falls to one connection/communication,

$$P_1' = \frac{P_1}{z} \text{ кг.} \qquad (297)$$

Key: (1). kg.

The advantageous relation of the radii of a circle of the arrangement of connections/communications r_c and bolts r_1 is within the limits $\frac{r_c}{r_1} \approx 0.45 \div 0.5.$

Poisson ratio μ is accepted:

for steels............. 0.3

For brasses. 0.33

For the bronze. 0.34

The spacing or anchor stays, which fasten rectangular tube plates, are designed from the smallest section/cut of connection/communication for the load, which falls to the area, supported by connection/communication.

One series/row of connections/communications along the line of centers to establish/install is not recommended.

Allowable stress on the bend in the tube plate is designated according to the formula

$$R_b = \frac{\sigma_b}{n_b}.$$ \hspace{2cm} (298)

Safety factor n_b with respect to the lower limit of the strength of material σ_b of the tube plate at operating temperature of medium to 200°C is accepted

$$n_b > 4.$$

Page 205.

At higher temperatures the value of ultimate strength is accepted at a prescribed/assigned calculated temperature with the subsequent testing of stresses/voltages on the yield point of material %; safety factor in this case must be not less than 1.8.

Addition C to the minus tolerances of rolled stock, treatment and for the corrosion of the tube plates, etc.:

	CM
for the thickness of panels to 2.0 cm.	0.1
For the thickness of panels from 2.1 to 4.0 cm.	0.3
For the thickness of panels from 4.1 to 6.0 cm......	0.3
For the thickness of panels are more than, 6.0 cm.	0.4

The smallest thickness of the tube plate in the place of the rolling of tubes, from the conditions of guaranteeing of strength and density of their rolling-out, must not be the less outside diameter of the tubes:

$$s > d_w$$

The smallest thickness or the tube plate in the place of weakening by its grooves, grooves and its envelopment under the

packing/seal flanges must not be less:

$$s_{min} > s\sqrt{1,5\varphi}.$$

The thickness of the sealing part of the welded tube plate must be designed just as flange.

Testing stresses/voltages in the bridge of tube plate, Fig. 103 (between four tubes), is produced according to to the formula

$$R_b > \frac{P}{3,6\left(1-\frac{d_0}{l}\right)\left(\frac{s}{l}\right)^2} \text{ кг/см}^2,(1) \qquad (299)$$

Key: (1). kg/cm².

where l — half-sum of the sides of the rectangle, formed by four tubes:

$$l = 0,5(t_1 + t_2).$$

The determination of values t_1 and t_2 see in Fig. 103.

Testing the reliability of fastening the ends of the tubes against their extraction is produced according to the formula

$$R > \frac{pf}{\pi d_m s}. \qquad (300)$$
Fig. 103. On the calculation of the bridge of the tube plate.

Page 206.

The area between four tubes f (in Fig. 103 cross-hatched) is determined:

for the tubes, arranged/located on equilateral triangle,

$$f = 0,866t^2 - 0,785d_H^2 \ cm^2;$$

for the tubes, arranged/located in the corridor or checkered order,

$$f = t_1t_2 - 0,785d_H^2 \ cm^2.$$

Allowable stresses on the extraction of tubes must be not more:

$R_{max} \leqslant 40$ kg/cm² - for the tubes, rolled in the cylindrical holes;

$R_{max} \leqslant 50$ kg/cm² - for the tubes, rolled and flanged from one end;

$R_{max} \leqslant 70$ kg/cm² - for the tubes, rolled and flanged from two

ends.

Stress/voltage in the anchor stays is determined

$$R_z = \frac{P_1}{0.785 d_0^2 z} \quad \text{или}^{(1)} \quad R_z = \frac{P_1'}{0.785 d_0^2} \, \text{кг/см}^3. \qquad (301)$$

by Key: (1). or kg/cm².

Allowable stress in the anchor stays during the hydraulic test must not exceed

$$R_z' \leqslant \frac{\sigma_t}{1.6} \, \text{кг/см}^2, \qquad (302)$$

Key: (1). kg/cm².

where σ_t — yield point of material, kg/cm².

Breaking stress on the buckling in stays-bolt:

$$R_{пp} = \frac{\pi^2 E}{\left(\frac{L}{i}\right)^2} \, \text{кг/см}^2. \qquad (303)$$

Key: (1). kg/cm².

Radius of inertia of connection/communication of the round cross-section

$$i = \frac{d_0}{4} \, \text{см}.$$

The modulus/module of the normal elasticity E is accepted:

for steels kg/cm². .... $(2.0-2.2) \cdot 10^6$

For brasses...................... $(0.65-1.0) \cdot 10^6$

For the bronze. .... $(0.9-1.2) \cdot 10^6$

Stability margin in stays-bolt with the buckling

$$x = \frac{R_{вр}}{R_z}t > 4.$$

Page 207.

Here by R_z is implied permissible compression stress, equal to permissible tensile stress.

For the purpose of a reduction/descent in the thermal stresses, which appear in the tube plates, and also the tubes in the places of their rolling in the housings of the heat exchangers, which have rigidly by them is more than 1 m the silt of the working under conditions relatively high temperatures, it is necessary to produce testing the compensation capacity of apparatus and in the necessary cases to provide for the installation of compensators.

§42. Calculation of the compensation capacity of apparatus.

If in the tube system of apparatus straight/direct tubes are rolled in two tube plates, rigidly fastened with the housing of apparatus, then in this case should be manufactured the verifying calculation of the compensation capacity of apparatus.

The elongation of the housing of apparatus under the action of a difference in the temperatures:

$$\Delta l_1 = \alpha_1 l_1 (t'_{cr} - t_0) \; cм, \qquad (304)$$

where α_1 - a coefficient of the linear expansion of the material of housing on $1^{\circ}C$;

l_1 —- length of housing (usually is accepted the distance between the tube plates), cm;

t'_{cr} — mean temperature of the wall of housing, $^{\circ}C$;

t_0 - temperature of apparatus during the assembly (it usually takes as the equal to $15-20^{\circ}C$), $^{\circ}C$.

The elongation of the tubes of apparatus under the action of a difference in the temperatures:

$$\Delta l_2 = \alpha_2 l_2 (t'_{cr} - t_0) \; cм, \qquad (305)$$

where α_2 - a coefficient of the linear expansion of the material of tubes on $1^{\circ}C$;

l_4 — length of tubes (distance between the tube plates), mm;

t'_{ct} — mean temperature of the wall of tube, °C;

t_0 — temperature of apparatus during the assembly, °C.

Difference in the elongations between the elongations of housing and tube (amount of strain):

$$\Delta l = \Delta l_1 - \Delta l_2 \ \text{c.m.} \qquad\qquad (306)$$

In obtaining Δl of positive the tubes additionally are dilated/extended under the action of the elongation of housing. In obtaining $\overline{\Delta l}$ of negative the housing additionally is dilated/extended under the effect of the elongation of tubes.

end section.

Page 208.

The effort/force which appears in the tube (housing), called by
the elongation of housing (tubes), according to the law of Hooke:

$$P_1 = \frac{\Delta l F E}{l} \ \text{kg},\qquad\qquad (307)$$

where E - modulus of elasticity of the material of tube (housing),
kg/cm^2;

F - cross-sectional area of tube (housing):

$$F = 0.785 \, (d_n^2 - d_n^2) \ cm^2,$$

where d_n - outside diameter of tube (housing), cm;

d_n - bore of tube (housing), cm.

The effort/force, which appears in the tube (housing), called by
the internal pressure:

$$P_2 = 0,785 d_s^2 p \quad \text{кg},\qquad\qquad (308)$$

where p - internal pressure in the tube (housing), kg/cm².

Total effort/force in the tube (housing) from the action of a difference in the temperatures and internal pressure:

$$\dot{P}_{cyм} = P_1 + P_2 \quad \text{кg}.\qquad\qquad (309)$$

Total stress/voltage on the breakage in the wall of tube (housing):

$$R_{cyм} = \frac{P_{cyм}}{F} \quad \text{кg/cm}^2.\qquad\qquad (310)$$

If obtained values $P_{cyм}$ and $R_{cyм}$ are insignificant, then compensator on the apparatus it is not required.

Compensator on the apparatus is established in such a case, when:

1) total stress/voltage on the breakage in the tube or the housing exceeds allowable stress, i.e.

$$R_{cyм} > R_{доп},$$

where $R_{\text{доп}}$ - allowable stress in the wall of tube (housing), cf kg/cm²;

2) the effort/force, which appears in the tube, exceeds the permissible load on the extraction of the ends of the tubes, i.e.

$$P_{\text{сум}} > P_{\text{max}}$$

where P_{max} - permissible load on the extraction of the ends cf the tubes: $P_{\text{max}} = R_{\text{max}} \pi d_{\text{н}} y$ kg;

R_{max} - allowable stresses cn the extraction cf the ends cf the tubes (see page 206), cf kg/cm²;

$d_{\text{н}}$ - the outside diameter cf tubes, cm,

y - depth of the rolling-cut cf tubes, cm.

According to the experimental data the safety factor of rolling-cut n, i.e., the ratic cf force $P_{\text{выр}}$, which extracts the rolled tube, to permissible load P_{max} on the extraction of the ends of the tubes composes 2-2.5.

Page 209.

For the approximate computations of efforts/forces and the stresses/voltages, which appear in the tube from the temperature elongations, can be reccomended the follcwing simplified formulas.

The force, which appears in the tube, in the absence of the compensation for temperature elcngations approximately is determined:

for the steel tubes

$$P = 75\Delta tds \text{ kg;} \qquad (311)$$

for the brass tubes

$$P = 57\Delta tds \text{ kg.} \qquad (312)$$

The compression stress or elongation in the tube from the action of temperature elongaticns in the absence of the compensation for tube is determined:

for the steel tubes

$$R = 24\Delta t \ kg/cm^2;\qquad\qquad (313)$$

for the brass tubes

$$R = 18\Delta t \ kg/cm^2.\qquad\qquad (314)$$

The bending deflection of tube in depending on its elongation approximately shares

$$y = \sqrt{0.375l\Delta l + y_0} - y_0 \ \text{мм.}\qquad\qquad (315)$$

Here Δt - increase in the temperature against the assembling, $^{\circ}C$;

d - the mean diameter of tube, cm;

s - the wall thickness of tube, cm;

l - length of tube, mm;

Δl - difference in the elongations of housing and tube, mm;

y_0 - initial sagging/deflection of tube, mm.

§ 43. Calculation of the expansion bellows.

The expansion bellows with the necessary calculated values is depicted in Fig. 104.

The wall thickness of the lens

$$s = 0.67H\sqrt{\frac{p}{R_b}} \ cm, \qquad (316)$$

where H - a projection of sizes/dimensions r_1, r_2, l lens (Fig. 104), cm;

p - internal pressure in the compensator kg/cm²;

R_b - allowable stress on the bend, kg/cm².

The complete effort/force from the internal pressure, received by the walls of the lens

$$P_s = 0.785p(d_1^2 - d_2^2) \ kg, \qquad (317)$$

where d_1 - diameter of the lens of compensator in section/cut AA, cm;

d_2 - diameter of lens in section/cut BB, cm.

Page 210.

Force from the internal pressure, which disrupts the wall of the lens cf compensator according to the diameter of lens d_1 in section/cut AA:

$$P_A = P_0 \frac{d_1}{d_1 + d_2} \ kg.$$ (318)

The reaction, compressive the wall of the lens cf compensator according to diameter d_2 in section/cut BB:

$$P_B = P_0 - P_A \ kg.$$ (319)

The force, which appears in the compensator from the deformation cf one lens to value $+-\Delta x--0.5\Delta l$ (with the precompression or the elongation of lens on $+-\Delta x$):

$$P_x = \pm \frac{EI_{cp}\Delta x}{\Sigma b - \frac{\Sigma a^3}{4\Sigma s_n}} \ kg,$$ (320)

where Δx - an amount of the deformation cf one lens of the compensator;

E - modulus of elasticity cf the material of lens, kg/cm^2;

$I_{cp} = 0.262 \ d_{cp} s^3$ - moment cf the inertia cf the cross section of the wave of lens, rectified on its average/mean diameter, cm^4;

$d_{cp} = 0.5(d_1 + d_2)$ - the mean diameter cf the lens cf compensator, cm;

DOC = 80040211   PAGE 474

Σb - coefficient of the configuration of lens, cm³;

Σa - coefficient of the configuration of lens, cm²;

Σs_n - the reduced length of the wall of lens, cm.
Fig. 104. On the calculation of the expansion bellows.

Page 211.

Values of the coefficients of configuration and reduced length:

1. For case of $r_1 \neq r_2$; $l \neq 0$:

$$\Sigma b = n \left\{ \frac{(3\pi - 8)}{4} r_2^2 + \left[r_2 (r_2 + l) + \frac{1}{3} l^2 \right] + r_1 \left[\frac{\pi}{2} (r_2 + l)^2 + \right. \right.$$
$$\left. \left. + 2 (r_2 + l) r_1 + \frac{\pi}{4} r_1^2 \right] \right\};$$

$$\Sigma a = n \left\{ (\pi - 2) r_2^2 + (2r_2 + l) + r_1 [\pi (r_2 + l) + 2r_1] \right\};$$

$$\Sigma s_n = n \left[\frac{\pi}{2} (r_2 + r_1) + l \right].$$

2. For case of $r_1 = r_2 = r$; $l \neq 0$:

$$\Sigma b = n \left\{ \frac{(3\pi - 8)}{4} r^2 + \left[r (r + l) + \frac{1}{3} l^2 \right] l + r \left[\frac{\pi}{2} (r + l)^2 + \right. \right.$$
$$\left. \left. + 2 (r + l) r + \frac{\pi}{4} r^2 \right] \right\};$$

$$\Sigma a = n \left\{ (\pi - 2) r^2 + (2r + l) l + r [\pi (r + l) + 2r] \right\};$$

$$\Sigma s_n = n (\pi r + l).$$

3. For case of $r_1 \neq r_2$; $l = 0$:

$$\Sigma b = n \left[\frac{(3\pi - 8)}{4} r_2^3 + r_1 \left(\frac{\pi}{2} r_2^2 + 2r_2 r_1 + \frac{\pi}{4} r_1^2 \right) \right];$$

$$\Sigma a = n \left[(\pi - 2) r_2^2 + r_1 (\pi r_2 + 2r_1) \right];$$

$$\Sigma s_n = n \frac{\pi}{2} (r_2 + r_1).$$

4. For case of $r_1 = r_2 = r$; $l = 0$;

$$\Sigma b = 4{,}71 n r^3;$$
$$\Sigma a = 6{,}28 n r^2;$$
$$\Sigma s_n = 3{,}14 n r,$$

where n — number of half-lenses in compensator.

Pinching moment/torque, called by the deformation of the lenses:

$$M_x = \pm \frac{\Sigma a P_x}{2\Sigma s_n} \text{ kgcm.} \qquad (321)$$

Bending moment in the critical section/cut of lens (section/cut AA):

$$M_a = P_x H - M_x \text{ kgcm.} \qquad (322)$$

END
DATE
FILMED

DTIC

Page 212.

Bending stress from the action of moment/torque in the critical section/cut:

$$\pm R_b' = \frac{M_{\theta} s}{2 I_A} \ \ \text{kg/cm}^2, \tag{323}$$

where $I_A = 0.262 \, d_1 s^3$ - moment of the inertia of lens in critical section/cut, cm⁴.

Bending stress from the internal pressure:

$$R_b'' = \frac{0.45 p H^2}{s^2} \ \ \text{kg/cm}^2. \tag{324}$$

Total bending stress:

$$\pm R_b = R_b' + R_b'' \ \ \text{kg/cm}^2, \tag{325}$$

Plus sign is - with the work of compensator on elongation.

Minus sign is - with the work of compensator on compression.

Stress/voltage on the breakage from the internal pressure:

$$R_z = \frac{pd_1}{2s} \text{ kg/cm}^2 . \tag{326}$$

Resulting stress/voltage in the critical section/cut

$$R_{pes} = \sqrt{R_b^2 + R_z^2} \text{ kg/cm}^2 . \tag{327}$$

Axial force in the housing of the apparatus:

$$P' = P_B + P_x \text{ kg} . \tag{328}$$

Stress/voltage in the wall of lens in the place of fastening to the housing (section/cut EE):

$$R_{s_E} = \frac{P'}{\pi d_2 s} \text{ kg/cm}^2 . \tag{329}$$

Page 213.

Chapter VII.

EXAMPLES OF THE CALCULATIONS OF THE STRENGTH OF PARTS.

§ 44. Calculation of the strength of the walls of housing.

Cylindrical wall.

Initial data for the calculation.

Material of the housing of fuel heater: steel st. 3.

$P = 26$ kg/cm^2.

Calculated (working) pressure of saturated steam in the housing $\wedge$
Bore of housing $D_o = 283$ мм.

We accept.

$\varphi = 0{,}8$ - the modulus of resistance of weld (on Table 50);

$\sigma_b = 38$ kg/mm^2 - limit of the strength of steel St. 3 (on Table 33);

$n_b = 4{,}25$ - safety factor with $t_s < 250°$ C (on Table 52);

C=1 mm - addition.

The allowable stress

$$R_z = \frac{q_b}{n_b} = \frac{38}{4.25} = 8.9 \ kg \ /mm^2.$$

The wall thickness of the cylinder

$$s = \frac{pD_n}{230 R_z \varphi - p} + C = \frac{26 \cdot 283}{230 \cdot 8.9 \cdot 0.3 - 26} + 1 = 5.6 \ мм.$$

We accept s=6 mm.

Flat/plane wall with the stiffening ribs.

Initial data for the calculation.

Material of the flat/plane wall: Copper M3.

Material of stiffening ribs (angle plate): steel st. 3.

Design pressure on the wall: p=1 kg/cm².

Large side of the flat/plane wall: l=1500 mm.

Smaller side of the flat/plane wall: c=1300 mm.

Page 214.

We accept.

Number of edges/fins along the larger side n_1=5.

Number of edges/fins along the smaller side n_2=4.

Profile/airfoil of angle plate on OCT 10015-39 N 6/4.

We determine (on the tables).

Limit of the strength of copper σ_b=2000 kg/cm^2.

Yield point of copper σ_e=700 kg/cm^2.

Limit of the strength of steel St. 3 σ_b'=3800 kg/cm^2.

Yield point of steel St. 3 σ_e'=2400 kg/cm^2.

Side of the rectangle, included between the stiffening ribs:

$$a = \frac{c}{n_2 + 1} = \frac{1300}{4+1} = 260 \ \text{мм}.$$

Second side of the rectangle

$$b = \frac{l}{n_1 + 1} = \frac{1500}{5+1} = 250 \ \text{мм},$$

The thickness of the flat/plane wall, included between the stiffening ribs

$$s = 0.53b \sqrt{\frac{p}{R_b\left(1 + \frac{b^2}{a^2}\right)}} + C = 0.53 \cdot 25 \sqrt{\frac{1}{440\left(1 + \frac{25^2}{26^2}\right)}} +$$
$$+ 0.3 = 0.755 \ \text{см},$$

where $R_b = 440 \ \text{кг/см}^2$- the allowable stress of copper (on Table 41);

C=03 cm - addition taking into account weakening of bore surface.

We accept s=8 mm.

Let us designate (see Fig. 82).

X_1X_1 - centroidal axis of the section/cut of edge/fin (elbow);

X_2X_2 - centroidal axis of the section/cut of the band of the flat/plane wall;

XX - centroidal axis of the section/cut of band and edge/fin;

OO - axis/axle of the base/root of band.

From the table of assortment for angle plate N 6/4 we determine:

Height/altitude of edge/fin (angle plate) h=6 cm.

Cross-sectional area of edge/fin F_1=5.72 cm².

Distance of the apex/vertex of edge/fin from axis/axle X_1X_1 equal to Z_0=2 cm.

Second moment of area of edge/fin relative to axis/axle X_1X_1 $I_{x_1} = 20,3$ cм⁴.

Distance of axis/axle X_1X_1 from axis/axle CC:
$$Y_1 = h + s - Z_0 = 6 + 0,8 - 2 = 4,8 \text{ cм.}$$

Distance of axis/axle X_2X_2 from axis/axle CC:
$$Y_2 = 0,5s = 0,5 \cdot 0,8 = 0,4 \text{ cм.}$$

Page 215.

Width of the band of wall, which receives loads along the larger side 1 of rectangle,
$$B = \frac{a}{2} = \frac{26}{2} = 13 \text{ cм.}$$

Cross-sectional area of the band
$$F_2 = Bs = 13 \cdot 0,8 = 10,4 \text{ cм,}$$

Distance of the neutral axis/axle XX from axis/axle OO

$$Z = \frac{F_1 Y_1 + F_2 Y_2}{F_1 + F_2} = \frac{5.72 \cdot 4.8 + 10.4 \cdot 0.4}{5.72 + 10.4} = 1,96 \ cm.$$

Distance between centers $X_1 X_1$ and XX

$$a_1 = Y_1 - Z = 4,8 - 1,96 = 2,84 \ cm.$$

Distance between centers $X_2 X_2$ and XX

$$a_2 = Z - Y_2 = 1,96 - 0,4 = 1,56 \ cm.$$

Distance of the outermost filament from axis/axle XX

$$Y_3 = s + h - Z = 0,8 + 6 - 1,96 = 4,84 \ cm.$$

Load, which effects on the edge/fin and the band,

$$Q = Blp = 13 \cdot 150 \cdot 1 = 1950 \ kg.$$

Greatest bending moment, which effects on the edge/fin and the band,

$$M = \frac{Ql}{12} = \frac{1950 \cdot 150}{12} = 24\,400 \ kgcm.$$

Second moment of area of band relative to axis/axle $X_2 X_2$

$$I_{x_2} = \frac{Bs^3}{12} = \frac{13 \cdot 0.8^3}{12} = 0,55 \ cm^4.$$

Second moment of area of edge/fin relative to axis/axle XX

$$I_1 = I_{x_1} + a_1^2 F_1 = 20,3 + 2,84^2 \cdot 5,72 = 66,6 \ cm^4.$$

The second moment of area of band relative to axis/axle XX

$$I_2 = I_{x_2} + a_2^2 F_2 = 0,55 + 1,56^2 \cdot 10,4 = 25,95 \ cm^4.$$

Total moment of the inertia of edge/fin and band relative to axis/axle XX

$$I = I_1 + I_2 = 66,6 + 25,95 = 92,55 \ cm^4.$$

Page 216.

Stress/voltage, which appears in the edge/fin from the action of moment/torque M,

$$R_1 = \frac{MY_3}{I} = \frac{24400 \cdot 4,84}{92,55} = 1275 \ kg/cm^2.$$

Stress/voltage, which appears in the band from the action of moment/torque M,

$$R_2 = \frac{MZ}{I} = \frac{24400 \cdot 1,96}{92,55} = 516 \ kg/cm^2.$$

Safety factor in the edge/fin
$$n_1 = \frac{\sigma_s'}{R_1} = \frac{2400}{1275} = 1,88.$$

Safety factor in the band
$$n_2 = \frac{\sigma_s}{R_2} = \frac{700}{516} = 1,36.$$

§ 45. Calculation of the strength of covers/caps and bottoms.

Convex stamped/die-forged bottcm.

Initial data for the calculation.

Material of convex bottcm cf the housing cf the preheater of the water: steel st. 3.

Calculated (workiry) pressure of vapors in the housing $p=2$ kq/cm².

Outside diameter cr nousing $D_n = 558$ мм.

We accept.

$\sigma_b = 38$kg /mm² - limit of the strenyth of steel St. 3 (on Table 33):

C=3 mm - addition;

y=1.65 - coefficient cr factor of shape cf bottcm (on Table 55); for the anechoic bottcm in the ratio of the height/altitude of bottom h to its cutside diameter D_n i.e. when $\frac{h}{D_n} = 0.22$.

Allowable stress witn t<250°C (on Table 56)

$$R_z = \frac{\sigma_b}{2,9} = \frac{38}{2,9} = 13,1 \ kg/cm^2.$$

The wall thickness of the dished bottom

$$s = \frac{D_w p y}{200 R_z} + C = \frac{558 \cdot 2 \cdot 1,65}{200 \cdot 13,1} + 3 = 3,71 \ mm.$$

We accept s=4 mm.

Page 217.

Flat/plane circular cover/cap.

Initial data for the calculation.

Material of the flat/plane cover/cap: steel st. 3.

Calculated (it is working) pressure p=2 kg/cm².

Diameter of a circle of the arrangement of bolts d=620 mm.

We accept.

$\sigma_b = 38$ kg /mm² - limit of the strength of steel St. 3.

$\mu = 0.3$ - for the covers/caps, which undergo preliminary bend from the tightening of the bolts [see formula (242)].

C=2 mm - addition.

Allowable stress on the bend (on Table 56)

$$R_b = \frac{\sigma_b}{3,2} = \frac{38}{3,2} = 11,9 \; \kappa g/mm^2 \, .$$

Thickness of the flat/plane circular cover/cap

$$s = d\sqrt{\mu\frac{p}{R_b}} + C = 62\sqrt{0,3\frac{2}{1190}} + 0,2 = 1,595 \; cm.$$

We accept s=16 mm.

Plate cover/cap.

Initial data for the calculation.

Material of cover/cap (cast): steel 55L.

Calculated (it is working) pressure in the cover/cap p=32 kg/cm².

We accept (on the made drawing/draft).

Radius of the spherical segment of cover/cap R=70 cm.

External radius of tne flange of cover/cap d=42.5 cm.

Radius of a circle cf the arrangement cf bolts r=39.25 cm.

Distance from the axis/axle cf cover/cap to the line of centers cf packing a=36 cm.

Load on the bolt (from tne calculation cf bolts) P_0=8350 kg.

Number of bolts z=28.

The wall thickness cf cover/cap s=5.5 cm.

Addition for the cast cover/cap C=0.5 cm.

The modulus of resistance cf weld (it is absent) ϕ=1.

Page 218.

Bending stress in the cover/cap

$$R_0 = \frac{3}{\pi(s-C)^2}\left[\frac{0,18P_0z\,(r^2-a^2)}{d^2}+1,48P_0z\lg\frac{r}{a}\right]+\frac{pR}{2\phi(s-C)} =$$
$$= \frac{3}{3,14\,(5,5-0,5)^2}\left[\frac{0,18\cdot8350\cdot28\,(39,25^2-36^2)}{42,5^2}+\right.$$
$$\left.+1,48\cdot8350\cdot28\lg\frac{39,25}{36}\right]+\frac{32\cdot70}{2\cdot1\cdot(5,5-0,5)}=940\ \kappa_2/c.m^2. \tag{1}$$

Key: (1). kg/cm².

Safety factor in the cover/cap on ultimate strength

$$n = \frac{z_b}{R_b} = \frac{6000}{940} = 6.4,$$

where $z_b = 6000$ kg/cm² - limit of the strength of steel 55L (on Table 29).

§ 46. Calculation of bolts and pins.

Calculation of the shank of bolt.

Initial data for the calculation.

Material of the bolts: steel 35X.

Design pressure in the cylindrical chamber/camera p=32 kg/cm².

Diameter of a circle of the arrangement of bolts $D_6 = 78.5$ см.

Diameter of the centerline of packing $D_{np} = 72$ см.

Complete effort/force, which effects on all bolts from the internal pressure of medium,

$$Q = 0,785 D_{np}^2 p = 0,785 \cdot 72^2 \cdot 32 = 130\,000 \; \kappa y.$$

We accept.

Quantity of bolts z=28.

Coefficient of the tightening of bolt k=1.8.

Calculated effort for one bolt

$$P_0 = \frac{kQ}{z} = \frac{1.8 \cdot 130\,000}{28} = 8350 \; \kappa g.$$

Distance between the bolts (space of bolts)

$$t = \frac{\pi D_6}{z} = \frac{3.14 \cdot 78.5}{28} = 8,8 \; c.\varkappa.$$

Page 219.

The nominal diameter of the bolt

$$d_0 = 1,13 \sqrt{\frac{P_0 n}{\tau_b}} + 0,5 = 1,13 \sqrt{\frac{8350 \cdot 6.5}{9500}} + 0,5 = 3,2 \; c\varkappa.$$

where $\sigma_b = 9500$ kg/cm² - limit of the strength of steel 35Kh (on Table 37)

n=6.5 - a safety factor for the well machined bolts.

We accept $d_0 = 3$ cm.

Stress/voltage in the rod of the bolt

$$R_z = 1,27 \frac{P_0}{d_b^2} = 1,27 \frac{8350}{2,56^2} = 1620 \text{ kg/cm}^2,$$

where $d_b = 2,56$ cm - diameter of bolt along the female thread.

Calculation of the fillet/shoulder of pin.

Initial data for the calculation (from the calculation of the shank of bolt).

Material of the pin: steel 35Kh.

Calculated effort for one pin $P_0 = 8350$ kg.

Nominal diameter of pin $d_0 = 3.0$ cm.

The thickness of the fillet/shoulder of the pin

$$\delta = \frac{P_0}{\pi d_0 R_{c\varphi}} = \frac{8350}{3.14 \cdot 3 \cdot 875} = 10.08 \ cm,$$

where $R_{c\varphi}$ - permissible shear stress:

$$R_{c\varphi} = 0.6 R_z = 0.6 \frac{\sigma_b}{n} = 0.6 \frac{9500}{6.5} = 875 \ kg/cm^2;$$

$\sigma_b = 9500 \ kg/cm^2$ - permissible tensile stress;

n=6.5 - safety factor for the well machined pins.

We accept $\delta = \frac{d_0}{3} = \frac{30}{10} = 10 \ mm.$

The diameter of the fillet/shoulder of the pin

$$d_0 = \sqrt{d_0^2 + \frac{1.27 P_0}{R_{cu}}} = \sqrt{3^2 + \frac{1.27 \cdot 8350}{2630}} = 3.63 \ cm,$$

where R_{cu} - permissible crumpling stress

$$R_{cu} = 1.8 R_z = 1.8 \frac{\sigma_b}{n} = 1.8 \frac{9500}{6.5} = 2630 \ kg/cm^2.$$

We accept $d_0 = 1.4 d_0 = 1.4 \cdot 30 = 42 \ mm.$

Page 220.

§ 47. Calculation of flanges.

Round cast flange.

Initial data for the calculation.

Material of the flange: steel 45L.

Limit of the strength of steel 45L: $\sigma_b = 5500$ kg/cm².

Calculated effort for one bolt (from the calculation of bolts) $P_0 = 8350$ kg.

Diameter of the critical section/cut of flange (from the made drawing/draft) $D_f = 74$ cm.

Arm of bend a=4.25 cm.

Number of bolts z=28.

The thickness of the cast flange

$$s = \sqrt{\frac{6 P_0 a z}{\pi D_f R_b k}} + C = \sqrt{\frac{6 \cdot 8350 \cdot 4,25 \cdot 28}{3,14 \cdot 74 \cdot 690 \cdot 1,8}} + 0,5 = 5 \ cm,$$

where R_b - allowable stress on the bend:

$$R_b = \frac{\sigma_b}{n_b} = \frac{5500}{8} = 690 \ kg/cm^2;$$

$n_b = 8$ - safety factor for steel casting;

k=1.8 - coefficient of the tightening of bolts;

C=0.5 cm - addition.

Circular welded flange.

Initial data for the calculation.

Material of the flange: steel st. 4.

Limit of the strength of steel St. 4 on Table 33 $\sigma_b = 4200$ kg/cm².

Calculated effort/force on pin $P_0 = 208$ kg.

Radius of a circle of the arrangement of pins $r_0 = 31.75$ cm.

Internal radius of housing $r = 27.5$ cm.

Space of pins t=8.3 cm.

Diameter of hole under the pin d=2.9 cm.

Page 221.

The thickness of the welded circular flange

$$s = \beta \sqrt{\frac{P_0 (r_0 - r) t}{R_\bullet (t - d) d}} + 1.2 =$$

$$= 0.43 \sqrt{\frac{208 (31.75 - 27.5) 8.3}{840 (8.3 - 2.9) 2.9}} + 1.2 = 1.52 \ cm,$$

where $R_\bullet$ - allowable stress on the bend:

$$R_\bullet = \frac{\sigma_b}{n} = \frac{4200}{5} = 840 \ \text{kg/cm}^2;$$

n=5 - safety factor of the flange;

β=0.43 - coefficient for the flanges, which are not subjected load from the tightening of bolts.

We accept s=16 mm.

Rectangular flange.

Initial data for the calculation.

Material of the flange: steel St. 4.

Limit of the strength of material on Table 33 σ_b = 4200 kg/cm².

Calculated effort/force to the bolt P_0=324 kg.

Space of bolts t=5.9 cm.

Diameter of bolt hole d=1.3 cm.

Arm of bend a=1.5 cm.

The thickness of rectangular flange will be determined

$$s=\sqrt{\frac{6P_0 a}{R_b(t-d)k}}+C=\sqrt{\frac{6\cdot3\cdot4\cdot1,5}{840(5,9-1,3)1,8}}+0,1=0,75 \; cm,$$

where $R_b=840$ kg/cm² - allowable stress on the bend;

k=1.8 the coefficient of the tightening of the bolts;

C=0.1 cm - addition.

We accept s=8 mm.

§ 48. Calculation of the tube plates.

Circular panel without the aronors.

Initial data for the calculation.

DOC = 80040211 PAGE 498

Material of the tube plate: brass LC62-1.

Design pressure p=32 kg/cm².

Radius of a circle of the arrangement of bolts r_1=39.25 cm.

The mean diameter of packing D_{np} = 72 CM.

Outside diameter of tubes d_μ = 1.6 CM.

Space of the arrangement of tubes on the triangle t=21 cm.

Number of tubes n=890.

We determine.

Limit of the strength of material (on Table 39) σ_b=3800 kg/cm².

Coefficient of the attachment of the tube plate (on Table 65) $\psi=0.5$.

Coefficient of weakening the tube plate (on Table 67) ϕ=0.474.

Page 222.

Coefficient of a change in the specific load for the circular
tube plate with the pencil of straight lines tubes (on Table 68)

$$z = 1 - \frac{d_w^2 n}{D_{np}^2} = 1 - \frac{1.6^2 \cdot 890}{72^2} = 0,563.$$

The safety factor of panel is taken n=4.

Allowable stress in the tube plate

$$R_{\phi} = \frac{z_b}{n} = \frac{3800}{4} = 950 \ kg/cm^2.$$

The thickness of the tube plate

$$s = r_1 \sqrt{\frac{\psi z p}{? R_\phi}} + C = 39,25 \sqrt{\frac{0,5 \cdot 0,563 \cdot 32}{0,474 \cdot 950}} + 0,3 = 5,85 \ cm,$$

where C=0.3 cm - an addition.

We accept s=60 mm.

Circular panel with the anchors.

Initial data for the calculation.

Material of the tube plate: steel 30.

Material of connections/communications: steel 35 Kh

Design pressure p=36 kg/cm². P Radius of a circle of the arrangement of belts r_1=31.75 cm.

Radius of a circle of the arrangement of anchors $r_c = 14.5$ CM.

The mean diameter of packing $D_{np} = 56.5$ CM.

Diameter of connection/communication along the female thread d_0=2.54 cm.

Calculated bond length is L=13.5 cm.

Number of connectors/communications z=6.

Outside diameter of tubes $d_H = 1.6$ CM.

Space of tubes on the triangle t=2.2 cm.

We determine.

Ultimate strength material (on Tables 34) $\sigma_b = 4800$kg/cm².

Poisson ratio for steel (on Table 38) $\mu = 0.3$.

Coefficient of the attacnment of the tube plate with the anchers (on Tables 65) $\psi = 0.75$.

Coefficient of weakening the tube plate (on Tables 67) $\phi = 0.52$.

Coefficient of a change in specific load of V-shaped tube (on Tables 68) $\varepsilon = 1$.

The safety factor of the tube plate is taken n=4.

Permissible stress in the tube plate

$$R_b = \frac{\sigma_b}{n} = \frac{4800}{4} = 1200 \quad \text{kg/cm}^2.$$

Page 223.

Specific load on the tube plate we preliminarily accept

$$p_2' = 0.55p = 0.55 \cdot 36 = 19.7 \text{ kg/cm}^2.$$

The thickness of the tube plate preliminarily will be determined

$$s_0 = r_1 \sqrt{\frac{\psi_0 p_2}{\varphi R_0}} = 37,75 \sqrt{\frac{0,75 \cdot 1 \cdot 19,8}{0,52 \cdot 1200}} = 4,94 \ cm \approx 5 \ cm.$$

Load, which falls cn connection/communication,

$$P_1 = \frac{\pi p \, (r_1^2 - r_c^2)^2}{s \left\{ \left[-2 r_c^2 \ln \frac{r_1}{r_c} + \frac{1}{2} \left(1 + \frac{r_c^2}{r_1^2} \right) (r_1^2 - r_c^2) \right] + \frac{8 s_0^3 \varphi L}{3 d_0^2 z \, (1 - \mu^2)} \right\}} =$$

$$= \frac{3,14 \cdot 36 \, (31,75^2 - 14,5^2)^2}{8 \left\{ \left[-2 \cdot 14,5^2 \ln \frac{31,75}{14,5} + \frac{1}{2} \left(1 + \frac{14,5^2}{31,75^2} \right)(31,75^2 - 14,5^2) \right] + \frac{8 \cdot 5^3 \cdot 0,52 \cdot 13,5}{3 \cdot 2,54^2 \cdot 6 \, (1 - 0,3^2)} \right\}} =$$

$$= 41\,000 \ kg.$$

Key: (1). kg.

Full load on the tube plate and the anchor stays

$$Q = 0,785 \, D_{mp}^2 \, p = 0,785 \cdot 56,5^2 \cdot 36 = 90\,300 \ kg.$$

Load, which falls to the tube plate,

$$P_2 = Q - P_1 = 90\,300 - 41\,000 = 49\,300 \ kg.$$

Given specific load on the tube plate

$$p_2' = \frac{P_2}{0,785 \, D_{mp}^2} = \frac{49300}{0,785 \cdot 56,5^2} = 19,7 \ kg/cm^2.$$

The thickness of the tube plate

$$s = r_1 \sqrt{\frac{\psi_1 p_2'}{\varphi R_0}} + C = 31,75 \sqrt{\frac{0,75 \cdot 1 \cdot 19,7}{0,52 \cdot 1200}} + 0,3 \approx 5,2 \ cm.$$

where C=0.3 - an addition.

We accept s=52 mm.

Stress/voltage in the anchor stays

$$R'_z = \frac{P_1}{0.785 \cdot d_0^2 \cdot z} = \frac{41000}{0.785 \cdot 2.54^2 \cdot 6} = 1350 \text{ kg/cm}^2.$$

Safety factor in anchor in the anchor stays

$$n' = \frac{\sigma'_b}{R'_z} = \frac{9500}{1350} = 7,$$

where $\sigma'_b = 9500$ kg/cm² - limit of the strength of the material of connections/communications.

Page 224.

Rectangular panel without the anchors.

Initial data for the calculation.

Material of the tube plate: brass LS59-1.

design pressure p=5 kg/cm².

Large side of rectangle, limited by the centerline of bolts,

a=53 cm.

Smaller side of rectangle, limited by the centerline of bolts, b=12.2 cm.

Outside diameter of tubes $d_H = 1.0 CM.$

Space of the arrangement of tubes in the series/row $t_1=15$ cm.

Space between the series/rows of the tubes with $t_2=1.25$ cm.

Number of tubes n=189.

We determine.

Limit of the strength of material (on Tables 39) $\sigma_b = 3500$ kg/cm².

Relation $\frac{a}{b} = \frac{53}{12.2} = 4.34.$

Coefficient of the attachment of tube heel pads (in Tables 66 in depending on relation a:b) $\psi = 0.625.$

Coefficient of weakening the tube plate (on Tables 67) $\varepsilon = 0.583.$

The coefficient of a change in the specific load for the rectangular tube plate with the pencil of straight lines tubes (on Table 68):

$$z = 1 - 0.785 \frac{d_n^2 n}{ab} = 1 - 0.785 \frac{1.0^2 \cdot 189}{53 \cdot 12.2} = 0.77.$$

The safety factor of the tube plate is taken $n_b = 4.5$.

Allowable stress in the tube plate

$$R_b = \frac{\sigma_b}{n_b} = \frac{3500}{4.5} = 780 \ \text{kg/cm}^2.$$

The thickness of the tube plate

$$s = b \sqrt{\frac{z \cdot p}{\varphi R_b}} + C = 12.2 \sqrt{\frac{0.6 \cdot 5 \cdot 0.77 \cdot 5}{0.583 \cdot 780}} + 0.1 = 0.99$$

where C=0.1 cm - allowance.

We accept s=12 mm.

Rectangular panel with the archers.

Initial data for the calculation.

Material of the tube plate: steel alloyed.

Material of connections/communications: steel 35 kh

Design pressure $p=10$ ky/cm^2.

Page 225.

Large side of rectangle, limited by the centerline of bolts, $a=264$ cm.

Smaller side of rectangle, limited by the centerline of bolts, $b=111.6$ cm.

Number of series/rows of connections/communications $n_1=2$.

Number of connections/communications in series/row $n_2=9$.

Distance between the axial bolt holes and the extreme series/row of connections/communications $c_1=40.6$ cm.

Distance between the series/rows of connections/communications $c_2=30.4$ cm.

Distance between connections/communications in the series/row $c_3=25.2$ cm.

Diameter of connection/communication along the female thread

$d_0 = 3.08$ cm.

Outside diameter cf tubes $d_u = 1,4 \; cm.$

Space of the arrangement of tubes in the series/row $t_1 = 2.1$ cm.

Space between the series/rows of the tubes with $t_2 = 1.9$ cm.

Number of tubes $n = 6100.$

The width (greatest) of the designed section of panel is $r = c_1 = 40.6$ cm.

Relation $\quad \dfrac{a}{c_1} = \dfrac{264}{40,6} = 6,5.$

Coefficient of the attacnment of the tube plate (on tables 66 in depending cn $a{:}c_1$), $\psi = 0,63.$

Coefficient cf weakening the tube plate
$$\varphi = 1' - 0,785 \frac{d_n^2}{t_1 t_2} = 1 - 0,785 \frac{1,4^2}{2,1 \cdot 1,9} = 0,614.$$

Coefficient of a change in the specific load for the rectangular tube plate with the pencil of straight lines tubes (on Table 68)
$$s = 1 - 0,785 \frac{d_u^2 n}{ab} = 1 - 0,785 \frac{1,4^2 \cdot 6100}{264 \cdot 111,6} = 0,682.$$

We determine (on the tables).

Limit of the strength of alloy steel at temperature of wall $t_{cT} = 400°C$, $\sigma'_b = 3600$ kg cm².

Ultimate strength stopped 35X: $\sigma_b = 9500$ kg/cm².

The safety factor of the tube plate is taken $n_b = 4$.

Allowable stress in the tube plate

$$R_b = \frac{\sigma'_b}{n_b} = \frac{3600}{4} = 900 \text{ кg/cm}^2.$$

The thickness of the tube plate
$$s = c_1 \sqrt{\frac{\psi \epsilon p}{\varphi R_b}} + C = 40,6 \sqrt{\frac{0,63 \cdot 0,642 \cdot 10}{0,614 \cdot 900}} + 0,2 = 3,8 \text{ см.}$$
where C=0.2 cm - an addition.

We accept s=40 mm.

Page 226.

Load, which falls to one connection/communication,

$$P'_1 = 0,5 (c_1 + c_2) c_s p = 0,5 (40,6 + 30,4) 25,2 \cdot 10 = 8900 \text{ kg.}$$

Stress/voltage in the anchor stays

$$R_s' = \frac{P_1'}{0,785 \cdot d_0^2} = \frac{8900}{0,785 \cdot 3,08^2} = 1200 \text{ kg/cm}^2.$$

Safety factor in connectiors/communications

$$n_b' = \frac{\sigma_b}{R_s'} = \frac{9500}{1200} = 7,9.$$

§ 49. Calculation of the compensation capacity of apparatus.

Initial data for the calculation.

Pressure within the housing of apparatus $p = 0.8$ kg/cm^2.

Temperature of medium in the intertube space $t_1 = 116.3°$C.

Mean temperature of medium in the tubes of apparatus $t_2 = 75°$C.

Temperature of apparatus during assembly $t_3 = 15°$C.

Temperature of surrounding air $t_4 = 30°$C.

Material of the housing: steel St. 3.

Material of the tubes: brass.

The length of tubes and housings is l=1.8 m.

Diameter of housing $D_s=0.55$ m.

The wall thickness of the tubes with $s_1=1$ mm.

The wall thickness of housing is $s_2=4$ mm.

We determine (on Tables 38). The coefficient of the linear expansion of the material of housing on 1°C, $\beta_1=1.25 \cdot 10^{-5}$.

Coefficient of the linear expansion of the material of tubes on 1°C, $\beta_2=1.9 \cdot 10^{-5}$.

For determining the temperature of wall we accept.

Heat-transfer coefficient from the vapor to the walls of housing and tubes with $\alpha_1=6600$ kcal/m²h °C.

Heat-transfer coefficient from the wall of housing to the

surrounding air $\alpha_2 = 10$ kcal/m²h °C.

Heat-transfer coefficient from the wall of tubes to the water $\alpha_3 = 4)00$ kcal/m²-hour °C.

Page 227.

Coefficient of the thermal conductivity of brass $\lambda_1 = 90$ kcal/m·h°C.

Coefficient of the thermal conductivity of steel $\lambda_2 = 50$ kcal/m-h°C.

Temperature of the internal surface of the wall of the tube

$$t'_{cm_1} = \frac{\alpha_3 t_2 + A_1 t_1}{\alpha_3 + A_1} = \frac{4000 \cdot 75 + 6150 \cdot 116,3}{4000 + 6150} \approx 100° C,$$

where

$$A_1 = \frac{1}{\frac{s_1}{\lambda_1} + \frac{1}{\alpha_1}} = \frac{1}{\frac{0,001}{90} + \frac{1}{6600}} = 6150.$$

Temperature of the external surface of the wall of the tube

$$t'_{cm_2} = \frac{t_2 + t_1 \alpha_1 B_1}{1 + \alpha_1 B_1} = \frac{75 + 116,3 \cdot 6600 \cdot 0,000261}{1 + 6600 \cdot 0,000261} \approx 101° C,$$

where

$$B_1 = \frac{1}{\alpha_3} + \frac{s_1}{\lambda_1} = \frac{1}{4000} + \frac{0,001}{90} = 0,000261.$$

Mean temperature of the wall of the tube

$$t_{cm_3} = 0,5 (t'_{cm_1} + t'_{cm_2}) = 0,5 (100 + 101) \approx 100° C.$$

Temperature of the internal surface of the wall of the housing

$$t_{cr_2}^{\cdot} = \frac{a_1 t_1 + A_2 t_4}{a_1 + A_2} = \frac{6600 \cdot 116,3 + 10 \cdot 30}{6600 + 10} = 116,2^{\circ} C,$$

where

$$A_2 = \frac{1}{\frac{s_2}{\lambda_2} + \frac{1}{a_2}} = \frac{1}{\frac{0,004}{50} + \frac{1}{10}} = 10.$$

Temperature of the external surface of the wall of the housing

$$t_{cr_2}^{\cdot} = \frac{t_1 + t_4 a_2 B_2}{1 + a_2 B_2} = \frac{116,3 + 30 \cdot 10 \cdot 0,000232}{1 + 10 \cdot 0,000232} = 116^{\circ} C,$$

where

$$B_2 = \frac{1}{a_1} + \frac{s_2}{\lambda_2} = \frac{1}{6600} + \frac{0,004}{50} = 0,000232.$$

Mean temperature of the wall of housing

$$t_{cr_2} = 0,5(t_{cr_1}^{\cdot} + t_{cr_2}^{\cdot}) = 0,5(116,2 + 116) \approx 116^{\circ} C.$$

Elongation of tube under the action of a difference in the temperatures

$$\Delta l_1 = \beta_2 l (t_{cr_1} - t_2) = 1,9 \cdot 10^{-5} \cdot 1,8 (100 - 15) = 0,0029 \, m = 2,9 \, mm.$$

Page 228.

Elongation of housing under the action of difference of temperatures

$$\Delta l_2 = \beta_1 l (t_{cr_2} - t_2)' = 1,25 \cdot 10^{-5} \cdot 1,8 (116 - 15) = 0,00227 = 2,27 \, mm.$$

Difference in the elongations of tubes and housing

$$\Delta l = \Delta l_1 - \Delta l_2 = 2,9 - 2,27 = 0,63 \, mm.$$

The effort/force, which appears in the housing, called by the elongation of the tubes

$$P_1 = \frac{\Delta l F_{\kappa} E}{l} = \frac{0,63 \cdot 69,5 \cdot 2,2 \cdot 10^6}{180} = 53\,500 \quad kg,$$

where F_s - cross-sectional area of housing, equal to

$$F_s = \pi(D_s + s_2)s_2 = 3,14(55 + 0,4)0,4 = 69,5 \ cm^2;$$

$E = 2.2 \cdot 10^6 \ kg/cm^2$ - modulus of elasticity of steel (on Table 38).

Effort/force, which appears in the housing from the internal pressure

$$P_2 = 0,785 \cdot D_s^2 p = 0,785 \cdot 55^2 \cdot 0,8 = 1900 \ kg.$$

Total effort/force, which appears in the housing,

$$P_3 = P_1 + P_2 = 53\,500 + 1900 = 55\,400 \ kg.$$

Total stress/voltage on the breakage in the wall of the housing

$$R_1 = \frac{P_3}{F_s} = \frac{55400}{69,5} \approx 800 \ kg/cm^2.$$

Effort/force, which appears in the tube, called by its compression,

$$P_4 = \frac{\Delta l F_T E_1}{l} = \frac{0,063 \cdot 0,47 \cdot 1 \cdot 10^6}{180} = 165 \ kg.$$

where F_{τ} - cross-sectional area or tube, equal (with its average/mean diameter $d_{c} = 1,5\,c.м$)

$$F_{\tau} = \pi d_{c} s_{1} = 3,14 \cdot 1,5 \cdot 0,1 = 0,47\ c.м^{2};$$

$E_{1} = 1,0 \bullet 10^{6}\ kg/cm^{2}$ - the modulus of elasticity of brass on Table 38.

Page 229.

The permissible load on the extraction of the ends of the tubes

$$P_{max} = R_{max} \pi d_{н} y = 40 \cdot 3,14 \cdot 1,6 \cdot 2 = 400\ kg,$$

where $R_{max} = 40$ kg/cm^{2} - allowable stress for the rolled tubes (see page 206):

$d_{н} = 1,6\ c.м$ - outside diameter of the tubes;

y=2 cm - depth of rolling/lapping tube.

The need of applying the compensator is determined from the following relationships/ratios

$$R = 800 < R_{доп} = 900\ кg/cm^{2},$$

where $R_{доп} = 900$ kg/cm^{2} - allowable stress in the wall of the housing

$$P_4 = 165 < P_{max} = 400 \text{ kg.}$$

On the allowable stresses and the loads on this apparatus of compensator it is not required.

§ 50. Calculation of the expansion bellows.

Initial data for the calculation.

Material of the lenses: steel st. 3.

Pressure of medium in the compensator $p=4 \text{ kg/cm}^2$.

Diameter of the housing of apparatus (over the mean section) $d_2=55.4 \text{ cm.}$

Amount of the deformation of compensator $\Delta l=0.126 \text{ cm.}$

Sizes/dimensions of compensator we accept.

Number of lenses in compensator $z=1$.

Diameter of the lens of compensator (over the mean section)
$d_1 = 69.6$ cm.

Radii of bending of lenses $r_1 = r_2 = r = 3$ cm.

Wave height of the lens
$$H = 0,5(d_1 - d_2) = 0,5(69,6 - 55,4) = 7,1 \ \text{см}.$$

The straight portion of the lens
$$l = H - 2r = 7,1 - 2 \cdot 3 = 1,1 \ \text{см}.$$

The wall thickness of the lens
$$s = 0,67 \cdot H \sqrt{\frac{p}{R_b}} = 0,67 \cdot 7,1 \sqrt{\frac{4}{900}} = 0,32 \ \text{см},$$

where $R_b = 900$ kg/cm² - the allowable stress accepted for steel St. 3.

We accept s=4 mm.

Page 230.

The amount of the deformation of one lens during its preliminary
compression on $-\dfrac{\Delta l}{2}$
$$\Delta x = \pm \frac{\Delta l}{2z} = \pm \frac{0,126}{2 \cdot 1} = \pm 0,063 \ \text{см},$$

where plus sign is - work of lens on the elongation;

minus sign is - operation of lens on compression.

Effort/force from the internal pressure, received by the walls of lens,

$$P_0 = 0.785 p (d_1^2 - d_2^2) = 0.785 \cdot 4 (69.6^2 - 55.4^2) = 5500 \text{ kg.}$$

Effort/force from the internal pressure, which disrupts the wall of lens according to diameter d_1,

$$P_A = P_0 \frac{d_1}{d_1 + d_2} = 5500 \frac{69.6}{69.6 + 55.4} = 3060 \text{ kg.}$$

The reaction, compressing the wall of lens along diameter d_2,

$$P_B = P_0 - P_A = 5500 - 3060 = 2440 \text{ kg.}$$

The mean diameter of the lens of the compensator

$$d_{cp} = 0.5 (d_1 + d_2) = 0.5 (69.6 + 55.4) = 62.5 \text{ cm.}$$

Moment of the inertia of the cross section of the wave of lens, rectified according to its mean diameter,

$$I_{cp} = 0.262 d_{cp} s^3 = 0.262 \cdot 62.5 \cdot 0.4^3 = 1.05 \text{ cm}^4.$$

Coefficients of the configuration of lens for case of $r_1 = r_2 = r$ and $\zeta \neq 0$ according to the data of § 43:

$$\Sigma b = n \left\{ \frac{(3\pi - 8)}{4} r^2 + \left[r(r + l) + \frac{l^2}{3} \right] l + \right.$$

$$+ r \left[\frac{\pi}{2} (r + l)^2 + 2(r + l) r + \frac{\pi}{4} r^2 \right] \right\} = 2 \left\{ \frac{(3 \cdot 3.14 - 8)}{4} 3^2 + \right.$$

$$+ \left[3(3 + 1.1) + \frac{1.1^2}{3} \right] 1.1 + 3 \left[\frac{3.14}{2} (3 + 1.1)^2 + 2(3 + 1.1)3 + \right.$$

$$\left. + \frac{3.14}{4} 3^2 \right] \right\} = 403.2 \ c\varkappa^3;$$

$$\Sigma a = n \{ (\pi - 2) r^2 + (2r + l) l + r [\pi (r + l) + 2r] \} =$$

$$= 2 \{ (3.14 - 2) 3^2 + (2 \cdot 3 + 1.1) 1.1 + 3 [3.14 (3 + 1.1) + \right.$$

$$\left. + 2 \cdot 3] \} = 149.2 \ c\varkappa^2.$$

Page 231.

The reduced length of wall of lens for the same case

$$\Sigma s_a = n (\pi r + l) = 2 (3.14 \cdot 3 + 1.1) = 21.04 \ c\varkappa.$$

Here n=2 - number is half lens in the compensator.

The force, appearing in the compensator from the deformation of one lens to value +-Δx, is determined from   the formula

$$P_x = \frac{EI_{cp} \Delta x}{\Sigma b - \frac{\Sigma a^2}{4 \Sigma s_a}} = \frac{2.2 \cdot 10^6 \cdot 1.05 \cdot 0.063}{403.2 - \frac{149.2^2}{4 \cdot 21.04}} = 1040 \ \kappa^2, \quad (1)$$

Key: (1). kg.

where $E = 2.2 \cdot 10^6$ kg/cm² - modulus of elasticity of the material of lens.

Pinching moment/torque, caused by the deformation of lens,

$$M_x = \frac{\Sigma a P_x}{2\Sigma s_n} = \frac{149.2 \cdot 1040}{2 \cdot 21.04} = 3680 \text{ кгсм.}$$

Bending moment in the critical section/cut of the lens
(section/cut AA, Fig. 104)

$$M_A = P_x H - M_x = 1040 \cdot 7.1 - 3680 = 3720 \text{ кгсм.}$$

Moment of the inertia of lens in the critical section/cut

$$I_A = 0.262 d_1 s^3 = 0.262 \cdot 69.6 \cdot 0.4^3 = 1.16 \text{ см}^4.$$

Bending stress from the action of moment/torque in the critical
section/cut

$$R_b^{'} = \frac{M_A s}{2 I_A} = \frac{3720 \cdot 0.4}{2 \cdot 1.16} = 640 \text{ kg/см}^2.$$

Bending stress from the internal pressure

$$R_b^{'} = \frac{0.45 \cdot p \cdot H^2}{s^2} = \frac{0.45 \cdot 4 \cdot 7.1^2}{0.4^2} = 566 \text{ kg/см}^2.$$

Total bending stress

$$R_b = R_b^{'} + R_b^{'} = 640 + 566 = 1206 \text{ kg/см}^2,$$

where the plus sign - with the work of compensator on the elongation;

minus sign is - with the work of compensator on compression.

Stress/voltage on the breakage from the internal pressure

$$R_z = \frac{pd_1}{2s} = \frac{4 \cdot 69.6}{2 \cdot 0.4} = 348 \quad \text{кg/cm}^2.$$

Page 232.

Resulting stress/voltage in the critical section/cut

$$R_{pe3} = \sqrt{R_b^2 + R_z^2} = \sqrt{1206^2 + 348^2} = 1250 \quad \text{kg/cm}^2.$$

Axial force in the housing of the apparatus

$$P_c = P_B + P_z = 2440 + 1040 = 3480 \quad \text{kg}.$$

Stress/voltage in the wall of lens in the place of fastening to the housing of the apparatus

$$R_z' = \frac{P_c}{\pi d_2 s} = \frac{3480}{3.14 \cdot 55.4 \cdot 0.4} \approx 50 \quad \text{kg/cm}^2.$$

Key: (1). Saturation pressure p atm(abs.). (2). Temperature t °C. (3). Specific volume of water at saturation pressure v₀ m³/kg. (4). Specific volume of vapor v kg/m³. (5). Specific gravity/weight of vapor γ kg/m³. (6). Enthalpy (enthalpy). (7). liquid q kcal/kg. (8). vapor i kcal/kg. (9). Heat of vaporization r kcal/kg.

(a) Наименование бассейна	Удельный вес, (b) т/м³	Соленость, (c) °Б (Брандта)
(1) Белое (2) в горле		3300
море (3) в средней части	1,019—1,021	2500—2600
(4) в Двинском заливе		1000
(5) (6) в Ботническом заливе		200—500
Балтийское (7) в Финском заливе	1,000—1,006	200—450
море (8) Гогланд и Аландские о-ва	1,010—1,016	600—670
(9) в проливе Бельт	1,010—1,016	1000—2200
(10) Черное (11) северо-западная часть	1,015—1,018	1700
море (12) средняя и южная часть	1,015—1,018	1850
(13) Каспийское (14) в середине	—	1000—1500
море (15) вдоль берега	—	100—1000
(16) Мраморное (17) у Босфора	—	2000—2100
море (18) у Дарданелл	—	2400—2500
(19) Азовское море	—	930—1200
(20) Средиземное море	—	to 4100
(21) Красное море	—	to 4100
(22) Японское море	—	3400
(23) Немецкое море	—	3400
(24) Северный Ледовитый океан	1,024—1,025	3500
(25) Атлантический океан	1,025—1,027	3700—3790
(26) Тихий океан	1,025—1,032	3400—3690
(27) Индийский океан	1,025—1,032	3200—3750

(28) Теплоемкость морской воды в зависимости от солености

(29) Соленость, °Б	0,000	2000	3000	3500	4000
(30) Средняя теплоемкость, ккал/кг °С	1,0	0,951	0,939	0,932	0,926

(31) Единицы измерения солености

$$1°Б = 10 \ мг/л = 0,001\%\text{(32)}$$

(33)
Значение коэффициентов вязкости и теплопроводности морской воды
в зависимости от солености и температуры

(34) Темпера- тура t, °С	(35) Коэффициент динамический вязкости 10⁶ μ кг·сек/м²			(36) Коэффициент теплопроводности λ ккал/м·час °С			
	(37) соленость °Б						
	1000	2000	3000	1000	2000	3000	3500
0	184,0	185,0	186,0	0,465	0,457	0,454	0,453
5	156,0	157,5	158,5	0,471	0,464	0,461	0,460
