## SUMMARY

An ongoing cooperative airfoil research program has been established between the National Aeronautics and Space Administration (NASA) and the Deutsche Forschungs- und Versuchsanstalt fur Luft- und Raumfahrt e. V. (DFVLR). The Langley 0.3-meter Transonic Cryogenic Tunnel (0.3-m TCT), with its unique test envelope and high Reynolds number capability, is being utilized for this program. This collaborative effort between NASA and the DFVLR will produce flight equivalent Reynolds number data on advanced supercritical type airfoils designed in the Federal Republic of Germany.

During the first series of tests in this cooperative effort, data were obtained on a 15.24 cm chord model of the CAST 10-2/DOA 2 airfoil. This report presents the experimental aerodynamic data obtained from tests of a 7.62 cm chord model of the CAST 10-2/DOA 2 airfoil in the 0.3-m TCT. This was the third of a series of tests conducted in the cooperative program. Test temperature was varied from 270 K to 110 K at pressures from 1.5 to 5.75 atmospheres. Mach number was varied from 0.60 to 0.80, and the Reynolds number (based on airfoil chord) was varied from 2 to 20 million. Descriptions of the 0.3-m TCT, the airfoil model, the test instrumentation, and the testing procedures are also included.

## INTRODUCTION

With the successful development and operation of the Langley 0.3-meter Transonic Cryogenic Tunnel (0.3-m TCT) at the NASA Langley Research Center (refs. 1 and 2), it has become possible to test airfoils over a wide range of Reynolds numbers, including Reynolds numbers at or near full-scale values. NASA has made an effort to effectively use this new testing capability by establishing a collaborative NASA/DFVLR program to test advanced technology airfoils, designed in the Federal Republic of Germany, in the 0.3-m TCT. The objectives of the cooperative program are the following: (1) to provide an aerodynamic assessment of DFVLR and other German advanced technology airfoil designs at flight equivalent Reynolds numbers; (2) to provide a systematic indication of Reynolds number sensitivity for this class of advanced airfoils; (3) to enable an evaluation (from low to high Reynolds numbers) of current DFVLR and NASA analytical techniques; and (4) to provide an opportunity to correlate the 0.3-m TCT results with results from other major transonic wind tunnels (ref. 3).

This report presents the aerodynamic data obtained from tests in the 0.3-m TCT of a 7.62 cm chord model of the CAST 10-2/DOA 2 airfoil, the third model tested in the cooperative NASA/DFVLR series of tests. The present tests are also aimed at isolating the possible two-dimensional wall interference effects on data obtained in the 0.3-m TCT. This effort is made possible by the fact that a 15.24 cm chord version of the CAST 10-2/DOA 2 airfoil was tested in the 0.3-m TCT as the first series of tests in this cooperative program (ref. 4). In order to expedite the publication of these advanced results, this report presents, without analysis, the data from tests of the 7.62 cm chord model in the 0.3-m TCT.

## SYMBOLS

The measurements of this investigation are presented in the International System of Units (SI). The symbols in brackets are those used on computer generated tables in the appendices.

$b$ ,[B]	airfoil model span, cm
$c$ ,[C]	airfoil model chord, cm
[CC]	section chord-force coefficient from airfoil pressures
$c_d$	section drag-force coefficient from wake measurements
[CD2] through [CD6]	section drag-force coefficients from wake measurements from pitot tubes on the traversing rake
$c_m$ ,[CM]	section pitching-moment coefficient about quarter-chord point
$c_n$ ,[CN]	section normal-force coefficient from airfoil pressures
$c_{n_\alpha}$	slope of normal-force coefficient versus angle-of-attack
[CP]	pressure coefficient
M,[MACH]	free-stream Mach number
[MLOC]	local Mach number
[P,L/PT]	ratio of local static pressure to tunnel stagnation pressure
$p_t$ ,[PT]	tunnel stagnation pressure, atm
$R_c$ ,[RC]	Reynolds number based on airfoil chord
$T_t$ ,[TT]	tunnel stagnation temperature, K
$T_{t,min}$	minimum tunnel stagnation temperature based on free-stream saturation, K
$x$ ,[X]	airfoil abscissa, cm
$y$ ,[Y]	spanwise distance along model from centerline of tunnel and model, cm
$z$	airfoil ordinate, cm
$\alpha$ ,[ALPHA]	uncorrected angle-of-attack, deg

## WIND TUNNEL AND MODEL

### Wind Tunnel

The airfoil was tested in the 20 cm x 60 cm two-dimensional test-section insert of the 0.3-m TCT. The 0.3-m TCT is a continuous flow, single-return, fan-driven wind tunnel which uses nitrogen as a test gas. A photograph and schematic drawing of the tunnel are shown in figures 1(a) and 1(b), respectively. The operating temperature range of the 0.3-m TCT is from about 78 K to 327 K with stagnation pressures ranging from slightly greater than 1 atmosphere to 6 atmospheres. With the two-dimensional test section installed, the test-section Mach number can be varied from 0.05 to about 0.9. The ability to operate at cryogenic temperatures and 6 atmospheres pressure provides an extremely high Reynolds number capability at relatively low model loadings. In addition, the unique ability to vary pressure and temperature independently of Mach number provides independent control and assessment of aeroelastic, viscous, and compressibility effects on the aerodynamic parameters being measured. The Reynolds number and Mach number capabilities of the tunnel are shown in figure 2.

A photograph and sketch of the 20 cm x 60 cm two-dimensional test section are shown in figures 3(a) and 3(b). Figure 3(a) is a top-view of the test section with the plenum lid and test section ceiling removed. This test section, which features a slotted floor and ceiling, incorporates computer-driven angle-of-attack and momentum rake systems. The angle-of-attack mechanism has a traversing range of  $\pm 20$  degrees which can be offset from zero degrees in either direction at model installation. The momentum rake, located just downstream of the airfoil, provides up to six total pressure measurements across slightly more than half the width of the tunnel. This test section also features removable model modules, one of which is shown in figure 4 in the raised position following the removal of the plenum lid and test section ceiling. There is also provision for test section side wall boundary layer removal just upstream of the model; however, this system was not used during these tests. Additional design features and characteristics of the 0.3-m TCT are presented in references 2 and 5.

3 inches. Model

Model design and fabrication.- The Dornier GmbH designed CAST 10-2/DOA 2 is a 12.1-percent-thick advanced technology airfoil (ref. 6). The airfoil model used during these tests has a chord of 7.62 cm. Table 1 lists both the design and measured section coordinates for the model which was designed and built at the DFVLR Research Center in Goettingen, Federal Republic of Germany.

The model was made of Germancode 1.4980 stainless steel (similar to AISI 660 stainless steel). The fabrication procedure for the model consisted of the following steps. Initially, the upper and lower model halves were pre-milled to rectangular blocks, followed by the stepwise milling of these blocks to approximate the final airfoil contours. These model halves were subsequently heat treated at the temperature to be used for brazing ( $1120^{\circ}$  C) in order to avoid warpage during the brazing processes.

The next step consisted of milling and electrically discharging channels in the inside surfaces of both halves of the model for the pressure tubing. In addition, elongated slots called "solder deposits" were milled out of the inside surface of the lower half to provide reservoirs for the silver solder to be used in the brazing

process. Sockets were then drilled in the channels to near the intended airfoil surface to accommodate 1.2 mm outside diameter stainless steel pressure tubing. The tubes were positioned and silver soldered in place, and the solder deposits were filled for the subsequent brazing process. Following that, the model dimensions were checked, the mating surfaces were cleaned, and the model halves were fitted and clamped together. The model halves were then joined together by brazing in a protective atmosphere. During this brazing process, the silver solder ran from the solder deposits by capillary action and thus distributed solder to the inside surfaces for the braze joint. A final check for possible model deformation was performed following this brazing process.

The next stage of model construction consisted of relieving any residual stresses in the assembled model by cooling it to liquid nitrogen ( $\text{LN}_2$ ) temperatures and then rearming it to ambient temperatures. Subsequently, the model was contoured by numerical milling, the surfaces hand finished, and the static pressure orifices drilled normal to the model surfaces to meet the tubes. Finally, another check of the model contour was performed. Additional details on the model design and construction techniques are given in reference 7.

Figure 5 shows the model installed in the 0.3-m TCT two-dimensional test section. In this view, the plenum lid and test section ceiling have been removed and the upper surface of the model can be seen.

The model is equipped with 53 static pressure orifices each having a nominal diameter of 0.3 mm. Figure 6 is a schematic drawing showing the general location of the orifices on the upper and lower surfaces of the model. Table 2 lists the  $x/c$  and  $y/(b/2)$  location for each orifice.

Model accuracy and integrity.- Past experience has shown that many metals undergo relatively drastic and irreversible changes in shape when exposed to a cryogenic environment. This has been vividly seen in some of the airfoil models built for testing in the 0.3-m TCT. For some of the models, the post-test model shapes have been found to be drastically different from the pre-test shapes. Procedures have been established in order to try to alleviate this problem. It is now standard practice that all airfoil models intended for testing in the 0.3-m TCT must be thermally cycled to cryogenic temperatures during the fabrication process in order that they might stabilize before the final model validation check.

The DFVLR cycled the CAST 10-2/DOA 2 model between room and  $\text{LN}_2$  temperature several times during the fabrication process and each time the model surface contour checked out successfully. When the model was received by NASA, a check of the model contour was performed in order to verify that the model represented the DFVLR's proposed airfoil shape and to establish a baseline for post-test measurements to determine possible model deformation. The model contours were measured using a "validator," which under ideal conditions has an accuracy of 0.00127 cm. The pre-test measurements of the airfoil model agreed closely with the DFVLR's proposed airfoil shape.

The results reported herein were obtained during fifty-four runs over a pressure range from 1.5 to 5.75 atmospheres. The model was subsequently used for condensation studies at extremely low temperatures in the 0.3-m TCT. Post-test measurements of the model contours agreed with those obtained during pre-test measurements. Post-test inspection of the model showed no structural damage, cracking, or erosion. The model in all respects was considered to be of good design and construction and fully acceptable for testing in a cryogenic wind tunnel.

## INSTRUMENTATION

A detailed discussion of the instrumentation and procedures selected for the calibration and control of the 0.3-m TCT can be found in reference 8. However, brief discussions of instrumentation related to the derivation of the primary airfoil data are presented herein.

Pressure Instrumentation.- For two-dimensional airfoil tests, the 0.3-m TCT is equipped to obtain static-pressure measurements on the airfoil surface, total head measurements in the airfoil wake, and static-pressure measurements on the test section sidewalls, floor, and ceiling. The pressures were measured using individual transducers except for the tunnel floor and ceiling pressures which were measured using a scanning valve system capable of operating ten 48-port scanning valves. Because of the large changes in pressure of the tunnel over its operational range, commercially available high-precision variable capacitive pressure transducers are used instead of conventional strain-gage pressure transducers.

Pressure transducers with a maximum range of 6.8 atmospheres are used for model and tunnel wall pressures. More sensitive transducers, having a maximum range of 1.36 atmospheres, are used for pressure measurements in the airfoil wake. The transducers have an accuracy of  $\pm 0.25$  percent of reading from -25 percent to 100 percent of full scale. A total of 81 pressure channels were used for this test.

Traversing Wake-Survey Probe.- A computer-controlled vertical traversing probe system is located on the left sidewall of the two-dimensional test section downstream of the turntable (fig. 3b). The mechanism has a traversing range of 25.4 cm. The probe support can be located with the probe measurement plane at either tunnel station 21.0 cm or 26.0 cm. For this test, the measurements were made at the 21.0 cm station which placed the measurement plane about 2.16 chord lengths downstream of the airfoil trailing-edge. The primary purpose of this system is to survey the total pressures in the airfoil wake by using a pitot-tube survey rake. Details of the multitube pitot rake are shown in figure 7. Nine pitot probes are mounted on the assembly. Five of the pitot probes were used during the present tests. Tunnel sidewall static-pressure taps are also provided in the plane of the pitot probes for use in the determination of the airfoil drag coefficient. Individual transducers are used for each tube on the probe assembly in order to keep pressure response time low. The vertical position of the probe is recorded by the data acquisition system using the output from a digital shaft encoder geared to the probe drive mechanism. Through computer control, the wake survey probe is synchronized with the scanning valves so that the probe is moved to a different vertical location each time the scanning valves are advanced to a new port.

## 0.3-m TCT DATA ACQUISITION SYSTEM

For the present study, data from the 0.3-m TCT was recorded on magnetic tape on a computer controlled high-speed digital data acquisition system located in the control room of the 0.3-m TCT. This system has a total of 192 analog channels of recording capability with a maximum range of 131 mV and a resolution of 1 part in 8191. All analog data were filtered with a 10 Hz low pass filter. An operating and acquisition program is used by the computer to scan the data acquisition hardware and to write the raw data on tape.

Through the use of a "real-time program," the computer calculates and provides real-time displays and plots of the various aerodynamic parameters and controls both the angle of attack and wake-survey-probe drive systems. The computer uses this program to correct the Mach number for real-gas effects and tunnel calibration and to calculate the local pressure ratios and pressure coefficients. The pressure coefficients are integrated around the airfoil in order to calculate  $c_n$  and  $c_m$ . The section drag-force coefficient,  $c_d$ , is calculated by integration of the total head loss through the airfoil wake. In addition, this program interfaces the computer with an intelligent graphics terminal which produces plots of the various aerodynamic parameters. These plots can be sent to a plotter/printer which produces hard copies if desired.

#### TEST PROGRAM

An effort was made by DFVLR and NASA engineers to establish a test program that overlapped the tests of the 15.24 cm chord model of the CAST 10-2/DOA 2 airfoil which was the first model tested in the cooperative NASA/DFVLR program. The overall aim was to establish the effects of transition (fixed and free), Reynolds number, and Mach number on the flow development. Figure 8 shows the Reynolds number and Mach number ranges for this test. Test temperature was varied from 270 K to 110 K at pressures from 1.5 to 5.75 atmospheres. The maximum angle of attack range was from -1 to +9 degrees.

#### TEST PROCEDURES

Pressure data.- For the tests reported herein, 10 samples of the airfoil static pressure data were taken per scan for the model. Due to the addition of individual transducers for each orifice on the model, each sample of the data consisted of taking simultaneous static pressure readings from all orifices on the model. The averaging period per scan was half a second. These 10 samples were all taken while the rake was located at its first position. Ten samples of the total pressure were taken at each step (vertical position) of the rake. There was a half second delay time between each step of the rake, as well as a half second averaging period per step. Typically, for each  $\alpha$  at each test condition, the rake was stepped 40 times through the wake. This resulted in a total of about 40 seconds being required to obtain the wake pressure measurements needed for the determination of airfoil drag at each  $\alpha$ , whereas the airfoil pressures were acquired in the first half second.

Transition.- Transition strips, located on both the upper and lower surfaces, were used during a portion of the testing to evaluate their effect on the aerodynamic characteristics of the model. The leading edge of the upper surface strip was located at the 6-percent chord line and the leading edge of the lower surface strip was located at the 5-percent chord line. Figure 8 shows the test conditions for fixed transition. The strips consisted of 0.0229 mm diameter glass beads that were applied using a clear acrylic spray. The spray may have added some thickness to the resulting transition strips which were approximately 1.575 mm wide.

## DATA REDUCTION

The test data were reduced according to a standard data reduction process described in an unpublished in-house manual. The normal force and pitching moment (at the quarter-chord) coefficients are calculated from a pressure integration around the airfoil. The total drag force coefficient is obtained from an integration of the total pressure decrement across the airfoil wake corrected for a threshold decrement, which accounts for any nonzero pressure decrement outside the wake. The threshold decrement used for this test is 0.0002. In order to compute the total drag, the threshold decrement is compared to the incremental drag for each rake tube at each rake position. If the incremental drag is greater than or equal to the threshold decrement, a weighting factor (incremental area) is applied and the incremental drag is included in the running sum of the total drag. If the incremental drag is less than the threshold decrement, the weighting factor is set to zero and the incremental drag is not included in the running sum of the total drag. The values of CD2 through CD6 in the appendices correspond to these total drag coefficients for the five rake pitot tubes used during these tests. These five tubes (2 through 6) are labeled in figure 7. Tube 2 is located at the centerline of the test section. The calculated drag coefficient from tube 2 is used in the plots, figures 10-21.

## PRESENTATION OF RESULTS

The experimental data are presented without corrections for wind tunnel wall interference effects. Discussions of various methods for determining angle of attack and Mach number corrections are contained in references 9, 10, and 11.

Some of the data of the present investigation was taken after the onset of boundary-layer separation from the tunnel sidewalls; therefore, some caution should be exercised when using the data in this region. To aid the user in this respect, figure 9 is presented to show a conservative region of "acceptable" (i.e. absence of any indication of wall separation) airfoil data in terms of normal force coefficient and Mach number. This figure was derived by assessing the  $c_n \alpha$  slope trends and the drag characteristics across

the tunnel which were obtained from the multtube wake survey rake (fig. 7). For instance, if the data reflected a premature "break" or reduction in the variation of  $c_n$  with  $\alpha$  and a noticeable inconsistency in the drag values across the tunnel, these trends were considered to be an indication of significant model induced sidewall boundary-layer separation. The region of "acceptable" data, as shown in figure 9, reflects the conditions at which there were no indications of abnormal variations in normal force or spanwise drag trends. This region is considered to be conservative because the drag rake measurements were taken 2.16 chord lengths downstream of the airfoil trailing-edge at a position where the "growth" of spanwise flow would be more extensive than at the model station.

All of the pressure data as well as the remainder of the tabulated results are presented in the appendices. Appendix A contains the transition free tabulated data and Appendix B contains the transition fixed tabulated data. An outline of the plotted data presented herein follows:

CONCLUDING REMARKS

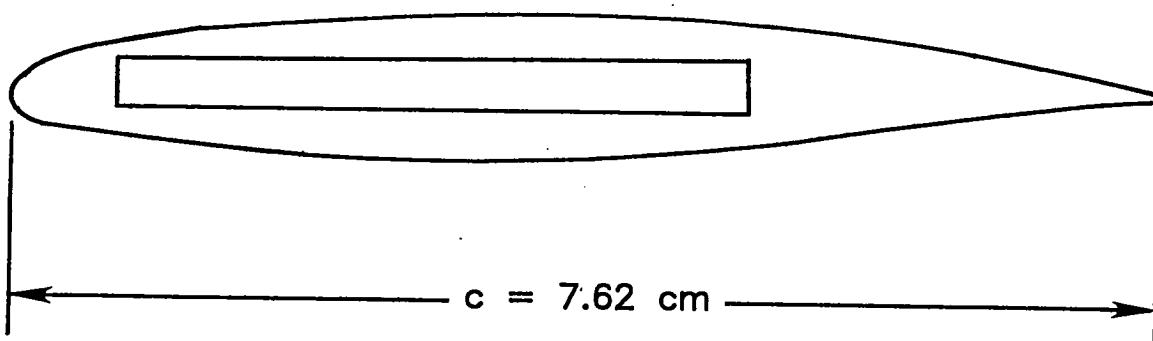

As part of a cooperative program between NASA and DFVLR, wind tunnel tests of a 7.62 cm chord model of the CAST 10-2/DOA 2 airfoil has been conducted in the Langley 0.3-m TCT at Mach numbers from 0.60 to 0.80 and Reynolds number (based on airfoil chord) from 2 to 20 million. During earlier tests, data were obtained on a 15.24 cm chord model of this same airfoil. The results of the present tests will, therefore, provide an opportunity to isolate the two-dimensional wall interference effects on airfoil data obtained in the 0.3-m TCT. The results are presented herein without analysis.

16. Abstract  Wind tunnel tests of an advanced technology airfoil, the CAST 10-2/DOA 2, been conducted in the Langley 0.3-Meter Transonic Cryogenic Tunnel (0.3-m TCT). This was the third of a series of tests conducted in a cooperative airfoil research program between the National Aeronautics and Space Administration (NASA) and the Deutsche Forschungs- und Versuchsanstalt fur Luft- und Raumfahrt e. V. (DFVLR). During the first series of tests in this cooperative effort, data were obtained on a 15.24 cm chord model of the CAST 10-2/DOA 2 airfoil. For these tests, temperature was varied from 270 K to 110 K at pressures from 1.5 to 5.75 atmospheres. Mach number was varied from 0.60 to 0.80, and the Reynolds number (based on airfoil chord) was varied from 2 to 20 million. The purpose of this report is to present, without analysis, the aerodynamic data for the 7.62 cm chord airfoil model used in these tests. This report also includes descriptions of the 0.3-m TCT, the airfoil model, the test instrumentation, and the testing procedures.
