18 **Abstract**

19 The two-domain protein RfaH, a paralog of the universally conserved NusG/Spt5 transcription  
20 factors, is regulated by autoinhibition coupled to the reversible conformational switch of its 60-  
21 residue C-terminal KOW domain between an  $\alpha$ -hairpin and a  $\beta$ -barrel. In contrast, NusG/Spt5-  
22 KOW domains only occur in the  $\beta$ -barrel state. To understand the principles underlying the  
23 drastic fold switch in RfaH, we elucidated the thermodynamic stability and the structural  
24 dynamics of two RfaH- and four NusG/Spt5-KOW domains by combining biophysical and  
25 structural biology methods. We find that the RfaH-KOW  $\beta$ -barrel is thermodynamically less  
26 stable than that of most NusG/Spt5-KOWs and we show that it is in equilibrium with a globally  
27 unfolded species, which, strikingly, contains two helical regions that prime the transition towards  
28 the  $\alpha$ -hairpin. Our results suggest that transiently structured elements in the unfolded form might  
29 drive the global folding transition in metamorphic proteins in general.

30

31

## 32 **Introduction**

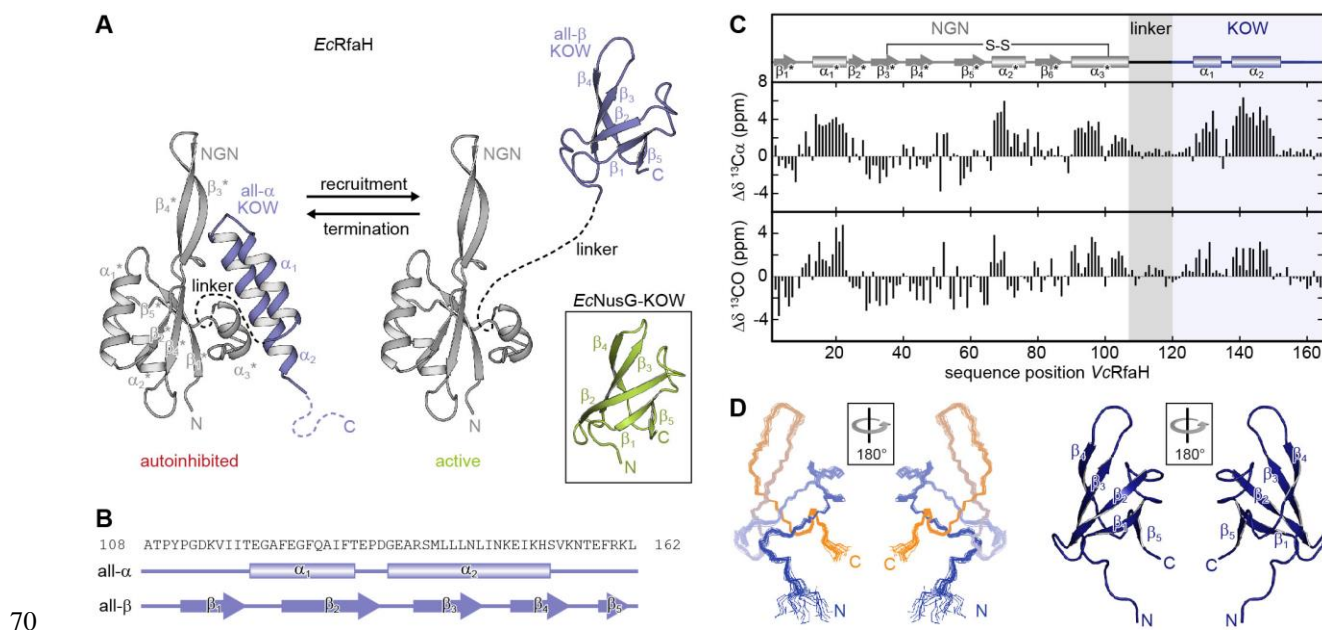

33 Fundamental understanding of how proteins fold has ever been one of the most important  
34 questions in structural biology and it is still not answered, despite recent progress in protein  
35 structure prediction (Jumper et al., 2021; Tunyasuvunakool et al., 2021). Since the formulation of  
36 the “thermodynamic hypothesis of protein folding” by Anfinsen (Epstein et al., 1963) it has been  
37 generally accepted that the amino acid sequence of a protein determines its three-dimensional  
38 structure and that a protein adopts only a single folded conformation, which is referred to as  
39 physiological state and which corresponds to its global energy minimum. This conformation, in  
40 turn, fulfills one distinct function. While this “one sequence – one structure – one function”  
41 dogma holds true for most well-folded (globular) proteins, it has been challenged by several  
42 discoveries over the past decades. Among those are, for instance, (i) moonlighting proteins,  
43 which fulfill two completely unrelated functions (Jeffery, 2014, 1999), (ii) intrinsically  
44 disordered proteins (IDPs), which do not adopt a defined secondary or tertiary structure at all,  
45 but sample an ensemble of sterically allowed conformations instead (van der Lee et al., 2014),  
46 and (iii), most strikingly, metamorphic proteins (also referred to as fold-switching proteins),  
47 which can reversibly interconvert between at least two well-defined conformations, sometimes in  
48 response to a molecular signal (Murzin, 2008).

49 The free energy landscape of globular, well-folded proteins is often portrayed as a rugged funnel,  
50 with the “rim” corresponding to the multitude of random-coil structures of the “unfolded state”  
51 (U state) and the deepest point (global minimum in Gibb’s free energy,  $G$ ), representing the  
52 “native” or “physiological” state (N state). IDPs, in contrast, exhibit a rather flat energy  
53 landscape and no specific conformation is favored, i.e. significantly populated. Fold-switching  
54 proteins are thought to reside in-between these two scenarios, that is their energy landscape may

55 be funnel-like, but it shows at least two major minima, each representing a distinct, well-folded  
56 conformation. The various conformations of a fold-switching protein may differ in the following  
57 aspects: (i) the type of secondary structure ( $\alpha$ -helices,  $\beta$ -strands, ...), (ii) the extent of secondary  
58 structure elements, and (iii) the tertiary structure, usually in combination with (i) and/or (ii)  
59 (Dishman and Volkman, 2018; Kim and Porter, 2021). Additionally, these states often exhibit  
60 different quaternary structures, e.g. monomeric in one state *vs.* multimeric in another state.

61 A particularly intriguing example of fold-switching proteins is the transcription factor RfaH from  
62 *E. coli* (*EcRfaH*), a member of the universally conserved family of NusG (bacteria) / Spt5  
63 (archaea and eukaryotes) proteins (Werner, 2012). NusG/Spt5 proteins exhibit a modular  
64 structure with several domains. Bacterial NusG consists of at least an N-terminal domain and a  
65 C-terminal Kyrpides, Ouzounis, Woese (KOW) domain connected by a flexible linker (Werner,  
66 2012). Spt5 proteins contain a NusG-like N-terminal (NGN) domain and one (archaea) or several  
67 (eukaryotes) KOW domains (Werner, 2012). All structurally characterized NusG/Spt5-KOW  
68 domains adopt a five-stranded  $\beta$ -barrel structure (**Figure 1A**; see e.g. (Klein et al., 2011; Meyer  
69 et al., 2015; Mooney et al., 2009; Zuber et al., 2018)).

70  
71 **Figure 1.** Fold-switching within the NusG/RfaH family. (A) Cartoon representation of *EcRfaH*  
72 in the closed, autoinhibited state (left; protein data bank identifier (PDB-ID): 5OND) and in the  
73 open, active conformation (right; PDB-ID all- $\beta$  *EcRfaH*-KOW: 2LCL) and of *EcNusG*-KOW  
74 (boxed; PDB-ID: 2JVV). Unstructured regions are shown as dashed lines, termini are labeled.  
75 (B) Secondary structures of *EcRfaH*-KOW in the all- $\alpha$  and the all- $\beta$  state. Tubes indicate  $\alpha$ -  
76 helical elements, arrows represent  $\beta$ -strands. The amino acid sequence is shown above. (C)  
77 Secondary chemical shift of *VcRfaH*. The plots show the difference between the observed  
78 chemical shift and the corresponding predicted random coil value of  $^{13}\text{C}\alpha$  (top) and  $^{13}\text{CO}$   
79 (bottom). Positive values indicate helical, negative values elongated ( $\beta$ -sheet) structures, and  
80 values close to zero are observed for random coil-like structures. The secondary structure  
81 elements inferred from the analysis are shown above the graphs (code for secondary structure  
82 elements as in (B)). The position of the identified disulfide bridge (see also [Figure 1 – Figure](#)  
83 [supplement 1A, B](#)) is indicated. (D) Left: Ribbon representation of the 20 lowest energy  
84 structures of *VcRfaH*-KOW (PDB-ID: 6TF4). Right: Cartoon representation of the lowest energy  
85 structure.  $\beta$ -strands and termini are labeled.

86 **Figure supplement 1.** Disulfide bridge formation in *VcRfaH*.

87 **Figure supplement 2.** Solution structure statistics for *VcRfaH*-KOW.

88 **Figure supplement 3.** Structure comparison of KOW domains used in this study.

89

90 *EcRfaH* is an operon-specific paralog of *E. coli* NusG (*EcNusG*) and – just like *EcNusG* –  
91 consists of an NGN domain that is loosely connected with a KOW domain *via* a flexible 15  
92 amino acid long linker. However, in free *EcRfaH* *EcRfaH*-KOW folds as an  $\alpha$ -helical hairpin  
93 (all- $\alpha$  state) that interacts with the *EcRfaH*-NGN domain. Thus, the binding site for RNA

94 polymerase (RNAP) at the domain interface on *EcRfaH*-NGN is masked and *EcRfaH* is locked  
95 in an autoinhibited state (Belogurov et al., 2007). Upon recruitment to a transcription elongation  
96 complex pausing at an *operon polarity suppressor (ops)* site, *EcRfaH* is activated (Artsimovitch  
97 and Landick, 2002; Zuber et al., 2019): the domains dissociate and the liberated *EcRfaH*-KOW  
98 refolds into a NusG-KOW-like  $\beta$ -barrel (all- $\beta$  state; **Figure 1A, B**) (Burmam et al., 2012; Zuber  
99 et al., 2019).

100 The refolding occurs spontaneously as soon as the domains are separated and *EcRfaH*-KOW,  
101 when produced as an isolated domain, also adopts the all- $\beta$  state, implying that the all- $\alpha$  fold is  
102 only stable in the presence of *EcRfaH*-NGN (Burmam et al., 2012; Tomar et al., 2013). Each of  
103 the *EcRfaH*-KOW states has a specific function: the all- $\alpha$  state prevents off-target recruitment of  
104 *EcRfaH* and competition with the general transcription factor NusG (Belogurov et al., 2007),  
105 whereas the all- $\beta$  *EcRfaH*-KOW serves as recruitment platform for ribosomes to activate  
106 translation (Burmam et al., 2012; Zuber et al., 2019). Upon release from RNAP *EcRfaH* is  
107 transformed back into its autoinhibited state, i.e. the structural switch of *EcRfaH*-KOW is fully  
108 reversible (Zuber et al., 2019). *EcRfaH* was not only considered a fold-switching protein, but  
109 termed a “transformer protein” to emphasize, that a complete domain cycles reversibly between  
110 two states with radically different stable secondary/tertiary structure and with each state  
111 performing a distinct function (Knauer et al., 2012).

112 The fine-tuned mechanism used by *EcRfaH* to control its functions may be widespread in nature  
113 (Porter and Looger, 2018). However, the molecular principles underlying the fold-switching  
114 process are only poorly understood. Here, we present a comprehensive thermodynamic and  
115 structural analysis of six KOW domains from NusG/Spt5/RfaH proteins from all domains of life.  
116 We combine circular dichroism (CD) spectroscopy, differential scanning calorimetry (DSC), and

117 solution-state nuclear magnetic resonance (NMR) spectroscopy to gain insight into the  
118 mechanism and the dynamics of fold-switching within the RfaH family on a molecular level and  
119 provide a rationale for the mechanism of fold-switching proteins in general.

120

## 121 **Results**

### 122 **Evolutionary conservation of fold-switching within the RfaH family**

123 To date, fold-switching within the RfaH family has only been shown for *EcRfaH*, although RfaH  
124 orthologs seem to employ a similar mechanism to affect RNAP (Carter et al., 2004). Thus, we  
125 first asked whether this ability might be a general feature of RfaH proteins. We chose RfaH from  
126 *Vibrio cholerae* (*VcRfaH*) for a structural analysis by solution-state NMR spectroscopy as it is  
127 evolutionarily remote from *EcRfaH* (sequence identity *Ec/VcRfaH*: 43.6 % (full-length) or  
128 35.8 % (KOW domain), respectively). We first identified the secondary structure elements of the  
129 full-length protein by performing an NMR backbone assignment and calculating the secondary  
130 chemical shift for each  $^{13}\text{C}\alpha$  and  $^{13}\text{CO}$  atom, which depends on the main chain geometry  
131 (**Figure 1C**). In full-length *VcRfaH*, the KOW domain exhibits two stretches with helical  
132 structure that are separated by about four residues and the overall pattern of secondary structure  
133 elements perfectly matches the one of autoinhibited *EcRfaH* (Burmam et al., 2012), suggesting  
134 similar tertiary structures for *EcRfaH* and *VcRfaH* (compare to **Figure 1A**), but with helix  $\alpha_3^*$   
135 being 1.5 turns longer in *VcRfaH*. Interestingly, the  $\text{C}\alpha$  and  $\text{C}\beta$  atoms of C34 and C102 exhibit  
136 chemical shifts typical for cystines ((Sharma and Rajarathnam, 2000), **Figure 1 – figure**  
137 **supplement 1A**). These residues are located at the end of helix  $\alpha_3^*$  and in strand  $\beta_3^*$ ,  
138 respectively, and are, most probably, in close proximity, as indicated by the structure of *EcRfaH*.  
139 The addition of a reducing agent to [ $^2\text{H}$ ,  $^{15}\text{N}$ ,  $^{13}\text{C}$ ]-*VcRfaH* led to drastic changes of the chemical  
140 shifts of C34 and C102 as well as residues in spatial proximity in a [ $^1\text{H}$ ,  $^{15}\text{N}$ ]-heteronuclear  
141 single quantum coherence (HSQC) spectrum (**Figure 1 – Figure supplement 1B**). From this we  
142 conclude that C34 and C102 form a disulfide bridge, that covalently tethers the  $\alpha_3^*$ -helix to the  
143 core of *VcRfaH*-NGN, a feature absent in *EcRfaH*. However, upon refolding from a solution

144 containing 8 M urea and reducing agent,  $^{15}\text{N}$ -*VcRfaH* adopted the same conformation as before  
145 denaturation (**Figure 1 – Figure supplement 1C**), suggesting that the disulfide bridge is not  
146 required for *VcRfaH* to fold into the autoinhibited state.

147 Next, we determined the solution structure of the isolated *VcRfaH*-KOW domain by NMR  
148 spectroscopy. *VcRfaH*-KOW also shows the 5-stranded  $\beta$ -barrel topology typical for NusG/Spt5-  
149 KOW domains (**Figure 1D and Figure 1 – Figure supplement 2**), with a  $\text{C}\alpha$  root mean square  
150 deviation (rmsd) of 1.4 Å as compared to isolated *EcRfaH*-KOW.

151 Although we do not present functional data on *VcRfaH* here, these results strongly suggest that  
152 *VcRfaH*-KOW can also switch between an all- $\alpha$  and an all- $\beta$  state and that *VcRfaH* is thus, most  
153 probably, also a transformer protein.

154

## 155 **The model systems**

156 The sequence of NusG/Spt5-KOW domains has been evolutionarily optimized to fold in only  
157 one defined conformation. Consequently, in the case of RfaH-KOW, the ability to switch  
158 between the all- $\alpha$  and the all- $\beta$  state must be encoded within the primary structure, whereas the  
159 “decision” which state to adopt solely depends on the availability of RfaH-NGN (Tomar et al.,  
160 2013). Sequence alignments and bioinformatical approaches (Balasco et al., 2015; Bernhardt and  
161 Hansmann, 2018; Gc et al., 2014; Joseph et al., 2019; Li et al., 2014; Shi et al., 2017; Xiong and  
162 Liu, 2015) gave first hints why RfaH, in contrast to NusG, is a metamorphic protein and how the  
163 structural switch might proceed. Yet, experimental evidence is still scarce. Thus, we analyzed  
164 isolated KOW domains of six NusG/Spt5 or RfaH proteins to identify characteristic properties of  
165 fold-switching proteins and to understand the molecular mechanisms underlying the refolding  
166 mechanism of RfaH-KOW. Due to the fact that NusG proteins are universally conserved, we

167 chose NusG-KOWs from *E. coli* and *Mycobacterium tuberculosis* (*Ec/MtNusG-KOW*), the Spt5-  
168 KOW from the hyperthermophilic archaeon *Methanocaldococcus jannaschii* (*MjSpt5-KOW*) and  
169 the fifth KOW domain from human Spt5 (*hSpt5-KOW5*) as representative NusG-/Spt5-KOWs  
170 and the *Ec/VcRfaH-KOWs* as representatives for RfaH proteins. The constructs used are about  
171 65 residues in length and contain the structured region and parts of the neighboring linker(s)  
172 (**Figure 1 – Figure supplement 3A**). All six domains exhibit the typical  $\beta$ -barrel topology  
173 (**Figure 1 – Figure supplement 3B**) with major differences only in the loops or turns connecting  
174 the  $\beta$ -strands (**Figure 1 – Figure supplement 3C**).

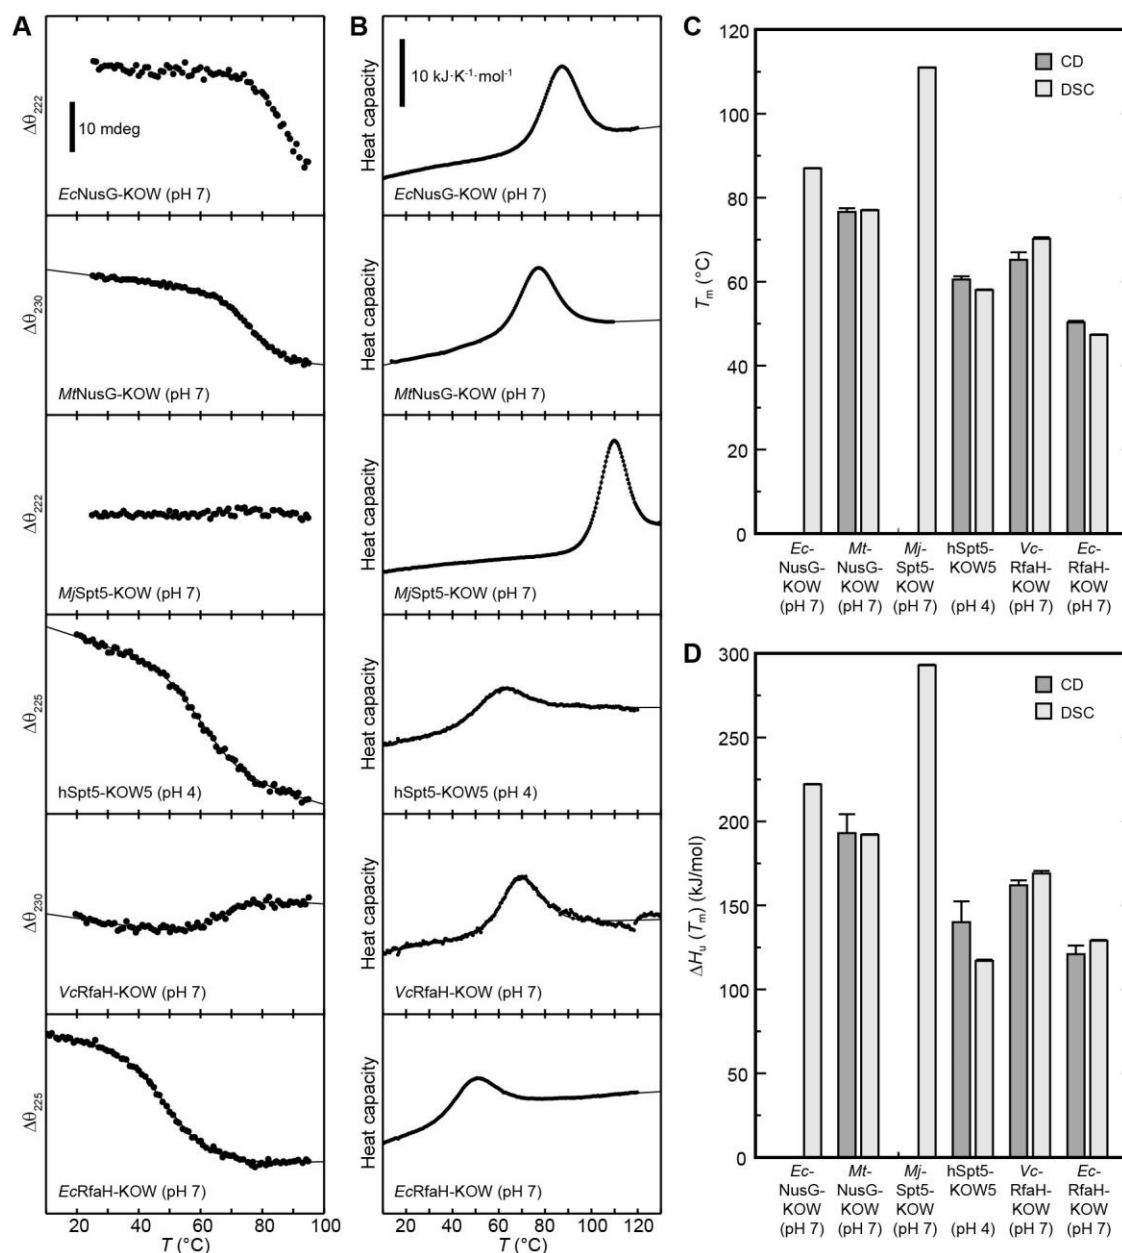

175

## 176 **Thermal and chemical stability of the KOW domains**

177 Metamorphic proteins that switch between two stable conformations are expected to show two  
178 main minima in their energy landscape, each corresponding to one of these states (Dishman and  
179 Volkman, 2018). This implicates that (i) in order to control the structural interconversion, one of  
180 the conformations has to be (de)stabilized according to a molecular signal, and (ii) the energy  
181 minima cannot be as deep as the global minimum of a protein with a single, stable conformation  
182 to avoid permanent trapping of one state. Consequently, the all- $\beta$  RfaH-KOW should show a  
183 limited thermodynamic stability to allow facile refolding to the all- $\alpha$  state when RfaH-NGN is  
184 available after transcription termination. To test this hypothesis, we analyzed the thermal stability  
185 of the six KOW domains by CD-based thermal denaturation experiments (**Figure 2A**) and by  
186 DSC (**Figure 2B**) at pH 4 and pH 7. At pH 7 unfolding was reversible for all KOW domains  
187 except for *hSpt5-KOW5*, which showed aggregation; the opposite effect was observed at pH 4  
188 (**Figure 2 – Figure supplement 1**). All observed unfolding transitions were analyzed with a two-  
189 state model to determine the melting temperature,  $T_m$ , the enthalpy of unfolding at  $T_m$ ,  $\Delta H_u(T_m)$ ,

190 and, in case of the DSC thermograms, the temperature-dependent difference in heat capacity  
 191 between the N and U states,  $\Delta C_p(T)$  (Figure 2C,D and Figure 2 – Figure supplement 2).

192

193

194 **Figure 2.** Thermal unfolding experiments of the six KOW domains. (A) Thermal unfolding  
 195 monitored *via* change in the CD signal with a temperature gradient from 20 to 95 °C. The line  
 196 corresponds to the best fit to a two state-unfolding model. Measurements were carried out with  
 197 proteins in 10 mM K-acetate (pH 4.0) buffer for hSpt5-KOW5 and in 10 mM K-phosphate  
 198 (pH 7.0) buffer for all other domains. The wavelength for monitoring the transition was chosen  
 199 based on the largest difference between the spectra of the folded and unfolded protein. Data for

200 *EcNusG*-KOW was not fitted due to the lack of the baseline of the unfolded state. *MjSpt5*-KOW  
201 could not be denatured at all. **(B)** Thermograms obtained from DSC measurements. All profiles  
202 are normalized to one molar of protein. The lines correspond to best fits to a two-state unfolding  
203 model that includes a  $T$ -dependent  $\Delta C_p$  change. Buffers are as in (A). **(C,D)**  $T_m$  **(C)** and  $\Delta H_u(T_m)$   
204 **(D)** values derived from thermal unfolding experiments monitored by CD and DSC.

205 **Source data 1.** Data for thermal denaturation experiments for all KOW domains.

206 **Figure supplement 1.** Reversibility of thermal unfolding.

207 **Figure supplement 2.** Thermodynamic parameters of the six KOW domains as derived from  
208 thermal unfolding experiments using CD spectroscopy and DSC.

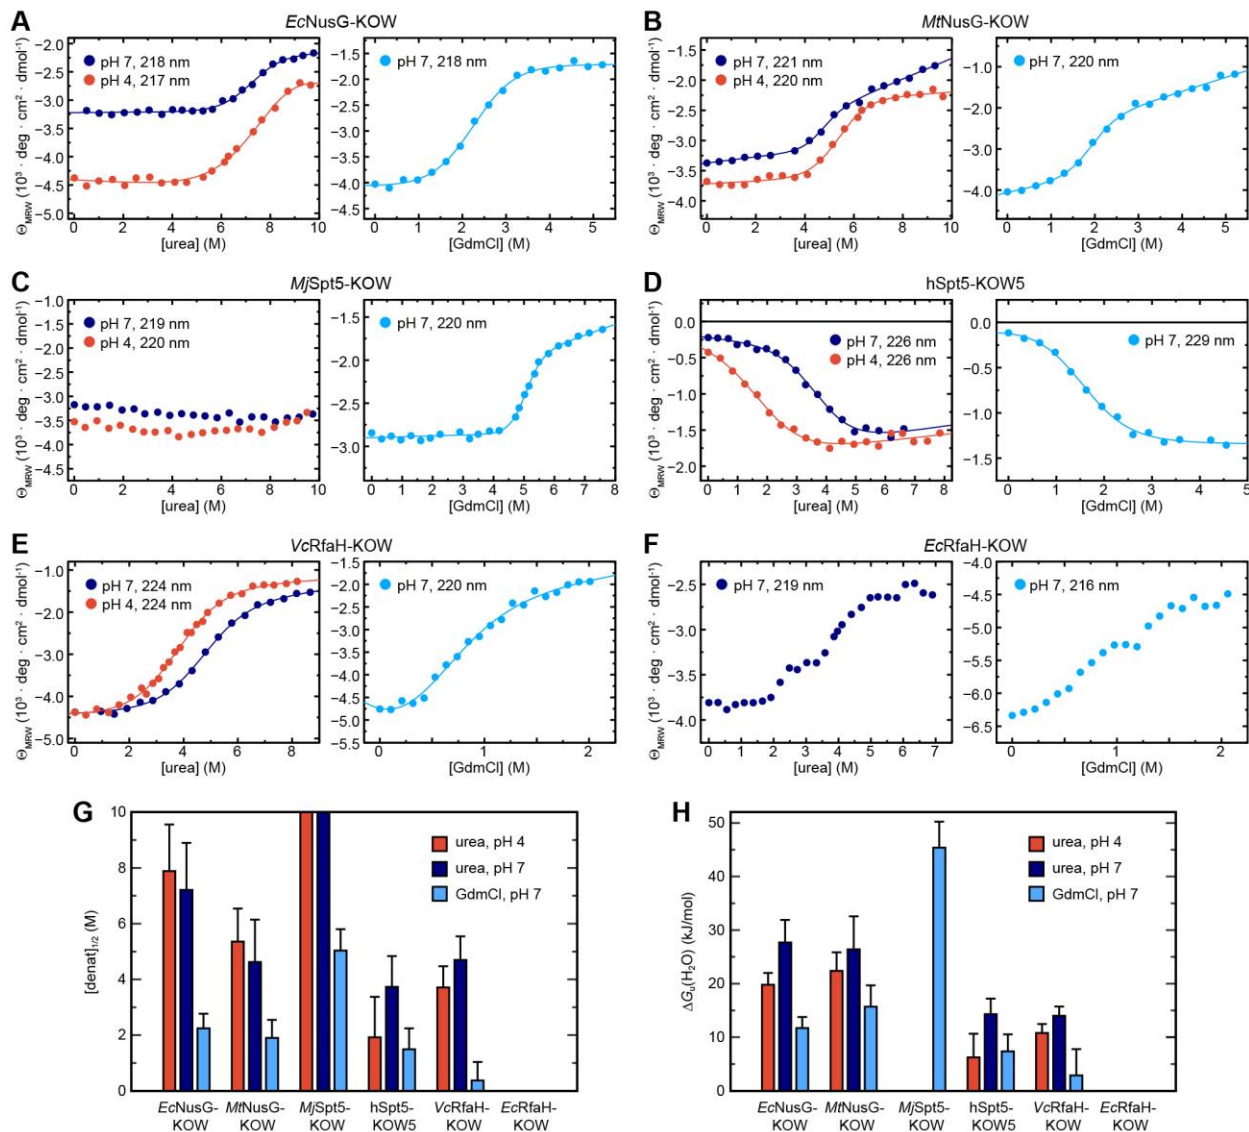

209  
210

211 Due to the fact that the KOW domains are  $\beta$ -barrels the precision of the thermodynamic  
212 parameters determined by CD spectroscopy is not as high as for proteins with helical elements.  
213 Nevertheless, the results obtained by DSC and CD spectroscopy are in good agreement showing  
214 that *EcNusG*-KOW, *MtNusG*-KOW, and *MjSpt5*-KOW have much higher  $T_m$  values (87 °C,  
215 77 °C and 111 °C, respectively) than hSpt5-KOW5 (58-60 °C), *EcRfaH*-KOW (47-50 °C), and  
216 *VcRfaH*-KOW (65-70 °C). The same trend was observed for  $\Delta H_u(T_m)$  values. Consequently, this  
217 data indicates that *EcNusG*-KOW, *MtNusG*-KOW, and *MjSpt5*-KOW have a higher  
218 thermodynamic stability than Spt5-KOW5, *EcRfaH*-KOW, and *VcRfaH*-KOW.

219

220 To corroborate and complement the previous findings, we next performed far-UV CD-based  
221 chemical unfolding experiments at pH 4 and pH 7 using urea as denaturant (**Figure 3A – F, left**).

222

223 **Figure 3.** CD spectroscopy-based chemical equilibrium unfolding of the six KOW domains. (A)  
 224 – (F): Change in  $\Theta_{MRW}$  of the indicated protein domain upon over-night incubation with  
 225 increasing concentrations of (left) urea in 10 mM K-acetate (pH 4.0; red circles) or 10 mM K-  
 226 phosphate (pH 7.0; dark blue circles), respectively, and (right) GdmCl in 10 mM K-phosphate  
 227 (pH 7.0; light blue circles). The detection wavelength is indicated and chosen based on the  
 228 maximum difference between the spectra of the folded and unfolded state. The lines correspond  
 229 to the best fits to a two-state unfolding model, except for *EcRfaH*-KOW, which exhibits a three-  
 230 state unfolding behavior. (G, H) Comparison of  $[\text{denat}]_{1/2}$  values (G) and  $\Delta G_u(\text{H}_2\text{O})$  values (H)  
 231 of the KOW domains derived from the chemical denaturation experiments shown in (A)-(E).

232 **Source data 1.** Data for chemical denaturation experiments for all KOW domains.

233 **Figure supplement 1.** Thermodynamic parameters of the six KOW domains.

234 **Figure supplement 2.** Chemical unfolding of VcRfaH-KOW monitored by change in Trp  
 235 fluorescence.

236 **Figure supplement 3.** Reversibility of chemical denaturations for all KOW domains.

237 *EcNusG*-KOW, *MtNusG*-KOW, hSpt5-KOW5, and *VcRfaH*-KOW show a sigmoidal unfolding  
238 curve at either pH, indicative of a two-state unfolding process. Analysis of this data by the linear  
239 extrapolation model yields transition midpoints ( $[\text{urea}]_{1/2}$  values) and  $\Delta G_u(\text{H}_2\text{O})$  values that  
240 confirm the relative order of the stability as determined by thermal denaturation (**Figure 3G, H,**  
241 **Figure 3 – Figure supplement 1, and Figure 2C**). For *MjSpt5*-KOW only the native state  
242 baseline is observable at both pH values, demonstrating that no denaturation could be achieved  
243 and that, consequently, this KOW domain exhibits the highest thermodynamic stability  
244 (assuming an  $m$ -value comparable to that of the other KOW domains, *MjSpt5*-KOW likely has a  
245  $\Delta G_u(\text{H}_2\text{O})$  value  $> 30\text{-}40$  kJ/mol). Notably, we obtained a  $\Delta G_u(\text{H}_2\text{O})$  value for hSpt5-KOW5 at  
246 pH 7, showing that this domain has a stability comparable to that of *VcRfaH*-KOW at  
247 physiological pH (**Figure 3 – Figure supplement 1**). As *VcRfaH*-KOW, in contrast to all other  
248 KOW domains in this study, contains a Trp residue an additional fluorescence-based denaturation  
249 experiment was performed, and the obtained parameters are in good agreement with the CD data  
250 (**Figure 3 – Figure supplement 1 and Figure 3 – Figure supplement 2A**).

251 To complement the analysis, we repeated the unfolding experiments at pH 7 using guanidinium  
252 chloride (GdmCl; **Figure 3A – F, right, Figure 3 – Figure supplement 1 and Figure 3 –**  
253 **Figure supplement 2B**). As GdmCl is a more potent denaturant than urea, we were now able to  
254 denature even *MjSpt5*-KOW, giving a  $[\text{GdmCl}]_{1/2}$  value of 5.03 M, which is more than twice the  
255 value of the next stable protein. In accordance with the urea-based unfolding experiments at pH  
256 7, *MjSpt5*-KOW, *EcNusG*-KOW and *MtNusG*-KOW exhibit higher  $\Delta G_u(\text{H}_2\text{O})$  and  $[\text{denat.}]_{1/2}$   
257 values than *VcRfaH*-KOW and hSpt5-KOW5, although the relative order of stability of *MtNusG*-  
258 KOW and *EcNusG*-KOW is swapped. This difference as well as the difference between the  
259 absolute  $\Delta G_u(\text{H}_2\text{O})$  values derived from the urea- and GdmCl-based denaturations is a well-

260 documented phenomenon and may be attributed to the limited applicability of the linear  
261 extrapolation model for the analysis of denaturations by GdmCl (see e.g. (Gupta et al., 1996;  
262 Makhatadze, 1999)). Thus, we base our conclusions on the relative comparison of the obtained  
263 values. We finally note that chemical unfolding was completely reversible in all cases (**Figure 3**  
264 **– Figure supplement 3**).

265 Surprisingly, and in contrast to all other domains, *EcRfaH-KOW* shows a more complex  
266 unfolding curve in both urea- and GdmCl-based denaturation experiments at pH 7, with an  
267 additional plateau at  $\approx 3$  M urea or  $\approx 1$  M GdmCl, respectively, between the N and U baselines  
268 (**Figure 3F**; no curve could be obtained at pH 4 due to native state aggregation). This suggests  
269 that the unfolding of *EcRfaH-KOW* may be described *via* a three-step model including an  
270 observable equilibrium intermediate that might play an important role in the fold-switching  
271 mechanism of *EcRfaH-KOW*.

272 In summary, the poor spectroscopic properties of the analyzed domains limit the precision of the  
273 absolute values of the thermodynamic parameters obtained from CD experiments. However, our  
274 findings reveal clear differences in the global stability of the six domains and allow a grouping  
275 into two classes: *MjSpt5-KOW* and *Ec/MtNusG-KOW* are considered as “stable domains”,  
276 whereas the  $\beta$ -barrel *Ec/VcRfaH-KOW* as well as *hSpt5-KOW5* show a reduced thermodynamic  
277 stability.

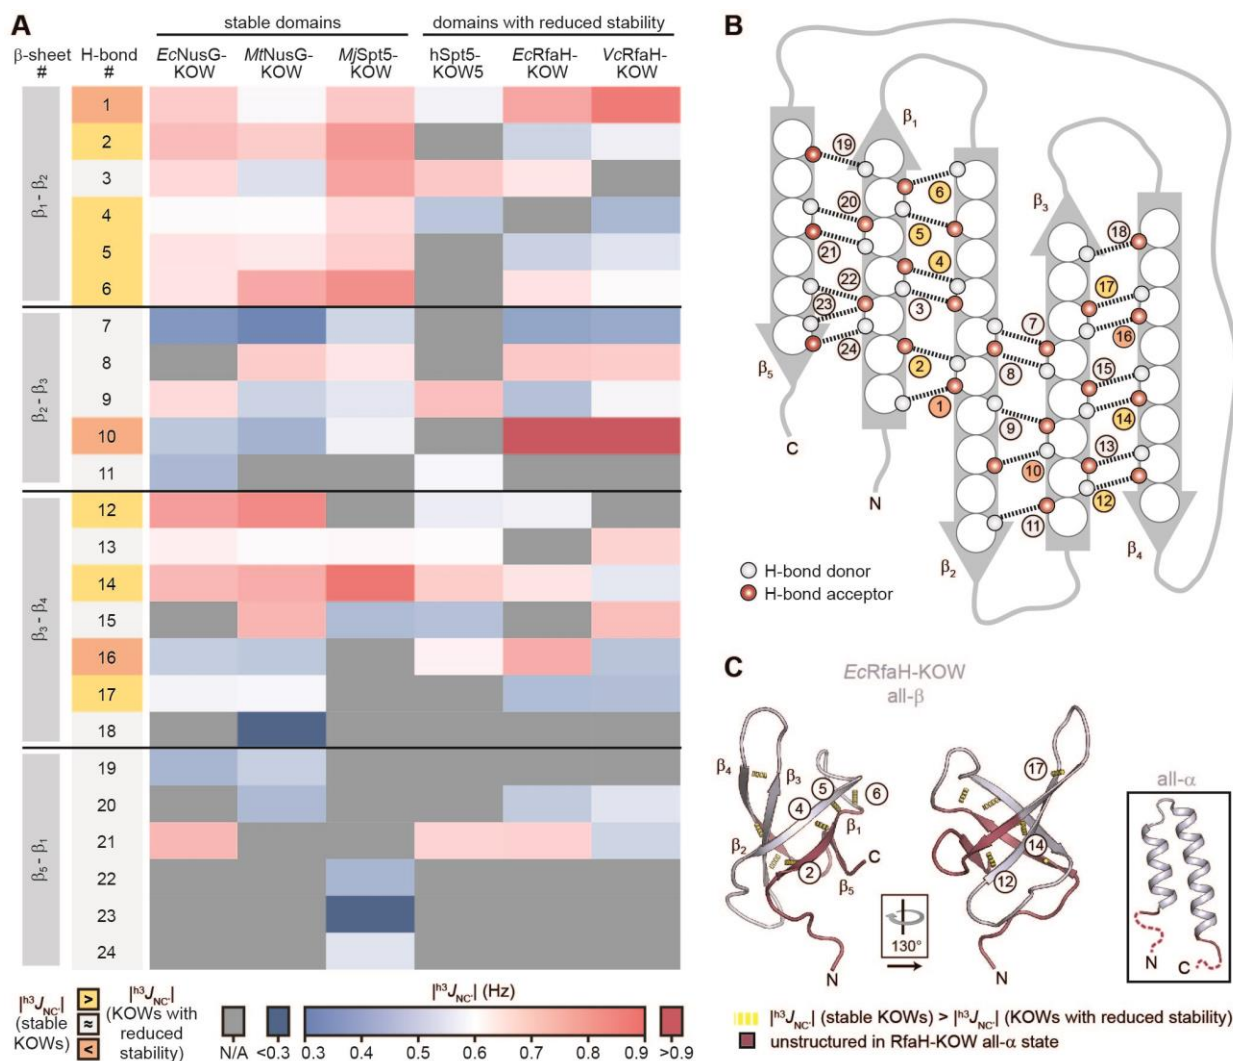

278

### 279 **Regions that are unfolded in all- $\alpha$ RfaH-KOW are destabilized in the all- $\beta$ conformation**

280 We next asked whether the less stable KOW domains also exhibit local differences in their  
281 stability as compared to the NusG-KOWs and *MjSpt5-KOW*. Therefore, we identified the  
282 backbone H-bond pattern in the six domains and quantified the magnitude of the through H-bond

283 coupling constant,  ${}^{\text{h}^3}J_{\text{NC}'}$ , by long-range HNCO NMR experiments (**Figure 4 – Figure**  
284 **supplement 1**). This parameter is inversely proportional to the length of the H-bond and the  
285 deviation from its optimum angle, thus reflecting the H-bond strength (Grzesiek et al., 2004). To  
286 allow comparison between the six domains, we grouped H-bonds that are located at equivalent  
287 positions of the  $\beta$ -barrels and ordered them according to their position in the individual  $\beta$ -sheets  
288 (**Figure 4A, B**). Most  $|{}^{\text{h}^3}J_{\text{NC}'}$ -values are in the range of 0.5 – 0.9 Hz, which is typical for H-  
289 bonds of  $\beta$ -sheets (Grzesiek et al., 2004). In line with having the highest  $T_m$ , *MjSpt5*-KOW often  
290 exhibits the highest coupling constants, which is indicative of a highly rigid packing of the  $\beta$ -  
291 barrel. Strikingly, *MjSpt5*-KOW has three additional H-bonds between strands  $\beta_5$  and  $\beta_1$  (# 22-  
292 24), which provides an extra stabilization of the C-terminal  $\beta$ -strand that may contribute to the  
293 high thermostability of this protein. The “stable” domains (i.e. *Ec/MtNusG*-KOW and *MjSpt5*-  
294 KOW) show their strongest H-bonds in two regions, namely between strands  $\beta_1:\beta_2$  and  $\beta_3:\beta_4$ . In  
295 addition, most of these H-bonds are more stable than corresponding H-bonds in *Ec/VcRfaH*-  
296 KOW and *hSpt5*-KOW5, implying that the H-bonds in the domains with reduced stability are  
297 more dynamic and on average longer or involve a less optimal bonding angle. From this we  
298 conclude that in *Ec/VcRfaH*-KOW and *hSpt5*-KOW5 strands  $\beta_1$  and parts of  $\beta_4$  are less stably  
299 bound to the rest of the  $\beta$ -barrel than in the stable domains. Moreover, together with the fact that  
300  $\beta_1$ , the C-terminal half of  $\beta_4$ , and  $\beta_5$  are disordered in the all- $\alpha$  state of the *Ec/VcRfaH*-KOW  
301 (**Figure 4C**), this also reflects the chameleonic folding behavior of these regions in the all- $\beta$   
302 state.

303

304

305 **Figure 4.** H-bond pattern and stability in the six KOW domains. (A) Heat map of the magnitude  
 306 of the  $^3J_{NC}$  coupling constants of the H-bonds determined by long-range HNC0 NMR  
 307 experiments. H-bonds that are located at equivalent positions are grouped and ordered according  
 308 to their location in the respective  $\beta$ -sheet (position within the  $\beta$ -barrel as indicated in (B)), and  
 309 colored according to their  $^3J_{NC}$  value as indicated at the bottom. H-bond numbers highlighted  
 310 in yellow: H-bonds that have lower  $^3J_{NC}$  values for at least two of the domains with reduced  
 311 thermodynamic stability compared to the stable domains; H-bond numbers highlighted in  
 312 orange: H-bonds that have higher  $^3J_{NC}$  values for at least two of the domains with reduced  
 313 thermodynamic stability compared to the stable domains. (B) Scheme of the positions of the H-  
 314 bonds (dashed lines) within the  $\beta$ -barrel. Amino acids are depicted as spheres. White and red  
 315 circles represent H-bond donors and acceptors, respectively. H-bonds are color-coded as in (A).  
 316 (C) Cartoon representation of all- $\beta$  EcRfaH-KOW (PDB-ID: 2LCL, gray). Regions that are  
 317 unstructured in the all- $\alpha$  conformation are colored in dark red. H-bonds that have lower  $^3J_{NC}$   
 318 values for at least two of the domains with reduced thermodynamic stability compared to the  
 319 stable domains are shown as yellow dashed tubes and labeled. The relative orientation of the  
 320 structures is indicated. The inset shows the all- $\alpha$  EcRfaH-KOW (PDB-ID: 5OND; gray;

321 unstructured regions at the termini are colored in dark red and correspond to the dark red regions  
322 in the all- $\beta$  *EcRfaH*-KOW).

323 **Figure supplement 1.** Quantification of H-bond strengths for all KOW domains.

324

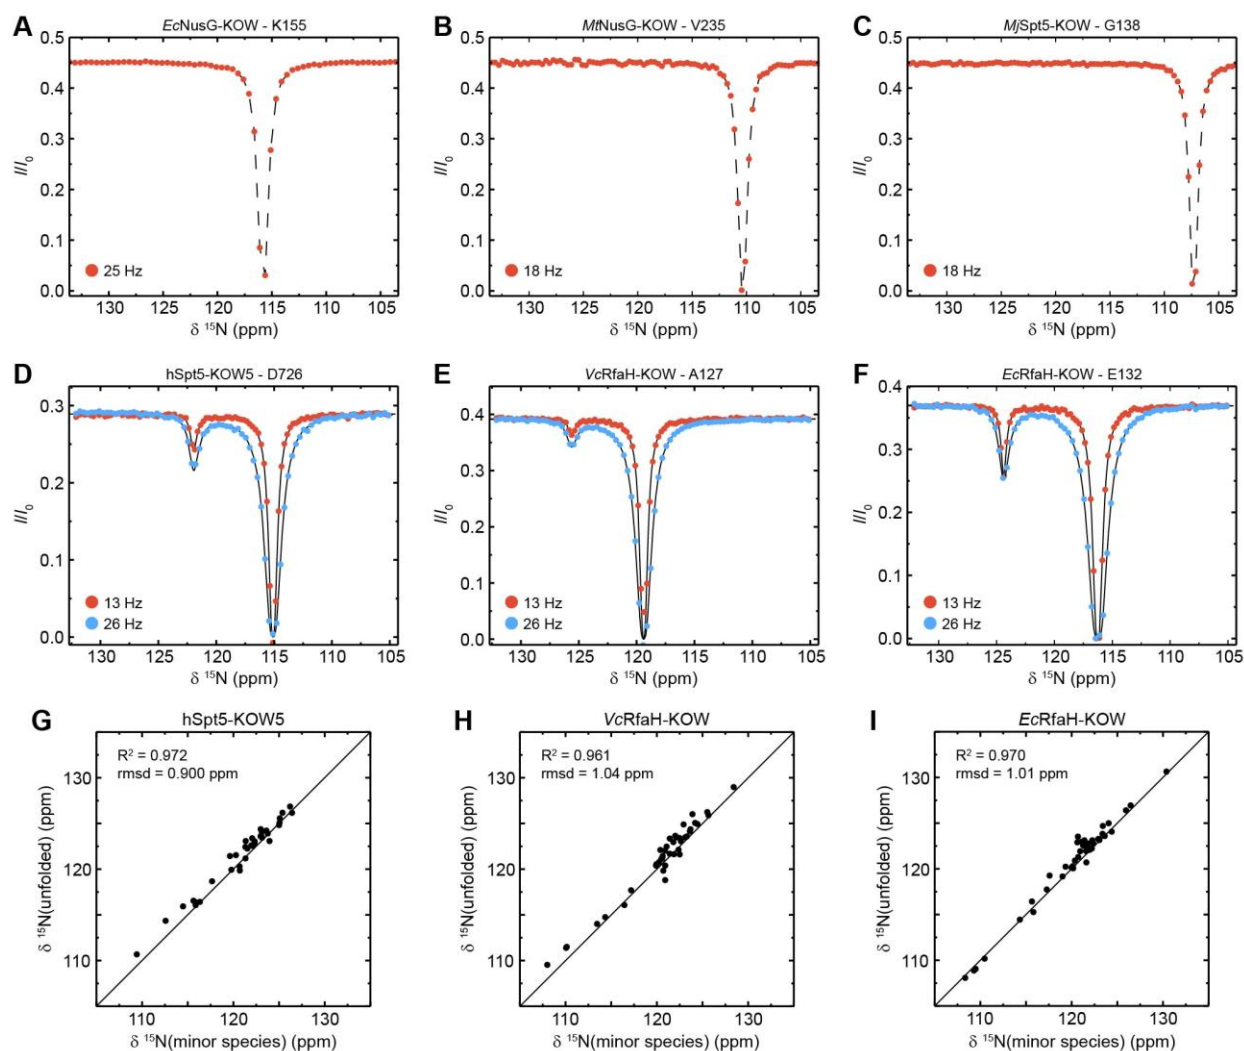

325

326 **hSpt5-KOW5, *Ec*- and *VcRfaH*-KOW exchange with a globally unfolded conformer on the**  
327 **ms-time scale**

328 To assess the folding mechanism of the KOW domains at the amino acid level, we performed an  
329 NMR-based analysis of the structural dynamics of the six  $\beta$ -barrel proteins. As larger structural  
330 rearrangements, such as folding events, mostly occur at the  $\mu$ s-ms time scale for small proteins  
331 or are even slower (Maxwell et al., 2005), we focused on the analysis of the slow chemical  
332 exchange regime. Therefore, we performed amide  $^{15}\text{N}$ -based chemical exchange saturation  
333 transfer (CEST) experiments (Vallurupalli et al., 2012). This method allows the sensitive  
334 detection and characterization of sparsely populated states (= minor species; relative population  
335  $p_B$ ) that exchange with a major species (relative population  $p_A = 1 - p_B$ ) with a rate  $k_{\text{ex}}$  of 10 –  
336 200  $\text{s}^{-1}$ . The detection is achieved by frequency-selective saturation along the  $^{15}\text{N}$  dimension that  
337 is “transferred” from the minor to the major species. This decreases the signal intensity of the  
338 major species and then leads to an additional dip in the CEST profile (major species signal  
339 intensity versus saturation frequency) next to the large major species minimum if there is a  
340 difference in the resonance frequencies of the two species.

341 None of the CEST profiles of *EcNusG*-KOW, *MtNusG*-KOW, and *MjSpt5*-KOW exhibits an  
342 exchange peak (**Figure 5A – C**), demonstrating that these domains are stable on the ms time  
343 scale, in agreement with their high thermodynamic stabilities (see above).

344

345 **Figure 5.** CEST analysis of the KOW domains. (A) – (F): Representative backbone  $^{15}\text{N}$ -CEST  
 346 profiles of the indicated KOW domain measured with one ((A) – (C)) or two ((D) – (F))  $B_1$  field  
 347 strengths and an exchange time of 0.5 s.  $B_0$  field for ((A)–(C)): 21.15 T;  $B_0$  field for ((A)–(C)):  
 348 16.45 T. The lines in (D) – (F) are fits to a two-state exchange model. (G) – (I): Correlation plots  
 349 showing the high similarity of the chemical shift of the minor CEST species and that of the  
 350 corresponding random coil value. The latter were obtained by backbone assignment in 8 M urea  
 351 (*EcRfaH*-KOW) or are theoretical values (*VcRfaH*-KOW, *hSpt5*-KOW5). The squared  
 352 correlation coefficient and the rmsd between the two corresponding sets of chemical shifts are  
 353 listed.

354 **Source data 1.** CEST fits for *EcRfaH*-KOW, *VcRfaH*-KOW and *hSpt5*-KOW5.

355 **Source data 2.** Experimentally determined chemical shift values of urea-denatured *EcRfaH*-  
 356 KOW and predicted random coil chemical shift values of *VcRfaH*-KOW and *hSpt5*-KOW5.

357 **Figure supplement 1.** Extended CEST analysis of *hSpt5*-KOW5, *VcRfaH*-KOW, and *EcRfaH*-  
 358 KOW.

359 **Figure supplement 2.** Exchange parameters derived from CEST experiments.

360 **Figure supplement 3.** Secondary structure prediction for the six KOW domains used in this  
 361 study by Net-CSSP.

362 In contrast, most CEST traces of hSpt5-KOW5, *Ec*RfaH-KOW, and *Vc*RfaH-KOW have a  
363 second dip, indicating exchange with a second, low populated state (exemplary traces are shown  
364 in **Figure 5D - F**). Using a two-state exchange model we fitted all CEST traces that showed an  
365 exchange signal individually to determine the residue-specific  $k_{\text{ex}}$  and  $p_{\text{B}}$  values. In all three  
366 cases, the  $k_{\text{ex}}/p_{\text{B}}$  values appear to cluster in one region, suggesting a global, cooperative process  
367 (**Figure 5 – Figure supplement 1A**). Thus, we next performed a global fit of all CEST traces for  
368 each of the three proteins resulting in global rate constants and populations as well as lifetimes of  
369 the two states (**Figure 5 – Figure supplement 2**). This analysis yields a relatively high  $p_{\text{B}}$  value  
370 (5.50 %) but low  $k_{\text{ex}}$  ( $15.0 \text{ s}^{-1}$ ) for *Ec*RfaH-KOW, a much lower  $p_{\text{B}}$  value (0.44 %) but higher  $k_{\text{ex}}$   
371 ( $75.0 \text{ s}^{-1}$ ) for *Vc*RfaH-KOW, and  $p_{\text{B}}/k_{\text{ex}}$  values of 0.85 % and  $89.0 \text{ s}^{-1}$  for hSpt5-KOW5.

372 To characterize the exchanging species structurally, we analyzed the chemical shifts of the minor  
373 species. In all three cases, the minor species shifts show a very good correlation with those of a  
374 completely unfolded conformation (**Figure 5G – I**;  $R^2 > 96 \%$ ,  $\text{rmsd} < 1.04 \text{ ppm}$ ). Note that the  
375 chemical shifts for the unfolded state of *Ec*RfaH-KOW were obtained experimentally by  
376 backbone assignment of the protein in 8 M urea, whereas those of *Vc*RfaH-KOW and hSpt5-  
377 KOW5 are predicted values (see Materials and Methods for details). Determination of the  
378 relative populations finally results in the equilibrium constant and the difference in Gibbs free  
379 energy,  $\Delta G$ , separating the energy levels of the two species (**Figure 5 – Figure supplement 2**).  
380 As expected, these  $\Delta G$  values are similar to those obtained from the urea-based unfolding  
381 experiments at pH 7 (**Figure 3 – Figure supplement 1**).

382 Taken together, the CEST experiments show that the folded all- $\beta$  state of the isolated RfaH-  
383 KOWs and also hSpt5-KOW5 is in equilibrium with a species that resembles the completely  
384 unfolded conformation. As this state is easily accessible from the  $\beta$ -barrel, we conclude that the

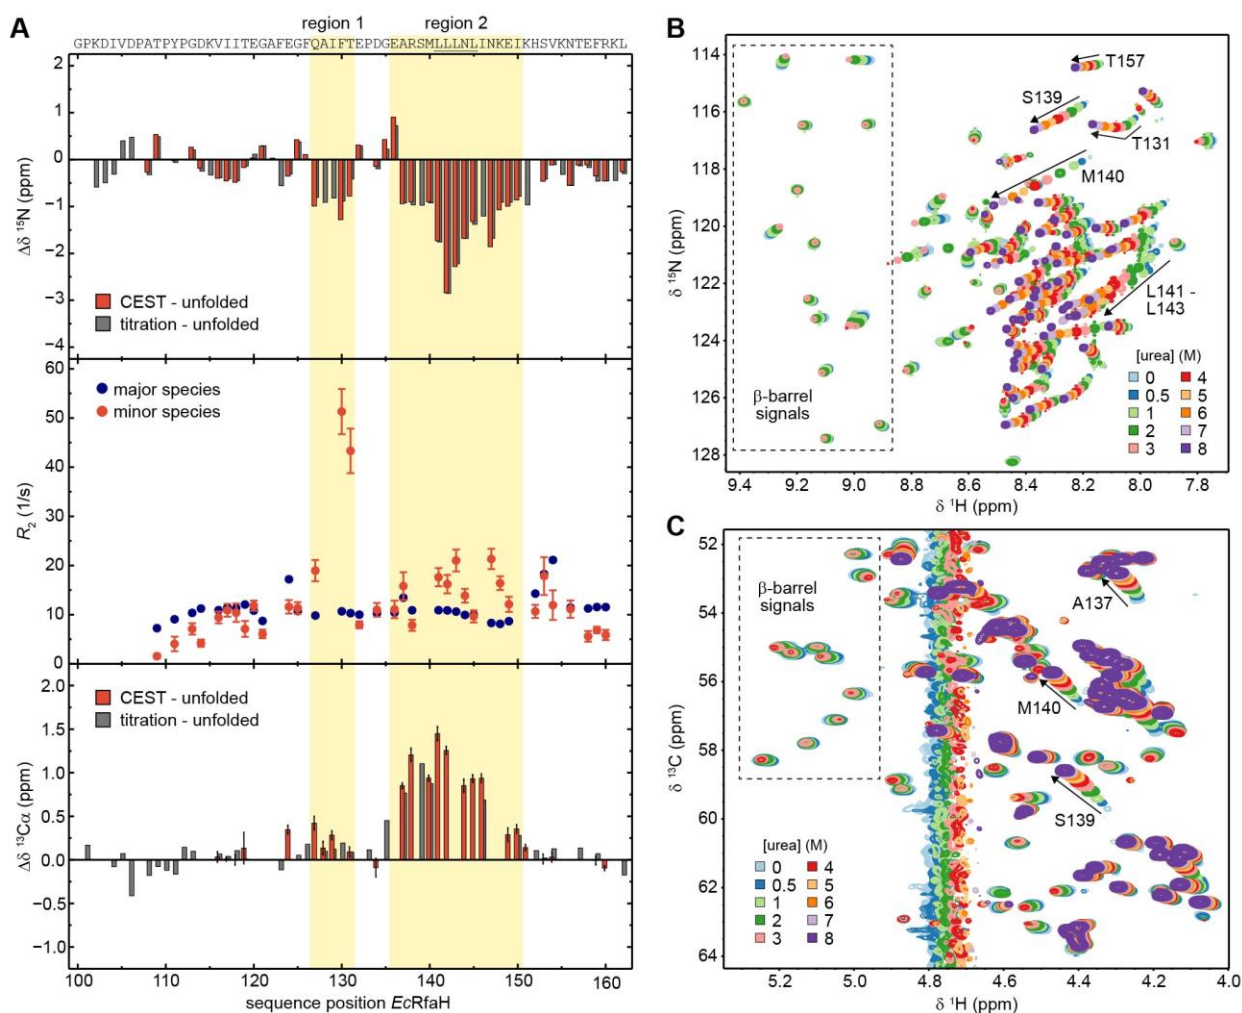

385 folding barrier separating the two states cannot be too high as this would prohibit an exchange on  
386 the ms time scale.

387

### 388 **The unfolded conformer of *EcRfaH*-KOW transiently forms helical structures**

389 Although chemical shifts of the minor species of *EcRfaH*-KOW nicely correlate with the  
390 chemical shifts of the urea-unfolded protein (**Figure 5I**), there are some noticeable differences in  
391 the  $^{15}\text{N}$  chemical shifts ( $\Delta\delta^{15}\text{N}$ ) of the two data sets (red bars in **Figure 6A, top panel**). In  
392 particular, two regions (region 1: Q127 – T131, region 2: E136 – I150) show significant  
393 deviations of -1 to -3 ppm, indicating local residual structures in these regions. This finding is  
394 supported by the transverse relaxation rates ( $R_2$  values) (**Figure 6A, mid panel**) as  $R_2$  values of  
395 regions 1 and 2 in the minor species are higher than corresponding rates in the  $\beta$ -barrel state,  
396 suggesting the presence of additional exchange processes on the fast chemical exchange (i.e.  $\mu\text{s}$   
397 – ms) time scale. Thus, the minor species itself is an ensemble of fast interconverting structures  
398 that differ in their conformations in regions 1 and 2. As the type of present (secondary) structure  
399 cannot be derived from  $^{15}\text{N}$  data, we recorded a CEST experiment on the  $^{13}\text{C}\alpha$  carbons of  $^{13}\text{C}$ -  
400 *EcRfaH*-KOW and calculated  $\Delta\delta^{13}\text{C}\alpha$  between the observed minor species values and the  
401 random coil values obtained from the urea-unfolded protein (red bars in **Figure 6A, bottom**  
402 **panel**). The deviations are positive in regions 1 and 2, indicating the presence of helical  
403 structures at these sites in one of the minor species' fast exchanging sub-states. This is in  
404 agreement with secondary structure predictions, which show that the Leu-rich motif (LLLNL) in  
405 region 2, where the deviations of  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}\alpha$  are most pronounced, has high  $\alpha$ -helical

406 propensity (Balasco et al., 2015). Moreover, the two helical elements are located at the positions  
 407 of the two  $\alpha$ -helices in the all- $\alpha$  form of *EcRfaH-KOW* (compare [Figure 1B](#)).

408

409 **Figure 6.** The minor species of *EcRfaH-KOW* comprises two sub-states, one with residual  
 410 structure. **(A)** Deviations of the minor species of *EcRfaH-KOW* from the urea-unfolded state.  
 411 **Top row:** Sequence-dependent difference between the  $^{15}\text{N}$  backbone amide chemical shifts of the  
 412 minor species and of the value obtained by assignment in 8 M urea. The values for the minor  
 413 species were either obtained from the CEST experiment (red bars, individual fits), or by tracing  
 414 back the chemical shift changes from 8 M to 0 M urea in the  $[^1\text{H}, ^{15}\text{N}]$ -HSQC-based urea  
 415 titration (grey bars; see panel (B)). Regions 1 and 2 show deviations of 1-3 ppm whereas the  
 416 termini have lower deviations with a maximum difference of -0.5 ppm. **Middle row:**  $R_2$  values  
 417 of the major species (*EcRfaH-KOW*  $\beta$ -barrel; blue) and minor species (red), obtained from  
 418 fitting the CEST profiles (global fit). Regions 1 and 2 have  $R_2$  values significantly higher than  
 419 those of their corresponding  $\beta$ -barrel conformation indicating additional exchange processes,  
 420 whereas N- and C-terminal regions have  $R_2$  values lower than those of their corresponding  $\beta$ -  
 421 barrel conformation, which is typical for random coil structures. **Bottom row:** Sequence  
 422 dependent difference between the  $^{13}\text{C}\alpha$  chemical shifts of the minor species and of the value

423 obtained by assignment in 8 M urea. The values for the minor species were either obtained from  
424 the CEST experiment (red bars, individual fits), or by tracing back the chemical shift changes  
425 from 8 M to 0 M urea in the [ $^1\text{H}$ ,  $^{13}\text{C}$ ]-ctHSQC-based urea titration (grey bars; see panel (C)).  
426 The sequence of *EcRfaH* is given above the diagram, the Leu-rich motif is underlined. Regions 1  
427 and 2 are highlighted. (B, C) NMR-based chemical equilibrium unfolding experiments of  
428 *EcRfaH*-KOW using urea as denaturant. The plots show an overlay of (B) [ $^1\text{H}$ ,  $^{15}\text{N}$ ]-HSQC, and  
429 (C) [ $^1\text{H}$ ,  $^{13}\text{C}$ ]-ctHSQC spectra of [ $^{15}\text{N}$ ,  $^{13}\text{C}$ ]-*EcRfaH*-KOW, acquired in the presence of varying  
430 urea concentrations. The system was buffered by 20 mM Na-phosphate (pH 6.5), 100 mM NaCl,  
431 1 mM EDTA, 10 % (v/v)  $\text{D}_2\text{O}$ . Arrows and labels indicate signals of residues that exhibit strong  
432 chemical shift changes in the indirect dimension ( $^{15}\text{N}$  in (B),  $^{13}\text{C}$  in (C)). The spectra are colored  
433 as indicated.

434 **Source data 1.** ANS binding by *EcRfaH*-KOW during urea-based denaturation.

435 **Figure supplement 1.** The intermediate state of *EcRfaH*-KOW is no equilibrium MG.

436 **Figure supplement 2.** Extended analysis of the urea-induced denaturation of *EcRfaH*-KOW  
437 with a three-state model.  
438

439

440 Like *EcRfaH*-KOW, the minor species of *VcRfaH*-KOW also seems to contain residual structure  
441 (**Figure 5 – Figure supplement 1B**). As the unfolded state of this domain was not assigned  
442 experimentally, predicted chemical shift values for the random coil structure were used for the  
443 correlation plot (**Figure 5H**). However, when plotting the  $\Delta\delta^{15}\text{N}$  values versus the sequence  
444 position (**Figure 5 – Figure supplement 1B**), the resulting pattern resembles the one obtained  
445 for *EcRfaH*-KOW (compare **Figure 6A, top panel**). The regions around residues 103 - 125  
446 (linker) and 155 - 165 (C-terminus) show relatively low values ( $\Delta\delta^{15}\text{N} \approx -1.5$  ppm), indicating a  
447 random coil structure, whereas the region around residues 140 - 150 exhibits  $\Delta\delta^{15}\text{N}$  values of >  
448 2 ppm, suggesting residual structure. Based on this similarity to *EcRfaH*-KOW we propose that  
449 the *VcRfaH*-KOW minor species also contains residual  $\alpha$ -helical structures, although the  
450 population of this species is much lower than that in the case of *EcRfaH*-KOW (0.4 % vs.  
451 5.5 %). This results in rather small minor species dips in the CEST profiles so that fitting of  $R_2$   
452 rates of the minor species was not possible with high precision (data not shown) and no

453 conclusion could be drawn regarding the presence of potential subspecies within the minor  
454 species.

455 The hSpt5-KOW5 domain is part of an “RNA clamp” during transcription elongation in  
456 eukaryotes (Bernecky et al., 2017) and exhibits the typical  $\beta$ -barrel fold in all available  
457 structures. Strikingly, hSpt5-KOW5 also exchanges with an unfolded species under non-  
458 denaturing conditions (**Figure 5 – Figure supplement 1C and Figure 5G**), just as *EcRfaH*-  
459 KOW and *VcRfaH*-KOW. However, in contrast to all other KOW domains in this study, hSpt5-  
460 KOW5 is not located at the very C-terminus of full-length hSpt5, but it is just one out of seven  
461 KOW domains being flanked by several hundreds of residues at either terminus. Thus, the  
462 stability of this domain may be different in its physiological environment. In line with this, the  
463 difference between the minor species chemical shifts and the predicted random coil values  
464 (**Figure 5 – Figure supplement 1C**) never exceeds  $\pm 2$  ppm and the  $R_2$  values of the minor  
465 species are lower than those of the  $\beta$ -barrel (data not shown), indicating that the minor species  
466 does not contain substantial residual structure. Finally, secondary structure predictions suggest  
467 that all NusG/Spt5-KOW domains adopt 4-5  $\beta$ -strands (**Figure 5 – Figure supplement 3**). In  
468 contrast, the RfaH-KOWs exhibit propensity for both  $\beta$ -strands and  $\alpha$ -helices, especially the  
469 regions with residual structure in the CEST minor species, in agreement with their chameleonic  
470 behavior. Taken together, this data suggests that hSpt5-KOW5 is a typical monomorphic  $\beta$ -barrel  
471 and that its decreased stability, accompanied by the existence of a minor, unfolded species, may  
472 be attributed to the absence of the neighboring domains, although we cannot completely rule out  
473 that these features are real, intrinsic properties of hSpt5-KOW5 in the full-length protein with  
474 (yet unknown) functional relevance.

475 As the completely unfolded state was only experimentally assigned for *EcRfaH*-KOW we will  
476 focus on this domain in the following analysis. Owing to its population of 5.5 % (**Figure 5 –**  
477 **Figure supplement 2**), *EcRfaH*-KOW's minor species should be detectable in a standard HSQC  
478 spectrum, given a sufficiently high signal-to-noise ratio. We therefore aimed at analyzing the role  
479 of the minor species during the chemical denaturation of *EcRfaH*-KOW by recording [<sup>1</sup>H, <sup>15</sup>N]-  
480 and [<sup>1</sup>H, <sup>13</sup>C]-correlation spectra of [<sup>15</sup>N, <sup>13</sup>C]-labeled *EcRfaH*-KOW in the presence of various  
481 urea concentrations (0 – 8 M) (**Figure 6B,C**). In both spectra series, we observed a decrease in  
482 peak intensity/volume of the  $\beta$ -barrel signals with increasing urea concentration (boxed regions  
483 in **Figure 6B,C**), which is completed at  $\approx$  4 M urea, indicating that the first transition in the far-  
484 UV-based chemical denaturation of *EcRfaH*-KOW (**Figure 3F**) corresponds to the unfolding of  
485 its  $\beta$ -barrel (tertiary) structure. This is also corroborated by near-UV CD spectroscopy-based  
486 chemical denaturation experiments using urea or GdmCl, respectively, (**Figure 6 – Figure**  
487 **supplement 1A, B**), which clearly show that the transition during the titration from 0 to 3 M  
488 urea/1 M GdmCl is accompanied by a loss in tertiary structure. The possibility that the resulting  
489 conformation corresponds an equilibrium molten globule is, however, excluded due to its  
490 inability to bind 8-anilino-1-naphthalenesulfonic acid (ANS, **Figure 6 – Figure supplement**  
491 **1C**).

492 In order to identify signals corresponding to the minor species in the [<sup>1</sup>H, <sup>15</sup>N]- and [<sup>1</sup>H, <sup>13</sup>C]-  
493 correlation spectra of *EcRfaH*-KOW we started with the spectra of the urea-unfolded protein  
494 (8 M urea). We observed that most of the corresponding signals shifted linearly with decreasing  
495 urea concentration and also lost intensity when entering the transition region (< 3 M urea). At  
496 0 M urea, finally, only a set of weak signals remained, which we identified as signals of the  
497 minor species based on their chemical shifts (compare red and grey bars in **Figure 6A**,

498 **top/bottom panels**). The linear transition between the positions of the (urea) unfolded state  
499 towards the positions of the minor species signals suggests that the minor species can be  
500 described as an ensemble of exchanging sub-states, some corresponding to the completely  
501 unfolded state and some exhibiting residual helical structure.

502 The urea-induced chemical shift perturbations experienced by the minor species signals in the  
503 [<sup>1</sup>H, <sup>15</sup>N]-HSQCs are then likely explained by a combination of two effects: (i) change of the  
504 chemical environment due to the presence of urea, which particularly affects  $\delta^1\text{H}$  (see e.g. signal  
505 of L162 in **Figure 6B**) and (ii) change in the relative populations of the minor species' sub-states  
506 towards the unfolded state, which mainly affects  $\Delta\delta^{15}\text{N}$ . Since the H $\alpha$ /C $\alpha$  chemical shifts are  
507 relatively independent of the solvent conditions, their perturbations in the urea denaturation  
508 series (**Figure 6C**) even better reflect the change in the ratio of the minor species' sub-states.  
509 Thus, we conclude that some of the exchanging states of the minor species correspond to a  
510 completely unfolded state, whereas the other sub-species contain ( $\alpha$ -) helical structures in  
511 regions 1 and 2, hereby referred to as  $\alpha$ -helical unfolding intermediate  $U\alpha$ . The shifting of the  
512 minor species' peaks in **Figure 6C** is completed at  $\approx 7$  M urea, implying that the second transition  
513 in the CD-based unfolding experiment (**Figure 4F**) corresponds to the denaturation of  $U\alpha$ .  
514 Interestingly, the  $R_2$  values of residues in region 1 are more than twice as high as those of  
515 residues in region 2 and, in the [<sup>1</sup>H, <sup>15</sup>N]-HSQC-based denaturation experiment (**Figure 6B**), the  
516 minor species' signals of residues in region 1 do not shift in a linear manner as it is typical for  
517 two exchanging states. Instead they show a curved transition that is "kinked" at  $\approx 2$  M urea (see  
518 e.g. T131), implying fast chemical exchange between at least three states. Although our  
519 experiments do not allow a precise structural characterization of all states of the minor species, it  
520 may be described as a structural ensemble of a completely unfolded state and a species that

521 contains  $\alpha$ -helical elements in regions 1 and 2 (i.e.  $U\alpha$ ), with region 1 exhibiting some structural  
522 heterogeneity.

523 Due to the fast chemical exchange between the two exchanging subspecies of *EcRfaH*-KOW's U  
524 and  $U\alpha$  states, their relative population in a certain titration step is encoded in the chemical shift  
525 of the minor species signal, whereas the volume of the minor species peak is proportional to the  
526 sum of the populations of both states (assuming similar transverse relaxation rates for the  
527 species). To first quantify the decay of the all- $\beta$  conformation and the increase of the minor  
528 species during the urea denaturation we analyzed the intensity and peak position of both species  
529 exemplarily for residue S139 in the [ $^1\text{H}$ ,  $^{13}\text{C}$ ]-ctHSQC-based titration (**Figure 6C** and **Figure 6 –**  
530 **Figure supplement 2A**). The resulting  $\Delta G$  value of  $\approx 7$  kJ/mol between the energy levels of  
531 major and minor species agrees well with the results from the CEST (7 kJ/mol). Additionally, the  
532  $m$  value of 3.4 kJ/(mol M) is very similar to the  $m$  values obtained for the other KOW domains  
533 (**Figure 3 – Figure supplement 1**), indicating that the minor species is indeed close to a  
534 completely unfolded state with a small buried surface area and that the stability of the minor  
535 species'  $U\alpha$  state is low.

536 The complete denaturation of the minor species, i. e. the transition of  $U\alpha$  to a fully unfolded  
537 state, can be followed in the [ $^1\text{H}$ ,  $^{13}\text{C}$ ]-ctHSQC-based denaturation experiment by analyzing the  
538 change of the minor state's chemical shift from the position of the more  $\alpha$ -helical conformation  
539 towards that of the completely unfolded state. For example, the  $\text{H}\alpha/\text{C}\alpha$  correlation peaks of  
540 residues A137, S139, or M140 clearly shift from regions typical for  $\alpha$ -helical structures (upfield  
541  $^1\text{H}$ , downfield  $^{13}\text{C}$ ) to positions corresponding to an unstructured conformation (downfield  $^1\text{H}$ ,  
542 upfield  $^{13}\text{C}$ ), and finally they localize next to the signals of the Ala, Ser or Met residues that do

543 not reside in regions with residual helical structure (**Figure 6C**). The chemical shifts of C $\alpha$ /H $\alpha$   
544 groups depend to a much lower extent on the urea concentration in the sample than the chemical  
545 shifts of amide groups and therefore they provide better measures for the exchange between U  
546 and U $\alpha$ . Plotting the changes of the chemical shifts of the C $\alpha$ /H $\alpha$  groups of residues A137, S139  
547 and M140 versus the urea concentration (**Figure 6 – Figure supplement 2B**) results in curves  
548 that resemble the second half of an unfolding transition (U $\alpha$   $\rightleftharpoons$  U) and approach the baseline of  
549 the unfolded state at  $\approx$  6 M urea. The absence of a baseline for U $\alpha$  precludes a quantitative  
550 analysis, but it shows that the transition mid-point of the curve is probably close to or below 0 M  
551 urea, implying that U $\alpha$  is unstable (i.e. higher in energy) relative to the fully unfolded state, and  
552 that U $\alpha$  buries a small amount of surface area (**Figure 3 – Figure supplement 1**).

## 553 Discussion

### 554 Fold-switching is conserved among RfaH proteins

555 Genes coding for RfaH orthologs can be found in many bacterial pathogens, including  
556 *Salmonella*, *Klebsiella*, *Vibrio*, and *Yersinia* spp (Carter et al., 2004). Despite their divergent  
557 evolution, RfaH proteins seem to have a conserved mechanism of action (Carter et al., 2004). To  
558 date only *EcRfaH* was structurally characterized, revealing that this protein has unique structural  
559 features classifying it as transformer protein (Belogurov et al., 2007; Burmann et al., 2012; Zuber  
560 et al., 2019). Here, we show that *VcRfaH*, an evolutionary quite divergent representative sharing  
561 35.8 % sequence identity with *EcRfaH*, exhibits very similar structural properties, i.e. *VcRfaH*-  
562 KOW, like *EcRfaH*-KOW, folds as  $\alpha$ -hairpin in the full-length protein, but adopts a NusG-type  
563  $\beta$ -barrel conformation in its isolated form (**Figure 1**). Interestingly, in *VcRfaH* helix  $\alpha_3^*$  is 1.5  
564 turns longer as compared to *EcRfaH* and *VcRfaH* has a disulfide bridge connecting strand  $\beta_3^*$   
565 and helix  $\alpha_3^*$ , stabilizing this helix. These two features imply a stabilization of the domain  
566 interface and thus an increased affinity between the domains as compared to *EcRfaH*. This might  
567 also explain the increased stability of the isolated *VcRfaH*-KOW domain ( $\approx 14$  kJ/mol), which  
568 compensates the higher energy gain of the domain interaction. Further, the increased stability of  
569 the *VcRfaH*-KOW domain may be the cause for the sigmoid-shaped CD-based chemical  
570 denaturation curves, in agreement with a two-state unfolding process: global unfolding of the  
571 folded state occurs at higher denaturant concentrations, where potential partly structured folding  
572 intermediates are already largely destabilized and therefore escape detection. This conclusion is  
573 supported by the Trp fluorescence-based denaturation data (**Figure 3 – Figure supplement 2**),  
574 suggesting that the change in the CD signal is almost exclusively caused by the decay of the  $\beta$ -  
575 barrel conformation and that the putative contribution of the intermediate state to the change of

576 the CD-signal is negligible. Nevertheless, we conclude that *VcRfaH* may be regulated by fold-  
577 switching just like *EcRfaH*, and that this metamorphic behavior is conserved in the class of RfaH  
578 proteins and may even be found in other NusG paralogs.

579

### 580 **Model for the structural plasticity of RfaH**

581 *EcRfaH* switches the conformation and function of its KOW domain in a reversible manner to  
582 achieve a tight control of gene expression (Zuber et al., 2019). In free *EcRfaH*, the  $\alpha$ -helical  
583 hairpin conformation is the preferred state of *EcRfaH*-KOW, whereas domain separation or  
584 isolation of *EcRfaH*-KOW foster population of the all- $\beta$  state in solution (Burmann et al., 2012),  
585 suggesting that the all- $\alpha$  conformation is intrinsically unstable, but becomes the thermodynamic  
586 minimum in free *EcRfaH* due to interaction with *EcRfaH*-NGN.

587 Interestingly, our thermodynamic analysis (**Figures 2 and 3**) of the isolated *EcRfaH*-KOW  
588 domain reveals that, although the all- $\beta$  conformation is the preferred state in isolation, it is only  
589 marginally stable, and it is in rapid equilibrium with an “unfolded” state, which is populated to a  
590 significant extent, even under physiological conditions. The “unfolded” state is a mixture of  
591 random-coil-type unfolded species and a species containing two helical regions ( $U\alpha$ ).

592 Based on our results, we suggest a model for the structural transitions of *EcRfaH*-KOW (**Figure**  
593 **7**).

594

595

596 **Figure 7.** Model for the conformational plasticity of *EcRfaH-KOW*. Qualitative Gibbs free  
 597 energy level diagram and associated structures for the all- $\alpha$  to all- $\beta$  transition of *EcRfaH-KOW*  
 598 and *vice versa*. In its ground state, i.e. the autoinhibited conformation, the energy of the all- $\alpha$   
 599 conformation of *EcRfaH-KOW* is strongly lowered by the extensive inter-domain contacts with  
 600 the *EcRfaH-NGN* domain. Upon recruitment, the domains dissociate, the helical structure of the  
 601 released KOW domain becomes destabilized in isolation, and rapidly decays towards an  
 602 ensemble of mainly unfolded sub-states that interconvert on the  $\mu$ s time scale. Some of the sub-  
 603 states correspond to the completely unfolded state (U) whereas others retain some residual ( $\alpha$ -)  
 604 helical elements ( $U\alpha$ ). The scheme displays exemplary structures of these sub-states. Due to  
 605 their fast structural interconversion, U and  $U\alpha$  may be grouped into a single macro-  
 606 state/ensemble (as is the case during the CEST experiments) that exhibits helical structures for a  
 607 limited amount of time and is otherwise unfolded.  $U\alpha$  is either marginally stable or even  
 608 unstable (therefore, its energy level is blurred). The disordered conformation then allows for easy  
 609 and rapid refolding to the all- $\beta$  conformation. Due to their low thermodynamic stability, or even  
 610 instability of all- $\beta$  and  $U\alpha$ , respectively, the last two steps are reversible, that is the all- $\alpha$  state  
 611 can be rapidly regained when the *EcRfaH-NGN* domain becomes available for re-association  
 612 after transcription termination.

613

614 In the autoinhibited state the all- $\alpha$  conformation of *EcRfaH-KOW* corresponds to the minimum  
 615 of the Gibbs free energy as it is stabilized by contacts to the *EcRfaH-NGN*. During recruitment  
 616 of *EcRfaH* to an *ops*-paused elongation complex, the *EcRfaH-NGN:KOW* interface is  
 617 destabilized (most probably *via* an encounter complex), the domains dissociate and *EcRfaH-*  
 618 *NGN* is sequestered to RNAP (Zuber et al., 2019). The freed all- $\alpha$  *EcRfaH-KOW* is not stable as

619  $G$  increases due to the loss of *EcRfaH*-NGN contacts. Consequently, *EcRfaH*-KOW unfolds,  
620 resulting in an ensemble of rapidly interconverting sub-states. Some of these sub-states still  
621 contain two residual  $\alpha$ -helical regions (intermediate  $U\alpha$ ) that correspond to the tip of the  $\alpha$ -  
622 hairpin in the all- $\alpha$  state, in agreement with hydrogen/deuterium exchange data, which indicate  
623 that the hairpin-tip is the most stable part of the all- $\alpha$  conformation (Galaz-Davison et al., 2020).  
624 Other sub-states represent the completely unfolded protein, which then rapidly refolds into the  
625 all- $\beta$  form. Upon transcription termination *EcRfaH* is released, and the process is reversed with  
626 unfolding of the  $\beta$ -barrel starting, most probably, by detaching  $\beta_1$  and  $\beta_4/\beta_5$  from the central  
627 strands as the corresponding H-bonds are the least stable ones (Figure 4). The U state is in  
628 equilibrium with  $U\alpha$ , where two  $\alpha$ -helical regions that will later constitute the  $\alpha$ -hairpin tip are  
629 formed transiently and may thus serve both as the nucleation point for the completion of the all-  
630  $\alpha$  structure and as starting point for recognition of its cognate binding site on the NGN. This  
631 mechanism ensures rapid re-autoinhibition and prevents aggregation of *EcRfaH*. Although we  
632 did not analyze *VcRfaH* as extensively as *EcRfaH*, our results suggest that the *VcRfaH*-KOW  
633 domain most likely employs a similar mechanism for its structural transformation, indicating that  
634 the presented model is a general scheme for RfaH proteins.

635 In support of our model, all computational studies on *EcRfaH* found that the all- $\alpha$  conformation  
636 is stable only when in contact with the NGN. Modification of the strength of the *EcRfaH*-  
637 NGN:KOW interface (Ramírez-Sarmiento et al., 2015) or deletion of the linker (Xun et al.,  
638 2016) destabilize the all- $\alpha$  fold and ultimately drive *EcRfaH*-KOW into the  $\beta$ -barrel state.  
639 Moreover, the  $\beta$ -barrel fold is stable and corresponds to or is close to the energy minimum of the  
640 energy landscape of *EcRfaH*-KOW, whereas the all- $\alpha$  fold rapidly unfolds and has a higher  $G$ -  
641 value than the all- $\beta$  state (Balasco et al., 2015; Bernhardt and Hansmann, 2018; Gc et al., 2014;

642 Joseph et al., 2019; Li et al., 2014; Xiong and Liu, 2015). Apart from these general concepts,  
643 most studies differ in several key points, such as the extent to which the all- $\alpha$  state is populated  
644 in the isolated *EcRfaH*-KOW, or the precise folding pathway from all- $\alpha$  to all- $\beta$ . Strikingly, a  
645 recent bioinformatical study very nicely mirrors our data as the authors also observed a  
646 significant portion of transiently formed helical structure within the unfolded state ensemble in  
647 their simulations (Seifi and Wallin, 2021).

648

### 649 **Requirements for fold-switching proteins**

650 Previous work on designed and naturally occurring fold-switching proteins has identified several  
651 specific properties that make fold-switching proteins distinct from others (Bryan and Orban,  
652 2010; Porter and Looger, 2018). In this study, we show that RfaH also meets all these  
653 requirements:

654 (i) Reduced thermodynamic stability (Bryan and Orban, 2010). A diminished stability is both the  
655 result of and key to the function of fold-switching proteins. As the fold-switching sequence must  
656 be compatible with both adopted topologies, it can only be optimized to a certain extent to  
657 stabilize one specific fold, ensuring that both conformations can be interconverted and that the  
658 structure is not “trapped” in one state. This is reflected by a dual-funneled energy landscape with  
659 two main minima, which are, however, not as deep as the global minimum of a stable protein.  
660 Our comprehensive thermodynamic analysis (**Figures 2 and 3**) reveals that the all- $\beta$  fold of both  
661 RfaH-KOWs is indeed less stable than the bacterial and archaeal NusG/Spt5-KOW domains. As  
662 general transcription factors, NusG/Spt5 proteins do not require an as-sophisticated regulation as  
663 RfaH (Artsimovitch and Knauer, 2019) (for hSpt5-KOW5 see below) and thus benefit from a  
664 stable structure to carry out their function.

665 (ii) Generation of new binding surfaces (Bryan and Orban, 2010). The regulation of  
666 conformational transitions in fold-switching proteins is achieved by energetically stabilizing one  
667 of the two conformations in response to a molecular trigger, resulting in a far more dynamic  
668 energy landscape than that of well-folded proteins as the energy level of a particular  
669 conformation strongly depends on the environment. This context-dependent stabilization of one  
670 state is possible because the two different folds exhibit different surface topologies, each  
671 allowing distinct interactions. The ability to selectively hide/expose “latent” binding sites within  
672 different folds is also the most important function of fold-switching in general, as it enables a  
673 level of control that cannot be achieved by other mechanisms. In RfaH, for instance,  
674 autoinhibition is coupled to a conformational switch, preventing off-target recruitment and  
675 interference with NusG (Belogurov et al., 2009).

676 (iii) Unfolded regions in one of the two states (Bryan and Orban, 2010). In RfaH, the all- $\alpha$  KOW  
677 domain contains unstructured N- and C-termini, whereas the corresponding regions form  $\beta$ -  
678 strands  $\beta_1$  and  $\beta_4/\beta_5$  in the all- $\beta$  conformation (**Figure 1B** and **Figure 4C**). These disordered  
679 parts provide an entropic stabilization of the respective state as they do not adopt a defined  
680 structure. A bioinformatic study indicated that these regions of the CTD additionally stabilize the  
681 NGN:KOW interface by forming transient, IDP-like interactions (Xun et al., 2016). We show  
682 that the structural interconversion between the two RfaH states proceeds *via* a chiefly unfolded  
683 intermediate and we propose that the disordered segments may help to facilitate and/or initiate  
684 this transition, similar to the mechanism suggested for the human chemokine XCL1  
685 (lymphotactin) (Tyler et al., 2011). Finally, disordered regions in one state have the advantage  
686 that they can be evolutionary optimized to selectively stabilize one of the two states of a fold-

687 switch pair, whereas there is no need to fit a defined three-dimensional structure in the other  
688 state.

689 (iv) Divergence in predicted and observed secondary structure (Porter and Looger, 2018).  
690 Secondary structure predictions show that both *VcRfaH-KOW* and *EcRfaH-KOW* contain  
691 stretches with high propensity for both  $\beta$ -strands and  $\alpha$ -helical structures (**Figure 5 – Figure**  
692 **supplement 3**), in agreement with other bioinformatical analyses (Balasco et al., 2015).  
693 Interestingly, this tendency is also visible in the isolated KOW domain as the disordered regions  
694 in the all- $\alpha$  fold correspond to the  $\beta$ -strands that are less stable in the RfaH-KOWs as compared  
695 to NusG-KOWs, whereas the helical propensity is reflected in the structure of U $\alpha$ .

696 (v) Cooperatively folding units (Porter and Looger, 2018). The folding cooperativity of *EcRfaH-*  
697 *KOW* depends on the presence of the *EcRfaH-NGN*, i.e. in the absence of *EcRfaH-NGN*  
698 *EcRfaH-KOW* folds cooperatively on its own. However, the cooperativity is generally rather low  
699 and the activation barrier separating the “unfolded” and the folded states is small, allowing fast  
700 transitions.

701  
702 Fold-switching is a highly efficient principle of regulation with a steadily increasing importance.  
703 To date about six fold-switching proteins have been studied in detail (summarized in refs.  
704 (Dishman and Volkman, 2018; Lella and Mahalakshmi, 2017; Zamora-Carreras et al., 2020)),  
705 but estimates suggest that up to 4 % of the proteins in the PDB may have the ability to switch  
706 folds (Porter and Looger, 2018). Our study demonstrates which molecular mechanisms confer  
707 RfaH its structural plasticity that allows operon-specific regulation without competing with its  
708 monomorphic paralog NusG/Spt5. In line with our findings, a recent study on XCL1, another

709 model system for fold-switching proteins, identified very similar principles for the evolution and  
710 design of fold-switching proteins (Dishman et al., 2021).

711

### 712 **Importance of a chiefly unfolded state in protein fold-switching**

713 In summary, our results highlight two key features in protein fold-switching: decreased  
714 thermodynamic stability and defined local structures in “unfolded” intermediates. Diminished  
715 stability is often thought to be detrimental for proteins as it favors non-native contacts and  
716 promotes aggregation. However, it is essential to confer fold-switching proteins their  
717 conformational plasticity, and, as all transitions from and to the unfolded states are very fast, and  
718 the population of these states is rather low, fold-switchers can evade aggregation. Further, the  
719 capability of the “unfolded” state to harbor residual defined structures, e.g.  $\alpha$ -helices, allows to  
720 pre-encode a second conformation that could be readily adopted upon a molecular signal.

721 **Materials and Methods**

722

723 **Cloning**

724 The *VcRfaH* expression vector pVS13 (*V. cholerae rfaH* from pH301 (Carter et al., 2004) in  
725 plasmid pTYB1 (NEB)) was a gift from I. Artsimovitch, The Ohio State University, Columbus,  
726 OH. The C-terminal *VcRfaH* residue, Thr165, is substituted by an Ala to ensure efficient  
727 cleavage of the resulting chitin binding domain (CBD) intein fusion protein (see below).  
728 Expression plasmids for *VcRfaH*-KOW (residues E103-T165), hSpt5-KOW5 (residues G699-  
729 G754), and *MjSpt5*-KOW (residues K83-D147) were created by cloning of the corresponding  
730 gene regions into vector pETGb1a (G. Stier, EMBL, Heidelberg, Germany) via *NcoI* and *BamHI*  
731 (*VcRfaH*-KOW), or *NcoI* and *EcoRI* (hSpt5-KOW5 and *MjSpt5*-KOW) restriction sites,  
732 respectively. Templates for PCR amplification were plasmids pH301 (Carter et al., 2004) for  
733 *VcRfaH*-KOW, pOTB7\_huSUPT5H (Zuber et al., 2018) for hSpt5-KOW5, and pGEX-  
734 2TK\_ *MjSpt5*-KOW ((Hirtreiter et al., 2010); kindly provided by F. Werner, University College  
735 London, UK) for *MjSpt5*-KOW. The primers used for cloning are listed in **Table 1**. All plasmids  
736 used in this study are listed in **Table 2**.

737 **Table 1.** Primers used for cloning.

| Primer                 | Sequence (5' → 3')                                    |

742

### 743 **Production of recombinant proteins**

744 *VcRfaH* was obtained from a CBD intein fusion protein encoded in plasmid pVS13, with  
 745 expression conditions and purification strategy as described for *E. coli* RfaH (Vassilyeva et al.,  
 746 2006). *EcNusG*-KOW and *MtNusG*-KOW were produced as previously described (Burmam et  
 747 al., 2010; Strauß et al., 2016). *MjSpt5*-KOW, hSpt5-KOW5, *EcRfaH*-KOW, and *VcRfaH*-KOW  
 748 were obtained from Gb1 fusions with expression and purification conditions similar to that of  
 749 *EcRfaH*-KOW (Burmam et al., 2012).

750 The quality of all recombinantly produced proteins was ensured according to the guidelines  
 751 established by ARBRE-MOBIEU and P4EU ([https://arbre-mobieu.eu/guidelines-on-protein-](https://arbre-mobieu.eu/guidelines-on-protein-quality-control/)  
 752 [quality-control/](https://arbre-mobieu.eu/guidelines-on-protein-quality-control/)) (de Marco et al., 2021). In brief, purity was checked by sodium dodecyl sulfate  
 753 polyacrylamide gel electrophoresis, the absence of nucleic acids by UV spectroscopy, the  
 754 identity by mass spectrometry and/or NMR spectroscopy, the folding state by CD and/or NMR  
 755 spectroscopy, and the absence of aggregation by analytical gel filtration or dynamic light  
 756 scattering.

757 **Isotopic labeling of proteins**

758 For the production of  $^{15}\text{N}$ - and  $^{15}\text{N}$ ,  $^{13}\text{C}$ -labelled proteins, *E. coli* cells were grown in M9  
759 medium (Green et al., 2012; Meyer and Schlegel, 1983) containing  $(^{15}\text{NH}_4)_2\text{SO}_4$  (Sigma/Merck  
760 KGaA, Darmstadt, Germany) or  $(^{15}\text{NH}_4)_2\text{SO}_4$  and  $^{13}\text{C}$ -D-glucose (Euriso-Top GmbH,  
761 Saarbrücken, Germany), respectively, as sole nitrogen or carbon sources. Deuteration was  
762 achieved by accustoming cells to M9 medium prepared with increasing concentrations of  $\text{D}_2\text{O}$   
763 (0 %, 50 %, 100 % (v/v); Euriso-Top GmbH, Saarbrücken, Germany). Expression and  
764 purification protocols were identical to those of the unlabeled proteins.

765

766 **NMR spectroscopy**

767 NMR experiments were conducted at Bruker Avance 600, Avance 700, Ascend Aeon 900, and  
768 Ascend Aeon 1000 spectrometers, each equipped with room temperature (Avance 600) or  
769 cryogenically cooled, inverse  $^1\text{H}$ ,  $^{13}\text{C}$ ,  $^{15}\text{N}$  triple resonance probes (all other spectrometers). All  
770 measurements were conducted in 5 mm tubes with a sample volume of 550  $\mu\text{l}$  at 25  $^\circ\text{C}$ , if not  
771 stated otherwise. NMR data was processed using in-house software and analyzed using  
772 NMRViewJ (OneMoon Scientific).

773 Backbone resonance assignments for *VcRfaH*, *VcRfaH-KOW*, *hSpt5-KOW5*, *MjSpt5-KOW*, and  
774 urea-unfolded *EcRfaH-KOW* were obtained using standard band-selective excitation short  
775 transient (BEST) (Lescop et al., 2007; Schanda et al., 2006) Transverse Relaxation Optimized  
776 Spectroscopy (TROSY)-based triple resonance experiments (Pervushin et al., 1997; Salzmann et  
777 al., 1998). Additionally, carbon-detected CACO, CAN, and NCO experiments (Bermel et al.,  
778 2005) were recorded for *VcRfaH-KOW*. Side chain assignments for *VcRfaH-KOW* were  
779 obtained from CCH- and H(C)CH-TOCSY, HBHA(CO)NH, C(CO)NH, aromatic [ $^1\text{H}$ ,  $^{13}\text{C}$ ]-

780 HSQC and  $^{13}\text{C}$ -edited aromatic Nuclear Overhauser Enhancement Spectroscopy (NOESY)  
781 experiments (Sattler et al., 1999). Three-dimensional assignment and NOESY experiments were  
782 acquired using a Non-Uniform Sampling scheme with a sparsity of 25 - 50 %. Spectra were  
783 subsequently reconstructed with in-house written software using the iterative soft thresholding  
784 algorithm (Hyberts et al., 2012). The *EcRfaH*-KOW, *VcRfaH*-KOW, *hSpt5*-KOW5 and *MjSpt5*-  
785 KOW samples contained 0.5 – 1 mM [ $^{15}\text{N}$ ,  $^{13}\text{C}$ ]-labeled protein in 20 mM Na-phosphate  
786 (pH 6.5), 100 mM NaCl, 1 mM Ethylenediaminetetraacetic acid (EDTA), 10 % (v/v)  $\text{D}_2\text{O}$ . The  
787 *EcRfaH*-KOW sample further contained 6 M urea. Due to limited sample stability and poor  
788 quality of the initial spectra, *VcRfaH* (0.3 mM) was [ $^2\text{H}$ ,  $^{15}\text{N}$ ,  $^{13}\text{C}$ ]-labeled and in an optimized  
789 buffer (25 mM Bis-Tris-Propane (pH 6.5), 25 mM Na-Tartrate, 50 mM NaCl, 10 % (v/v)  $\text{D}_2\text{O}$ )  
790 and the measurements were conducted at 20 °C. The  $\text{C}\alpha$  and CO secondary chemical shift for  
791 *VcRfaH* was calculated as difference between the observed chemical shift and the predicted  
792 random coil value (Wishart and Sykes, 1994) using a deuterium correction as given in (Venters  
793 et al., 1996). Chemical shift assignments for *EcNusG*-KOW, *MtNusG*-KOW and native *EcRfaH*-  
794 KOW were taken from previous studies (Burmam et al., 2012; Mooney et al., 2009; Strauß et  
795 al., 2016). The random coil chemical shifts for characterization of the minor species in case of  
796 *VcRfaH*-KOW and *hSpt5*-KOW were calculated using the Poulsen IDP/IUP random coil  
797 chemical shifts calculator tool ([https://spin.niddk.nih.gov/bax/nmrserver/Poulsen\\_rc\\_CS/](https://spin.niddk.nih.gov/bax/nmrserver/Poulsen_rc_CS/)).

798  
799 Distance restraints for the structure calculation of *VcRfaH*-KOW were obtained from standard  
800  $^{13}\text{C}$ - , and  $^{15}\text{N}$ -edited 3D NOESY experiments (Sattler et al., 1999) with mixing times of 120 ms.  
801 NOESY cross signals were classified according to their intensities and converted to distance  
802 restraints with upper limits of 3 Å (strong), 4 Å (medium), 5 Å (weak) and 6 Å (very weak),

803 respectively. Hydrogen bonds were identified from corresponding experiments (see below).  
804 Psi/Phi angle restraints were obtained from the geometry dependence of the backbone chemical  
805 shifts using TALOS (Cornilescu et al., 1999). The structure calculation was performed with  
806 XPLOR-NIH version 2.1.2 using a three-stage simulated annealing protocol with floating  
807 assignment of prochiral groups including a conformational database potential (Schwieters et al.,  
808 2003). Structures were analyzed with XPLOR-NIH and PROCHECK-NMR (Laskowski et al.,  
809 1996).

810  $^{15}\text{N}$ -based CEST experiments were conducted according to (Vallurupalli et al., 2012). All  
811 samples contained  $\approx 0.7 - 1$  mM  $^{15}\text{N}$ -labeled protein. For initial CEST experiments, the domains  
812 were in 20 mM HEPES (pH 7.5), 100 mM NaCl, 10 % (v/v)  $\text{D}_2\text{O}$  and a single CEST  $B_1$  field ( $\nu_1$   
813 = 18 - 25 Hz) during an exchange period of 500 ms was employed. Proteins showing an  
814 exchange peak in their CEST profiles were further studied in 20 mM Na-phosphate (pH 6.5),  
815 100 mM NaCl, 1 mM EDTA, 10 % (v/v)  $\text{D}_2\text{O}$  to decrease amide proton- $\text{H}_2\text{O}$  exchange. CEST  
816 experiments were then recorded using two different  $B_1$  fields ( $\nu_1 = 13$  Hz/26 Hz) and an  
817 exchange period of 500 ms. The  $B_1$  frequencies were calibrated using a 1D approach on an  
818 isolated signal (Guenneugues et al., 1999). The CEST traces obtained at 13/26 Hz were fitted  
819 simultaneously according to a two-state exchange model using ChemEx (version 0.6.1,  
820 (Vallurupalli et al., 2012)). Due to the monodisperse distribution of the resulting  $k_{\text{ex}}/p_{\text{B}}$  values  
821 (**Figure 5 – Figure supplement 1**), the CEST traces were then fitted globally, yielding a global  
822  $k_{\text{ex}}$  and  $p_{\text{B}}$  value. Only those CEST profiles were included in the global fit that showed a  $\Delta\omega >$   
823 1 ppm.  $^{13}\text{C}\alpha$ -CEST experiments for *EcRfaH-KOW* were recorded on a [ $^{15}\text{N}$ ,  $^{13}\text{C}$ ]-labeled protein  
824 sample using a [ $^1\text{H}$ ,  $^{13}\text{C}$ ] constant-time (ct) HSQC based approach (Bouvignies et al., 2014). To  
825 maximize the number of analyzable signals, the protein was in 20 mM Na-phosphate (pH 6.5),

826 100 mM NaCl, 1 mM EDTA, 99.9 % (v/v) D<sub>2</sub>O (pH uncorrected for D<sub>2</sub>O). In this case, the  
827 chemical shift was referenced *via* 0.5 mM internal DSS. The experiment was performed at a  
828 single B<sub>1</sub> field strength (25 Hz) at an exchange period of 500 ms. The obtained CEST traces were  
829 fitted with ChemEx keeping  $p_B$  constant at 5.5 %.

830 NMR-based chemical denaturation experiments of the KOW domains were done by recording  
831 [<sup>1</sup>H, <sup>15</sup>N]-HSQC and [<sup>1</sup>H, <sup>13</sup>C]-ctHSQC spectra of 80 μM [<sup>15</sup>N, <sup>13</sup>C]-*EcRfaH*-KOW in 20 mM  
832 Na-phosphate (pH 6.5), 100 mM NaCl, 1 mM EDTA, 10 % (v/v) D<sub>2</sub>O buffer containing 0 – 8 M  
833 urea. The chemical shifts were referenced to 0.5 mM internal DSS.

834 For the NMR-based refolding experiment of *VcRfaH* under reducing conditions a [<sup>1</sup>H, <sup>15</sup>N]-  
835 HSQC spectrum of <sup>15</sup>N-*VcRfaH* in refolding buffer (50 mM Na-phosphate (pH 6.5), 50 mM  
836 NaCl, 2 mM DTT) was recorded before the protein was incubated in refolding buffer containing  
837 8 M urea for 24 hours. Having recorded another [<sup>1</sup>H, <sup>15</sup>N]-HSQC spectrum urea was removed by  
838 stepwise dialysis against 4 l of refolding buffer containing 4 M, 2 M, 1 M, 0.5 M, and 0 M urea,  
839 respectively (2-4 hours for the first four steps and overnight for the last step). Finally, a  
840 [<sup>1</sup>H, <sup>15</sup>N]-HSQC spectrum of the refolded protein was recorded.

841 Hydrogen bonds were identified from 2D or 3D long range (LR) TROSY based HNC  
842 experiments as previously described (Cordier et al., 2008). All samples contained [<sup>15</sup>N, <sup>13</sup>C]-  
843 labeled proteins at 0.7 – 1 mM in 20 mM Na-phosphate (pH 6.5), 100 mM NaCl, 1 mM EDTA,  
844 10 % (v/v) D<sub>2</sub>O.

845

846

847

848

849 **CD spectroscopy**

850 CD data were collected at a Jasco J-1100 spectrometer (Jasco Deutschland GmbH, Pfungstadt,  
851 Germany), using quartz cuvettes (Hellma GmbH & Co. KG, Müllheim, Germany). CD spectra  
852 were normalized (**Equation 1**) to obtain the mean residue-weighted ellipticity ( $\Theta_{MRW}$ ):

$$\Theta_{MRW} = \frac{100 \cdot \theta}{N \cdot c \cdot d} \quad (1)$$

853  $\theta$  is the ellipticity in mdeg,  $N$  the number of amino acids,  $c$  the protein concentration in mM, and  
854  $d$  the pathlength of the cuvette in cm.

855 Thermal unfolding and refolding curves were obtained by measuring the CD signal of 15  $\mu$ M  
856 ( $\approx 0.1$  mg/ml) protein buffered by either 10 mM K-phosphate (pH 7.0) or 10 mM K-acetate  
857 (pH 4.0), respectively, in a 1 cm quartz cuvette upon heating to 95 °C and subsequently re-  
858 cooling to the initial temperature. The scan speed was 1 °C/min, the dwell time 1 min, and the  
859 integration time 4 s. Checking the reversibility of thermal unfolding and determination of the  
860 wavelength used for temperature transition curves was done by recording far-UV CD spectra at  
861 25 °C, then 95 °C, and after subsequent re-cooling to 25 °C in a 2 mm pathlength cuvette using  
862 25  $\mu$ M protein solutions in either 10 mM K-phosphate (pH 7.0) or 10 mM K-acetate (pH 4.0).

863

864 Changes in ellipticity ( $\theta$ ) upon thermal unfolding were analyzed with a two-state model using  
865 Fit-o-Mat version 0.752 (Möglich, 2018) to obtain the melting temperature ( $T_m$ ) and enthalpy  
866 change at  $T_m$  ( $\Delta H_u(T_m)$ ) of the transition (both fit parameters) (**Equation 2**):

867

$$\theta = f_N \cdot (y_N + m_N \cdot (T - T_m)) + (1 - f_N) \cdot (y_U + m_U \cdot (T - T_m)) \quad (2)$$

868

869 with  $T$  being the absolute temperature in K,  $y_N$  and  $y_U$  the y-intercepts, and  $m_N$  and  $m_U$  the slopes  
870 of the N- and U-state baselines, respectively.  $f_N$  is the fraction of folded molecules, which is  
871 related to the equilibrium constant  $K_u$  according to **Equation 3**:

872

$$f_N = \frac{1}{1 + K_u} \quad (3)$$

873

874 Finally,  $K_u$  is related to the change in Gibb's free energy of the unfolding reaction ( $\Delta G_u$ ) and  
875  $\Delta H_u(T_m)$  by **Equation 4**:

876

$$K_u = e^{-\Delta G_u/(RT)} \quad \text{with} \quad \Delta G_u = \Delta H_u(T_m) - \frac{T}{T_m} \cdot \Delta H_u(T_m) \quad (4)$$

877

878  $R$  is the ideal gas constant.

879

880 CD-based chemical equilibrium unfolding experiments were performed at 25 °C. Urea  
881 (BioScience Grade;  $\approx 10$  M) and GdmCl ( $\approx 8$  M; both from Carl Roth GmbH & Co. KG,  
882 Karlsruhe, Germany) stock solutions were prepared according to (Pace et al., 1990). Far-UV CD  
883 unfolding experiments were conducted using a 1 mm cuvette. All points of the unfolding curves  
884 were obtained from individual samples, each containing 40 - 60  $\mu$ M ( $\approx 0.25 - 0.4$  mg/ml) protein  
885 in either 10 mM K-phosphate (pH 7.0) or 10 mM K-acetate (pH 4.0), respectively. All samples  
886 were equilibrated over-night. The denaturant concentration of each sample was determined  
887 refractrometrically after CD data acquisition. Unfolding curves that indicate a two-state

888 transition were analyzed using the linear extrapolation method (Santoro and Bolen, 1988) with  
889 Fit-o-Mat version 0.752 (Möglich, 2018) to obtain  $\Delta G_u(\text{H}_2\text{O})$  and the  $m$ -value (**Equation 5**):

890

$$S = f_N \cdot (y_N + m_N \cdot [\text{denat}]) + (1 - f_N) \cdot (y_U + m_U \cdot [\text{denat}]) \quad (5)$$

891

892  $S$  is the signal derived from far-UV CD spectroscopy (i.e. the  $\Theta_{\text{MRW}}$ -value), intrinsic Trp  
893 fluorescence (for *VcRfaH*-CTD), or the normalized peak volumes of the [ $^1\text{H}$ ,  $^{13}\text{C}$ ]-ctHSQC  
894 major/minor species signals for *EcRfaH*-KOW residue S139, respectively. [denat] is the  
895 denaturant (i.e. urea or GdmCl) concentration in M,  $y_N$  and  $y_U$  are the y-intercepts, and  $m_N$  and  
896  $m_U$ , the slopes of the N- and U-state baselines, respectively.  $f_N$  is given by **Equation 3**. In this  
897 case,  $K_u$  is defined as (**Equation 6**):

898

$$K_u = e^{-\Delta G/(RT)} \quad \text{with} \quad \Delta G = \Delta G(\text{H}_2\text{O}) - m \cdot [\text{denat}] \quad (6)$$

899

900 Finally, the [denat] $_{1/2}$  value is obtained by (**Equation 7**):

901

$$[\text{denat}]_{1/2} = \frac{\Delta G(\text{H}_2\text{O})}{m} \quad (7)$$

902

903 Near-UV CD unfolding experiments of *EcRfaH*-KOW were conducted using a 1 cm quartz  
904 cuvette and 0.5 mM protein in 10 mM K-phosphate (pH 7.0). As the exchange between folded  
905 and unfolded state is reasonably fast ( $k_{\text{ex}} \approx 15 \text{ s}^{-1}$  at 0 M urea/GdmCl), all points were obtained  
906 from a titration of the initial denaturant-free protein sample with a 10 M urea or 8 M GdmCl

907 solution in 10 mM K-phosphate (pH 7.0). The sample was then incubated for 5 min at 25 °C to  
908 reach equilibrium. Curves were smoothed mathematically using a Savitzky-Golay filter.  
909 To probe reversibility of chemical unfolding and validate incubation times used to reach  
910 equilibrium, proteins were dialyzed against 20 mM  $\text{NH}_4\text{HCO}_3$  (pH 7.0) buffer, shock-frozen,  
911 lyophilized and subsequently solved in 10 mM K-phosphate (pH 7.0) or 10 mM K-acetate  
912 (pH 4.0) with or without 10 M urea/8 M GdmCl, respectively. CD samples containing the  
913 identical denaturant concentration (1–2 samples in pre-transition region, 1 at  $[\text{denaturant}]_{1/2}$ , 1 in  
914 post-transition region) were then prepared from the native or unfolded proteins. All samples were  
915 equilibrated over-night; far-UV CD spectra were then recorded using a 1 mm quartz cuvette.

916

### 917 **Fluorescence spectroscopy**

918 Fluorescence spectra were recorded at 25 °C using a Peltier-controlled Fluorolog-3 fluorimeter  
919 (Horiba Europe GmbH, Oberursel, Germany) equipped with a 1 cm quartz cuvette (Hellma  
920 GmbH & Co. KG, Müllheim, Germany). Samples for chemical denaturation of *VcRfaH-KOW*  
921 contained  $\approx 11 \mu\text{M}$  protein and were prepared as described for the far-UV CD samples. The  
922 *VcRfaH-KOW* Trp residue was excited at 295 nm; emission spectra were then recorded from 300  
923 to 400 nm with slit widths between 2.65/2.65 nm and 2.8/2.8 nm (excitation/emission) and an  
924 integration time of 0.2 s. Analysis of the resulting denaturation curve was performed as described  
925 for CD data.

926 ANS (Sigma/Merck KGaA, Darmstadt, Germany) interaction experiments were conducted by  
927 preparing a urea denaturation series of *EcRfaH-KOW* (final concentration: 5  $\mu\text{M}$ ) as described  
928 for the CD-based unfolding experiments, equilibrating over-night and adding ANS at a  
929 fluorophore:protein ratio of 100:1. Fluorescence spectra were then recorded from 410 to 650 nm

930 following excitation at 395 nm with slit widths of 2.6/2.6 nm (excitation/emission) and 0.1 s  
931 integration time. A control experiment was conducted with identical experiment and instrument  
932 setup, respectively, but samples lacking protein. The obtained fluorescence at a given  
933 wavelength was then plotted against the urea concentration of the respective sample.

934

### 935 **DSC**

936 The KOW domains were in either 10 mM K-acetate (pH 4.0; hSpt5-KOW5) or 10 mM K-  
937 phosphate (pH 7.0; all other domains), respectively. Given a lack of Trp residues in most  
938 domains, the protein concentration was determined *via* absorption at 205 nm using the molar  
939 extinction coefficient ( $\epsilon_{205}$ ) as calculated by the Protein Calculator tool (Anthis and Clore, 2013).

940 Initial DSC experiments were carried out on a MicroCal VP-DSC instrument (MicroCal/Malvern  
941 Panalytical, Malvern, UK; active volume: 509  $\mu$ l). The samples were vacuum degassed at room  
942 temperature just before the measurements. Prior to the protein-buffer scans, several buffer-buffer  
943 scans were performed. All thermograms were recorded at a scan rate of 1.5 K/min under an  
944 excess pressure of 30 psi in passive feed-back mode from  $\approx 10$  °C to 110 °C or 130 °C (*MjSpt5*-  
945 KOW5), respectively. The unfolding was calorimetrically reversible for *EcNusG*-KOW, *MtNusG*-  
946 KOW, *MjSpt5*-KOW and *EcRfaH*-KOW (data not shown). hSpt5-KOW5 aggregated at pH 7.0  
947 upon unfolding at all tested concentrations, whereas *VcRfaH*-KOW aggregated at concentrations  
948  $> 0.2$  mg/ml.

949 We repeated the measurements for all proteins but *MtNusG*-KOW using a MicroCal VP-  
950 Capillary DSC instrument (Malvern Panalytical, Malvern, UK; active volume 137  $\mu$ l). The  
951 thermograms were obtained at a heating rate of 1.5 K/min with excess pressure (30 psi) and at  
952 mid gain feed-back mode. Buffer-buffer runs were done prior to the protein measurements.

953 Thermograms were recorded from  $\approx 5$  °C to 130 °C. The protein concentration was 0.2 –  
954 1 mg/ml for *EcNusG*-KOW, 0.25 – 1 mg/ml for *MjSpt5*-KOW, 0.15 – 0.25 mg/ml for hSpt5-  
955 KOW5, 0.2 – 1 mg/ml for *EcRfaH*-KOW and 0.1 – 0.15 mg/ml for *VcRfaH*-KOW. The  
956 measurement for hSpt5-KOW5 was carried out with 10 mM K-acetate (pH 4.0), all other KOW  
957 domains were in 10 mM K-phosphate (pH 7.0).  
958 The obtained raw DSC data (VP-DSC data for *MtNusG*-KOW, VP-Capillary DSC data for all  
959 other KOW domains) was scan-rate normalized, the corresponding buffer-buffer baseline was  
960 subtracted, and the thermograms were then normalized to one mol of protein. To extract the  
961 thermodynamic parameters, the data was fitted to a two-state unfolding model including a  
962 temperature-dependent change in heat capacity from native to unfolded state (Viguera et al.,  
963 1994). The temperature dependence of the native state heat capacity ( $C_{p,0}$ ) is assumed to be linear  
964 (**Equation 8**; note that  $C_{p,0}$  contains an instrument-specific offset), whereas the difference in heat  
965 capacity to the unfolded state ( $\Delta C_{p,u}(T)$ ) is approximated by a parabolic function (**Equation 9**):

966

$$C_{p,0} = a_0 + b_0 \cdot T \quad (8)$$

$$\Delta C_{p,u}(T) = a + b \cdot T + c \cdot T^2 \quad (9)$$

967 The value for the pre-factor of the quadratic term,  $c$ , was obtained by calculating the theoretical  
968 partial molar heat capacity,  $C_p(T)$ , of the unfolded state for each of the six protein domains at 5,  
969 25, 50, 75, 100 and 125 °C, respectively, according to Makhatadze and Privalov (Makhatadze  
970 and Privalov, 1990). Then, the values for  $C_p(T)$  were plotted over the temperature and a parabolic  
971 function was fitted, yielding  $c$ .  
972 The concentration-normalized heat capacity ( $C_p$ ) then is the sum of  $C_{p,0}$ , the change of the  
973 “internal” heat capacity that depends on the fraction of the protein in the folded and unfolded

974 state (i.e. the equilibrium constant  $K_u$ ),  $\delta C_p^{\text{int}}$ , and the excess heat absorption of the unfolding  
975 reaction  $\delta C_p^{\text{exc}}$  (**Equation 10**):

$$C_p = C_{p,0} + \delta C_p^{\text{int}} + \delta C_p^{\text{exc}} \quad (10)$$

976

977 With  $\delta C_p^{\text{int}}$  and  $\delta C_p^{\text{exc}}$  given in **Equation 11**:

978

$$\delta C_p^{\text{int}} = \Delta C_{p,u} \cdot \frac{K_u}{1 + K_u} \quad \text{and} \quad \delta C_p^{\text{exc}} = \frac{(\Delta H_u(T))^2}{RT^2} \cdot \frac{K_u}{(1 + K_u)^2} \quad (11)$$

979

980  $K_u$  is related to the change in Gibbs energy of the unfolding reaction ( $\Delta G_u(T)$ ) by (**Equation 12**):

981

$$K_u = e^{-\Delta G_u(T)/(RT)} \quad \text{with} \quad \Delta G_u(T) = \Delta H_u(T) - T \cdot \Delta S_u(T) \quad (12)$$

982

983 The temperature-dependent enthalpy and entropy change ( $\Delta H_u(T)$ , and  $\Delta S_u(T)$ , respectively) are

984 given by **Equations 13** and **14**:

985

$$\Delta H_u(T) = \Delta H_u(T_m) + a \cdot (T - T_m) + \frac{b}{2} \cdot (T^2 - T_m^2) + \frac{c}{3} \cdot (T^3 - T_m^3) \quad (13)$$

$$\Delta S_u(T) = \frac{\Delta H_u(T_m)}{T_m} + a \cdot \ln\left(\frac{T}{T_m}\right) + b \cdot (T - T_m) + \frac{c}{2} \cdot (T^2 - T_m^2) \quad (14)$$

986

987 During fitting of  $C_p$ , parameters  $a_0$ ,  $b_0$ ,  $a$ ,  $b$ ,  $T_m$  and  $\Delta H_u(T_m)$  were allowed to float, while  $c$  was

988 kept constant.

989

990 **Acknowledgments**

991  
992 We thank I. Artsimovitch for providing pVS13 and F. Werner for providing pGEX-  
993 2TK\_MjSpt5-KOW. Our sincere thanks go to F.X. Schmid for detailed discussions and valuable  
994 comments on the manuscript. We also thank A. Matagne and Birgitta M Wöhrl for helpful  
995 discussions, C. M. Johnson for performing DSC measurements, A. Häussermann for carrying out  
996 the NMR-based refolding experiment of VcRfaH, and A. Hager for technical support, as well as  
997 the Northern Bavarian NMR Centre (NBNC) for providing access to NMR spectrometers. The  
998 project was supported by the German Research Foundation grant Ro617/21-1 (to P. Rösch) and  
999 COST action CA 15126 ARBRE-MOBIEU (to PKZ, TD, SHK).

1000  
1001 **Author contributions:** SHK and PKZ conceived the project and designed the experiments. SHK  
1002 supervised the study. UP, RH and PKZ cloned, expressed and purified the constructs. KS, SHK,  
1003 and PKZ performed and analyzed the NMR experiments. PKZ determined the structure of  
1004 VcRfaH-KOW. PKZ performed the CD and fluorescence experiments. DSC measurements were  
1005 carried out by TD and PKZ. Analysis and interpretation of CD, fluorescence and DSC data was  
1006 done by PKZ. The manuscript was prepared by PKZ and SHK with input of TD and KS.

1007  
1008 **Competing interests:** The authors declare that they have no competing interests.

1009  
1010 **Data and materials availability:** Coordinates for VcRfaH-KOW have been deposited to the  
1011 Protein Databank (ID: 6TF4). Chemical shifts have been deposited in the Biological Magnetic  
1012 Resonance Databank under the following accession numbers: #28039 (hSpt5-KOW5), #28040

1013 (*MjSpt5*-KOW), #28041 (*VcRfaH*) and #34450 (*VcRfaH*-CTD). All other data needed to  
1014 evaluate the conclusions in the paper are present in the paper, in the Supplemental Material,  
1015 and/or as source data. Plasmids may be requested from the authors (a material transfer agreement  
1016 is required).

1242 **Supplemental Material**

1243

1244

1245 **Figure 1 – Figure supplement 1.** Disulfide bridge formation in *VcRfaH*. (A) Strips of the  
1246 HNCACB experiment corresponding to *VcRfaH* residues C34 and C102, respectively. Signals  
1247 arising from the cystein's  $\text{C}\alpha$  and  $\text{C}\beta$  carbons (indicative of a cysteine in a disulfide-bridge) are  
1248 labeled. (B)  $[\text{H}, \text{N}]\text{-HSQC}$  spectra of  $[\text{H}, \text{C}, \text{N}]\text{-VcRfaH}$  in the absence (black) or presence

1249 (red) of 20 mM DTT. Signals of the two disulfide bridge forming residues, C34 and C102, and  
1250 their sequential neighbors are labeled. (C) Refolding of *VcRfaH* under reducing conditions. [<sup>1</sup>H,  
1251 <sup>15</sup>N]-HSQC spectra of 150 μM <sup>15</sup>N-*VcRfaH* (black), 39 μM <sup>15</sup>N-*VcRfaH* after incubation in the  
1252 presence of 8 M urea for 24 hours (red), and 40 μM <sup>15</sup>N-*VcRfaH* upon refolding (cyan).  
1253

1254 **Figure 1 – Figure supplement 2.** Solution structure statistics for VcRfaH-KOW.

1255 \* The precision of the coordinates is defined as the average atomic root mean square difference between the accepted simulated annealing  
1256 structures and the corresponding mean structure calculated for the given sequence region.

1257 † calculated for residues 116 - 165

1258 ‡ Ramachandran plot statistics are determined by PROCHECK and noted by most favored/ additionally allowed/generously  
1259 allowed/disallowed.

1260

1261 **Figure 1 – Figure supplement 3.** Structure comparison of KOW domains used in this study. (A)

1262 Structure-based sequence alignment of the KOW constructs used in this study. Highly conserved

1263 residues are highlighted in green, residues that differ among NusG-KOW/Spt5-KOW and RfaH-

1264 KOW domains are colored red. (B) Structures of the six KOW domains shown in cartoon

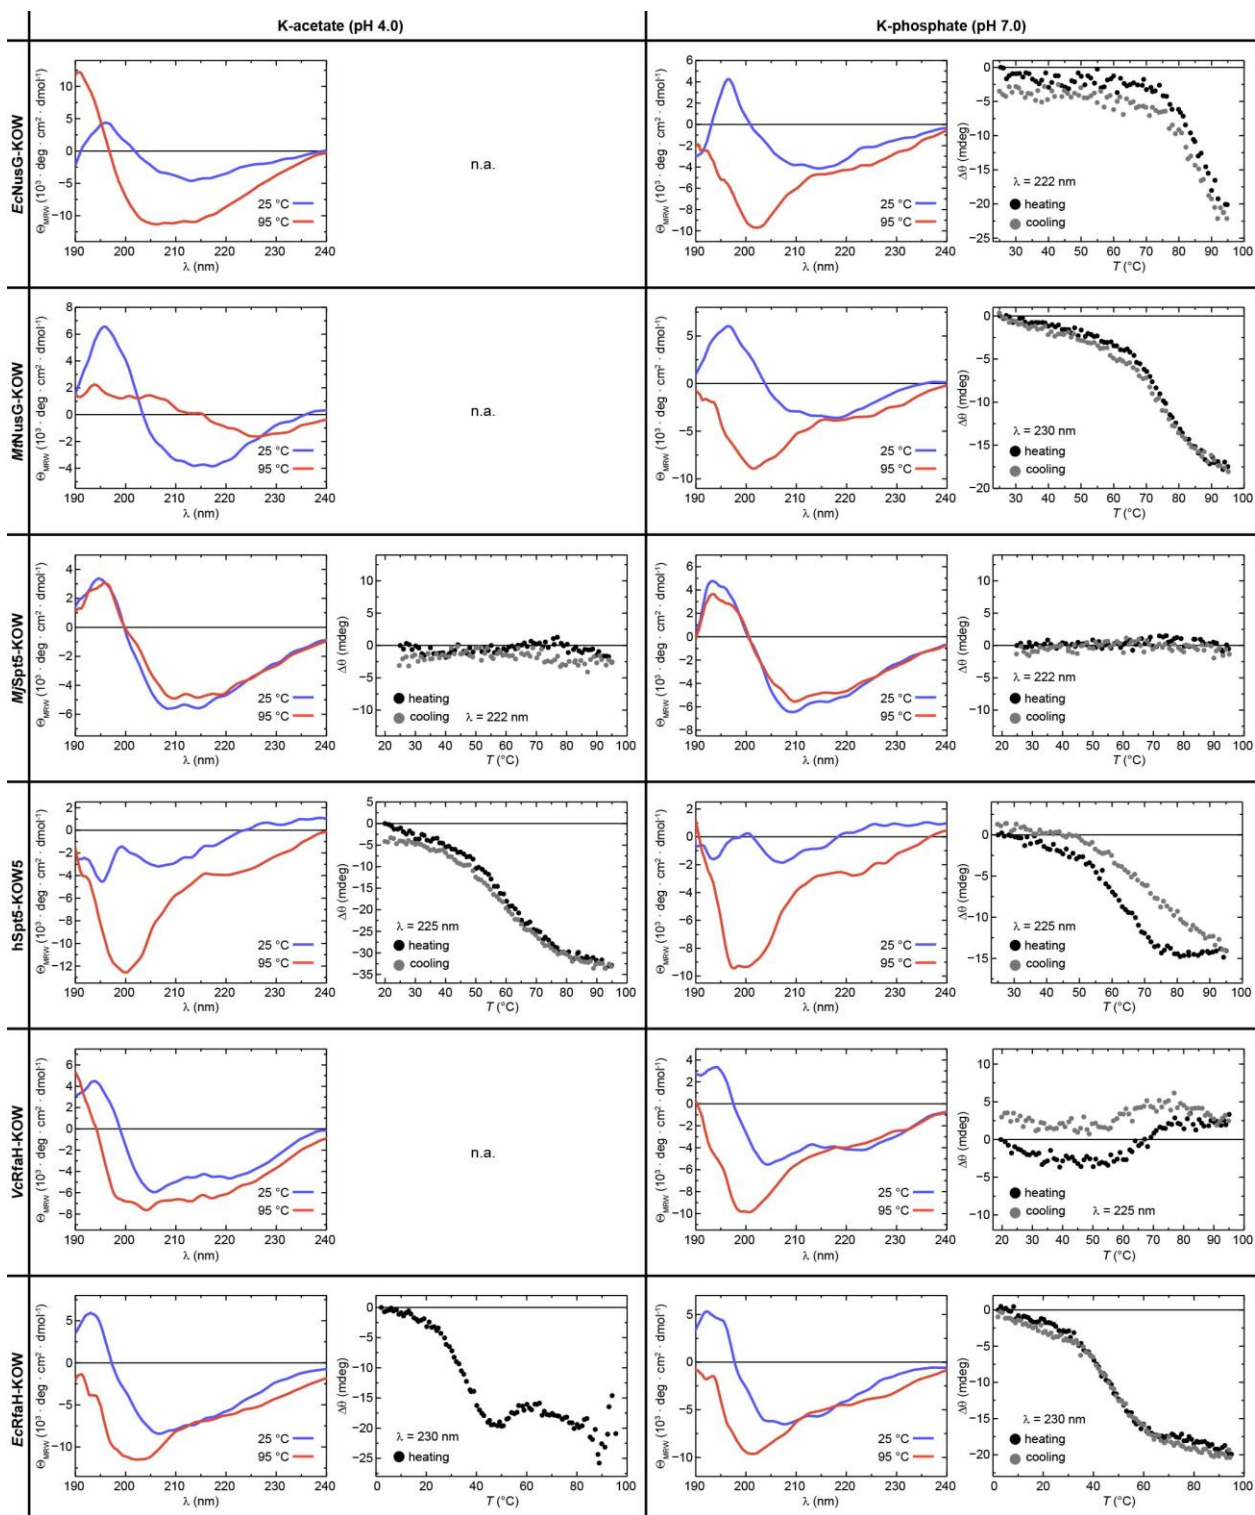

1265 representation. N- and C-termini are labeled. PDB-IDs: 2JVV (*EcNusG-KOW*), 2MI6 (*MtNusG-*

1266 *KOW*), 4ZN3 (*MjSpt5-KOW*), 2E70 (*hSpt5-KOW5*), 2LCL (*EcRfaH-KOW*), 6TF4 (*VcRfaH-*

1267 *KOW*). (C) Structural alignment of the six KOW domains. The proteins are shown as ribbons.

1268 Orientation and colors as in (B).

1269

1270

1271 **Figure 2 – Figure supplement 1.** Reversibility of thermal unfolding. The graphs show CD

1272 spectra of the six KOW domains at 25 °C (blue) and at 95 °C (left) together with the change in

1273 ellipticity,  $\Delta\theta$ , during heating from 25 °C to 95 °C (filled black circles) and subsequent cooling  
1274 to the initial temperature (filled grey circles), each at pH 4.0 (left) and pH 7.0 (right). When  
1275 aggregation was already apparent from the CD spectra acquired at 95 °C (i.e. the shape of the  
1276 spectrum did not correspond to that of an unfolded protein), no thermal unfolding/refolding  
1277 curves were recorded (n.a.). Due to its hyperthermophilic source organism, *MjSpt5-KOW* could  
1278 not be denatured at either pH.

1279

1280 **Figure 2 – Figure supplement 2.** Selected thermodynamic parameters of the six KOW domains.

1281 The values were derived from thermal denaturations monitored by DSC and CD spectroscopy.

1282 Standard deviations result from data fitting.

1292

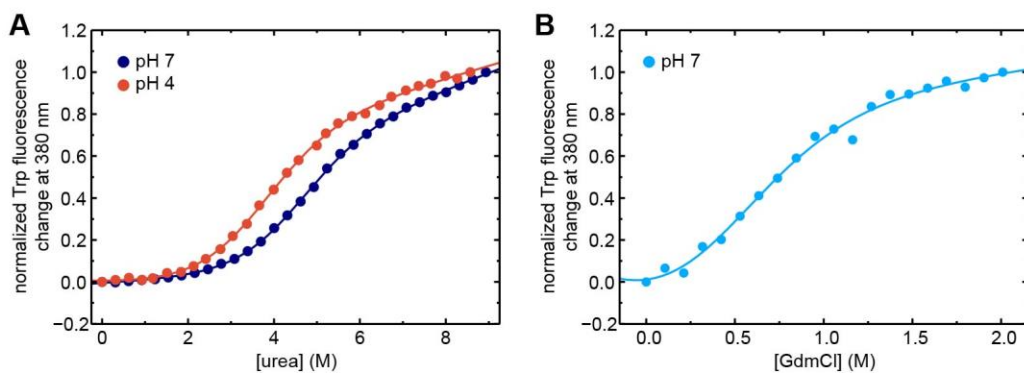

1293 \* Values were determined by fluorescence-based unfolding experiments

1294 ‡ No denaturation possible.

1295 || The  $m$ -value is a measure of the broadness of the transition and correlates with the difference in the accessible surface area between N and U,  
 1296 and the transition midpoint.

1297

1298

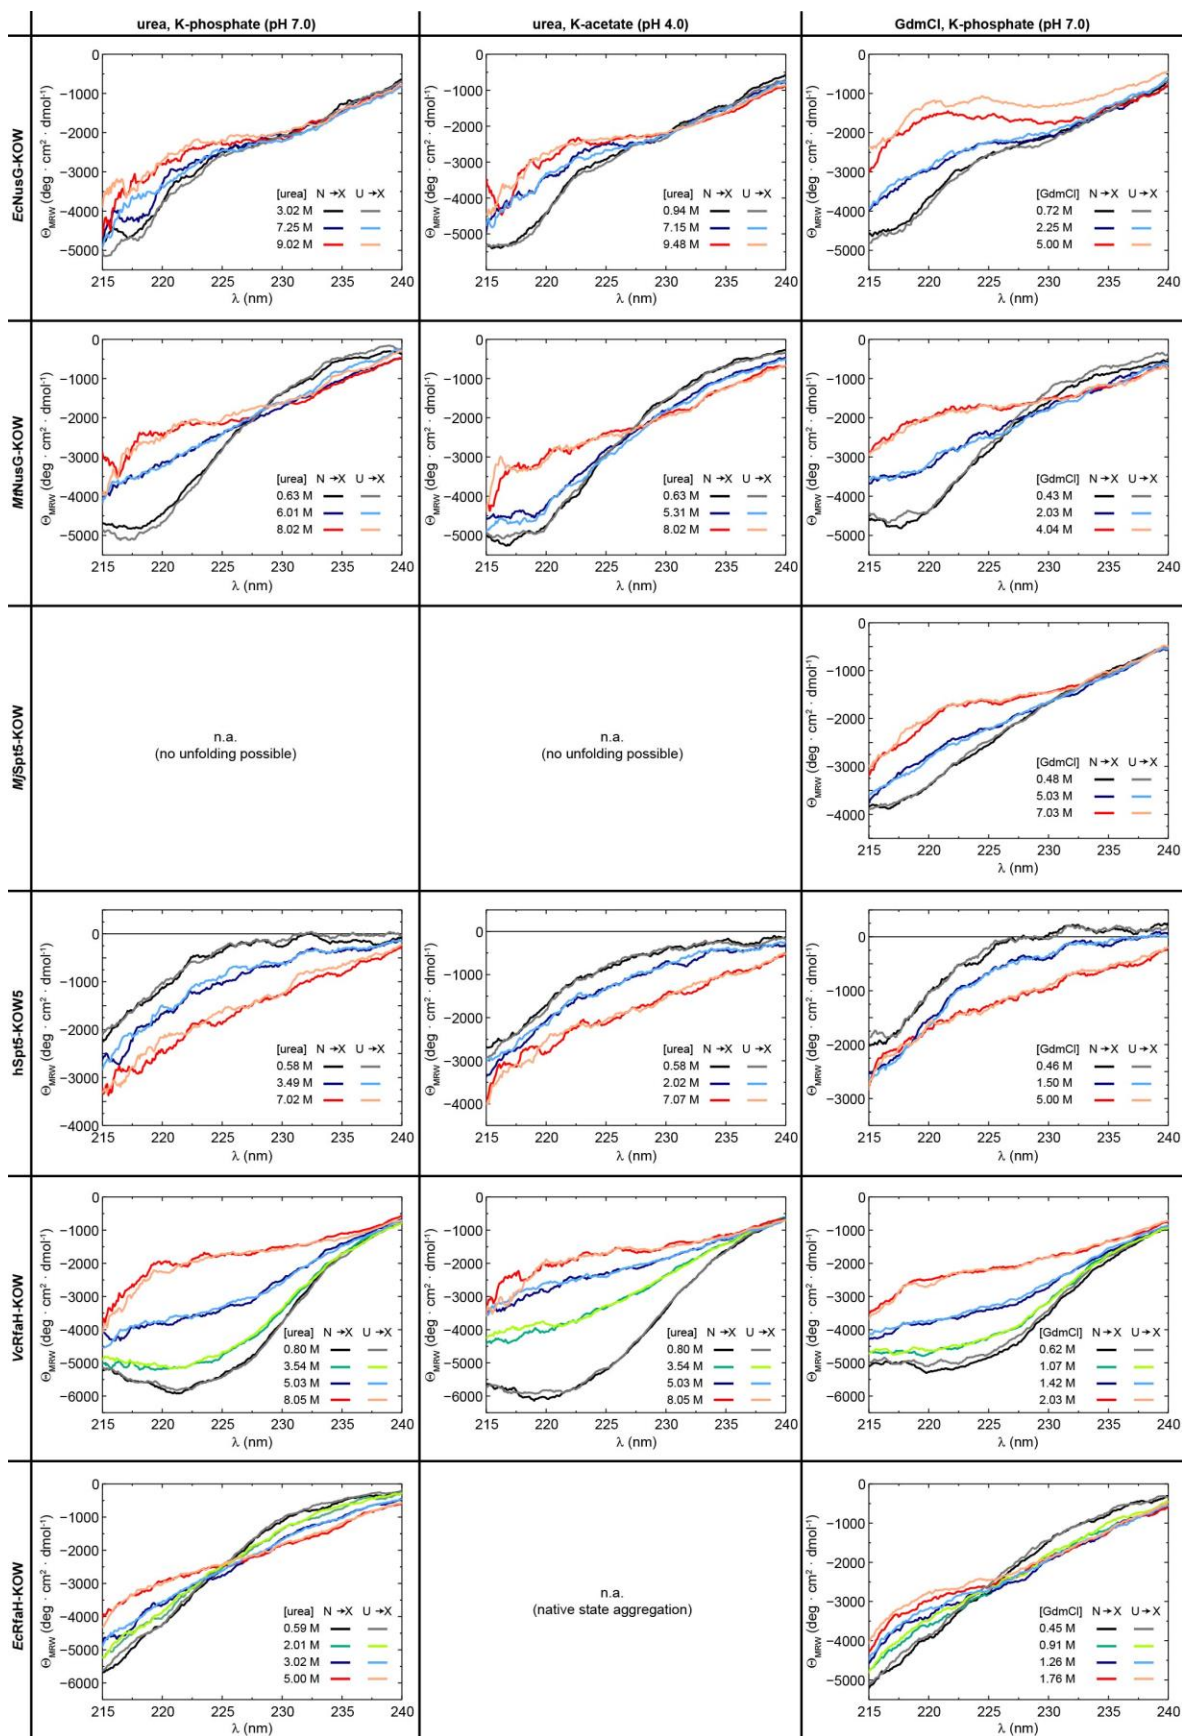

1299

1300 **Figure 3 – Figure supplement 2.** Chemical unfolding of *VcRfaH-KOW* monitored by change in  
1301 Trp fluorescence. (A), (B) The curves show the normalized Trp fluorescence change at 380 nm  
1302 of *VcRfaH-KOW*, obtained after over-night incubation of the protein in the presence of  
1303 increasing concentrations of (A) urea at pH 4.0 (filled blue circles) or pH 7.0 (filled red circles)  
1304 or (B) GdmCl at pH 7.0 (filled light blue circles). The lines represent fits to a two-state unfolding  
1305 model.

1306

1308 **Figure 3 – Figure supplement 3.** Reversibility of chemical denaturation. CD spectra of the six  
1309 protein domains acquired at the indicated denaturant concentration and buffer. In order to check  
1310 the reversibility, two spectra at identical denaturant concentration were obtained by adding the  
1311 native protein from a solution containing no denaturant to the desired denaturant concentration  
1312 (N → X), or by adding the unfolded protein from a solution containing 10 M urea/8 M GdmCl to  
1313 a solution containing the desired denaturant concentration (U → X). The color code is indicated.  
1314

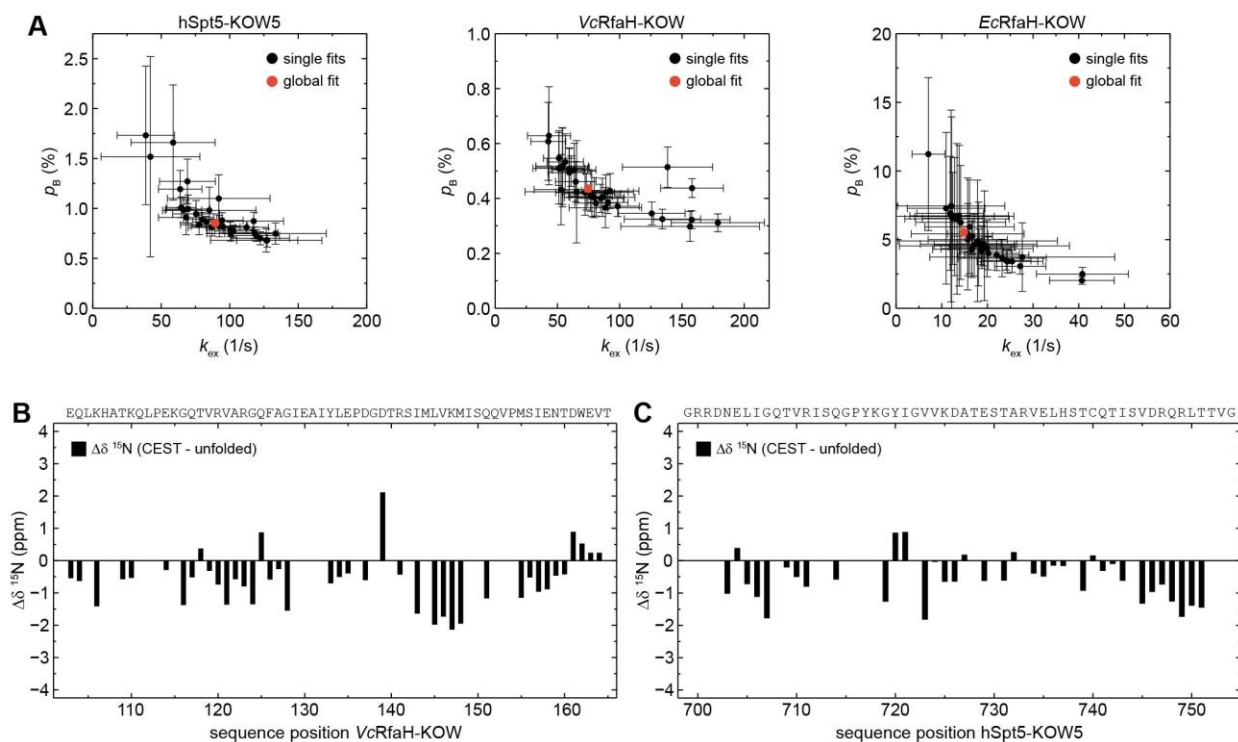

1315 **Figure 4 – Figure supplement 1.** Quantification of H-bond strengths from LR-HNCO NMR experiments for all KOW domains.

1319 **Figure 5 – Figure supplement 1.** Extended CEST analysis of hSpt5-KOW5, VcRfaH-KOW, or  
 1320 *EcRfaH-KOW*. **(A)** Plots of  $k_{ex}$  vs. the population of the minor species ( $p_B$ ) obtained from  
 1321 individual fits (black symbols) or a global fit (red symbol) of the CEST profiles of (left) hSpt5-  
 1322 KOW5, (middle) VcRfaH-KOW, and (right) *EcRfaH-KOW*. Error bars represent the standard  
 1323 deviation of the fits. **(B, C)** Sequence dependent difference between the  $^{15}N$  backbone amide  
 1324 chemical shifts of the CEST minor species of **(B)** VcRfaH-KOW and **(C)** hSpt5-KOW5 and the  
 1325 corresponding theoretical random coil value. The sequence of the two protein constructs is given  
 1326 above the diagrams.

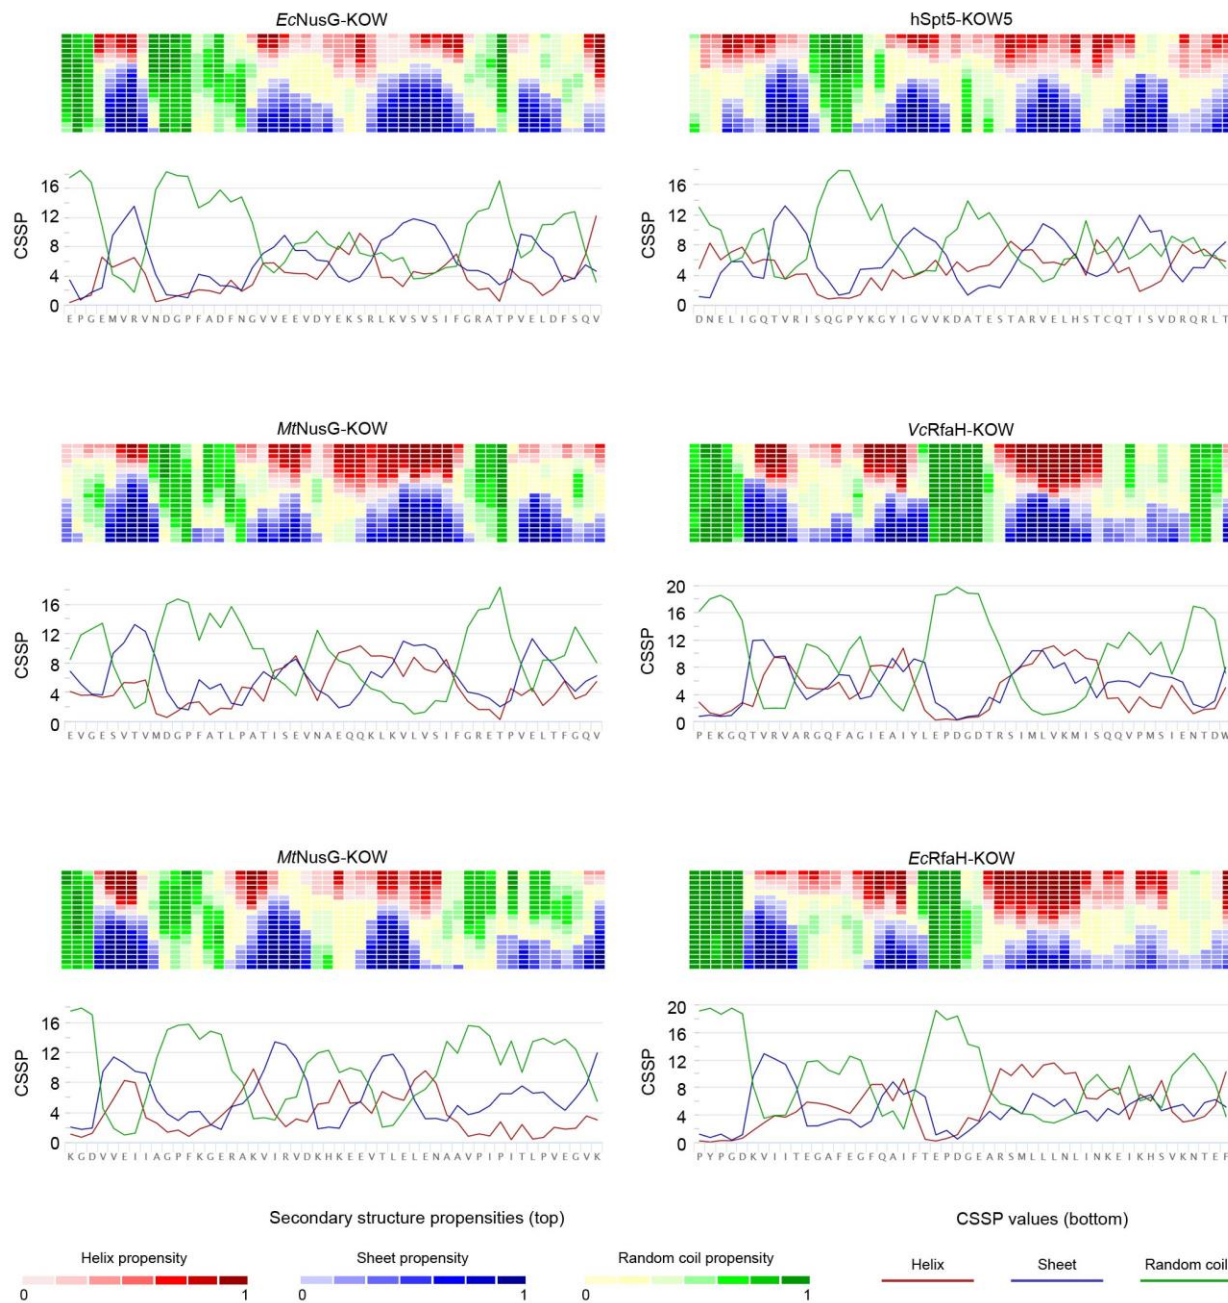

1327

1328 **Figure 5 – Figure supplement 2.** Exchange parameters derived from global fitting of the CEST  
1329 experiments to a two-state exchange model. Standard deviations result from data fitting.

| <b>Parameter</b>      | <b>hSpt5-KOW5</b> | <b>VcRfaH-KOW</b> | <b>EcRfaH-KOW</b> |
|-----------------------|-------------------|-------------------|-------------------|
| $p_A$ (%)             | $99.15 \pm 0.02$  | $99.57 \pm 0.01$  | $94.47 \pm 0.46$  |
| $p_B$ (%)             | $0.85 \pm 0.02$   | $0.43 \pm 0.01$   | $5.53 \pm 0.46$   |
| $k_{AB}$ ( $s^{-1}$ ) | $0.76 \pm 0.03$   | $0.32 \pm 0.02$   | $0.82 \pm 0.10$   |
| $k_{BA}$ ( $s^{-1}$ ) | $88.62 \pm 3.12$  | $74.24 \pm 3.17$  | $13.98 \pm 1.24$  |
| $k_{ex}$ ( $s^{-1}$ ) | $89.38 \pm 3.15$  | $74.57 \pm 3.18$  | $14.80 \pm 1.31$  |
| $\tau_A$ (s)          | $1.31 \pm 0.05$   | $3.08 \pm 0.15$   | $1.22 \pm 0.15$   |
| $\tau_B$ (ms)         | $11.28 \pm 0.40$  | $13.47 \pm 0.57$  | $71.52 \pm 6.33$  |
| $\Delta G$ (kJ/mol)   | $11.81 \pm 0.05$  | $13.48 \pm 0.07$  | $7.18 \pm 0.21$   |

1330

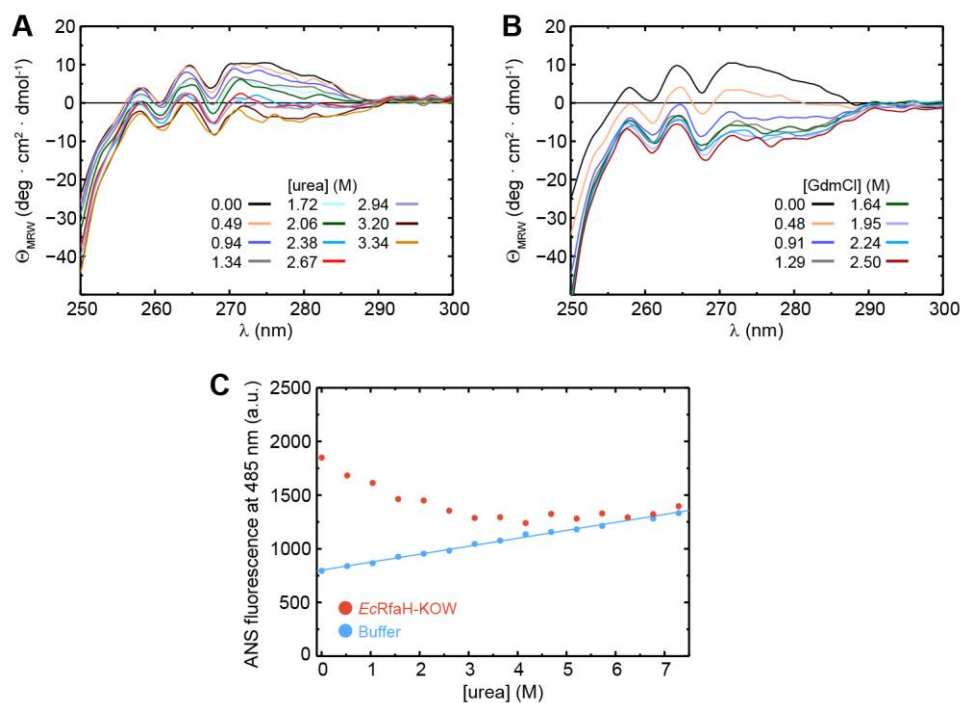

1331

1332

1333 **Figure 5 – Figure supplement 3.** Secondary structure prediction for the six KOW domains used  
1334 in this study by Net-CSSP (Kim et al., 2009). The contact-dependent secondary structure  
1335 propensity (CSSP) of each domain is plotted against the amino acid sequence (red: helices; blue:  
1336 beta structures; green: random coil). The heat map above each graph displays the propensity of

1337 each amino acid to adopt helical (red), beta (blue), or random coil (green) structures using a  
1338 gradient from dark (high propensity) to light (low propensity) colors.  
1339

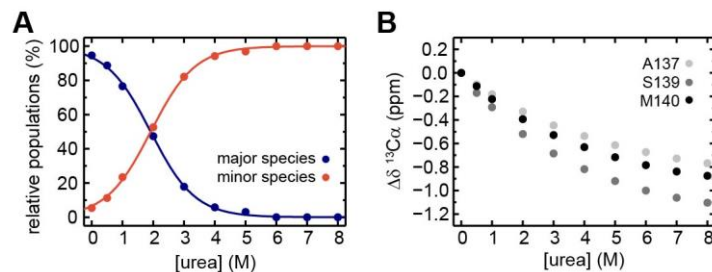

1340

1341 **Figure 6 – Figure supplement 1.** The intermediate state of *EcRfaH-KOW* is no equilibrium  
1342 MG. **(A, B)** Near-UV CD-spectra of *EcRfaH-KOW* during a titration with (A) 10 M urea and (B)  
1343 8 M GdmCl. In both cases, the solution was buffered by 10 mM K-phosphate (pH 7.0). The  
1344 denaturant concentrations at which the spectra were recorded are indicated. **(C)** ANS binding  
1345 experiments. The graph shows the ANS fluorescence at 485 nm after over-night incubation of  
1346 ANS in the presence (filled red circles) or absence (filled blue circles) of *EcRfaH-KOW* at  
1347 increasing urea concentrations. The system was buffered by 10 mM K-phosphate (pH 7.0).

1348

1349

1350 **Figure 6 – Figure supplement 2.** Extended analysis of the urea-induced denaturation of  
1351 *EcRfaH-KOW* with a three state-model. (A) Relative populations of the minor (filled red circles)  
1352 and major (filled blue circles) species during the [ $^1\text{H}$ ,  $^{13}\text{C}$ ]-ctHSQC-based urea denaturation of  
1353  $^1\text{H}$ ,  $^{13}\text{C}$ -*EcRfaH-KOW*. The populations at a certain urea concentration were calculated from the  
1354 ratio of volumes of the  $\text{H}\alpha/\text{C}\alpha$  correlation peaks of S139 minor or major species signals,  
1355 respectively, to the sum of both values. The curves were fitted to a two-state model to extract the  
1356 parameters of the transition from the major species to the minor species. The minor species was  
1357 treated as a single species neglecting the fact that it is actually an ensemble of at least two  
1358 subspecies. Fitting to a three-state (or even higher-state) model with an increased number of  
1359 fitting parameters would not be appropriate due to the limited number of data points. (B)  
1360 Chemical shift changes of  $^{13}\text{C}\alpha$  signals,  $\Delta\delta^{13}\text{C}\alpha$ , of A137, S139 and M140 in the [ $^1\text{H}$ ,  $^{13}\text{C}$ ]-  
1361 ctHSQC spectra during urea denaturation.
