FINAL UPPER VAULT WASTE INCINERATION MEMORANDUM

Dear Mr. Dappolone:

In accordance with Work Assignment No. 200-3LC9, the REM III Project Team is pleased to submit 15 copies (14 bound and 1 unbound) of this Final Technical Memorandum for the Whitmoyer Laboratories Site entitled "Arsenic Volatilization, Capture, and Risks Resulting from Incineration of the Upper Vault Waste." This memorandum was prepared per your instruction to develop a realistic estimate of the human health risks resulting from the proposed onsite incineration of the upper vault wastes.

If you have any questions regarding this submittal, please call me; or Mr. John Trepanowski, the Site Manager, at (215) 971-0900.

Very truly yours,

John F Gorgol, P.E.

1.0 INTRODUCTION

1.1 PURPOSE AND SCOPE

NUS Corporation (NUS) under contract to Ebasco Services Incorporated (Ebasco), prepared this Technical Memorandum for the U.S. Environmental Protection Agency (EPA), under Work Assignment Number 200-3LC9, Contract Number 68-01-7250. This document was prepared in response to public comments received on EPA's Whitmoyer Laboratories Site preferred alternative for remediation of the upper vault waste as presented in the Proposed Plan for Operable Unit Two (EPA, 1990). The preferred alternative includes onsite incineration of the upper vault waste, followed by fixation and offsite landfilling of the incineration residuals (see Figure 1-1).

The comments received on the alternative dealt with concerns of significant arsenic volatilization from the waste and inadequate capture of the arsenic in the air pollution control (APC) devices. Under this scenario, potentially significant risk to human health and the environment may result. The modeling approach for incinerator emissions was also questioned. Each of these issues will be evaluated in further detail in this report.

1.2 PREVIOUS ARSENIC VOLATILIZATION/RISK ESTIMATES

The Proposed Plan (EPA, 1990) and Feasibility Study (FS) report (Ebasco, 1990) addressing the upper vault wastes provided estimates for volatilization of arsenic based on treatability testing conducted on the lower vault wastes. The volatilization of arsenic, in the presence of cement and/or lime at the temperatures considered, was observed to range from less than 1 percent to about 9.3 percent. Five percent was selected as a representative average. The APC train was not identified in detail in these documents. Potentially applicable devices cited included a baghouse, high efficiency particulate air (HEPA) filter, forced flux condenser, electrostatic precipitator, and a packed tower absorber. Estimated removal efficiencies for the volatilized arsenic using this equipment ranged from about 86 percent to about 99.6 percent. The Industrial Service Complex Short Term (ISCST) air quality model was then used to model the dispersion of the stack gases under these two removal efficiency scenarios. Both inhalation and deposition of arsenic were considered. Based on the model output, a risk assessment calculation was performed. The risk estimates ranged from about 2×10^{-4} excess lifetime cancer risk (ELCR) for the 86 percent removal scenario and 1×10^{-5} ELCR for the 99.6 percent removal. A risk range of 1×10^{-4} ELCR to 1×10^{-6} ELCR is considered acceptable for Superfund cleanups (40 CFR Part 300).

1.3 REPORT ORGANIZATION

This technical memorandum is comprised of five sections and supporting appendices. The organization and content are as follows:

- Section 1.0 summarizes the scope and previous arsenic volatilization, capture, and risk estimates.
- Section 2.0 summarizes the properties and assumptions for characterizing the upper vault waste. Additional details are presented for the incineration and fixation of the arsenic and destruction of the organics.
- Section 3.0 presents common APC equipment and demonstrated arsenic removal efficiencies.
- Section 4.0 presents arsenic emissions dispersion modeling, using the APC removal efficiencies presented in Section 3.0.
- Section 5.0 presents the risk assessment for the proposed incineration of the upper vault waste, based on the dispersion modeling. Both the inhalation and soil ingestion pathways are evaluated.

2.0 ARSENIC VOLATILIZATION DURING INCINERATION

2.1 CHARACTERIZATION AND ASSUMPTIONS

The upper vault waste is believed to consist of about 3000 CY of a mixture of drummed and undrummed aniline still bottoms, spent activated carbon used for decolorization, diaminodiphenyl arsonic acid contaminated soils, and miscellaneous laboratory wastes. A summary of available analytical data is presented in Table 2-1. The Whitmoyer Laboratories Site RI report (Ebasco, 1989) presents the full range of available data.

In order to proceed with the evaluation of thermally treating the wastes, several assumptions were developed. These assumptions and other characterization parameters are presented in Table 2-2 and discussed below. The volume estimate is based on the dimensions of the vault. As a result, this estimate should be fairly accurate. The density value is based on density measurements of the lower vault waste. For the upper vault waste this value may be considered high, because of anticipated voids in the bulk waste and the lower density of aniline tars and carbon. The arsenic concentration was selected as a mid-range of measured values. The nitrogen-based organics value is based on the aniline and n-nitrosodiphenylamine concentrations measured in a sample of the still bottoms material. The total organic and moisture values are assumed mid-range values. Actual values may be higher or lower. The inerts are assumed to be the balance of material in the upper vault. The BTU value is based on a typical heat of combustion for organics, assuming the material is 50 percent organic. The RCRA classifications are based on wastes reportedly disposed in the vault and analytical testing.

2.2 THERMAL AND CHEMICAL FIXATION OF ARSENIC

No direct treatability study results are available for the upper vault waste. As a result, fixation treatability results from a study conducted on the lower vault wastes (Ebasco, 1990) are used herein. The sample evaluated for the lower vault treatability study likely contained a portion of the upper vault organics, as an oil-like liquid (potentially aniline still bottoms) was observed on the surface of the sample. This oil layer was mixed into the sludge prior to conducting the treatability study. The detailed results of this study are presented in the FS report (Ebasco, 1990).

A comparison of the major characteristics of the upper vault wastes with the lower vault wastes are summarized as follows:

Parameter	Upper Vault Waste	Lower Vault Waste
Arsenic	12%	16%
Total Organics	50%	4%

TABLE 2-1

ANALYTICAL CHARACTERIZATION OF UPPER VAULT WASTES
WHITMOYER LABORATORIES SITE

TABLE 2-2

TREATABILITY CHARACTERIZATION AND ASSUMPTIONS
FOR THE UPPER VAULT WASTES
WHITMOYER LABORATORIES SITE
LEBANON COUNTY, PENNSYLVANIA

Volume	3,000 CY
Density	120 lb/CF
Arsenic	12%
Nitrogen-based organics	14%
Total organics	50%
Moisture	10%
Inerts (soils, drums, etc.)	28%
BTU content	7,500 BTU/lb
RCRA classifications	K101, K102, D004, D006

In general, the upper vault waste may be considered to contain slightly less arsenic, but significantly more organics than the lower vault waste.

Results from the cement-and/or lime-based fixation of the lower vault are summarized as follows:

Cement and Lime to Sludge Ratio	Roasting Temperature °F	Percent Arsenic Volatilization	TCLP Leachate Results (As mg/L)
0	No roasting	0	2,300
0	1,300	37	1,500
1 (cement only)	1,100	2.7	11
1 (lime only)	1,300	<1	1.6
1.3 (cement/lime)	1,300	3.8	1.8
2 (cement/lime)	1,300	<1	1.3
3 (cement only)	1,300	9.2	1.2

One general conclusion of this study was that the use of cement and/or lime significantly reduced the volatilization of arsenic. The formation of a relatively nonvolatile calcium-arsenic compound is believed to cause this reduced volatility. This formation may occur in the solid waste phase as well as from gas phase adsorption of arsenic onto calcium particles. A second conclusion was that cement and/or lime fixation with a preroasting step resulted in 5 to 360 times less leachable arsenic in the treated waste than cement and/or lime fixation treatment without roasting.

2.3 INCINERATION

Common incinerators are typically based on a two chamber system, the primary chamber and the secondary chamber. The main function of the primary chamber is to volatize organics present in the waste at moderately high temperatures (1100 to 1300°F). For the upper vault waste, this is also the location where the insoluble calcium-arsenic compounds would be formed. In the secondary chamber, the primary chamber offgas temperature is elevated to about 1800°F in the presence of excess oxygen. This would complete the destruction of the toxic organic compounds, with an end product of water, carbon dioxide, and salts. Destruction of in excess of 99.99 percent of the principal organic compounds is commonly achieved in incinerators.

The major constituents anticipated to be found in the upper vault wastes are arsenic compounds, nitrogen-based organics, and other organics. The types of arsenic believed present in the upper vault waste are organic-arsenic compounds and sodium-arsenic compounds. The organic-arsenic compounds would be expected to be more volatile than the inorganic arsenic

compounds. However, some of the inorganic arsenic compounds would also be expected to break down into relatively volatile arsenic trioxide (As_2O_3) as well. Offsetting this volatilization in the primary chamber would be the presence of calcium (from the cement and/or lime), which would have the tendency to form very low volatility arsenic salts. There is also the potential for arsine (AsH_3), a gas at room temperature, to form in the primary chamber.

In the secondary chamber, the organically-bound arsenic and arsine would be converted to As_2O_3. Also, because of turbulence in the primary chamber, dust containing calcium would also be conveyed to the secondary chamber. As a result, gas phase conversion of As_2O_3 to relatively nonvolatile calcium-arsenic compounds would be expected to occur in the secondary chamber. The nitrogen-based organic compounds would be expected to form nitrous oxides (NO, N_2O, NO_2, etc.,) also referred to as NO_x. Also, chlorinated compounds, if present, would form hydrogen chloride (HCl).

The ash from the primary chamber would be allowed to air cool, tested for arsenic leachate concentrations (TCLP) to demonstrate compliance with RCRA land disposal restrictions, hydrated (if necessary), and disposed of offsite in a hazardous waste landfill. Ash handling considerations for the APC devices are discussed in Section 3.1.3.

3.0 AIR POLLUTION CONTROL DEVICES

3.1 DESCRIPTION

Two general types of air pollution control (APC) devices considered are dry and wet systems. Dry systems operate in the absence of liquid water and wet systems operate in the presence of liquid water.

3.1.1 Dry Systems

Dry systems are used primarily for particulate removal, although some removal of vapor phase constituents may occur because of adsorption onto particles. During incineration of the upper vault waste, dry systems could be used for removal of particulate carryover from the incinerator and condensed arsenic. Three types of dry APC devices discussed here are cyclones, electrostatic precipitators and baghouses. Free moisture in these units can cause significant operating problems. As a result, they are typically operated above the dewpoint of water, with a very dry dust being generated.

Cyclone - A cyclone is generally a medium to low efficiency, low cost dust precleaning device. The dust-laden gases are forced to swirl around inside a cylindrical body. Centrifugal forces cause the particulates to move toward the outer wall. Air exits the cyclone from the inner vortex, while particulates migrate to the bottom of the unit for removal.

Electrostatic Precipitators - Electrostatic precipitators (ESPs) are generally high efficiency particulate removal devices, with removal efficiencies of about 99 percent to 99.8 percent. In ESPs, particulates and gases pass between positively and negatively charged plates and/or electrodes. The naturally (or induced) charged particles migrate to the plates/electrodes where they are collected. A variation of ESPs is wet ESPs, in which water is sprayed into the unit to improve particulate removal.

Baghouse - Baghouses are generally a high efficiency particulate removal device, with removal efficiencies of 99.9 percent to 99.99 percent. In the baghouse, the air passes through a fabric filter. Removal mechanisms include filtering, settling, and electrical attraction. Precoating of the bag typically is required for high percentage particulate removal. For cleaning, generally, the air flow is reversed and/or the bag shaken to dislodge the collected dust. The dust is then removed from the bottom of the bag. A HEPA filter is a variation on baghouses in which a finer cloth is used.

3.1.2 Wet Systems

Wet systems are used for both particulate and vapor phase constituent removal. During incineration of the upper vault waste, wet systems could be used for particulate removal, vapor-

phase arsenic removal, and removal of other gases (e.g., NO_x, HCl). The contaminant removal efficiencies of wet systems can be significantly improved by increasing air-water contact and adding additional units. Theoretically, almost any degree of removal desired can be achieved. Practical limits are based on economics. Wet systems require a treatment system for the liquid blowdown. Three types of wet systems considered are venturi scrubbers, spray scrubbers, and packed tower scrubbers. Wet ESPs are discussed briefly in Section 3.1.1.

Venturi - The general concept of venturi scrubbers is to contact the air stream with a liquid (generally water) through converging and diverging sections. The particulates become slurried by impacting the liquid. Gases are removed by absorption.

Spray Scrubbers - Spray scrubbers utilize nozzles to inject a water mist into the gas stream. The water is collected at the bottom of the chamber and demister, and recycled and/or discharged for subsequent treatment.

Packed Towers - Packed towers utilize packing supported in a column to achieve good air-to-water contact. Water is distributed over the packing and flows down through it. The air stream typically is introduced near the bottom of the packing and flows upward. Particulate removal efficiencies for packed towers are typically not as good as for other APC devices. Additionally, high particulate loadings can result in plugging problems. However, gas phase constituent removal can typically be achieved more cost effectively than with the other wet scrubbers.

3.1.3 Ash and Sludge Considerations

Each of the APC devices would generate either an ash or a wet sludge. The solids in this material would be expected to contain arsenic trioxide, calcium-arsenic compounds, lime and/or cement, and other dusts generated from the incineration process. Based on the process used, the presence (or absence) of calcium and the temperature history, these solids may or may not leach arsenic above RCRA Land Disposal Restriction (LDR) standards. If the leachate concentrations are at an acceptable level, the solids may be directly landfilled with the incinerator primary chamber ash. Otherwise, the solids may be introduced back into the primary chamber with the untreated waste for subsequent fixation, or treated with the lower vault waste using chemical fixation alone.

3.2 DEMONSTRATED ARSENIC REMOVAL IN APC DEVICES

3.2.1 Wet ESP and Hydrosonic Scrubber

In 1989, tests were conducted at a pilot-scale incineration test facility to evaluate the APC performance of a two-stage ESP and Hydro-sonic wet scrubber on particulate, metals and HCl

emissions (Radian, 1989). Fly ash, aluminum sulfate, carbon tetrachloride, and monosodium methylarsonic acid (an organic-arsenic compound) were fed to the incinerator fired at 1600°F. Offgas temperatures were quenched to about 180°F prior to the APC devices. The removal efficiencies of these units are summarized below.

Parameter	Influent Concentration (PPM-wt)	WET ESP Percent Removal	Hydro-sonic Scrubber Percent Removal
Particulates	3,800 19,000	99.2% 99.8%	99.6% 99.8%
Arsenic (MSMA)	15	99.94%	99.84%

The temperatures in these units varied from about 145°F for the ESP to 175°F for the Hydro-sonic scrubber. An evaluation of vapor-phase arsenic, similar to that presented in the FS, indicates that a calculated saturated vapor pressure of arsenic at 160°F is about 22 PPM-wt. (i.e., at 15 PPM, the arsenic should be all vapor phase). Therefore, these results indicate that either vapor phase arsenic is being removed at these levels, or particle adsorption followed by particle removal is resulting in this reduction. In either case, there should be similar dust (with high calcium) levels under the proposed system and similar removals should be achievable if these units are employed.

3.2.2 Chemical Waste Management - Fixed Based Units

Chemical Waste Management owns and operates fixed-base incinerators at Port Arthur, Texas, and Sauget, Illinois. Arsenic removal data collected during the trial burns (Valenti, 1990) on these units are summarized as follows:

Location	APC Devices	Arsenic Removal
Port Arthur	4 stage wet electro-static precipitator	99.9%
Sauget	Spray dryer, baghouse	99.6%

3.2.3 Ogden Environmental - Mobile Unit

Ogden Environmental Services, Inc. owns and operates fixed-base and transportable fluidized bed incinerators. Based on conversations with Ogden personnel concerning this waste (Sexton, 1990), Ogden would expect to achieve the RCRA particulate standard of 0.08 grams/DSCF using a venturi scrubber/packed tower APC device. Based on calculations presented in Appendix 1, approximately 86 percent of the arsenic would be removed in this stage. A second stage Wet ESP would

then remove an additional 95 percent of the arsenic. The calculated combined arsenic removal would be 99.3 percent.

3.2.4 Weston - Mobile Unit

Weston Services, Inc. owns and operates transportable incinerators. Arsenic removal efficiencies across the APC devices were measured to exceed 98.8 percent during trial burns (Cosmos, 1990). The waste stream tested was relatively low in arsenic; no arsenic was detected in the treated offgas.

3.2.5 Copper Smelting

An evaluation of APC devices for capture of arsenic from copper smelters was conducted by the EPA in 1982 (EPA, 1983). The results of this evaluation are summarized as follows:

APC	Arsenic			
	Influent Concentration (PPM-Wt)	Effluent Concentration (PPM-Wt)	Percent Removal	Temperature °F
Baghouse (1) (2)	240 2,400	0.8 49	99.7% 95.7%	187 169
Spray chamber/ baghouse	740	8	98.9%	214
Electrostatic precipitator	Not measured	19	--	207
Spray chamber/ESP	260	5	98.1%	219
Venturi scrubber	22	0.3	98.4%	102
ESP/venturi scrubber/ packed bed scrubber	813	1.25	99.8%	153

3.2.6 Summary

Based on the demonstrated arsenic removal efficiencies presented above, existing APC devices (namely a wet ESP in combination with other APC) should be able to remove about 99.3 percent of the arsenic volatilized. Also, if required, additional arsenic removal could likely be achieved by including additional APC devices. The estimated arsenic emission rate is 400 pounds total over 90 days of remediation (0.028 g/sec.). This corresponds to 0.037 g/sec. of arsenic trioxide. Wet scrubbers should also be able to achieve 99 percent removal of acid gases such as NO_x and HCl.

4.0 AIR QUALITY AND DRY DEPOSITION MODELING

4.1 METHODOLOGY

The purpose of this modeling effort was to estimate the maximum annual quarterly and 1-hour ambient concentrations for arsenic trioxide and nitrogen oxide, and also the maximum annual and 1-hour dry deposition rate for arsenic trioxide as particulate matter, given the APC removal efficiencies presented in Section 3.0. Modeling methodology was based on two possible size distributions for the arsenic trioxide emissions as particulate matter. The lower bound size distribution was based on a mean particle diameter of 0.5 microns, while the upper bound size distribution was based on a mean diameter of 2.0 microns. Operating parameters for each scenario are given below:

Flow Rate = 7,520 scfm (3.55 m^3/sec.)
Stack Diameter = 1.2 meters
Stack Temperature = 344.3° K
Stack Height = 65 meters (maximum GEP)
Base Elevation = 146.3 meters

Pollutant Emission Rates:
Arsenic Trioxide = 0.037 g/sec.
Nitrogen Oxide = 0.367 g/sec.

The emission rate for arsenic trioxide was based on an estimated operating period of 1,800 hours per quarter and a total of 400 pounds of arsenic per quarter.

The emission rate for nitrogen oxide was based on an in-stack concentration of 39 ppm by volume, based on a 99 percent APC removal efficiency.

4.2 MODEL SELECTION

The Industrial Source Complex Short Term (ISCST) air quality model was used to calculate ambient concentrations and dry deposition rates.

The ISCST dispersion model combines various algorithms that can be used to assess the air quality impact from a wide variety of sources in flat or rolling terrain. ISCST is an EPA-approved model that can be used to estimate ambient concentrations and dry deposition rates in rural and urban environments. In this exercise the ISCST model is run in the rural mode based on an evaluation of USGS topographic maps depicting the land use characteristics within 3 km of the Whitmoyer Site. Annual quarterly average concentrations and dry deposition rates were determined on the basis that the incinerator operated no more than one seasonal period per year. Maximum concentrations and dry deposition rates were determined for each seasonal period of each annual meteorological period.

4.3 MODEL OPTIONS

The ISCST model contains a number of options that are designed to consider complicated source configurations, emission characteristics and special atmospheric effects. In this study the regulatory default option was selected. This option automatically selects stack tip downwash, final plume rise, buoyancy induced dispersion, the vertical potential temperature gradient and default wind profile exponents.

4.4 SOURCE EMISSIONS

Emissions parameters for this study were based on the operating conditions described previously above. All source emissions were assumed to be emitted over the period of approximately 1,800 hours/season. Separate ISCST model runs were made for each season to determine the maximum "worst case" quarterly and 1-hour impact during the year.

The ISCST model requires information on the particle size distribution of the source emissions in order to calculate gravitational settling and dry deposition. For the purpose of this study the following assumptions were made regarding the arsenic trioxide emissions from the incinerator.

- Two mean particle diameters of 0.5 microns (lower bound) and 2.0 microns, (upper bound) as described above.
- Gravitational settling velocities of 0.000027 meters/sec. for the 0.5 micron particles and 0.00044 meters/sec. for the 2.0 micron particles. These settling velocities were based on a 3.7 gram/cm^3 density for arsenic trioxide.
- Reflection coefficients of 0.99 for the 0.5 micron particles and 0.92 for the 2.0 micron particles.

Due to the uncertainty of the particle size distribution of the arsenic trioxide emissions, a lower bound and a upper bound mean particle diameter was selected to bracket the potential impacts of each operating scenario. The selected mean particle diameters were based on available information regarding control technology collection efficiency. The gravitational settling velocity and reflection coefficient for each particle diameter was based on guidance provided in the ISCST User's Guide, (EPA, 1987).

4.5 METEOROLOGICAL DATA

The meteorological database chosen for this study consisted of five years (1984 through 1988) of hourly surface data from the Harrisburg, Pennsylvania National Weather Service Reporting Station. Corresponding upper air data used to calculate mixing heights during the same time period was obtained from the Sterling, Virginia upper air station. These two databases were

preprocessed through the RAMMET program to create the necessary input file for ISCST.

Quarterly meteorological periods were selected for each model run by using the IDAY parameter in the ISCST input file. The quarterly periods corresponded to the normal 4 annual seasons; winter, spring, summer and fall.

4.6 RECEPTOR NETWORK

Initial model calculations of ambient concentrations and dry deposition rates were based on a 250 meter Cartesian grid interval extending out 2.5 km from the incinerator stack. This initial modeling run was used to identify potential hot spot zones for both contaminants.

All hot spot zones identified in the initial modeling runs were then analyzed further using a 50 meter Cartesian grid interval to identify the maximum quarterly hand and 1-hour ambient concentrations and dry deposition rate for arsenic trioxide.

Receptor elevations were taken from the USGS Richland and Bethel quadrangles. All receptor elevations within the 2.5 km grid were well below the stack top elevation of 693 feet.

4.7 MODELING RESULTS

ISCST modeling results for maximum ambient arsenic trioxide and nitrogen oxide concentrations and maximum arsenic trioxide deposition rates are given in Tables 4-1 and 4-2, respectively. Results are given for maximum annual quarterly and 1-hour time periods. In addition, results for arsenic trioxide include impacts based on lower bound and upper bound mean particle diameters of 0.5 and 2.0 microns. Concentrations are reported as $\mu g/m^3$, whereas deposition rates are given as $grams/m^2$. Computer printouts of the ISCST model results presented in Tables 4-1 and 4-2 are contained in Appendix 2 of this report.

The maximum quarterly concentration of arsenic trioxide was 0.0174 $\mu g/m^3$ for the lower bound case at receptor location x = 1,150 m, y = -750 m in the second quarter of 1984. The maximum hourly arsenic trioxide concentration was calculated to be 0.511 $\mu g/m^3$ for the lower bound case in the fourth quarter of 1984. The hourly maximum occurred at receptor location x = -250 m, y = -800 m on day 283, hour 17.

Maximum quarterly and hourly concentrations of nitrogen oxide were calculated to be 0.1742 and 5.10 $\mu g/m^3$, respectively, as receptor locations x = 1,150 m, y = -750 m and x = -250 m, y = -800 m. The maximum quarterly concentration occurred in the second quarter of 1984. The hourly maximum concentration of nitrogen oxide occurred on day 283, hour 17 in the fourth quarter of 1984.

MAXIMUM ARSENIC TRIOXIDE DEPOSITION RATES FOR THE WHITMOYER INCINERATION UNIT

1	QUARTERLY *Maximum Lower Bound Concentration: 0.0001 grams/m^2 Receptor Location: x = 300 m, y = -450 m Meteorological Period: 3rd Quarter, 1987 *Maximum Upper Bound Deposition: 0.0012 grams/m^2 Receptor Location — Meteorological Period x = 400 m, y = -300 m — 2nd Quarter, 1984 x = 350 m, y = -250 m — 3rd Quarter, 1984 x = 300 m, y = -450 m — 3rd Quarter, 1987
2	HOURLY *Maximum Lower Bound Deposition: 3.2 x 10^{-6} grams/m^2 Receptor Location: x = 100 m, y = -600 m Meteorological Period: 4th Quarter, 1987 Day 304, Hour 15 *Maximum Upper Bound Deposition: 0.00006 grams/m^2 Receptor Location — Meteorological Period x = -100 m, y = -300 m — 2nd Quarter, 1984, 1988 x = 100 m, y = 250 m — 3rd Quarter, 1984 x = -50 m, y = -300 m — 2nd Quarter, 1985, 1987 3rd Quarter, 1985, 1988 x = -150 m, y = -250 m — 2nd Quarter, 1986 3rd Quarter, 1987

Arsenic trioxide deposition rates given in Table 4-2 indicate that the maximum quarterly deposition rate occurred with the upper bound mean diameter case. A maximum of 0.0012 grams/m^2 was reported at three different receptor locations for the second quarter in 1984 and the third quarters of 1984 and 1987.

The maximum hourly deposition of arsenic trioxide also occurred for the upper bound mean particle diameter. A maximum of 0.00006 g/m^2 was reported at four different receptor locations. Maximum hourly deposition rates of 0.00006 g/m^2 were generally reported in second and third quarters of each annual meteorological period with the exception of 1986.

5.0 RISK ASSESSMENT

5.1 ARSENIC

The risk assessment assumptions and calculations presented in this report are identical to those used in the Feasibility Study (Ebasco, 1990). In summary, two pathways for contacting the arsenic were developed. The first pathway is direct arsenic inhalation during the 90-day incinerator operating period. The second pathway is arsenic deposition onto the soils and accidental ingestion of these soils over a resident's 70-year lifetime. Arsenic deposition was converted to soil concentrations by assuming that the arsenic is mixed into the top 12 inches of soil and remains there over the 70-year period. For the risk assessment calculations, a resident was assumed to be at the location of the maximum, 90-day average arsenic air concentration or soil deposition. These calculations are presented in Appendix 3.

The results of the risk assessment are summarized as follows:

	Excess Lifetime Cancer Risk	Hazard Quotient
Inhalation	2×10^{-7}	NA*
Soil Ingestion	8×10^{-9}	<0.1

* An arsenic reference dose is not available for the inhalation route.

For Superfund sites, a maximum acceptable excess lifetime cancer risk is considered to range from 1×10^{-6} to 1×10^{-4} and a maximum acceptable hazard quotient is considered to be 1.0. Therefore, the estimates indicate that significant risk to human health and the environment should not result from arsenic emissions during the onsite incineration of the upper vault wastes. In addition, the arsenic emission rate to the atmosphere can be increased by a factor of 5 to 500 without resulting in unacceptable risks.

5.2 NO_x

The dispersion modeling for NO_x predicted a quarterly maximum average NO_x concentration of 0.17 $\mu g/m^3$ and a hourly maximum concentration of 5.1 $\mu g/m^3$. Both of the predicted concentrations are significantly less than the annual average standard for NO_x of 100 $\mu g/m^3$ under the Clean Air Act - National Ambient Air Quality Standards.

APPENDIX 1

ARSENIC VOLATILIZATION CALCULATIONS

NUS CORPORATION AND SUBSIDIARIES — **STANDARD CALCULATION SHEET**

CLIENT: EPA	FILE NO.: 1817	BY: DJB	PAGE 1 OF 5
SUBJECT: On-site Incineration - Whitmoyer Laboratories Site - Lebanon County, Pa		CHECKED BY: GJR	DATE: 7/11/90

Upper vault Characteristics

Volume 3,000 CY (4,800 tons)

Mix mix 3000 CY cement to minimize Arsenic volatilization & stabilize ash

Total 6000 CY (9,600 tons)

Properties of Mix

As : ~ 6%
Ash : 5%
N-N. bis(2-phenylamine) : 2.3%
Carbon & other Organics : 18%
BTU : 3,500 BTU/lb
H_2O : 5%

Requirements

Primary Chamber - Ash Fixation
Temperature : 1100 to 1300°F
Residence time (min) : ½ to 1 hr.

Air pollution Controls
As : discharge ~ 400-1000 lb total
NO_x : ? ~ 99% removal

Comments :
- Under the primary chamber conditions about 5-10% of the arsenic would volatilize
- Secondary Chamber - 99.99% destruction of Organics

NUS CORPORATION AND SUBSIDIARIES			STANDARD CALCULATION SHEET
CLIENT:	FILE NO.: 1717	BY: DJB	PAGE 2 OF 5
SUBJECT:		CHECKED BY: GJR	DATE: 7/11/90

Information Requested

1) Units Available - Operational Status
Capacity - tons/hr & mm BTU/hr

2) Air pollution controls - Net Indiv.
Efficiency for
Particulates - RCRA Standards
Arsenic - 98.3 to 99.3 %, total volatized
NO_x - ~ 99%

3) As H_3 formation, Info in secondary chamber, removal in APC devices

4) Budgetary Costs for Treatment
- Exclude Excavation, Shredding, Mixing, wastewater blowdown treatment, disposal.
- Include Breakdown of
  - Mob/demob
  - Trial burn
  - Treatment
  - Specialty APC devices
  - Stack, Standard versus USA

5) Schedule

NUS CORPORATION AND SUBSIDIARIES			STANDARD CALCULATION SHEET
CLIENT: EPA	FILE NO.: 1817	BY: NJB	PAGE 3 OF 5
SUBJECT: Arsenic Volatilization		CHECKED BY: GJR	DATE: 1/21/90

Through put

Incinerators are rated on heat load for high BTU waste.

A typical transportable incinerator is rated at 50 mm BTU/hr

Time Required : $\frac{7{,}500 \text{ BTU/lb} \times 3200 \text{ lb/ft} \times 3000 \text{ CY}}{50 \times 10^6}$

= 1440 hours

or 60 days

Assume a 70% operation

Duration : $\frac{60}{0.7}$ = 86 day

Say 90 days

NUS CORPORATION AND SUBSIDIARIES			STANDARD CALCULATION SHEET
CLIENT: EPA	FILE NO.: 1817	BY: AAB	PAGE 4 OF 5
SUBJECT: Arsenic Volatilization & Cap.		CHECKED BY: GSR	DATE: 8/21/90

Arsenic Volatilization

1) Assume 5% volatilized

% Vol.

$3000\ CY \times 3200\ \frac{lb}{CY} \times 0.12\ \frac{lb\text{-}As}{lb\text{-}unit} \times 0.05$

= 58,000 lb As Volatilized.

Demonstrated Arsenic removal efficiencies, ranges from 98.4% to 99.94%

Use 99.3%

Calculated Emissions

58,000 x (1 - 0.993) = 410 lbs

Say 400 lbs

2 - If arsenic volatilization increases to say 50%,

Use additional or better APCs, with 99.94% removal

580,000 lb As Volatilized

580,000 (1 - 0.9994) = 348 lbs

Say 400 lbs

NUS CORPORATION AND SUBSIDIARIES — STANDARD CALCULATION SHEET

CLIENT: EPA	FILE NO.: 1817	BY: JJB	PAGE 5 OF 5
SUBJECT: Arsenic Volatilization		CHECKED BY: GJR	DATE: 8/21/90

Arsenic Baghouse Removal - Ogden

Ogden states ability to achieve particulate standard of 0.08 grains/dscfm

$= \frac{0.08\ gr}{dscf} \times \frac{lb}{7000\ gr} \times \frac{dscf}{0.075\ lb} = 150\ ppm$

Particulate Arsenic if all gas is about

$(360 - 140) \times \frac{198}{150} = 550$ ppm-wt as As_2O_3

3% volatile & 34,300 lb gas / CY waste

↑ V.P. at 2400°F

Assume total particulate is 50% As_2O_3

$\Rightarrow 550 \times 2 = 1100$

Particulate removal efficiency

$\frac{1100 - 150}{1100} = 86\%$

NUS 186A REVISED 03/85

AR303993

APPENDIX 2

AIR QUALITY AND DRY DEPOSITION MODELING

APPENDIX 2
EMISSION RATE ADJUSTMENT MEMORANDUM

The ISCST model output files contained in Appendix 2 have been based on an emission rate of 0.0083 g/sec or 90 pounds/quarter. The actual emission rate for arsenic trioxide as arsenic will be 0.037 g/sec or 528 pounds/quarter. Modeling results reported in Section 4.7 of this report have been adjusted by a factor of 5.86 which is the ratio of 400 pounds/90 pounds and the conversion of arsenic trioxide to arsenic. This adjustment procedure is valid because the emission rate term Q in the ISCST model concentration and deposition equations is based on a linear relationship. These equations are given in Section 2.4 and Section 2.4.3.2 of the ISC User's Guide, Second Edition (Revised), Volume I.

APPENDIX 3

RISK ASSESSMENT CALCULATIONS

NUS CORPORATION AND SUBSIDIARIES — STANDARD CALCULATION SHEET

CLIENT: EPA	FILE NO.: 1817	BY: JJL	PAGE 1 OF 4
SUBJECT: Risk assessment Arsenic Ingestion & Inhalation		CHECKED BY: JAB	DATE: 6/24/90

Revised 9/25/90

Inhalation

1. Assumptions: CPF_{Inh} for Arsenic = 50 (mg/kg-day)$^{-1}$ ✓
   Inhalation Rate: 20 m^3/day ✓
   Duration (Inhalation): 70 days ✓
   Body Wt: 70 Kg ✓
   RFD_{Inh}: 0.001 ✓
   Absorption Factor: 0.3

2. Carcinogenic Risks (Excess lifetime cancer risk)
   = CPF x dose = 1×10^{-6} to 1×10^{-4}

$$\text{Dose} = \frac{20\ m^3/day \times [mg/kg] \times 70\ kg \times 0.3 \times 1}{70\ Kg \times 70\ yrs\ (365\ days/yr)}$$

$$= 3 \times 10^{-4}\ [mg/m^3] \checkmark$$

Concentration for 1×10^{-6} ELCR

$$= \frac{1 \times 10^{-6}}{3 \times 10^{-4} \times 50} = 7 \times 10^{-5}\ mg/m^3 \checkmark$$

or 0.07 ug/m^3 ✓

Concentration for 1×10^{-4} ELCR = 7 ug/m^3 ✓

Risk (lower bound) 0.5% prob

$$\frac{3 \times 10^{-4} \times 0.0132\ ug/m^3 \times 50}{1000\ ug/mg}$$

$$= 2 \times 10^{-7} \checkmark$$

AR304169

NUS 168A REVISED 0886

Ingestion

1) Assumptions:

CPF$_{Ing}$: 1.8 [mg/kg-day]$^{-1}$ ✓

Ingestion Rate: 200 mg-soil/day (0-5 yr)

: 100 mg-soil/day (6-70 yr)

Absorption: 100% ✓

Body wt: 13 Kg (0-5 yr) ✓

70 Kg (6-70 yr) ✓

Exposure: 70 yrs for ELCR

: 1 yr for HQ ✓

RFD$_{Ing}$: 0.001 (mg/Kg-day)

2) Carcinogenic Risks (ELCR)

$$Dose = \left([mg/Kg] \times \frac{Kg}{10^3 g} \times \frac{365 days/yr}{365 days/yr} \times \frac{1}{70 yr}\right) \times \left(\frac{0.2 g/day \times 5 yr + 0.1 g/day \times 65 yr}{13 Kg \quad\quad 70 Kg}\right)$$

$$= [mg/Kg] \times 2.4 \times 10^{-6} \checkmark$$

Concentration for 1×10^{-6} ELCR

$$\frac{1 \times 10^{-6}}{2.4 \times 10^{-6} \times 1.8} = 0.23 \text{ mg/Kg} \checkmark$$

Concentration for 1×10^{-4} ELCR = 23 mg/Kg ✓

3) Hazard Quotient (Short Term Risk)

For HQ = 1, use a

$$Dose: \frac{[mg/Kg] \times 0.2 g/day \text{ ingest.}}{13 Kg} \times 10^{-5} [mg/Kg] \checkmark$$

AR304170

So. / Concentration for HQ = 1

$$\frac{0.001}{1.5 \times 10^{-5}} = 65 \text{ mg/kg}$$

4 Risks (upper bound - 2.0 u)

So. / concentration (see sheet 4 for conversion)

$$\frac{0.0009 \text{ g/m}^2 \times 2 \text{ mg/kg}}{1.0 \text{ g/m}^2} = 0.0018 \text{ mg/kg}$$

Carcinogenic Risk

$$\frac{0.0018}{0.23} \times .1 \times 10^{-6} = 8 \times 10^{-9}$$

Hazard Quotient

$$\frac{0.0018}{65} = 3 \times 10^{-5}$$ ✓

Say <0.1 ✓

NUS CORPORATION AND SUBSIDIARIES			STANDARD CALCULATION SHEET
CLIENT: EPA	FILE NO.: 1817	BY: DJB	PAGE 4 OF 4
SUBJECT: Conversion of deposition to soil concentration		CHECKED BY: MRS	DATE: 2/24/90

Assume deposition mixed in soil in the top 12" of soil.

Assume a soil density of 100 lb/CF

For a 1 gram/m² deposition,

$$\frac{1 \text{ gram}}{\text{m}^2} \times \frac{\text{lb}}{454 \text{ grams}} \times \frac{3.28^2 \text{ ft}^2}{\text{m}^2} = \frac{2.0 \times 10^{-4} \text{ lb}}{\text{SF}}$$

For a 1 ft mix zone,

$$= \frac{2.0 \times 10^{-4} \text{ lb}}{\text{CF}}$$

Concentration =

$$\frac{2.0 \times 10^{-4} \text{ lb/CF}}{100 \text{ lb/CF}} = \frac{2 \times 10^{-6} \text{ lb}}{\text{lb}} = 2 \text{ mg/kg}$$
