(57) Abstract: Disclosed herein are compounds of Formula (I) which inhibit, regulate and/or modulate tyrosine kinase receptors, particularly Axl and Mer signal transduction pathways related to the changes in cellular activities, compositions containing the compounds, methods of using the compounds to treat kinase-dependent diseases and conditions, and methods for making the compounds.

## COMPOUNDS FOR THE TREATMENT OF KINASE-DEPENDENT DISORDERS

### Cross-Reference to Related Applications

[0001] This application claims priority to U.S. Provisional Application Serial Number 62/856,920, the entire contents of which is incorporated by reference herein.

### Field of the Invention

[0002] The invention relates to compounds that modulate cellular activities such as proliferation, differentiation, programmed cell death, migration, and chemoinvasion by modulating protein kinase enzymatic activity. Even more specifically, the invention relates to compounds which inhibit, regulate, and/or modulate Axl and Mer receptor tyrosine kinases, compositions which contain these compounds, methods of using them to treat kinase-dependent diseases and conditions, synthesis of the compounds, and processes for formulating the compounds for pharmaceutical purposes.

### Background of the Invention

[0003] Human Axl belongs to the TAM subfamily of receptor tyrosine kinases that includes Mer. TAM kinases are characterized by an extracellular ligand binding domain consisting of two immunoglobulin-like domains and two fibronectin type III domains. Axl is overexpressed in a number of tumor cell types and was initially cloned from patients with chronic myelogenous leukemia. When overexpressed, Axl exhibits transforming potential. Axl signaling is believed to cause tumor growth through activation of proliferative and anti-apoptotic signaling pathways. Axl has been associated with cancers such as lung cancer, myeloid leukemia, uterine cancer, ovarian cancer, gliomas, melanoma, thyroid cancer, renal cell carcinoma, osteosarcoma, gastric cancer, prostate cancer, and breast cancer. The over-expression of Axl results in a poor prognosis for patients with the indicated cancers.

[0004] Activation of Mer, like Axl, conveys downstream signaling pathways that cause tumor growth and activation. Mer binds ligands such as the soluble protein Gas-6. Gas-6 binding to Mer induces autophosphorylation of Mer on its intracellular domain, resulting in downstream signal activation. Over-expression of Mer in cancer cells leads to increased metastasis, most likely by generation of soluble Mer extracellular domain protein as a decoy receptor. Tumor cells secrete a soluble form of the extracellular Mer receptor which reduces the ability of soluble Gas-6 ligand to activate Mer on endothelial cells, leading to cancer progression.

[0005] Therefore, a need exists for compounds that inhibit TAM receptor tyrosine kinases such as Axl and Mer for the treatment of selected cancers.

### Summary of the Invention

[0006] In one aspect, the invention includes a compound of Formula I:

[00013] The symbol “-” means a single bond, and “=” means a double bond.

[00014] As used herein, the singular forms "a," "an," and "the" include plural reference unless the context clearly dictates otherwise.

[00015] When a variable is defined generically, with a number of possible substituents, each individual radical can be defined with or without the bond. For example, if R<sup>z</sup> can be hydrogen, this can be indicated as “-H” or “H” in the definition of R<sup>z</sup>.

[00016] When chemical structures are depicted or described, unless explicitly stated otherwise, all carbons are assumed to have hydrogen substitution to conform to a valence of four. For example, in the structure on the left-hand side of the schematic below, there are nine hydrogens implied. The nine hydrogens are depicted in the right-hand structure. Sometimes a particular atom in a structure is described in textual formula as having a hydrogen or hydrogens as substitution (expressly defined hydrogen), for example, -CH<sub>2</sub>CH<sub>2</sub>-

. It is understood by one of ordinary skill in the art that the aforementioned descriptive techniques are common in the chemical arts to provide brevity and simplicity to description of otherwise complex structures.

[00017] If a group “R” is depicted as “floating” on a ring system, as for example in the formula:

then, unless otherwise defined, a substituent “R” may reside on any atom of the ring system, assuming replacement of a depicted, implied, or expressly defined hydrogen from one of the ring atoms, so long as a stable structure is formed.

[00018] If a group “R” is depicted as floating on a fused ring system, as for example in the formulae:

then, unless otherwise defined, a substituent “R” may reside on any atom of the fused ring system, assuming replacement of a depicted hydrogen (for example the -NH- in the formula above), implied hydrogen (for example, in the formula above, where the hydrogens are not shown but understood to be present), or expressly defined hydrogen (for example, where in the formula above, “Z” equals =CH-) from one of the ring atoms, so long as a stable structure is formed. In the example depicted, the “R” group may reside on either the 5-membered or the 6-membered ring of the fused ring system. When a group “R” is depicted as existing on a ring system containing saturated carbons, for example in the formula:

where, in this example, “y” can be more than one, assuming each replaces a currently depicted, implied, or expressly defined hydrogen on the ring; then, unless otherwise defined, where the resulting structure is stable, two “R”s may reside on the same carbon. A simple example is when R is a methyl group, there can exist a geminal dimethyl on a carbon of the depicted ring (an “annular” carbon). In another example, two R’s on the same carbon,

including that carbon, may form a ring, thus creating a spirocyclic ring (a “spirocyclic” group) structure with the depicted ring as for example in the formula:

**[000128]** In one aspect, the invention includes a pharmaceutical composition comprising a compound of the invention, or a pharmaceutically acceptable salt thereof and a pharmaceutically acceptable carrier or excipient.

[000129] In another aspect, the invention includes a method for inhibiting a protein kinase, the method comprising contacting the protein kinase with a compound of the invention.

[000130] In one embodiment of this aspect, the protein kinase is Axl, Mer, c-Met, KDR, or a combination thereof.

[000131] In one aspect, the invention includes a method for treating a disease, disorder, or syndrome in a subject, the method comprising administering to the subject in need thereof a therapeutically effective amount of a compound, or a pharmaceutical composition of the invention.

[000132] In one embodiment of this aspect, the disease, disorder, or syndrome is cancer.

#### **General Administration**

[000133] Administration of the compounds of the invention, or their pharmaceutically acceptable salts, in pure form or in an appropriate pharmaceutical composition, can be carried out via any of the accepted modes of administration or agents for serving similar utilities. Thus, administration can be, for example, orally, nasally, parenterally (intravenous, intramuscular, or subcutaneous), topically, transdermally, intravaginally, intravesically, intracistemally, or rectally, in the form of solid, semi-solid, lyophilized powder, or liquid dosage forms, such as, for example, tablets, suppositories, pills, soft elastic and hard gelatin capsules, powders, solutions, suspensions, aerosols, and the like, preferably in unit dosage forms suitable for simple administration of precise dosages.

[000134] The compositions will include a conventional pharmaceutical carrier or excipient and a compound of the invention as the/an active agent, and, in addition, may include other medicinal agents, pharmaceutical agents, carriers, adjuvants, and the like. Compositions of the invention may be used in combination with anticancer or other agents that are generally administered to a patient being treated for cancer. Adjuvants include preserving, wetting, suspending, sweetening, flavoring, perfuming, emulsifying, and dispensing agents. Prevention of the action of microorganisms can be ensured by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, sorbic acid, and the like. It may also be desirable to include isotonic agents, for example sugars, sodium chloride, and the like. Prolonged absorption of the injectable pharmaceutical form can be brought about by the use of agents delaying absorption, for example, aluminum monostearate, and gelatin.

[000135] If desired, a pharmaceutical composition of the invention may also contain minor amounts of auxiliary substances such as wetting or emulsifying agents, pH buffering agents, antioxidants, and the like, such as, for example, citric acid, sorbitan monolaurate, triethanolamine oleate, butylated hydroxytoluene, and the like.

[000136] Compositions suitable for parenteral injection may comprise physiologically acceptable sterile aqueous or nonaqueous solutions, dispersions, suspensions or emulsions, and sterile powders for reconstitution into sterile injectable solutions or dispersions. Examples of suitable aqueous and nonaqueous carriers, diluents, solvents, or vehicles include water, ethanol, polyols (propyleneglycol, polyethyleneglycol, glycerol, and the like), suitable mixtures thereof, vegetable oils (such as olive oil), and injectable organic esters such as ethyl oleate. Proper fluidity can be maintained, for example, by the use of a coating such as lecithin, by the maintenance of the required particle size in the case of dispersions, and by the use of surfactants.

[000137] One preferable route of administration is oral, using a convenient daily dosage regimen that can be adjusted according to the degree of severity of the disease-state to be treated.

[000138] Solid dosage forms for oral administration include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound is admixed with at least one inert customary excipient (or carrier) such as sodium citrate or dicalcium phosphate or (a) fillers or extenders, as for example, starches, lactose, sucrose, glucose, mannitol, and silicic acid, (b) binders, as for example, cellulose derivatives, starch, alginates, gelatin, polyvinylpyrrolidone, sucrose, and gum acacia, (c) humectants, as for example, glycerol, (d) disintegrating agents, as for example, agar-agar, calcium carbonate, potato or tapioca starch, alginic acid, croscarmellose sodium, complex silicates, and sodium carbonate, (e) solution retarders, as for example paraffin, (f) absorption accelerators, as for example, quaternary ammonium compounds, (g) wetting agents, as for example, cetyl alcohol, and glycerol monostearate, magnesium stearate, and the like (h) adsorbents, as for example, kaolin and bentonite, and (i) lubricants, as for example, talc, calcium stearate, magnesium stearate, solid polyethylene glycols, sodium lauryl sulfate, or mixtures thereof. In the case of capsules, tablets, and pills, the dosage forms may also comprise buffering agents.

[000139] Solid dosage forms as described above can be prepared with coatings and shells, such as enteric coatings and others well known in the art. They may contain pacifying

agents and can also be of such composition that they release the active compound or compounds in a certain part of the intestinal tract in a delayed manner. Examples of embedded compositions that can be used are polymeric substances and waxes. The active compounds can also be in microencapsulated form, if appropriate, with one or more of the above-mentioned excipients.

**[000140]** Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs. Such dosage forms are prepared, for example, by dissolving, dispersing, and the like, a compound(s) of the invention, or a pharmaceutically acceptable salt thereof, and optional pharmaceutical adjuvants in a carrier, such as, for example, water, saline, aqueous dextrose, glycerol, ethanol, and the like; solubilizing agents and emulsifiers, as for example, ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propyleneglycol, 1,3-butyleneglycol, and dimethylformamide; oils, in particular, cottonseed oil, groundnut oil, corn germ oil, olive oil, castor oil, and sesame oil, glycerol, tetrahydrofurfuryl alcohol, polyethyleneglycols, and fatty acid esters of sorbitan; or mixtures of these substances, and the like, to thereby form a solution or suspension.

**[000141]** Suspensions, in addition to the active compounds, may contain suspending agents, as for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol, and sorbitan esters, microcrystalline cellulose, aluminum metahydroxide, bentonite, agar-agar, and tragacanth, or mixtures of these substances, and the like.

**[000142]** Compositions for rectal administrations are, for example, suppositories that can be prepared by mixing the compounds of the present invention with for example suitable non-irritating excipients or carriers such as cocoa butter, polyethyleneglycol, or a suppository wax, which are solid at ordinary temperatures but liquid at body temperature and therefore melt while in a suitable body cavity and release the active component therein.

**[000143]** Dosage forms for topical administration of a compound of this invention include ointments, powders, sprays, and inhalants. The active component is admixed under sterile conditions with a physiologically acceptable carrier and any preservatives, buffers, or propellants as may be required. Ophthalmic formulations, eye ointments, powders, and solutions are also contemplated as being within the scope of this invention.

**[000144]** Generally, depending on the intended mode of administration, the pharmaceutically acceptable compositions will contain about 1% to about 99% by weight of a compound(s) of the invention, or a pharmaceutically acceptable salt thereof, and 99% to

1% by weight of a suitable pharmaceutical excipient. In one example, the composition will be between about 5% and about 75% by weight of a compound(s) of the invention, or a pharmaceutically acceptable salt thereof, with the rest being suitable pharmaceutical excipients.

**[000145]** Actual methods of preparing such dosage forms are known, or will be apparent, to those skilled in this art; for example, see Remington's Pharmaceutical Sciences, 18th Ed., (Mack Publishing Company, Easton, Pa., 1990). The composition to be administered will, in any event, contain a therapeutically effective amount of a compound of the invention, or a pharmaceutically acceptable salt thereof, for treatment of a disease-state in accordance with the teachings of this invention.

**[000146]** The compounds of the invention, or their pharmaceutically acceptable salts, are administered in a therapeutically effective amount which will vary depending upon a variety of factors including the activity of the specific compound employed, the metabolic stability and length of action of the compound, the age, body weight, general health, sex, diet, mode, and time of administration, rate of excretion, drug combination, the severity of the particular disease-states, and the host undergoing therapy. The compounds of the present invention can be administered to a patient at dosage levels in the range of about 0.1 to about 1,000 mg per day. For a normal human adult having a body weight of about 70 kilograms, a dosage in the range of about 0.01 to about 100 mg per kilogram of body weight per day is an example. The specific dosage used, however, can vary. For example, the dosage can depend on a number of factors including the requirements of the patient, the severity of the condition being treated, and the pharmacological activity of the compound being used. The determination of optimum dosages for a particular patient is well known to one of ordinary skill in the art.

**[000147] Combination Therapy**

**[000148]** A compound as disclosed herein can be administered as a single therapy or in combination ("co-administered") with one or more additional therapies for the treatment of a disease or disorder, for instance a disease or disorder associated with hyper-proliferation such as cancer. Therapies that may be used in combination with a compound disclosed herein include: (i) surgery; (ii) radiotherapy (for example, gamma radiation, neutron beam radiotherapy, electron beam radiotherapy, proton therapy, brachytherapy, and systemic radioactive isotopes); (iii) endocrine therapy; (iv) adjuvant therapy, immunotherapy, CAR T-cell therapy; and (v) other chemotherapeutic agents.

**[000149]** The term “co-administered” (“co-administering”) refers to either simultaneous administration, or any manner of separate sequential administration, of a compound of the invention or a salt thereof, and a further active pharmaceutical ingredient or ingredients, including cytotoxic agents and radiation treatment. If the administration is not simultaneous, the compounds are administered in a close time proximity to each other. Furthermore, it does not matter if the compounds are administered in the same dosage form, e.g. one compound may be administered topically and another compound may be administered orally.

**[000150]** Typically, any agent that has activity against a disease or condition being treated may be co-administered. Examples of such agents for cancer treatment can be found, for instance, at <https://www.cancer.gov/about-cancer/treatment/drugs> (last visited January 22, 2019) and in publically available sources such as Cancer Principles and Practice of Oncology by V. Immunotherapy can help the immune system recognize cancer cells, or enhance a response against cancer cells. Immunotherapies include active and passive immunotherapies. In some embodiments, administration of a therapeutically effective amount of a combination comprising a compound of the invention and an immunotherapeutic agent, results in synergistic anti-tumor activity and/or antitumor activity that is more potent than the additive effect of administration of a compound of the invention or immunotherapeutic agent alone.

**[000158]** Human cancers harbor numerous genetic and epigenetic alterations, generating neoantigens potentially recognizable by the immune system (Sjoblom et al. (2006) Science 314:268-74). The adaptive immune system, comprised of T and B lymphocytes, has powerful anti-cancer potential, with a broad capacity and exquisite specificity to respond to diverse tumor antigens. Further, the immune system demonstrates considerable plasticity and a memory component. The successful harnessing of all these attributes of the adaptive immune system would make immunotherapy unique among all cancer treatment modalities.

**[000161]** In certain embodiments of each of the aforementioned aspects, as well as other aspects and embodiments described elsewhere herein, the immunotherapeutic agent enhances the activity of the compound of the invention.

**[000162]** In certain embodiments of each of the aforementioned aspects, as well as other aspects and embodiments described elsewhere herein, the compound of the invention and the immunotherapeutic agent act synergistically. In various embodiments described herein, an exemplary immunotherapeutic agent is an immune cell (e.g. T-cell, dendritic cell, a natural killer cell and the like) modulator chosen from an agonist or an activator of a costimulatory molecule, wherein the modulator is a monoclonal antibody, a bispecific antibody comprising one or more immune checkpoint antigen binding moieties, a trispecific antibody, or an immune cell-engaging multivalent antibody/fusion protein/construct known in the art. In some embodiments, the immunotherapeutic agent can be an antibody that modulates a costimulatory molecule, bind to an antigen on the surface of an immune cell, or a cancer cell. In each of these different embodiments, the antibody modulator can be a monoclonal antibody, a polyclonal antibody, a bispecific antibody, a trispecific or multispecific format antibody, a fusion protein, or a fragment thereof, for example, a Diabody, a Single-chain (sc)-diabody (scFv)<sub>2</sub>, a Miniantibody, a Minibody, a Barnase-barstar, a scFv-Fc, a sc(Fab)<sub>2</sub>, a Trimeric antibody construct, a Triabody antibody construct, a Trimerbody antibody construct, a Tribody antibody construct, a Collabody antibody construct, a (scFv-TNFa)<sub>3</sub>, or a F(ab)<sub>3</sub>/DNL antibody construct.

**[000163]** In certain embodiments of each of the aforementioned aspects, as well as other aspects and embodiments described elsewhere herein, the immunotherapeutic agent is an agent that modulates immune responses, for example, a checkpoint inhibitor or a checkpoint agonist. In some embodiments, the immunotherapeutic agent is an agent that enhances anti-tumor immune responses. In some embodiments, the immunotherapeutic agent is an agent that increases cell-mediated immunity. In some embodiments, the immunotherapeutic agent is an agent that increases T-cell activity. In some embodiments, the immunotherapeutic agent is an agent that increases cytolytic T-cell (CTL) activity.

**[000164]** In some embodiments, the present methods of treatment may include administering a compound of the present invention together in combination with a molecule, for example, a binding agent, for example, an antibody or functional fragment thereof that modulates (activates or inhibits) a checkpoint protein. A checkpoint inhibitor can be any molecule, agent, treatment and/or method of inhibiting an immune checkpoint, and/or promoting an inhibitor of an immune checkpoint, e.g., by promoting an intrinsic immune checkpoint inhibitor; inhibiting a transcription factor involved in the expression of an immune checkpoint; and/or by acting in concert with some additional extrinsic factor. For example, a checkpoint inhibitor could include a treatment that inhibits transcription factors involved the expression of immune checkpoint genes, or promotes the expression of transcription factors for tumor-suppressor genes, e.g., BACH2 (Luan et al., (2016). Transcription Factors and Checkpoint Inhibitor Expression with Age: Markers of Immunosenescence. *Blood*, 128(22), 5983). Moreover, a checkpoint inhibitor can inhibit the transcription of immune checkpoint genes; the modification and/or processing of immune checkpoint mRNA; the translation of immune checkpoint proteins; and/or molecules involved in immunity or the immune checkpoint pathway, e.g., PD-1 transcription factors such as HIF-1, STAT3, NF-KB, and AP-1, or the activation of common oncogenic pathways such as JAK/STAT, RAS/ERK, or PI3K/AKT/mTOR (Zerdes et al., Genetic, transcriptional and post-translational regulation of the programmed death protein ligand 1 in cancer: biology and clinical correlations, *Oncogene* volume 37, pages463 9-4661 (2018), the disclosure of which is incorporated herein by reference in its entirety).

**[000165]** Checkpoint inhibitors can include treatments, molecules, agents, and/or methods that regulate immune checkpoints at the transcriptional level, e.g., using the RNA-interference pathway co-suppression, and/or post-transcriptional gene silencing (PTGS) (e.g., microRNAs, miRNA; silencing-RNA, small-interfering-RNA, or short-interfering-

RNA (siRNA). Transcriptional regulation of checkpoint molecules has been shown to involve mir-16, which has been shown to target the 3'UTR of the checkpoint mRNAs CD80, CD274 (PD-L1) and CD40 (Leibowitz et al, Post-transcriptional regulation of immune checkpoint genes by mir-16 in melanoma, *Annals of Oncology* (2017) 28; v428-v448). Mir-33a has also been shown to be involved in regulating the expression of PD-1 in cases of lung adenocarcinoma (Boldini et al, Role of microRNA-33a in regulating the expression of PD-1 in lung adenocarcinoma, *Cancer Cell Int.* 2017; 17: 105, the disclosure of which is incorporated herein by reference in its entirety).

**[000166]** T-cell-specific aptamer-siRNA chimeras have been suggested as a highly specific method of inhibiting molecules in the immune checkpoint pathway (Hossain et al, The aptamer-siRNA conjugates: reprogramming T cells for cancer therapy, *Ther. Deliv.* 2015 Jan; 6(1): 1-4, the disclosure of which is incorporated herein by reference in its entirety).

**[000167]** Alternatively, members of the immune checkpoint pathway can be inhibited using treatments that affect associated pathways, e.g., metabolism. For example, oversupplying the glycolytic intermediate pyruvate in mitochondria from CAD macrophages promoted expression of PD-L1 via induction of the bone morphogenetic protein 4/phosphorylated SMAD1/5/IFN regulatory factor 1 (BMP4/p-SMAD1/5/IRF1) signaling pathway. Accordingly, implementing treatments that modulate the metabolic pathway can result in subsequent modulation of the immunoinhibitory PD-1/PD-L1 checkpoint pathway (Watanabe et al, Pyruvate controls the checkpoint inhibitor PD-L1 and suppresses T cell immunity, *J Clin Invest.* 2017 Jun 30; 127(7): 2725-2738).

**[000168]** Checkpoint immunity can be regulated via oncolytic viruses that selectively replicate within tumor cells and induce acute immune responses in the tumor-micro-environment, i.e., by acting as genetic vectors that carry specific agents (e.g., antibodies, miRNA, siRNA, and the like) to cancer cells and effecting their oncolysis and secretion of cytokines and chemokines to synergize with immune checkpoint inhibition (Shi et al., *Cancer Immunotherapy: A Focus on the Regulation of Immune Checkpoints*, *Int J Mol Sci.* 2018 May; 19(5): 1389). Currently, there are clinical trials underway that utilize the following viruses as checkpoint inhibitors: poliovirus, measles virus, adenoviruses, poxviruses, herpes simplex virus (HSV), coxsackieviruses, reovirus, Newcastle disease virus (NDV), T-VEC (a herpes virus encoded with GM-CSF (granulocyte-macrophage colony stimulating factor)), and HI01 (Shi et al., supra).

[000169] Checkpoint inhibitors can operate at the translational level of checkpoint immunity. The translation of mRNA into protein represents a key event in the regulation of gene expression, thus inhibition of immune checkpoint translation is a method in which the immune checkpoint pathway can be inhibited.

[000170] Inhibition of the immune checkpoint pathway can occur at any stage of the immune checkpoint translational process. For example, drugs, molecules, agents, treatments, and/or methods can inhibit the initiation process (whereby the 40S ribosomal subunit is recruited to the 5' end of the mRNA and scans the 5'UTR of the mRNA toward its 3' end. Inhibition can occur by targeting the anticodon of the initiator methionyl-transfer RNA (tRNA) (Met-tRNAi), its base-pairing with the start codon, or the recruitment of the 60S subunit to begin elongation and sequential addition of amino acids in the translation of immune-checkpoint-specific genes. Alternatively, a checkpoint inhibitor can inhibit checkpoints at the translational level by preventing the formation of the ternary complex (TC), i.e., eukaryotic initiation factor (eIF)2 (or one or more of its  $\alpha$ ,  $\beta$ , and  $\gamma$  subunits); GTP; and Met-tRNAi.

[000171] Checkpoint inhibition can occur via destabilization of eIF2a by precluding its phosphorylation via protein kinase R (PKR), PERK, GCN2, or HRI, or by precluding TCs from associating with the 40S ribosome and/or other initiation factors, thus preventing the preinitiation complex (PIC) from forming; inhibiting the eIF4F complex and/or its cap-binding protein eIF4E, the scaffolding protein eIF4G, or eIF4A helicase. Methods discussing the translational control of cancer are discussed in Truitt et al., *New frontiers in translational control of the cancer genome*, *Nat Rev Cancer*. 2016 Apr 26; 16(5): 288-304, the disclosure of which is incorporated herein by reference in its entirety.

[000172] Checkpoint inhibitors can also include treatments, molecules, agents, and/or methods that regulate immune checkpoints at the cellular and/or protein level, e.g., by inhibiting an immune checkpoint receptor. Inhibition of checkpoints can occur via the use of antibodies, antibody fragments, antigen-binding fragments, small-molecules, and/or other drugs, agents, treatments, and/or methods.

[000173] Immune checkpoints refer to inhibitory pathways in the immune system that are responsible for maintaining self-tolerance and modulating the degree of immune system response to minimize peripheral tissue damage. However, tumor cells can also activate immune system checkpoints to decrease the effectiveness of immune response ('block' the immune response) against tumor tissues. In contrast to the majority of anti-cancer agents,

checkpoint inhibitors do not target tumor cells directly, but rather target lymphocyte receptors or their ligands in order to enhance the endogenous antitumor activity of the immune system. (Pardoll, 2012, Nature Reviews Cancer 12:252-264).

**[000174]** In some embodiments, the immunotherapeutic agent is a modulator of PD-1 activity, a modulator of PD-L1 activity, a modulator of PD-L2 activity, a modulator of CTLA-4 activity, a modulator of CD28 activity, a modulator of CD80 activity, a modulator of CD86 activity, a modulator of 4-1BB activity, an modulator of OX40 activity, a modulator of KIR activity, a modulator of Tim-3 activity, a modulator of LAG3 activity, a modulator of CD27 activity, a modulator of CD40 activity, a modulator of GITR activity, a modulator of TIGIT activity, a modulator of CD20 activity, a modulator of CD96 activity, a modulator of IDO 1 activity, a cytokine, a chemokine, an interferon, an interleukin, a lymphokine, a member of the tumor necrosis factor (TNF) family, or an immunostimulatory oligonucleotide. In some embodiments, the immune checkpoint modulator, i.e. is an inhibitor or antagonist, or is an activator or agonist, for example, a CD28 modulator, a 4-1BB modulator, an OX40 modulator, a CD27 modulator, a CD80 modulator, a CD86 modulator, a CD40 modulator, or a GITR modulator, a Lag-3 modulator, a 4-1BB modulator, a LIGHT modulator, a CD40 modulator, a GITR modulator, a TGF-beta modulator, a TIM-3 modulator, a SIRP-alpha modulator, a TIGIT modulator, a VSIG8 modulator, a BTLA modulator, a SIGLEC7 modulator, a SIGLEC9 modulator, a ICOS modulator, a B7H3 modulator, a B7H4 modulator, a FAS modulator, and/or a BTNL2 modulator. In some embodiments, the immunotherapeutic agent is an immune checkpoint modulator as described above (e.g., an immune checkpoint modulator antibody, which can be in the form of a monoclonal antibody, a bispecific antibody comprising one or more immune checkpoint antigen binding moieties, a trispecific antibody, or an immune cell-engaging multivalent antibody/fusion protein/construct known in the art).

**[000175]** In some embodiments, the immunotherapeutic agent is an agent that inhibits the activity of PD-1. In some embodiments, the immunotherapeutic agent is an agent that inhibits the activity of PD-L1 and/or PD-L2. In some embodiments, the immunotherapeutic agent is an agent that inhibits the activity of CTLA-4. In some embodiments, the immunotherapeutic agent is an agent that inhibits the activity of CD80 and/or CD86. In some embodiments, the immunotherapeutic agent is an agent that inhibits the activity of TIGIT. In some embodiments, the immunotherapeutic agent is an agent that inhibits the

activity of KIR. In some embodiments, the immunotherapeutic agent is an agent that enhances or stimulates the activity of activating immune checkpoint receptors.

**[000176]** PD-1 (also known as Programmed Death 1, CD279, PDCD1) is a cell surface receptor with a critical role in regulating the balance between stimulatory and inhibitory signals in the immune system and maintaining peripheral tolerance (Ishida, Y et al. 1992 EMBO J. 11 3887; Kier, Mary E et al. 2008 Annu Rev Immunol 26 677-704; Okazaki, Taku et al. 2007 International Immunology 19 813-824). PD-1 is an inhibitory member of the immunoglobulin super-family with homology to CD28. The structure of PD-1 is a monomeric type 1 transmembrane protein, consisting of one immunoglobulin variable-like extracellular domain and a cytoplasmic domain containing an immunoreceptor tyrosine-based inhibitory motif (ITIM) and an immunoreceptor tyrosine-based switch motif (ITSM). Expression of PD-1 is inducible on T cells, B cells, natural killer (NK) cells and monocytes, for example upon lymphocyte activation via T cell receptor (TCR) or B cell receptor (BCR) signalling (Kier, Mary E et al. 2008 Annu Rev Immunol 26 677-704; Agata, Y et al 1996 Int Immunol 8 765-72). PD-1 is a receptor for the ligands CD80, CD86, PD-L1 (B7-H1, CD274) and PD-L2 (B7-DC, CD273), which are cell surface expressed members of the B7 family (Freeman, Gordon et al. 2000 J Exp Med 192 1027; Latchman, Y et al. 2001 Nat Immunol 2 261). Upon ligand engagement, PD-1 recruits phosphatases such as SHP-1 and SHP-2 to its intracellular tyrosine motifs which subsequently dephosphorylate effector molecules activated by TCR or BCR signalling (Chemnitz, J et al. 2004 J Immunol 173 945-954; Riley, James L 2009 Immunological Reviews 229 114-125) In this way, PD-1 transduces inhibitory signals into T and B cells only when it is engaged simultaneously with the TCR or BCR.

**[000177]** PD-1 has been demonstrated to down-regulate effector T cell responses via both cell-intrinsic and cell-extrinsic functional mechanisms. Inhibitory signaling through PD-1 induces a state of unresponsiveness in T cells, resulting in the cells being unable to clonally expand or produce optimal levels of effector cytokines. PD-1 may also induce apoptosis in T cells via its ability to inhibit survival signals from co-stimulation, which leads to reduced expression of key anti-apoptotic molecules such as Bcl-XL (Kier, Mary E et al. 2008 Annu Rev Immunol 26 677-704). In addition to these direct effects, recent publications have implicated PD-1 as being involved in the suppression of effector cells by promoting the induction and maintenance of regulatory T cells (TREG). For example, PD-L1 expressed on dendritic cells was shown to act in synergy with TGF- $\beta$  to promote the induction of CD4+

FoxP3+TREG with enhanced suppressor function (Francisco, Loise M et al. 2009 J Exp Med 206 3015-3029).

**[000178]** TIM-3 (also known as T-cell immunoglobulin and mucin-domain containing-3, TIM-3, Hepatitis A virus cellular receptor 2, HAVCR2, HAVcr-2, KIM-3, TIMD-3, TIMD3, Tim-3, and CD366) is a ~33.4-kDa single-pass type I membrane protein involved in immune responses (Sanchez-Fueyo et al, Tim-3 inhibits T helper type 1-mediated auto- and alloimmune responses and promotes immunological tolerance, Nat. Immunol. 4:1093-1101(2003)).

**[000179]** TIM-3 is selectively expressed on Th1 -cells, and phagocytic cells (e.g., macrophages and dendritic cells). The use of siRNA or a blocking antibody to reduce the expression of human resulted in increased secretion of interferon  $\gamma$  (IFN- $\gamma$ ) from CD4 positive T-cells, implicating the inhibitory role of TIM-3 in human T cells. Analysis of clinical samples from autoimmune disease patients showed no expression of TIM-3 in CD4 positive cells. In particular, expression level of TIM-3 is lower and secretion of IFN- $\gamma$  is higher in T cell clones derived from the cerebrospinal fluid of patients with multiple sclerosis than those in clones derived from normal healthy persons (Koguchi K et al, J Exp Med. 203:1413-8. (2006)).

**[000180]** TIM-3 is the receptor for the ligands Galectin-9, which is a member of galectin family, molecules ubiquitously expressed on a variety of cell types and which binds  $\beta$ -galactoside; Phosphatidyl serine (PtdSer) (DeKryff et al., T cell/transmembrane, Ig, and mucin-3 allelic variants differentially recognize phosphatidylserine and mediate phagocytosis of apoptotic cells, J Immunol. 2010 Feb 15;184(4): 1918-30); High Mobility Group Protein 1 (also known as HMGB1, HMG1, HMG3, SBP-1, HMG-1, and high mobility group box 1) Chiba et al, Tumor-infiltrating DCs suppress nucleic acid-mediated innate immune responses through interactions between the receptor TIM-3 and the alarmin HMGB1, Nat Immunol. 2012 Sep;13(9):832-42); and Carcinoembryonic Antigen Related Cell Adhesion Molecule 1 (also known as CEACAM1, BGP, BGP1, BGPI, carcinoembryonic antigen related cell adhesion molecule 1) (Huang et al, CEACAM1 regulates TIM-3-mediated tolerance and exhaustion, Nature. 2015 Jan 15;517(7534):386-90).

**[000181]** BTLA (also known as B- and T-lymphocyte attenuator, BTLA1, CD272, and B and T lymphocyte associated) is a ~27.3-kDa single-pass type I membrane protein involved in lymphocyte inhibition during immune response. BTLA is constitutively expressed in both

B and T cells. BTLA interacts with HVEM (herpes virus-entry mediator), a member of the tumor-necrosis factor receptor (TNFR) family (Gonzalez et al., Proc. Natl. Acad. Sci. USA, 2005, 102: 1116-21). The interaction of BTLA, which belongs to the CD28 family of the immunoglobulin superfamily, and HVEM, a costimulatory tumor-necrosis factor (TNF) receptor (TNFR), is unique in that it defines a cross talk between these two families of receptors. BTLA contains a membrane proximal immunoreceptor tyrosine-based inhibitory motif (ITIM) and membrane distal immunoreceptor tyrosine-based switch motif (ITSM). Disruption of either the ITIM or ITSM abrogated the ability of BTLA to recruit either SHP1 or SHP2, suggesting that BTLA recruits SHP1 and SHP2 in a manner distinct from PD-1 and both tyrosine motifs are required to block T cell activation. The BTLA cytoplasmic tail also contains a third conserved tyrosine-containing motif within the cytoplasmic domain, similar in sequence to a Grb-2 recruitment site (YXN). Also, a phosphorylated peptide containing this BTLA N-terminal tyrosine motif can interact with GRB2 and the p85 subunit of PI3K in vitro, although the functional effects of this interaction remain unexplored in vivo (Gavrieli et al., Biochem. Biophys Res Commun, 2003, 312, 1236-43). BTLA is the receptor for the ligands PTPN6/SHP-1; PTPN11/SHP-2; TNFRSF14/HVEM; and B7H4.

**[000182]** VISTA (also known as V-domain Ig suppressor of T cell activation VSIR, B7-H5, B7H5, GI24, PP2135, SISP1, DD1alpha, VISTA, C10orf54, chromosome 10 open reading frame 54, PD-1H, and V-set immunoregulatory receptor) is a ~33.9-kDa single-pass type I membrane protein involved in T-cell inhibitory response, embryonic stem cells differentiation via BMP4 signaling inhibition, and MMP14-mediated MMP2 activation (Yoon et al., Control of signaling-mediated clearance of apoptotic cells by the tumor suppressor p53, Science. 2015 Jul 31; 349(6247): 1261669). VISTA interacts with the ligand VSIG-3 (Wang et al., VSIG-3 as a ligand of VISTA inhibits human T-cell function, Immunology. 2019 Jan;156(1):74-85)

**[000183]** LAG-3 (also known as Lymphocyte-activation gene 3, LAG3, CD223, and lymphocyte activating 3) is a ~57.4-kDa single-pass type I membrane protein involved in lymphocyte activation that also binds to HLA class-II antigens. LAG-3 is a member of the immunoglobulin supergene family, and is expressed on activated T cells (Huard et al., 1994, Immunogenetics 39:213), NK cells (Triebel et al., 1990, J. Exp. Med. 171:1393-1405), regulatory T cells (Huang et al., 2004, Immunity 21:503-513; Camisaschi et al., 2010, J Immunol. 184:6545-6551; Gagliani et al., 2013, Nat Med 19:739-746), and plasmacytoid dendritic cells (DCs) (Workman et al., 2009, J Immunol 182:1885-1891). LAG-3 is a

membrane protein encoded by a gene located on chromosome 12, and is structurally and genetically related to CD4. Similar to CD4, LAG-3 can interact with MHC class II molecules on the cell surface (Baixeras et al, 1992, *J. Exp. Med.* 176:327-337; Huard et al, 1996, *Eur. J. Immunol.* 26:180-186). It has been suggested that the direct binding of LAG-3 to MHC class II plays a role in down-regulating antigen-dependent stimulation of CD4<sup>+</sup> T lymphocytes (Huard et al, 1994, *Eur. J. Immunol.* 24:3216-3221) and LAG-3 blockade has also been shown to reinvigorate CD8<sup>+</sup> lymphocytes in both tumor or self-antigen (Gross et al, 2007, *J Clin Invest.* 117:3383-3392) and viral models (Blackburn et al, 2009, *Nat. Immunol.* 10:29-37). Further, the intra-cytoplasmic region of LAG-3 can interact with LAP (LAG-3-associated protein), which is a signal transduction molecule involved in the downregulation of the CD3/TCR activation pathway (Iouzalén et al, 2001, *Eur. J. Immunol.* 31:2885-2891). Moreover, CD4<sup>+</sup>CD25<sup>+</sup> regulatory T cells (Treg) have been shown to express LAG-3 upon activation, which contributes to the suppressor activity of Treg cells (Huang, C. et al, 2004, *Immunity* 21:503-513). LAG-3 can also negatively regulate T cell homeostasis by Treg cells in both T cell-dependent and independent mechanisms (Workman, C. J. and Vignali, D. A., 2005, *J. Immunol.* 174:688-695).

**[000184]** LAG-3 has been shown to interact with MHC class II molecules (Huard et al, CD4/major histocompatibility complex class II interaction analyzed with CD4- and lymphocyte activation gene-3 (LAG-3)-Ig fusion proteins, *Eur J Immunol.* 1995 Sep;25(9):2718-21).

regions distinct from the primary tumor or cancer after a metastasis has formed or has been established, 4) reducing or inhibiting formation or establishment of additional metastasis after the metastasis has been formed or established, 5) prolonged overall survival, 6) prolonged progression free survival, or 7) disease stabilization. The methods include administering to a subject in need thereof a compound of the present invention in combination with a checkpoint inhibitor as described herein.

**[000215]** In an embodiment of the disclosure, administration of a compound of the present invention with the immunotherapeutic agent provides a detectable or measurable improvement in a condition of a given subject, such as alleviating or ameliorating one or more adverse (physical) symptoms or consequences associated with the presence of a cell proliferative or cellular hyperproliferative disorder, neoplasia, tumor or cancer, or metastasis, i.e., a therapeutic benefit or a beneficial effect.

**[000216]** A therapeutic benefit or beneficial effect is any objective or subjective, transient, temporary, or long-term improvement in the condition or pathology, or a reduction in onset, severity, duration or frequency of adverse symptom associated with or caused by cell proliferation or a cellular hyperproliferative disorder such as a neoplasia, tumor or cancer, or metastasis. It may lead to improved survival. A satisfactory clinical endpoint of a treatment method in accordance with the disclosure is achieved, for example, when there is an incremental or a partial reduction in severity, duration or frequency of one or more associated pathologies, adverse symptoms or complications, or inhibition or reversal of one or more of the physiological, biochemical or cellular manifestations or characteristics of cell proliferation or a cellular hyperproliferative disorder such as a neoplasia, tumor or cancer, or metastasis. A therapeutic benefit or improvement therefore may be, but is not limited to destruction of target proliferating cells (e.g., neoplasia, tumor or cancer, or metastasis) or ablation of one or more, most or all pathologies, adverse symptoms or complications associated with or caused by cell proliferation or the cellular hyperproliferative disorder such as a neoplasia, tumor or cancer, or metastasis. However, a therapeutic benefit or improvement need not be a cure or complete destruction of all target proliferating cells (e.g., neoplasia, tumor or cancer, or metastasis) or ablation of all pathologies, adverse symptoms or complications associated with or caused by cell proliferation or the cellular hyperproliferative disorder such as a neoplasia, tumor or cancer, or metastasis. For example, partial destruction of a tumor or cancer cell mass, or a stabilization of the tumor or cancer mass, size or cell numbers by inhibiting progression or worsening of the tumor or cancer,

can reduce mortality and prolong lifespan even if only for a few days, weeks or months, even though a portion or the bulk of the tumor or cancer mass, size or cells remain.

**[000217]** Specific non-limiting examples of therapeutic benefit include a reduction in neoplasia, tumor or cancer, or metastasis volume (size or cell mass) or numbers of cells, inhibiting or preventing an increase in neoplasia, tumor or cancer volume (e.g., stabilizing), slowing or inhibiting neoplasia, tumor or cancer progression, worsening or metastasis, or inhibiting neoplasia, tumor or cancer proliferation, growth or metastasis.

**[000218]** In an embodiment of the disclosure, administration of the immunotherapeutic agent, in combination therapy with a compound of the invention, provides a detectable or measurable improvement or overall response according to the irRC (as derived from time-point response assessments and based on tumor burden), including one or more of the following: (i) irCR—complete disappearance of all lesions, whether measurable or not, and no new lesions (confirmation by a repeat, consecutive assessment no less than 4 weeks from the date first documented), (ii) irPR—decrease in tumor burden >50% relative to baseline (confirmed by a consecutive assessment at least 4 weeks after first documentation).

**[000219]** Optionally, any method described herein may not take effect immediately. For example, treatment may be followed by an increase in the neoplasia, tumor or cancer cell numbers or mass, but over time eventual stabilization or reduction in tumor cell mass, size or numbers of cells in a given subject may subsequently occur.

**[000220]** Additional adverse symptoms and complications associated with neoplasia, tumor, cancer and metastasis that can be inhibited, reduced, decreased, delayed or prevented include, for example, nausea, lack of appetite, lethargy, pain and discomfort. Thus, a partial or complete decrease or reduction in the severity, duration or frequency of adverse symptom or complication associated with or caused by a cellular hyperproliferative disorder, an improvement in the subjects quality of life and/or well-being, such as increased energy, appetite, psychological well-being, are all particular non-limiting examples of therapeutic benefit.

**[000221]** A therapeutic benefit or improvement therefore can also include a subjective improvement in the quality of life of a treated subject. In additional embodiment, a method prolongs or extends lifespan (survival) of the subject. In a further embodiment, a method improves the quality of life of the subject.

**[000222]** In one embodiment, administration of the immunotherapeutic agent, in combination therapy with a compound of the invention, results in a clinically relevant

improvement in one or more markers of disease status and progression selected from one or more of the following: (i): overall survival, (ii): progression-free survival, (iii): overall response rate, (iv): reduction in metastatic disease, (v): circulating levels of tumor antigens such as carbohydrate antigen 19.9 (CA19.9) and carcinoembryonic antigen (CEA) or others depending on tumor, (vi) nutritional status (weight, appetite, serum albumin), (viii): pain control or analgesic use, (ix): CRP/albumin ratio.

**[000223]** Treatment with a compound of the invention in combination with an immunotherapeutic agent gives rise to more complex immunity including not only the development of innate immunity and type-1 immunity, but also immunoregulation which more efficiently restores appropriate immune functions.

**[000224]** In various exemplary methods, a checkpoint inhibitor antibody (monoclonal or polyclonal, bispecific, trispecific, or an immune cell-engaging multivalent antibody/fusion protein/construct) directed to a checkpoint molecule of interest (e.g., PD-1) may be sequenced and the polynucleotide sequence may then be cloned into a vector for expression or propagation. The sequence encoding the antibody or antigen-binding fragment thereof of interest may be maintained in vector in a host cell and the host cell can then be expanded and frozen for future use. Production of recombinant monoclonal antibodies in cell culture can be carried out through cloning of antibody genes from B cells by means known in the art. See, e.g. Tiller et al, 2008, J. Immunol. Methods 329, 112; U.S. Pat. No. 7,314,622.

**[000225]** Pharmaceutical compositions containing a compound of the invention according to the present disclosure will comprise an effective amount of a compound of the invention, an immunotherapeutic agent, and/or both, typically dispersed in a pharmaceutically acceptable carrier. The phrases "pharmaceutically or pharmacologically acceptable" refers to molecular entities and compositions that do not produce adverse, allergic or other untoward reaction when administered to animal, such as, for example, a human, as appropriate. The preparation of a pharmaceutical composition that contains a compound of the invention will be known to those of skill in the art in light of the present disclosure, as exemplified by Remington's Pharmaceutical Sciences, 18th Ed. Mack Printing Company, 1990. Moreover, for animal (e.g., human) administration, it will be understood that preparations should meet sterility, pyrogenicity, general safety and purity standards. A specific example of a pharmacologically acceptable carrier for a combination compositions, containing a compound of the invention in admixture with an immunotherapeutic agent as described herein is borate buffer or sterile saline solution (0.9% NaCl).

[000226] Formulations of the an immunotherapeutic agent, for example an immune checkpoint modulator antibody used in accordance with the present disclosure can be prepared for storage by mixing an antibody having the desired degree of purity with optional pharmaceutically acceptable carriers, excipients or stabilizers as amply described and illustrated in Remington's Pharmaceutical Sciences 16th edition, Osol, A. Ed. [1980], in the form of lyophilized formulations or aqueous solutions and/or suspensions. Acceptable carriers, excipients, buffers or stabilizers are nontoxic to recipients at the dosages and concentrations employed, and include suitable aqueous and/or non-aqueous excipients that may be employed in the pharmaceutical compositions of the disclosure, for example, water, ethanol, polyols (such as glycerol, propylene glycol, polyethylene glycol, and the like), and suitable mixtures thereof, vegetable oils, such as olive oil, and injectable organic esters, such as ethyl oleate. Proper fluidity can be maintained, for example, by the use of coating materials, such as lecithin, by the maintenance of the required particle size in the case of dispersions, and by the use of surfactants, buffers such as phosphate, citrate, and other organic acids. Antioxidants may be included, for example, (1) water soluble antioxidants, such as ascorbic acid, cysteine hydrochloride, sodium bisulfate, sodium metabisulfite, sodium sulfite and the like; (2) oil-soluble antioxidants, such as ascorbyl palmitate, butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), lecithin, propyl gallate, alpha-tocopherol, and the like; and (3) metal chelating agents, such as citric acid, ethylenediamine tetraacetic acid (EDTA), sorbitol, tartaric acid, phosphoric acid, and the like; preservatives (such as octadecyltrimethylbenzyl ammonium chloride; hexamethonium chloride; benzalkonium chloride, benzethonium chloride; phenol, butyl or benzyl alcohol; alkyl parabens such as methyl or propyl paraben; catechol; resorcinol; cyclohexanol; 3-pentanol; and m-cresol); low molecular weight (less than about 10 residues). Other exemplary pharmaceutically acceptable excipients may include polypeptides; proteins, such as serum albumin, gelatin, or immunoglobulins; hydrophilic polymers such as polyvinylpyrrolidone; amino acids such as glycine, glutamine, asparagine, histidine, arginine, or lysine; monosaccharides, disaccharides, and other carbohydrates including glucose, mannose, or dextrans; chelating agents such as EDTA; sugars such as sucrose, mannitol, trehalose or sorbitol; salt-forming counter-ions such as sodium; metal complexes (e.g. Zn-protein complexes); and/or non-ionic surfactants such as TWEEN™, PLURONICS™ or polyethylene glycol (PEG).

**[000227]** In one illustrative embodiment, the pharmaceutical compositions can optionally contain pharmaceutically acceptable auxiliary substances as required to approximate physiological conditions such as pH adjusting and buffering agents and toxicity adjusting agents, for example, sodium acetate, sodium chloride, potassium chloride, calcium chloride and sodium lactate. In some embodiments, the checkpoint inhibitor antibodies or antigen-binding fragments thereof of the present disclosure are formulated for and can be lyophilized for storage and reconstituted in a suitable excipient prior to use according to art-known lyophilization and reconstitution techniques. In one exemplary pharmaceutical composition containing one or more checkpoint inhibitor antibodies or antigen-binding fragment thereof, the composition is formulated as a sterile, preservative-free solution of one or more checkpoint inhibitor antibodies or antigen-binding fragment thereof for intravenous or subcutaneous administration. The formulation can be supplied as either a single-use, prefilled pen, as a single-use, for example containing about 1 mL prefilled glass syringe, or as a single-use institutional use vial. Preferably, the pharmaceutical composition containing the checkpoint inhibitor antibody or antigen-binding fragment thereof is clear and colorless, with a pH of about 6.9-5.0, preferably a pH of 6.5-5.0, and even more preferably a pH ranging from about 6.0 to about 5.0. In various embodiments, the formulations comprising the pharmaceutical compositions can contain from about 500 mg to about 10 mg, or from about 400 mg to about 20 mg, or from about 300 mg to about 30 mg or from about 200 mg to about 50 mg of the checkpoint inhibitor antibody or antigen-binding fragment thereof per mL of solution when reconstituted and administered to the subject. Exemplary injection or infusion excipients can include mannitol, citric acid monohydrate, dibasic sodium phosphate dihydrate, monobasic sodium phosphate dihydrate, polysorbate 80, sodium chloride, sodium citrate and water for parenteral administration, for example, intravenously, intramuscularly, intraperitoneally, or subcutaneous administration.

**[000228]** In another exemplary embodiment, one or more immunotherapeutic agents, or an antigen-binding fragment thereof is formulated for intravenous or subcutaneous administration as a sterile aqueous solution containing 1-75 mg/mL, or more preferably, about 5-60 mg/mL, or yet more preferably, about 10-50 mg/mL, or even more preferably, about 10-40 mg/mL of antibody, with sodium acetate, polysorbate 80, and sodium chloride at a pH ranging from about 5 to 6. Preferably, the intravenous or subcutaneous formulation is a sterile aqueous solution containing 5, 10, 15, 20, 25, 30, 35, 40, 45, or 50 mg/mL of the immunotherapeutic agent, for example, an immune checkpoint inhibitor antibody or an

antigen-binding fragment thereof, with 20 mM sodium acetate, 0.2 mg/mL polysorbate 80, and 140 mM sodium chloride at pH 5.5. Further, a solution comprising a checkpoint inhibitor antibody or an antigen-binding fragment thereof, can comprise, among many other compounds, histidine, mannitol, sucrose, trehalose, glycine, poly(ethylene)glycol, EDTA, methionine, and any combination thereof, and many other compounds known in the relevant art.

**[000229]** In one embodiment, a pharmaceutical composition of the present disclosure comprises the following components: 5-500 mg of an immunotherapeutic agent or antigen-binding fragment thereof of the present disclosure, 10 mM histidine, 5% sucrose, and 0.01% polysorbate 80 at pH 5.8, and a compound of the invention. This composition may be provided as a lyophilized powder. When the powder is reconstituted at full volume, the composition retains the same formulation. Alternatively, the powder may be reconstituted at half volume, in which case the composition comprises 10-500 mg of an immunotherapeutic agent or antigen-binding fragment thereof of the present disclosure, 20 mM histidine, 10% sucrose, and 0.02% polysorbate 80 at pH 5.8.

**[000230]** In one embodiment, part of the dose is administered by an intravenous bolus and the rest by infusion of the immunotherapeutic agent formulation. For example, from about 0.001 to about 200 mg/lcg, for example, from about 0.001 mg/lcg to about 100 mg/lcg, or from about 0.001 mg/lcg to about 50 mg/lcg, or from about 0.001 mg/lcg to about 10 mg/lcg intravenous injection of the immunotherapeutic agent, or antigen-binding fragment thereof, may be given as a bolus, and the rest of the antibody dose may be administered by intravenous injection. A predetermined dose of the immunotherapeutic agent, or antigen-binding fragment thereof, may be administered, for example, over a period of an hour to two hours to five hours.

**[000231]** In a further embodiment, part of the dose is administered by a subcutaneous injection and/or infusion in the form of a bolus and the rest by infusion of the immunotherapeutic agent formulation. In some exemplary doses, the immunotherapeutic agent formulation can be administered subcutaneously in a dose ranging from about 0.001 to about 200 mg/lcg, for example, from about 0.001 mg/lcg to about 100 mg/lcg, or from about 0.001 mg/lcg to about 50 mg/lcg, or from about 0.001 mg/lcg to about 10 mg/lcg intravenous injection of the immunotherapeutic agent, or antigen-binding fragment thereof. In some embodiments the dose may be given as a bolus, and the rest of the immunotherapeutic agent dose may be administered by subcutaneous or intravenous injection. A predetermined dose

of the immunotherapeutic agent, or antigen-binding fragment thereof, may be administered, for example, over a period of an hour to two hours to five hours.

**[000232]** The formulation herein may also contain more than one active compound as necessary for the particular indication being treated, preferably those with complementary activities that do not adversely affect each other. For example, it may be desirable to provide one or more immunotherapeutic agents with other specificities. Alternatively, or in addition, the composition may comprise an anti-inflammatory agent, a chemotherapeutic agent, a cytotoxic agent, a cytokine, a growth inhibitory agent and/or a small molecule antagonist. Such molecules are suitably present in combination in amounts that are effective for the purpose intended.

**[000233]** The formulations to be used for in vivo administration should be sterile, or nearly so. This is readily accomplished by filtration through sterile filtration membranes.

**[000234]** In various embodiments, illustrative formulations of the pharmaceutical compositions described herein can be prepared using methods widely known in the field of pharmaceutical formulations. In general, such preparatory methods can include the step of bringing the active ingredient into association with a carrier or one or more other accessory ingredients, and then, if desirable, packaging the product into a desired single-or multi-dose unit.

**[000235]** In some embodiments, the composition comprising a compound of the invention can be also delivered in a vesicle, and the immunotherapeutic agent can be delivered in the same liposome formulation, or in a separate formulation that is compatible with the liposomal formulation containing the compound of the invention. In some illustrative examples, a liposome containing one or more liposomal surface moieties for example, polyethylene glycol, antibodies and antibody fragments thereof that target a desired tumor surface antigen, receptor, growth factor, glycoprotein, glycolipid or neoantigen, which are selectively transported into specific cells or organs, thus enhance targeted drug delivery.

**[000236]** In another embodiment, a compound of the invention can be delivered in a vesicle, in particular a liposome (see Langer, *Science* 249:1527-1533 (1990); Treat et al, in *LIPOSOMES IN THE THERAPY OF INFECTIOUS DISEASE AND CANCER*, Lopez-Berestein and Fidler (eds.), Liss, N.Y., pp. 353-365 (1989); Lopez-Berestein, *ibid.*, pp. 317-327; see generally *ibid.*).

**[000237]** In yet another embodiment, a compound of the invention, or the composition containing the combination, or a composition containing the immunotherapeutic agent, can be delivered in a controlled release system. In one embodiment, a pump can be used (see Langer, *supra*; Sefton, *CRC Crit. Ref. Biomed. Eng.* 14:201 (1987); Buchwald et al, *Surgery* 88:507 (1980); Saudek et al, *N. Engl. J. Med.* 321:574 (1989)). In another embodiment, controlled release of the compound of the invention can comprise polymeric materials to provide sustained, intermediate, pulsatile, or alternate release (see *MEDICAL APPLICATIONS OF CONTROLLED RELEASE*, Langer and Wise (eds.), CRC Pres., Boca Raton, Fla. (1974); *CONTROLLED DRUG BIOAVAILABILITY, DRUG PRODUCT DESIGN AND PERFORMANCE*, Smolen and Ball (eds.), Wiley, New York (1984); Ranger and Peppas, *J. Macromol. Sci. Rev. Macromol. Chem.* 23:61 (1983); see also Levy et al, *Science* 228:190 (1985); During et al, *Ann. Neurol.* 25:351(1989); Howard et al, *J. Neurosurg.* 71:105 (1989)). Other controlled-release systems discussed in the review by Langer (*Science* 249:1527-1533 (1990)) can be used.

**[000238]** The optimum concentration of the active ingredient(s) in the chosen medium can be determined empirically, according to procedures well known to the skilled artisan, and will depend on the ultimate pharmaceutical formulation desired and the use to be employed.

**[000239]** The present disclosure also provides a pharmaceutical pack or kit comprising one or more containers filled with one or more of the ingredients of the pharmaceutical compositions of the disclosure, which at minimum will include a compound of the invention and one or more checkpoint inhibitor antibodies or antigen-binding fragment thereof as described herein. In other embodiments, the kit may contain one or more further containers providing a pharmaceutically acceptable excipient, for example a diluent. In one embodiment a kit may comprise at least one container, wherein the container can include a compound of the invention, a checkpoint inhibitor antibody or an antigen-binding fragment thereof of the present disclosure. The kit may also include a set of instructions for preparing and administering the final pharmaceutical composition to the subject in need thereof, for the treatment of a checkpoint molecule-mediated disease or disorder.

**[000240]** Some embodiments of the present disclosure, the immunotherapeutic agent is a population of immune cells, which can be administered in combination with a compound of the invention to treat a subject with cancer. In some embodiments, the immunotherapeutic agent is a population of immune cells, such as leukocytes (nucleated white blood cells),

comprising (e.g., expressing) a receptor that binds to an antigen of interest. A leukocyte of the present disclosure may be, for example, a neutrophil, eosinophil, basophil, lymphocyte or a monocyte. In some embodiments, a leukocyte is a lymphocyte. Examples of lymphocytes include T cells, B cells, Natural Killer (NK) cells or NKT cells. In some embodiments, a T-cell is a CD4<sup>+</sup> Th (T helper) cell, a CD8<sup>+</sup> cytotoxic T cell, a  $\gamma\delta$ T cell or a regulatory (suppressor) T cell. In some embodiments, an immune cell is a dendritic cell.

**[000241]** Immune cells of the present disclosure, in some embodiments, are genetically engineered to express an antigen-binding receptor. A cell is considered "engineered" if it contains an engineered (exogenous) nucleic acid. Engineered nucleic acids of the present disclosure may be introduced into a cell by any known (e.g., conventional) method. For example, an engineered nucleic acid may be introduced into a cell by electroporation (see, e.g., Heiser W. C. *Transcription Factor Protocols: Methods in Molecular Biology*. 2000; 130: 117-134), chemical (e.g., calcium phosphate or lipid), transfection (see, e.g., Lewis W. H., et al, *Somatic Cell Genet.* 1980 May; 6(3): 333-47; Chen C., et al., *Mol Cell Biol.* 1987 August; 7(8): 2745-2752), fusion with bacterial protoplasts containing recombinant plasmids (see, e.g., Schaffner W. *Proc Natl Acad Sci USA.* 1980 April; 77(4): 2163-7), microinjection of purified DNA directly into the nucleus of the cell (see, e.g., Capecchi M. R. *Cell.* 1980 November; 22(2 Pt 2): 479-88), or retrovirus transduction.

**[000242]** Some aspects of the present disclosure provide an "adoptive cell" approach, which involves isolating immune cells (e.g., T-cells) from a subject with cancer, genetically engineering the immune cells (e.g., to express an antigen-binding receptor, such as a chimeric antigen receptor), expanding the cells *ex vivo*, and then re-introducing the immune cells into the subject. This method results in a greater number of engineered immune cells in the subject relative to what could be achieved by conventional gene delivery and vaccination methods. In some embodiments, immune cells are isolated from a subject, expanded *ex vivo* without genetic modification, and then re-introduced into the subject.

**[000243]** Immune cells of the present disclosure comprise receptors that bind to antigens, such as an antigen encoded by an exogenously delivered nucleic acid, as provided herein. In some embodiments, a leukocyte is modified (e.g., genetically modified) to express a receptor that binds to an antigen. The receptor may be, in some embodiments, a naturally-occurring antigen receptor (normally expressed on the immune cell), recombinant antigen receptor (not normally expressed on the immune cell) or a chimeric antigen receptor (CAR). Naturally-occurring and recombinant antigen receptors encompassed by the present disclosure include

T cell receptors, B cell receptors, NK cell receptors, NKT cell receptors and dendritic cell receptors. A "chimeric antigen receptor" refers to an artificial immune cell receptor that is engineered to recognize and bind to an antigen expressed by tumor cells. Generally, a CAR is designed for a T cell and is a chimera of a signaling domain of the T-cell receptor (TcR) complex and an antigen-recognizing domain (e.g., a single chain fragment (scFv) of an antibody) (Enblad et al., *Human Gene Therapy*. 2015; 26(8):498-505), the disclosure of which is incorporated herein by reference in its entirety.

**[000244]** In some embodiments, an antigen binding receptor is a chimeric antigen receptor (CAR). A T cell that expressed a CAR is referred to as a "CAR T cell." A CAR T cell receptor, in some embodiments, comprises a signaling domain of the T-cell receptor (TcR) complex and an antigen-recognizing domain (e.g., a single chain fragment (scFv) of an antibody) (Enblad et al, *Human Gene Therapy*. 2015; 26(8):498-505) the disclosure of which is incorporated herein by reference in its entirety.

**[000245]** There are four generations of CARs, each of which contains different components. First generation CARs join an antibody-derived scFv to the CD3zeta (zeta. or z) intracellular signaling domain of the T-cell receptor through hinge and transmembrane domains. Second generation CARs incorporate an additional domain, e.g., CD28, 4-1BB (41BB), or ICOS, to supply a costimulatory signal. Third-generation CARs contain two costimulatory domains fused with the TcR CD3-zeta chain. Third-generation costimulatory domains may include, e.g., a combination of CD3z, CD27, CD28, 4-1BB, ICOS, or OX40. CARs, in some embodiments, contain an ectodomain (e.g., CD3), commonly derived from a single chain variable fragment (scFv), a hinge, a transmembrane domain, and an endodomain with one (first generation), two (second generation), or three (third generation) signaling domains derived from CD3Z and/or co-stimulatory molecules (Maude et al., *Blood*. 2015; 125(26):4017-4023; Kakarla and Gottschalk, *Cancer J*. 2014; 20(2):151-155) the disclosure of which is incorporated herein by reference in its entirety.

**[000246]** In some embodiments, the chimeric antigen receptor (CAR) is a T-cell redirected for universal cytokine killing (TRUCK), also known as a fourth generation CAR. TRUCKs are CAR-redirectioned T-cells used as vehicles to produce and release a transgenic cytokine that accumulates in the targeted tissue, e.g., a targeted tumor tissue. The transgenic cytokine is released upon CAR engagement of the target. TRUCK cells may deposit a variety of therapeutic cytokines in the target. This may result in therapeutic concentrations at the targeted site and avoid systemic toxicity.

[000247] CARs typically differ in their functional properties. The CD3zeta signaling domain of the T-cell receptor, when engaged, will activate and induce proliferation of T-cells but can lead to anergy (a lack of reaction by the body's defense mechanisms, resulting in direct induction of peripheral lymphocyte tolerance). Lymphocytes are considered anergic when they fail to respond to a specific antigen. The addition of a costimulatory domain in second-generation CARs improved replicative capacity and persistence of modified T-cells. Similar antitumor effects are observed in vitro with CD28 or 4-1BB CARs, but preclinical in vivo studies suggest that 4-1BB CARs may produce superior proliferation and/or persistence. Clinical trials suggest that both of these second-generation CARs are capable of inducing substantial T-cell proliferation in vivo, but CARs containing the 4-1BB costimulatory domain appear to persist longer. Third generation CARs combine multiple signaling domains (costimulatory) to augment potency. Fourth generation CARs are additionally modified with a constitutive or inducible expression cassette for a transgenic cytokine, which is released by the CAR T-cell to modulate the T-cell response. See, for example, Enblad et al, *ITuman Gene Therapy*. 2015; 26(8):498-505; Chmielewski and Tinrich, *Expert Opinion on Biological Therapy*. 2015; 15(8): 1145-1154 the disclosures of which are incorporated herein by reference in their entireties.

[000248] In some embodiments, an illustrative immunotherapeutic agent is a first generation chimeric antigen receptor CAR. In some embodiments, a chimeric antigen receptor is a third generation CAR. In some embodiments, a chimeric antigen receptor is a second generation CAR. In some embodiments, a chimeric antigen receptor is a third generation CAR. In some embodiments, the chimeric antigen receptor is a fourth generation CAR or a T-cell redirected for universal cytokine killing (TRUCK).

[000249] In some embodiments, a chimeric antigen receptor (CAR) comprises an extracellular domain comprising an antigen binding domain, a transmembrane domain, and a cytoplasmic domain. In some embodiments, a CAR is fully human. In some embodiments, the antigen binding domain of a CAR is specific for one or more antigens. In some embodiments, a "spacer" domain or "hinge" domain is located between an extracellular domain (comprising the antigen binding domain) and a transmembrane domain of a CAR, or between a cytoplasmic domain and a transmembrane domain of the CAR. A "spacer domain" refers to any oligopeptide or polypeptide that functions to link the transmembrane domain to the extracellular domain and/or the cytoplasmic domain in the polypeptide chain. A "hinge domain" refers to any oligopeptide or polypeptide that functions to provide

flexibility to the CAR, or domains thereof, or to prevent steric hindrance of the CAR, or domains thereof. In some embodiments, a spacer domain or hinge domain may comprise up to 300 amino acids (e.g., 10 to 100 amino acids, or 5 to 20 amino acids). In some embodiments, one or more spacer domain(s) may be included in other regions of a CAR.

**[000250]** In some embodiments, a CAR of the disclosure comprises an antigen binding domain, such as a single chain Fv (scFv) specific for a tumor antigen. The choice of binding domain depends upon the type and number of ligands that define the surface of a target cell. For example, the antigen binding domain may be chosen to recognize a ligand that acts as a cell surface marker on target cells associated with a particular disease state, such as cancer or an autoimmune disease. Thus, examples of cell surface markers that may act as ligands for the antigen binding domain in the CAR of the present disclosure include those associated with cancer cells and/or other forms of diseased cells. In some embodiments, a CAR is engineered to target a tumor antigen of interest by way of engineering a desired antigen binding domain that specifically binds to an antigen on a tumor cell encoded by an engineered nucleic acid, as provided herein.

**[000251]** An antigen binding domain (e.g., an scFv) that "specifically binds" to a target or an epitope is a term understood in the art, and methods to determine such specific binding are also known in the art. A molecule is said to exhibit "specific binding" if it reacts or associates more frequently, more rapidly, with greater duration and/or with greater affinity with a particular target antigen than it does with alternative targets. An antigen binding domain (e.g., an scFv) that specifically binds to a first target antigen may or may not specifically bind to a second target antigen. As such, "specific binding" does not necessarily require (although it can include) exclusive binding.

**[000252]** In some embodiments, immune cells expressing a CAR are genetically modified to recognize multiple targets or antigens, which permits the recognition of unique target or antigen expression patterns on tumor cells. Examples of CARs that can bind multiple targets include: "split signal CARs," which limit complete immune cell activation to tumors expressing multiple antigens; "tandem CARs" (TanCARs), which contain ectodomains having two scFvs; and "universal ectodomain CARs," which incorporate avidin or a fluorescein isothiocyanate (FITC)-specific scFv to recognize tumor cells that have been incubated with tagged monoclonal antibodies (Mabs).

**[000253]** A CAR is considered "bispecific" if it recognizes two distinct antigens (has two distinct antigen recognition domains). In some embodiments, a bispecific CAR is

comprised of two distinct antigen recognition domains present in tandem on a single transgenic receptor (referred to as a TanCAR; see, e.g., Grada Z et al. *Molecular Therapy Nucleic Acids* 2013; 2:e105, incorporated herein by reference in its entirety). Thus, methods, in some embodiments, comprise delivering to a tumor a combination comprising a compound of the invention and an immunotherapeutic agent, wherein the immunotherapeutic agent is an engineered nucleic acid that encodes an antigen, or delivering to a tumor an engineered nucleic acid that induces expression of a self-antigen, and delivering to the tumor an immune cell expressing a bispecific CAR that binds to two antigens, one of which is encoded by the engineered nucleic acid.

**[000254]** In some embodiments, a CAR is an antigen-specific inhibitory CAR (iCAR), which may be used, for example, to avoid off-tumor toxicity (Fedorov, V D et al. *Sci. Transl. Med.* published online Dec. 11, 2013, incorporated herein by reference in its entirety). iCARs contain an antigen-specific inhibitory receptor, for example, to block nonspecific immunosuppression, which may result from extra tumor target expression. iCARs may be based, for example, on inhibitory molecules CTLA-4 or PD-1. In some embodiments, these iCARs block T cell responses from T cells activated by either their endogenous T cell receptor or an activating CAR. In some embodiments, this inhibiting effect is temporary.

**[000255]** In some embodiments, CARs may be used in adoptive cell transfer, wherein immune cells are removed from a subject and modified so that they express receptors specific to an antigen, e.g., a tumor-specific antigen. The modified immune cells, which may then recognize and kill the cancer cells, are reintroduced into the subject (Pule, et al, *Cytotherapy*. 2003; 5(3): 211-226; Maude et al, *Blood*. 2015; 125(26): 4017-4023, each of which is incorporated herein by reference in their entireties).

**[000256]** According to other aspects of the disclosure, the tumor antigenic component in the vaccine of the invention is any natural or synthetic tumor-associated protein or peptide or combination of tumor-associated proteins and/or peptides or glycoproteins or glycopeptides. In still yet other aspects, the antigenic component can be patient-specific or common to many or most patients with a particular type of cancer. According to one aspect, the antigenic component consists of a cell lysate derived from tumor tissue removed from the patient being treated. In another aspect, the lysate can be engineered or synthesized from exosomes derived from tumor tissue. In yet another aspect, the antigenic component consists

of a cell lysate derived from tumor tissue extracted from one or more unrelated individuals or from tumor-cell lines.

**[000257]** In various embodiments, an illustrative immunotherapeutic agent comprises one or more cancer vaccines, for use in combination with a compound of the invention. The tumor-associated antigen component of the vaccine may be manufactured by any of a variety of well-known techniques. For individual protein components, the antigenic protein is isolated from tumor tissue or a tumor-cell line by standard chromatographic means such as high-pressure liquid chromatography or affinity chromatography or, alternatively, it is synthesized by standard recombinant DNA technology in a suitable expression system, such as *E. coli*, yeast or plants. The tumor-associated antigenic protein is then purified from the expression system by standard chromatographic means. In the case of peptide antigenic components, these are generally prepared by standard automated synthesis. Proteins and peptides can be modified by addition of amino acids, lipids and other agents to improve their incorporation into the delivery system of the vaccine (such as a multilamellar liposome). For a tumor-associated antigenic component derived from the patient's own tumor, or tumors from other individuals, or cell lines, the tumor tissue, or a single cell suspension derived from the tumor tissue, is typically homogenized in a suitable buffer. The homogenate can also be fractionated, such as by centrifugation, to isolate particular cellular components such as cell membranes or soluble material. The tumor material can be used directly or tumor-associated antigens can be extracted for incorporation in the vaccine using a buffer containing a low concentration of a suitable agent such as a detergent. An example of a suitable detergent for extracting antigenic proteins from tumor tissue, tumor cells, and tumor-cell membranes is diheptanoyl phosphatidylcholine. Exosomes derived from tumor tissue or tumor cells, whether autologous or heterologous to the patient, can be used for the antigenic component for incorporation in the vaccine or as a starting material for extraction of tumor-associated antigens.

**[000258]** In some embodiments of the present disclosure, a combination therapy comprises a compound of the present invention in combination with a cancer vaccine immunotherapeutic agent. In various examples, the cancer vaccine includes at least one tumor-associated antigen, at least one immunostimulant, and optionally, at least one cell-based immunotherapeutic agent. In some embodiments, the immunostimulant component in the cancer vaccine of the disclosure is any Biological Response Modifier (BRM) with the ability to enhance the therapeutic cancer vaccine's effectiveness to induce humoral and

cellular immune responses against cancer cells in a patient. According to one aspect, the immunostimulant is a cytokine or combination of cytokines. Examples of such cytokines include the interferons, such as IFN-gamma, the interleukins, such as IL-2, IL-15 and IL-23, the colony stimulating factors, such as M-CSF and GM-CSF, and tumor necrosis factor. According to another aspect, the immunostimulant component of the disclosed cancer vaccine includes one or more adjuvant-type immunostimulatory agents such as APC Toll-like Receptor agonists or costimulatory/cell adhesion membrane proteins, with or without immunostimulatory cytokines. **[000278]** In some embodiments, the bispecific antibody immunotherapeutic agent has specificities for a tumor antigen and a CIK cell, which brings the tumor antigen expressing tumor cell in close proximity of the CIK cell, leading to the elimination of the tumor cell through anti-tumor cytotoxicity of CIK cell. In some embodiments, the bispecific antibody has specificity for a tumor antigen but does not have specificity for a CIK cell, however, the Fc region of the bispecific antibody can bind to the Fc receptor of the CIK cell, which in turn brings the tumor cell in close proximity of the CIK cell, leading to the elimination of the tumor cell through anti-tumor cytotoxicity of CIK cell. In some embodiments, the bispecific antibody has specificity for a CIK cell but does not have specificity for tumor cell, however, the Fc region of the bispecific antibody can bind to the Fc receptor of the tumor cell, which in turn brings the tumor cell in close proximity of the CIK cell, leading to the elimination of the tumor cell through anti-tumor cytotoxicity of CIK cell.

**[000279]** In some embodiments, a compound of the invention can be used in combination with an immune cell-engaging multivalent antibody/fusion protein/construct immunotherapeutic agent. In various embodiments, an exemplary immunotherapeutic agent can include immune cell-engaging multivalent antibody/fusion protein/construct which may comprise a recombinant structure, for example, all engineered antibodies that do not imitate the original IgG structure. Here, different strategies to multimerize antibody fragments are utilized. For example, shortening the peptide linker between the V domains forces the scFv to self-associate into a dimer (diabody; 55 kDa). Bispecific diabodies are formed by the noncovalent association of two VHA-VLB and VHB-VLA fragments expressed in the same cell. This leads to the formation of heterodimers with two different binding sites. Single-chain diabodies (sc-diabodies) are bispecific molecules where the VHA-VLB and VHB-VLA fragments are linked together by an additional third linker. Tandem-diabodies (Tandabs) are tetravalent bispecific antibodies generated by two scDiabodies.

**[000280]** Also included are the di-diabodies known in the art. This 130-kDa molecule is formed by the fusion of a diabody to the N-terminus of the CH3 domain of an IgG, resulting

in an IgG-like structure. Further diabody derivatives are the triabody and the tetra-body, which fold into trimeric and tetrameric fragments by shortening the linker to <5 or 0-2 residues. Also exemplified are (scFv)<sub>2</sub> constructs known as ‘bispecific T cell engager’ (BITE). BITEs are bispecific single-chain antibodies consisting of two scFv antibody fragments, joined via a flexible linker, that are directed against a surface antigen on target cells and CD3 on T cells. Also exemplified are bivalent (Fab)<sub>2</sub> and trivalent (Fab)<sub>3</sub> antibody formats. Also exemplified are minibodies and trimerbodies generated from scFvs. Exemplary constructs useful to target tumor antigens as can include one or more of: Diabody, Single-chain (sc)-diabody (scFv)<sub>2</sub>, Miniantibody, Minibody, Bamase-barstar, scFv-Fc, sc(Fab)<sub>2</sub>, Trimeric antibody constructs, Triabody antibody constructs, Trimerbody antibody constructs, Tribody antibody constructs, Collabody antibody constructs, (scFv-TNFα)<sub>3</sub>, F(ab)<sub>3</sub>/DNL. Exemplary cytotoxic immune cells include, but are not limited to CIK cells, T-cells, CD8<sup>+</sup> T cells, activated T-cells, monocytes, natural killer (NK) cells, NK T cells, lymphokine-activated killer (LAK) cells, macrophages, and dendritic cells.

**[000281]** In some embodiments, a compound of the invention can be used in combination with a radioconjugate immunotherapeutic agent.

**[000282]** In various embodiments, a radioconjugate is a small molecule or large molecule (herein referred to as a “cell targeting agent”), for example and polypeptide, an antibody or an antibody fragment thereof, that is coupled to or otherwise affixed to a radionuclide, or a plurality of radionuclides, such that the binding of the radioconjugate to its target (a protein or molecule on or in a cancer cell), will lead to the death or morbidity of said cancer cell. In various embodiments, the radioconjugate can be a cell targeting agent labelled with a radionuclide, or the cell targeting agent may be coupled or otherwise affixed to a particle, or microparticle, or nanoparticle containing a plurality of radionuclides, wherein the radionuclides are the same or different. Methods for synthesizing radioconjugates are known in the art, and may include the class of immunoglobulin or antigen binding parts thereof, that are conjugated to a toxic radionuclide.

Examples of cell targeting agents include, but are not limited to, small molecules (e.g., folate, adenosine, purine) and large molecule (e.g., peptide or antibody) that bind to or target a tumor associated antigen. Examples of tumor associated antigens include, but are not

limited to, adenosine receptors, alpha v beta 3, aminopeptidase P, alpha fetoprotein, cancer antigen 125, carcinoembryonic antigen, cCaveolin-1, chemokine receptors, clusterin, oncofetal antigens, CD20, epithelial tumor antigen, melanoma associated antigen, Ras, p53, Her2/Neu, ErbB2, ErbB3, ErbB4, folate receptor, prostate-specific membrane antigen, prostate specific antigen, purine receptors, radiation-induced cell surface receptor, serpin B3, serpin B4, squamous cell carcinoma antigens, thrombospondin, tumor antigen 4, tumor-associated glycoprotein 72, tyosinase, and tyrosine kinases. In some embodiments, the cell targeting agent is folate or a folate derivative that binds specifically to folate receptors (FRs). In some embodiments, the cell targeting agent is an antibody, a bispecific antibody, a trispecific antibody or an antigen binding construct thereof, that specifically binds to a cancer antigen selected from: EGFR, HGFR, Her2, Ep-CAM, CD20, CD30, CD33, CD47, CD52, CD133, CEA, gpA33, Mucins, TAG-72, CIX, PSMA, folate-binding protein, GD2, GD3, GM2, VEGF, VEGFR, Integrin  $\alpha$ V(13), Integrin  $\alpha$ 5 $\beta$ 1, MUC1, ERBB2, ERBB3, MET, IGF1R, EPHA3, TRAILR1, TRAILR2, RANKL, FAP and Tenascin among others.

**[000284]** The use of folate as a targeting agent in the radioconjugate also allow both tumor cells and regulatory T (Treg) cells to be targeted for destruction. It is well accepted that high numbers of Treg cells suppress tumor immunity. Specifically, Treg cells suppress (foreign and self) reactive T cells without killing them through contact-dependent or cytokine (e.g., IL-10, TGF-.beta., and the like.) secretion. FR4 is selectively upregulated on Treg cells. It has been shown that antibody blockade of FR4 depleted Treg cells and provoked tumor immunity in tumor-bearing mice. Thus, folate-coated PBM nanoparticles carrying a cytotoxic agent would take FR-expressing cells for their destruction, which would both directly (i.e., BrCa cell) and indirectly (i.e., breast tumor associated and peripheral Treg cells) inhibit tumor progression.

**[000285]** In another further embodiment, the targeting agent is an antibody or peptide, or immune cell-engaging multivalent antibody/fusion protein/constructs capable of binding tumor associated antigens consisting of but not limited to: adenosine receptors, alpha v beta 3, aminopeptidase P, alpha fetoprotein, cancer antigen 125, carcinoembryonic antigen, caveolin-1, chemokine receptors, clusterin, oncofetal antigens, CD20, Human Growth Factor Receptor (HGFR), epithelial tumor antigen, melanoma associated antigen, MUC1, Ras, p53, Her2/Neu, ErbB2, ErbB3, ErbB4, folate receptor, prostate-specific membrane antigen, prostate specific antigen, purine receptors, radiation-induced cell surface receptor, serpin B3,

serpin B4, squamous cell carcinoma antigens, thrombospondin, tumor antigen 4, tumor-associated glycoprotein 72, tyrosinase, tyrosine kinases, and the like.

[000286] In some embodiments, a compound as described herein can be used in combination with a vaccination protocol for the treatment of cancer. In some embodiments, a compound as described herein can be used in combination with an immunotherapeutic agent such as a vaccine. In various embodiments, exemplary vaccines include those used to stimulate the immune response to cancer antigens.

[000287] The amount of both the compound disclosed herein or salt thereof and the additional one or more additional therapeutic agent (in those compositions which comprise an additional therapeutic agent as described above) that may be combined with carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration. In certain embodiments, compositions of this invention are formulated such that a dosage of between 0.01-100 mg/kg body weight/day of an inventive can be administered.

[000288] The additional therapeutic agent and the compound disclosed herein may act synergistically. Therefore, the amount of additional therapeutic agent in such compositions may be less than that required in a monotherapy utilizing only that therapeutic agent, or there may be fewer side effects for the patient given that a lower dose is used. In certain embodiments, in such compositions a dosage of between 0.01-10,000  $\mu\text{g}/\text{kg}$  body weight/day of the additional therapeutic agent can be administered.

[000289] **Labeled Compounds and Assay Methods**

[000290] Another aspect of the present invention relates to labeled compounds of the invention (radio-labeled, fluorescent-labeled, and the like.) that would be useful not only in imaging techniques but also in assays, both in vitro and in vivo, for localizing and quantitating TAM kinases in tissue samples, including human, and for identifying TAM kinase ligands by inhibition binding of a labeled compound. Accordingly, the present invention includes TAM kinase assays that contain such labeled compounds.

[000291] The present invention further includes isotopically-labeled compounds of the invention. An "isotopically" or "radio-labeled" compound is a compound of the invention where one or more atoms are replaced or substituted by an atom having an atomic mass or mass number different from the atomic mass or mass number typically found in nature (i.e., naturally occurring). Suitable radionuclides that may be incorporated in compounds of the present invention include but are not limited to  $^2\text{H}$  (also written as D for deuterium),  $^3\text{H}$  (also

written as T for tritium),  $^{11}\text{C}$ ,  $^{13}\text{C}$ ,  $^{14}\text{C}$ ,  $^{13}\text{N}$ ,  $^{15}\text{N}$ ,  $^{15}\text{O}$ ,  $^{17}\text{O}$ ,  $^{18}\text{O}$ ,  $^{18}\text{F}$ ,  $^{35}\text{S}$ ,  $^{36}\text{Cl}$ ,  $^{82}\text{Br}$ ,  $^{75}\text{Br}$ ,  $^{76}\text{Br}$ ,  $^{77}\text{Br}$ ,  $^{123}\text{I}$ ,  $^{124}\text{I}$ ,  $^{125}\text{I}$ , and  $^{131}\text{I}$ . The radionuclide that is incorporated in the instant radio-labeled compounds will depend on the specific application of that radio-labeled compound. For example, for in vitro metalloprotease labeling and competition assays, compounds that incorporate  $^3\text{H}$ ,  $^{14}\text{C}$ ,  $^{82}\text{Br}$ ,  $^{125}\text{I}$ ,  $^{131}\text{I}$ , or  $^{35}\text{S}$  will generally be most useful. For radio-imaging applications  $^{11}\text{C}$ ,  $^{18}\text{F}$ ,  $^{125}\text{I}$ ,  $^{123}\text{I}$ ,  $^{124}\text{I}$ ,  $^{131}\text{I}$ ,  $^{75}\text{Br}$ ,  $^{76}\text{Br}$ , or  $^{77}\text{Br}$  will generally be most useful.

**[000292]** It is understood that a “radio-labeled” or “labeled compound” is a compound that has incorporated at least one radionuclide. In some embodiments, the radionuclide is selected from the group consisting of  $^3\text{H}$ ,  $^{14}\text{C}$ ,  $^{125}\text{I}$ ,  $^{35}\text{S}$ , and  $^{82}\text{Br}$ .

**[000293]** The present invention can further include synthetic methods for incorporating radio-isotopes into compounds of the invention. Synthetic methods for incorporating radio-isotopes into organic compounds are well known in the art, and a person of ordinary skill in the art will readily recognize the methods applicable for the compounds of invention.

**[000294]** A labeled compound of the invention can be used in a screening assay to identify/evaluate compounds. For example, a newly synthesized or identified compound (i.e., test compound) which is labeled can be evaluated for its ability to bind a TAM by monitoring its concentration variation when contacting with the TAM kinases, through tracking of the labeling. For example, a test compound (labeled) can be evaluated for its ability to reduce binding of another compound which is known to bind to a TAM kinase (i.e., standard compound). Accordingly, the ability of a test compound to compete with the standard compound for binding to the TAM kinase directly correlates to its binding affinity. Conversely, in some other screening assays, the standard compound is labeled, and test compounds are unlabeled. Accordingly, the concentration of the labeled standard compound is monitored in order to evaluate the competition between the standard compound and the test compound, and the relative binding affinity of the test compound is thus ascertained.

### Synthesis

**[000295]** Compounds of this invention can be made by the synthetic procedures described below. The starting materials and reagents used in preparing these compounds are either available from commercial suppliers such as Sigma Aldrich Chemical Co. (Milwaukee, Wis.), or Bachem (Torrance, Calif.), or are prepared by methods known to those skilled in the art following procedures set forth in references such as Fieser and Fieser's Reagents for Organic Synthesis, Volumes 1-17 (John Wiley and Sons, 1991); Rodd's Chemistry of Carbon Compounds, Volumes 1-5 and Supplementals (Elsevier

Science Publishers, 1989); Organic Reactions, Volumes 1-40 (John Wiley and Sons, 1991); March's Advanced Organic Chemistry, (John Wiley and Sons, 4<sup>th</sup> Edition); and Larock's Comprehensive Organic Transformations (VCH Publishers Inc., 1989). These schemes are merely illustrative of some methods by which the compounds of this invention can be synthesized, and various modifications to these schemes can be made and will be suggested to one skilled in the art having referred to this disclosure. The starting materials and the intermediates of the reaction may be isolated and purified if desired using conventional techniques, including but not limited to filtration, distillation, crystallization, chromatography, and the like. Such materials may be characterized using conventional means, including physical constants and spectral data.

**[000296]** Unless specified to the contrary, the reactions described herein take place at atmospheric pressure and over a temperature range from about -78 °C to about 150 °C, more preferably from about 0 °C to about 125 °C, and most preferably at about room (or ambient) temperature, e.g., about 20 °C. Unless otherwise stated (as in the case of a hydrogenation), all reactions are performed under an atmosphere of nitrogen.

**[000297]** The compounds disclosed and claimed herein have asymmetric carbon atoms or quaternized nitrogen atoms in their structure and may be prepared through the syntheses described herein as single stereoisomers, racemates, or mixtures of enantiomers and diastereomers. The compounds may also exist as geometric isomers. All such single stereoisomers, racemates, and geometric isomers, and mixtures thereof are intended to be within the scope of this invention.

**[000298]** Some of the compounds of the invention may exist as tautomers. For example, where a ketone or aldehyde is present, the molecule may exist in the enol form; where an amide is present, the molecule may exist as the imidic acid; and where an enamine is present, the molecule may exist as an imine. All such tautomers are within the scope of the invention.

**[000299]** Methods for the preparation and/or separation and isolation of single stereoisomers from racemic mixtures or non-racemic mixtures of stereoisomers are well known in the art. For example, optically active (R)- and (S)- isomers may be prepared using chiral synthons or chiral reagents, or resolved using conventional techniques. Enantiomers (R- and S-isomers) may be resolved by methods known to one of ordinary skill in the art, for example by: formation of diastereomeric salts or complexes which may be separated, for example, by crystallization; via formation of diastereomeric derivatives which may be

separated, for example, by crystallization; selective reaction of one enantiomer with an enantiomer-specific reagent, for example enzymatic oxidation or reduction, followed by separation of the modified and unmodified enantiomers; or gas-liquid or liquid chromatography in a chiral environment, for example on a chiral support, such as silica with a bound chiral ligand or in the presence of a chiral solvent. It will be appreciated that where a desired enantiomer is converted into another chemical entity by one of the separation procedures described above, a further step may be required to liberate the desired enantiomeric form. Alternatively, specific enantiomers may be synthesized by asymmetric synthesis using optically active reagents, substrates, catalysts, or solvents, or by converting on enantiomer to the other by asymmetric transformation. For a mixture of enantiomers, enriched in a particular enantiomer, the major component enantiomer may be further enriched (with concomitant loss in yield) by recrystallization.

**[000300]** In addition, the compounds of the present invention can exist in unsolvated as well as solvated forms with pharmaceutically acceptable solvents such as water, ethanol, and the like. In general, the solvated forms are considered equivalent to the unsolvated forms for the purposes of the present invention.

**[000301]** The methods of the present invention may be carried out as semi-continuous or continuous processes, more preferably as continuous processes.

**[000302]** The present invention as described above unless indicated otherwise may be carried out in the presence of a solvent or a mixture of two or more solvents. In particular the solvent is an aqueous or an organic solvent such as the ether-like solvent (e.g. tetrahydrofuran, methyltetrahydrofuran, diisopropyl ether, t-butylmethyl ether, or dibutyl ether), aliphatic hydrocarbon solvent (e.g. hexane, heptane, or pentane), saturated alicyclic hydrocarbon solvent (e.g. cyclohexane or cyclopentane), or aromatic solvent (e.g. toluene, o-, m-, or p-xylene, or t-butyl-benzene), or mixture thereof.

**[000303]** The starting materials and reagents, which do not have their synthetic route explicitly disclosed herein, are generally available from commercial sources or are readily prepared using methods well known to the person skilled in the art.

**[000304]** The following general synthetic schemes and examples are provided for the purpose of further illustration and are not intended to limit the scope of the claimed invention.

### General Synthesis

[000305] In the following general schemes, the variables  $R^1$ ,  $R^2$ ,  $R^3$ ,  $R^4$ ,  $R^5$ ,  $R^6$ ,  $R^7$ ,  $R^8$ ,  $R^9$ , Y, m, n, and p are described above.

[000306] Scheme 1: Synthesis of Intermediate Compounds

[000307] Intermediate compounds of Formula 8' can be synthesized starting from a bromoaniline compound of Formula 4' by first reacting with 2,2-dimethyl-1,3-dioxane-4,6-dione in the presence of trimethyl orthoformate to provide a compound of Formula 5'. A compound of Formula 6' can be synthesized by exposing a compound of Formula 5' to high heat in an appropriate solvent to accomplish the cyclization. Conversion of the phenolic oxygen of a compound of Formula 6' to the corresponding chloride moiety can be accomplished using a reagent such as phosphorus oxychloride. The resulting compound of Formula 7' can then be coupled with a compound of Formula 3', wherein Y' is a nucleophilic moiety such as -OH, -SH, -SOH, -SO<sub>2</sub>H, -N<sup>3/4</sup>, or -NH((C<sub>1</sub>-C<sub>6</sub>) alkyl), using an appropriate base and solvent system to produce a compound of Formula 8'.

[000308] Scheme 2: Synthesis of a Compound of Formula 3'

[000309] Compounds of Formula 3' can be synthesized via a coupling reaction between a compound of Formula 1' and a compound of Formula 2'. Coupling reagents appropriate

for this transformation are well known in the art, and include EDCI, DCC, BOP, HATU, HBTU, and T3P, among many others.

[000310] Scheme 3: Synthesis of the Compounds of Formula I

[000311] Compounds of Formula 8' can be converted to compounds of Formula I by coupling with boron compounds of the Formula Z, wherein Ring X can be a carbocycle, such as 3,3,4,4-tetramethylborolane, using coupling chemistry known to those skilled in the art. Typical reagents to accomplish this type of coupling are palladium-containing complexes, such as 4-di-tert-butylphosphanyl-N,N-dimethyl-aniline;dichloropalladium ([Bis(di-tert-butyl(4-dimethylaminophenyl)phosphine) dichloropalladium(II)]; Pd(amphos)Cl<sub>2</sub>).

### Biological Examples

#### [000389] Example A : Kinase Assays

[000390] Kinase activity and compound inhibition were investigated using the <sup>33</sup>P-Phosphoryl transfer radiometric kinase assay, performed using the KinaseProfiler™ service of Eurofins Pharma Discovery Services UK Limited. Dose-response experiments were performed using nine compound concentrations in a 96-well microtiter plate. For each assay, all compounds were prepared to a 50x final assay concentration (50 μM) in 100% DMSO, then diluted in a half-log series, with the final top concentration at 1 pM. This working stock of the compound was added to the assay well as the first component in the reaction, followed by the remaining components as detailed in the following assay protocols below. The positive control wells (100% kinase activity) contain all components of the reaction including 2% DMSO (control for solvent effects), except the compound of interest. Blank wells contain all components of the reaction, with the reference inhibitor, staurosporine. This reference compound was used to abolish kinase activity and generated the 0% kinase activity base-line. IC<sub>50</sub> values were calculated by nonlinear regression analysis using the sigmoidal dose-response (variable slope) curve fit on XLFit version 5.3 (ID Business Solutions).

**[000410] Example J: Pharmacokinetic studies**

**[000411]** Pharmacokinetic properties of select compounds were assessed in male Sprague-Dawley rats.

**[000412]** The non-GLP study was designed to investigate the pharmacokinetics of chosen compounds in plasma following an intravenous or oral dose administration to male Sprague Dawley rats.

**[000413]** Two groups of male Sprague-Dawley rats (three animals per group) received either an intravenous or oral (gavage) dose of compound at target dose levels of 3 mg/kg. Animals were observed for any clinically relevant abnormalities during dosing and at each sample collection period.

**[000414]** Animals in the PO group were fasted overnight prior to dose administration. Food was returned following the collection of the 4-hour blood sample. Water was not withheld.

**[000415]** Immediately prior to dosing, the body weight of each animal was recorded. Doses (rounded to the nearest 0.001 mL) were calculated based on the pretreatment body weight (kg) and a dose volume of 2.5 mL/kg for intravenous administration and 5 mL/kg for oral administration. Intravenous formulations were administered via a jugular vein cannula. Immediately after dosing, the cannula was flushed with saline and the line was tied off. The oral dose was administered via a ball-tipped feeding needle. Dosing syringe volumes for administration were second-person verified prior to dosing and that volume along with the results for the concentration verification analysis were used to calculate the actual dose administered. Dosing syringes were weighed immediately prior to and immediately after dosing each animal as a gravimetric check.

**[000416]** Serial blood samples (approximately 200  $\mu$ L per sample) were collected from each animal at 0.083 (IV dosing only), 0.25, 0.5, 1, 2, 4, 6 (PO dosing only), 8, 24, 32, 48, and 72 hours after dosing. Blood samples were collected into tubes containing K2EDTA via the non-dosing jugular-vein cannula (JVC), which was flushed with an approximately equal volume of saline following each collection.

**[000417]** Blood samples were stored on wet ice until processed to plasma by centrifugation (3500 rpm at 5°C for 10 minutes) within 1 hour of collection. Plasma samples were transferred into matrix tubes and then stored in a -80°C freezer.

**[000418]** Plasma samples and dose formulation samples were analyzed for the compounds of interest using liquid chromatography-tandem mass spectrometry (LC-MS/MS) methods. Pharmacokinetic parameter estimates were calculated from the individual animal plasma concentration-time data using the actual dose based on the analysis of the dosing formulations, nominal sampling times (all collections were within an acceptable range of target), and non-compartmental methods. The concentration-time data were analyzed to fit either an intravenous - bolus (IV) plasma analysis model (201) or extravascular (PO) dosing plasma analysis model (200) using the software WinNonlin Phoenix version 6.3 (Pharsight). The single-dose pharmacokinetic parameters assessed include, as appropriate:  $C_{max}$  (observed peak or maximum concentration);  $T_{max}$  (observed time of peak concentration);  $T_{1/2}$  (terminal half-life);  $V_z$  (volume of distribution based on the terminal phase);  $V_{ss}$  (volume of distribution at steady state);  $AUC_{INF}$  (area under the concentration-time curve computed from time zero to infinity);  $AUC_{iast}$  (area under the concentration-time curve computed from time zero to the time of the last quantifiable concentration);  $C_0$  (back-extrapolated concentration at time zero); CL (total body clearance);  $V_z/F$  (volume of distribution for extravascular administration based on the terminal phase);  $CL/F$  (total body clearance for extravascular administration); F% (bioavailability); and  $MRT_{iast}$  (mean residence time).

**[000419]** Areas-under-the -plasma concentration-time curves (AUC) were estimated using the linear-log trapezoidal rule. The area through the time ( $T_{iast}$ ) of the last observable concentration ( $C_{iast}$ ) is reported as  $AUC_{iast}$ . AUC extrapolated to infinity, ( $AUC_{INF}$ ) was estimated by adding  $AUC_{iast}$  and the ratio of  $C_{iast}/\lambda_z$ , where  $\lambda_z$  is the terminal rate constant. Apparent terminal half-life ( $T_{1/2}$ ) was calculated as  $\ln(2)/\lambda_z$  and determined using the slope of the log-linear terminal phase of the concentration-time curve, defined by a minimum of three plasma concentration-time points. Half-lives are reported if the correlation for the regression line, as measured by r squared, is  $\geq 0.9$  when rounded. After IV administration, volume of distribution ( $V_z$ ) was calculated as  $Dose/L_z * AUC_{iNF-obs}$ , clearance (CL) was calculated as  $Dose/AUC_{iNF-obs}$  and volume of distribution at steady state ( $V_{ss}$ ) was estimated as  $MRT_{iNF} * CL$ . Mean residence time (MRT) from the time of dosing to the time of the last measurable concentration was calculated as  $AUMC_{iast}/AUC_{iast}$ . For model 200 the bioavailability (i.e. fraction of total dose that reaches the systemic circulation) cannot be calculated. Consequently, volume and clearance for this model is  $V_z/F$  or  $CL/F$ ,

respectively; where F is defined as bioavailability (i.e. fraction of total dose that reaches the systemic circulation;  $(\text{Average AUC}_{\text{ast-Po}}/\text{Average AUC}_{\text{ast-iv}})*[\text{Dose}_{\text{iv}}/\text{Dose}_{\text{po}}]*100$ ).
