## Part I

### Theory and Tables

With an Appendix

By A. R. CURTIS and H. H. ROBERTSON,  
OF THE MATHEMATICS DIVISION, N.P.L.

#### *Summary.*

A method of calculating the tunnel interference due to oscillating loadings on wings in rectangular tunnels is described. This will apply to incompressible flow for all frequencies or to subsonic flow for small frequencies. The interference upwash due to a horse-shoe vortex of oscillating strength is derived from that for a steady horse-shoe vortex and hence the interference on wings with symmetrical or antisymmetrical loadings. An Appendix describes tables of a function basic to the theory for any rectangular section. Some other functions applicable in the particular case of a  $9 \times 7$  tunnel are tabulated and their use is discussed. The effect of frequency variation on a typical interference upwash is illustrated.

---

#### 1. Introduction.

The problem of determining the wall interference on an oscillating wing in a wind tunnel of closed circular section was considered in Ref. 1 (Acum and Garner, 1954). The present report describes a method of dealing with the corresponding problem for a closed tunnel of rectangular section. An approximate expression for the interference upwash due to an oscillating wing will be derived by replacing the vorticity distribution round it by horse-shoe vortices of strength periodic in time. It has been shown in Ref. 1 that the interference due to such an oscillating vortex can be computed from the upwash due to a steady vortex provided that this is known everywhere in its plane.

---

\* Previously issued as A.R.C. 19,593 and 19,756. Published with the permission of the Director, National Physical Laboratory.

The amount of work previously done on three-dimensional oscillating wings in wind tunnels is comparatively small. Goodman<sup>2</sup> (1953) has indicated a general method for small wings and applied it to the case of circular tunnel and a wing between two horizontal or vertical walls. W. P. Jones<sup>3</sup> (1943) has determined the corrections for wings of rectangular planform in square tunnels.

The two-dimensional case has been more extensively treated by Reissner<sup>4</sup>, Jones<sup>5</sup>, Timman<sup>6</sup>, and others. These analytical investigations indicate two facts which may complicate the three-dimensional case. Some theoretical work of Jones<sup>7</sup> and Runyan and Watkins<sup>8</sup> indicates that at certain frequencies the interference may become very large due to compressibility effects. This resonance phenomenon appears to occur in practice<sup>9</sup> (Runyan, Woolston and Rainey, 1956), but the present report cannot deal with it, as the theory is restricted to either incompressible flow or low-frequency oscillations in compressible flow. The other fact is that in practice the trailing vortices are not of infinite length as is usually assumed in the theory, but are truncated at some distance downstream of the wing determined by the tunnel geometry. P. F. Jordan<sup>10</sup> (1953) has shown that in two dimensions this effect can be significant under some circumstances. A similar investigation in three dimensions could be made using the functions tabulated in this report.

The steady interference upwash is determined by the function  $f(X, Y)$  defined in equation (3) by an infinite series which can be summed straightforwardly for any particular pair of values of  $X$  and  $Y$ . However, since  $f(X, Y)$  is required for all values of  $X$  and  $Y$  an interpolable table of  $f(X, Y)$  has been prepared in the Mathematics Division, N.P.L. Its use is described in the Appendix.

## 2. Steady Interference Upwash.

It has been shown by Glauert (Ref. 11, Section 12.2) that in the absence of tunnel walls the upwash due to a horse-shoe vortex of constant strength,  $K$ , situated as in Fig. 1 is given by

$$w = \frac{K}{4\pi} \left\{ \frac{x(y-t)}{\sqrt{x^2 + (y-t)^2 + z^2}} \left[ \frac{1}{(y-t)^2 + z^2} + \frac{1}{x^2 + z^2} \right] - \right. \\ - \frac{x(y+t)}{\sqrt{x^2 + (y+t)^2 + z^2}} \left[ \frac{1}{(y+t)^2 + z^2} + \frac{1}{x^2 + z^2} \right] + \\ \left. + \frac{y-t}{(y-t)^2 + z^2} - \frac{(y+t)}{(y+t)^2 + z^2} \right\}. \quad (1)$$

The presence of tunnel walls may be simulated in the usual way by introducing a doubly infinite array of image vortices spaced at a distance  $h$  in the vertical, or  $z$ -direction, and distance  $b$  in the horizontal or  $y$ -direction. In any horizontal row the vortices all have the same sign but in a vertical column their signs alternate.

From (1) it follows that the upwash at  $(x, y, 0)$  due to the column including the original vortex is given by

$$w = \frac{K}{4\pi} \sum_{n=-\infty}^{+\infty} (-1)^n \left\{ \frac{x(y-t)}{\sqrt{x^2 + (y-t)^2 + n^2h^2}} \left[ \frac{1}{(y-t)^2 + n^2h^2} + \frac{1}{x^2 + n^2h^2} \right] - \right. \\ - \frac{x(y+t)}{\sqrt{x^2 + (y+t)^2 + n^2h^2}} \left[ \frac{1}{(y+t)^2 + n^2h^2} + \frac{1}{x^2 + n^2h^2} \right] + \\ \left. + \frac{(y-t)}{(y-t)^2 + n^2h^2} - \frac{(y+t)}{(y+t)^2 + n^2h^2} \right\}. \quad (2)$$

Now define the functions  $f(X, Y)$  and  $f_1(X, Y)$  by

$$f(X, Y) = \frac{XY}{\sqrt{(X^2 + Y^2)}} \left( \frac{1}{X^2} + \frac{1}{Y^2} \right) + 2 \sum_{n=1}^{\infty} (-1)^n \frac{XY}{\sqrt{(X^2 + Y^2 + n^2)}} \left( \frac{1}{X^2 + n^2} + \frac{1}{Y^2 + n^2} \right) \quad (3)$$

and

$$f_1(X, Y) = f(X, Y) - \frac{XY}{\sqrt{(X^2 + Y^2)}} \left( \frac{1}{X^2} + \frac{1}{Y^2} \right). \quad (4)$$

Since it is known that

$$\frac{1}{Y} + 2 \sum_{n=1}^{\infty} (-1)^n \frac{Y}{Y^2 + n^2} = \pi \operatorname{cosech} \pi Y, \quad (5)$$

equation (2) may now be written.

$$w = \frac{K}{4\pi h} \left\{ f \left( \frac{x}{h}, \frac{y-t}{h} \right) - f \left( \frac{x}{h}, \frac{y+t}{h} \right) + \pi \operatorname{cosech} \frac{\pi(y-t)}{h} - \pi \operatorname{cosech} \frac{\pi(y+t)}{h} \right\}. \quad (6)$$

For the other columns  $y$  is replaced by  $(y+mb)$ , ( $m = \pm 1, \pm 2, \dots$ ). In order to obtain the interference upwash the expressions (6) corresponding to each column must be summed with the exception that in the column passing through the original vortex the term in equation (2) corresponding to  $n = 0$  must be omitted. Hence the interference upwash is given by

$$\begin{aligned} w = & \frac{K}{4\pi h} \left\{ f_1 \left( \frac{x}{h}, \frac{y-t}{h} \right) - f_1 \left( \frac{x}{h}, \frac{y+t}{h} \right) + \left[ \pi \operatorname{cosech} \frac{\pi(y-t)}{h} - \frac{h}{(y-t)} \right] - \right. \\ & - \left[ \pi \operatorname{cosech} \frac{\pi(y+t)}{h} - \frac{h}{(y+t)} \right] + \sum_{m=1}^{\infty} \left[ f \left( \frac{x}{h}, \frac{y-t+mb}{h} \right) + \right. \\ & + f \left( \frac{x}{h}, \frac{y-t-mb}{h} \right) - f \left( \frac{x}{h}, \frac{y+t+mb}{h} \right) - f \left( \frac{x}{h}, \frac{y+t-mb}{h} \right) + \\ & + \pi \operatorname{cosech} \frac{\pi(y-t+mb)}{h} + \pi \operatorname{cosech} \frac{\pi(y-t-mb)}{h} - \pi \operatorname{cosech} \frac{\pi(y+t+mb)}{h} - \\ & \left. \left. - \pi \operatorname{cosech} \frac{\pi(y+t-mb)}{h} \right] \right\}. \end{aligned} \quad (7)$$

The function  $f(X, Y)$  is tabulated in Table 1; instructions for interpolation are given in the Appendix. With equation (7) this permits the calculation of the interference upwash at the point  $(x, y, 0)$  due to a steady horse-shoe vortex in any rectangular wind tunnel.

### 3. Oscillatory Interference Upwash.

Consider now a vortex of oscillatory strength such that the transverse part has the circulation

$$K = \bar{K} \exp(i\omega T). \quad (8)$$

Downstream of this in the strip,  $x > 0$ ,  $|y| \leq t$ , there will be a trailing vortex sheet. Since the pressure must be continuous across this strip it follows that on its upper surface the velocity potential,  $\phi$ , satisfies the equation

$$\frac{\partial \phi}{\partial T} + V \frac{\partial \phi}{\partial x} = 0$$

so that

$$\phi = \frac{1}{2} \bar{K} \exp \left[ i\omega \left( T - \frac{x}{V} \right) \right], \quad (9)$$

and since the value of  $\phi$  on the lower surface is equal and opposite to that on the upper surface,

$$\begin{aligned} \phi_{\text{upper}} - \phi_{\text{lower}} &= \bar{K} \exp(i\omega T) \exp(-i\omega x/V) \\ &= \bar{K} \exp(i\omega T) \left\{ H(x) + \int_0^\infty (-i\omega/V) \exp(-i\omega x'/V) H(x-x') dx' \right\} \end{aligned} \quad (10)$$

where

$$H(x) = 0 \text{ if } x < 0, \quad H(x) = 1 \text{ if } x > 0.$$

Now the velocity potential for a steady horse-shoe vortex of strength  $\bar{K}$  with its transverse part at  $x = x'$  satisfies

$$\phi_{\text{upper}} - \phi_{\text{lower}} = \bar{K} H(x-x'). \quad (11)$$

Moreover if the fluid is incompressible the velocity potential satisfies Laplace's equation in unsteady as well as in steady flow. On the tunnel walls both have zero normal gradient, or in free-stream flow both vanish at infinity. Then the distribution of  $\phi$  in the boundary condition (10) may be regarded as the limiting sum of those in equation (11), and the velocity potential and velocities in unsteady flow obtained by combining those for steady flow in the same proportion.

Now let the interference upwash angle be

$$\frac{w}{V} = \frac{\bar{w}}{V} e^{i\omega T} = e^{i\omega T} \frac{\bar{K}}{Vb} \delta \left( \frac{x}{b}, \frac{y}{b}; \frac{t}{b}, \frac{\omega b}{V} \right). \quad (12)$$

It follows from equation (10) that

$$\begin{aligned} \delta \left( \frac{x}{b}, \frac{y}{b}; \frac{t}{b}, \frac{\omega b}{V} \right) &= \delta \left( \frac{x}{b}, \frac{y}{b}; \frac{t}{b}, 0 \right) + \\ &+ \int_{x'=0}^{\infty} \left( -\frac{i\omega}{V} \right) e^{-i\omega x'/V} \delta \left( \frac{x-x'}{b}, \frac{y}{b}; \frac{t}{b}, 0 \right) dx'. \end{aligned} \quad (13)$$

Let  $\xi = x/b$ ,  $\eta = y/b$ ,  $\tau = t/b$ ,  $\mu = \omega b/V$ , and change the variable of integration by putting  $\theta = \xi - x'/b$ . Then

$$\delta(\xi, \eta; \tau, \mu) = \delta(\xi, \eta; \tau, 0) - i\mu e^{-i\mu\xi} \int_{-\infty}^{\xi} e^{i\mu\theta} \delta(\theta, \eta; \tau, 0) d\theta. \quad (14)$$

Since  $\delta(\xi, \eta; \tau, 0)$  can easily be derived from equations (7) and (12) this gives the required method of calculating the interference due to an oscillating vortex. This was proved by another method in Ref. 1, and applies to any closed cylindrical tunnel.

If the fluid is not incompressible,  $\phi$  will not satisfy Laplace's equation. However, in subsonic flow of Mach number  $M$  if a new variable  $\phi_1$  is taken defined by

$$\phi_1 = \phi \exp \left[ -\frac{i\omega x}{V} \frac{M^2}{1-M^2} \right] \exp (-i\omega T), \quad (15)$$

then  $\phi_1$  satisfies

$$(1-M^2) \frac{\partial^2 \phi_1}{\partial x^2} + \frac{\partial^2 \phi_1}{\partial y^2} + \frac{\partial^2 \phi_1}{\partial z^2} + \frac{\omega^2}{V^2} \frac{M^2}{1-M^2} \phi_1 = 0 \quad (16)$$

which is simply transformed to Laplace's equation provided  $\mu^2 M^2$  is negligible. Then  $\phi_1$  satisfies the same equation as does the velocity potential for steady flow and a relation analogous to (14) may be constructed by similar arguments.

#### 4. Symmetrically Oscillating Wings.

It will now be assumed that the wing is symmetrical with respect to  $y$ , both in planform and mode of oscillation, and further that the vorticity and lift distributions associated with it have been determined, theoretically or experimentally, to an accuracy sufficient for tunnel-interference calculations. The lift distribution can be expressed by

$$l = (l_r + i l_i) e^{i\omega T} = \frac{\dot{p}_b - \dot{p}_a}{\frac{1}{2} \rho V^2} \quad (17)$$

where  $l_r$  and  $l_i$  are functions of  $x$  and  $y$ . The functions  $l_r$  and  $l_i$  will be treated quite separately and the resulting interference added at the end of the calculation.

With  $l_r$  will be associated a centre-of-pressure locus whose position is given by  $x = \bar{x}_r(y)$  and a complex circulation  $\Gamma_r(y)$  defined by the lift distribution at each spanwise section. It is assumed that for the purpose of tunnel-interference calculations it is sufficiently accurate to take the vorticity as concentrated at the local centre of pressure. This could be refined if necessary by assuming two or more such concentrations of vorticity. The interference upwash due to  $l_r e^{i\omega T}$  is then given approximately by

$$\begin{aligned} \frac{w(x, y)}{V} &= \int_0^s \frac{\Gamma_r(t)}{Vb} \frac{\partial}{\partial t} \delta \left( \frac{x - \bar{x}_r(t)}{b}, \frac{y}{b}; \frac{t}{b}, \mu \right) dt \\ &= \int_0^\sigma \frac{\Gamma_r(\tau)}{Vb} \frac{\partial}{\partial \tau} \delta \{ \xi - \bar{\xi}_r(\tau), \eta; \tau, \mu \} d\tau, \end{aligned} \quad (18)$$

where  $\sigma = s/b$  and  $\bar{\xi}_r(\tau) = \bar{x}_r(\tau b)/b$ . In the differentiations with respect to  $t$  and  $\tau$  the variation of  $\bar{x}_r(t)$  and  $\bar{\xi}_r(\tau)$  is to be ignored.

A similar equation may be written down for the interference upwash due to  $i l_i e^{i\omega T}$ .

It can be shown that the interference upwash is given exactly by the equation

$$\frac{w}{V} = \int_{t=0}^s \int_{x'=x_l}^{x_l} \frac{l(x', t)}{2b} \frac{\partial}{\partial t} \delta \left( \frac{x - x'}{b}, \frac{y}{b}; \frac{t}{b}, \mu \right) dx' dt, \quad (19)$$

but the more elaborate computation implied by this expression is not likely to be justified.

Now by equation (14)

$$\frac{\partial}{\partial \tau} \delta(\xi, \eta; \tau, \mu) = \frac{\partial}{\partial \tau} \delta(\xi, \eta; \tau, 0) - i\mu e^{-i\mu\xi} \int_{-\infty}^{\xi} e^{i\mu\theta} \frac{\partial}{\partial \tau} \delta(\theta, \eta; \tau, 0) d\theta, \quad (20)$$

and by equation (7)

$$\delta(\xi, \eta; \tau, 0) = F_1(\xi, \eta - \tau) - F_1(\xi, \eta + \tau) \quad (21)$$

where

$$F_1(\xi, \lambda) = \frac{b}{h} \frac{1}{4\pi} \left\{ f_1 \left( \frac{b}{h} \xi, \frac{b}{h} \lambda \right) + \pi \operatorname{cosech} \frac{\pi b \lambda}{h} - \frac{h}{b \lambda} + \sum_{m=1}^{\infty} \left[ f \left( \frac{b}{h} \xi, \frac{b}{h} (\lambda+m) \right) + f \left( \frac{b}{h} \xi, \frac{b}{h} (\lambda-m) \right) + \pi \operatorname{cosech} \frac{\pi b (\lambda+m)}{h} + \pi \operatorname{cosech} \frac{\pi b (\lambda-m)}{h} \right] \right\}. \quad (22)$$

Hence in equation (20)

$$\frac{\partial}{\partial \tau} \delta(\xi, \eta; \tau, 0) = F_2(\xi, \eta - \tau) + F_2(\xi, \eta + \tau) \quad (23)$$

where

$$F_2(\xi, \lambda) = - \frac{\partial}{\partial \lambda} F_1(\xi, \lambda). \quad (24)$$

Thus for the calculation of interference the tabulation of  $F_2$  is required for the tunnel concerned; this is a straightforward matter when  $f$  is known, since the infinite series in equation (22) is rapidly convergent.

### 5. Antisymmetrically Oscillating Wings.

Consider the system of vorticity consisting of two equal and opposite horse-shoe vortices on opposite sides of the centreline of the tunnel, as shown in Fig. 2. The vorticity distribution round a wing whose lift distribution is antisymmetrical with respect to  $y$  may be expressed as a distribution of vortices of this sort. The upwash due to such a vortex distribution is

$$\begin{aligned} \frac{w}{V} &= \frac{K}{4\pi V} \left\{ \frac{x(y-t)}{\sqrt{x^2 + (y-t)^2 + z^2}} \left[ \frac{1}{(y-t)^2 + z^2} + \frac{1}{x^2 + z^2} \right] + \right. \\ &\quad + \frac{x(y+t)}{\sqrt{x^2 + (y+t)^2 + z^2}} \left[ \frac{1}{(y+t)^2 + z^2} + \frac{1}{x^2 + z^2} \right] - \\ &\quad \left. - \frac{2xy}{\sqrt{x^2 + y^2 + z^2}} \left[ \frac{1}{y^2 + z^2} + \frac{1}{x^2 + z^2} \right] + \frac{(y-t)}{(y-t)^2 + z^2} + \frac{(y+t)}{(y+t)^2 + z^2} - \frac{2y}{y^2 + z^2} \right\}. \quad (25) \end{aligned}$$

Hence for a column of images

$$\begin{aligned} \frac{w}{V} &= \frac{K}{4\pi V h} \left\{ f \left( \frac{x}{h}, \frac{y-t}{h} \right) + f \left( \frac{x}{h}, \frac{y+t}{h} \right) - 2f \left( \frac{x}{h}, \frac{y}{h} \right) + \right. \\ &\quad \left. + \pi \operatorname{cosech} \frac{\pi(y-t)}{h} + \pi \operatorname{cosech} \frac{\pi(y+t)}{h} - 2\pi \operatorname{cosech} \frac{\pi y}{h} \right\}. \quad (26) \end{aligned}$$

The calculation may now be carried through in a manner analogous to that used in the symmetrical case, and leads to the formula

$$\delta = F_3\{\xi, (\eta - \tau)\} + F_3\{\xi, (\eta + \tau)\} - 2F_3(\xi, \eta) \quad (27)$$

where

$$\begin{aligned} F_3(\xi, \lambda) = & \frac{1}{4\pi} \frac{b}{h} \left\{ f\left(\frac{b}{h}\xi, \frac{b}{h}\lambda\right) + \pi \operatorname{cosech} \frac{\pi b \lambda}{h} - \frac{h}{b \lambda} + \right. \\ & + \sum_{m=1}^{\infty} (-1)^m \left[ f\left(\frac{b}{h}\xi, \frac{b}{h}(\lambda+m)\right) + f\left(\frac{b}{h}\xi, \frac{b}{h}(\lambda-m)\right) + \right. \\ & \left. \left. + \pi \operatorname{cosech} \frac{\pi b(\lambda+m)}{h} + \pi \operatorname{cosech} \frac{\pi b(\lambda-m)}{h} \right] \right\} \end{aligned} \quad (28)$$

and so to further expressions corresponding to those of Section 4.

### 6. Small Wings.

If a symmetrical wing is small enough the interference may be calculated by regarding its vorticity distribution as being concentrated into a single vortex of small span. If  $t \rightarrow 0$  and  $K \rightarrow \infty$  in such a way that  $Kt$  tends to a constant, then in steady flow by equation (7)

$$\begin{aligned} \frac{*w(\xi, \eta; 0, 0)}{V} = & \lim_{\tau \rightarrow 0} \frac{Kt}{Vb^2} \frac{1}{4\pi} \frac{b}{h} \frac{1}{\tau} \left\{ f_1\left(\frac{b}{h}\xi, \frac{b}{h}(\eta - \tau)\right) - f_1\left(\frac{b}{h}\xi, \frac{b}{h}(\eta + \tau)\right) + \right. \\ & + \left[ \pi \operatorname{cosech} \frac{\pi b(\eta - \tau)}{h} - \frac{h}{b(\eta - \tau)} \right] - \left[ \pi \operatorname{cosech} \frac{\pi b(\eta + \tau)}{h} - \frac{h}{b(\eta + \tau)} \right] + \\ & + \sum_{m=1}^{\infty} \left[ f\left(\frac{b}{h}\xi, \frac{b}{h}(\eta - \tau \pm m)\right) - f\left(\frac{b}{h}\xi, \frac{b}{h}(\eta + \tau \pm m)\right) + \right. \\ & \left. \left. + \pi \operatorname{cosech} \frac{\pi b(\eta - \tau \pm m)}{h} - \pi \operatorname{cosech} \frac{\pi b(\eta + \tau \pm m)}{h} \right] \right\} \\ = & \frac{Kt}{Vb^2} \left( \frac{b}{h} \right)^2 \frac{1}{2\pi} \left\{ - \frac{\partial f_1}{\partial Y} \left( \frac{b}{h}\xi, \frac{b}{h}\eta \right) - \left[ \frac{d}{dx} \left( \pi \operatorname{cosech} \pi x - \frac{1}{x} \right) \right]_{x=b\eta/h} - \right. \\ & \left. - \sum_{m=1}^{\infty} \left[ \frac{\partial f}{\partial Y} \left( \frac{b}{h}\xi, \frac{b}{h}\eta \right) + \left( \frac{d}{dx} (\pi \operatorname{cosech} \pi x) \right)_{x=b(\eta \pm m)/h} \right] \right\}. \end{aligned}$$

Hence, by equations (22) and (24)

$$\frac{w(\xi, \eta; 0, 0)}{V} = \frac{2Kt}{Vb^2} F_2(\xi, \eta), \quad (29)$$

and in the oscillating case

$$\frac{\bar{w}(\xi, \eta; 0, \mu)}{V} = \frac{2Kt}{Vb^2} \left\{ F_2(\xi, \eta) - i\mu \exp(-i\mu\xi) \int_{-\infty}^{\xi} \exp(i\mu\theta) F_2(\theta, \eta) d\theta \right\}, \quad (30)$$

and in particular

$$\frac{\bar{w}(0, 0; 0, \mu)}{V} = \frac{2Kt}{Vb^2} \left\{ F_2(0, 0) - i\mu \int_{-\infty}^0 \exp(i\mu\theta) F_2(\theta, 0) d\theta \right\}. \quad (31)$$

\*  $\pm$  indicates that the sum of both possible terms is to be taken.

For sufficiently small wings

$$\frac{2Kt}{Vb^2} = \frac{SC_L}{bh} \frac{h}{2b}, \quad (32)$$

so that in the low-frequency case

$$\begin{aligned} \frac{\bar{w}(\xi, 0; 0, \mu)}{V} &= \frac{SC_L}{bh} \frac{h}{2b} \left\{ F_2(0, 0) + \xi \left[ \frac{\partial}{\partial \xi} F_2(\xi, 0) \right]_{\xi=0} - \right. \\ &\quad \left. - i\mu \int_{-\infty}^0 F_2(\theta, 0) d\theta - i\mu \xi F_2(0, 0) + O(\xi^2) \right\} \\ &= \frac{SC_L}{bh} \left\{ \delta_0 + \frac{x}{h} \delta_1 + i \frac{h}{b} \mu \left( \delta'_0 + \frac{x}{h} \delta'_1 \right) + O\left(\left(\frac{x}{h}\right)^2\right) \right\}, \end{aligned} \quad (33)$$

where

$$\begin{aligned} \delta_0 &= \frac{h}{2b} F_2(0, 0), & \delta_1 &= \frac{h^2}{2b^2} \left[ \frac{\partial}{\partial \xi} F_2(\xi, 0) \right]_{\xi=0}, \\ \delta'_0 &= -\frac{1}{2} \int_{-\infty}^0 F_2(\theta, 0) d\theta, & \delta'_1 &= -\frac{h}{2b} F_2(0, 0). \end{aligned} \quad (34)$$

Values of  $\delta_0$ ,  $\delta_1$ ,  $\delta'_0$ , and  $\delta'_1$  calculated from a table of  $F_2$  for  $b/h = 9/7$  agree with those calculated by a different method in Table AII of Ref. 1.

The circulation round any section of a wing is

$$\Gamma(y) = \frac{V}{2} \int_{x_l}^{x_l} l \exp\left(\frac{i\omega(x-x_l)}{V}\right) dx. \quad (35)$$

Equation (32) is obtained by taking the exponential factor in the integrand to be unity. Evidently this will be valid provided  $\omega c/V$  is small enough, that is when the wing is small and the frequency is low. The error in equation (32) will be of order  $i\mu\bar{c}/b$  and this implies that in equation (33)  $\delta'_0$  and  $\delta'_1$  may be in error by amounts of order  $(\bar{c}/h)\delta_0$  and  $(\bar{c}/h)\delta_1$  respectively.

### 7. Discussion.

It will have become apparent from the preceding sections that, in order to carry out the evaluation of interference upwash as a matter of routine, it is necessary to have a table of the function  $F_2(\xi, \lambda)$  for the tunnel concerned. The range of values of  $\lambda$  for which this is needed is finite, namely  $-1 < \lambda < 1$ , but equations (20), (23) and (24) show that values of  $F_2(\xi, \lambda)$  are needed for all values of  $\xi$  from  $-\infty$  up to a positive value which will depend on the possible streamwise extent of the models. An upper limit of  $\xi = 1$  will probably cover most practical cases. As  $\xi$  tends to  $-\infty$ ,  $F_2(\xi, \lambda) = O(1/\xi^2)$  and an asymptotic form for large negative  $\xi$  may be obtained. Such a table of  $F_2(\xi, \lambda)$  has been tabulated in the Mathematics Division of the N.P.L. for the case  $b/h = 9/7$ , but unfortunately it is far too lengthy to be included in this report. A similar table of  $F_3(\xi, \lambda)$  would be required for antisymmetrically loaded wings.

This difficulty may to some extent be overcome by the use of tables such as those given in Table 2. This gives  $\text{Re}(wb/\Gamma)$  and  $\mu^{-1}\text{Im}(wb/\Gamma)$  as functions of  $\xi$  and  $\eta$  for various values of  $\sigma$ , due to an oscillating horse-shoe vortex of circulation  $\Gamma$  and span  $2\sigma b$  when the origin is at the mid-point of the finite part of the vortex. The frequency is assumed to be small in Table 2 but a similar table could be constructed for any other value of  $\mu$ .

Table 2 may be used to calculate the interference upwash due to either the in-phase or out-of-phase lift distribution on a symmetrical wing in a  $9 \times 7$  rectangular tunnel in the following manner. The wing is divided up spanwise by the lines  $\eta = -\tau_k, -\tau_{k-1}, -\tau_{k-2}, \dots, -\tau_1, 0, \tau_1, \tau_2, \dots, \tau_{k-1}, \tau_k$ , where  $2b\tau_k$  is the span of the wing (see Fig. 3). It is assumed that in any interval  $(\tau_n, \tau_{n+1})$  the circulation is constant, i.e.,

$$\begin{aligned}\Gamma &= \frac{1}{2}\{\Gamma(\tau_n) + \Gamma(\tau_{n+1})\} \\ &= \Gamma_n, \text{ say.}\end{aligned}\quad (36)$$

Moreover the distributed vorticity in this strip is assumed to be at the local centre of pressure, i.e., at

$$\xi = \bar{\xi}(\frac{1}{2}[\tau_n + \tau_{n+1}])$$

where  $\xi = \bar{\xi}(\tau)$  is the locus of the centre of pressure. Then the effect of the vorticity between  $\tau_n$  and  $\tau_{n+1}$  and the equal vorticity between  $-\tau_{n+1}$  and  $-\tau_n$  is approximately that due to the sum of two horse-shoe vortices, one of span  $2\tau_{n+1}$  and strength  $+\Gamma_n$ , and the other of span  $2\tau_n$  and strength  $-\Gamma_n$ , both with their spanwise parts on the line  $\xi = \bar{\xi}(\frac{1}{2}[\tau_n + \tau_{n+1}])$ . Since the upwash due to these two vortices may be obtained from Table 2, the interference due to the whole wing may be obtained by summation with respect to  $n$ . In fact equation (18) is the limiting form of such a summation.

Since in Table 2 the frequency is assumed to be small,  $\text{Re}(wb/\Gamma)$  gives the interference upwash due to a steady horse-shoe vortex of strength  $\Gamma$ , and calculations of steady interference may be carried through simply as particular cases of oscillatory calculations.

Table 3 illustrates the effect of frequency for the case  $\sigma = 0.2$ , by giving the interference upwash on the line  $\eta = 0$  for  $\mu = 0(0.4)2.0$ . These values have been plotted in Figs. 4 and 5 which show the marked effect of variations in frequency especially for points well downstream of the vortex. This suggests that frequency effects may be important especially for wings of large streamwise extent.

There remains the problem of calculating the overall interference forces and moments on the wing. Satisfactory methods exist for doing this when  $\mu$  is small, for example that of Ref. 12, but when  $\mu$  is not small the matter is more difficult and it is not clear what is the best course to adopt. A discussion of some lifting-surface theories which have recently been proposed is given in Ref. 13. Fortunately for most tunnel-interference calculations high accuracy is not required in this stage of the computation. In particular the range of frequency for which the low-frequency theory is adequate is likely to be larger than in ordinary wing calculations.

As far as pitching wings are concerned a procedure analogous to that used in steady flow may be adopted, that is a correction may be applied to the incidence of the wing rather than to the forces acting on it. The numbers concerned are now all complex. Assume that the following quantities have been determined:

- (1) The experimentally determined lift coefficient,  $C'_L$ , and pitching-moment coefficient,  $C'_m$ , for a wing oscillating in the tunnel about a known axis, with a known instantaneous incidence  $\alpha = \alpha_0 \exp(i\omega T)$ .
- (2) The theoretical free-stream lift and pitching-moment derivatives,  $\partial C_L / \partial \alpha$  and  $\partial C_m / \partial \alpha$  for oscillations of small amplitude about the same axis.
- (3) The additional theoretical lift and pitching-moment derivatives due to the tunnel-induced upwash caused by the lift distribution giving rise to  $\partial C_L / \partial \alpha$  and  $\partial C_m / \partial \alpha$ . Let these quantities be denoted by  $\partial(\Delta C_L) / \partial \alpha$  and  $\partial(\Delta C_m) / \partial \alpha$ , respectively.

Then the lift corresponding to  $C'_L$  would theoretically be caused by an incidence  $C'_L/\partial C_L/\partial\alpha$ . The theoretical interference lift due to this would be

$$C'_L \frac{\partial(\Delta C_L)}{\partial\alpha} / \left( \frac{\partial C_L}{\partial\alpha} \right)$$

and the corresponding mean angle of incidence is

$$(\Delta\alpha)_m = C'_L \frac{\partial(\Delta C_L)}{\partial\alpha} / \left( \frac{\partial C_L}{\partial\alpha} \right)^2. \quad (37)$$

The angle of incidence corresponding to  $C'_L$  is therefore taken to be  $\alpha + (\Delta\alpha)_m$ . In general  $(\Delta\alpha)_m$  is complex so a phase shift as well as a change in magnitude is implied. This process is in effect an averaging of the interference upwash using lifting-surface theory.

The residual interference contribution to the measured  $C'_m$  is now the moment due to the interference upwash less that due to the distribution of upwash corresponding to  $(\Delta\alpha)_m$ . Hence

$$\begin{aligned} (C'_m)_{\text{corrected}} &= (C'_m)_{\text{measured}} - \left\{ \frac{C'_L}{\frac{\partial C_L}{\partial\alpha}} \frac{\partial(\Delta C_m)}{\partial\alpha} - (\Delta\alpha)_m \frac{\partial C_m}{\partial\alpha} \right\} \\ &= (C_m)_{\text{measured}} + \frac{C'_L}{\left( \frac{\partial C_L}{\partial\alpha} \right)^2} \left[ \frac{\partial C_m}{\partial\alpha} \frac{\partial(\Delta C_L)}{\partial\alpha} - \frac{\partial(\Delta C_m)}{\partial\alpha} \frac{\partial C_L}{\partial\alpha} \right]. \end{aligned} \quad (38)$$

In general as much reliable experimental information as possible should be employed in computing corrections. In equations (37) and (38) the measured  $C'_L$  is used but  $C'_m$  is not. This might be improved if the in-phase and out-of-phase concentrations of vorticity on  $\xi = \bar{\xi}_r(\eta)$  and  $\xi = \bar{\xi}_i(\eta)$  were moved bodily streamwise until

$$C'_m/C'_L = \frac{\partial C_m}{\partial\alpha} / \frac{\partial C_L}{\partial\alpha}.$$

Some applications of the method to an actual planform are described in Part II.

#### 8. Acknowledgements.

Table 1 was computed in the Mathematics Division of the N.P.L. The other numerical work was carried out by Miss S. W. Skan and Miss B. Burnham.

## LIST OF SYMBOLS

$b$	Breadth of tunnel
$c$	Chord of wing
$\bar{c}$	Mean chord of wing
$C_L, C_m$	Theoretical lift and pitching-moment coefficients for wing in free stream
$C'_L, C'_m$	Experimentally measured values of $C_L, C_m$
$f, f_1$	Functions defined by equations (3) and (4)
$F_1, F_2, F_3$	Functions defined by equations (22), (24) and (28)
$h$	Height of tunnel
$H$	Unit step function; $H \equiv 0$ if $x < 0$ , $H \equiv 1$ if $x > 0$
$K$	Circulation of horse-shoe vortex
$\bar{K}$	Modulus of $K$
$l$	Non-dimensional lift distribution on wing {see equation (17)}
$l_r, l_i$	In- and out-of-phase parts of $l$
$p$	Pressure
$s$	Semi-span of wing
$S$	Area of wing planform
$t$	Semi-span of horse-shoe vortex
$T$	Time
$V$	Velocity of air stream in tunnel
$w$	Upwash
$\bar{w}$	Modulus of complex upwash
$x, y, z$	Cartesian co-ordinates (see Fig. 1)
$x_l, x_t$	Co-ordinates of leading and trailing edges of wing respectively
$\bar{x}_r, \bar{x}_i$	Co-ordinates of in- and out-of-phase local centres of pressure
$X, Y$	Independent variables
$\alpha$	Instantaneous incidence of wing, $\alpha = \alpha_0 e^{i\omega}$

LIST OF SYMBOLS—*continued*

$\Gamma$	Circulation of wing or vortex
$\Gamma_r, \Gamma_i$	Circulations corresponding to $l_r$ and $l_i$ respectively
$\delta$	Non-dimensional interference upwash {see equation (12)}
$\delta_0, \delta'_0, \delta_1, \delta'_1$	Parameters for the interference upwash of a small wing {see equation (33)}
$\Delta$	(Prefix) increment due to tunnel interference
$\eta$	Non-dimensional spanwise co-ordinate, $y/b$
$\mu$	Frequency parameter $\omega b/V$
$\xi$	Non-dimensional streamwise co-ordinate, $x/b$
$\bar{\xi}_r, \bar{\xi}_i$	$\bar{x}_r/b, \bar{x}_i/b$
$\rho$	Density of air stream
$\sigma$	Non-dimensional semi-span of wing, $s/b$
$\tau$	Non-dimensional semi-span of horse-shoe vortex, $t/b$
$\phi$	Velocity potential
$\phi_1$	See equation (15)
$\omega$	Angular frequency of oscillation.

*Suffixes*

$a, b$	Values on upper and lower surfaces of wing respectively
$r, i$	Real and imaginary parts of complex number.

## APPENDIX

### *Tables of Functions Used in Calculating Tunnel-Wall Corrections*

By A. R. Curtis and H. H. Robertson  
of the Mathematics Division, N.P.L.

*November, 1955*

#### *Description of Tables.*

The function

$$f(X, Y) = \sum_{n=-\infty}^{\infty} \frac{(-1)^n XY}{(X^2 + Y^2 + n^2)^{1/2}} \left\{ \frac{1}{X^2 + n^2} + \frac{1}{Y^2 + n^2} \right\} \quad (\text{A.1})$$

occurs in aerodynamic theory, and Table 1 is designed to facilitate its evaluation. To simplify interpolation we have found it convenient to tabulate the auxiliary functions

$$F(X, Y) = -f(X, Y) + (X^2 + Y^2)^{1/2}/XY \quad (\text{A.2})$$

$$G(X, Y) = -f(X, Y) + \pi \operatorname{cosech} \pi X + \pi \operatorname{cosech} \pi Y \quad (\text{A.3})$$

from which the required  $f(X, Y)$  can be obtained with little difficulty. We have also used auxiliary arguments  $X/Y$  and  $Y$ , in place of  $X$  and  $Y$ , to reduce the number of entries in the table.

The arrangement of the table, and the range of values of  $X/Y$  and  $Y$  for which  $F(X, Y)$  and  $G(X, Y)$  are given, are as follows

	Function	Values of $Y$	Values of $X/Y$
Table 1a	$F$	0.0(0.05)0.50	0.000(0.005)1.015
Table 1b	$G$	0.50(0.05)1.00	0.000(0.005)1.015
Table 1c	$G$	1.0(0.1)2.0	0.00(0.01)1.01
Table 1d	$G$	2.0(0.1)4.0	0.00(0.02)1.06

Tabular values are given to five decimal places, and the error in the last figure nowhere exceeds 2 units and is generally not greater than 0.8 units. When  $Y > 4$  the function  $G(X, Y)$  is zero to this precision.

The calculation of  $f(X, Y)$  from (A.3) is facilitated by the fact that

$$G(0, Y) = \pi \operatorname{cosech} \pi Y, \quad (\text{A.4})$$

so that

$$f(X, Y) = G(0, Y) + G(0, X) - G(X, Y) \quad (\text{A.5})$$

and no tables of  $\operatorname{cosech} \pi X$  are needed.

### *Interpolation.*

Linear interpolation is accurate everywhere in the  $X/Y$ -direction.

In the  $Y$ -direction second differences  $\delta_m^2$  modified according to the formula

$$\delta_m^2 = \delta^2 - 0.184\delta^4 \quad (\text{A } 6)$$

are given where needed, for use either with the modified formula of Everett

$$\phi(a+nh) = (1-n)\phi(a) + n\phi(a+h) + E_2\delta_m^2\phi(a) + F_2\delta_m^2\phi(a+h), \quad (\text{A.7})$$

or that of Bessel

$$\phi(a+nh) = (1-n)\phi(a) + n\phi(a+h) + B_2\{\delta_m^2\phi(a) + \delta_m^2\phi(a+h)\}, \quad (\text{A.8})$$

where  $h$  denotes the argument interval, and  $\phi$  denotes either  $F$  or  $G$ . Suitable tables of the coefficients  $E_2$ ,  $F_2$  and  $B_2$  are given in Ref. 14. Formula (A.8) should be used only when

$$|\delta_m^2\phi(a+h) - \delta_m^2\phi(a)| < 60 \quad (\text{A.9})$$

in units of the last decimal place.

Provided that a guarding figure is retained in carrying out the interpolation, the total error in an unrounded interpolate will in no case exceed 3 units in the fifth decimal place.

## Part II

### Applications to a Delta Planform in a $9 \times 7$ Tunnel

#### 1. Introduction.

Part II contains an application of the method proposed in Part I to a cropped delta wing of aspect ratio 1·8. All the computation applies to incompressible flow in a  $9 \times 7$  rectangular tunnel. In Section 2 the formulae necessary for the calculations are quoted or derived, and in Section 3 they are used for three ratios of wing span to tunnel breadth on the assumption that the frequency is small. The wing is assumed to be pitching or to have a full-span trailing-edge flap which is oscillating. Some calculations for the wing in pitching or heaving motion at a higher frequency are described in Section 4. In conclusion Section 5 contains a brief discussion of computability and accuracy.

#### 2. The Calculation of Circulation and Interference Upwash.

Consider a wing oscillating in such a way that it always lies close to the plane  $z = 0$ . It will be assumed that the lift distribution,  $l(x, y)$ , has been determined to an accuracy sufficient for tunnel-interference calculations. As extensive pressure plotting of oscillating wings is not usually undertaken at present these values of  $l$  will normally have to be found theoretically. Linearized lifting-surface theories such as those of Refs. 1, 2 and 3 provide ways of doing this.

The circulation,  $\Gamma$ , at any section  $y = \text{constant}$  may be obtained from  $l$ . According to linearized theory

$$p - p_\infty = -\rho(V\phi_x + i\omega\phi),$$

and for thin wings the velocity potential on the upper and lower surfaces satisfies  $\phi_a = -\phi_b$ . It follows that

$$\frac{1}{2}\rho V^2 l = p_b - p_a = 2\rho(V\partial\phi_a/\partial x + i\omega\phi_a). \quad (1)$$

Thus

$$\begin{aligned} \int_{x_l}^{x_t} (p_b - p_a) \exp(i\omega x/V) dx &= 2\rho V \int_{x_l}^{x_t} \exp(i\omega x/V) (\partial\phi_a/\partial x + i\omega\phi_a/V) dx \\ &= 2\rho V(\phi_a)_t \exp(i\omega x_t/V), \quad \{\text{since } (\phi_a)_l = 0\}. \end{aligned}$$

Hence

$$\Gamma = 2(\phi_a)_t = \frac{1}{2}V \int_{x_l}^{x_t} l \exp\left[\frac{i\omega(x-x_t)}{V}\right] dx. \quad (2)$$

Let

$$l = l_r + il_i, \quad (3)$$

where  $l_r$  and  $l_i$  are real. Then the corresponding circulations are

$$\frac{\Gamma_r}{Vb} = \frac{1}{2b} \int_{x_l}^{x_t} l_r \exp\left[\frac{i\omega(x-x_t)}{V}\right] dx, \quad (4)$$

and

$$\frac{\Gamma_i}{Vb} = \frac{1}{2b} \int_{x_l}^{x_t} l_i \exp\left[\frac{i\omega(x-x_t)}{V}\right] dx. \quad (5)$$

These complex circulations are connected with the quantities  $\bar{x}_r(y)$  and  $\bar{x}_i(y)$  which give the positions of the centre-of-pressure loci corresponding to  $l_r$  and  $l_i$  and are determined by straightforward integration.

The interference upwash for symmetrical loading may now be calculated. By equation (21) of Part I

$$\frac{\partial \delta}{\partial \tau}(\xi, \eta; \tau, 0) = F_2(\xi, \eta - \tau) + F_2(\xi, \eta + \tau)$$

where  $F_2$  is defined by equations (22) and (24) of Part I. Hence by equation (20) of Part I

$$\begin{aligned} \frac{\partial \delta}{\partial \tau}(\xi, \eta; \tau, \mu) &= \frac{\partial \delta}{\partial \tau}(\xi, \eta; \tau, 0) - i\mu e^{-i\mu\xi} \int_{-\infty}^{\xi} e^{i\mu\theta} \frac{\partial \delta}{\partial \tau}(\theta, \eta; \tau, \theta) d\theta \\ &= \bar{G}(\xi, \eta - \tau) + \bar{G}(\xi, \eta + \tau), \end{aligned} \quad (6)$$

where

$$\bar{G}(\xi, \lambda) = F_2(\xi, \lambda) - i\mu e^{-i\mu\xi} \int_{-\infty}^{\xi} e^{i\mu\theta} F_2(\theta, \lambda) d\theta. \quad (7)$$

Since  $-\frac{1}{2} < \tau < \frac{1}{2}$  and  $-\frac{1}{2} < \eta < \frac{1}{2}$ ,  $F_2$  and  $G$  are required for  $0 \leq \lambda < 1$  since they are even functions of  $\lambda$ . As  $\xi \rightarrow -\infty$ ,  $F_2 = O(\xi^{-2})$  so that the infinite integral in (7) is convergent. Then the part of the interference due to  $\Gamma_r$  is  $w_I$ , given by

$$\frac{w_I}{V} = \int_0^\sigma \frac{\Gamma_r(\tau)}{Vb} \{ \bar{G}(\xi - \bar{\xi}_r(\tau), \eta - \tau) + \bar{G}(\xi - \bar{\xi}_r(\tau), \eta + \tau) \} d\tau, \quad (8)$$

and similarly the part due to  $\Gamma_i$  is

$$\frac{w_{II}}{V} = \int_0^\sigma \frac{\Gamma_i(\tau)}{Vb} \{ \bar{G}(\xi - \bar{\xi}_i(\tau), \eta - \tau) + \bar{G}(\xi - \bar{\xi}_i(\tau), \eta + \tau) \} d\tau, \quad (9)$$

and the total interference upwash is

$$\frac{w}{V} = \frac{w_I + iw_{II}}{V}. \quad (10)$$

The assumption that the vorticity may be regarded as concentrated on the curves  $\xi = \bar{\xi}_r(\eta)$  and  $\xi = \bar{\xi}_i(\eta)$  may be a cause of significant error for wings of large streamwise extent. In order to obtain a more accurate expression consider the velocity potential,  $\phi_a$ , on the upper surface of a symmetrically oscillating wing. Divide the wing by a number of lines,  $y = \text{constant}$ , into a number of streamwise strips. Consider first the symmetrical pair of strips  $-(t + \delta t) < y < -t$  and  $t < y < t + \delta t$ , and assume that  $\delta t$  is sufficiently small for the variation of  $\phi_a$  with  $y$  to be neglected. By symmetry the variation of  $\phi_a$  with  $x$  is the same in each strip.

For an oscillating horse-shoe vortex of span  $2t$  with its finite part on the line  $x = 0$

$$\left. \begin{array}{ll} \text{if } |y| > t, & \phi_a = 0 \\ \text{if } |y| < t, & \phi_a = \frac{1}{2} K e^{i\omega T} \psi_0(x), \end{array} \right\} \quad (11)$$

where

$$\left. \begin{array}{ll} \psi_0(x) = 0 & \text{for } x < 0 \\ \psi_0(x) = \exp \left( \frac{-i\omega x}{V} \right) & \text{for } x > 0 \end{array} \right\}. \quad (12)$$

Now suppose  $\phi_a(x, t)$  can be expressed as the weighted sum of the corresponding potentials for a distribution of horse-shoe vortices, so that a function  $\bar{K}$  exists such that

$$\phi_a(x, t) = \int_{-\infty}^{+\infty} \frac{1}{2} \bar{K}(x', t) e^{i\omega T} \psi_0(x - x') dx'. \quad (13)$$

Then, since the interference upwash corresponding to a vortex described by equations (11) and (12) is given by

$$\frac{w}{V} = \frac{\bar{K}}{Vb} e^{i\omega T} \delta \left( \frac{x}{b}, \frac{y}{b}; \frac{t}{b}, \frac{\omega b}{V} \right),$$

(Part I, Section 3) the upwash due to the symmetrical pair of strips is

$$\begin{aligned} \frac{w}{V} &= \int_{-\infty}^{+\infty} \frac{\bar{K}(x', t)}{Vb} e^{i\omega T} \left[ \delta \left( \frac{x - x'}{b}, \frac{y}{b}; \frac{t + \delta t}{b}, \frac{\omega b}{V} \right) - \right. \\ &\quad \left. - \delta \left( \frac{x - x'}{b}, \frac{y}{b}; \frac{t}{b}, \frac{\omega b}{V} \right) \right] dx' \\ &= \int_{-\infty}^{+\infty} \frac{\bar{K}(x', t)}{Vb} e^{i\omega T} \frac{\partial \delta}{\partial t} \left( \frac{x - x'}{b}, \frac{y}{b}; \frac{t}{b}, \frac{\omega b}{V} \right) \delta t dx' \end{aligned}$$

to the first order in  $\delta t$ .

The interference due to the whole wing is then obtained by integrating with respect to  $t$ :

$$\frac{w}{V} = \int_{t=0}^s \int_{-\infty}^{+\infty} \frac{\bar{K}(x', t)}{Vb} e^{i\omega T} \frac{\partial \delta}{\partial t} \left( \frac{x - x'}{b}, \frac{y}{b}; \frac{t}{b}, \frac{\omega b}{V} \right) dx' dt. \quad (14)$$

It remains to determine  $\bar{K}$  to satisfy equation (13). Since  $\psi_0(x - x') \equiv 0$  for  $x' > x$ , the upper limit may be replaced by  $x$ . Then (13) becomes

$$\phi_a(x, t) = \int_{-\infty}^x \frac{1}{2} \bar{K}(x', t) e^{i\omega T} \exp \left( \frac{i\omega(x' - x)}{V} \right) dx'.$$

By differentiation

$$\frac{1}{2} \bar{K}(x, t) e^{i\omega T} = \frac{\partial \phi_a}{\partial x} + \frac{i\omega}{V} \phi_a$$

and hence by equation (1)  $\bar{K} = \frac{1}{2} V l(x, t) e^{-i\omega T}$ .

Substitution in (14) gives

$$\begin{aligned} \frac{w}{V} &= \int_{t=0}^s \int_{x_l}^{x_t} \frac{l(x', t)}{2b} \frac{\partial \delta}{\partial t} \left( \frac{x - x'}{b}, \frac{y}{b}; \frac{t}{b}, \frac{\omega b}{V} \right) dx' dt \\ &= \int_{\tau=0}^{\sigma} \int_{\xi_l}^{\xi_t} \frac{1}{2} l(\xi', \tau) \{ \bar{G}(\xi - \bar{\xi}_r(\tau), \eta - \tau) + \bar{G}(\xi - \bar{\xi}_i(\tau), \eta + \tau) \} d\xi' d\tau \end{aligned} \quad (15)$$

by (6).

Evidently an alternative approximation to (8) and (9) would be to replace  $\Gamma_r/Vb$  and  $\Gamma_i/Vb$  by  $\frac{1}{2} l_r$  and  $\frac{1}{2} l_i$  respectively and to use mean values  $\bar{\xi}' = \bar{\xi}_r(\tau)$  and  $\xi' = \bar{\xi}_i(\tau)$  in the functions  $\bar{G}$ :

$$\frac{w_I}{V} = \int_{\tau=0}^{\sigma} \left\{ \int_{\xi_l}^{\xi_t} \frac{1}{2} l_r(\xi', \tau) d\xi' \right\} \{ \bar{G}(\xi - \bar{\xi}_r(\tau), \eta + \tau) + \bar{G}(\xi - \bar{\xi}_r(\tau), \eta - \tau) \} d\tau \quad (16)$$

and

$$\frac{w_{II}}{V} = \int_{\tau=0}^{\sigma} \left\{ \int_{\xi_l}^{\xi_t} \frac{1}{2} l_i(\xi', \tau) d\xi' \right\} \{ \bar{G}(\xi - \bar{\xi}_i(\tau), \eta + \tau) + \bar{G}(\xi - \bar{\xi}_i(\tau), \eta - \tau) \} d\tau. \quad (17)$$

The relative merits of the approximations in (8) and (9) as compared with those in (16) and (17) could only be assessed by evaluating (15) in representative cases. In the present calculations (8) and

(9) were mostly used. In the low-frequency case additional calculations using (16) and (17) gave results which were little different. (See Table 1.) However, such agreement is not to be expected for high frequency; indeed either approximation may then be erroneous.

When the chord is small the two approximations tend to equality. For the limiting case of a horse-shoe vortex of span  $2s$  and strength  $\bar{K}e^{i\omega T}$  on the line  $\xi = 0$ ,  $\bar{\xi}_r \equiv \bar{\xi}_i \equiv 0$ ,  $\Gamma_r = \bar{K}e^{i\omega T}$ ,  $\Gamma_i = 0$ . Hence

$$\frac{w}{b} = \frac{\bar{K}e^{i\omega T}}{Vb} \int_0^\sigma [\bar{G}(\xi, \eta - \tau) + \bar{G}(\xi, \eta + \tau)] d\tau, \quad (18)$$

which may be useful in estimating the order of magnitude of interference effects.

### 3. The Low-frequency Case.

This section describes the calculation of the tunnel interference for the cropped delta wing shown in Fig. 1, when it is oscillating at a low frequency in a tunnel of breadth to height ratio 9/7.

It is first necessary to assume some distribution of lift,  $l$ . For the present purpose this was taken to be the free-stream distribution as given by the theory of Ref. 1, which was known from previous calculations. In this method the load distribution is obtained as

$$l = \frac{8se^{i\omega T}}{\pi c(y)} \left\{ \bar{\gamma}(y) \cot \frac{1}{2}\bar{\theta} + 4\bar{\mu}(y) [\cot \frac{1}{2}\bar{\theta} - 2 \sin \bar{\theta}] + \right. \\ \left. + \bar{\kappa}(y) [\cot \frac{1}{2}\bar{\theta} - 2 \sin \bar{\theta} - 2 \sin 2\bar{\theta}] + \dots \right\}, \quad (19)$$

where  $\bar{\theta}$  is the angular chordwise co-ordinate defined by

$$x = x_l(y) + \frac{1}{2}c(y)(1 - \cos \bar{\theta}), \quad (20)$$

and  $\bar{\gamma}(y)$ ,  $\bar{\mu}(y)$ ,  $\bar{\kappa}(y)$ , ... are complex functions known for certain values of  $y$  in the wing span  $-s < y < s$ . Of course  $\bar{\gamma}$ ,  $\bar{\mu}$ ,  $\bar{\kappa}$ , ... are also functions of the frequency parameter  $\nu$  but, provided  $\nu^2 \log \nu$  is small, they may be expressed in the form

$$\begin{aligned} \bar{\gamma} &= \bar{\gamma}_1 + i\nu(\bar{\gamma}_2 + \bar{\gamma}_3) \\ \bar{\mu} &= \bar{\mu}_1 + i\nu(\bar{\mu}_2 + \bar{\mu}_3) \\ \bar{\kappa} &= \bar{\kappa}_1 + i\nu(\bar{\kappa}_2 + \bar{\kappa}_3) \end{aligned} \left. \right\}, \quad (21)$$

where  $\bar{\gamma}_1, \dots, \bar{\kappa}_3$  are all real functions of  $y$ .

The method of calculation adopted below is such that the tunnel-induced lift and pitching moment,  $\Delta C_L$  and  $\Delta C_m$ , are proportional to  $l$ . Together with the mode of application outlined in Part I, leading to  $(\Delta\alpha)_m/C'_L$  and the residual correction to pitching moment, this means that an arbitrary factor in  $l$  is permissible. The shape of the distribution alone is important as the appropriate size is determined by the measured  $C'_L$ .

When equations (21) are substituted into equation (4) and terms of order  $\mu^2$  are neglected it follows that

$$\frac{\Gamma_r}{Vb} = (\Gamma_0 + i\mu\Gamma_1)e^{i\omega T} \quad (22)$$

where

$$\Gamma_0 = 2\sigma\bar{\gamma}_1$$

and

$$\Gamma_1 = -\sigma \frac{c(y)}{b} \left( \frac{3}{2}\bar{\gamma}_1 + 2\bar{\mu}_1 \right). \quad (23)$$

Similarly from equation (5)

$$\frac{\Gamma_i}{Vb} = i\mu \Gamma_2 e^{i\omega T}, \quad (24)$$

where

$$\Gamma_2 = 2\sigma \frac{\bar{c}}{b} (\bar{\gamma}_2 + \bar{\gamma}_3). \quad (25)$$

The centre-of-pressure loci follow by simple integration.

$$\left. \begin{aligned} \bar{\xi}_r(\eta) &= \frac{x_l}{b} + \frac{c(\eta)}{b} \left( \frac{1}{4} - \frac{\mu_1}{\gamma_1} \right) \\ \text{and} \quad \bar{\xi}_i(\eta) &= \frac{x_l}{b} + \frac{c(\eta)}{b} \left( \frac{1}{4} - \frac{\bar{\mu}_2 + \bar{\mu}_3}{\bar{\gamma}_2 + \bar{\gamma}_3} \right) \end{aligned} \right\}, \quad (26)$$

except at kinks in the leading or trailing edges, where these formulae have to be modified as described in Ref. 1.

When  $\mu^2$  is negligible, equation (7) becomes

$$\bar{G}(\xi, \lambda) = F_2(\xi, \lambda) - i\mu \int_{-\infty}^{\xi} F_2(\theta, \lambda) d\theta. \quad (27)$$

Equations (22) to (25) and (27) may now be used to reduce (9) and (10) to the forms

$$\begin{aligned} \frac{w_I}{V} &= e^{i\omega T} \int_0^\sigma \Gamma_0 [F_2(\xi - \bar{\xi}_r(\tau), \eta - \tau) + F_2(\xi - \bar{\xi}_r(\tau), \eta + \tau)] d\tau + \\ &\quad + i\mu e^{i\omega T} \int_0^\sigma \{ \Gamma_1 [F_2(\xi - \bar{\xi}_r(\tau), \eta - \tau) + F_2(\xi - \bar{\xi}_r(\tau), \eta + \tau)] - \\ &\quad - \Gamma_0 \int_{-\infty}^{\xi - \bar{\xi}_r(\tau)} [F_2(\theta, \eta - \tau) + F_2(\theta, \eta + \tau)] d\theta \} d\tau \end{aligned} \quad (28)$$

and

$$\frac{w_{II}}{V} = \mu e^{i\omega T} \int_0^\sigma \Gamma_2 [F_2(\xi - \bar{\xi}_i(\tau), \eta - \tau) + F_2(\xi - \bar{\xi}_i(\tau), \eta + \tau)] d\tau. \quad (29)$$

The function  $F_2(\xi, \lambda)$  was computed in the Mathematics Division, N.P.L. for the case  $b/h = 9/7$  over the ranges  $-1.6 \leq \xi \leq 1.6$ ,  $-0.9 \leq \lambda \leq 0.9$ .  $F_2 \rightarrow 0$  as  $\xi \rightarrow -\infty$ , and a fairly simple asymptotic expression exists for  $\xi < 1.6$ . The integration to obtain  $\int_{-\infty}^{\xi} F_2(\theta, \lambda) d\theta$  can be carried out quite easily by numerical methods. Thus the interference upwash due to any given lift distribution can be computed at any designated points,  $(\xi, \eta)$ .

In the example considered the interference forces were calculated by the vortex-lattice theory<sup>2</sup> with 6 collocation points. The interference upwashes were therefore calculated by the method outlined above for the collocation points indicated in Fig. 1. Three sizes of wing were considered,  $\sigma = 0.125, 0.250, 0.375$ , for two modes of oscillation,

- (i) pitching about an axis through the apex of the wing,
- (ii) oscillation of a full-span control.

Interference forces and moments  $\Delta C_L$  and  $\Delta C_m$  were evaluated by the procedure of Ref. 2, and are given in Tables 1 and 2.

Using the alternative formulae (16) and (17) is equivalent to putting  $\Gamma_1 = 0$ , so that the calculation is now slightly simpler. Values of the interference forces and moments thus computed are given in Tables 1 and 2. The difference in the out-of-phase parts is small except for  $\sigma = 0.375$ , which represents a model larger than would normally be used. Probably for low frequencies it matters little which is used.

In order to facilitate comparison between Tables 1 and 2 they contain also the interference forces divided by the corresponding lift coefficients. The difference between corresponding values in Tables 1 and 2 is now due entirely to the shape of the lift distribution.

Table 3a gives values of the corrected mean incidence  $(\Delta\alpha)_m$  and the residual correction to measured pitching moment, as defined by equations (37) and (38) of Part I. The lower half of Table 3a was calculated by taking  $C'_L$  to be the theoretical free-stream value. The corrected value of the incidence,  $\alpha + (\Delta\alpha)_m$ , shows such a rapid increase with  $\sigma$ , that a model of the size  $\sigma = 0.375$  could be rather too large for an accurate experiment. The residual corrections to pitching moment are much smaller.

#### 4. Calculations for Finite Frequency.

When the frequency is not small the calculations are more complicated, although there is no difference in principle. In this section an application to the same delta wing in the same tunnel is described. The frequency was taken to be  $\mu = 1.6$ , which implies that  $\nu = \omega c/V = 4/9$ . The oscillations treated were rigid pitching and vertical heaving.

As in the low-frequency case it was assumed that the lift distribution,  $l$ , had its theoretical free-stream value. In order to carry through the calculation it was therefore necessary to have available a lifting-surface theory applicable for  $\nu = 4/9$ . In the present case the vortex-lattice method of Ref. 3 was used with the same 6 collocation points (Fig. 1). If the upwash is assigned at each of these points then the corresponding lift distribution may be calculated in the form

$$l(x, y) = 2e^{i\omega T} \frac{s}{c} \left[ 2 \cot \frac{1}{2}\bar{\theta} \left( C_{01} + C_{03} \frac{y^2}{s^2} + C_{05} \frac{y^4}{s^4} \right) \sqrt{1 - \frac{y^2}{s^2}} + \left( \cot \frac{1}{2}\bar{\theta} - 2 \sin \bar{\theta} + \frac{i\omega c}{2V} \{ \sin \bar{\theta} + \frac{1}{2} \sin 2\bar{\theta} \} \right) \left( C_{11} + C_{13} \frac{y^2}{s^2} + C_{15} \frac{y^4}{s^4} \right) \right] \quad (30)$$

where  $C_{01}, \dots, C_{15}$  are complex numbers. The circulation and centre-of-pressure distributions may be calculated by simple integration if it is remembered that (Ref. 4, p. 21)

$$\int_0^\pi \exp \left( -\frac{i\omega c}{2V} \cos \bar{\theta} \right) \cot \frac{1}{2}\bar{\theta} \sin \bar{\theta} d\bar{\theta} = \pi J_0 \left( \frac{\omega c}{2V} \right) - i\pi J_1 \left( \frac{\omega c}{2V} \right)$$

and that there are similar expressions for the other integrals.

$F_2(\xi, \lambda)$  had already been calculated in connection with the low-frequency case, and the evaluation of  $\bar{G}(\xi, \lambda)$  as given by equation (7) involved mostly straightforward numerical integration. The ranges  $\xi = -0.8(0.1)0.8$  and  $\lambda = 0(0.025)0.45$ , were sufficient for the present example.

The interference upwashes were then obtained from equations (8), (9) and (10) and the interference forces calculated. The values thus obtained are given in Table 4 together with the corresponding low-frequency values. The frequency effect is seen to be quite large especially for heaving motion. Table 4 also gives the corrections for pitching about any axis, obtained by taking a suitable linear combination of heaving and pitching about the apex.

Table 3b contains values of  $(\Delta\alpha)_m/C'_L$ ,  $(\Delta\alpha)_m/\alpha$  and residual corrections to pitching moment for  $\mu = 1.6$ . The frequency effect is greater on  $(\Delta\alpha)_m/C'_L$  than on  $(\Delta\alpha)_m/\alpha$  and this in turn is greater than that on  $\partial(\Delta C_L)/\partial\alpha$  and  $\partial(\Delta C_m)/\partial\alpha$ . This indicates that it may be possible to use low-frequency  $\Delta C_L$  and  $\Delta C_m$  with finite-frequency  $\partial C_L/\partial\alpha$ ,  $\partial C_m/\partial\alpha$  and extend somewhat the range of frequency for which the low-frequency tunnel-interference forces are useful.

A possible complication in such calculations is that at certain sections of the wing the real or imaginary part of the local lift may vanish. In such a case  $\bar{\xi}_r$  (or  $\bar{\xi}_i$ ) has an infinite discontinuity of the form

$$\bar{\xi}_r = \frac{\text{Constant}}{\eta - \eta_0} + \text{continuous function},$$

when the lift vanishes at  $\eta = \eta_0$ . Since  $\bar{G}$  remains finite for  $\xi \rightarrow +\infty$  or  $\xi \rightarrow -\infty$  the integral remains convergent, but the calculation is much simplified if the curve of  $\xi = \bar{\xi}(\eta)$  is faired to be smooth at  $\eta = \eta_0$ . This can probably be done without seriously affecting the accuracy.

### 5. Discussion.

The calculations required by the method of this report are of unusual length for tunnel-interference work. First it is necessary to use a lifting-surface theory covering the frequency range required; the computation for this is likely to be fairly lengthy whichever of the available methods is used. However, such calculations are often carried out on digital computers in connection with tunnel tests.

The tabulation of  $F_2(\xi, \lambda)$  is also lengthy but need only be carried out once for each shape of tunnel, while  $\bar{G}$  need only be calculated once for each tunnel and each frequency parameter. If such tables are available, the low-frequency case, which should be adequate for many experiments, does not involve undue labour, but the work necessary for the higher frequencies is considerably more and some simplification is desirable. Tables such as Table 2 of Part I may help here, especially in estimating the order of magnitude of corrections.

The choice of evaluating the interference upwash from a concentrated circulation as in equations (8) and (9) or the lift distribution as in equations (16) and (17) appears to have little effect on the results provided  $\mu$  is small. The difference between upwashes calculated by the two methods is  $O(\mu)$  and hence may be significant. Probably equations (16) and (17) are preferable in such cases but only a check against the complete formula (15) could settle this.

### 6. Acknowledgements.

The calculations leading to Tables 1 to 4 were carried out by Miss B. Burnham and Miss S. W. Skan.

## LIST OF SYMBOLS

As for Part I, with the addition of the following:

$A$	Aspect ratio of wing ( $= 2s/c$ )
$c_0$	Root chord of wing
$C_L$	Lift coefficient ( $= \text{lift}/\frac{1}{2}\rho V^2 S$ )
$C_m$	Pitching-moment coefficient ( $= \text{nose-up pitching moment}/\frac{1}{2}\rho V^2 S \bar{c}$ )
$C_{01}, C_{11}$ $C_{03}, C_{13}$ $C_{05}, C_{15}$	Coefficients in a formula for the lift distribution {see equation (30)}
$\bar{G}$	
$\bar{h}$	
$p_\infty$	Pressure at infinity upstream
$w_I, w_{II}$	Parts of the interference upwash due to in- and out-of-phase lift distributions respectively
$z_0$	Amplitude of heaving oscillation (upward displacement $= z_0 e^{i\omega T}$ )
$(\Delta\alpha)_m$	Mean interference upwash
$\bar{\gamma}, \bar{\mu}, \bar{\kappa}$	Coefficients in a formula for the lift distribution {see equation (19)}
$\bar{\gamma}_1, \bar{\mu}_1, \bar{\kappa}_1$ $\bar{\gamma}_2, \bar{\mu}_2, \bar{\kappa}_2$ $\bar{\gamma}_3, \bar{\mu}_3, \bar{\kappa}_3$	Coefficients in a formula for the lift distribution {see equation (21)}
$\bar{\theta}$	
$\nu$	
$\xi_0$	Downward angle of control deflection
$\psi_0(x)$	See equation (13)

### Suffixes

$l$	Value at leading edge of wing
$t$	Value at trailing edge of wing
