

SSC CONCEPTUAL DESIGN REPORT LATTICE

E. D. COURANT, A. A. GARREN,
D. E. JOHNSON AND K. STEFFEN

February 1986

ABSTRACT

The lattice design used for the SSC Conceptual Design Report is described below. Each of the units which are used in the design are described and plots of lattice functions are shown. A final SYNCH output of the lattice as tuned for both injection and collision optics is included.

Introduction

This report contains summary information on the Conceptual Design Report lattice. The main features of the machine are beamlines separated vertically by 70 cm, 6.6 Tesla, 1-in-1 magnets, 192 meter long cells with 60° phase advance, and eight 1152 meter long straight sections located in two clusters.

Global Structure

The lattice has a racetrack shape with eight long straight sections placed in two clusters of four each, see Figures 1 and 2. Two straight sections in each cluster contain crossing interaction regions. The IRs in the East cluster are the medium- β IRs $M1$ and $M2$ with ± 102 m free space about the IPs; those in the West cluster are the low- β IRs $L1$ and $L2$ with ± 20 m. The other two straight sections U in the East cluster are utility regions; the two labeled XF in the West cluster are identical to the U straight sections, but are reserved for future development as IRs. The (vertical) crossings occur only in the four experimental straight sections. The East and West clusters are connected by the North and South arcs. Both arcs are identical and each contains 166 cells.

Each cluster contains four insertion modules which are matched to the beta functions and dispersion of the regular cells. Every module contains a dispersion suppressor, a straight section, another dispersion suppressor, and a half-cell. Apart from the final half-cell, each module is antisymmetric about its center. All of the corresponding dispersion suppressors in the eight modules are identical. All of the straight sections (and modules) have equal length. Each module has betatron phase advance equal to an odd multiple of 90° , so that for each pair of IRs there is cancellation of chromatic perturbations.^[1-4] These phase advances do not change between collision and injection optics. The modules are shown in Figures 4, 5, and 6.

Because the two beams pass through common quadrupoles in the IRs, the focussing polarity of two quadrupoles above and below each other on the two beamlines have the opposite sign.

Another global feature concerns the disposition of the correction spools, which are invariably on the clockwise side of each quadrupole when the ring is viewed from above.

Arc Cells C

A diagram of a cell is shown schematically in Fig. 7. The 96 meter long half-cells contain five dipoles whose field at 20 TeV is 6.6 tesla. The quadrupole gradients at 20 TeV have magnitude 212 T/m. There are two types of regular cells: those that contain two chromaticity correcting sextupoles and those that have none. Those with sextupoles occur in multiples of six, i.e., in integral numbers of betatron wavelengths.

Dispersion Suppressors

The suppressor consists of three cells identical to regular ones, except that their quadrupoles have five different lengths but normal gradients and spacing. The five lengths are chosen to fit the cell dispersion and slope values at one end to zero values at the other. The matching is done in such a way that the two suppressors on either side of the straight section, which have equal lengths but opposite gradients in the corresponding quadrupoles, match the dispersion to the centers of QD and QF quadrupoles in the cells respectively.

Crossing Insertions L

The two proton beams collide at the IP at the centers of these low- β crossing insertions (Figures 5 and 8), which have 20 meters of magnet-free space on either side of the IP for the detectors. Just beyond these triplets the beams are separated by dipole splitter magnets and led into separated, parallel beamlines. The quadrupole lengths are such that the gradients do not exceed those of the cells (212 T/m) for any optics, except for the IR triplets which can go up to 235 T/m.

Crossing Insertions M

The medium- β insertions (Figures 6 and 9) are similar to the L s but they produce collision β values of 10 rather than 0.5 meters, and they have ± 102 meters of free space.

Vertical Beam Splitting and Dispersion Matching

Fig. 3 shows a side view of the vertical beamlines of the two rings. Moving towards the IP, the beams are brought to horizontal, parallel sections separated by 35 cm from each other by pairs of vertical dipoles that bend the beam through equal and opposite angles. Following these sections the beams are brought to the common beamline containing the IP by additional pairs of equal and opposite vertical bends.

The intermediate vertical step between the cells and the collinear region matches the vertical dispersion caused by the vertical bending, by means of the set of five quadrupoles which comprise two 90° FODO cells. The transfer matrix for the two cells is ideally $M = -1$, which reverses the vertical dispersion and exactly cancels the effects of the vertical bends. Moreover the section is invisible for the beta function matching between the cells and the IP. However, since the center quadrupole, Q4, has little effect on the dispersion (which is zero at its center), it is used to improve the beta function behaviour by allowing its value to be different from that of the QV quadrupoles.

Utility Insertion U

A utility insertion U and its dispersion suppressors are shown in Fig. 4. These insertions are used for the injection, beam abort and radiofrequency acceleration systems. Dipoles in the center (not shown) produce doglegs needed for the beam abort and injection systems. Since there is no quadrupole focussing included in these doglegs, they do not effect the optics. The RF system is to be located in one of the end regions.

Optics

Two principal optical configurations are included in the CDR design, an injection optics where all of the interaction points have relatively large beta values, and an experimental optics where the betas are much smaller. For each optics, both medium- β IRs are tuned identically as are the two low- β IRs.

This report concludes with SYNCH output^[5] for both of these optics. Magnetic fields, gradients, lengths and beta functions are given in this part of the report. The SYNCH program was used for designing this lattice. Chromatic properties of the lattice are given in another report.^[6]

Acknowledgements

We wish to thank the other participants in the Realistic Lattice workshop and Clustered IR Option workshop held at the CDG for their contributions, and we are especially grateful to A. Chao, M. Harrison, S. Peggs, J. Peterson, and R. Tallman for their valuable work and ideas.

 6.60 T, 212 T/M, 235 T/M MAXIMUM IN Q1,Q2,Q3 TRIPLET, 60 DEGREE CELLS
 ARCS ---
 96 METER HALF-CELLS, FIVE 16.54 M DIPOLES
 3.32 M QUADRUPOLE, 5.98 M SPOOL DRIFT, 0.8 M DIPOLE SEPARATION DRIFTS.
 ALL SPOOLS DOWNSTREAM FROM QUADS.

VERTICAL BEAM SEPARATING SECTION --- CONTAINS STEP WITH TWO 90 DEGREE CELLS
 --- 70 CM BEAMLINE SEPARATION
 --- SPLITTER MAGNET 79.5 METERS FROM IP

ARCS CONTAIN 166 CELLS EACH
 TWO 1152 METER LONG CROSSING STRAIGHTS WITH +- 20 METERS FREE SPACE (X)
 TWO 1152 METER LONG CROSSING STRAIGHTS WITH +-101.75 METERS FREE SPACE (XX)
 2400 METERS BETWEEN IP'S
 FOUR 1152 METER UTILITY STRAIGHTS (U)
 STRAIGHTS SEPARATED BY 6 1/2 CELL DISPERSION SUPPRESSORS
 STRAIGHTS X, XX, AND U IMBEDDED IN 2400 M LONG SUPER-CELLS Z, ZZ, AND UU
 ONE SUPERPERIOD, CROSSINGS ALL HAVE DE SEQUENCE, 90 DEG PHASE INTERVALS
 BETWEEN STRAIGHTS (MOD 180 DEG)
 3840 DIPOLES IN RING, CIRCUMFERENCE 82.944 KM, TUNE 78 1/3
