Microwave Spectral Tables

This five-volume NBS Monograph will present a comprehensive compilation of microwave spectra including measured frequencies, assigned molecular species, assigned quantum numbers, and molecular constants determined from these data. Four volumes are now available and the other one will be available in about two months.

Titles of the volumes

I. Diatomic Molecules, $2.00
II. Line Strengths of Asymmetric Rotors, $3.00
III. Polyatomic Molecules With Internal Rotation (In press).
IV. Polyatomic Molecules Without Internal Rotation, $5.50
V. Spectral Line Listing, $4.75

The volumes are available by purchase from the Superintendent of Documents, Government Printing Office, Washington, D.C. 20402. Orders from foreign countries should include an additional one-fourth of the price of the publication to cover the postage.

Library of Congress Catalog Card Number: 63-62235

Foreword

Volume IV concludes the present compilation of data under the title of Microwave Spectral Tables–NBS Monograph 70, begun in 1953 by Dr. Paul F. Wacker. Volume V, published prior to this volume, contains a numerical listing of spectral lines given in Volumes I, III, and IV. Volume I, Diatomic Molecules, and Volume II, Line Strengths of Asymmetric Rotors, were completed under the supervision of Dr. Wacker and published in December, 1964.

In May, 1964, general supervision of the project was assumed by Dr. Yardley Beers. Subsequently, Mrs. Marian Cord was appointed project leader for the completion of Volume III, Polyatomic Molecules with Internal Rotation, Volume IV, Polyatomic Molecules Without Internal Rotation, and Volume V, Spectral Line Listing.

Extensive efforts have been made to reduce the number of errors in recording the data to a minimum. Any corrections, criticisms, or suggestions will be appreciated by the authors.

Acknowledgments

The authors wish to express appreciation for much assistance in the preparation of this volume; for preliminary reviewing: Masataka Mizushima, Allen Garrison and William Dambeck; for preliminary programming: Raymond Kukol and Jean Troyer; for checking: Emmett MacKenzie, Judy Stephenson and Carol Nielsen; for the INTRODUCTION, general consultation and valuable advice: Paul Wacker and Yardley Beers. To this list should be added the names of many scientists in the field of microwave spectroscopy who readily and graciously complied to requests for information.

Contents

Microwave Spectral Tables

Volume IV. Polyatomic Molecules Without Internal Rotation

Marian S. Cord, Jean D. Petersen, Matthew S. Lojko, and Rudolph H. Haas

Measured frequencies, assigned molecular species, and assigned quantum numbers are given for abour 14,000 spectral lines of polyatomic molecules without internal rotation observed by coherent radiation techniques. Molecular data, such as rotational constants, dipole moments, and various coupling constants, determined by such techniques, are also tabulated. References are given for all included data.

Key words: Centrifugal distortion constant; coherent radiation technique; dipole moment; l-doubling; microwave spectra; molecular spectra; polyatomic molecules; quadrupole coupling constants; rotational constant; spectral lines.

1. Introduction

This volume contains data on the microwave spectra of 166 polyatomic molecules incapable of exhibiting internal rotation. These data are based upon a systematic search of the literature up to January 1961 and include some information of later dates. Molecules capable of exhibiting internal rotation are those whose atoms can be arranged in groups which may rotate separately about a common axis. This rotation is known to take place, or supposed to be observable, when the bond between adjacent atoms in two groups is a single one. However, the splittings due to torsional oscillation about a multiple bond are so very small that it is usually more suitable to treat such phenomena with techniques developed for vibrational spectra. The microwave spectra of molecules capable of exhibiting internal rotation about single bonds are tabulated in Volume III of this series. The present volume contains data on all the other polyatomic molecules covered by this survey, including linear polyatomic molecules.

One special topic which deserves some brief mention, as it is not encountered extensively in other volumes of this series, is l-type doubling. This phenomenon occurs with molecules having degenerate modes of vibration. The linear motions of the nuclei belonging to the two modes are in orthogonal directions. Therefore, if both modes are excited, the combined effect generally is to cause the nuclei to appear to travel in elliptical orbits. Associated with this motion is the concept of "vibrational angular momentum," which is quantized with the quantum number "l". If the molecule as a whole has rotation as well, however, the two normal mode vibrations are not completely equivalent, since the directions of linear vibrations generally have different angles with the vector representing the other rotation. Therefore, the Coriolis forces corresponding to the two modes are different, and generally there results a splitting of the otherwise degenerate levels. The class of molecules in which the effect has been most extensively studied is that of linear triatomic molecules. For a linear molecule, the angular momentum is $l\text{h}/2\pi$, where l is an integer no greater in absolute value than the corresponding vibrational quantum number v, and is even or odd as is the latter. Neglecting the bending which occurs if the amplitudes of the two component modes are unequal, the linear molecule is similar to an asymmetric top with l analogous to the prolate quantum number K_{-1}. Commonly only the absolute value of l is given in both the microwave and infrared literature. If the sign is definite, a + sign or a − sign is used; if the sign is known relative to that of the axial quantum number K in a symmetric top molecule, then ± or ∓ is used with K and l to indicate this correspondence. If the quantum number l is nonzero, the energy for a given J value is dependent upon the sign of l, i.e., upon whether the vibrational rotation is clockwise or counterclockwise [see H. H. Nielsen and W. H. Shaffer, J. Chem. Phys., **11**, 142 (1943)].

The l-splitting in the case of $|l| \geqslant 1$, is of the order of magnitude of $B_e(B_e/\omega_2)^{2|l|-1}$ for singlet states, where B_e is the rotational constant and ω_2 is the bending frequency in comparable units [H. H. Nielsen in Encyclopedia of Physics XXXVII/1, page 280 (1959)]. Hence, the splitting is so small for $|l|>1$ that attention is confined here to the usual $|l|=1$ case. Then, to a first approximation, which is adequate for most purposes, the splitting (frequency units) is given by

$$\Delta W_l = \frac{q_l}{2}(v_2+1)J(J+1),$$

where q_l is a constant, J is a total angular momentum ($J \geqslant |l|$), and v_2 is quantum number pertaining to the bending vibration. Transitions can take place according to either of the following selection rules: (1) $\Delta J = \pm 1$, $\Delta l = 0$, or (2) $\Delta J = 0$ and $\Delta |l| = 0$. As a consequence of the first set of selection rules, each $\Delta J = \pm 1$ rotational line originating from the ground vibrational state is accompanied by a vibrational satellite or pair, displaced slightly from it for each finite value of v_2 (and $|l|$). The second set of selection rules give rise to the "l-type" spectra mentioned earlier, and the frequencies of the lines, to the first approximation, are given by the above formula. This formula is to be considered as an approximation adequate for nearly all cases which have been investigated. However, for a few molecules, especially HCN and ClCN, there have been obtained data of sufficient quantity and accuracy to show a slight variation of q_l with J. In such cases the tables will list an approximate value and in some cases a footnote will give the best available formula for q_l as a function of J along with a suitable reference.

An extensive discussion and bibliography pertaining to "l-type doubling" may be found in "Microwave Spectroscopy" by C. H. Townes and A. L. Schawlow [McGraw-Hill Book Company, Inc., New York, 1955], especially Section 2–2, for which the following suggestions are given:

(A) The factor h should be added to (2–13) and to the second and third terms of (2–11);

(B) The denominator of (2–16) should be $J(J+1)$ as in their (3–41) rather than $(J+1)(2J+1)$;

(C) The order of magnitude of the l-splitting is that given by the first sentence of our previous paragraph rather than $B_e(B_e/\omega_2)^l$.

2. Explanation of Tables

Data for these Microwave Spectral Tables have been compiled from a review of articles found in worldwide journals as well as in private communications regarding unpublished work. Generally speaking, date and accuracy of data measurement were the criteria by which any required selection was made. An explanation of the format and contents of the Tables follows.

The first line of data contains an identification number and the Chemical Abstracts name. The lines immediately following give alternate names, if any. The last line of the heading contains the empirical formula, the symmetry point group of the molecule, and, where possible, the "quasi"-structural formula. The point group given assumes only one isotopic form of each element and the molecular configuration believed to have the lowest potential energy. Molecules are ordered first according to empirical formula, as in Chemical Abstracts, then by name. A numbering system has been established for identification of the molecules and their isotopic species for convenience in programming and referencing. Each molecule was given a number ending in zero in order of its occurrence on the list. Its species have been numbered consecutively from that point, skipping the next zero when the number of isotopic species exceeds nine. Every species is given for which any molecular constants or spectral lines from microwave sources have been reported up to January 1961. However, a glance at the bibliography will show that a considerable number of later references have been included. In the formulas for the species, mass numbers have been placed as superscripts to the right of the atomic symbols. Hydrogen is the one exception—for the normal mass of "1" the superscript is omitted, and for deuterium (H^2) the symbol D is used.

In the second column of the molecular constant table, the overall symmetry point group (Pt. Gp.) has been given for each isotopic species of the molecule, as the analysis permits. Some consideration of structural information was necessarily a part of these assignments.

Most of the rotational constants tabulated have been derived from microwave sources and this is indicated by the M occurring after the values. In a few instances, other experimental sources have been designated by the code letters N or F (for near or far infrared measurements). Use of symmetry has been made in reporting rotational constants A, B, and C (with $A \geqslant B \geqslant C$). If, for example, the axis of symmetry of a symmetric top is known to be the axis of least moment of inertia, then the constants B and C are equal and are so recorded. All moments of inertia have been converted to the corresponding constant, A, B or C (in megahertz) by multiplication with the appropriate conversion factor. These factors are given later following the list of symbols and abbreviations.

Centrifugal distortion effects are indicated by the constants D_J, D_{JK}, and D_K which are dependent upon the rotational constants and the vibrational force constants. The first two of these are given in the molecular constant tables, but the third, D_K, when reported, is to be found in the data given following the molecular constant table for each molecule.

With planar molecules, the inertial defect, $\Delta = I_c - I_a - I_b$, is frequently of interest. Classically, for a rigid planar molecule, this is zero, but in actuality it is non-zero because of the existence of zero point vibrations.

Ray's asymmetry parameter is a measure of the variation from the symmetric top. The value of κ $\left(\text{defined as } \dfrac{2B-A-C}{A-C}\right)$ ranges between -1 for a prolate top and $+1$ for an oblate top. In cases where the original papers have used other asymmetry parameters, these have been converted to κ values. Formulas which were used for these conversions are as follows:

$$\kappa=2\delta-1=\frac{3b_p+1}{b_p-1}=\frac{1+3b_0}{1+b_0}=\frac{6\epsilon-1}{2\epsilon+1},$$

where

$$b_p=\frac{C-B}{2A-B-C},\ b_0=\frac{A-B}{2C-B-A},$$

$$\delta=\frac{B-C}{A-C},\ \text{and}\ \epsilon=\frac{B-C}{2(2A-B-C)}$$

In many instances, the total dipole moment μ was found in the literature, but it had not been resolved into components parallel to the axes of least, intermediate, and greatest moments of inertia, respectively (denoted by the subscripts a, b, and c). Symmetric top molecules have two equal principal moments of inertia, designated by I_b. The dipole moment of such molecules lies along the third principal axis. Some of the original papers did not specify whether this moment of inertia was smaller or larger than the two others and, therefore, did not indicate how this third axis should be labelled. An effort was made to resolve the question by making use of available structural information to calculate the moment of inertia with respect to the symmetry axis as described in Volume III. Using the convention $I_a \leq I_b \leq I_c$, if the computed value was smaller than the given I_b, then the figure axis was considered to be "a" and, if greater than I_b, then the figure axis was considered to be "c". A symbol M follows the value if the dipole moment was measured by microwave techniques, usually the Stark effect. In the case of asymmetric molecules, if the components of the dipole moment were not specified, the reported dipole moment was entered under the component which was adjudged the major one (according to transitions assigned to spectral lines, or, if these were lacking, according to structural information available). In addition, the letter "u" designates the unknown, but possible, second component. The fact that certain dipole moment components are known to be zero by virtue of established symmetries is indicated by an X, after the data (for example, a component perpendicular to the plane of symmetry, or one in a plane perpendicular to the axis of symmetry, would always be zero). Effects of isotopic substitution on symmetry of the molecule have been taken into account. Where dipole moments are reported which were obtained by other than microwave techniques, different code letter designations are used. If the moments are reportedly obtained from the Debye equation with temperature-variation for the molar polarization of the gas or liquid, the code letters G or L, respectively, are used. A code letter P, denotes that the value was reported in the literature as computed from the molar polarization α. In all other cases of non-microwave sources for these data the code letter T is used.

Quadrupole coupling constants, eQq, obtained from hyperfine structure measurements are reported as found in the literature. In some cases authors have reported these as referred to particular bonds or axes, and if so, they are recorded thus. To facilitate later description of transitions involving excited vibrational states, each vibrational mode excited in any observed microwave transition is assigned a letter subscript and is identified by the frequency, ω, in cm^{-1}, and the degeneracy d.

For a limited number of molecules some additional molecular constant data, not described in the foregoing paragraphs, were available. This has been condensed, where practicable, and inserted after the regular molecular constant tables for each molecule. No effort is made here to define these miscellaneous constants. The interested reader is therefore referred to the particular paper from which the data were abstracted.

The table of reported spectral lines for each molecule starts on a new page following the molecular constant tables. Immediately following the heading for the spectral lines, the formula and identification number of each isotopic molecular species are printed. Lines are arranged in the following pattern: ascending order of rotational quantum numbers according to (1) J', (2) J, (3) K'_{-1}, (4) K_{-1}, (5) K'_{+1}, (6) K_{+1}, then in ascending magnitude of the frequency. For asymmetric tops the rotational quantum numbers are arranged in the pattern J', K'_{-1}, $K'_{+1} \leftarrow J$, K_{-1}, K_{+1}, where primes denote upper state. For prolate or oblate symmetric tops the arrangement is J', $K'_{-1} \leftarrow J$, K_{-1} or J', $K'_{+1} \leftarrow J$, K_{+1}, respectively. Blanks occur where the identification is not complete in the literature. Unassigned lines are indicated by the term "not reported." It should be recognized that lines for which rotational quantum numbers have not been assigned may be due to impurities.

It should be mentioned that in a few $\Delta J = \pm 1$ transitions of very asymmetric top molecules it is difficult to ascertain which is the upper state, even if quantum numbers have been assigned to both states. There is indication that some authors have not clearly stated the existence of this uncertainty or that they have been careless with their notation in this regard. In some instances clarification has been obtained from the author, but in others this was not possible. In any event the quantum numbers on the left denote the state which is believed to be the upper state.

There is considerable non-uniformity in the listing of the hyperfine components, mainly because many times only a few of the rotational transitions of a given molecule may have their hyperfine splittings analyzed. If the hyperfine splitting is resolved, the individual lines are ordinarily reported separately with the total angular momenta F' and F of the upper and lower states, respectively. If the splitting is partially resolved, the assigned F values are given for the resolved lines. For large J values, the $\Delta F = \Delta J$ components are relatively strong and displaced but little from the frequency the line would have if there were no hyperfine splitting. If the hyperfine splitting is quite small (less than 5 MHz), the frequency of the hypothetical line for zero quadrupole moment is commonly listed and shifts from these frequencies are given in the text or in footnotes.

Efforts were made to determine from the author's statements, the accuracies to which spectral lines were measured, though, in many cases, these were not well defined in the literature. References are indicated for all data, but wherever possible, footnotes have been given to obviate the necessity of referring to these. References are arranged in order of year of publication, then alphabetically according to first author and numbered consecutively. A few exceptions occur in the case of books and of articles which were not found until after the numbering had been completed and a change in reference number would have necessitated extensive changes throughout the entire volume.

3. List of Symbols, Abbreviations, and Conversion Factors

3.1. Symbols and Abbreviations

The following symbols and abbreviations are listed in the order in which they may first occur in the tables.

Molecular Constant Table

:	Double bond.
⋮	Triple bond.
. . .	Extra (cyclic) bond between two atoms preceding these symbols.
a—	Asymmetric.
b	As a superscript to an atomic symbol, indicates isotope not stated.
c—	Cis structure.
g—	Gauche structure.
t—	Trans structure.
s—	Symmetric.
Pt. Gp.	Symmetry point group of the molecular species.
Id. No.	Identification number of the molecule or molecular isotopic species.
A, B, C	Rotation constants (MHz). $A \geqslant B \geqslant C$.
M	Microwave determination.
N	Near infrared determination.
F	Far infrared determination.
L	Liquid temperature variation procedure used for determination.
G	Gas temperature variation procedure used for determination.
P	Value reported as computed from molar polarization α.
$D_{J,JK,K}$	Centrifugal distortion constants (MHz).
κ	Ray's asymmetry parameter $(2B-A-C)/(A-C)$.
Δ	Inertial defect (amu Å^2).
a, b, c	Principal axes corresponding to A, B, and C, respectively.
$\mu_{a,b,c}$	Components of the dipole moment along the principal axes (Debye).
D	Abbreviation for Debye units.
u	Value not known.
X	Value precisely zero due to symmetry.
Acc	Accuracy of the previous quantity.
eQq	For a symmetric top, the electric quadrupole coupling constant along the symmetry axis (MHz).
$\omega_{a,b,\ldots}$	Vibrational frequencies of modes, a, b, . . . excited in observed microwave spectral lines (cm^{-1}).
d	Degeneracy of the preceding vibrational mode.
Ref.	Numbers are reference numbers as in the bibliography.
$eQq_{aa}, \ldots$ / $\chi_{aa}, \ldots$	Electric quadrupole coupling constant along indicated principal axis (MHz).
I_α	Coupling parameter, i.e., moment of inertia of rotatable group (amu Å^2).
$I_{a,b,c}$	Moments of inertia of the whole molecule with respect to the indicated principal axis.

Spectral Line Table

v_a; v^l; . . .	Quantum number of the vibrational mode identified as a, b, . . . in the molecular constant table. The l quantum number is given after a comma rather than as a superscript.
F_1', . . ., F	Total angular momentum quantum number. Primed values are for the upper state, unprimed values for the lower state. Those with subscript "1" include nuclear spin only for nucleus with largest eQq.

3.2. Conversion Factors

The following formulas were used to convert the literature values x, to the values y, of the tables. The respective units are given in parentheses. It should be pointed out that the conversion factor given here for amu-Å^2 to MHz, is based on the atomic weight scale in which $C^{12}=12$. However, most data covered in these tables were based on the older scale in which $O^{16}=16$. The formulas used are:

amu Å^2 to MHz: $$y(\mathrm{MHz}) = \frac{(8.391420 \times 10^5)}{x(\mathrm{amu}\ \text{Å}^2)\ (1.6604345)} = \frac{(5.0537497 \times 10^5)}{x(\mathrm{amu}\ \text{Å}^2)}$$

cm^{-1} to MHz: $$y(\mathrm{MHz}) = (2.997925 \times 10^4)\ x\ (\mathrm{cm}^{-1})$$

gm-cm^2 to MHz: $$y(\mathrm{MHz}) = \frac{(8.3914204 \times 10^5)}{x(\mathrm{gm\text{-}cm}^2)}.$$

1. Some quadrupole splitting was observed in the high J transitions in the first excited bending mode, however they were not assigned F values. These are listed as given in the 1956 article by Burrus and Gordy.

1. Some quadrupole splitting was observed in the high J transitions in the first excited bending mode, however they were not assigned F values. These are listed as given in the 1956 article by Burrus and Gordy.

1. Two lines in the ground state could not actually be seen at zero field, but their frequencies were fixed by extrapolation. The transitions given are normally forbidden, but they can be identified in the presence of the Stark field.

1. Calculations for B and C for $C^{12}HD_2Cl^{35}$ were made from ref. 296 by adding the quantities for 3B + C and 3C + B to obtain B + C, then combining this with the given value for 2(B − C).

1. A typographical error in Table 1 of Jenkins, Kewley, and Sugden's article has been corrected to read $J=8\leftarrow7$.
2. These lines for the transition origin (ν for $K=0$) were stated to have been found graphically.

For species 521, $v_2=1$, $\mu=.700$ D, Ref: 238; $q_1=6.344$ MHz, $\alpha_1=20.56$ MHz, $\alpha_2=10.563$ MHz, $\alpha_3=52.6$ MHz.

For this molecule Fermi resonance interactions occur between various vibrationally excited states. Values given here for α_i are those which will allow accurate prediction of the rotational frequencies in the lowest excited vibrational state according to the usual formula; see Ref. 402.

Experimental B values for excited vibrational states are given in the same reference.

For species 529, ref. 349 gives eQq $(O^{17})=-1.32$ MHz.

Add. Ref. 86, 115, 195, 217, 355, 491, 1030

For species 547, the dipole moments for excited states are given in ref. 169: for (1, 0, 0), μ = .728D.; for (0, 1, 0), μ = .730 D.

For the molecule in general, ref. 217 gives the "Fermi resonance" interaction energy W_{ni} = 45.7 cm^{-1} and (unperturbed) α_1 = 14.01 MHz, α_2 = −6.88 MHz.

1. Presence of quadrupole coupling renders interpretation of Stark effect data difficult, hence no dipole moment is given. However, a value of $\mu_b = 1.6$ Debye is indicated in a preliminary treatment.

Add. Ref. 180,283,284,412

For excited vibrational states the following constants are given in ref. 364 (all values in MHz):

Species	State	$a_b + a_c$	$a_b - a_c$	D_J	D_{JK}
711 712 713	$v_9 = 1$	57.66 53.27 55.97	18.39	.020	.505
711 713	$v_8 = 1$	10.72 11.08	−27.0	−.026	
711 712 713	$v_7 = 1$	22.39 25.18	−27.88 34.66	.019	.550

Ref. 879 also gives $D_K = 39.0535$ MHz for species 711 and 9.1058 MHz for species 712.

The values reported for D_J and D_{JK} vary significantly from those previously given by Johnson and Strandberg.

3. The author indicates an additional hyperfine assignment for this frequency, but due to a misprint, the quantum numbers violate the selection rule $\Delta F = 0, +1$, and therefore it has been omitted.

1. These lines were observed for the excited vibrational state associated with the lowest fundamental vibrational mode at a frequency of 361 cm^{-1}, but hyperfine structure was not resolved.
2. These lines were taken to be hyperfine structure components $F=J+1 \leftarrow F=J$.
3. These lines were taken to be a superposition of the hyperfine structure components $F=J \leftarrow F=J-1$ and $F=J+2 \leftarrow F=J+1$.

950 — 3-Bromopropyne[1]
Bromomethylacetylene, Propargyl Bromide

Molecular Constant Table

C_3H_3Br C_s $H_2BrCC:CH$

Reference: 867

1. The only literature found for this molecule was the letter by Kikuchi, Hirota, and Morino in J.C.P. *31*, 1139L (1959). Since scant information was given, none is recorded here.

960 — Chloroallene
1-Chloropropadiene

Add. Ref. 409

Ref. 573 gives the rotational constant $\delta = 0.0102615$ (species not given). For species 1021, $R_6 = -0.0026$ MHz (for the C^{13} and N^{15} species, R_6 = same value within experimental error). Ref. 851.

1. These values are averages from three different methods of calculation by the same authors.

2. Normal, 1D, 3D, and totally deuterated isotopic species have "a" type transitions: 2D and 2,3,4,5-D species have "b" type transitions.

1. For molecules with identical chlorine nuclei, the axis of least moment of inertia (a axis) is the figure axis; hence for these molecules, $\mu_b = \mu_c = 0$. C. P. Smyth et al. found the dipole moment of an isotopic mixture to be 1.41 Debye, using classical techniques. In the absence of Stark effect data, we have taken this value for μ_a. However, according to Itoh, "For $SPCl^{35}_2Cl^{37}$, $\mu^2_b = .02D$, μ^2_a and $\mu^2_c = 0$" which seems inconsistent with the above.

Add. Ref. 541,829

For species 1592, the following parameters for various vibrational states have been reported:

State:	eQq (MHz)	α^B (MHz)	q_l (MHz)
$v_3 = 1$:	−27.0	12.3	
$v_3 = 2$:	−17.0		
$v_3 = 1$, $v_6 = 1$:	−37.0		
$v_3 = 2$, $v_6 = 1$:	−25.7		
$v_5 = 1$:	−34.9	−10.91	16.31
$v_6 = 1$:	−58.2	2.52	5.00

$B_0^{185} - B_0^{187} \approx .050$ MHz, eQq (Re^{185}) ≈ 1.07 eQq (Re^{187}). Ref. 873.

ABC: 764 μ: 764

Add. Ref. 345,346,698

Reference 764 has listed for species 1631 the following rotational constants for excited vibrational states (assignments not completely determined):

for $v_4=1$ or $v_5=1$, $B_e=5057.27$ MHz, $C_e=5055.83$ MHz;

for $v_5=1$ or $v_4=1$, $A_e=4923.7$ MHz, $B_e=5067.03$ MHz, $C_e=5050.38$ MHz;

for $v_7=1$ or $v_9=1$, $B_e=(B+C)/2=5065.47$ MHz.

1. Relative intensities of these lines yield a vibrational frequency of 380 ± 35 cm^{-1}. Therefore these lines have been tentatively assigned to the $\omega_4 = 388 \pm 15$ cm^{-1} bending mode or to the $\omega_5 = 388$ cm^{-1} torsional mode.
2. These lines have been tentatively assigned to the $\omega_5 = 388$ cm^{-1} torsional mode or to the $\omega_4 = 388 \pm 15$ cm^{-1} bending mode.
3. Relative intensities give a vibrational frequency of 550 ± 50 cm^{-1}, making tentative assignment possible either to the $\omega_9 = 539$ cm^{-1} or $\omega_7 = 553$ cm^{-1} vibrational modes.
4. Measurements inaccurate because of overlapping by strong line at 20 244.21 MHz.

Ref. 330 gives: for species 1773, (A−C)/2 = 74350 MHz, κ = −.315; for species 1774, (A−C)/2 = 55200 MHz, κ = −.1385.

For species 1775, ref. 823 gives eQq(D) = 200 MHz.

For species 1774, some inversion splittings are also to be found in ref. 330.

NATIONAL BUREAU OF STANDARDS

The National Bureau of Standards[1] was established by an act of Congress March 3, 1901. Today, in addition to serving as the Nation's central measurement laboratory, the Bureau is a principal focal point in the Federal Government for assuring maximum application of the physical and engineering sciences to the advancement of technology in industry and commerce. To this end the Bureau conducts research and provides central national services in three broad program areas and provides central national services in a fourth. These are: (1) basic measurements and standards, (2) materials measurements and standards, (3) technological measurements and standards, and (4) transfer of technology.

The Bureau comprises the Institute for Basic Standards, the Institute for Materials Research, the Institute for Applied Technology, and the Center for Radiation Research.

THE INSTITUTE FOR BASIC STANDARDS provides the central basis within the United States of a complete and consistent system of physical measurement, coordinates that system with the measurement systems of other nations, and furnishes essential services leading to accurate and uniform physical measurements throughout the Nation's scientific community, industry, and commerce. The Institute consists of an Office of Standard Reference Data and a group of divisions organized by the following areas of science and engineering:

Applied Mathematics—Electricity—Metrology—Mechanics—Heat—Atomic Physics—Cryogenics[2]—Radio Physics[2]—Radio Engineering[2]—Astrophysics[2]—Time and Frequency.[2]

THE INSTITUTE FOR MATERIALS RESEARCH conducts materials research leading to methods, standards of measurement, and data needed by industry, commerce, educational institutions, and government. The Institute also provides advisory and research services to other government agencies. The Institute consists of an Office of Standard Reference Materials and a group of divisions organized by the following areas of materials research:

Analytical Chemistry—Polymers—Metallurgy — Inorganic Materials — Physical Chemistry.

THE INSTITUTE FOR APPLIED TECHNOLOGY provides for the creation of appropriate opportunities for the use and application of technology within the Federal Government and within the civilian sector of American industry. The primary functions of the Institute may be broadly classified as programs relating to technological measurements and standards and techniques for the transfer of technology. The Institute consists of a Clearinghouse for Scientific and Technical Information,[3] a Center for Computer Sciences and Technology, and a group of technical divisions and offices organized by the following fields of technology:

Building Research—Electronic Instrumentation — Technical Analysis — Product Evaluation—Invention and Innovation— Weights and Measures — Engineering Standards—Vehicle Systems Research.

THE CENTER FOR RADIATION RESEARCH engages in research, measurement, and application of radiation to the solution of Bureau mission problems and the problems of other agencies and institutions. The Center for Radiation Research consists of the following divisions:

Reactor Radiation—Linac Radiation—Applied Radiation—Nuclear Radiation.

NBS TECHNICAL PUBLICATIONS

PERIODICALS

JOURNAL OF RESEARCH reports National Bureau of Standards research and development in physics, mathematics, chemistry, and engineering. Comprehensive scientific papers give complete details of the work, including laboratory data, experimental procedures, and theoretical and mathematical analyses. Illustrated with photographs, drawings, and charts.

Published in three sections, available separately:

- **Physics and Chemistry**

Papers of interest primarily to scientists working in these fields. This section covers a broad range of physical and chemical research, with major emphasis on standards of physical measurement, fundamental constants, and properties of matter. Issued six times a year. Annual subscription: Domestic, $5.00; foreign, $6.00*.

- **Mathematical Sciences**

Studies and compilations designed mainly for the mathematician and theoretical physicist. Topics in mathematical statistics, theory of experiment design, numerical analysis, theoretical physics and chemistry, logical design and programming of computers and computer systems. Short numerical tables. Issued quarterly. Annual subscription: Domestic, $2.25; foreign, $2.75*.

- **Engineering and Instrumentation**

Reporting results of interest chiefly to the engineer and the applied scientist. This section includes many of the new developments in instrumentation resulting from the Bureau's work in physical measurement, data processing, and development of test methods. It will also cover some of the work in acoustics, applied mechanics, building research, and cryogenic engineering. Issued quarterly. Annual subscription: Domestic, $2.75; foreign, $3.50*.

TECHNICAL NEWS BULLETIN

The best single source of information concerning the Bureau's research, developmental, cooperative and publication activities, this monthly publication is designed for the industry-oriented individual whose daily work involves intimate contact with science and technology—*for engineers, chemists, physicists, research managers, product-development managers, and company executives.* Annual subscription: Domestic, $1.50; foreign, $2.25*.

*Difference in price is due to extra cost of foreign mailing.

NONPERIODICALS

Applied Mathematics Series. Mathematical tables, manuals, and studies.

Building Science Series. Research results, test methods, and performance criteria of building materials, components, systems, and structures.

Handbooks. Recommended codes of engineering and industrial practice (including safety codes) developed in cooperation with interested industries, professional organizations, and regulatory bodies.

Special Publications. Proceedings of NBS conferences, bibliographies, annual reports, wall charts, pamphlets, etc.

Monographs. Major contributions to the technical literature on various subjects related to the Bureau's scientific and technical activities.

National Standard Reference Data Series. NSRDS provides quantitative data on the physical and chemical properties of materials, compiled from the world's literature and critically evaluated.

Product Standards. Provide requirements for sizes, types, quality and methods for testing various industrial products. These standards are developed cooperatively with interested Government and industry groups and provide the basis for common understanding of product characteristics for both buyers and sellers. Their use is voluntary.

Technical Notes. This series consists of communications and reports (covering both other agency and NBS-sponsored work) of limited or transitory interest.

CLEARINGHOUSE

The Clearinghouse for Federal Scientific and Technical Information, operated by NBS, supplies unclassified information related to Government-generated science and technology in defense, space, atomic energy, and other national programs. For further information on Clearinghouse services, write:
