FOREWORD

This research was conducted in the Department of Chemistry, University of Utah, Salt Lake City, Utah 84112 under Air Force Contract F33615-73-C-5025. This work was initiated under project 7360 "Research on Characterization and Properties of Materials for Air Force Systems" task 736005, Physical Chemical Methods for Materials Analysis. The project engineer was Mr. W. R. Powell of the Air Force Materials Laboratory, Technical Services Division, Analytical Services Branch (TUA).

This report was prepared by Professor Jean H. Futrell of the Departments of Chemistry and Materials Science, University of Utah. Professor Futrell wishes to acknowledge the contributions of Dr. Thomas Elwood, Dr. Paul Abegglen, and Mr. Fred Hileman to the research reported herein.

This report covers work conducted from January 1973 through June 1974. The report was submitted by the author in December 1974.

This technical report has been reviewed and is approved for publication.

SECTION I

INTRODUCTION

This document reports a continuation of research efforts described in previous technical reports by the author, AFML-TR-70-65, "High Resolution Chemical Ionization Mass Spectroscopy" (May, 1970), AFML-TR-71-98, "Studies in Chemical Ionization Mass Spectroscopy" (June, 1971), and AFML-TR-73-63, "An Improved Chemical Ionization Mass Spectroscopy System" (March, 1973).

Briefly these research efforts have involved studies in chemical ionization mass spectrometry which have lead to improved instrumentation, techniques and methodology for trace analysis. Much of the work has emphasized instrumental developments. These have included the development of high pressure ion sources for chemical ionization studies with a high resolution mass spectrometer, the development of super pressure (20 torr) ion sources for exploring maximum sensitivity of chemical ionization mass spectrometry, and, most recently, the development of combined gas chromatography-electron impact-chemical ionization mass spectrometry using a dual source, dual-beam mass spectrometer. This report describes some applications of the latter instrument plus the computer software developed for accumulation of data and data reduction.

Chemical ionization mass spectroscopy is a new technique for chemical analysis which uses a series of ion molecule reactions to develop the characteristic ion spectrum from which the unknown substance is identified. The sequence of ion molecule reactions responsible for generating the spectrum are carried out under controlled conditions inside a high pressure ion source operated in such a manner that ions undergo thousands of collisions before effusing from the ion source into the mass analyzer region. A reagent gas is

chosen for these experiments which generate a simple ion spectrum--a small number of ions, or in some cases, a single ionic species--which constitutes the reagent ions for the generation of CI spectra. These ions are so chosen that they are unreactive with the reagent gas but react with high efficiency with substances under investigation. The choice of reagent gas and the concomitant choice of reagent ions produces a useful control of the ionization processes which can be made selective for molecules with high proton or electron affinities. Through choice of reagent gas the type of chemical reaction and exothermicity of reaction are both controlled, usually resulting in chemically specific and selective, high sensitivity ionization.

Research carried out in these laboratories and elsewhere suggests that there are two general areas of application for this new technique in which chemical ionization mass spectrometry is likely to prove particularly useful for the identification of unknown compounds. The area which has received most attention to date is the tailoring of a reagent ion to a particular problem. In this approach a great deal of background information is usually available concerning the mixture of substances involved, and it is possible to choose a reagent ion which will identify the particular molecular weights and functional groups of the molecule in question. A relatively newer approach which is addressed in this report is the broad application of chemical ionization mass spectrometry as an alternative ionization means for generating mass spectra for a large variety of molecules. Here much less attention is paid to generating chemical ionization spectra under precisely controlled conditions and to the selection of particularly suitable reagent gases. Rather attention is given to the fact that the basic physics and chemistry of chemical ionization is quite different from that of electron impact mass spectrometry; therefore this

alternative ionization means constitutes an independent analytical method. This approach is particularly powerful when used in conjunction with conventional electron impact mass spectrometry and gas chromatography. The combination of these three analytical perspectives for the same molecule generates a tremendous amount of information for the unknown molecule whose identity is sought. Several examples are given illustrating the usefulness of this approach.

As indicated in previous reports chemical ionization mass spectrometry appears to be substantially more sensitive for many compounds than electron impact mass spectrometry. The consequence of this fact is that bleeding of column substrate material from gas chromatography columns into the ion source of a mass spectrometer constitutes a rather more severe limitation for CIMS than for conventional GCMS. For this reason we have given some attention to the development and characterization of porous polymers as GC agents in conjunction with CIMS. We have also used high boiling silicone polymers and have explored briefly the use of molecular sieves and other solid absorption type packing materials for gas solid chromatography. This work is reported briefly.

It is also important to make use of gas chromatography retention time as another parameter characterizing molecular structure. The most convenient form in which this information may be discussed is the use of normalized Kovats retention indices. We discuss this technique and report some data obtained for particular examples of compounds.

A corollary of this approach to analytical mass spectrometry is the necessity for having on-line data reduction capability to accommodate the enormous amount of information generated in a relatively short time by the combined GC-EI CI mass spectrometer.

A third phase of this effort has been concerned with the development of suitable software for data reduction using combined GC-MS techniques. As of this date a single beam has been used for the recording of data either by electron impact or chemical ionization mass spectrometry. In the near future we anticipate that a double beam capability will be established. The interface which has been used in this work and the hardware implementation of the computerized mass spectrometry capability has been described in the earlier report, AFML-TR-73-63. The general program and the computer-operator dialogue of the present operating system is described in Section IV. The expansion of the program to include dual beam data reduction is relatively straightforward.

This report constitutes a progress report on our continuing effort to develop an analytical system involving computerized GC-CI-EI mass spectrometry. Although Air Force sponsorship has been terminated the ongoing effort will be reported in the scientific literature.

SECTION II
INSTRUMENTAL DEVELOPMENTS

Two mass spectrometers--a Varian-MAT CH-7 medium resolution magnetic sector instrument and an AEI MS-30 dual-beam double-focusing instrument with Nier-Johnson geometry--have been substantially modified for chemical ionization studies. These instruments will be described briefly.

A. Varian-MAT CH-7 Spectrometer. We illustrate in Figs. 1,2, and 3 a new chemical ionization mass spectrometer system which has been designed to provide maximum flexibility for investigating high pressure ion source phenomena. Figure 1 illustrates schematically the fairly elaborate electron gun and ion gun optics. A cathode lens followed by an Einzel lens forms an intermediate and final image of the filament which slightly demagnifies the image of the electron emitter and injects electrons into the ionization source. A power supply adjustable up to 3.1 KV with respect to the ion source injects the electrons at high energy so that they will penetrate the high pressure gas sufficiently to generate an ion plasma in the central region of the source which is favorable for ion extraction. Note the tunnel construction of the electron entrance aperture which provides a reasonably large opening for admitting more than 10 microamps of electrons while presenting the pumping characteristics of a tube rather than an orifice of the same diameter. At the same time the fact that the filament is separated from the ion source chamber by a distance of some 8 centimeters produces good thermal isolation so that the temperature of the ion source is independent of the temperature of the cathode.

The ion acceleration optics are identical in basic design to the electron gun and also produce a demagnified image of the ion beam exiting the source

Fig. 1. Schematic of high pressure ion source, electron gun, and strong-focusing optics of CH-7 mass spectrometer.

Figure 2. CH-7 Ion Source

Figure 3. CH-7

chamber on the object slit of the mass spectrometer itself. An additional Einzel lens perpendicular to the plane of the main optical path (the main lens is y-direction focusing, with the x-direction defined as the direction of ion travel, and the z-direction defined as parallel to the magnetic field) provides z-focusing to minimize ion losses in the vertical plane. The main purpose of the strong focusing acceleration optics is to maximize ion transmission through the mass analyzer. Actual measurements indicate some 55 percent of the ions effusing from the ion source are transmitted through the entire optical system.

Direct access to the source chamber is provided by three additional holes bored into the source block. All of these holes are threaded connections so that gas-tightness is extremely good. One of these couples a gas chromatograph directly into the ion source of the spectrometer without any intervening enrichment interface. A second port provides direct access for any sampling system desired by the experimenter. At present this is attached to an MKS Baratron and a Wallace and Tiernan direct reading absolute manometer for precise pressure measurement. The third port is used for the introduction of samples by means of a solids probe and for the introduction of reagent gas. Because gas flow is over the tip of the probe and into the source the solids probe may be inserted within the source chamber or withdrawn to a distance of 1.5 centimeters from the source block while remaining within the vacuum seal of the inlet probe assembly.

Also attached to the source block shown in the photograph of Figure 2 is a stainless steel coil which passes through the vacuum housing to the exterior of the instrument. This coil is used for circulation of cryogenic fluids and has been used to chill the source block below a hundred degrees Kelvin. A series of heater inserts can be used to heat the block to at least 800°K.

Because of the good thermal isolation of the filament of the electron gun assembly, one can operate the system indefinitely anywhere between the temperature extremes cited.

Figure 2 is a photograph of the actual source, while Figure 3 is a photograph of the Varian-MAT CH-7 mass spectrometer with the ion source assembly and source pumping system installed. The source pump is an NRC VHS-6 diffusion pump with a rated pumping capacity of 2400 liters/second directly at the source housing itself. The analyzer tube of the mass spectrometer is pumped by a 2-inch oil diffusion pump and liquid nitrogen trap system attached to the analyzer tube about 14 centimeters away from the differential pumping slit of the instrument. The very high differential pumping achieved permits us to operate at pressure up to 10 torr within the ion source while maintaining an analyzer tube pressure in the 10^{-6} torr region. The intrinsic resolving power $\frac{M}{\Delta M}$ of greater than 5,000 of the instrument has been maintained in the chemical ionization configuration and the scan circuitry has been modified to permit us to examine molecules of molecular weight up to 6800.

We have also modified the ion detector circuitry of the mass spectrometer for pulse-counting operation. For this purpose we have installed on EMI 9604 venetian blind electron multiplier, a pulse amplifier and discriminator, and a scaler. This permits both positive ion and negative ion measurements with digital read-out of the detected signal. With the addition of a pulse generator to gate the electron beam and a multi-channel scaler as the ion detect element, we can measure the arrival time distribution of each ion species as a function of time after the initial ions are generated within the ion source. Collectively these modifications will permit us to measure the distribution of primary ions, reagent ions and product ions as a function of time and, consequently, as

a function of the number of collisions which the average ion has undergone. The time evolution of the high pressure mass spectrum displays directly the approach to equilibrium of the ion distribution. This means of data presentation is especially useful for ion equilibrium studies.

D. AEI MS-30 Dual Beam Double-Focusing Mass Spectrometer. Considerable interest is attached to the examination of molecules by both electron impact and chemical ionization mass spectrometry.¹ The AEI MS-30 dual beam double-focusing instrument is the obvious choice for this aspect of analytical mass spectrometry. The fact that two independent but identical ion paths exist in the instrument suggested to us the construction of a dual ion source which will provide several different combinations of mass spectra--viz., (1) simultaneous electron impact and chemical ionization spectra using a low energy reagent gas such as isobutane ($t\text{-C}_4\text{H}_9^+$ reagent ion); (2) simultaneous electron impact and chemical ionization spectra using a high energy reagent ion such as hydrogen (H_3^+) or methane (CH_5^+ and C_2H_5^+ reagent ions); (3) simultaneous CI spectra in both sources using high energy and low energy reagent ions; (4) simultaneous chemical ionization and electron impact spectra using a charge transfer reagent gas such as argon, neon or nitrogen and (5) combination of charge transfer and proton transfer reagent gases to give simultaneous CI spectra for which the basic ionization process is fundamentally different.

The first configuration in which we have utilized the dual source mass spectrometer includes a gas chromatograph and enrichment device indicated schematically in Fig. 4. As indicated in the figure the carrier gas for the gas chromatograph may be the chemical ionization reagent gas chosen for the particular experiment; alternatively reagent switching (described later) may

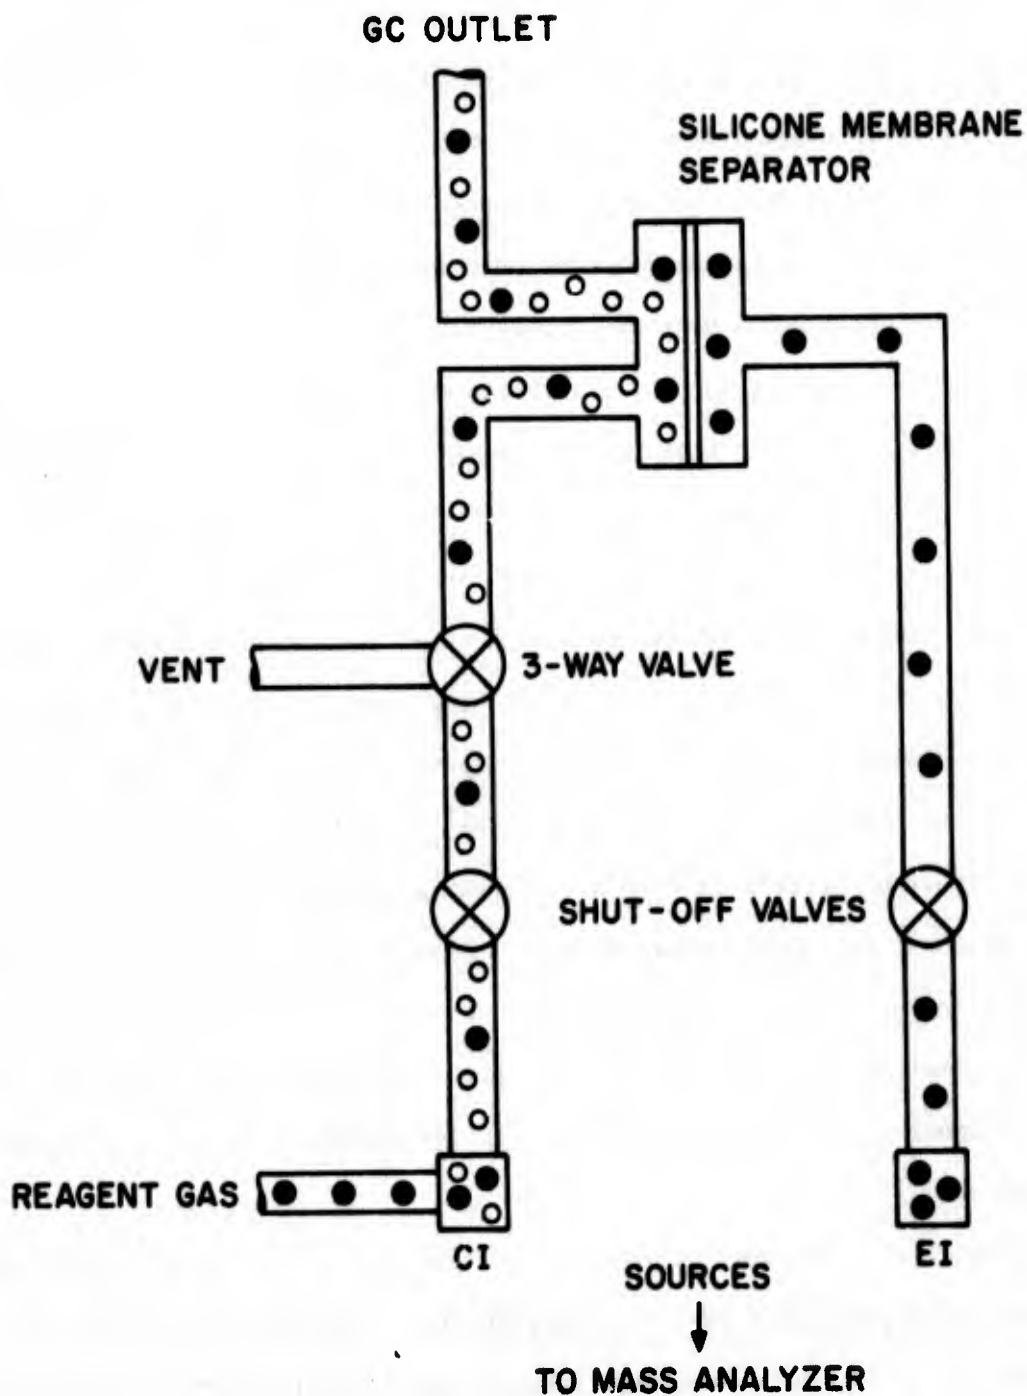

Figure 4 . Schematic of gas chromatographic splitter and dual beam electron impact and chemical ionization ion sources.

be used to generate reagent ions. The enricher shown utilizes a 0.001 inch nominal thickness silicon rubber membrane of 3 cm² cross-sectional area to remove 5-50% of the fractionated sample from the GC effluent, plus a minimum amount of the carrier gas, which are then admitted to the electron impact ion source. Most of the carrier gas and a portion of the unknown substance eluted from the gas chromatograph are pumped into the chemical ionization ion source where a characteristic chemical ionization spectrum is generated by a sequence of ion molecule reactions. The enriched sample is passed at reduced pressure into the electron impact source. Using this method, therefore, chemical ionization and electron impact mass spectra are generated for the same molecule essentially simultaneously.

The dual ion sources of the mass spectrometer are shown in Figure 5. The acceleration optics are similar to those described earlier for the CH-7 instrument. A cathode lens, two Einzel lenses, horizontal and vertical deflectors, and z-focus lenses present a focused intermediate image to the source electric sectors of the spectrometer.² Sufficient control of ion beam properties and sufficient degrees of freedom are provided by this arrangement to present an optimized ion beam at the object slits of the spectrometer. Ion focusing, transmission, and detection are then accomplished by the otherwise standard MS-30 instrument.

As described earlier the physical processes by which the mass spectrum is developed are fundamentally different for electron impact and chemical ionization. Consequently the simultaneously generated mass spectra constitute independent analyses of the same sample. It has been pointed out Jurs, Isenhour, Kowalski and Reilley³ that these circumstances amplify greatly the probability for successful identification of an unknown whenever an authentic sample is

not available for comparison or when limitations on spectral quality exist. This hypothesis will be explored in future research utilizing computerized interpretation of mass spectral data. The rapid, simultaneous acquisition of CI and EI mass spectra will also facilitate rational judgment concerning the relative merits of the two approaches to analytical mass spectrometry for various classes of compounds.

SECTION III

EXPLORATORY STUDIES OF NEW ANALYTICAL CHEMISTRY TECHNIQUES

A. Total Effluent Gas Chromatography--Chemical Ionization Mass Spectrometry.

Since the first combination of gas chromatography and mass spectrometry by Holmes and Morrel in 1957,⁴ there has been an unending search for better and more efficient separators. What is desired is efficient and complete transfer of the eluted G.C. peak into the mass spectrometer while effectively removing all the carrier gas. The parallel development of chemical ionization mass spectrometry has provided high pressure ion sources equipped with sufficiently powerful roughing and diffusion pumps to sustain low pressures in the mass analyzer. These chemical ionization sources are continuously being filled with a reagent gas and it seems only natural that this reagent gas could also be used as the carrier gas for transport of compounds through a column in gas-liquid chromatography. By directly coupling the G.C. to the mass spectrometer it is evident that problems intrinsic to the separator of compound selectivity and mass discrimination are avoided. If the carrier gas is selected carefully then full advantage can be taken of simplified chemical ionization spectra of the eluted peaks.

In this work we have developed the technique of directly coupled GC-MS-chemical ionization (GC/CIMS) and demonstrated its utility for analyzing selected compounds. Particular attention has been given to the utilization of gas-solid chromatography with its inherent advantage of zero column bleed. Applications of gas-solid chromatography have been limited previously by the conflicting requirements of low sample loadings necessary for high column efficiency and low sensitivity of detectors for compounds for which GSC is a useful separation technique. This sensitivity problem is overcome using the highly sensitive chemical ionization mass spectrometer.

A Varian model 2700 gas chromatograph was coupled to the CH-7 spectrometer described earlier. It was modified by the inclusion of a 1 inch piece of narrow bore glass tubing followed by 2 feet of narrow bore stainless steel tubing between the exit of the column and the ion source. This assembly isolates the GC from the source high voltage, while the capillary tubing maintains a high pressure in the glass insulator to prevent electrical discharge. Typically, columns were 1 to 8 feet long and 1/8" to 1/4" O.D. Flow rates were normally 30-40 atm cc/min for H₂ carrier gas. This resulted in a source pressure of approximately 1 torr. The complete inlet is illustrated schematically in Fig. 5.

In most applications of GC-MS, an electrometer attached to the total ion current monitor slit generates a "normal" GC chart record. Whenever chemical ionization is involved, this total ion mode cannot be used, since each product ion is formed at the expense of a reagent ion. In order to obtain a GC/CIMS chromatogram, the spectrometer is rapidly and repeatedly scanned over a desired mass range throughout the entire chromatographic run. The computer continuously stores the mass and intensity of the peaks obtained during a scan. During the back scan of the mass spectrometer, the computer sums the intensities of all peaks for that scan and subtracts the sum of reagent ion peaks and plots this corrected total ion intensity on a cathode ray tube display unit. The result is a reconstructed real time chromatogram. Fig. 6 shows the sequential display of a chromatogram of a series of light unsaturated hydrocarbons eluted on a one foot Porapak Q column operated at 150°C with a flow of 30 atm ml/min of H₂. After the GC run is completed, the mass spectrum for any of these chromatographic peaks is available from disk and may be plotted, listed, or displayed on the CRT.

Figure 5. Schematic of GC Interface for CH-7 Mass Spectrometer

Figure 6. Sequences of CRT Trace for Real Time Chromatogram.

One application of this technique is an extension of the work of Taylor *et al.*⁵ in which the amount of chromium in blood was determined by forming the volatile trifluoroacetylacetonate (tfa) chelate of chromium and analyzing the resulting mixture by GC/EIMS. In this work, an in-situ-formed polyurethane column⁶ was used which gives excellent separation of the chelate from any interfering contaminants. Fig. 7 shows a sample chromatogram for $\text{Cr}(\text{tfa})_3$ with monitoring of the mass 512 ($m+1$) peak. If there is any doubt as to whether the peak in question is $\text{Cr}(\text{tfa})_3$ it is only necessary to scan over the peak as it elutes and observe the characteristic chromium isotope ratios (Fig. 8). In this example, H_2 was used as both carrier gas and reagent gas; reaction of H_3^+ with $\text{Cr}(\text{tfa})_3$ gives mainly molecular ion with little fragmentation (Fig. 9). This may be contrasted with the EI spectrum shown in Fig. 10. The major peak is m/q 358 peak (M-tfa), but extensive fragmentation is evident. This reduction in fragmentation using chemical ionization should result in greater ultimate sensitivity of GC/CIMS over the electron impact method.

We have also applied this technique to light gas analysis and, in particular, to the analysis of carbon monoxide in nitrogen. This has been a difficult analysis for mass spectrometers since the two gases have the same nominal molecular mass; this has required high resolution to quantitate them. However, the separation of nitrogen and carbon monoxide by GC is very easily accomplished using a molecular sieve column. It is nevertheless still difficult to analyze for CO in N_2 with normal GC/MS techniques since the separators which use differential solubility (silicone membrane) usually show low solubilities for these gases and separators based on a diffusion principle (jet separator) usually discriminate against low molecular weight gases.

Fig. 11 illustrates the application of total effluent GC-CIMS to this

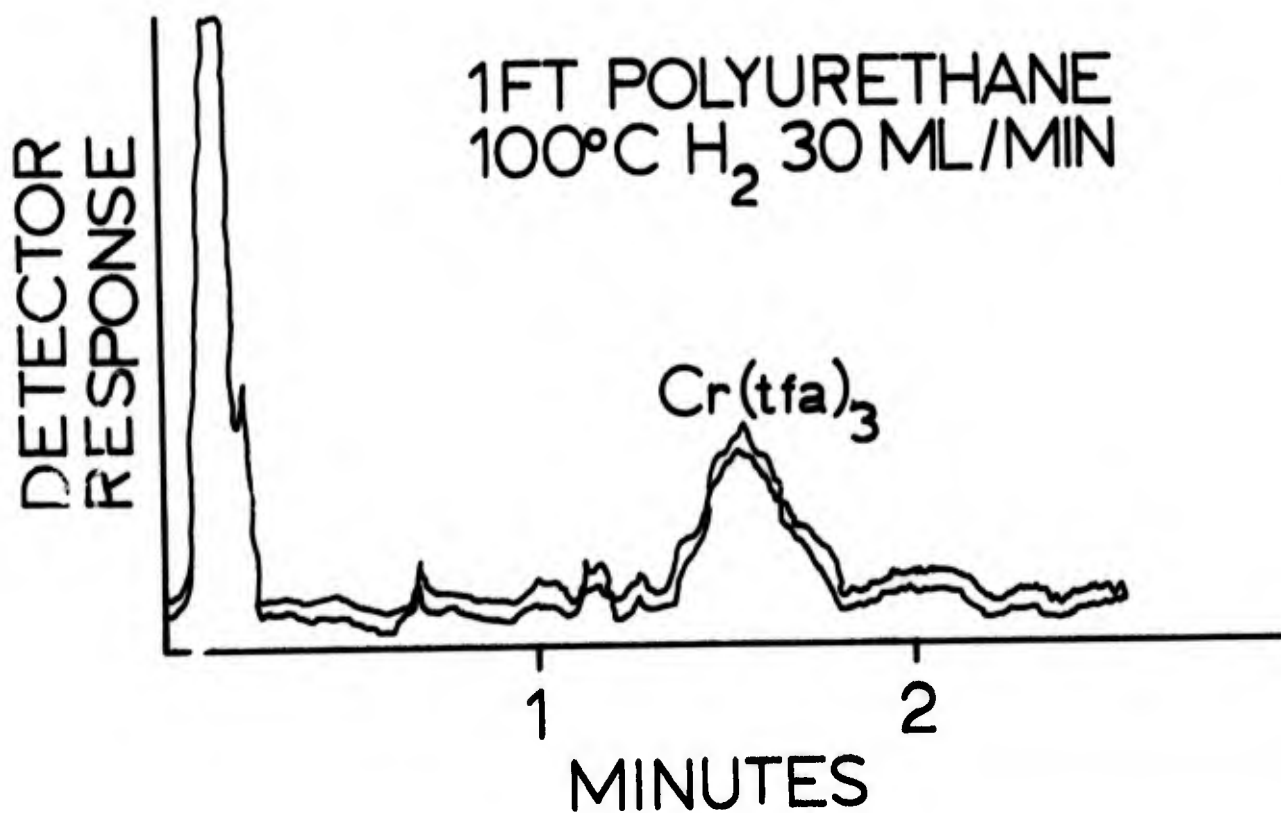

Figure 7. Detector Trace for Cr (tfa)₃ by GC-CIMS

problem. An 8 foot molecular sieve 5A column with H₂ as carrier gas and a flow rate of 40 atm cc/min. was used to separate the light gases. As with the Cr(tfa)₃ work, a single peak-mass 29 (COH⁺ and N₂H⁺)-was monitored to obtain the chromatogram.

B. Dual Beam Electron Impact/Chemical Ionization Mass Spectrometry.

As described earlier and shown schematically in Figure 4, the modified AEI MS-30 mass spectrometer has been placed in operation as a GC-EI-CI mass spectrometer system. One possible means of sample introduction is to use reagent gas as the GC carrier gas in an analogous manner to that described in Section III A. An improved system illustrated in Figure 4 was devised to utilize low molecular weight carrier gases such as H₂, D₂ and He in order to standardize GC retention volumes for reference compounds on columns which were conditioned and calibrated on conventional flame ionization detector gas chromatographs. Reagent ions are generated by adding 3-10% of reagent gas as shown in Figure 4 using the technique we describe as "reagent switching." This may be illustrated by considering a mixture of gases consisting of 97 percent hydrogen, 3 percent methane, and 0.001 percent added sample. The initial ionization and ion molecule reactions generate the reagent ion H₃⁺ which may react with the added methane or with the sample gas according to the following reaction sequence:

If we assume that the rate coefficients for these ion molecule reactions are comparable, then the relative probability of reactions (1) and (2) is governed by the relative concentrations of CH₄ and M. Obviously, therefore, the only

reaction of H_3^+ which need be considered is the formation of the protonated methane reagent ion, CH_5^+ . Essentially quantitative conversion of H_3^+ to CH_5^+ will therefore occur, and the chemical ionization reactions of the sample molecule will be the reactions of CH_5^+ in eq. (3) rather than H_3^+ in eq. (2).

Thus we may use kinetic control of reagent ion identity as a means for rapidly switching from one reagent ion to another without the long term tailing effect associated with switching carrier gases. Using hydrogen as a carrier gas for the GC/chemical ionization mass spectrometer it should be possible first to record the chemical ionization spectrum characteristic of hydrogen, then inject a small amount of methane and record the CI spectrum characteristic of CH_5^+ reagent ions, switch to isobutane and use $t-C_4H_9^+$ reagent ions, etc. We have also demonstrated that 10% CH_4 :90% He mixtures generate CI spectra pragmatically indistinguishable from pure methane reagent gas spectra. In this case scattered electrons and charge transfer processes are jointly responsible for generating the CI reagent ions.

Using the system we have initiated the generation of a library of EI-CI mass spectra obtained simultaneously for pure compounds fractionated by GC. Table I lists the spectra generated in our initial experiments, chosen to explore rapidly the merits of simultaneous generation of both kinds of mass spectra.

Figs. 12 and 13 illustrate the superiority of CI for identification of alkanes. Nonane is a typical medium molecular weight alkane which fragments so extensively under electron impact that it cannot be identified on the basis of its EI mass spectrum. However, the well-established hydride transfer reaction generates a characteristic $M-1$ peak giving the molecular weight directly.

Figure 13. EI Mass Spectrum of n-C₉H₂₀

Further random scission of the chain gives the homologous series of alkyl ions.

Figures 14 and 15 illustrate the complimentary features of obtaining EI and CI mass spectra simultaneously. Figure 14 is the total ion current trace for a synthetic mixture of alkenes. It is completely equivalent to a gas chromatogram developed in the usual manner. This trace also provides a cross comparison between results taken from the MS-30 and the CH-7 mass spectrometer systems using TIC monitoring as described previously.

Figure 15 shows the simultaneously generated electron impact and chemical ionization spectra corresponding to peak 2 of the chromatogram of Figure 14. The lower part of the figure displays the chemical ionization mass spectrum for the component 1-heptene. Under the chosen ion source conditions, the CI spectrum gives the characteristic doublet M-1 and M+1 at m/q 97 and 99 respectively. The molecular weight is thus m/q 98, identifying this compound as a heptene isomer. Peaks indicated by X in Figure 15 are the characteristic reagent ions of the methane plasma: CH_5^+ (m/q 17), C_2H_5^+ (m/q 29), and C_3H_5^+ (m/q 41). A trace quantity of water, representing a partial pressure of the order of 10^{-9} torr, is readily identified by the large peak H_3O^+ (m/q 19).

The upper part of Figure 15 with upward deflection of the galvanometers records the simultaneously-developed electron impact spectrum which is also readily identified as belonging to 1-heptene. The base peak for the spectrum is C_3H_5^+ (m/q 41), followed closely by the C_4H_8^+ peak (m/q 56). The remaining fragment ions are readily identified as characteristic of the electron impact cracking pattern of 1-heptene. Superposed on the 1-heptene spectrum is the electron impact spectrum of methane carrier gas consisting primarily of the ions CH_4^+ (m/q 16) and CH_3^+ (m/q 15). The water vapor noted as a substantial

PEAK 2 1-HEPTENE

Figure 15 . EI/CI spectra of Heptene.

component of the chemical ionization spectrum is not detected in the electron impact spectrum. The enhanced sensitivity of CI mass spectroscopy is readily apparent for this simple example. For the synthetic mixture described in these figures the molecules in question are readily identified by both chemical ionization and electron impact mass spectra. For the general case of totally unknown compounds the ability to cross-correlate the fingerprint mass spectral data for the compound in question will enhance greatly our capability for identifying unknowns.

An analogous experiment for a synthetic mixture of amines is illustrated in Figs. 16 and 17. Electron impact spectra of amines are often not readily interpreted; their spectra are temperature sensitive, they fragment easily, and many times there is no parent ion. Fig. 16 shows the total ion current trace for a series of amines. Fig. 17 shows the EI/CI trace for peak 1, which was isopropyl amine (M.W. 59). Note the highest peak on the EI side was m/q 58, which might be erroneously assumed to be the molecular ion. However, the CI spectrum shows the protonated molecular ion to be m/q 60. This even m/q for the protonated molecular ion suggests that molecule contains an odd number of nitrogens. The M-1 peak in the CI spectra (m/q 58) suggested a primary amine of molecular weight 59. Thus it is a propyl amine. Since n-propyl amine shows a small peak and no 58 peak under EI conditions, the EI spectrum tells us that it is isopropyl amine.

The application of dual beam EI-CI mass spectrometry to polymer pyrolysis is illustrated in Figs. 18-20. Fig. 18 is a mass chromatogram of the pyrolysis of Kerimid-601, a straight-chain polyimide polymer. A 5' X 1/8" column containing Chromosorb 103 was temperature programmed from 50 to 200° at 10°C/min. from which the sample was eluted into both EI and CI sources, using the separator

Figure 18 . Mass chromatogram of pyrolysis products of Kerimid - 60I.

Figure 19. EI Mass Spectrum of peak 10 from Keramid 601 Pyrolysis.

Figure 20. CI Mass Spectrum of peak 10 from Keramid 601 Pyrolysis.

of Figure 4. A total of 12 peaks were eluted from the column after a pyrolysis of 20 seconds at 1000°C. Methane was used as the CI reagent gas.

Identification of most of the products formed in the pyrolysis by GC/MS, as described previously, was straightforward. However, the EI mass spectrum of peak number 10, shown in Figure 19, was not directly interpretable. The great abundance of m/q 93 and 103 and the unusual loss of 10 mass units between them suggested that either the molecular ion was not present in the mass spectrum or that more than one compound was eluting from the column with identical retention indices. The simultaneously generated CI spectrum, shown in Figure 20, was very helpful in resolving this problem. The ions at mass 17 (CH_5^+), 19 (H_3O^+), 29 (C_2H_5^+) and 41 (C_3H_5^+) were generated by the methane reagent gas (which contains a trace amount of water) under CI conditions and should be ignored. The simple spectra that remain and comparison with the complimentary CI spectrum, suggests that m/q 94 and 104 are the most likely protonated molecular ions. It therefore appears that chromatographic peak number 10 is actually a mixture of two compounds with molecular weights of 93 and 103, respectively. The combination of an odd mass molecular ion in the EI spectrum and the simultaneous appearance of an $M+1$ ion in the CI spectrum is indicative of compounds containing an odd number of nitrogen atoms. The high degree of aromaticity and nitrogen content in the Kerimid-601 polymer suggested that two likely products of thermal degradation are aniline and benzonitrile. Duplicate GC-MS runs of a mixture of aniline and benzonitrile produced EI and CI mass spectra and retention indices, that were identical to the unknown structure, confirming this hypothesis.

C. Resolution of Complex Mixtures. The combination of gas chromatography-mass spectrometry has come into widespread use in the identification of components of complex mixtures. In most cases the mass spectrometer is utilized for qualitative analysis while the characteristic retention times of the components on the column are often ignored. However these retention volumes-- best expressed as retention indices as defined by Kovats⁷--offer considerable qualitative information which nicely compliments the mass spectral data. If retention indices for the eluted compounds are determined on two columns of different polarity, the indices themselves give a great deal of structural information.⁸ Also the extensive tables of retention index data can be used for compound identification or proper column selection for a particular separation.⁹

One application of this technique in our laboratory has involved analysis of the pyrolysis products from a variety of polymers using the GC-EI and CI-MS computer combination. The polymers are typically pyrolyzed in the injection part of the gas chromatograph with the products separated on one of many possible columns. The effluent is examined by a rapidly scanning mass spectrometer with masses and intensities taken and stored by the computer. In order to establish the retention indices for the pyrolysis-products a mixture of hydrocarbons of appropriate range is injected onto the same column used to separate the pyrolysis products. Care is taken to ensure identical chromatographic conditions for both the pyrolysis run and standard run. The standard hydrocarbon mixture retention volumes are then used to assign retention indices to all eluted compounds.

In order to utilize both the mass spectral and retention index data for all eluted peaks, a conversations library search program similar to that of Heller¹⁰ has been developed and is reported in the Appendix. The data base consists of 200 compounds which have been observed in the pyrolysis of polymers.

As additional compounds are postulated their mass spectral and retention data are added to the file.

In utilizing the search program, the operator can search the data on either mass spectral parameters such as base peak and molecular ion, or on retention indices for a variety of columns. The error limits on the searched parameter can be set as narrow or as broad as desired. After searching, the number of compounds having the searched parameter within the selected error limits is printed out. If another parameter is then selected, then only the compounds fitting all the previous criteria are searched. In this way one is constantly scanning the number of possible compounds in the library which might be related to the unknown peak. If no possible candidates are found, one can re-sort the search program and vary the search order or error limits in order to find a possible match.

The retention indices that are obtained are obviously of value only in relation to the effectiveness of the column used for the separation. If the column develops adsorption sites, significant changes in retention index data will occur, thus making good qualitative identification very difficult. In a similar manner the mass spectral data for an eluted peak are only of value if it can be distinguished from the background resulting from column bleed. Thus if mass spectral peaks resulting from the column bleed are mixed with the mass spectral peaks of the eluted compound, qualitative analysis will be very difficult.

In order to avoid many of these problems, we have found many porous polymer supports which are now available,^{11,12} to be especially useful. These include the Poropak, the Chromosorb Century Series, and others such as

Tenax. A particular advantage in using these supports is the fact that there is no liquid phase and thus no column bleed to interfere with the mass spectral data. This is especially important for high sensitivity CIMS. Further, since the porous polymer is also the solid support, there are no active sites from the support which can cause changes in retention volumes. Also for many of these porous polymers (i.e. Johns-Manville Chromasorb Century Series) the retention indices for a variety of compounds are used as a quality factor in the production of the resin.¹³ Thus a column packed with polymer from entirely different batches will give the same retention indices. It should also be pointed out that columns packed with this support have high efficiencies (typically 600-800 plates per foot in this laboratory).

Since these porous polymers have no liquid phase they can be operated at sub-ambient temperatures without freezing the liquid phase. What this means in practical terms is that the same column which separates the isomers of xylene at high temperatures can separate N₂ from CO at sub-ambient temperatures. Thus one column has an extensively wide utility range. By using these porous polymer columns we are able to pack efficient, no-bleed columns with good retention index reproducibility from column to column.

Since a mass spectrometer can distinguish hydrocarbons from other compounds, a rapid scanning mass spectrometer coupled to a gas chromatograph and a computer can be used to single out the normal hydrocarbons used to define the retention index scale which are co-injected with the unknown compounds. Thus technique has been successfully applied by several labs^{14,15} in which the operator tells the computer approximately where to find the eluted hydrocarbon standards. The computer then searches the appropriate portions of the chromatograms and determines the centroid of the hydrocarbon peak. The

hydrocarbon identity is confirmed by an algorithm which ensures that all peaks characteristic of the hydrocarbon have the same variation of intensity with time. Using the information around the assigned centroid, provided by both the operator and the centroid algorithm, the computer calculates and assigns a retention index to all eluted peaks. In subsequent search programs the retention index and mass spectral data are parameters used in peak identification.

One of the drawbacks in using this system is that it requires appreciable operator interaction to specify the hydrocarbon peaks. This results from the fact that most hydrocarbon mass spectra are very similar, possessing large $\frac{m}{q}$ 43 and 57 peaks and small (less than 5% above undecane) molecular ions to aid in carbon number assignment. With the MS-30¹⁶ peak identification is no longer a serious problem. As a normal hydrocarbon is eluted, the EI spectrum gives the characteristic hydrocarbon peaks. In addition the CI spectrum includes an intense M-1 peak which results from hydride abstraction. Thus the CI spectrum can be used to identify the carbon number of the standard hydrocarbon and thus aid in its identification. Once the first few hydrocarbon standards have been found, then all succeeding hydrocarbons can be more easily located from the approximately logarithmic relationship between retention volume and carbon number for isothermal GC runs. This logarithmic relationship can also be used to ensure that the first few peaks assigned as hydrocarbons were assigned correctly.

With the accurate determination of the retention volumes of the hydrocarbon peaks the computer can then assign a retention index scale to the reconstructed chromatogram. Thus all eluted peaks are assigned a retention index. With the expansion of the library to include chemical ionization mass spectral data the conversational search program could utilize the CI parameters to obtain

greater ease and accuracy in the identification of unknown compounds.

An example of the application of this technique is shown in Fig. 21. This chromatogram resulted from the injection port pyrolysis of 2mg of rigid urethane foam. In order to have the retention index compounds produced at the same time as the urethane foam pyrolysis products, a small amount (~1mg) of normal tetracosane was added to the foam. The pyrolysis products of the tetracosane are the entire series of C₁-C₂₃ 1-normal alkenes which can act as a secondary set of retention index reference standards. For this particular column the ΔI for normal alkanes and 1-alkenes is so slight that the alkenes can be used directly for retention index calculations.

The normal alkenes used to assign retention indices were readily determined using their characteristic chemical ionization mass spectra. Little confusion should result from copyrolysis of the urethane foam and the hydrocarbon since their higher molecular weight thermolysis products are significantly different.

Using the alkenes to assign retention indices the starred peak in Figure 21 was given a retention index of 1825. Its electron impact and chemical ionization mass spectra are shown in Figure 22. The electron impact mass spectrum is uninformative since it shows a base peak of 59 and no high intensity high mass peaks, as might be expected for a compound with a retention index of 1825. In contrast the chemical ionization mass spectrum shows a very strong M+1 ion at mass 251 suggesting a molecular weight of 250.

When the original urethane is considered, this mass 250 compound could result from either of two sources. The foam is prepared by reacting 4,4'-diphenylmethane-diisocyanate (M.W. 250) with a polyetherpolyol prepared by propoxylating trimethylpropane. The diproxy derivative of the trimethylpropane also has a molecular weight of 250. However, now the electron impact mass spectrum of the isocyanate should show the 250 mass peak as the base peak. This suggests that the compound

Figure 21. GC Trace of CO-pyrolysis run of Polyurethane Foam.

Figure 22. EI and CI Mass Spectrum of MW 250 Compound from Polyurethane Pyrolysis.

is a dipropoxytrimethylpropane polyether. This conclusion is supported by the 59 base peak in the EI spectra which is characteristic of ethers.

When a reference table of retention indices for this particular column is checked the isocyanate is found to have a retention index of 2263 while the dipropoxypolyol had a retention index of 1825. thus the mass spectral and retention data confirm the identification of the compound as the dipropoxy-trimethylpropane polyether.

SECTION IV

COMPUTER SOFTWARE OPERATING SYSTEM

The MS-30/CH-7 Mass Spectral Data Gathering System is a comprehensive system of modular computer programs which provide a real-time data acquisition, storage and retrieval capability for the AEI MS-30 mass spectrometer and the MAT CH-7 mass spectrometer. Magnetic field strength and ion intensity data are gathered automatically via hardware interfaces and stored in a systematic way on a removable medium RK-11 disc which is part of the DEC-PDP-11-20 computer system. In this section we provide a description of how the system is operated from the computer side. No attention is paid to the intricacies of how one operates the spectrometers except for those minor operation details which affect the computer.

The Data Gathering System is organized to provide several levels of interaction depending on the needs of the user. For lack of better labels, (also, the program is organized this way) these levels are called LEVEL 0 through LEVEL N interactions. The remainder of this document will consist of a description of the various user actions which can be accomplished at these levels.

The computer program which executes these instructions interactively is included as Appendix B.

A. Loading the Monitor

Before running the Data Gathering System, several actions must be taken to initialize the system. The first action is the loading of the resident monitor. The following steps are necessary to accomplish this task:

1. Mount the proper disc pack on the RK-11 disc drive. This is done using the following steps:
 - a. Put the "Load/Run" switch on the front of the disc drive in the "Load" position.

- b. Wait for the disc drive to stop, the interlock to drop, and the "Load" light to come on.
 - c. Open the door on the disc drive by pulling down from the top.
 - d. Remove the disc pack currently mounted by pulling it straight back.
 - e. Mount the proper data gathering pack on the disc drive.
 - f. Close the door.
 - g. Put the "Load/Run" switch to the "Run" position.
 - h. Turn off the "Write Lock" light by pressing the light.
 - i. Wait for the "Ready" light to come on. (The interlock is automatically raised.)
2. Turn the "Off/Local/Line" switch on the system teletype to the "Line" position.
 3. Put the "Halt/Enable" switch on the system console to the "Halt" position. (Down position.)
 4. Put all of the numbered switches on the system console to the down position.
 5. Put numbered switches 6, 9, 10, 12, 13, 14 and 15 to the up position.
 6. Depress the "Load Address" switch. (Switch is spring loaded and will return automatically to the "Up" position when pressure is released.)
 7. Repeat Step 4.
 8. Put numbered switches 1, 2, 8, 9, 10, 11, 12, 13, 14 and 15 to the up position.
 9. Put the "Halt/Enable" switch to the "Enable" position. (Up position.)
 10. Depress the "Start" switch. (Also spring loaded.)

At this point the resident monitor is loaded into memory and begins executing. This is indicated by the monitor typing on the system teletype (or display) the following:

DOS V008A

DA 01-JAN-72

TI 00:00:00

The § in the above typeout indicates that the monitor is expecting a response from the user. Each time the system responds with a §, it is expecting a user/monitor interaction. In the above typeout and henceforth in this document, automatic typeouts are "underlined" and other inputs by the user are not. Hopefully, this helps indicate "who is doing what."

B. LEVEL Ø Interactions

LEVEL Ø interactions are those actions between the user and the resident monitor which invoke execution of the Data Gathering System. The following sequence of interactions will invoke execution of the system provided only that it resides on the system disc.

1. Identify yourself to the monitor by logging in. This is accomplished by typing the following:

§ LOG XXX,YYY <CR>

where XXX,YYY is the user identification code (UIC) assigned to you by systems personnel (if you don't have one, get one) and <CR> is a "carriage return."

2. Set the Date and Time parameters by typing the following:

§ DATE Ø3-NOV-73 <CR>

§ TIME 13:51:32 <CR>

where the proper date and time are inserted in place of Ø3-NOV-73 and 13:51:32 in the above type-ins. (Notice that time is based on a 24-hour clock.)

3. Invoke execution of the Data Gathering System by typing the following:

§ RUN PEAKS <CR>

The system will then load the Data Gathering System into memory and begin executing it. This is indicated by the message:

MS30/CH7 MASS SPECTRAL DATA SYSTEM

COLD START

C. LEVEL 1 Interactions

Several types of interaction must be accomplished either by the user or automatically by the computer during initialization of the data gathering system. These interactions will be known as LEVEL 1 Interactions. Three different situations must be taken into account by these kinds of interactions. First, the situation where the system has never been run on a particular disc must be handled. This situation occurs whenever a new disc is used or when an old disc is reinitialized via a "system generation." Obviously, in this situation it is not possible to have any relevant information stored in data areas on disc which can be used by the data gathering system to update its relevant parameters. Thus, whenever this situation is encountered the system must take positive action to initialize the data areas for future use. This is commonly known as a "cold start" situation and is common to all systems initialization situations. Since it is not usually the case that one starts from a cold start, this is treated as an abnormal case requiring user intervention. This is the purpose of the "COLD START" question at the beginning of system execution. If the system is being "COLD STARTED" the user should respond with a "YES <CR>" to this question. The system will then respond:

CONFIRM

and the user should respond with:

OK <CR>

(The "CONFIRM" question is used to provide some "forgiveness" for inadvertent positive responses.) The system will then appear to hang for approximately 5 minutes. During this time it is actually setting all data areas on the disc to zero and initializing the various parameters associated with locations where the

various types of data are to be stored on the disc. It should be noted that any data previously existing on the disc is completely destroyed; therefore, great care should be exercised to verify that no important data is lost by this action. At the conclusion of the "COLD START" sequence the system will type:

COMMAND MODE

Any other response to the "COLD START" question will cause the system to assume that data exists on the disc which is to be retained. In this case, the system automatically initializes its parameters to retain existing data and store new data in available free data areas. Thus, it immediately responds with:

COMMAND MODE

It should be noted that the system will never return to the "COLD START" phase unless it is reloaded from disc. In all likelihood, the system will "crash" if a new disc is used and a negative response to "COLD START" is given. Thus, new discs must be subjected to the "Cold Start" routine.

D. LEVEL 2 Interactions

Beginning with the "COMMAND MODE" question, the major processors of the system become available to the user. Most users will never need to go to any higher level. There are two different modes of operation available for interaction at this level. These are "COMMAND MODE" and "SKIPPING MODE." If the user responds with a "YES <CR>" to the "COMMAND MODE" question the system enters Command Mode. Any other response cause Skipping Mode to be entered. In Command Mode the user is able to input various two letter commands which invoke execution of the various LEVEL 2 processors. A list of the various commands and the corresponding processor which is entered is as follows:

<u>COMMAND</u>	<u>PROCESSOR</u>
OF	Offset Calibration

MF	MFI A/D Converter Zero
AD	DEC A/D Converter Zero
DA	Acquire Data
SC	Scope Chromatogram Display
CC	Calcomp Chromatogram Display
CS	Calcomp Spectrum Display
RO	Raw Data Lineprinter Output
SD	Save Raw Data
MO	Change Mode
NB	Notebook Information Input
CN	Control (Systems Programmer Only)
HE	Help Output
EX	Exit

Each of these processors is discussed in detail later in this document. When the system enters Command Mode, it types a "%" to indicate that the command interpreter has been invoked. Each time the command interpreter is expecting an input command, a "%" is typed. The user is then expected to enter one of the above commands followed by a "Carriage Return." If a legal command is entered, the system immediately begins executing the corresponding processor. If an illegal command is entered, the system responds with a "?" and returns to the beginning of the command interpreter. In general, commands can be entered in any order since no processor within LEVEL 2 depends on any other LEVEL 2 processor. Obviously, certain sequences of commands make more sense than others since the purpose of the system is to gather data from the mass spectrometers. A typical sequence of commands is as follows (interactions with each of the various processors are omitted and a sequence of . . . is used to mark where these would occur):

COMMAND MODE YES <CR>

% MF <CR>

MFI A/D ZERO

. . .

. . .

↑ Z

% AD <CR>

DEC A/D ZERO

. . .

. . .

↑ Z

% NB <CR>

NOTEBOOK INFORMATION

. . .

. . .

↑ Z

% SC <CR>

CHROMATOGRAM SCOPE DISPLAY

. . .

. . .

↑ Z

% SD

SAVE DATA

. . . 54

↑ Z

% EX

EXIT

§

The above sequence of commands would cause the A/D Converters to be calibrated, pertinent information concerning the data to be stored on disc, data to be taken from the spectrometer and stored on disc, a total ion current versus scan number plot to be displayed on the graphics display, the raw data to be retrieved from the disc and written on DEC TAPE and an exit to the monitor to be performed. Notice in the above sequence of commands that as each processor is entered, it identified itself with a title. Also, each processor exits back to command mode after typing "↑ Z". Under some conditions, the processor automatically exits while under other conditions, the user must force an exit by typing "↑ Z" (Control Z, typed by depressing the "CNTRL" key on the teletype and typing "Z"). The automatic exit is taken whenever it is possible for the processor to know when to exit (i.e., whenever there exists a fixed termination criterion). For those cases where this is not true, the processor continues to execute until the user causes an exit. For example, the MFI A/D ZERO routine continues to sample the output of the MFI (Magnetic Field Integrating) A/D convertor and display the results until the user requests an exit by typing an "↑ Z" thereby allowing the user time to adjust the trim pots on the converter hardware to obtain zero output for zero input.

If Skipping Mode is entered, the system sequentially outputs questions about whether a particular processor is to be entered. A user response of YES <CR> causes that processor to be entered. Any other response cause the next question to be output. For example, the same sequence of events as was accomplished previously in the Command Mode example could be accomplished using

SKIPPING MODE as follows:

§

The reason for providing both modes of operation is to facilitate use of the system by a wide range of users. As can be seen in the previous example, Skipping Mode has two disadvantages which are implicit in the sequential access method. First, some positive user response is required for each question. This is somewhat alleviated by the fact that any response other than YES <CR> is interpreted to be a negative response. Therefore it is not necessary to type anything other than a <CR>. Thus, in the above example, all instances of NO <CR> could be replaced with a <CR>. This makes skipping down through the commands much faster and thus not so inconvenient. The other problem with sequential access is the question of where to return in the access list at the completion of a processor. In the above example it is evident that ↑ Z causes a return to the beginning of the list. Another return is provided in this mode by a ↑ N. ↑ N causes a return to the next sequential question. Thus, when it was desired to go from the "Chromatogram Scope Display" processor to the "Save Data" processor, a ↑ N termination would have eliminated the need to respond to the five questions preceding the "Chromatogram" question and that question

itself. Thus, the interactive sequence for this procedure actually is as follows:

```
. . .  
. . .  
CHROMATOGRAM SCOPE DISPLAY YES <CR>  
. . .  
. . .  
↑ N  
CHROMATOGRAM CALCOMP DISPLAY NO <CR>  
SPECTRUM CALCOMP DISPLAY NO <CR>  
LINEPRINTER OUTPUT NO <CR>  
SAVE DATA YES <CR>  
. . .  
ETC.
```

COMMAND MODE is provided for those users who make extensive use of the system and need or desire maximum speed. It has the inherent disadvantage that the user must either memorize or have at hand a long list of somewhat mnemonic commands. SKIPPING MODE is provided for occasional users who have no need to memorize a command list.

E. LEVEL 3 Interactions:

In the previous section, direct interactions with the various processors were deliberately omitted from the examples to maintain clarity. Before discussing these interactions in detail it is instructive to consider part of the fundamental strategy used in the system. There are three different kinds of data stored by the system. These are spectral data, total ion current data, and information type data. Two different types of spectral data can be stored--namely, raw

data, which consist of magnetic field strength and ion intensity data, and reduced spectral data, which consist of mass number (to 1/100th of a mass unit) and ion intensity data. As far as the user is concerned, these two different kinds of spectra are the same except that the original raw data cannot be reconstructed from the reduced data. Total ion current data consists of an ordered list of the sum of the ion intensities for each particular scan of the spectrometer. Mathematically, total ion current is defined as follows:

$$TIC_J = \sum_{i=1}^{N_i} I_i$$

where I_i is the intensity of the i -th peak in the j -th scan and there are N_j peaks in the j -th scan. Information type data consists of answers to relevant questions asked by the computer prior to data acquisition. Each of these three forms of data is stored in a distinct area on the system disc pack. Access to these areas is accomplished via a directory (which is located at a fixed place on the disc) which consists of a list of identification parameters along with the appropriate disc addresses for the above-mentioned data. In most senses, the directory is similar to a table of contents (or index) to a book; that is, it contains pointers to relevant information within the three data areas mentioned above.

Interactions with each processor is different because of the differences in objectives; therefore each will be described briefly. First, let us consider the "NOTEBOOK INFORMATION" processor. As its name indicates, the "NOTEBOOK INFORMATION" processor is intended to allow entry of data similar to that which would be entered in a laboratory notebook by a conscientious experimenter during the process of conducting an experiment. The processor sequentially interrogates the system operator regarding a whole sequence of relevant parameters for a mass spectral experiment. The operator is expected to reply

to each interrogation with a character string not longer than seventy-two characters which indicates in some way the value of that parameter. The following is a typical example of the interactions required by that processor (assume that the system is in command mode):

F-INFORMATION DISC ADDRESS: 005400

§

As can be seen in this example, even the null response is accepted by the processor. Obviously, the null response conveys very little information. Many times mass spectral experiments involve identical instrument and computer parameters; therefore a "default" set of parameters is included in the "Notebook Information" processor along with a way of invoking one or several of these defaults easily. As can be seen in the above example, the interrogations are split into three distinct levels. The highest level is numbers 1 through 12, the second level is lettered A through H and the third level is again numbered much in the fashion of a topic outline. Two levels of defaults are provided. The first is the single interrogation default. It is invoked by the user responding to an interrogation by typing a ↑D character. This causes the processor to fill in the default value for that particular response and then to proceed to the next sequential interrogation. The second level is the so-called "high-level" default. It is invoked by typing a ↑A character and causes the processor to fill in default values for the current interrogation and all succeeding interrogations until an interrogation on the highest level is encountered. Thus, whole sections of the processor can be defaulted by a single response. The following is a list of the current defaults (where <null> is the "null" response):

1-DATE: 27-DEC-74
2-TIME: 00:02:42
3-OPERATOR: <null>
4-SAMPLE NAME: <null>
5-INSTRUMENT: MS-30
6-RUN TIME: <null>
7-CHARGES: <null>
8-INSTRUMENT SETTINGS:

A-MASS RANGE: 10-600 AMU
B-FILTER SETTING: OPEN
C-SCAN RATE: 10 SEC/DECADE
D-SOURCE PRESSURE: <null>
E-GAIN: <null>
F-RESOLUTION: 1000
G-ACCELERATING POTENTIAL: 4 KV
H-EI OR CI: EI

9-SAMPLE PARAMETERS:

A-TYPE: SOLID
B-AMOUNT: <null>
C-INLET METHOD: PROBE
D-SOURCE TEMPERATURE: <null>
E-MOLECULAR FORMULA: <null>
F-MOLECULAR WEIGHT: <null>
G-COMMENT: <null>

10-G/C PARAMETERS:

11-COMPUTER PARAMETERS:

A-SAMPLING RATE: 140 MICROSECONDS
B-INTENSITY THRESHOLD: 5
C-LOW MASS THRESHOLD: <null>
D-HIGH MASS THRESHOLD: <null>
E-CENTERING METHOD: <null>
F-COMMENT: <null>

The second processor we will consider is the "INTENSITY A/D ZERO" processor. The purpose of this processor is to provide the necessary information to allow the user to adjust the collector sensitivity output voltage on the spectrometer to an average value of zero. This is a necessary adjustment because of the strategy of thresholding used in the peak detection portion of the data acquisition software. The following is a typical example of the output from the "A/D ZERO" processor:

```

% AD

Final Value Reached

000000

000000

000000

000000

000000

↑V

Each value shown in the above example is the average of 1000 intensity A/D samples. The final value sought is zero so as to minimize the sensitivity of the peak detection algorithm to additive noise.

The third and probably most important processor available is the "Data Acquisition" processor. It provides the necessary interrupt-driven code to acquire and store on disc mass spectra in the form of raw magnetic field and raw intensity values. As an integral part of the processor, both peak detection and peak integration is performed, thereby yielding an ordered pair of numbers corresponding to the peak intensity and the magnetic field of the centroid of the detected peak. Figure 23 shows a hypothetical mass spectral peak and the relevant samples and results.

The integrated peak intensity for a peak such as is shown in Figure 23 given by:

$$I_r = \sum_{i=1}^n I_i$$

where n is the total number of samples across the peak waveform, I_i are the

Figure 23. Hypothetical Mass Peak Sent to computer by Interface.

individual intensity samples and I_T is the resultant integrated intensity. An index to the magnetic field sample nearest to the actual centroid of the peak is given by:

$$m = \sum_{i=1}^n i = \sum_{i=1}^i i / \sum_{i=1}^n i$$

where m is the index of the nearest sample and the outer sum in the numerator is the sum of the partial sums. This formula follows directly from the basic planar figure centroid equations. Table 2 shows the results of applying these formulas to the hypothetical peak of Fig. 22.

Table 2. Calculation of Centroid

Sample No.	M	1	1	1	
0	16	6	6	6	
1	17	9	15	21	
2	18	11	26	47	
3	19	13	39	86	$n = 10$
4	20	16	55	141	$I_T = 112$
5	21	15	70	221	$m = 5$
6	22	16	86	307	$M_m = 21$
7	23	13	99	406	
8	24	8	107	513	
9	25	5	112	625	

With a little thought one sees that the centroid index formula is independent of which direction the sum is done to within one sample uncertainty. Other parameters which are calculated by the "Data Acquisition" processor include the number of peaks in each scan, the total intensity of each scan, etc. An example of the output from the processor is as follows:

% DA
DATA ACQUISITION

```

SCAN PEAKS    TIC    SCAN PEAKS    TIC    SCAN PEAKS    TIC
000001 00007 0000001672 00002 00010 0000002539 00003 00008 0000002054

000013 00006 0000002019 00014 DONE

```

The last processor which will be included in this section is the "Mass Assignment" processor. This processor takes as input the results from the "Data Acquisition" processor and yields as output a table of correspondence between masses and intensities. A typical example of the output of this processor is shown below:

RUN NUMBER: 5
 UIC: 401
 SCAN NUMBER: 4
 NUMBER OF PEAKS: 44
 TOTAL ION CURRENT: 52948.
 MAXIMUM INTENSITY: 17705.

Kovats Searching Program (KSEARCH)

Introduction

The Kovats Search Program has been devised around the retention indices data base combined with the molecular weight, base mass spectral peak and response factors for some 200 compounds. In using the program, one can search any or all of the parameters listed above in any combination. Error limits on the values chosen for searching can be as broad or as narrow as desired.

Using the Program

PRN? KSEARCH

Calls the program and loads the data into memory. The computer will immediately respond with:

TYPE OPTION...-1=INSTRUCTIONS

This command allows one to select which type of data will be searched. If you are unsure of the option number you wish to use, type -1 and the following will appear:

INSTRUCTIONS ARE:

0=RESET; 1=TC-RF; 2=FID-RF; 3=MW; 4=LGPK; 5=C101; 6=PPQ;
7=C103; 8=OV-1; 9=DEX; 10=OV17; 11=C-20M; 12=DEGS; 13=MISC

Each of these options is defined as follows:

0=RESET

As you search, the number of possible hits is continually being reduced by previous searches. For example, if on the first search you asked for all compounds with molecular weight 58 you would have 20 possible hits. On the second search, if you asked for all compounds with RI of 1000 on C-103, the program would look for compounds with RI 1000 on C-103 and having molecular weight 58 and so on thru successive searches. If you desire to start over with the entire file than type 0 for option. The computer will immediately respond with TYPE OPTION again at which time you could initialize a new search.

1=TC-RF

Searches for a particular Response factor for the TC detector. The response factor in this case is defined as (actual area) X (RF) = true area.

2=FID-RF

Similar as above except uses response factors for flame detector.

3=MW

Searches for a particular molecular weight.

4=LGPK

Searches for a particular mass spectral base peak.

5=C101, 6=PPQ, 7=C103, 8=OV-1, 9=DEX, 10=OV17, 11=C-20M, 12=DEGS, 13=MISC

Searches for the retention index for the particular liquid phase or solid support listed.

After the option number has been typed in, the computer will respond with:

TYPE VALUE AND DEV.

The value you type in will have the deviation added and subtracted from it giving the boundaries of tolerable values to be accepted in the search.

The computer will next respond with:

20 HITS...PRINT

This indicates that it found 20 compounds with the type of data requested falling within the error limits. If you wish to print out the hits, type Y to which the computer will respond with:

PENTANAL	716
TETRACHLOROMETHANE	720
.	.
.	.
.	.
PROPYL	735

The first column is the name of the compound and the second column is the searched value for that compound.

After the hits have been listed or after an N or <CD> has been typed for the previous question, the computer will respond with:

ANOTHER SEARCH?

A Y will return you to the OPTION question. If you wish to search from the complete file rather than the file limited by the previous searches, type 0 for RESET. All the other options operate as described previously.

An N or <CD> will stop the program in a normal termination.

1          SBTTL TELETYPE I/O ROUTINE
2          *****
3          TELETYPE INPUT/OUTPUT ROUTINE
4          LINEPRINTER OUTPUT ROUTINE
5          BY: P. C. ABEGGLEN
6          OCT. 25, 1972
7          CALLING SEQUENCE:
8          INPUT
9              MOV     #MSG, -(SP)
10             MOV     #MSGEND, -(SP)
11             JSR     R5, TTYI
12          OUTPUT
13             MOV     #MSG, -(SP)
14             MOV     #MSGEND, -(SP)
15             JSR     R5, TTYO
16          OUTPUT(ASCII STRING MUST BE TERMINATED WITH NULL)
17             MOV     #MSG, -(SP)
18             JSR     R5, STRING
19
20          NOTE:
21          TWO SPECIAL EXITS FROM TTYI ARE PROVIDED.
22          ONE IS TAKEN TO A USER DEFINED LABEL CALLED
23          "STRT" IN THE EVENT OF A "CONTROL-B" BEING
24          INPUT AND THE OTHER IS TAKEN TO A LABEL CALLED "BKK" IN THE EVENT OF A "CONTROL-P"
25          BEING INPUT. IF THE "STRING" ENTRY POINT TO
26          THE TELETYPE OUTPUT ROUTINE IS USED, CARE MUST
27          BE TAKEN TO INSURE THAT THE STRING TO BE OUTPUT
28          IS @#ACTUALLY TERMINATED BY A NULL CHAR#ACTER.
29          OTHERWISE, THE OUTPUT MAY NEVER TERMINATE .
30          MSG=STARTING ADDRESS OF BUFFER HEADER
31          MSGEND=ENDING ADDRESS OF MESSAGE+1
