Introduction to the ISEA2015 Proceedings

Thecla Schiphorst & Philippe Pasquier

Computerization of society is ongoing, and digital media are the main communication and expression vehicles of our times. We live in a world saturated with electronic devices, that we literally spend a third of our awaken life on.

– Where does this lead us when it comes to culture, art, and their making?

– How does that influence the ways we make art?

– What is electronic art and how can it change the world?

Since its first edition in 1988, the International Symposium on Electronic Art has been focussing on the impact of technology on art making, and the impact of art on technology, techno-science and society at large.

ISEA2015 proceedings are no exception, and gather 184 contributions: 29 extended abstracts (2 pages) 79 short papers (4 pages) and 76 long ones (8 pages) grouped in 43 sessions. These sessions are the answers from the community to our call for papers under the overarching theme of disruption. Sessions span topics ranging from global warming, geopolitics, bio-art, generative systems and computer-brain interfaces. All these critical aspects of our societies are looked at through the lens of electronic art, and its disruptive potential.

Hyperdressing: Wearable Technology in the Time of Global Warming

Susan Elizabeth Ryan

Louisiana State University
Baton Rouge, Louisiana, USA
faryan@lsu.edu

Abstract

"Hyperdressing" is inspired by the writings of Timothy Morton and his concepts hyperobjects and ecological thought. This paper views the evolution of wearable technologies in terms of both dressing and environmental awareness. Historically, dressing has always been bound up with technology. Ideas, behaviors, and materials come together on our bodies so as to administer to our human condition. Since the rise of capitalism, the dominant paradigm for dressing has been fashion. And fashion is one of the premises driving current wearable technology trends. The others are ubiquitous computing, affective computing, our innate yearning for perfection, and the Quantified Self. Sleek products like Google Glass offer both style and enhancement: a framing of reality as expanding information brought under our control and tailored to our wants. But the paper describes an alternative view of wearable technology that presumes a world increasingly beyond our control. As technology changes, dressing now undergoes a slow, steady disruption—a transformation from the fashion paradigm that serves individual self or self-identity, to a next phase. Will future dressing accessorize a Quantified Self based in biometric devices that accelerate environmental waste? Or might we dress for greater intimacy and openness amid overpowering natural forces and hyperobjects?

Keywords

Biometrics, Body, Dressing, Environment, Fashion, Hyperobjects, Quantified Self, Wearable Technology, Ubiquitous Computing

Introduction

My title is inspired by the philosophical/ecological writings of Timothy Morton. In several books, including his 2010 *The Ecological Thought* and his 2013 *Hyperobjects*, Morton writes that hyperobjects are giant physical and social systems that engulf us but cannot be completely perceived—like global warming or capitalism. We (humans) are objects among countless numbers of objects, some material and some not, comprising a mesh of phenomena and relations that impinge upon us. [1] My use of the term "hyperdressing," in light of Morton's ideas, is (admittedly) hyperbole—somewhat metaphorical, but based on the fact that dressing in any era comprises beliefs, behaviors, and a vast range of objects and technologies arrayed on our bodies that express our awareness of our condition. Since the rise of capitalism, the dominant paradigm for dressing has been fashion. I hope to show that our behavior of dressing now is undergoing a slow but steady disruption—a transformation from the paradigm of fashion expressing individual self or self identity, to a next phase: clothing and equipping a "no-self," a condition of far greater intimacy with a vast array of objects (including what we archaically call beings). This state of intimacy within interobjectivity is illustrated for Morton by the photographer Judy Natal's *Future Perfect: Steam Portrait #28*, about which he says: "The uncanny nothingness of the cloud forces the viewer into a disturbing intimacy with the clothed figure" (Fig 1). The role of technologies that are worn on the body, amid our emerging awareness of such disturbing intimacies, is a subject of this paper.

Figure 1. Judy Natal, *Future Perfect: Steam Portrait #28*. © Judy Natal 2012, as illustrated in Morton, *Hyperobjects*, p. 96.

Although the total *gestalt* of hyperobjects is by definition not perceptible, usually due to their expansiveness and pervasiveness, they evidence themselves through traumatic events and measurable changes that take place over time. In the case of dressing (behavior that responds to the relations or perceived relations between our bodies and other "objects" in our environment) there are two drivers of accelerating change: (1) dressing's historical ability to absorb and embody technologies including its role in the current race toward wearable technologies; and (2) the counterforce of ecological and environmental realities.

Dress and Technology

In my recent study of dress and technology, *Garments of Paradise: Wearable Discourse in the Digital Age*, I argue that historians and archeologists have always considered garments to be among the technological advancements of civilizations since ancient times. [2] Dress is a technology, something that absorbs the latest discoveries and incorporates ever better solutions for our physical and psychological needs. Part of the technological boundupedness of dress is its ability to manifest our cravings for physical enhancement, to launch abilities beyond our bodies.

Historically, from providing warmth and advantages in battle to facilitating sexual reproduction and social selection, technologies have adapted to the body to allow us to become (or imagine becoming) more agile and powerful, more sexual and desirable (e.g., the attention to sleekness was aided by the development of synthetic fibers in the early twentieth century), or more or less noticeable—I have written elsewhere about our ancient and ongoing wish for invisibility, something I will come back to in a moment. During the first half of the previous century, driven by two world wars and the rhetoric of eugenics, our popular imaginations were filled with powerfully dressed superheroes, often with garments or gadgets enabling enhanced strength, vision, speed, even the ability to fly (early super clothes or adornments appear from Batman to Green Lantern). The actual technologies to bring about such fantasies would be generated by the electronic devices developed only after World War II, with strides in computing power and miniaturization. For example, the notorious SONY Walkman, introduced in 1979, spawned generations of mobile (wearable) entertainment products. By the end of the last century we explored the fantasy of merging with machines: bionic superheroes, fictional cyborgs, and finally the first actual wearable computers.

Those began to be developed in the 1990s at centers like the MIT Media Lab, Carnegie Mellon, and Georgia Tech in the U.S. The early, geeky, hard-box wearable computers were complicated and expensive, and start-up companies like Charmed Technologies, that tried to forge a market for them, by presenting them as fashion, had an uphill climb. As Maggie Orth, wearable technology designer and founder of International Fashion Machines observed, clothing lines in the nineties were interested in garments that lit up or responded to the wearer with functioning electronics. Once an electronic module was tooled, hundreds of thousands had to be sold to create a profit, whereas clothing producers projected on a scale of tens of thousands of units because of the scope and rapid turnover of the fashion industry. One popular wearable tech (henceforth WT) item in the nineties was LA Gear's Lights sneakers. With LEDs in the heels that flashed with the pressure of heal strikes, the Lights sold over five million pairs and became iconic, if isolated, evidence of industry's aspirations for WT. But aspirations outraced abilities. Breakthroughs for marketable WT came slowly and were rarely adopted by mainstream dressing. Despite many campaigns for WT products, only illuminated garments received much attention. 2008-10 were banner years for LED couture, a short-lived red carpet trend in the midst of the economic downturn. But with the rise of social media accessed through mobile phones, in the past few years it has been devices rather than garments that have evolved to display sophisticated design and are marketed in tune with digital capitalism. Watches and other wearables, most notably Google's Glass, have leveraged the accomplishments of hand-held phones and their systems to mete out the enhancements we crave—instantaneous memory access, communication, and security (albeit in the form of surveillance). Through it all has been the steady growth in health monitoring systems, long strapped onto bodies in the medical environment, but now walking the streets. In the 2010s, Fitbits and related devices have become accessories of choice, by which we constantly measure our personal progress or decline.

Our sleek new devices now take on the very issue of dress itself. If, as Orth points out, wearable electronics are far more instrumentalized than fashionable dress, then they support a more computational and socially monitored perception of ourselves than does traditional fashion that changes season-by-season. So is dress itself changing in concert with the evolving manner in which we relate to the world and each other? Is dress gravitating toward something akin to the literary and social utopian dress posited by early modernism? Vladimir Tatlin's unisex worker's clothing, or the uniforms in nearly all modernist wonderlands, from Thomas More's *Utopia* (1516), to Alexsander Bogdanov's sci fi novel *Red Star* (1908, about a socialist utopia on Mars), George Orwell's *1984* (1934), and even Mao Zedong's Chinese Cultural Revolution (beginning in 1966) all advocated functional universal dress, often blocky suits or overalls with little or no difference between individuals. In support of this, some point to the recent rise of "normcore"—bland, anti-fashion attire—the latest trend for plain traditional clothes that fade to black as we focus on our devices. In the Google-Apple version of future dress, our sleekly designed enhancements signal that individuality is inside, or invisible, or dispersed across a wider net. Our bodies and social lives are endlessly attended to, but will our reliance on walk-in

closets fade away? As early as 1964 Marshall McLuhan (like other modernists before him) suggested that societies developing electronic media would adopt nudity—might he be right after all? [3]

Dress, Technology, and Environmental Impact

So far there is no sign that the fashion industry is in jeopardy; it adapts. In the twenty-first century, under accelerated post-industrial capitalism and aided by markets' increasing ability to exploit dress's psychological potential through brand imaging and social media (YouTube and blog posts of "beauty gurus"), we have fast fashion—cheap outsourced gobs of garments with incredibly rapid obsolescence. The term "landfill fashion" has been used for the trendy, low-cost garments of certain fashion chains serving consumers with shrinking attention spans facing an increasing vastness of choices, and sourced from expanding factories turning out fast fashion in China and Viet Nam—and Bangladesh, until the appalling factory collapse in 2013. [4] Mountains of cast-off clothes pass to thrift stores and are carted to postconsumer sorting facilities where about 30% of it is recycled, and the rest baled for export to developing nations. Most of it becomes garbage, contributing to escalating dumpsites, and trash islands in nearly every ocean. The presence of toxic chemicals, fire retardants, dyes made of heavy metals, and petroleum and other toxic processing agents in synthetic fibers make this trash lethal.

By the same token, the amount of electronic devices and components, increasing exponentially in accordance with Moore's Law, is also creating vast piles of garbage. According to the U.S. EPA, in 2000 4.6 million tons of e-waste—discarded electronics and components that include toxic chemicals that leach into land over time or are released into the atmosphere—ended up in landfills in the U.S. CBS News reported in 2013 that 50 million tons of e-waste per year were sent to dumps. A 2013 United Nations study estimated that e-waste would grow from 48.9 million metric tons worldwide in 2012 to 65.4 million metric tons in 2017. The numbers do not all coordinate precisely, but by all accounts they are astronomical. [5]

As we consider the potential expansion of WT as mobile devices, based on the heated market in the past few years, we might imagine two enormous flows of toxic trash converging. E-textiles, including nanoparticle-coated fibers, present upwardly scaling challenges that we have barely begun to study. As fashion-based WT grows, we can project a situation that compares figuratively with Walter Benjamin's image of the "Angel of History" (based on Paul Klee's 1920 painting, *Angelus Novus*):

> [The angel's] eyes are staring, his mouth is open, his wings are spread. This is how one pictures the angel of history. His face is turned towards the past. Where we perceive a chain of events, he sees one single catastrophe which keeps piling wreckage upon wreckage . . . A storm is blowing from Paradise . . . The storm irresistibly propels him into the future to which his back is turned, while the pile of debris before him grows skyward. This storm is what we call progress. [6]

But now the piles of debris are real, not imagery—they are toxic, and the angel is us.

Invisible Computing and WT

The backward vision presented by Benjamin also portrays our fundamentally flawed perception of a situation beyond our reach. Timothy Morton describes this as the ontological asymmetry between humans and nonhumans in a time of hyperobjects. Global warming (Morton rejects the polite term, climate change) already engulfs us—we cannot recycle our way out it: "we discover that the space we inhabit is not open and neutral, but is the interior of a gigantic iceberg whose seeming transparency was simply a matter of our less than adequate eyes. Flying through the universe in the space shuttle of modernity, . . . we have woken up inside an object, like a movie about being buried alive." [7] Our eyes are already asymmetrical with our bodies, which are entangled with the world of objects.

As an iconic example of WT (at least a great creator of buzz), Google's Glass forms a case study of how we seek to control and manipulate our vision (Fig. 2). A culmination of techno dreams of physical and mental enhancements, Glass offers us immediacy of information access and communication, and power over our physical contexts via its camera and GPS, all packaged in a heads-up, hands-free accessory that can imitate glasses or accommodate the most stylish frames. Of course, power works both ways, and alongside the privacy concerns that were raised are possible health and environmental hazards from Glass's micro-wave emissions, and impacts on vision such as binocular rivalry, visual interference, and phoria, a latent deviation or misalignment occurring when both eyes are not looking at the same thing. [8] But Glass also fictionalizes reality by asserting that we are in control of all that we see. The chaos of the world is reorganized

Figure 2. Google Glass, simulated view of data "timeline" overlaid on normal view. Google photo.

through the data overlay. Why fear climate change when we can call up statistical forecasts and chart a safe course? As Morton says, it is not as easy as that. "The more data we have about hyperobjects the less we know." [9]

Like almost all the prototypes for industrially produced WT today, Glass was built on the assumptions of ubiquitous computing, a term coined by Mark Weiser in 1980s. Weiser's fundamental principle was technology's drive to disappear. In a talk given at Xerox PARC in 1994 he said, "Good technology is invisible . . . ubiquitous computing is about 'invisible' computing." [10] Weiser envisioned ubiquitous technology (ubicomp) as augmentation, a way of being in the world, and the opposite of virtual reality, which involved withdrawal from the world. He imagined ubiquitous technology would become the natural and empowered way to deal with the overwhelming realities around us, release us from the stresses of information overload. It would calm us down.

Weiser was a thoughtful techno-scientist, but his untimely death in 1999 prevented the evolution of his ideas and any reassessments he might have made as technologies advanced. Instead of being improved or re-evaluated, Weiser's calm world of augmented reality became the norm for developers. In 1997 Rosalind Picard presented the concept of affective computing whereby devices that read our biometrics activate on our behalf, allowing computers to become more invisible still, operating on their own around us. Most technology that interfaces with our bodies, developed since that time, has sought this holy grail of "intuitiveness" by making the computational interface seem like it is a seamless part of us, that we are invisibly enhanced and at the center of our world. The model of invisible control trades on our age-old desire to leap beyond the limitations of our bodies and effortlessly navigate our complex environments free of stress. And so the market for these devices has accelerated like a runaway train.

But as Morton points out, the very notion of our "world" is itself a concept that we create and believe in. Our belief is "a token, a mental object that you grip as hard as possible, like your wallet or your keys." Nothing is more manufactured than the smooth, controllable data flows that Glass or even our smart phones offer as part of our personal vision. Nevertheless, the very scale of what we experience at this time—extreme weather, Big Data, and violent social upheavals—means that cracks in our world-view, no matter how enhanced, arise with increasing frequency. Morton writes, "*World* is a fragile aesthetic effect whose corners we are beginning to see." [11]

Asymmetrical WT

On the other side, there are artists and designers who work with electronics and garments in order to dramatize our smallness and our potential for intimacy amid the uncontrollable objects around us. Take Ricardo O'Nascimento, Ebru Kurbak, and Fabiana Shizue's *Taiknam Hat* (2007), with feathers that levitate in the presence of EMF waves. The hat materializes the invisible and dramatizes our engulfment in electromagnetic radiation in our environment emitted by our physical devices. This unseen electrosmog is an object with biological effects on humans and animals.

The WT created by Canadian designer Joanna Berzowska provides us with more examples. Rather than perpetuating modernist fictions of enhancement and control, her one-of-a-kind wired-up wearables display the "otherness" of technology, an effect rendered uncanny when worn on the body. Her work deploys not merely representation or metaphor, but reveals our asymmetrical relationship with an object world that impinges upon and, indeed, infuses us.

At Concordia University in Montreal, Berzowska collaborated with Di Mainstone on *Skorpions* (2007), five electronic garments that integrate Nitinol (a shape memory alloy or SMA), mechanical actuators such as magnets, soft electronic circuits, and traditional textile construction techniques such as sculptural folds and drapes of fabric (Figs. 3-4). *Skorpions* move and change on the body, controlled by their own internal programming.

Figures 3-4. Joanna Berzowska and Di Mainstone, *Skwrath* and *Luttergill* from Skorpions, 2007. Photo Nico Stinghe. ©XS Labs

The series was intended to explore an adversarial relationship with technology, how we sometimes fear it, and how, in opposition to the perfection technology is supposed to represent, it is ultimately unpredictable. The *Skorpion* garments do not create sound or light up, nor do they augment the wearer's abilities—rather the opposite. They slide around the wearer's body on their own like live skins or animals, opening pulsating gashes like breathing gills. Rather than embodying function, they malfunction—as if as clothes they are not just consumed, but "possessed," and threaten to possess us. *Skorpions* exploit characteristics such as anticipation, anxiety, and surprise.

The *Skorpions* have a feral nature and the series pays homage to their formidable namesake arthropod and its elegant but deadly tail. The dress called *Skwrath* ("Skorpion wrath") has an abdomen made up of three insectile, interlocking leather segments, embroidered with threads of SMA, which are activated through a custom electronic board to curl back, revealing slashes of red silk. *Skwrath* warns people to stand back. When they get too close, its plates crawl and retract, and red silk suggests blood. In contrast, *Luttergill* is a soft, quilted cotton cocoon. Its seams roll open and closed, controlled through SMA and custom electronics, revealing serene blue silk inside. As garments, *Skorpions* revisit Donna Haraway's notions about "companion species" by animating digital technology and wrapping us in its uncontrollable interface. Berzowska refers to such pieces as "reactive garments": rather than responding to us and administering to some perceived need, as with affective computing, we, as wearers, react to what we are wearing. She says, "My work . . . undermines our expectations about technology. These works are not meant to solve problems but pose questions about how design might operate." [12]

Berzowska's *Sticky* (from the group, *Captain Electric and Battery Boy*) revives the 1930s superhero, whose garments performed futuristic powers, and responds to the modernist eugenics fantasy with a human enhancement farce about electricity generated by the human body. *Sticky* is a hooded leather dress with sleeves tethered to shells on the abdomen such that the wearer must strain to move (Figs. 5-6). "*Sticky* binds the arms, restricting their motion, keeping them close to the body. It coerces the body into a state of isolation. Attempts to free oneself from the

Figures 5-6. Joanna Berzowska, *Sticky*, from *Captain Electric and Battery Boy*, 2007-10. Photo Guillaume Pelletier. © XS Labs.

restraints, by reaching away from the body, generate energy to soft luminescent blue pebbles in the pockets . . . concealed silicone forms [which offer] a comforting glow" that persists after the wearer has stopped struggling. [13] The "pocket pebbles" are warm, tactile objects similar to "calming stones," providing an unexpected spoof on Mark Weiser's notion of "calm technology."

In the above designs, the goal of augmentation or enhancement sought by builders of wearable computers and personal area network systems is entirely overthrown and replaced by non-product-based, experimental or ironic design that is highly coded but references the world of dress and culture as well as technology. These wearables are not only commercially unfeasible, but preposterous, even comic.

Some designers of ironic technological clothes focus on the external relationships between wearers and their environment (Figs. 7-8). Diffus Design's *Climate Dress* (Michel Guglielmi and Hanne Louise Johannesen), uses conductive thread embroidery, LilyPad Arduino, sensor, and LEDs. It illuminates in accordance with CO2 concentrations in the ambient air, so the dress is a platform for environmental awareness, pitting beauty against health or against the environment: the more carbon emissions, the more the radiant the dress becomes. What better reminder that beauty resides alongside immanent danger in hyperobjects?

Figures 7-8. Diffuse Design (Hanne-Louise Johannsen and Michel Guglielmi), Climate Dress, 2009. Courtesy Diffus Design.

Capitalism and the "Empire of Fashion"

Turning back to the evolution of industrially produced wearables, it is clear that the dynamics between bodies and environments are changing. Environments include the larger context of dressing, too, and that includes fashion, the dominant dressing paradigm since the industrial revolution. Fashion is the essential expression of modern, democratic societies. What French social philosopher Gilles Lipovetsky called *The Empire of Fashion* (1987) operated at the level of civic behavior. He argued that mass-produced fashion offers nuances of choice and

symbolism, which in turn enable consumers to behave as complex individuals within democratic societies: "Fashion is one of the faces of modern artifice, of the effort of human beings to make themselves masters of the conditions of their own existence." [14] Moreover, Lipovetsky writes that modern democracies are structured by fashion, meaning that taste in dress (among other things) navigates media and information and nurtures an essential skill set for individuals.

In the 1990s Lipovetsky updated the text, adding that the "logic of appearances" had moved from dress to the body, and prestige based on distinctions of dress was ebbing in favor of skin-based display involving tattoos, body-building regimens, and plastic surgery. Today, body-based enhancements coordinate with the growing interest in health monitoring systems and in the self as a physical project—monitoring will improve our exercise, weight loss, and sleep habits in a never-ending process of perpetual training, what Gilles Deleuze placed at the heart of "Societies of Control." [15] In fact, we acquiesce to the never-ending programming and retraining regimens in continuous cycles of self-improvement that are never complete but must be constantly maintained.

Quantified Self Vs. "No-Self"

The WT industry has leveraged itself on our intense fixation with ourselves as bundles of flesh and functions that are increasingly monitored and measured, a movement termed the Quantified Self (QS) by Gary Wolf in 2007. [16] The proliferation of health monitoring devices drives expectations for WT. In 2013 *Forbes* predicted 2014 as the "Year of the Wearable" and a year later Gartner Market Research reported that personal health and fitness devices would be a five billion dollar market by 2016. [17] The problem is, the more data we generate about ourselves, the more data we encounter, and the larger the task of maintaining systems, training plans, and upgrades, all seeming to manifest control society beyond even Deleuze's wildest dreams.

If this is a trend it seems likely that devices will eventually challenge our notion of dress as based in the practices of making choices (Lipovetsky), and move toward a different paradigm based on analyzing biometrics. And the possibilities are expanding. Already, a macabre chronometer watch called Tikker, from a start-up company crowdfunded in 2013, calculates its wearer's life expectancy and proceeds to count down to her projected time of death.

Some, like Dawn Nafus and Jamie Sherman, view the emergence of the QS-as-driver-of-wearable-devices as a dialectical response to universal corporate control represented by Big Data. They write that self-monitoring via wearable biometric devices, while still a part of the reach of Big Data, constitutes a "soft resistance" by which individuals retain the possibility to evaluate the data they receive and choose how they deploy it. While the devices' algorithms programmatically analyze data according to corporate categories and the marketing goals behind them, users work through "the constant unfolding of meaning to critically question what constitutes relevant information, whether individual datapoints or entire categories of information." But in the end the independence of the user is limited, and Nafus and Sherman concede that "self-trackers are making a lateral move," working both beyond and within received categories. [18] Even a wearable like Glass, that attempts to control the intersection between biometrics and Big Data, offers a framed experience that is always pointed toward us. That is what customizing algorithms do. Glass "fits" Big Data to us, just as fitness bands and health devices also put us at the center of data and "tailor" it to us. It is sartorial, fitted to our desires—the ultimate custom couture.

Morton talks about our frequent encounters with massive amounts of data as an indicator that we—humans—are becoming more aware of hyperobjects and our inability to truly measure them due to their vastness in time and space and their ability to both "stick to" us and, at the same time, withdraw. Global warming is like that and so is Big Data. Data sticks to us through our wearable devices yet we can never finally grasp it all. We deal with greater and greater scales of things. For Morton what is occurring is "the gradual realization by humans that they are not running the show, at the very moment of their most powerful technical mastery on a planetary scale." [19] Morton points to possibilities other than mastery. He references the philosopher Derek Parfit's idea of "no-self,": "a liberating abandonment of dominating self-interest." Parfit writes, "[Before,] I seemed imprisoned in myself . . . I now live in the open air. There is still a difference between my life and the lives of other people, but that difference is less. Other people are closer. I am less concerned about the rest of my own life and more concerned about the lives of others." [20] This "no-self" is not self-obliteration and not dehumanization (as the Quantified Self appears to be) but a "radical encounter with intimacy." Unlike Tikker, that tracks our progress toward death, hyperobjects force a closeness with mortality, with other beings and objects, and with the unknowable. And according to Morton, "Intimacy and the no-self view come together in ecological awareness." [21]

One means of becoming open to the reality of our condition might be by accessing cognition via aesthetics—actually a particular aesthetic Morton characterizes as demonic or uncanny, that incorporates the "terrifying glimpse" of, say, ghosts, "a glimpse that makes one's physicality resonate"—and he references Adorno's comment that the primordial aesthetic experience is goose bumps. [22] This physical glimpse supports a sense of intimacy, even of being "too close" to other life and other objects—and the life in other objects.

I will always remember an early childhood nightmare from which I awoke in a sweat. In the dream, a familiar floor lamp with a bare electrical bulb moved toward me in my bedroom. It reminds me of some early artistic uses of wearable technology, like Atsuko Tanaka's *Electric Dress*

(1956), which appeared as a giant pile of light bulbs, replete with tangled wiring, moving toward the audience in the performance space (Fig. 9). The bizarreness of the experience was felt even more by the artist who wore the "dress" and contemplated electrocution. Tanaka told an interviewer "I had a fleeting thought, is this how a death-row inmate would feel?" [23]

Feeling unsafe around technology is a feature of our imbrication in a world of forces that we try to push into the background. The "uncanny" brings about both an aesthetic closeness (not aesthetic distance) and an openness that Morton calls rest. Rest is an aesthetic event reflected in Tanaka's work. Rest-as-aesthetic includes (according to Morton) shock, stunned silence, and an attunement to the not human. If we compare Morton's concept of "rest" to Mark Weiser's notion of "calm" (as in calm technology) that has been the driving conceptual premise behind capitalist technological evolution, we find the two notions, linguistically so close (synonyms for Roget), are opposites. Weiser's calm technology, as he wrote about it in the 1990s, involved the fact that when we focus on anything—

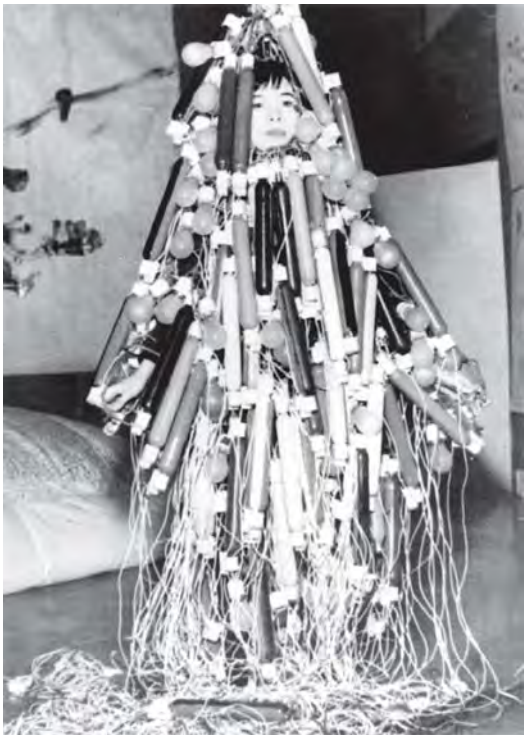

Figure 9. Atsuko Tanaka, *Electric Dress*, performed at the 2nd Gutai Art Exhibition, 1956. © Ryoki Ito. Photos © The former members of the Gutai Art Association.

driving a car is the example he used—we also notice things that happen on the periphery, like a child playing in the passenger seat. True calmness involves effective mastery of the movement between focus and periphery to achieve a sense of our locatedness. For Weiser, the job for a technology is master center/periphery such that users remain aware, but can focus on what they want: "As we learn to design calm technology, we will enrich not only our space of artifacts, but also our opportunities for being with other people. Thus may design of calm technology come to play a central role in a more humanly empowered twenty-first century." [24]

Since Weiser wrote that in 1995 technology design has changed. First, interaction is increasingly treated not as something to be eradicated but rather as a sensually appealing experience that attracts us. [25] Second, this experience has expanded opportunities for brandedness and more sophisticated tools that direct users' actions more effectively, rather than (as Weiser envisioned) enhancing user awareness. Simon Penny notes the recent development of ubiquitous computing on two fronts: (1) the still invisible: "clandestine, faceless technologies that involve distributed units in a larger control array . . ," and (2) "garrulous, clingy technologies close to the body"—encompassing WT that has commercially come of age. Penny finds neither of these trends particularly calming: "how far have we come . . . is the automated processing of logical operations necessarily applicable and an asset in every aspect of life?" [26]

On the other hand, rest or restfulness within the context of hyperobjects is not about human empowerment, but the opposite. Hyperobjects is of course not a technical term, but for Morton it is applicable to the technological age, which is also the age of global warming and events and objects that overwhelm us. The kind of rest he refers to is not safe and does not provide the illusion of security, but rather the acceptance of coexistence. He cites John Keats, who wrote about the poet as a spirit that has no self, but absorbs everything around him—Keats called himself a "Camelion Poet" [*sic*]. [28] If we happen one day to be overcome by environmental trauma, or, for whatever reason, we find ourselves catapulted beyond our capitalist behavior and reliance on technologies of control, then perhaps our future dressing might become hyperdressing. It would involve accepting our asymmetrical existence and, chameleon-like, becoming intimate in the time of hyperobjects.

Turbulent World: An Artwork Indicating the Impact of Climate Change

Angus Graeme Forbes*
Electronic Visualization Laboratory
University of Illinois at Chicago
Chicago, IL, USA
aforbes@uic.edu

Abstract

This paper describes an artwork created in response to a question about the role of the artist in communicating climate change issues. The artwork, titled *Turbulent World*, incorporates turbulence and surprise as a means to visualize the potential instability of our culture and the environment due to climatic changes indicated by increased worldwide temperatures. The artwork makes use of a custom fluid engine that can represent any amount of turbulence and energy. A dataset encoding a simulation of rising surface-air temperatures over the next century is mapped to the turbulence system; and the visualization is updated as the months and years flow by, based on the projected temperatures at different areas of the world. That is, the increased turbulence of the system causes a representation of a map of the world to become distorted in different ways. A secondary view is overlaid, showing numerical data and providing a more dispassionate display of the inexorable increase in world temperature.

Keywords

Climate change, art-science, software art.

Introduction

Turbulent World is a time-based artwork that displays an animated atlas that changes in response to the increased deviation in world temperature over the next century. The changes are represented by visual eddies, vortices, and quakes that distort the original map. Additionally, the projected temperatures are themselves shown across the world, increasing or decreasing in size to indicate the severity of the change. The data used in the artwork was generated by a sophisticated climate model that predicts the monthly variation in surface air temperature across different regions of the world through the end of the century (Delworth et al. 2006). The various datasets that are output from this model are available at the National Climatic Data Center (NCDC), run by the National Oceanic and Atmospheric Administration (NOAA).

Motivation

Turbulent World was first created in response to a call for entries by curators Emmanuelle Namont Kouznetsov and Kathrine Worel of OFF Space for an exhibition titled "Brave New World." In their call for entries, they asked artists to think about creative responses to climate change: "What is the role of the artist as citizen in this climate? How might we reclaim our choice, our connection, our social power when immersed in a deteriorating environment?"[1] *Turbulent World* was originally featured in this show, presented within the Spare Change Artist Space in downtown San Francisco. It was installed for the duration of the exhibition, which ran from late 2013 through early 2014.

The goal of *Turbulent World* is to provide insight into a data model that represents current thinking by leading scientists about climate change. Scientific visualization often focuses on individual data samples; visualizations that effectively capture large-scale systems are more difficult to represent (Johnson 2004). Additionally, climate change represents multiple, intertwined systems and necessitates new thinking about economics, policy-making, urban development, and other activities (Folke et al. 2010). An additional issue in representing climate change is that it exists at a scale that is hard to reason about (Opdam and Wascher 2004). Despite the major implications of climate change for civilization, due to these issues in scale and complexity, people do not take the time to reflect upon climate change very often (Chia 1998). Since modeling, representing, and explaining climate change is so challenging, *Turbulent World* does not attempt to include a comprehensive information visualization of the relevant data, but rather presents one aspect (the projected surface-air temperature) in order to provide a window into this complex system.

The piece was motivated in part by scientific visualizations that were developed by the geoscientists Jeremy Weiss and Jonathan Overpeck, both affiliated with the Institute of the Environment at University of Arizona. Their research includes simulations of the coastal regions that will be affected by a rising sea level (Overpeck and Weiss 2009; Weiss, Overpeck, and Strauss 2011). Additionally, it was inspired by other artworks that explore ways to represent the impact of climate change, including Bruce Caron's *Light Blue Line* outdoor installation, which painted a blue line throughout the city of Santa Barbara at exactly seven meters above sea level, dramatically showing the potential effects of melting glaciers and sea ice decline due to climate

change.[2] Work by other artists and artist collectives that took part in the Brave New World show, including Amy Balkin, Gioj de Marco, Alicia Escott, Alan Hopkins, Andréanne Michon, Barbara Milman, Emmanuelle Namont Kouznetsov and Elyse Hochstadt, and Kathrine Worel, among others, also influenced the creation of *Turbulent World*.

Though a range of artists have produced works that in some way use data related to climate change as a material, or that explicitly comment on climate change, both artists and scholars can be uncertain of the cultural impact of these types of works. For example, a recent article by Adam Corner argues that through the invention of novel forms of representation artistic projects keep environmental issues "in the public eye."[3] Jonathan Rowson notes that public events, while briefly generating hope and inspiration, are also "tampered with a little sadness," since the false belief that simple awareness is useful is "part of what prevents us from facing up to the monstrous complexity and embarrassing urgency of the problem."[4]

Other commentators believe however that artworks, more than simply raising awareness, can make issues tangible and thus meaningful. An article jointly penned by the professors Elke Weber and Irena Bauman and the artist Olafur Eliasson makes the claim that art is precisely the appropriate vehicle for change. The article describes Olafur Eliasson and Minik Thorleif Rosing's 2014 work *Ice Watch*, which consists of 100 tons of ice transported from the Nuup Kangerlua fjord to Copenhagen and arranged in City Hall Square in a circle resembling a clock.[5] The spectacle of the installation literally melting away is presented as a means to permanently change perceptions about climate change. They write that the scientific community is failing because "[t]he information presented by the IPCC is overwhelming and [...] too complex to be able to translate into effective actions." Thus, they argue that "strategy plans, position papers, and limits for CO2 omissions" need to be accompanied by "art, architecture, storytelling, and other cultural activities."[6]

Description of Artwork

Unlike many other artworks that explore topics related to climate change, rather than staging a dramatic portrayal of the effects of climate change, *Turbulent World* includes a more direct representation of the data indicating a projected change in climate, as modeled by the Geophysical Fluid Dynamics Laboratory at the National Oceanic and Atmospheric Administration. The artwork begins in the current month of the current year by showing a still image of the world map using an equirectangular projection. The average surface-air temperature (SAT) for locations across the world for the current month are overlaid on top of the map in an eight-column by five-row grid containing cells of uniform size. As the animation begins, the deviations from the expected SATs (that is, if there were no increase in CO_2 into the atmosphere) are indicated by a change in size of the numbers representing the tem-

peratures. The total deviation in temperature across the world (from the original baseline) in shown in the upper righthand corner. The artwork uses an interpolation of the values in the CM2.1 model (described below) in order to better fit them on the screen, but they are otherwise faithful to the model.

As the surface-air temperature deviates from the baseline values, the magnitude of the deviation within a particular cell distorts the map by either pulling the map toward the point where the number is centered, if the projected temperature rises, or pushing it away, if the temperature falls. The artwork uses the Fluid Automata system (Forbes, Höllerer, and Legrady 2013; Forbes and Odai 2012) for creating turbulent fluid effects. The overall turbulence of the fluid system becomes more chaotic as the deviation to the temperature increases. Additionally, a series of image processing techniques are used to augment the turbulence in the fluid system by changing the saturation and brightness of the map. Figure 1 shows a screenshot of the installation when displaying projected data for Septmeber 2067.

Climate Change Data

The dataset for the artwork consists of the projected average surface-air temperatures across the world through December, 2099. The data was retrieved from a repository hosted by Geophysical Fluid Dynamics Laboratory at NOAA,[7] where the model was developed. Specifically, the CM2.1 model was used, which is a coupled ocean-atmosphere general circulation model using an idealized 1% increase in carbon dioxide emissions per year. That is, it models the climate as an interconnected system composed of atmosphere, land, ocean, and sea ice systems. The CM2.1 model was used to "conduct a suite of climate change simulations for the 2007 Intergovernmental Panel on Climate Change (IPCC) assessment report" (Pachauri and Reisinger 2007). A 2013 report reiterates that scientists have a "very high confidence that models reproduce the general features of the global-scale annual mean surface temperature increase over the historical period" (Flato and Marotzke 2013). That is, the CM2 model has been effective at simulating "the main features of the observed warming of the twentieth century," and is thus seen as a reasonable, though potentially conservative, model for predicting probable changes in the climate (Delworth et al. 2006). More detailed information about CM2 Global Coupled Climate Models (and the data itself) can be found at the Geophysical Fluid Dynamics Laboratory (GFDL) website.[8]

Discussion

Turbulent World was discussed during a panel interview led by the environmental poet Eric Magrane, which was partially summarized in the online magazine *Proximities*.[9] The discussion focused on the use of visual representations, whether artistic or scientific, and how they function as a tool to *communicate* the meaning of data, rather than simply to represent it. The artwork was used a means to think about the tension between telling a story from a biased perspective and presenting neutral data. Specifically, we discussed the use of scientific data as a material for data-centric artworks and artistic techniques for representing scientific data.

Participants on the panel, which also included the geoscientist Jeremy Weiss and the graphic designer Kim Daly, had differing perspectives about how visual representations should emphasis climate change data. However, the panelists agreed that, since climate change is a complicated topic involving researchers from many different fields, it is simply too big an issue to be summarized by any one visual representation. Artists and designers can only capture and illustrate pieces that can provide a window into this complex system. Providing users with a chance to see the data unfold through a artistic visualization allows them to reach their own conclusions about the data, even as the piece presents a clear provocation about the impact of the data. At the minimum, it communicates the data in a clearer way that might encourage a viewer to do further research into these types of climate change models, and, ideally, if we agree with Weber, Bauman, and Eliasson, it widens cultural space to include interconnected and interdependent experiences.

Abstract

World-Wide-Walks have been performed by Peter d'Agostino on six continents over the past four decades to explore elements of natural, cultural & virtual identities: mixed realities of walking through physical environments and virtually surfing the web. Initiated as video "documentation/performances" in 1973, the Walk Series evolved into video/web projects during the 1990s, and mobile/locative media installations in the 2000s. During the past decade, the World-Wide-Walks / between earth & water projects have considered the dire crisis of climate change and its ominous threat to impact on human civilization by operating as part of a long tradition of walking practice as exploration, meditation, political activism, community engagement.

This paper focuses on Walks that explore the immediate peril of global warming. Melting ice has the capacity to raise sea levels and change the configuration of civilization in heavily populated coastal regions. These Walks record the real time deterioration of glaciers, while noting their historic loss. Recent books by Elizabeth Kolbert and Naomi Klein contextualize the challenges of climate change. Kolbert talks about the precariousness of species, exacerbated by human environmental abuse. Klein discusses how wealth, worldwide economics, and the negotiation of geo-political differences challenge the mobilization to enact timely change.

The arts have a role to play on the cutting edge of these issues through the production of works of significant cultural resonance and art the transmission of urgent concerns about a world at risk.

Walking in Changing Environments

Humanity, upright, went into the caves, made markings by leaving imprints of hands, painted bison, and created great ritualistic spaces. Young Aboriginal men came of age by walking to learn about country, history, politics, time and space, geography, horticulture, fauna, natural boundaries, language. In the virtual age, walkabout has diminished. Losing that profound contact with the environment, losing the stories shared, the Law, the community suffers. Identity disappears. Environmental memory disappears. Humanity stamps the landscape with an economically driven, utilitarian, self-engaged framework that distances other operative systems that offer insight, meaning, and an alternative.

The act of walking, literally and metaphorically, from first steps to daily routines, still holds a key to individual and collective human identity. Walking positions the individual within a world of empirical awareness, statistical knowledge, expectation and surprise - anticipation of unknown encounters around the bend.

In mediating the frontiers of human knowledge, walking and other forms of exploration remain a critical means of engaging global challenges. Walking also constitutes a political act, most notably now when traversing environmental boundaries undergoing radical and potential cataclysmic change.

In *The Sixth Extinction: An Unnatural History* (2014), Elisabeth Kolbert discusses predictions that almost half of all living species on earth might vanish within this century.

> One of the defining features of the Anthropocene is that the world is changing in ways that compel species to move, and another is that it's changing in ways that create barriers roads, clear-cuts, cities - that prevent them from doing so.
>
> Thomas Lovejoy has written that "in the face of climatic change, even natural climatic change, human activity has created an obstacle course for the dispersal of biodiversity," the result of which could be "one of the greatest biotic crises of all time." [1]

In *This Changes Everything: Capitalism vs. The Climate*, Naomi Klein takes the issue head on-today and for a not too distant future. Klein's exploration covers the geo-political terrain.

Klein also explores the meaning of individual humanengagement with the environment. During a difficult pregnancy, she describes how walking became a meditative process enhancing political insight into traditional understanding, awakening consciousness.

> What helped most was hiking, and during the final anxious weeks before the birth, I would calm my nerves by walking for as long as my sore hips would let me on a well-groomed trail along a pristine creek. [2]

Klein bridges the individual's growing singularity on the technological age with that of the individual reconnecting with the surrounding environment. She expands the metaphor through her own reproductive narrative:

> If the earth is indeed our mother, then far from the bountiful goddess of mythology, she is a mother facing a great many fertility challenges of her own. Indeed, one of the most distressing impacts of the way in which our industrial activities affect the natural world is that they are interfering with systems at the heart of the earth's fertility cycles, from soil to precipitation. [3]

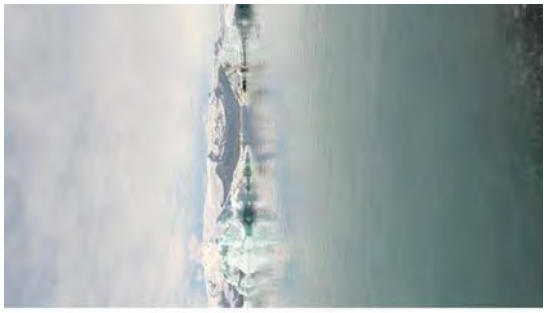
World-Wide-Walks

In their fragility, the World-Wide-Walks, over the past four decades, assemble a finite human figure's making of micro and macro meaning within natural and mediated cultural environments. Individual experience must continue to resonate to sustain a greater political awareness and mobilization.

> Many years later, as he faced the firing squad, General Aureliano Buendia was to remember that distant afternoon when his father took him to discover ice. [4]

The news of Gabriel García Márquez's passing in 2014 rekindles the memory of these opening lines to *One Hundred Years of Solitude,* the saga of a family in a village on "the bank of a river of clear water."

While walking in California's Sierra Nevada mountains during the summer months, there are experiences of drinking clear water flowing directly from the melting snow pack at the higher elevations. Other walks through the Canadian Rockies to the Columbia Ice Fields in 1972 set a baseline for witnessing glacial retreat. On revisiting the ice fields two decades later, a video walk records strategically placed signs at five year intervals - beginning in 1965 and proceeding to 1990 - marking the path toward rapidly receding glaciers.



Walk: Vatnajokull © 2012 pdA

World-Wide-Walks / between earth & water / ICE

Recent walks at the edge of glaciers at the top and bottom of the globe - in Iceland, Alaska, and Tierra del Fuego, Argentina - were performed to witness the consequences of man-made global warming.

Juxtaposed with the ICE Walks and a sound score of evolving glacial dynamics composed by Reese Williams, cautionary texts serve as a counterpoint to the sheer beauty of these places - reminders of the fragility of massive glaciers during this current era of accelerating climatic changes. Informed by scientific studies and local knowledge, this project focuses on direct physical experiences of dramatically receding glaciers to address 'glocal' - global / local ecological concerns for a sustainable future.

Iceland Walks

Iceland marks a place of coexisting 'fire and ice', where the European and North American continental shelves meet, characterized by factual and mythic histories, (notably the remarkable sagas.) Icelandic sagas (13th century) provide the first written documentation of geographic names of Iceland's glaciers although most of the glacier names originated after 1890. "During the last half of the 20th century, 6 named glaciers 'disappeared;' 3 mountain glaciers melted and 2 distributary outlet glaciers and 1 outlet glacier receded into the parent outlet glacier or ice-cap margin." [5]

Two of the most significant sites for the Walks are rapidly receding glaciers: Snaefellsjokull and Vatnajokull. Snaefellsjokull sits on top of an active volcano believed by some to be one of the 'seven primary energy centers' of the earth, and the setting for Jules Verne's novel *Journey to the Center of the Earth*. Vatnajokull, in southeast Iceland, is Europe's largest glacier. In 2009 a leading glaciologist at the University of Iceland explained the outcome of continued global warming. "The glacier ice will melt. The water that runs off will go to the sea. The sea level will rise about 7 metres, which means we'll have catastrophic effects on the highly populated areas all over the globe." [6]

Walk: Grand Pacific © 2013 pdA

Alaska Walks

Alaska harbors more than 100,000 glaciers. The Alaska Walks focus on Glacier Bay ranging from Bartlett Cove to the Grand Pacific Glacier (sites of walk performances). The Bay epitomizes the natural, cultural and virtual issues related to effects of climate change on the glaciers.

> Although a handful of Alaska's large glaciers are, surprisingly, advancing, more than 99 percent of them are retreating. In the past decade, Alaska's coastal glaciers have added as much (or more) melt water to the global ocean as the ice sheets of Greenland or

Antarctica, making these glaciers a significant factor in global sea-level rise. [7]

The Ecological Society of America argued that establishing Glacier Bay as a national park in 1923 would help with the study of the natural processes of glacial advance and retreat within the confines of the bay.

> Unlike many park service sites that commemorate a single event or significant features, Glacier Bay celebrates change and natural processes. However, no natural cycle can explain the current warming of our planet. [8]

The park recognized the history of the bay and its associations with British explorer George Vancouver (1791) and naturalist John Muir (1879). Before his research in Alaska, Muir's original studies of glacial trace history in Yosemite supported the designation of this California valley as a National Park in 1890. Two years later, Muir helped found the Sierra Club, which has perpetuated his legacy as a naturalist and ecologist well into the 21st century.

The cultural history of Glacier Bay, however, begins with the aboriginal peoples who populated the area well before the arrival of Muir, Vancouver or the Russian explorers, who first arrived in Southeast Alaska in 1741.

> Eskimos from the west initially pushed into lands bordering on the [Glacier Bay] park's northwest boundary. Athabascans later migrated from the interior headwaters of the Alsek River toward the river's mouth at Dry Bay. The Alsek eventually served as a transportation corridor, linking the Athabascans with their neighbors the Tlingit Chilkat tribe. [9]

In addition to these significant natural and cultural histories of Glacier Bay, the Walks explore important virtual issues related to the present state of global climate change. Beyond direct ground level experiences at Glacier Bay, mediated by the use of video/web and GPS systems, the walks reference the Satellite Image Atlas of Glaciers of the World, which forms the basis of glacial studies by the U.S. Geological Survey.

> The Atlas remotely sensed images, primarily from the Landsat 1, 2, and 3 series of spacecraft, are used to study the glacierized regions of our planet and to monitor glacier changes. [10]
>
> Changes in the volume of glacier ice on land produces changes in global (eustatic) sea level. Seasonal changes in sea ice and snow cover and decadal changes in glacier area can be monitored regionally and globally with image and other data from Earth-orbiting satellites. [11]

Walk: Martial Glacier © 2012 pdA

Argentina Walks

Walking glaciers at the top of the globe in Iceland and Alaska led to an interest in pursuing several parallel natural and cultural features in Tierra del Fuego, Argentina, at the southern tip of South America.

Framed by the Straits of Magellan and the Beagle Channel, this archipelago is referred to as the 'Uttermost Part of the Earth' by E. Lucas Bridges in his memoir of the same title (1947). He recounts his life as a European settler growing up with the indigenous Fuegian Indians.

L. Bergreen documents the first written account of glaciers in this region in *Over the Edge of the World*:

> Magellan pauses at Santa Cruz because of storms and comes upon the Strait of Magellan, Oct 21, 1520. He sees fires in the distance, and calls the land Tierra del Fuego (Land of Fire). They pass glaciers with deep blue ice, view the Southern Cross in the heavens. Consisting of packed snow and ice, the glaciers never rested; they cracked, they groaned, they roared, and they threatened to decompose and tumble onto the beaches and water below. [12]

The Walks were performed in Tierra del Fuego at the Martial Glacier and at the Perito Moreno Glacier, located in the Andes on the border with Chile. Perito Moreno is one of 48 glaciers in the Patagonian ice field, the world's third largest fresh water reserve.

> South America is perhaps most often associated with the Amazon jungle. But along its western edge, from Ecuador to southern Chile and Argentina, it also harbors huge glaciers, which are rapidly melting due to global warming. The melting of the glaciers

means the loss of vast reserves of fresh water for human consumption, and for the rivers that provide hydroelectric power. [13]

Argentine government agency researchers issued warnings that the Martial Glacier was rapidly disappearing. Jorge Rabassa, a geologist associated with the National Scientific and Technical Research Council (CONICET) proclaimed that "by 2050, 'nothing' will remain of it." [14]

Re-Discovering the meaning of ICE

The memory of "discovering ice," while facing a "firing squad," as portrayed in the Marquez tale, suggests an apt metaphor for the global climate situation.

Is this the kind of perceived threat necessary for a call to action as humanity stands on a precipice at the edge of an abyss - a tipping point of no return as a direct consequence of man-made global warming ?

Countries, individual citizens must now mobilize against complacency and economic expediency for the sake of the earth and its future inhabitants. Our survival depends upon it.

Authors Biographies

Peter d'Agostino's pioneering photograhy, video and interactive projects have been exhibited internationally. Surveys of his work include: Interactivity and Intervention, 1978-99, Lehman College Art Gallery, New York; the World-Wide-Walks projects at the University Art Gallery, Bilbao, Spain (2012); and the University of Paris I Partheon-Sorbonne (2003), Major group exhibitions include: The Whitney Biennial, Sao Paulo Bienal, Brazil, and Kwangju Biennial, Korea. His works are in the collections of The Museum of Modern Art, New York, University Art Museum, Berkeley, and is distributed by Electronic Arts Intermix. D'Agostino has been awarded grants and fellowships and awards from: the NEA, Japan Foundation, Onassis Foundation, Pew Trusts, Fulbright Program, MIT's Center for Advanced Visual Studies, Banff Centre for the Arts, Rockefeller Foundation's Bellagio Center, Italy, the American Academy in Rome, the Art / Sci Center, University of California, Los Angeles. He is Professor of Film and Media Arts, Temple University.

David I. Tafler is Professor of Media and Communication at Muhlenberg College in Allentown, Pennsylvania. As a consultant for the Irish Red Cross Society (IRCS) in Banda Aceh (the ground zero site of the 2004 Tsunami) in 2009, he co-developed and authored a manual on communication and new communication technologies for the support of beneficiary populations in disaster prone regions. David Tafler has worked with the Pitjantjatjara, Yankunytjatjara, and Ngaanyatjarra people in central Australia since 1991 as a consultant, writer, and web designer/administrator. Tafler has authored and published many articles on interactive media, camcorder activism, avant-garde cinema, electronic art, and community media. His publications include journals such as Afterimage, Wide Angle, Media Information Australia, Continuum, Kunstforum, and a book that he co-edited with Peter d'Agostino, Transmission: Toward A Post-Television Culture.

Audiovisual Installation as Ecological Performativity

Teresa Marie Connors

The University of Waikato
Hamilton, New Zealand
tmconnor@waikato.ac.nz

Abstract

This paper stems from my practice-based research as a composer of collaborative multimedia works. The majority of artifacts that result are audiovisual installations that explore new relationships from an ecological perspective—that is—the perspective that considers the world to be a network of interconnected and interdependent phenomena. In an attempt to contextualize my research and explore new possibilities for creative practice, I have become interested in a number of theories about the agency and performativity of living and non-living systems. I present several of these theories within a historical context, and describe the audiovisual installations *Aspects of Trees*, *Undercurrent*, and the work-in-progress, *Bridgings,* all of which illustrate my evolving practice and ontological notion of *Ecological Performativity*.

Keywords

Audiovisual Installation; Ecological Performativity; Agency; New Materialism; Systems Theory; Ontology; Autopoiesis; Cognition; Interconnectedness; Practice-based research.

Introduction

Over the past twenty years, my creative practice as a composer has increasingly become a multidisciplinary and collaborative endeavor. This work has been an enriching enterprise covering numerous perspectives that have expanded both my artistic practice and philosophical thoughts on creativity. In order to develop a supportive discourse for these creative activities, and explore new patterns of inquiry and networks of communication, I have recently been drawn to several scholarly discussions about the agency and performativity of living and non-living systems. In this paper I present several of these dialogues in their historical context, and give a descriptive account of the audiovisual installations, *Aspects of Trees, Undercurrent*, and the work-in-progress, *Bridgings*, which illustrate my evolving practice and ontological notion of *Ecological Performativity*.

Historical Background

The idea of agency and performativity in Western thought evolved from a variety of philosophical, scientific and artistic research, the majority of which took place over the last century and continues into the 21st century. [1] This work reflects a paradigmatic shift away from a mechanistic, representational model to one of an interrelated, performative network in which the "stuff of the world" is considered an operative agent. [2] From emergent properties, cybernetic theory, autopoiesis, and systems theory to the new paradigms of expression in creative practice, a shift in ontological thinking had begun—away from representational models to a more performative, time-based and non-linear practice. [3]

Advances in mechanical and computational technologies influenced this transformation and are well documented in Chris Salter's book, *Entangled: Technology and the Transformation of Performance*. He writes: "Technology does something in and to the world by modifying existing relations and constructing new ones between humans, tools, processes and the environment which are deeply entangled." [4] Within a few decades theatre, dance, literature and music responded to the shift in ontological thinking, fostering the convergence and synthesis of artistic forms. [5] Salter suggests that "…these new relationships and interactions of discrete aspects of experience [opened] deeper understandings of the nature of consciousness and the workings of the mind...the reorganization of human interaction and the reimagination of interrelatedness." [4]

To briefly summarize this shift, we need only look at a selection of fine art works throughout this time period. Picasso's *The Old Guitarist* of 1904 was completed just one year before Einstein published his "Special Theory of Relativity." This singular perspective painting is remarkably different from his *Guitar Player* of 1910; we can note the transformation of a static representational viewpoint to that of a "multipositional dialect of space and time." [5] Kandinsky's *Composition VIII* from 1928 was completed three years after C. D. Broad first proposed his idea of emergent properties, whereby properties of a system emerge at higher levels of complexity due to the relationship of all parts. The more common research approach at the time focused on the smaller parts of a system rather than the whole—that is, its dissection. Broad's theory encouraged an ecological perspective that later became known as systems thinking. [6] From this as well as from cybernetics theory, Roy Ascott's artistic efforts developed. [7] Ascott introduced cybernetics into art education during the 1960s and believed this theory "opened the door to understanding the nature of mind as a systems phenomenon and became the first successful attempt in science to overcome the Cartesian division between mind and body." [8]

It was from cybernetics theory that Humberto Maturana began to develop his theory of autopoiesis (*self-creation*).

He explored this notion while researching visual perception and the organization of living systems posing the question, "How do I do what I do as an observer in observing?" [10] In reply, he proposed a new concept of circular organization claiming that "living systems are cognitive systems, and living as a process is a process of cognition." [10] All of his subsequent research came from this basic epistemological and ontological shift of thinking, which eventuated into the Santiago Theory of Cognition. With this theory, Maturana, along with Francisco Varela, proposed that "to live is to know" and that cognition is a "continual bringing forth of a world through the process of living." [11] The particular world that is brought forth depends, first, on the structure of the organism, and, second, on its relationship to its environment. [12]

This theory was a profoundly new view of cognition that included all processes of life such as perception, emotion, action, and emergence. It involved the concept of mind as a process, not a thing, and extended the act of cognition to all living systems including organisms that do not have a brain, such as simple-celled organisms. [12] At the time of its introduction, the Santiago Theory of Cognition provided the comprehensive scientific framework necessary to challenge the Cartesian division between mind and body, and afforded a "new synthesis of mind, matter, and life." [9]

Maturana[1] and Varela, respectively, expanded on this theory of cognition that, in Varela's case, would evolve into what is now widely accepted in cognitive science as the "embodied mind." [14] Varela *et al.* introduced this term in the early 1990s with the central thesis that cognition, including knowledge, meaning, and emotion, is intrinsically linked to our body, to the active living of that body, and to the environment in which these activities, or "enactions" take place. [14] Since then, the concept has widened to include the very structure of human reason as arising from our bodies, brains and bodily experience evoking a quality of emergence and agency. The concepts "embodiment" and "enaction" are now part of the lexicon of contemporary creative researchers.

Recent Theoretical Discourse

Currently there is a rigorous discourse throughout the arts, humanities and sciences about the interconnected agency, or "performativity" of living and non-living systems, and between the human and non-human—so much so that "formerly fast held distinctions between the inert and the active, the human and the non-human and life and matter are cracking." [15]

Noted contributors to this discussion include Chris Salter, who, as previously mentioned, has written comprehensively on the trajectory and development of agency and performativity in the arts. His recent publication, *Alien Agency: Ethnographies of Nonhuman Performance,* continues this enquiry by describing works in which the materials of art—the "stuff of the world"—behave and perform in ways beyond the creator's intent. They each encourage "a radically different vision of the world—dynamic, temporally emergent, contingent, and performative." [2]

Andrew Pickering joins the discussion with his notion of the "dance of agency." This is Pickering's attempt to move away from the idea that agency is specific only to humans, or to what he refers to as "human exceptionalism." He suggests that the world, in all its heterogeneous multiplicity, is full of agency and processes of emergence. By exploring these processes and performative relationships between things, including those beyond the human realm, Pickering suggests that we invite the "possibility of a non-modern stance of revealing rather than enframing which, in turn, invites open-ended extensions." [16]

Karen Barad elaborates on the notion of performativity in her substantial book *Meeting the Universe Halfway*. Here, Barad introduces the term "intra-action" which refers to the idea that "existence is not an individual affair [where entities] pre-exist their interactions," but rather, an ongoing ebb and flow of agency where individuals and things emerge through and as part of their entangled intra-relating. [17]

Similarly, Jane Bennett's concept of "thing-power" gives voice to the energetic vitality intrinsic to matter and the active, earthy, and complex entanglements of humans and non-humans. [18] She fosters the notion of "greater recognition of the agential powers of natural and artifactual things, greater awareness of the dense web of their connections with each other and with human bodies, and, finally, a more cautious, intelligent approach to our interventions in that ecology." [19]

Timothy Morton expands the discussion to include his idea of the "hyperobject," meaning agents or objects "so massively distributed in time and space as to transcend localization, such as the biosphere, global warming, or the sum of all the whirring machinery of capitalism." [20] Morton argues that these objects are the result of "the mesh"[2] of human and non-human agency, particularly those which took place during and after the Industrial Revolution. He further suggests that art in the time of the hyperobject can function as an attunement to the reality of the coexistence of all things on Earth:

> Thus the art in the time of hyperobjects explores the uncanniness of beings, the uniqueness of beings, the irony and interrelationships between beings, and the ironic secondariness of the intermeshing between beings. [22]

[1] In the context of this conference, it is interesting to note Maturana's own reflections on technology and art: "As different technologies open and close different relational dimensions, they offer different possibilities for social and nonsocial coexistence, as well as different possibilities for the artist to create the relational experience that he or she may want to evoke. In all cases, though, whatever he or she does, the artist will be a participant creator of some virtual reality that may or not become a grounding reality in the course of human history." [13]

[2] In Morton's writing, "the mesh" substitutes words such as interdependence and interconnectedness. [21]

Fritjof Capra and Pier Luigi Luisi weigh in with their 2014 publication, *The Systems View of Life: A Unifying Vision*. The authors present a coherent systemic worldview that integrates the biological, cognitive, social, and ecological dimensions of life. They discuss the philosophical, social, political and spiritual implications of such a unifying vision, in an attempt to overcome, what they define as "a crisis of perception," or a human-centric use-value worldview. [23] The broader intention of this book is to provide an appropriate framework for discussing one of the "great challenges of our time—the building and nurturing of sustainable communities." [23]

While all of these concepts and discussions resonate at their own frequency, the fundamental ideas are similar: the world is a mesh of agency, and because of this, a host of ecological, social, cultural, and political observations and concerns are raised and challenged.

Ecological Performativity

The intention of my research, or, "mode of artist practice,"[3] is to contribute to this discourse in an artistic, experiential, and dynamic way. I do so in an attempt to develop a creative practice that I refer to as *Ecological Performativity*. I introduce this term to bridge my creative research with the ideas outlined above, that is, the ecological perspective of interconnectivity, the cognitive components that include all processes of life, the "dance of agency," the intra-action of living and non-living systems, and the complex systems and entanglements of humans, nonhumans, and hyperobjects. Beyond technical and aesthetic choices, my research attends to the performative substance of place and time. It stems from the premise that artistic practice can enable different perspectives of the world and become, in and of itself, an apparatus of change—promoting what I (and other practitioners) consider to be "a long overdue ontological shift in how we exist in the world." [25]

Ecological Performativity has resulted from a series of collaborative mixed-media audiovisual installations. Similar to other ecologically-grounded creative practices,[4] these installations explore the relationships of environment, material, and process, and are derived from an intensive data-gathering procedure and immersion within the respective environments. At the same time, by considering the interdependent performative agency of all components involved (the cognition, environment, and autopoietic units), *Ecological Performativity* attempts to explore new networks of communication and meaning from a systemic understanding; in other words, its pattern of organization (Figure 1).

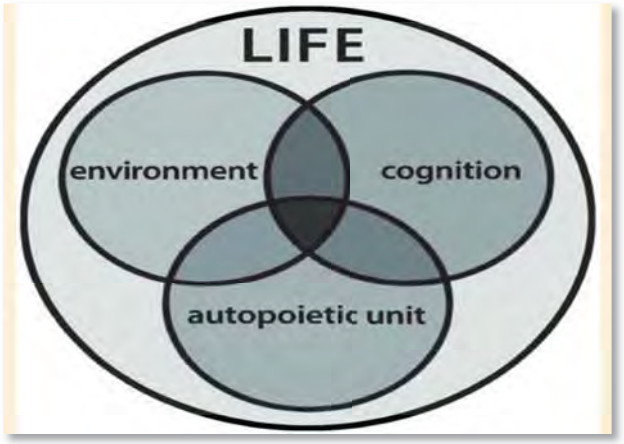

Figure 1. The Trilogy of Life. [31]

Studio Practice

For the purpose of my creative research, the generative audiovisual installations are understood then as "the embodiment of the shared meaning generated by the networks of communications." [32] These networks include multimedia collaboration as the creative field of activity, which nurtures an environment where the 'possibility of something to happen' is cultivated. From a philosophical perspective, this touches on Stuart Kauffman's notion of "the adjacent possible—" that within the components of any given moment, many untapped possibilities are available. [33]

> The strange and beautiful truth about the adjacent possible is that its boundaries grow as you explore those boundaries. Each new combination ushers new combinations into the adjacent possible. [34]

These possibilities emerge from the creative interactions of practices, processes and potentials activated by the visceral, in-person experiential engagement with the chosen environments. Immediacy, unpredictability and surprise register in this relational liveliness of matter and material, forming an open-ended experimentation process that embraces the unexpected. Salter suggests that experimentation, as process, "takes its materials or entities as active, dynamic, and changeable, rather than passive, inert, and immutable…[transforming them] into agents…that have actual effects in the world." [2]

In my research, the exploration of materials is done in part through the development of specifically designed computational systems. These systems vary in construction and are intrinsically linked to the collected location data that include audio field recordings, moving images and photos, as well as weather, meteorological, and environmental data. What emerges does so in an iterative, non-deterministic manner, which affords a holistic interaction

[3] I borrow this turn of phrase from Manning and Massumi in which they claim: "Every practice is a mode of thought, already in the act. To dance: a thinking in movement. To paint: a thinking through color. To perceive in the everyday: a thinking of the world's varied ways of affording itself." Each is a technique, or, springboard that sets in motions "a practice from within." [24]

[4] Terms used to denote other ecologically-grounded creative practices include *ecocomposition, sonic ecologies, EcoSon, ecosystems, and audible ecosystems*. [26, 27, 28, 29, 30]

Figure 2. *Aspects of Trees* - opening section. Photo: Andrew Denton

between material, practice and process. This interaction subsequently involves the recording of live musical improvisations in response to the developed system. Recordings have taken place in live multimedia concert improvisations, studio settings, and their respective environments. What this provides is a cumulative database that in turn folds back into the final installation system. The 'performativity of improvisation' becomes an active agent in the process and evolution of the artifact.

From the systems theory perspective, Capra and Luisi suggest that process is the link between organization and structure. Here, they speak to the emergent and agential qualities of living and non-living systems and to the interdependent and fundamental interconnectedness of all levels of life. They do so through a conceptual synthesis of what they consider to be the four perspectives of life: *form, matter, process, and meaning.* [32] In general, *form* corresponds to patterns of organization, or self-generating networks of communications, of which through *process* the material embodiment, or *matter* of the form emerges. *Meaning,* which relates to the inner world of reflective consciousness, is generated by extending *form, matter, and process* into the social dimension, including "rules of behavior, values, intentions, goals, strategies, designs, and power relations." [32] Human action, then, is understood to flow from the *meaning* we attribute to our surroundings. This meaning, in turn, gives rise to material structures in a process of continual embodiment.

In this context the initial engagement with the chosen environments, the creative experimentations, and the cognitive experience of the resulting artifact become part of the co-evolution of the process and meaning. Reflection, contemplation, and consciousness are then considered part of the network. This evokes a cyclical aliveness and an empathic discourse[5] that extends to include the larger biosphere, and contributes to the flow of internal and external networks of communication and meaning. In modern science this cyclical process of life is called metabolism, or the "breath of life." [36]

The following descriptive accounts of the audiovisual installations *Aspects of Trees, Undercurrent* and the work-in-progress *Bridgings* will illustrate the creative practice, informing the conceptual development of *Ecological Performativity.*

Aspects of Trees

Aspects of Trees (2013 installation version) is my sixth collaboration with filmmaker Andrew Denton, and is an extension of our previous artistic explorations of human impact on the Earth's landscapes and ecologies. The subject of this work is the escalating pine beetle epidemic that has decimated forests on the west coast of North America. Due to the increase of pine beetle activity in this location, this devastation has more of a human touch than global warming alone. Western Canadian reforestation practices during the latter half of the 20th century implemented a mono-species program, which has resulted in a pine-tree-only forest. The combination of these mono-species plantations and the increasing average winter temperatures have cultivated an environment for the beetle to flourish. Currently, over 16 million hectares of British Columbia forests alone have been destroyed.

Initiated by Denton, *Aspects of Trees* is the result of a two-year field recording process that comprises video footage and stills from the decimated forests, as well as audio captured inside and on the surface of affected pine trees.[6] Having both worked in BC reforestation before, during and after the epidemic, Denton and I have a visceral and multi-layered engagement with this landscape. Because of this, a contemplative practice emerged during the collection process of which Denton writes: "Once time is taken to absorb [the location], I attempt to record material that communicates my sensations and experiences of being there." [37] He reflects that by "letting go of a need to understand, comprehend, and categorize, … the intensity of the making–feeling–thinking [could] take over in the moment of capture, leave[ing] the reflection and reinterpretation for a

[5] Jeremy Rifkin suggests that empathy is the "invisible hand" that allows us to stretch our sensibility to all life. He proposes that more technologically advanced cultures have evolved into that of *homo empathicus*, which is ushering in a biosphere consciousness. This evolution has occurred due to the diversity of human interaction, creating a more complex system of communication and emergence [35].

6 David Dunn and Felix Wilson provided additional field recordings of internal and external tree sounds.

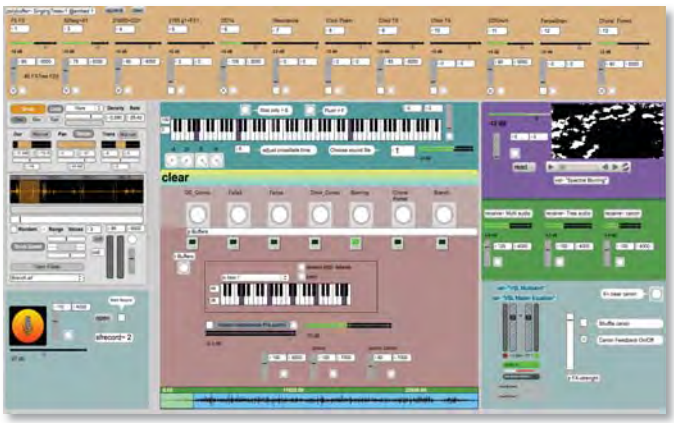

Figure 4. The 'tree instrument' Max6 patch.

later distanced encounter with the material during post-production." (Figure 2) [37]

From these field recordings, and coinciding with Denton's post-production visual experimentations, I began the development of the 'tree instrument.' Constructed in Max6, this portion of the research developed and amalgamated sonic material and computational processes for the purpose of live improvisation with cello, laptop performer (Max6 patch), and visual projections (Figure 3). Components of the 'tree instrument' include sonification of still and moving images, live convolution of cello with field recordings, an eight-part canonic system based on the numerical ratios taken from tree growth, and live granulation and transposition. [33] A series of improvisations took place in studio settings and live concerts, featuring myself, cellist Charlotte Ketel (New Zealand), and cellist Anna Bourne (Canada). Recorded and incorporated into the final installation, these improvisations fostered the relational potentials between subject, material and the cognitive agency of improvisation in which the performativity of components co-composed the resulting artifact: a system of engagement.

The final installation comprises multi-projections with composite images, surround sound and a 30-minute looping sequence, the trajectory of which moves, uncannily, from known to unknown, or rather, concrete to abstract. "It is melancholy and loss for an idea and a fantasy of nature that is no longer there…the invisible made visible, the unsayable now hearable. It is a eulogy." [37]

Observations made during this research focused on the need for open-ended exploration in the chosen environment, in the iterative interactions with the material, and in the methods, pathways, and techniques employed in the creative practice. [37] These observations underscored the conceptual, philosophical, and artistic notion of *Ecological Performativity*. The stimulus was equally informed by the questions that surfaced: If we broaden our understanding of agency and performativity, is it possible to explore different vocabularies and networks of communication? Can this encourage, as Morton suggests, an attunement to the reality of the coexistence of all things on Earth? If so, as a creative practitioner, what then is my response?

Undercurrent

As it was presented at the *Balanced/Unbalanced 2015 International Conference* in Tempe, Arizona, *Undercurrent* is a generative installation that features multi-channel video projections and surround sound. It is my third collaboration with media artist Shannon Harris, and is an interpretation of the ecological and personal landscape explored through moving image, video tracking, improvisation and data sonification.

Undercurrent emerged from what was initially a personal journey for Harris. Shot in the Yalakom River, British Columbia, her visit became a pilgrimage in memory of her recently deceased father, as they had camped often in this region. She writes: "I had no intention of filming on this pilgrimage but usually bring my cameras wherever I go. As I spent time by this quick river listening to the 'shrush and bubble' I was filled with a profound sense of completion: of cycles and patterns, beginnings and endings. I started shooting. Watching light." [38] Harris's still photography and moving images are known for their exquisite and evocative use of light and landscape. Her creative process is embedded in presence, place, and time in which the camera "becomes embodied, my eye/I, my experience." [38]

Through refined experimentation, and with breaks to warm her hands from the glacial freeze, the *Undercurrent* footage was eventually captured while "try[ing] to find the light under water." [38] It was the quality of light that prompted my decision to use video tracking as a generative tool. Imbued with a hypnotic play of light, these underwater shafts of sunlight become the triggering agents that afford an interaction between experience, material, and creative process. With no prior knowledge of Harris's intention of a "pilgrimage," my visceral response to the play of light was additionally influenced by a concurrent audiovisual

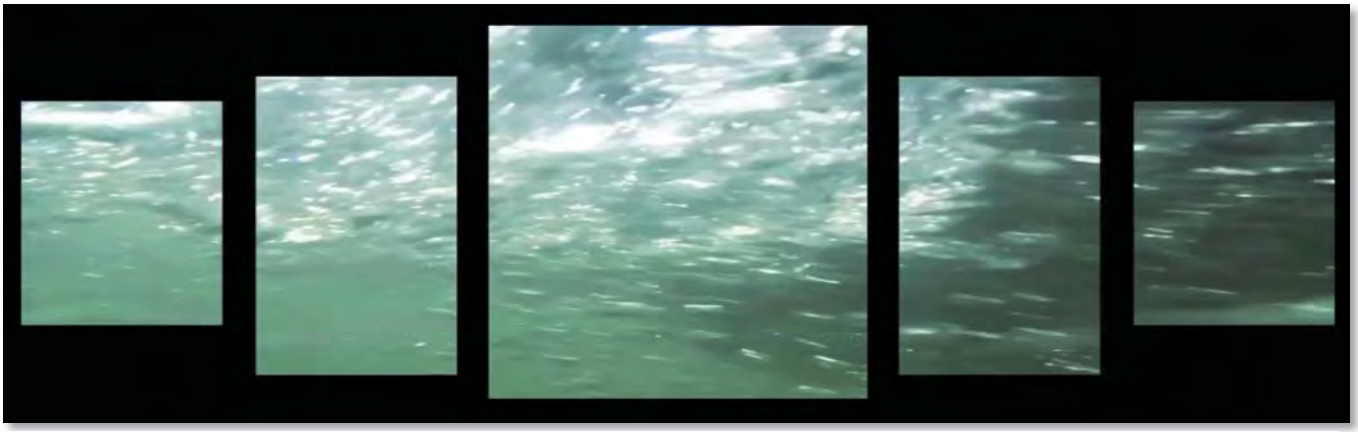

Figure 3. *Undercurrent.*

collection process throughout the Southwestern drought regions of the United States. This was a grueling three-week journey with collaborator Andrew Denton that brought us to many bleakly sunbaked landscapes found in this region. Water, or lack thereof, was at the forefront of our minds.

With this in mind, a single underwater video was selected and subsequently divided into five panels (Figure 4). Through the movement of light, each video panel randomly triggers a databank of sonic material: hydroponic recordings from the primary river location; sonification of Acoustic Doppler Current Profiler data[7] using piano samples; vocal snippets from on-line media in which global warming is debated; and, a catalogue of pre-recorded short improvisation using bassoon, cello, and Bb clarinet convoluted with underwater recordings. Constructed in Max7, these accumulated resources layer into a web of emergent realizations. With no beginnings, middles, or ends, this generative installation becomes more of a contemplation on time and place, process and meaning, or, a meditation in the time of crisis.

Bridgings

I include this descriptive account of the work-in-progress, *Bridgings,* as it occurs at a noteworthy place in the development of *Ecological Performativity*. Having benefitted from the observations made in the previous collaborations, and having absorbed the varied contemporary discourses on agency and performativity, *Bridgings,* is, I believe, a synthesis of different modes of thought: everyday perception, artistic practice, and philosophical thought—"creatively in the act." [24] As research is often reported on after the fact, describing this work-in-progress affords a view into the middle-of-the-making.

Bridgings is Stephanie Symns and my first collaboration, and is the result of data collection that took place on the Granville Street Bridge in Vancouver, BC, Canada between 2013 and 2014. This work-in-progress, in part, was conceptually inspired by the following quote found in *The Sketchbooks of Paolo Soleri*:

> Of all things that are man-made, bridges are, with dams, the most "structural," single-minded, and imposing. As connectors at a breaking point, they have a heroic force that is aided by a challenging structuralism. As a strand of continuity in a non-continuum, the bridge is full of implied meanings. It is the opposite of devisiveness[sic], separation, isolation, irretrievability, loss, segregation, abandonment. To bridge is as cogent in the psychic realm as it is in the physical world. The bridge is a symbol of confidence and trust. It is a communications medium as much as a connector. [39]

The initial research began with a series of weavings, designed by abstracting photo images of the Granville Street Bridge. The original image was taken underneath the bridge and manipulated in Photoshop. By posterizing the image to a certain number of layers that later corresponded to weave structures, the image was subsequently mirrored, both horizontally and vertically, to form a singular pattern unit. Of this process Symns writes: "I am inspired by minimalist architecture and the interrelationship of people, space, and structure. The intention with this series was to create compelling, graphic designs that would make a strong statement with the repetitive use of pattern and geometry." (Figure 5) [40]

Figure 5. Sample design and weaving. (photo/weaving Stephanie Symns)

These would eventually transform into a number of large-sized weavings realized with the use of copper thread (Figure 6). Coinciding with the developments of these weavings, a number of audio recordings were captured on the bridge with the use of contact microphones that were attached to the metal components of the bridge. These recordings took place at different times of day and in varying weather conditions, resulting in a folder of sonic materials influenced by the movement of traffic, the bridge vibrations, and the movement of air through the cylinder components of the bridge.

Figure 6. Copper weaving (photo/weaving Stephanie Symns)

[7] Provided by Stephens Scott of NIWA Taihoro Nukurangi.

Satisfied with the initial collaborative processes, Symns and I envision the final installation to include a series of similarly rendered copper weavings embedded with motion sensors that, once triggered, will randomly select from the following components: images generated from visual data captured from the Granville Street Bridge Webcam (Figures 7 and 8) and a databank of sonic materials developed from the initial field recording and subsequent vocal improvisations. The webcam images will be displayed on small monitors mounted throughout the installation space along with a multichannel surround sound system. One additional consideration is the development of a computational system based on the architectural design of the bridge that would become a performative agent during the vocal improvisations. As such, this would be similar to the 'tree instrument' developed for *Aspects of Trees*. In this case, the 'bridge instrument' would afford an interaction between the architectural matter of the bridge and the agency of improvisation.

With these combined components, then, the final installation might be considered an immersive space of "emergent collectivities," or, "an event-based ecology of experiences" [24] which co-evolves between object and collaborators, material and process, and structure and meaning: a "dance of agency." [16]

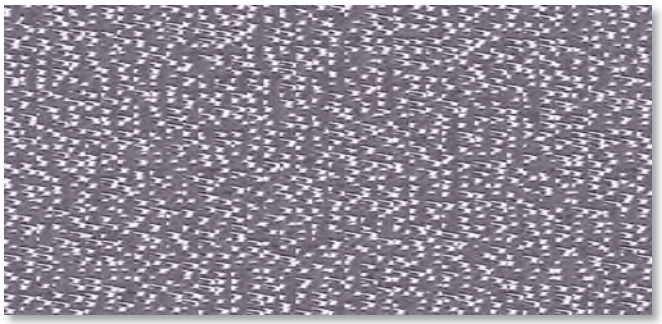

Figure 8. Generated from street marking image obtained from Granville Street Bridge Webcam.

Conclusion

Ultimately, my practice-based research is a multimodal endeavor deeply entangled in the mesh of the world: matter, material, and modes of thinking. In line with the discussions on agency and performativity, this research considers the complex, emergent, and dynamic encounters available through experience and experimentation. By considering the world as a network of phenomena that are fundamentally interconnected and interdependent, the result is a performative engagement and attunement with the world that can function as an aid to the imagination. Human activity is placed into a larger environmental context by intersecting with forces greater than those of human design, which provides a multi-layered point of creative enquiry. This, I believe, works towards an artistic philosophy that considers how we imagine the world and how we act in it reciprocally informs one another. [16] As such, the concept of *Ecological Performativity* has developed alongside the iterative creative practice, the trajectory of which will continue in two future collaborative installations: *Flight Variant* with Andrew Denton and *Signal to Noise* with Shannon Harris.

Author Bibliography

Teresa Connors is active as an acoustic/electroacoustic composer, opera singer, film scorer, and multimedia installation artist. Originally from Newfoundland, Canada, Teresa holds a Master of Music degree in composition (1st class honours) from Waikato University in New Zealand and studied both composition and opera singing at Dalhousie University in Nova Scotia as well as the Banff Center for the Arts. Her creative works have received awards and support from the Canada Council for the Arts, British Columbia Arts Council, Bravo Fact and have been presented at international conferences, film festivals, and galleries. Her current practice-based PhD research includes developing new techniques and methodologies for multimedia collaborations and resulted in Teresa being awarded the 2014 Creative and Performing Art Person of the Year at the University of Waikato. www.divatproductions.com

Abstract

The equilibrium between a healthy environment, the energy our society needs to maintain or improve this lifestyle and the interconnected economies could pass more quickly than expected from the current complex balance to a complete new reality where human beings would need to be as creative as never before to survive. Environmental problems, economic uncertainty and political complexity have been around for a long time. What was different before was the speed and depth of transformations compared with today's sudden changes. The frequent occurrence and severity that certain weather and climate-related events are having around us is increasing, and the ability of human beings on modifying adjacent surroundings as well as distant places have turn into a power capable of altering the planet. Have electronic art a role in all this? Have electronic artists a responsibility in this context? Aiming to use electronic art as a catalyst with the intent of engendering a deeper awareness and creating lasting intellectual working partnerships in solving our global environmental crisis, three initiatives were launched: *Balance-Unbalance*, '*art*! ⋈ *climate*' and EChO.

Keywords

Electronic arts, media arts, sound arts, humanitarian actions, climate change, environmental crisis.

Introduction

We are living in a world reaching a critical point where the equilibrium between a healthy environment, the energy our society needs to maintain or improve this lifestyle and the interconnected economies could pass more quickly than expected from the current complex balance to a complete new reality where unbalance would be the rule and human beings would need to be as creative as never before to survive. Environmental problems, economic uncertainty and political complexity have been around for a long time. What was different before was the speed and depth of transformations compared with today's sudden changes. The frequent occurrence and severity that certain weather and climate-related events are having around us - such as floods, twisters, etc. - is increasing, and the ability of human beings on modifying adjacent surroundings as well as very distant places have turn into a power capable of altering the whole planet.

The global climate is changing, and communities around the world are suffering the consequences. Traditional disaster management approaches are not enough to deal with rising risks, and new forms of collaboration are needed to inspire people and organizations to link knowledge with action. Have computer artists a responsibility in this context? Have computer art a role in all this?

Artists could inspire new explorations regarding how to actively participate in this major challenge of our environmental crisis. We need to develop innovative ways to facilitate a paradigm shift towards a sustainable future. We need to discuss proposals for the future from a diversity of cultural perspectives and socio-economic situations with open minds. Creative thinking, innovative tools and transdisciplinary actions could help to produce perceptual, intellectual and pragmatic changes. It is not about an indulgent utopia for the future nor about a desire, but a matter of survival.

Aiming to use digital art as a catalyst with the intent of engendering a deeper awareness and creating lasting intellectual working partnerships in helping to solve our environmental crisis, three initiatives were launched and have been well received by the international community of computer-based artists and by humanitarian and cultural organizations, policy makers, educators and experts from a variety of fields. Those initiatives are: the Balance-Unbalance program, the '*art*! ⋈ *climate*' contest, and the online EChO network.

Balance-Unbalance

The arts could play a major part in helping the global society to understand the magnitude of the crisis we are facing, and in promoting the awareness around environmental matters. And it could also be a very good vehicle to disseminate proposals that could produce changes in our behavior and decisions, influencing our chances for the future. Artists could promote inter and transdisciplinary actions focusing on the global environmental crisis and our responsibility regarding the turning point we are living in defining the future of life on Earth.

The *Balance-Unbalance* project was launched with an international conference in 2010, aiming to develop the role of the media arts and artists in dealing with environmental challenges. *Balance-Unbalance* explores intersections between nature, art, science, technology and society as we are moving into an era of unprecedented ecological threats. The first conference was held in Buenos Aires, Argentina and was named in Spanish "Equilibrio-Desequilibrio". It was organized by the Electronic Arts Research and Experimentation Centre (CEIArtE) from the National University of Tres de Febrero. Papers were delivered by a representative of the National Secretary of Environment and Sustainable Development of Argentina, experts and graduate students from different universities with chemical, agricultural and environmental engineering backgrounds (some of them specialists in pollution, renewable energies and food technologies), a lawyer, a sociologist and philosopher, artists coming from Argentina, Brazil and Canada, and an astrophysicist. [1]

Balance-Unbalance (a.k.a. BunB) was held again in 2011, this time at Concordia University, in the city of Montreal, Canada. Those were two days of reflection, debate, information exchange and promotion of projects and actions regarding the environment and our responsibility at this crucial moment in history. This conference was possible thanks to the direct involvement of faculty from Concordia University coming from very diverse backgrounds, like communication, political sciences, geography, management, music, digital arts and design. There was an amazing number of submissions received to participate in the conference with paper presentations, posters, films, electroacoustic and computer music, art installations and also a diversity of transdisciplinary sessions with open structures to accommodate all kind of innovative proposals, always considering digital art as the interconnecting hub and the environmental crisis as the umbrella covering us all. [2]

Once again in 2013, a third edition of *Balance-Unbalance* was showing the high potential of these actions. The expected catalyzer started to work and the digital arts were, step-by-step, leading the way. This time the conference was held at the Noosa biosphere, an ecological reserve recognized by UNESCO in Australia. The Noosa Biosphere is a dynamic learning laboratory for sustainability in one of the most pristine and diverse environments in Australia. The three-day conference took place at Central Queensland University, with satellite events in several other places, including Lake Cootharaba. [3]

An e-book with some of the papers presented at the 2013 *Balance-Unbalance* conference was published and it can be downloaded from the Internet for free. [4]

The conference theme: 'Future Nature, Future Culture[s]' aimed to challenge our expectations of Earth, provoke our understanding of nature and inspire our actions for a sustainable future. *Balance-Unbalance* was proposing to ask ourselves: "What we will be calling nature in 20, 50 or 100 years? How we will live in the future? How could creativity help us shape a society of understanding and interconnectedness? What role could transdisciplinary thought and action play in reimaging a sustainable future?" considering that: "All is interconnected. No person, no animal, no object or idea can exist independently. Our limited knowledge of life can be expanded, but to do so we need better ways to understand each other. This includes a deeper awareness of how different human societies can comprehend cultural differences and synergies. There is a dramatic need for a paradigm shift and we need to act now if we are going to survive as a species." (from the *Balance-Unbalance* 2013 website).

Like in previous editions, digital art was not only part of the papers in the form of theoretical analysis and proposals but a substantial component of the event. Works and papers by Nicolas Bullot, Krista Caballero, Frank Ekeberg, Hamilton Mestizo, Ian Clothier, Karola Obermueller, Sarah Pirrie, Roslyn Taplin, Peter Gilbert, Teresa Connors, Andrew Denton, Rene Burton, Damian Castaldi, Leah Barclay, Todd Ingalls, Mary Bates Neubauer, Suzon Fuks, Mónica Mendes, Pedro Ângelo, Nuno Correia, Jim Denley, Monika Brooks, Dale Gorfinkel, Garth Paine, Ben McMullen, Sabine Feisst, Andrea Polli, Julie Arrighi, Perdita Phillips, John Dahlsen, Michel van Dartel, Anne Nigten, Susan Davis, Tony Fry, Jodi Newcomb, Claudio Rivera-Seguel, John Coulter, Lisa Chandler, Ramón Guardans, Susan Frykberg, Daro Montag, Jordan Lacey, Paul James, Proyecto AbRiGo, Feral Arts and members of the Australian Forum for Acoustic Ecology, among others, were presented at Queensland Central University and the Noosa Regional Gallery, where also the Leweton Cultural Group was performing (traditional music and dance from Vanuatu's endangered islands). A number of artistic events were also held in partnership with the Floating Land festival and presented in Boreen Point and locations within the region. Fifteen short articles on research and creation projects presented during this conference have been published by The MIT Press on Leonardo, the Journal of the International Society for the Arts, Sciences and Technology, on a special section devoted to *Balance-Unbalance*. [5]

After the first *Balance-Unbalance* conference was held in Argentina in 2010, other associated initiatives were also produced: "Balance-Unbalance. Environmental Responsibility" ("Equilibrio-Desequilibrio. Responsabilidad medioambiental") was a digital arts exhibiton presented by CEIArtE at the National University of Lomas de Zamora, Buenos Aires province, in 2011. A second exhibition was presented at the same venue in 2012: "Balance-Unbalance. Sustainably economy, sustainable energy, habitable environment" ("Equilibrio-Desequilibrio. Economía sostenible, energía sustentable, medio ambiente habitable"). The third exhibition of the series was held in a central location of downtown Buenos Aires, the San Martin Cultural Centre, during the 2012 *Electronic November* large-scale festival of media arts: "Balance-Unbalance. Knowledge-Action in Times of Uncertainty" ("Equilibrio-Desequilibrio. Conocimiento-Acción en Tiempos de Incertidumbre"). In 2014, a new edition of this exhibition series was presented

at the original venue, the National University of Lomas de Zamora, under the name of "Balance-Unbalance. Posthumanity and Environment" ("Equilibrio-Desequilibrio. Posthumanidad y Medio Ambiente"). Always linking computer art with environmental issues, these exhibitions presented Internet works, electronic sculptures, video installations, telematic pieces, artistic interventions, site-specific interactive installations, electroacoustic and soundscape works as well as sound art installations by artists from Argentina, Austria, Brazil, Canada, Chile, Colombia, France, Italy, Mexico, The Netherlands, New Zealand, Portugal, South Korea, Spain, the United Kingdom, United States and Venezuela

The fourth edition of *Balance-Unbalance* was held in March, 2015. It was hosted by Arizona State University and its main focus was set on: "Water, Climate and Place. Reimagining Environments". The subject reflects some particularly relevant circumstances considering the location: the Southwestern desert of the United States.

Balance-Unbalance 2016 is being organized in Manizales, Colombia. This city is part of the coffee-growers axis and it is built in a mountain region with seismic instability. A rich, changing and challenging environment, with a subtropical highland variety of climate and an average of 1,500 millimeters (59 inches) of precipitation a year, that will allow participants to have a contrasting experience considering the places where previous editions of the conference where held.

'*art*! ⋈ *climate*'

Sometimes experiments take their own way, and an unexpected positive consequence in the form of a project - with an excellent potential- becomes a possibility. *Balance-Unbalance* had no resources to invite keynote speakers for the conference but still we were able to bring in Dr. Pablo Suarez, Associate Director of the Red Cross / Red Crescent Climate Centre to Montreal for the conference in 2011. As a direct result of Dr. Suarez participation in *Balance-Unbalance*, the '*art*! ⋈ *climate*' project was born shortly after. [6]

The Red Cross / Red Crescent Climate Centre and the Electronic Arts Research and Experimentation Centre (CEIArtE) joined forces to develop the *art*! ⋈ *climate* contest for the creation of digital sound-based art miniatures focusing on the environmental crisis and climate change related issues. The Climate Centre's mission is to help address the humanitarian consequences of climate change and extreme weather events. In its efforts to engage people at risk, government agencies, academic institutions and other stakeholders, it has become clear that information is rarely sufficient to trigger behavior change. As a result, the Climate Centre is designing and facilitating methods for learning and dialogue that involve not only the brainpower but also the emotions of participants (such as collaborative workshops, participatory games and short educational films, linking information, decisions and consequences on disaster management).

The *art*! ⋈ *climate* contest had two main objectives: a) Provide the Climate Centre with sound-based art material that can support their actions; and b) Improve knowledge about the human dimensions of the environmental crisis and promote awareness about the effects of climate change, both among creative artists and among those exposed to their work.

The first *art*! ⋈ *climate* contest has been co-sponsored by Hexagram, the Research-Creation Centre in Media Arts and Technologies of Concordia University, Canada, the Central Queensland University and the Noosa Biosphere Reserve in Australia, and Leonardo/ISAST.

For this contest, sound art miniatures implied short creations of sound art/music produced using new technologies and encompassing what is known as soundscapes, electroacoustic and computer compositions, sonorizations, and sonifications.

The categories available for the contest were two: 'Mosquitoes' and 'Open Theme'. The 'Mosquitoes' category aimed to support initiatives to raise awareness and better manage the growing risk of malaria, dengue and other mosquito-borne diseases that are showing new regional and seasonal patterns due to changes in rainfall and temperature - an issue highlighted in several Red Cross projects in Africa, Asia and the Americas. The 'Open Theme' category invited submissions about other dimensions of changing environmental conditions.

The works were selected by a jury of internationally recognized composers and new media artists: Marc Battier, Andrés Burbano, Joel Chadabe, Ricardo Dal Farra, Alireza Farhang, Rajmil Fischman, Arturo Gervasoni, Leigh Landy, Fabián Luna, Raúl Minsburg, Jaime Oliver, Julien Ottavi, Garth Paine, Andrea Polli, Paul Rudy, Suzanne Thorpe, Barry Truax, Michel van Dartel, and members of the Climate Centre as well, finding that was possible to have good artistic works that could also fulfill the specific needs of an humanitarian organization for its daily field actions. Selected works came from sound artists and electroacoustic composers from all over the world: Argentina, Australia, Austria, Brazil, Canada, Colombia, Czeck Republic, France, Germany, Greece, Israel, Italy, Mexico, New Zealand, Peru, Portugal, Romania, Spain, The Netherlands, South-Korea, United Kingdom, United States and Venezuela. [7]

All pieces are now available in SoundCloud both for listening online and for downloading, under a Creative Commons license. [8]

Composing digital sound art miniatures proved to be a great way for musicians to stop being spectators and start to contribute actively to humanitarian goals.

A second contest was launched on October of 2014. This time, several organizations are teaming up: the original two organizers, CEIArtE and the Red Cross / Red Crescent Climate Centre, are now working together also with the Climate and Development Knowledge Network (CDKN), the International Institute for Environment and

Development (IIED), and the Overseas Development Institute (ODI). [9]

There are also two categories on this second *art*! ⋈ *climate* contest but are not the same proposed on the first instance. The categories are always defined according to the needs specified by the humanitarian organizations, on this opportunity they were: 'Sea level rise' and 'Zero poverty. Zero Emissions. Within one generation'. [10]

This new contest had two deadlines, the first one targeted the Climate and Development Days that were held in the context of the UN Climate Change Conference (United Nations Framework Convention on Climate Change - UNFCCC COP) in Lima, Peru during December 6 and 7, 2014. [11]

Four sound-art miniatures were selected from this round and one from each category was then publicly announced and shared during the international event.

The second and final deadlline, in February of 2015, allowed sound artists and composer more time to research and create their miniatures. Worth mentioning that there is no limit to the number of works to be selected by the artistic jury and the humanitarian organizations jury.

This time the artistic jury was composed by: Alex Adriaansens, Leah Barclay, Marc Battier, Sandeep Bhagwati, Adriana Casas, Joel Chadabe, John Coulter, Ricardo Dal Farra, David de Gandarias, Orlando Jacinto García, Goh Lee Kwang, Amin Hammami, Fernando Iazzetta, Adina Izarra, Leigh Landy, Neil Leonard III, Fabián Luna, Andra McCartney, Raúl Minsburg, David Monacchi, Daniel Quaranta, Jaime Reis, David Rothenberg and Rodrigo Sigal. Then members of the Climate Centre and associated organizations were working on the last part of the selection process, aiming to find the works that best fit with their humanitarian needs. Pieces came from sound artists and composers living in: Argentina, Australia, Brazil, Canada, Italy, Kosovo, Mexico, Portugal, South Korea, The Netherlands, United Kingdom and the United States.

The selected pieces have been already presented during the *Balance-Unbalance* 2015 conference in Arizona and the Festival Internacional de la Imagen 2015 in Manizales, Colombia, among other events. Same as with the first edition of *art*! ⋈ *climate*, they will be made available in SoundCloud for listening online and for downloading, and the Red Cross / Red Crescent Climate Centre -and associated humanitarian organizations- will be using them according to their field actions needs.

EChO

EChO is a project focusing on how the media arts have responded to the challenging problems of the environmental crisis, looking forward towards an increased role for the media artists. It seeks to understand how art has served and can further serve as an essential link between science, social science, activism, and policy formation.

There are many projects by artists and artist-related organizations working in the media arts field and focusing on environmental problems. There are also many governmental, intergovernmental and non-governmental organizations, as well as private institutions, searching for solutions to the ecological danger for human life either at the local, regional or global level. EChO's goal is to connect, hence empower initiatives from around the world aiming to help in facing major ecological threats and finding solutions for a sustainable -and humanly livable- future.

EChO is proposing to match a public online database devoted to electronic art projects focusing on environmental issues with a virtual meeting point to facilitate communication. It has an openly proactive orientation as it seeks to produce knowledge that could be used for inspiring and enabling collective actions, connecting media art projects using science and digital technologies.

A transformational knowledge network to facilitate the generation of links among similar art-science-technology projects around the world, empowering and helping them also to connect with key players (research groups, humanitarian organizations, policy makers, artists associations, opinion formers, technology innovators, etc.) having interests alike.

This project proposes to facilitate the building of links to give power to otherwise unrelated initiatives and actions.

ECHO will be cataloguing and analyzing efforts by media artists to represent the causes, nature, extent, and possible solutions to environmental problems ranging from climate change-related issues to hazardous waste disposal, habitat destruction, the introduction of invasive species, and many others. The resulting database will: create links between artists' projects and actions, and between artists and other possible partners. The outcomes of EChO will have the potential of converting limited-reach projects with significant potential into something that could influence an international community, and eventually develop and increase its original scope.

The information will be organized according to different criteria, currently under analysis. Some examples could be: disaster type (e.g. biological, geophysical, hydrological, climatological); consequences (e.g. drought, flood, storm, mass earth move); artworks characteristics (e.g. focus, supporting concepts, potential applications, methodologies, technical requirements, possibilities for achieving the goal of solving a specific environmental problem: water scarcity, air pollution, etc).

The fundamental concept supporting EChO is to create a network to develop forces large enough to turn good will into actions. It could be a way to analyze, test and promote artistic projects considering solutions for environmental problems defying our existence and life in general.

Conclusions

In this context of global threats: Can the electronic arts and artists help? Yes, we can help. Everyone has a responsibility in the construction of the future, electronic artists too.

We can reflect, research and create. We can act and also invite others to reflect, engage, envision and act.

A large part of the population is living in uncertainty [regarding basic needs] and many barely surviving. When the *Balance-Unbalance* project started some years ago it probably appeared to be a naïve, good-will based, utopian initiative, trying to join intelligence and forces from a variety of fields in using e-art as a catalyst to face a problem we all share: the complex environmental crisis. Bringing people from very different sectors of society together, today *Balance-Unbalance* and its associated projects are not only proving it is feasible to connect artistic creation and realistic tools for change but to actually help in making that social changes could happen. The electronic arts as a driving force for…? Yes, the possibility to work on a project where artistic quality, knowledge building and humanitarian actions are all together in a balanced equation to confront the unbalance is feasible.

The '*art*! ⋈ *climate*' project became possible as a creation-knowledge-action proposal to reach those who are already affected or in imminent danger from the consequences of climate change, and also to those who are not directly touched by it yet. It can be seen as a tool but it is not less artistic for being that. On the contrary, the principal idea here grows from a cooperative effort, having powerful means based on artistic creations -with a value independently from its potential functionality- and simultaneously, a tangible application in humanitarian actions. The Red Cross / Red Crescent Climate Centre has found the '*art*! ⋈ *climate*' project helpful according to its goals and objectives. It seems to be a true collaboration that can have an effect on "real people" while preserving the significance and meaning of each contribution and action. [12]

EChO is still in an early stage of development but many people is convinced of its potential "benefits" in a variety of ways. EChO wants to help in building a network that should not duplicate other efforts and would extend our possibilities to learn from each other, empowering the significant actions that artists working with digital means could offer to face environmental challenges. Please, feel welcomed to share your thoughts and send your feedback about it.

Acknowledgements

My thanks go to Pablo Suarez and Leah Barclay for their contributions to this text and their support to several of the activities and projects mentioned here. Also to all members of the Electronic Arts Research Centre and the authorities of the National University of Tres de Febrero, to Roger Malina from Leonardo/ISAST, to my colleagues at Concordia University, and to colleagues at Arizona State University, Central Queensland University and the Noosa Biosphere Reserve, who have been helping to make all of the projects mentioned here a reality.

Author Biography

Dr. Ricardo Dal Farra is a composer and new media artist, associate professor at the Music Department of Concordia University, Canada and director of the Electronic Arts Research Centre (CEIArtE) at UNTREF, Argentina. He has been director of Hexagram, Canada; researcher for UNESCO, France; director of the Multimedia Communication national program at the Federal Ministry of Education, Argentina; coordinator of the Documentation and Conservation of the Media Arts Heritage - DOCAM international alliance, Canada; and senior consultant of Amauta, the Andean Media Arts Centre in Cusco, Peru. As an electroacoustic music composer and new media artist his work has been presented in over 40 countries and recordings of his pieces are published in 23 international editions. Funded by The Daniel Langlois Foundation he created the largest collection publicly available of *Latin American Electroacoustic Music*. Dal Farra started the *Balance-Unbalance*, “*art*! ⋈ *climate*”, EChO, BaDArtE and *Understanding Visual Music* international projects.

The Listen[n] Project: Acoustic Ecology as a Tool for Remediating Environmental Awareness

Garth Paine, Leah Barclay, Sabine Feisst, Daniel Gilfillan

Arizona State University
Tempe, AZ, USA
garth.paine@asu.edu, leah.barclay@asu.edu, sabine.feisst@asu.edu, dgilfil@asu.edu

Abstract

The Listen[n] project[1] is an interdisciplinary media arts project, investigating the pristine acoustic ecologies of Southwest deserts of America. Establishing the largest database of ambisonic and stereo field recordings of the Southwestern landscapes of the United States, the Listen[n] project is designed to not only archive sound, but to explore how virtual environmental engagement through media arts and sound can cultivate environmental awareness and community agency. It delivers community partnerships and capacity building with enthusiastic communities in four American Southwest desert communities: Joshua Tree, Sequoia & Kings Canyon and Organ Pipe Cactus National Parks and the Mojave Desert Trust. Aiming to empower and encourage communities to make creative contributions to and have agency in the development of the Listen[n] project, this paper outlines the fieldwork undertaken in 2014 and 2015 and discusses the substantial online listening database, virtual reality and web based tools deployed and currently in development. It will also provide information on the project's innovative application of ambisonic audio recording and playback to create 360-degree immersive experiences online and through the Oculus Rift VR headset (EcoRift).

Keywords

acoustic ecology, field recording, ambisonics, immersion, virtual reality, modes of listening.

Introduction

The Listen[n] project is an interdisciplinary media arts project, investigating the invaluable sonic ecologies of Southwest deserts of the United States. At its core, accessibility is actively designed into the digital platforms, community workshops and media artworks to support their creative use by as many different people as possible. The outcomes support engagement with rich natural environments for the broader public whilst also advocating for the proper recognition, respect and the active involvement of indigenous communities, elderly individuals and people with disabilities who would not traditionally have visitation access to these environments. The Listen[n] project aims to empower individuals of different abilities to collaborate and engage communities that do not traditionally have access to audio-visual technology. The project's collaborative media artworks and forthcoming touring exhibition will provide immersive environmental experiences for audiences all over the world.

Contested Spaces

The Listen[n] project focuses on the acoustic ecologies of pristine natural environments in the American Southwest. The term, "pristine natural environments" is of course problematic. It romanticizes and commodifies the land and our engagement with it. All landscapes are contested spaces, they are constructions of enculturation, be that perceptions of the energy and spirits within the land, and reflected by the land and the animals inhabiting it; a Western romanticized notion of settlement, belonging, entitlement, or an industrial view of the potential of wealth production, the gallons of oil, tons of ore, gold etc. and all the possible nuances between. Beyond these critical notions of land and place we can perceive an interplay of sharing commonalities, conflict and the transformation that occurs as the lobbyists and activists dance around each other over time.

The acoustic ecology of a space often tells a story of intervention and the relationship between the quality of the land surface, the vegetation, and the sounds of habitation, be they human or otherwise. Made up of two principal components, the acoustic ecology can be described as consisting of the substrate; the sonic properties of the land itself, the reverberation, the softness or harshness of the sound, the land's quietness. It also consists of a second principal component containing the sounds of activity of animals for whom the land is their habitat, the sounds of the critters, insects, birds, and larger animals [biophony], and non-sentient sound sources such as water, rocks, wind, weather [geophony] and above these naturally occurring sounds is a third dimension made up of human sounds [anthrophony], airplanes, motor vehicles, air-conditioning etc. - the sound of human presence, activity and intervention, sounds that often overlay the sounds of the natural habitat. These acoustic ecology dimensions indicate the rich and dynamic interplay between natural, cultural and industrial presence on any site.

This point is well illustrated by the experience of standing in the middle of the vast Soda Lake salt pan at 4:00 a.m., May 28, 2014. The terminus of the Mojave River in the Mojave Desert of California, contained within the Mojave Desert Preserve, one could hear the I15 freeway, some miles away, but reverberating across the flat surface of the

[1] See http://www.ecolisten.org , viewed 23 May 2015.

salt pan,the occasional air conditioner, maintaining comfort at the research station several miles in the opposite direction. Simultaneously one is aware of the soft enveloping acoustic of the site, established by a quietness, a fullness of air, characterized by the absorbent qualities of the salt lake surface, the reverberant qualities of the surrounding hillsides and the minimal bird and insect life active at that time of day. The sound of the freeway predominated the underlying acoustic of the site.

Soda Lake is part of the UNESCO Mojave and Colorado Deserts' Man in the Biosphere Reserve designated by UNESCO in 1984 to promote ecological conservation. The Mojave and Colorado Deserts Biosphere Reserve includes the Death Valley National Park (in the Mojave Desert), Joshua Tree National Park (in the Mojave/Colorado transition zone), the Santa Rosa Mountains Wildlife Management Area (in the Colorado Desert) and the Anza-Borrego Desert State Park (in the Colorado Desert). It is a vast land area which has a long history of human intervention and protection. What is now the Mojave Desert Preserve witnessed some of the first Spanish expeditions through eastern California in the late 18th century. In 1860, the U.S. Army maintained a fort at the site named Hannock's Redoubt, but a twentieth-century maverick gave it its lasting appellation, Zzyzx Mineral Springs and Health Resort which remained an active alternative community until 1974. In 1976, the California State University system negotiated with the U.S. Bureau of Land Management to establish The Desert Studies Center, a research facility that draws scientists and students year-round. Almost any site of human habitation could have as diverse a history. This evolution of occupation, intervention, and transformation is made explicit through the site's acoustic ecology in a unique manner. Listening deeply to the sonic environment makes one feel increasingly present – deeply present. Just listening for the delicate and intricate web of sounds that are there, but that one doesn't hear most of the time makes one aware that these spaces are neither silent nor empty. They reveal an ecology, made up of acoustic features - an acoustic ecology, that carries with it, even in the recorded medium, a sonic signature of the environment in which it was created, a sonic signature for the environment to which we have a somatic response – a bodily, phenomenological response. In this way, the I15 traffic noise, the distant sound of the air-conditioner at the research center, the quietness and softness of air, and the qualities of reverberation across the salt pan surface, all combine to provide an abstract, experiential history of the Soda Lake site. This experiential history is not a concrete, fact-based narrative but more a felt, somatic engagement with the qualities of the site through listening.

It should be noted that the terminology used in soundscape studies references sources – birds, wind, humans, etc. – but does not really address a notion of a baseline soundfield, a sonic a-priori.

R. Murray Schafer's key terms include:

- Keynote Sounds – sounds created by nature (geography and climate): wind, water, forests, plains … including birds, insects, animals.
- Sound Signals - foreground sounds, which are listened to consciously: bells, whistles, horns, sirens, etc.
- Soundmarks – "sounds that make the acoustic life of a community unique."[3]

A challenge that remains even with Stuart Gage and Bernie Krause's remaking of these terms into:

- Geophony - non-biological natural sources such as wind in the trees, water in a stream or waves at the ocean, and earth movement.
- Biophony - non-human, non-domestic biological soundscape sources of sound.
- Anthrophony - all of the sound signatures generated by humans.

Anthropologists have sought a more phenomenological approach. One approach being Steven Feld's phenomenological discussion of sensing place "as place is sensed, senses are placed; as places make senses, senses make place" and his term acoustemology: "one's sonic way of knowing and being in the world"; He talks about "how sounding and the sensual, bodily, experiencing of sound is a special kind of knowing."[2]

These responses are subtle, somatic and yet profound – one might reflect here on Richard Shusterman's proposal of Somaesthetics – which is said to "foreground the role of bodily experience in aesthetic appreciation." Shusterman says we must differentiate between representational foregrounding and experiential foregrounding. In the former, the body is seen and treated as an external object. In the latter, the body is a fundamental part or vehicle of lived experience. (n.b. also Dewey, *Art as Experience*,1934).

In an attempt to move away from citing sound sources (the excitation - representational foregrounding) and acknowledge a baseline sonic atmosphere (experiential foregrounding), we might consider extending the existing terminologies to focus on whole being, direct experience of sound rather than sound as an external object and in so doing, recall Gregory Bateson's (Bateson, 1972) proposition that the patterns of mind (consciousness) and the patterns of matter are reflections of one another and part of an unbroken dynamic whole, suggesting that the body, the space, and the resulting sense of place are inseparable.

During a keynote presentation at the Ecomusics & Ecomusicologies 2014: Dialogues conference in Asheville, Garth Paine proposed the term: *Somaphony* - *Soma* meaning the subtle body and *phon*, denoting sound.[3] Somaphony hints at a sense of being present – of being in a place that is defined as much by its baseline sonic signature as it is by

[2] Steven Feld, "From Ethnomusicology to Echo-Muse-Ecology" Reading R. Murray Schafer in the Papua New Guinea Rainforest," *Soundscapes Writings Essays 2001*, accessed 23 May 2015, http://www.acousticecology.org/writings/echomuseecology.html.

[3] See Ecomusics & Ecomusicologies 2014: Dialogues, accessed 23 May 2015 http://www.ecomusicologies.org/.

the presence of sound signals and keynote sounds, an inclusive experience of "knowing and being in the world," a "bodily, experiencing of sound [as] a special kind of knowing" whilst simultaneously acknowledging the sonic as an object as referenced by the standard acoustic ecology terminology. Paine is drawing attention to a whole-body mode of listening where perception is singular and cumulative and in line with Feld's "ways of knowing," rather than a concrete, separable and identifiable mode in the sense of traditional acoustic ecology concepts.

Embodied Interaction

Embodied interaction drives the technology development of the Listen[n] project which includes a large-scale online field recording database, an Oculus Rift VR experience (EcoRift) and a set of tools for mobile devices that allow the users to translate their current geolocation into one of the documented UNESCO Biospheres and National Parks and to immediately make recordings, take pictures or write stories for upload to the Listen[n] community portal. This strategy aims to engage users through embodied experiences in the rich potential of pristine natural environments.

Phase One

In 2014 two sets of field trips were undertaken and ambisonic and stereo field recordings were made in the early morning (dawn), early afternoon, and early evening (dusk) in each of the American Southwest desert Biospheres/National Parks named above. More than sixty hours of recordings were made, and subsequently auditioned and tagged before being added to a searchable online database which provides the public with direct multi-format access to listen to the documented sound fields from anywhere in the world. Five composers from around the globe, Ros Bandt, Leah Barclay, Ricardo dal Farra, Douglas Quin, and Garth Paine, used these recordings to create acousmatic compositions which were premiered in Tempe, Arizona in 2014.[4] In addition, 360-degree photographic panoramas were created at the location of each recording. The recordings and images have been combined in several experiential media outcomes: 1) as a navigable panorama on the website which ties together the 360-degree image with realtime spatial audio navigation of the 360-degree audio recording made using the ambisonic technique. 2) This experience has been further developed for offline high resolution deployment as an Oculus Rift VR experience called the EcoRift which offers a truly immersive engagement with the represented high-value natural environment, providing full 3D Point-of-view and stimuli in both the audio and visual domains.

A website containing the above recordings and information about the project has been developed in a manner that enables each community near the featured National Park/Biosphere Reserves to add to the recordings made by the Listen[n] team through audio, photographs, video, and text. The website is structured around each geographical location, with a single page for each site containing the 360-degree panorama, a description of the location, the UNESCO Biosphere Reserve data, a map showing the geolocation of the recordings available in the database, a search pane that provides direct listening access to the soundfields. It also offers a community PlaceStories portal where the local community can upload media related to the project using skills developed in Listen[n] project community workshops and equipment left in the communities for this purpose.

Initial experiments with the EcoRift system have shown that realtime dynamic movement through both the visual and auditory domains produces a strong sense of presence and immersion in the represented natural environments. We postulate that this is because the ambisonic soundfield provides full 3D auditory cues, and that linking the head-tracking to roll, pitch, yaw and zoom in the auditory field provides the same ability in the EcoRift experience of moving the head slightly to determine or check auditory spatial coordinates as would be experienced in the real world. When synchronized with a 3D panoramic visual representation of the recording site, users have reported a very strongly embodied experience of being present in these natural locations.

The final aspect of the first phase of this project is the development of a mobile platform application that allows users to select one of the documented National Park/Biosphere Reserves they wish to walk through; they then select a walking route in their local environment - perhaps their route to work through an urban environment - wearing noise-cancelling headphones and push go - the app geo-locates them in the desert soundfield as they walk through their local environment, providing an embodied experience of traversing, or sitting and listening in a unique natural environment. This application also uses ambisonic sound sources providing full spatial panning and zooming in the 3D soundfield and constructs contiguous soundfields by extracting features from conjoined static recordings to form a seamless sonic space.

Phase Two

In 2015 the Listen[n] team made public presentations in Joshua Tree and Sequoia & Kings Canyon National parks and offered workshops for young people on listening and field recording as part of National Parks Week. A further two periods of immersive community engagement will take place in each location. The first involves workshops on listening and recording natural environments and an exploration of the ideas of acoustic ecology for school children and visitors to the park respectively and a work-

[4] The compositions are: *Raptor* (Bandt); *Ground Interference* (Barclay); *Listening* (dal Farra); *Contested Landscapes: Singularities, Granularities and Sonorities* (Quin); and *Becoming Desert* (Paine). Paine also created the interactive work *Forest* (2015) which combines desert field recordings and live flute performance.

shop focusing on field recording by the Listen[n] team in locations suggested by the community followed by introductory and advanced workshops on listening, acoustic ecology, and ambisonic audio recording. The final stage of this period features participatory opportunities, including the sharing of field recordings on the Listen[n] Database and the publishing of digital stories around listening to desert sounds on the Listen[n] PlaceStories portal.[5] The longer workshops take place in collaboration with local community groups who will support volunteers in a long-term endeavor to re-record the acoustic ecology of each site at monthly intervals for the next decade(s), forming the basis for comparative studies of changing sonic ecologies due to changing climates, land use and habitation.

The second workshop period involves collaborations with the community in creative responses to the environmental field recordings made in the first workshops. The workshop participants will have the opportunity to make their own media art using Listen[n] project recording equipment left in the communities in the first workshop period. Participants will create solo and collaborative sound and media artworks based on environmental and heightened auditory engagement..

These Listen[n] project sound and media artworks will be curated into a touring exhibition and concert. The exhibition will include a dynamic website streaming the environmental field recordings for exhibition attendees (and local and global audiences). It will also offer unique 360 EcoRift VR experiences, The concert will feature immersive sound compositions disseminated on three listening stations and multi-channel acousmatic musical works drawing on the field-recording database..The exhibition and concert will premier at the ASU Art Museum in 2016.

Transmedia Approach

The Listen[n] project may remind of a number of endeavors involving nature sound recordings. However, it is unique in its scope, its many different and interdisciplinary components, its innovative technologies, its extended time span (designed to evolve over several decades), its concentration on national parks in the American Southwest, and its focus on community engagement.[6] The PlaceStories software, for instance, inspires the formation of strong cohorts by establishing a framework of Community, Project, and Story.[7] It allows for the development of extensible and dynamic communities by supporting the storytelling and communication needs of groups with a common interest. PlaceStories's application in the domain of acoustic ecology is well demonstrated by the Bioshpere Soundscapes project founded and directed by Listen[n] team member Leah Barclay in 2012.[8] Biosphere Soundscapes has built communities committed to "listening to the environment and exploring the value of sound as a measure for environmental health in UNESCO Biosphere Reserves." The Listen[n] project builds on the success of such trans-disciplinary ventures.

The distinctive components of the Listen[n] project combine in a single interface - each feeding into the overall vision of the project. This multi-platform approach is essential in our accessibility strategy and community engagement methods. The contemporary practice of a transmedia methodology requires cultural assets that fuse not just audio and visuals, but also design, interactivity, and a host of other disciplines. The multiplicity of digital distribution channels, balanced by the ease with which they connect to each other, demands that the artist of the future designs cultural assets that can seamlessly blend across multiple platforms. We are reaching an age in which audiences are consciously creating and viewing the narrative of their own lives across various platforms (e.g. via Instagram, Flickr, Facebook). Artists and humanities researchers should be aware of this trend when designing forms of community engagement and outreach. Listen[n] combines highly accessible outcomes (such as listening to high-quality field recordings) with technologies at the forefront of entertainment (such as the embodied EcoRift and mobile geo-locating walk experiences). It does so to enable communities to take agency in this project and to foster stewardship in their local environments whilst contributing to and/or driving the discourse of the project over decades and beyond.

Conclusion

Listen[n] gives voice to a wide range of constituencies: to communities living in proximity to the featured sites; to communities distant from these sites; and to the non-human and non-sentient constituents of these sites. The digital tools and dynamic website facilitate both a disruption of traditional visitation of pristine natural environments and simultaneously through this remediation, a broadened access. Listen[n] uses technologies to question embodied experience and to encourage new forms of embodied actions. It integrates significant discussions about sound, sustainability, and the place of human experience through creative storytelling, digital mapping, and community collaboration. Listen[n] builds important connections between the humanities, the environmental sciences, and media arts through development of new technologies, interdisciplinary research, creative endeavors as well as educational and outreach initiatives. It seeks to foster new en-

[6] Neither Marc Anderson's *Nature Soundmap* (a database of binaurally recorded nature soundscapes and satellite images), nor James Bulley and Daniel Jones's *Living Symphonies* (a work with sounds from British forests recorded in 2014 and sounds performed on Western musical instruments) or Canada's 2011 National Parks Project (involving nineteen film makers and thirty-nine musicians to create works about Canada's national parks) engage local and global communities directly in creative placemaking in such a multi-faceted manner as does the Listen[n] project.

[8] See http://www.biospheresoundscapes.org viewed 23 May 2015.

vironmentally aware communities who through social media can use their voice as stewards of these protected, yet vulnerable landscapes.

Given such ever-growing challenges as environmental degradation and climate change, the multifaceted outcomes of this project will hopefully nurture more sustainable lifestyles and stabilize park ecosystems. The participating communities will learn to critically interpret their relationships to natural and built environments through new forms of listening enabled by technology. Across each of these outcomes, sound plays an important role for establishing and cultivating individual/community agency and environmental stewardship. In giving voice to individuals and community members to articulate their own positions in these natural spaces, Listen[n] opens up new opportunities for exploring the importance of place and the vibrancy of sound for its audience.

Authors' Biographies

Garth Paine is internationally regarded as an innovator in the field of interactivity in experimental music and media arts. He is a Professor of Digital Sound and Interactive Media in the School of Arts Media + Engineering and a professor of composition in the Schoolof Music at Arizona State University. As an Associate Professor in Digital Musics at the University of Western Sydney, Australia, he established and directed the Virtual, Interactive, Performance Research environment (VIPRe). He is fascinated with sound as an exhibitable object, which has led to several interactive responsive environments where their inhabitants generate the sonic landscape through their presence and behavior. It has also led to music scores for dance works, generated through real-time video and/or bio-sensing of the dancers. Paine is widely published, retains positions on editorial boards of in the USA, UK, and Australia and performs his own compositions regularly at international festivals.

Leah Barclay is an Australian composer, sound artist and creative producer working at the intersection of art, science and technology. Her work has been commissioned, performed and exhibited to wide acclaim internationally and she has directed and curated interdisciplinary projects across the Asia-Pacific. Barclay's PhD involved site-specific projects across the globe and a feature length documentary exploring the value of creativity in environmental crisis. Her research has been published internationally and her creative work has been selected for major international festivals and conferences. She is currently an artist in residence at the Australian Rivers Institute investigating the creative possibilities of aquatic bioacoustics, the president of the Australian Forum for Acoustic Ecology and the founder and artistic director of Biosphere Soundscapes, a large-scale interdisciplinary art project connecting the soundscapes of UNESCO Biosphere Reserves across the world.

Sabine Feisst is Professor of Music and Senior Sustainability Scholar at Arizona State University. Focusing on twentieth and twenty-first century music studies, she published the monographs *Ideas of Improvisation in New Music* (Studio Verlag, 1997) and *Schoenberg's New World: The American Years* (Oxford University Press, 2011), as well as numerous essays in European, American and Australian professional journals, essay collections, and encyclopedias. She is currently editing the *Oxford Handbook of Ecomusicology*. With Denise Von Glahn, she is editing the book series *Music, Nature, Place* for Indiana University Press.

Daniel Gilfillan is Associate Professor of German Studies at Arizona State University. His research focuses on twentieth-century literature, film and media studies in the German-speaking sphere, with particular interests in avant-garde/experimental approaches to new forms of media in the past (radio, film) and the influence of these earlier instances of new media on contemporary artistic and cultural practices with telecommunications media. His first book, *Pieces of Sound: German Experimental Radio* was published by University of Minnesota Press (2009). He is currently working on a second book titled *Sounding the World: Sustainability and the Art of Sound*, which explores the role of sound within the key concepts of resilience and precariousness as they function across complex adaptive systems, and these systems' need for sustainable infrastructures.

Abstract

Based on a practical somaesthetics framework emphasizing the values of self experiences, this paper presents the design rationale of a responsive dress, Laughing Dress, which employs laughter as an agent to highlight the unobvious and unspoken social distance between strangers and inverting our cultural notion of public self-containment. The proposed wearable dress is used to investigate the concept, "disruption for reformation". Throughout the design process, the prototype addressed the research question, "Can exposing self-representations through synthetic sound as inner voice and rhythmic light as somatic energy rattle and provoke reposition of us against existing social norms of private-public space?" The research instrument aims to break personal boundaries by magnifying wearer's self-presence, enticing a psychophysiological mirroring of laughter in another entity, and evoking a sense of curiosity through a display of visual aesthetics. The unusual display and magnification of self-presence within public setting contributes to disruption of social expectation on self-containment in public, reflection upon the organic form of human-to-human interaction, and initiation to realign our behaviour.

Introduction

City is built upon decades of structures and regulations, where its culture plays a major role in its inhabitants' social behavior. Social changes emerged from new innovations and political movements reconcile behaviour incrementally, but the repercussion might be far-reaching. Advancing technologies have created a new era of communication where people of different location and time are able to connect and reconnect quickly and effectively via telecommunication. The emerging behaviour led to the major shift of attentional focus towards handheld devices and other forms of electronic, thus consequencing on a lack of face-to-face communication between one another.

Laughter is a universal form of human communication that indicates intrinsic emotion, mood or personal expression outwardly. Neuman et al. describe this involuntary mimicry of expression as mood contagion, which aligned with Van Barren et al.'s view point of a mirroring of postural, emotional, and behavioural reaction from the observer [9, 20]. Laughter's contagious ability makes it an intuitive, yet fitting medium outcasting positive energy from oneself to another, thus disturbs the social silence within a self-containing culture and invites a merging of personal space.

Research Potential

Advances in telecommunication technologies have allowed our communication across distances to be instantaneous, efficient, and dynamic. While they have allowed for users to remain socially connected across multiple platforms simultaneously in the digital realm, it has also created a phenomenon of physical isolation between users in our physical world, resulting in the loss of intimacy and connection between persons.

A recent meta-analysis of social interaction in Vancouver, Canada, demonstrates that large numbers of residents in metro Vancouver experience social isolation and disconnection [21]. The largest community foundation, Vancouver Foundation, conducted a mixed method study with 3,841 participants in 2012, where 34% of the participants felt difficult to build new social connection in Vancouver. 60 % of the participants only have short conversation with any of their neighbors less than 2 or 3 times a month. Moreover, 26 % of house tenants never speak with their neighbor more than once a year. 25% of the participations felt lonely, where young adults, new comers to the country, and new members of the neighborhood aged 25 to 34 experienced social isolation the most. In addition, Perissinotto et al. pursued a longitudinal cohort study of 1604 participants in psychological and health condition and found that 43% participants experienced a lack of social contacts and felt disconnected with their community [11]. They assert that the social isolation in adults older than 60 years could cause some functional decline in mobility of their body and even death.

The desire to revitalize the diminishment of face-to-face communication in our technological advancing society motivated a research exploration on the concept of "disrup-

tion for reformation" through interactive public art. We implemented a research prototype that encompasses materiality, poetics, and semantics of interaction for practical somaesthetics. The interactive dress aims to investigate whether a combination of synesthetic laughter with rhythmic light patterns provides sufficient somatic stimulations to provoke self-reflection and induce physiological mirroring of positive bodily expression for behavioural changes among others in public settings [Figure 1].

Research Domain & Related Work

Catalytic creations can cause social changes. We see the potential of disruptive innovation to trigger realization, reflect, and reactions to ingrained social norms. With the overarching inquiry of "whether a display of self-representations through synthetic sound as inner voice and expressive light as somatic energy rattle and provoke reposition of self among others within the same public space", the research instrument, Laughing Dress, ameliorates the domains of interactive body visualization art, psychophysiological mirroring of laughter, and practical somaesthetic.

Public Art on Body Visualization

The initiation to cause change in our society calls for a work that engages the public. This elicited researches and works to explore the notion of self as an agent to transform one's situated space. Rafael Lozano-Hemmer's Pulse Room [8] bio-detects and translates participants' unique heart rates into one of the 300 incandescent lamps within the overall installation space. This process leads to 300 individual flickering light patterns as means to explore self-regulation of one's intimate heart within public space. George Zisiadis's Pulse of the City [22] converts a pedestrian's real-time pulse data into music that projects through a speaker at one of Boston's city sidewalk. This installation aims to reconnect pedestrians with their body rhythms while celebrating their use of public space in a playful manner. Additionally, installation works such as Feel_Perspire [4] and Pulse and Bloom [14], highlight the potentials of displaying biofeedback interaction for audiences' reflections upon the relationship of their personal bodies within public and social realm. Thus, inspired by the problem of self-isolation within public spaces, the display of personal body visualization on the Laughing Dress is a viable form for a controversial interplay between private and public.

Psychophysiological Mirroring of Laughter

Laughing is one of the natural body expressions that represent joyful emotional states in ourselves [15]. Provine further highlights the contagious quality of the sound of laughter and its ability to increase feelings of warmth and connection between individuals [12, 13]. Fukushima et al explored the concept of psychophysiological mirroring behaviour by developing a system, which produces laughing soundtracks that synchronize with the user's desire to laugh in order to induce more laugher [3]. Through the experimental study, they demonstrated that the synthetic laughter extended the duration of user's laugh. Shahid et al.'s study [19] with the Adaptive Affective Mirror further reinforces the potentials of laughter as audiovisual feedback to elicit positive emotions from users. Through Laughing Dress, we hypothesize the following: Laughter is a contagion for happiness, which can foster opportunities for social interaction between strangers.

Practical Somaesthetics

Practical Somaesthetics is one of three fundamental branches of Somaesthetics introduced by Richard Shusterman [18]. It highlights the participants' aesthetic appreciation of bodily experience and their embodied reactions to the interaction. Through soft(n) [16], Schiphorst argues the consideration of poetics, materiality, self-experience, and interaction semantics as invaluable design resource in the craftsmanship of embodied interaction. Exhale [17], Cardiomorphologies [7], and Below the Belt [5] examine the correlation of personal breath and emotional expression between individuals during the making of interactive experience across bodily and social realms. These bio-interactive installations align with the framework as they afford somatic experience through the processes of self-awareness, -reflection, and -representations to provoke understanding on the research concept and engage the audience within their situated, public space. Wo.Defy [6] further highlights the use of this framework by crafting a wearable, narrative space that allows the wearer and audience to culturally reconnect and reengage with the Chinese suffragette history from the late 19th to early 20th century. In our motivation to reveal the self-lived experience to the public realm, Laughing dress applied the bodily practices in somaesthetics framework to magnify self-representation of wearer, disrupt social boundary, shift the attention of passerby, and reform social interaction.

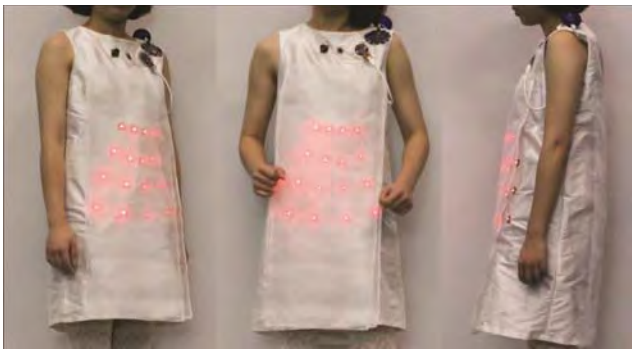

Figure 1. Laughing Dress. © SFU SIAT Soma Embodied Wearable Group 2014

Design Rationale: Laughing Dress

We aim to probe with the expression and communication of laughter on interactive wearable to encourage prosocial behaviour between the wearer and speculators within a public space. The materiality of raw technologies on the Laughing Dress and the poetic expression of wearer's presence as visual aesthetics serve to welcome interaction

through honest epiphany of the wearer's being. To help establish a connection between individuals, the prototype's interaction module is driven by interpersonal proximity to obscure the boundary between personal and public space. The subconscious psychophysiological mirroring of synthetic expression in the body and the generated opportunity to connect among one another stimulate thoughts about the disruptive experience as ways to reflect upon our being. Laughing Dress amplifies wearer's presence both visually and audibly as a non-conventional paradigm to rattle existing social structure of public behaviour.

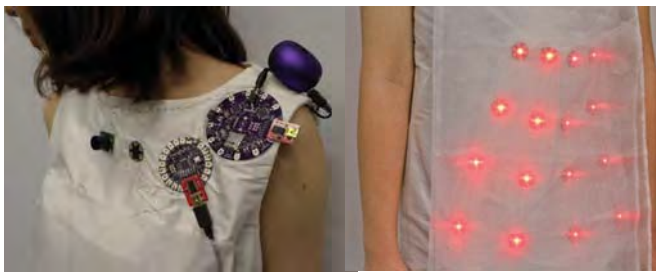

Figure 2. (Left) 4 series of Lilypad LED Pixels, (Right) From left to right: Ultrasonic distance sensor, tri-axis accelerometer, Lilypad Arduino microcontroller, Lilypad MP3 player, mini speaker. © SFU SIAT Soma Embodied Wearable Group 2014

Materiality and Poetics of Revealing Inner Self

Laughing Dress displays wearer's body state and presence as synthetic positive expressions to external entities to establish curiosity and conversation in hopes to foster social comfort and trust. With laughter as agent for emotional transference through psychophysiological mirroring, we translate the by-product of laughter into a series of expressive light patterns. The generated lights accompany the simulated sound of laughter on the wearable prototype as an allegorical reference to the invisible energy radiating from the wearer's laughter. The tri-axis accelerometer at the collarbone region cause changes to the LED light pattern at the lower torso region [Figure 2]. As the gestural movements of the wearer increase, the XYZ values detected by the accelerometer increase, which maps to a higher intensity output in the LED lights [Figure 3].

The exposing technologies on the soft interface align with the conceptual intention to reveal the authentic self; the work extends an invitation to the spectators to overcome self-containment. The visual aesthetics of Laughing Dress represents the wearer's presence, which breaks the veiled social boundary, initiates opportunities for social interaction, and aims to increase prosocial behaviour between the wearer and her spectators.

Interaction Semantic: Breaking Private-Public Boundaries

We employed a human-computer interaction approach to explore a solicitation of positive face-to-face communication; the dress elicits a positive feeling and fosters trust between strangers to disrupt against our culturally accepted practice on personal space. Research highlights that physical distance correlates to the social distance between two persons [2]. Using an ultrasonic proximity sensor at the collarbone region, we map the amplification of the laughing sounds to the physical distance between the wearer and spectator; the increase in volume indicates a closer social distance between the two. As a result, the expressions of laughter infers to the intensity of positive mood generated from the interaction between the wearer (conceptualizer) and participating spectators (interlocutor).

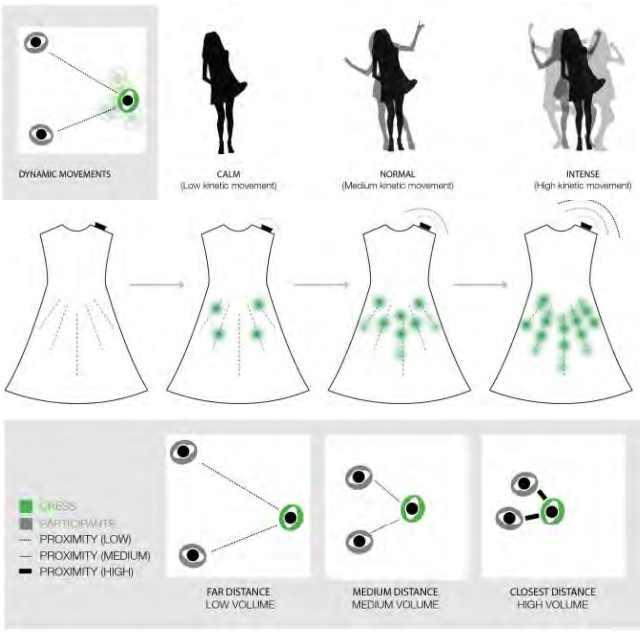

Figure 3. The Interaction Model (Wearer's Moveents, Sound & Light Output, Proximity) © SFU SIAT Soma Embodied Wearable Group 2014

Somatic Experience for Reformation

While individuals differ in their sensitivity towards emotional contagion [10], research indicates positive mood has greater inter-influences than negative mood [1]. As a result, Laughing Dress uses laughter as a positive emotional contagion to encourage social interaction between strangers within a public space. Through the wearable display of laughter accompany with light pattern expressions, the dress transmits enjoyment and positive mood from the wearer to the spectators through the involuntary mimicry of laughter. The interaction aligns with Neuman et al.'s description of mood contagion [7] and reveals a similar impact as Van Baaren et al.'s as they claim that the wearer's facial, postural, and behavioural expressions can produce movement, facial, and vocal mimicry synchronously as evidences of emotional responses [20]. To foster positive social bonding in a public space, Laughing Dress can be used to encourage spectators to smile, laugh and make eye contact, then stimulate prosocial responses and behaviour between the wearer and spectators through psychophysiological mirroring of positive audiovisual expressions.

Conclusion and Future Work

Laughing Dress is a research instrument that aims to investigate whether an interactive garment can repurpose an existing human quality, laughter, within an everyday design context to highlight the salient proximal distance between people within public spaces and bear prosocial behaviour through involuntary mimicry. This interactive public work employs a disruptive medium for self-reflection to cause reformation of self, towards others, and within our society. Laughing dress generates visual and audio expressions by means of one's physical energy and the proximal distance between individuals of a shared space. The alienation of this familiar bodily experience arises awareness, induces interest, and creates dialogues among strangers; the psychophysiological mirroring encourages prosocial behaviour towards one another, which challenges the existing self-containing culture.

We believe that laughter holds a charismatic quality where people of all ethnic background can understand intrinsically. We aim to take the responses from Laughing Dress experience to proceed forward to a practical solution where an appropriation of laughter can be used in an everyday application to elicit social connection, positive attitude, and prosocial behaviour in public setting.

Art, Affect and Aging: Creativity Vs Deficit.

Dr Gail Kenning
University of Technology Sydney, Faculty of Arts and Social Sciences,
Sydney, Australia
Gail.Kenning@UTS.edu.au

Abstract

As the median age of the global population increases a larger proportion of the population will be what is considered old. The aging process causes physical, cognitive and emotional changes and shifts the individual's perception of their world.

Artists and designers are increasingly working with practices that intervene, interact and bring about transformation. They engage with publics that operate as participants and co-creators and as such are increasingly likely to engage with older people.

Western culture has increasingly pathologized aging with a focus on countering its impact and delaying the inevitable end. The individual is addressed as a less able version of him or herself and assessed in terms of deficit, lack and loss.

Art and design projects with older people often get caught up in the pathologizing of aging. They are viewed and assessed in terms of art therapies or positioned as assistive technologies within medical, scientific and technological discourses.

This critical analysis explores how aging can be addressed in terms of the capacity and potentiality of older people. It investigates how, by employing ethnographic, person-centered approaches focusing on personhood and affect, artists and designers can challenge and transform accepted views of aging.

Introduction

Artists and designers increasingly work with socially and culturally engaged practices and technologies that intervene, interact, bring meaning, develop understandings and facilitate transformation. They engage directly with publics, are embedded within communities that operate as audiences, consumers and co-creators, and facilitate exploration of novel technologies and practices. The median age of the global population is increasing significantly with more people living longer. As a result a higher proportion of the population will be over 60, an age often considered the entry point to 'old age'. Therefore, the publics that artists and designers encounter will inevitably include older people including those, pre or post diagnosis, dementia. So, how do we ensure that older members of the public have access to the challenging and transformational aspects of art and design and are not limited or compromised by current perceptions of what it means to be old?

The increase in the median age of the population will have significant impact socially, culturally and economically. This shift will bring challenges to nation states, families and individuals. In addition, it will also challenge our perception of the aging process and what it means to be old, or be considered old. Western culture in particular, pathologizes the aging process, prioritizing scientific ways of understanding and situating aging within the domain of medical science and research. The focus here is on countering the impacts of aging, such as the perceived decrease in physical and cognitive functioning, and in delaying the inevitable end. The older individual is addressed in terms of a less able version of him or herself, or is compared, unfavorably, to an idealized younger societal norm. Thus the individual is viewed in terms of deficit, lack and loss

Art and design projects that engage with older people and communities, or age-related conditions such as dementia, all too easily get caught up in the pathologizing of aging. Projects are frequently assessed in terms of art therapy in the service of mental health professionals; craft is subjugated to occupational therapy or positioned in relation to restorative therapies such as reminiscence theory or behavior management. Here art is no longer an experience in itself, but operates as distraction. Design is no longer about choice, preference, and opportunity, but viewed in terms of its assistive potential.

Health care systems and health professionals are increasingly turning to person-centered care for older people and those with dementia. This involves embracing the concept of personhood, finding alternative approaches to care, that focus on quality of life and reassess the frequency of scientific and medical interventions. It involves a shift away from the pathologizing of aging and dementia and embraces positive approaches that recognize the capacity and potential of every individual throughout their life-course. It recognizes that aging and dementia involve changed perceptions of the world.

This analysis will provide an overview of the extent of the aging population and the changes in perception that occur as a result of aging and dementia. It will briefly comment on socially engaged practices, the impact of technology, and suggest that as art and design increasingly draw on medical and scientific practices and technologies, they can also draw on ethnographic methods to question the assumed aesthetics of deficit and counter the overwhelming scientific and medical discourse.

The aging population

Successes in scientific discovery, medical research and intervention, and improved social and economic conditions have resulted in people living longer and with the potential for more people to live well-beyond 100 years. The extended lifespan together with a reduction in fertility rates is causing an ongoing significant global shift in the median age of the population. More of the population will be in an age group that is currently considered old. The number of people over 60 is set to more than double by 2050 and

those over 80 will increase to almost four times that of 2001. By 2100 a substantial number of countries will have a median population age above 40. [1]

This substantial shift in the median age of the global population presents challenges. It will bring about change in relation to infrastructure, health and welfare systems, jobs and housing and resources generally. In addition, there are social and culture implications. Globally countries that have institutionalized aged care are now moving towards deinstitutionalization — driven, in the large part, by economics. Care of the elderly will increasingly be reliant on informal carers and immediate family members as older people 'stay in place' and remain in their homes and in their communities longer. As people live longer there is a predicted increase in prevalence of age-related conditions, such as dementia, which will inevitably become more apparent in many areas of everyday life.

The potential effects of an aging population on artists and designers are multifarious. Art and design, as acts of *doing,* engage with the social through an 'aesthetics continuum' that connects art to everyday life. [2] The majority (but, arguably not all) of art and design has a relationship, albeit often mediated, with an audience, consumer, user, co-creator or co-participant. Electronic immersive, interactive and screen-based works frequently foreground this relationship. As artists, designers, curators and theoreticians envisage an audience for these works, in the near future the audience will inevitably include older people and people with dementia.

However, it is not to suggest that artists or designers become intentioned about making work solely for older people or people with dementia. The issue is one of not unnecessarily designing out accessibility. It involves recognizing how the social is framed, and questioning what informs our understanding of what it is to be old. Artists and designers (who are also increasingly likely to be older people themselves) can then facilitate access to critically engaged work and transformative experiences for people regardless of their age.

Pathologizing of aging

While some cultures regard aging as the getting of knowledge, experience and wisdom, in Western culture the perception of aging is frequently one of decline of the body, mind, abilities, and functioning. [3] These views reflect a pathologizing of aging that can be located within the discourse of the 'medical gaze' identified by Michel Foucault. [4] Here the body is situated within scientific and medical domains. [5] Pathologizing leads to a medicalization of the aging process with the potential for over-reliance on pharmacological interventions. Such approaches focus on maintenance of the failing body and mind in order to achieve long-life, often to the detriment of the quality of that life. [6] The perception of deficit, lack and loss are compounded in relation to persons with dementia. The disruption to memory processing, that occurs in many dementias can signal the loss of the person. With loss of memory the body is seemingly 'emptied' of the mind and with it the person that once was. [7] A diagnosis of dementia can change how family and friends view a person, almost overnight. Focus shifts from ability to lack and loss. [8]

Simon Biggs suggests that the perceived 'failings' of the body and mind have broader implications leading to the construction of perception of aging as, not only physical decline, but also a process of economic and social decline. [9] The aging person, then, is positioned in terms of what they are no longer able to do, achieve, or generate, as 'failing', lacking, having deficits, and not the person they once were.

The 'system' of caring

This 'loss of person' also has implications for how the individual is treated and cared for. [10] The pathologizing of aging is predominant in health and social care systems and impacts, often to the detriment, on how people — who enter the 'caring professions', with the intention of improving quality of life — provide care. All too often health care professionals are not given time or resources to even get to know the person they are caring for. [11]

There is growing concern about how quality of care is delivered and assessed. Particularly in relation to the increased focus on 'evidence-based' standards of assessment through 'data gathering'. Increasingly, claims are made that the top-down approaches to quality care, which frequently require such measurement are not conducive to individualized quality care. [12] Over emphasis on data and measurement serves to reinforce perceptions as body as object, rather than body as subject. [13] Whereas alternatives such as ethnographic and narrative approaches can bring insight and meaning to what warrants successful or quality care. A recent colloquium of health professionals, academics and patient representatives in the UK identified tensions between scientific and person-centered approaches, these included:

— biometric assessment versus affective engagement;
— measurement versus description;
— scientific evidence versus imagination;
— treating the person as the 'end' versus treating the person as the 'means';
— knowing versus not knowing;
— universal generalization versus local experience;
— trust in 'practice' versus confidence 'in the system'.

[14]

Person-centered and embodied

Healthcare professionals are now exploring ways to ensure that quality health care focuses on the needs of the individual as they transition through the aging process. This involves organizing systems that meet the needs of individuals, engaging in person-centered care, and creating person-centered environments. [15] The aim of such an approach is to recognize that every journey through the aging process is individual and different, and none more so than for those impacted by the many forms of dementia. Person-centered care focuses on Personhood, that is, it recognizes

every individual as an individual with capacity and potentiality. [16] While such approaches do not reject medical intervention and scientific research they present a stark contrast to the view the 'medical gaze' gives us of aging and dementia as ongoing deficit, lack and loss, without reprieve.

Sustainability of existing care systems

The sustainability of existing healthcare systems, and in particular aged care, is in question as both established and emerging economies seek solutions for how to shape and support the healthcare needs of an aging population. Social, cultural and economic imperatives are increasingly driving towards effective alternatives to expensive clinical interventions and increased self-management of general good health and wellbeing by individuals, carers and communities. Visions of future healthcare systems foresee individuals negotiating health systems (as opposed to *healthcare* systems). In these scenarios "Super-empowered individuals" will manage their own health and wellbeing through "healthy living" and lifestyle decisions, with access to medical and social support as consumers, and systems that enable community engagement and participation. [17]

Perceptions of aging

The view of older people remaining engaged and active and retaining agency over their own lives for longer is increasingly being reflected back to society through media and marketing. Western culture, in particular, is embracing the notion of active, wealthy retirees. Slogans abound that encourage older people to go 'SKIing (Spending the Kids Inheritance), to go Gramping (camping with their grandchildren), to engage in 'adventure before dementia', and to become a 'gray nomad' and spend the 'gray dollar'. While not everyone has the financial freedom or inclination to travel or take on extreme challenges marketed to them, older people and those facing retirement frequently stress their desire and need to remain engaged, active and to contribute. [18] With the sheer numbers of 'baby boomers' reaching retirement age, the economic implications, and issues of sustainability means that their needs are more likely to be acknowledged than at any time before. [19] Supporting healthy, engaged older people is now becoming an imperative and increasingly our expectations are beginning to be challenged with regard to the visibility and engagement of older people in public sphere(s); the agency afforded older individuals; and how to meaningfully engage in negotiations between generational groups. [20]

Increasingly focus has turned to the importance of creativity and the role of the arts. Community interventions have been established to enable groups to engage, interact and participate in art and design projects. [21] However, we might question the extent to which artists, engaging with older publics in creative projects, are operating with assumed, inherited, and pathologized understandings of what it is to grow old, think of oneself as old, or be considered old.

Old age happens to the majority of people. Aging brings challenges, but also has potentialities. It is a process of ongoing change that is personal, individual and transformative. [22] Changes happen physically and psychologically; there are socio-cultural shifts; there are changes to environments as a result moving house, home, workplace or in giving up work; there are changes of status at home, in work, in social relationships; changes to the individuals' sense of self, belonging, who they are and what they like to do. [23] Aims, ambitions, desires and needs are refocused. Overall there is a change of perception, a change in how the world is viewed and how meaning is made. [24] For persons with dementia the physical, psychological and social changes are likely to operate at greater speed and the change of perception is profound. [25]

The contribution of art and design

What then is the role of artists and designers? How do they work with concepts of person-centered and personhood, and in creating art and design practices and experiences that are inclusive for older people and people with dementia? Socially engaged art and design and practices that foreground their relationship with an audience aim to engage with and challenge perception. But, whose perception? Aging as a process begins from birth physical changes to the brain and body continually impact on how the world is sensed. The aging process causes physical changes to, for example, the eyes. Aging and dementia can bring about a changed spectrum of color and color intensity. [26] Sound is spatially shifted and 'flattened' and older people are sometimes not able to differentiate between foreground and background noises. Taste and smell and propriocentric and kinesthetic functioning are attuned differently. [27] Our perception of the world is constituted through our bodies. In bringing about a transformative experience art and design engage with embodied experiences. If we accept that aesthetics "is primarily concerned with material experiences, with the way the sensual world greets the sensate body, and with the affective forces that are generated in such meetings" then we must also give consideration to the potential range of aesthetic experiences and bodies experiencing. [28] Focusing on the aesthetic and the embodied, lived experience, foregrounds the ongoing capacity of the aged body. This body viewed through personhood reiterates the concept of a person endowed with capacity and potentiality even in late stage dementia. [29]

Works that aim to directly address older people or persons with dementia often by default focus on deficit. For example, on memory loss and memory recall. It should not be taken as given that addressing memory loss is necessary, wanted or is helpful for the older individual or person with dementia. Families and carers may take comfort in displays of memory that enable stories to be shared, or to see that their loved one is 'still there'. But this approach does not necessarily address personhood and the capacity and potentiality of the individual.

However, there are some excellent art and design projects that draw on memory that do not dwell on recall, nostalgia and reminiscence, but offer experience, capacity and

potential. [30] Certeau offers a view of memory as construction, possibility, and potential, related to social and sensory experience. He suggests:

> [memory's] details are never *what* they are: they are not objects, for they are elusive as such; not fragments, for they yield the ensemble they forget; not totalities, since they are not self-sufficient; not stable, since each recall alters them. [31]

So, in coming to understand personhood, the capacity and potentiality of the individual constituted through the aged body we might begin to think the individual through construction rather than recall, and in terms of changed perception, aesthetics, and affect rather than deficit and loss.

Affect

Eliciting affective response and engaging with the experiencing body has long been the domain of art and design. Affect arrives through "visceral perception"; through the sensate body". [32] Feeling builds on affect, and implicit memory builds on feeling to create emotion. The body throughout the life-course retains sensing and is receptive to the forces and intensities of affect and to feelings and emotions. [33]

Research in relation to persons with late stage dementia shows that while explicit memory, memory of events, places, people, may be lost, implicit, tacit, procedural and pre-reflexive memory is retained. Unconditioned physiological responses and emotional responses continue to be accessible to the individual throughout the life-term, and the potential to experience in the moment joy is retained. [34]

Examples of affective responses can be seen in a number of videos released to YouTube by various organizations advocating for a broader understanding of capacity and potentiality of aging persons and persons with dementia. For example, Henry, a person with late-stage dementia is withdrawn with only limited abilities to verbally communicate and engage. But, he is physically and mentally transformed when listening to music. Gladys is seemingly an example of the 'loss of a person' as a result of dementia, but, she is able to re-engage and connect through singing. [35] These examples reiterate how affective responses show potentiality and capacity, or personhood, and reveal the presence of the individual. Furthermore, what such examples can show is the contagious nature of affect. They show how, as Anna Gibbs suggests: "Bodies can catch feelings as easily as catch fire; affect leaps from one body to another…" (quoted in S. Ahmed). [36] However, we are not speaking of one affect that is generalizable, but affects; operating in a myriad of ways and operating at different levels of pre-personal, precognition, pre-reflexivity. [37]

Socially and culturally engaged practice

In engaging with aesthetics and affective experiences artists and designers draw on a range of practices and technologies to promote engagement, interaction, and to challenge and transform. Artists are increasingly working outside the 'studio' and seeking alternative ways of engaging with publics. Such approaches are couched in terms of socially engaged art, community-based art, experimental communities, dialogic art, littoral art, interventionist art, relational aesthetics, social justice art, participatory art, contextual art and social practice. [38] These approaches focus on processes such as activating communities, increasing public awareness of social issues, and expanding models of art. They are characteristic of art practices of the last twenty years and may be considered a 'social turn' they produce effects and affects instead of placing a focus on form" Such works have been undertaken in school, prisons, hospitals and supermarkets and are designed to integrate with and challenge the everyday. [39] Projects that engage with publics will inevitably include older peoples and persons with dementia, pre or post diagnosis. An example of a successful projects\ that explores the capacity of older people can be seen in the work of the Danish art group Superflex and their project to set up internet streaming for older members of a Liverpool community. [40]

While some of these projects signal that they are 'art' through performative and theatrical approaches the 'art' element is not always clear. There is often a tension with regard to whether the projects is assessed as 'art' —which may set up an hierarchy — or through its efficacy. [41] This tension is compounded when socially engaged art projects engage with older publics and persons with dementia. For example, how does a socially engaged art project in an aged care center retain it's art status when the flow-on effect of the pathologizing of aging means that art that has any engagement with older people or age-related conditions, is at risk of being reconstituted and represented as therapy; addressing perceived deficit and loss. In addition, they may be couched in such terms to 'tick the boxes' or satisfy Key Performance Indicators (KPIs) of funding organizations. Such issues have been prominent in relation to socially engaged practices from their outset. As Hal Foster suggests in 1996:

> artists today may seek to work with sited communities with the best motives of political engagement and institutional transgression, only in part to have this work recoded by its sponsors as social outreach, economic developments, public relations…or art. [42]

Methodologies for engagement

Socially engaged art approaches are complex and often problematic as negotiations are undertaken between the art, the social, and the practices. In engaging with publics such approaches involve "careful listening, thoughtful conversation and community organizing". [43] Adaptations of anthropological and ethnographic methodologies are employed to understand the environment, the people and the social practices at play, with varying successes. Artists draw on interviews and methods of observation to research and gain an understanding of existing social and material practices, communities and customs. However, Bishop suggests embracing positivist social sciences approach from which these methodologies emerge is not always useful. [44] Foster also highlights the problematic position of artists engaging unconsciously in such practices and ap-

proaches and the risk of becoming the self-other in taking on the role of the anthropologist or ethnographer. [45] Facilitating the co-constructed, the collaborative, and the participatory, requires breaking down 'othering', and reflectivity and reflexivity from the artist on their position as artist and researcher. However, this should not deter artists from engaging in empirical research using interpretive and critical qualitative anthropological and ethnographic approaches to enable artists to challenge existing discourse; observe; engage with social practices; experience in an informed and embodied way; and to affect and be affected.

Design

It is not within the scope of this paper to fully explore the blurring boundaries between art and design. However, it is useful to note how artists employing socially engaged practices operate within design parameters. Here the 'art' work requires creative design approaches to structuring, logistics and planning, organization and in investigating social and material practices. Similarly, designers frequently use art practice approaches in the production of one-off designs, or 'design art', they work with socially engaged practices in the form of co and participatory design, and offer transformative possibilities through affective engagement. When electronic media and new technologies are brought into this mix we see individuals and groups operating as both artist and designer at once, using scientific technologies to explore aesthetic experience and affective responses. It is useful to note the role that technology has played in contributing to the amorphous nature of art and design. Particularly in relation to media art practices and the use of 'new' technologies. [46]

While socially engaged art projects are positioned in terms of a 'social turn' or 'affective turn' design is engaging with a 'semantic turn'. [47] It's role is not to make objects for manufacture and distribution *per se,* but to provide meaning and "to support a society that is in the process of reconstructing itself in unprecedented ways". So while design may include the production and distribution of objects, it exists in the "*proposition* of the realizable". Designers are motivated by

> challenges, troublesome conditions, problems, or conflicts that have escaped (re) solution; Opportunities to change something for the better — not recognized by others — to contribute to their own or other communities lives; possibilities to introduce variations into the world that others may not dare to consider…creating something new and exciting…aimlessly and for fun. [48]

As with socially engaged art, this semantic turn heralds a shift towards engaging with the social and the individual. Human-centered and user-centered approaches explore how technologies impact on what human beings are, can be and what it is to be human. In claiming a human, or person-centered approach, designs' challenge, then, is to truly prioritize the human, the person, and embodied enacted experiences. Assistive technologies and design then become ways to *extend* what it is to be human. This extension can only occur when design is not the technology, but becomes part of language and is implicated in the development of meaning. Design can become a condition for understanding self, other, and of enacting reality, presupposing the bodily participation of human beings. It becomes a constructivist enactment of understanding. [49]

In understanding design as a language we understand that design describes what is already in existence, contributes to the ongoing construction of meaning, and in doing so changes phenomenon. Design as language is subject to the restrictions of language, in that it opens up possibilities while also creating traps that can restrict and confine. For design discourse is developed in and through the artifacts created.

With a focus on embodied, human centered, individualized approaches, design is shifted from one of a top down technical problem solving approach to one that accommodates the participation of stakeholders at the very core of the design process. [50] It takes into account existing social and 'everyday practices', 'ways of operating', and ways of doing. Things, are not the 'obscure background' of social activity, but the very essence. [51]

In the same way that Bishop cautions artists against qualitative positivist social science approaches, designers aiming to assess human experiences, or user-experiences, need to engage with embodied perception. This requires interpretive and critical qualitative approaches. Ethnographic approaches can allow the designer to gain an understanding of the aged person at an individual level to counter the existing pathologizing discourse, to engage meaningfully with the person in person-centered and human centered approaches.

Electronic arts, new media, and digital technologies.

The difficulties facing artists and designers using electronic and digital media are compounded. For the most part art and projects are not about technology *per se* but how technology facilitates interaction, engagement and aesthetic and affective experiences. [52] Artists working in this field face the same issues discussed with regard to socially engaged practices that focus on the human being as source and form. [53] In addition, they are also impacted by the legacies of the military, industry complex and scientific approaches that have shaped expectations of, responses to, and the form of many of the technologies currently used. [54] In addition, artists working with scientific and medical data, such as neuro imaging, Magnetic Resonance Imaging (MRI) and biometrics etc., risk being caught up in the scientific paradigm.

If engagement and interaction is to be meaningful with human beings then acknowledging that our perceptions of each other are socially and culturally constructed, mediated and framed. This is key to facilitating authentic and transformative experiences. To this end increasingly ethnographic methodologies are being employed in researching the audience, user, consumer and in facilitating co-participatory and co-design approaches. [55] In addition, such approaches can provide deeper foundational insights for artists seeking to gain access to the person behind the

data, and as source material and form for media art works. [56] Such approaches not only enrich 'data gathering', they provide insights about human beings as potential audience, user, consumer, co-producer, co-designer, source, content, and form of work but also reveal how particular groups are framed.

Discussion

Artists are increasingly working in socially engaged practices; designers engage in meaningful non-hierarchical collaborative, participatory, co-design approaches; and electronic, digital and media artists foreground the relationship with the audience. There is usually intent to intervene, interact and facilitate transformative experiences. Inevitably as the population ages these approaches will engage with older members of the population. As incidences of dementia grow at significant rates artists and designers will engage with people pre and post-diagnosis dementia. But, all too frequently older peoples voices become lost, as they are perceived as lacking, this is particularly so for persons with dementia, who from the time of diagnosis undergo 'prescribed disengagement' where they increasingly have less power over their own lives and reduced access to social and cultural interaction. [57] The aims, ambitions, and desires, and perception of the world, differ for older people and people with dementia. Therefore, as artists and designers gain an awareness of the different views of aging it may prompt them to engage with individuals as subject rather than object.

In attempting to gain an understanding of aging publics artists and designers encounter risks when borrowing from other disciplines. In trying to understand older publics as audience, participators, makers, and collaborators, artists and designers, and the sponsoring institutions, organizations and funding bodies, all to frequently adopt a scientific and medical approach of pathologizing the aging process and age related conditions. This means aging individuals are addressed through deficit and lack, and art and design projects positioned as therapy and assistive technologies rather than about experience, meaning, and potentiality. Ethnographic approaches borrowed from the social science risk 'othering'. 'Borrowing' scientific and medical understandings and technologies may bring with them pathologizing and quantifying tendencies not appropriate to human or person-centered art and design practices.

However, artists and designers can learn from some of the advances that are being made in health care particularly in relation to the increasing focus on person-centered care, person-centered environments and personhood. In focusing on quality of life such approaches are embracing a whole range of alternative 'therapies' and lifestyle possibilities alongside the medical and scientific. The aim being to take a broad approach in exploring capacity and potentiality—personhood—and in provide meaningful opportunities to individuals, throughout the life course. Artists and designers have the potential to be co-facilitators, and enablers, not in addressing deficit, but contributing to potentiality through offering art and design experiences, not as therapies.

Conclusion

Art and design engages with emotional and affective responses and can promote wellbeing, be transformative and have physical, cognitive or emotional therapeutic, and assistive qualities. However, if the therapeutic and assistive aspect of art and design are the only aspects that older people or persons with dementia have access to or are made inclusive of, quality of life, capacity and potentiality are being curtailed. Art and design for older people or those with age related conditions can challenge, provoke and broaden horizons and need not be reduced to therapeutic outcomes or be limited by the perceived deficit that a particular view of aging gives us.

While recognizing the important role of clinical and therapeutic approaches this analysis challenges the scientific and medical dominance of the aging process and suggests that art and design practices can challenge the existing discourse that pathologizes aging and dementia. Assumed hierarchies need to be questioned with regard to the contribution they make to societal quality of life. Again we might look to de Certeau in discussion of art and science and the complementarity:

> …art is a kind of knowledge essential in itself but unreadable without science. This is a dangerous position for science to be in because it retains only the power of expressing the knowledge which it lacks [58]

Art and design has opportunities to engage meaningfully with publics consisting of older people and persons with dementia and those with different perceptions of the world and improve quality of life. By engaging with ethnographic and approaches on more than a surface level, artists and designers can gain a critical understanding of the current state of the domain. By thinking of audiences in terms of personhood, that is, capacity and potentiality; affect; meaning; and by building on pre-existing social practices, artists can gain alternative perspectives on aging. Artists and designers are then in an informed position to include older publics in a meaningful way, offering engaging, challenging and transformative experiences that enhance quality of life.

Author Biography

Dr Gail Kenning is Research Associate at the University of Technology, Sydney, Australia, and Design United Visiting Fellow at University of Technology Eindhoven, The Netherlands. Her art practice and research explores the relationship between art, creativity and health and wellbeing with a particular focus on aging and dementia. She explores extended textiles through animation and digital technologies, and investigates how ethnographic methodologies can be used in art practice to build stories and create affective experience. Gail has exhibited and published nationally and internationally in relation to art, craft wellbeing, aging and dementia.

The Patient Subject: Collaborative Biomedical Art and Curatorial Care

Bec Dean

PhD Candidate Art & Design, UNSW and Curator at Large, Performance Space
Sydney, Australia
curator@performancespace.com.au, rebecca.dean@unsw.edu.au

Abstract

How can curatorial practice bring into contemporary art programming/contexts and to visiting publics, the profound collaborations between artists and scientists in the creation of biomedical art? This paper outlines a curatorial proposal that investigates the practice of three artists working at intersections of the Museum, the Laboratory and the Clinic, they are: John A Douglas, Helen Pynor and Guy Ben-Ary.

This research addresses the atmosphere of openness between individuals and institutions across art and medicine, and the increasing porosity of institutions that allow artistic biomedical collaboration to take place. As a curatorial project, it questions the hidden nature of experiences surrounding disease, disability and bodily transformation and experimentation within our culture, and attempts to shift paradigms around corporeal representation, exhibition design and public knowledge.

Central to the research is theory on the body, including feminist theory; a review of literature engaging with the connections between art and medicine, particularly bio-art; and recent discourse around curating and collaborating. The program aims to interpret and transform artistic and scientific reciprocity in clinical, laboratory and museum contexts, where curatorial presence is essential and involved through all stages of collaborative research & development and presentation.

Keywords

Biomedicine, Curation, Artist, Patient, Care, Clinic, Laboratory, Museum, Collaboration.

Introduction

This short paper outlines curatorial research addressing new, collaborative artistic work being produced in the realm of biomedicine and the questions and possibilities the work raises for the presentation of biomedical art exhibitions and experiences to visiting publics.

Informing this research is the history and practice of Bio-Art over the last two decades, and observing the ways in which pioneering work of artists and collectives including Eduardo Kac and SymbioticA among many others have generated an atmosphere as well as contexts for exchange between art and science, encouraging collaboration. While these artists and groups, whose projects have variously speculated on scientific futures, experimented with genetic material and evolutionary processes, or engaged provocatively and fantastically with many forms of life, the work of artists in this research use the possibility for biomedical collaboration to delve deeply into both scientific and experiential examples of human life, illness, death and life's prolongment. Rather than reaching outwards and forwards towards "the entire gamut of life processes and entities", and an expanded biological spectrum, they are tuned-in to comprehending and elucidating the complex present/presence of human experience. [1]

Museum, Laboratory and Clinic

As a curator with over fifteen years professional practice, I have become increasingly involved in artistic projects related or proximate to research in science and medicine, across artforms, from photomedia and video to performance and forms of art as social engagement.

Through this research into interdisciplinary, collaborative, biomedical art, the capacity for an exhibition space and program that can encompass and integrate the differently culturally inscribed white-cube contexts of the museum, the clinic and the laboratory will be designed and tested. These are the places in which biomedical art is negotiated and fabricated by artists and their collaborators, but can these spaces be integrated conceptually, aesthetically and ethically to form another kind of space and exhibition experience? As a curator in the 21st Century I find myself and the cultural institutions I engage with as part of my practice, lagging somewhat conservatively behind the modes of enquiry and artistic outcomes of experimental, collaborative artists.

The artists engaged for this research and exhibition connect with the three spaces of the museum, the clinic and the laboratory in different ways and to different extents. While Guy Ben-Ary's practice is located predominantly in the laboratory, the use of his own cells has taken him into the clinic as patient in the harvesting of his own biological material. Helen Pynor's work roves between the clinic in her work with communities of former patients and their support groups and carers, to the laboratory for her study of cellular life, death and growth. While John A Douglas's practice has been undertaken predominantly in the context of the museum, he is a transplant recipient whose experiences are punctuated by visits to the clinic and his new work enters the space of the laboratory for the first time.

I want to discover through curating, if audiences can be brought inside the collaborative relationships that inform the production of biomedical artistic practice. Would an exhibition that integrated the social, political, scientific and historical situations that informed the making of the work enhance viewer experience and comprehension of the concepts and ideas in biomedical art?

Interdisciplinary Intersections

Bio-Art is an area of experimental arts practice in which all of the case study artists have worked to varying degrees in support of, or as the main focus of, their work. Artist and academic Eduardo Kac has written a comprehensive history of this field, which includes his own practice and the work of his peers. In *Signs of Life* he articulates three "defining principles" for bio-art, which may be "wholly or singly adopted by bio-artists." They are "(1) the coaching of bio-materials into specific inert shapes or behaviors; (2) the unusual or subversive use of biotech tools and processes; (3) the invention or transformation of living organisms…"[2] Kac takes the position of the objective scientist in his definition of bio-art with a focus on subversion, "randomness," "transgenic" future life and radical possibilities of intervening in evolutionary processes. The artists with whom I am engaged however, seem to be involved in a critique of the possibilities of the heterogeneous, human present, and a deeper understanding of life, cognition, health and death as we think we know it.

One of the key questions in my research is whether the sciences and the humanities are moving closer together? Australian medical sociologist Deborah Lupton's book *Medicine as Culture: Illness, Disease and the Body in Western Societies* (2003) outlines the present context in which the supposedly benign, neutral or truthful realm of medicine has been challenged – by feminists, sociologists and theorists – over several decades from the late 20th Century onwards.

Through reference to the work of Michel Foucault in particular, and his conception of the body as "the ultimate site of political and ideological control, surveillance and regulation," as well as the work of key feminist theorists such as Donna Haraway in arguing the social construction of the body, Lupton charts the relationship of society to medicine – its ethical, philosophical, political and moral dimensions. This text provides my research with important grounding and a broader understanding of Medicine in a social context, including its presence in art, literature and mass media. [3]

Also in the realm of medicine as culture, Susan Sontag's *Illness as Metaphor* (1978) is a key text written from the perspective of author as patient. It engages with the spiritual, religious and artistic representations of disease throughout history and its affects in contemporary life. For my research it provides background for the kinds of tropes and metaphors that the case study artists use in their new work – either consciously or though pervasive social doctrine. [4]

Contemporary artists have been working in the realm of body-based performance practice since the 1960s, through conceptualism and the second wave of feminism. For this research I am particularly engaged with the scholarship of Petra Kuppers, whose work has drawn attention to the practice of artists undertaking performance-based projects through their experience of illness and disability, and through the support of communities of care.

Her book *The Scar of Visibility: Medical Performances and Contemporary Art* (2007) is grounded in her research and personal work with artists, at a grassroots level, as an artist and activist living with disability. The book presents a phenomenological approach to performance art practice and an "affective way of knowing bodies". Using the metaphor of the scar, Kuppers discusses the knitting together of biomedical and artistic concerns, of procedures and the experience of them. Kuppers is concerned with the ownership of knowledge and expression around these issues and so her analysis traverses the celebrated contemporary artists of recent history including Kiki Smith, Mona Hatoum and Orlan, and then work by lesser-known, "community artists" which can be found at railway stations or in shopping centres. [5]

Kuppers' focus on both the experience of artists and the experience of audience/publics is of particular significance. I am investigating the possibilities of bringing together an encounter in space where the ethics, aesthetics and processes of art and medicine come together – the knitted "scar" space that she evokes.

Artists that have worked in this realm as patients, through embodied processes of pain-management, surgery and treatment include Bob Flanagan, Jo Spence, Hannah Wilke and Orlan. Wilke's final work, with Donald Goddard was Intra-Venus (1992-93) a documentary portrait series of the artist while she battled lymphoma, depicting Wilke in the last months of her life. This work completed a life's work making photographic portraiture as a means to address the "trauma of illness." [6] The embodiment of pain in Bob Flanagan's *The Pain Journal* is an important reference point to my work in terms of valuing the artist's first-person perspective.[7]

The work of SymbioticA and particularly its directors Oron Catts and Ionat Zurr is crucial to my research and practice related to the ethical and moral questions involved in the presentation of live and 'vital' material in the space of the gallery. Their work has frequently been at the provocative forefront of conversations about museum ethics in relation to the presentation of living material. In Janet Marstine's Museum Ethics, Ellen K. Levey uses the exhibition *Design*

and the Elastic Mind at the Museum of Modern Art in New York in 1999 and Catts & Zurr's project *Victimless Leather* to illustrate the need for a different curatorial approach to the maintenance of live materiality in the gallery space. [8]

A key curatorial and research project engaged with the embodied space of the biomedical is *PITH – Hybrid Bodies* in Montreal, including the collaborative work of academics, artists and writers Margrit Shildrick, Ingrid Bachmann and Alexa Wright. The program explores specifically the heart transplant process, and the patient experience of living with a hybrid, transgenic body. The work is of particular note for my research as it engages in both biomedical enquiry as well as the engagement of transplant recipients as interview subjects. [9] Science-based foundations and institutions including The Wellcome Trust and the Science Museum, Dublin have a substantial history of engagement with contemporary art and artists in the context of their object-based, historical collections as well as producing exhibitions, events and experiences which transcend the arts and science divide. Pedro Reyes' project *Sanatorium* (2011), a transient 'clinic' presented by the Guggenheim Museum, New York is a key work presenting challenges to the uses of the museum for different kinds of audience engagement around ideas of health and wellness. [10]

The 'care' undertaken through the process of curation and collaboration within my three artistic case studies and final presentations will also examine a shift away from the care of objects, to the care of subjects, artists and audiences. My practice links conceptual rigour with logistics and real world concerns which I am considering through the lens of Donald Schön's *The Reflective Practitioner*, and the work of Lizzie Muller in interpreting his theories towards the realm of curatorial practice. [11] [12]

Curatorial Care

Ben-Ary, Douglas and Pynor work in a materially 'alive' way in muesum and gallery spaces through their performative presentations and their presentation of living material. Experiencing the laboratory contexts in which they create these works will enable an analysis of creative and institutional collaboration between art and science, as well as inform decision-making processes around exhibition design, care for the artists, their works and audience care as they encounter them.

John A Douglas is an artist who until recently as been living with renal failure. He began addressing his medical experiences directly in his art practice from 2011, by performing during the process and timeframe of dialysis treatment. Douglas's upcoming work *Circles of Fire,* "investigates the artist's life-changing experience and embodiment of his recent (April 2014) renal transplant, drawing upon the aesthetics of medical imaging, landscape as metaphor and the relationship of the performing body to medical treatment. Douglas aims to inform and engage audiences, awakening them to the medical and non-medical (emotional) experiences of a transplant recipient and the challenges that need to be met in order to prevent rejection."[13]

Douglas is working collaboratively with artist Helen Pynor, Derek Williamson from the School of Human Disease and has undertaken a preliminary artist residency at SymbioticA. Through his work I investigate relationships between artists-as-patients with scientific researchers, and the opening-out of art and science discourse into embodied territories.

Helen Pynor simultaneously addresses emotional and physiological questions around the liminal space between life and death in her work. Pynor's new work (as yet *Untitled*), engages on a tissue-based and microscopic level, the testing of the 'liveness' of animal flesh presented for consumption on supermarket shelves. Concurrently, the artist is interviewing both surgeons and former patients around experiences of lucidity and awareness during periods of actual, clinical death.

"The proposed art work will reflect on the contested boundary of death in deeply provocative but empathic ways, proposing instead a form of continuity between the states of living and dead. The project makes use of Pynor's unique position as an artist with scientific training which enables her to engage with science practice at depth and make a rare and insightful contribution to art-science interdisciplinary practice."[14]

Pynor has undertaken research for this project at the Max Planck Institute of Molecular Cell Biology in Dresden, Germany. Her process of interviewing patients and Doctors will take place in London, UK where she is currently based. Through her work I explore the integration of hard scientific data, alongside a community-based approach to information sharing and art-making. The project will expand ethical issues of using animal flesh in the context of research, to bringing this material into an exhibition, as well as the presentation of deeply personal life-after-death experiences to public audience.

Guy Ben-Ary is an artist long associated with the SymbioticA Centre of Excellence at the Department of Anatomy and Human Biology, University of Western Australia. Ben-Ary has been at the forefront of innovating around tissue culture and art for the past fifteen years. The method of his enquiry has generally involved the harvesting, growing and culturing of neurons from fish and rats and other small animals bred specifically for the laboratory. When advances were made in stem-cell research in 2007 - Induced Pluripotent Stem Cells (iPSc) - that enable human subjects to have living skin or any other cells engineered

into stem cells, Ben-Ary adopted this technology in his practice.

The artist has since undertaken a biopsy procedure where his skin cells were harvested. The tissue was grown and then induced to become stem cells for a project called *cellF* – a self-portrait as sonic, biofeedback loop. Ben-Ary is now working with neurological scientists to grow his stem cells into neurons that are then attached to an electronic circuit. Simultaneously he is working with a musician to create synthesiser feedback for the neurons, and a feedback loop so that the activity of the neurons is stimulated by its own synthesised sound. [15]

For *cellF*, Ben-Ary has reconnected with the scientist he engaged with for previous work, Dr Douglas Bakkum, who continues to work on the project for the potential value that it brings to his own research into neurological trauma. *cellF* brings into sharp focus for my research, ideas of 'care' around object-subjects that are semi-living and curatorial 'care' for these works as well as the artist, from whose body they stem.

The Patient Subject: Meeting the Public

The exhibition I will be curating for the Galleries UNSW titled *The Patient Subject* in late 2016, will be an exhibition in three parts: *New Enquiry, Documents & Engagement*. The exhibition and its three constituent parts will offer space for immersion in new artistic works by the case study artists, reflection on historical precedents in the field of art and medicine; and provide context for audience and specialist engagement, discourse and scientific experimentation. Through research and case study engagement I intend to create an exhibition environment that brings together participatory aspects of the clinic, experimental aspects of the laboratory and communication aspects of the museum.

Author Biography

Bec Dean is a curator and writer who trained as a visual artist. She is currently a PhD candidate and casual tutor at UNSW Art & Design, University of New South Wales and Curator at large for Performance Space. She joined Performance Space as Associate Director in 2007 and became Co-Director with Jeff Khan in January 2012 until February 2014. Bec was previously curator at the Australian Centre for Photography (2005-2007) and Exhibition Manager at Perth Institute of Contemporary Arts (2002-2005). Bec's curatorial interests revolve around interdisciplinary and participatory practices, performance, site-specificity, biomedical art and art/science collaborations. Bec is the co-curator of the recent iteration of the interdisciplinary art laboratory *Time_Place_Space: Nomad* produced by Performance Space and ArtsHouse, Melbourne. Her current research on collaborative biomedical art will be presented as a large-scale exhibition and touring project, *The Patient Subject* in 2016. She has been published widely in Australia since 2000.

[Personal Nature]: An Artist's Approach to Assistive Technology

Dave Dowhaniuk

Artist
itchener, Canada
dave.dowhaniuk@gmail.com

Abstract

[Personal Nature] is an artistic intervention rooted in assistive communication technology. By using physiological sensors on the body a sonification is created, this is to amplify the minute non-verbal communication cues found in our heart and breath rates, temperature, and in the amount of moisture found on our skin, all processed through time. The goal of this sonification is to replicate the sounds of a park through real world recordings including birdsong, children's laughter, wind and water as to create a space conductive to communication. The intended user of this technological intervention is a person who is in a coma or is otherwise (seemingly) unresponsive and their loved ones. This article explores the artist's process of using art, design and research methodologies. By looking at the disruption through the lens of different philosophies while considering the benefits of nature, music therapy and communal healing this paper attempts to fully explore aesthetics within the hospitals critical care unit.

Keywords

Assistive, Communication, Sonification, Embodiment, Art, Design, Therapy, Music, Data, Generative

Introduction

When tragedy strikes and a loved one is in an accident or their illness increases causing them to lose consciousness there is an abundance of emotions including anxiety, stress and confusion. These emotions can cause an even larger disruption in communication. Families have been known to talk about the patient as if they were not present or even worse sit in silence. [1 – 3] Considering Shusterman's somaesthetics, these emotions can be transferred to the patient through unintentional communication such as touch and tone of voice. [4, 5] Current medical information tools greatly support the medical staff but do not necessarily benefit loved ones. This information is compounded when consciousness is viewed on an axes between awakeness and awareness meaning that many seemingly unresponsive persons are more awake or aware than they appear. [6]

[Personal Nature] is an interactive intervention rooted in medical informatics research [1, 2], where the autonomic nervous system (ANS) is regarded as a great indicator of stimulus and response particularly emotion. [7] The *[Personal Nature]* prototype is guided by artistic intuition and aesthetic research with aims at shedding light on the lack of aesthetic consideration in the hospital soundscape. Using sonification concr te methods, recordings containing snippets of real world sounds and synthetic representations are triggered to play and have their variables change according to sensor data (speed, L/R, volume, etc.). The goal is to create a virtual space which is conductive of positive communication, specifically that of a park or picnic setting. By using birdsong, children's laughter, wind and water sounds an expectedly relaxing yet cognitively alert environment is created. [8] At higher levels of awakeness and awareness the environment changes reflecting the non-verbal communication of the person with impaired consciousness' ANS when these levels are lower a presence for the individual is still created, both of these outcomes and the spectrum in-between can be conductive to community healing.

Disruption

Reflecting on Lefebvre's rhythmanalysis the body is viewed as a bouquet of rhythms, from the individual rhythms of the cells to the variety of cycles in the organs. [9] When a person is ill it is thought that there is an arrhythmic function in the body or in parts of the body. This could be an invasive bug, constantly reproducing cells or a malfunctioning organ lessening blood filtration. For Lefebvre in rhythmanalysis there is embodiment which involves being in tune with one's body in order to cognitively catch the arrhythmia as early as possible. This can lessen or even prevent disruptions in one's health and wellbeing.

When this rhythmic function is disruptive to the point of impaired consciousness (IC) communication channels are obviously strained. This is when well-intentioned loved ones can unintentionally increase stress or anxiety in the person with IC. Not knowing whether you can be heard or understood can be very stressful to loved ones and medical staff. This can cause them to lose their perception of personhood for the affected individual "because they cannot demonstrate the putative cardinal human attributes of co-presence and reciprocity." [1, p. 2] All of this could become apparent to the person with IC through the somaesthetics (touch, tone of voice, goose bumps, etc.) of their loved ones and caretakers. [5]

When lifesaving machinery is employed there is often an abundance of tubes, pumps and sensors. This dras-

tically changes the visual and auditory appearance of the affected person, further complicating the already strained communication channels. The beeps and whirs of the machines indicate certain aspects of the ill person's health but their meaning is often only clear to medical staff and trained professionals. This is troubling considering many persons with IC can hear and/or feel (physical touch) more than they are able to visibly or audibly indicate. Is this technology not disruptive in this case?

Un/disruption

The person may lie completely still, present in the room yet lacking presence. However they most certainly embody presence. Even if the person is in the deepest coma their presence is still important for communal healing. By externalizing the recovery process communal healing means that the "healing transformation may take place in the group rather than the individual." 10, p. 36 This is where the loved ones having a more relaxed and confident somaesthetic is important as it may be interpreted by the individual with IC.

Lefebvre described the present as static whereas presence is the present when time is considered when poetry is considered. 9 Take into account the medical staff on their routine visits only a stationary number or small range of data is collected. However projects such as *[Personal Nature]* look at these physiological signals through time, amplifying the smallest changes in nonverbal communication. In most medical settings the presence of the unconscious person is reliant on disruptive albeit lifesaving technology whereas rather than attempting to add an additional layer of perception and communication. Initial research into using sound and the ANS such as Holland Bloorview ids Rehabilitation Hospital's (HB RH) *biomusic* has shown an increased perception of personhood for the seemingly unresponsive person 5 to me this indicates an improved projection of embodiment because of or resulting in greater empathy. The individual's non-verbal communication and rhythms are being made poetic through sonification, generative music, and technology.

Out of my experiences with my immediate and extended family members I put great thought into how this technology could be used as an artistic medium. *[Personal Nature]* is the result of my empathy and experience combined with an extensive literature review and artistic intuition. I knew the resulting sonification had to be unobtrusive yet the ebb and flow of its rhythms had to be obvious. An environment conductive to positive communication is to be achieved. Through the simulation of a natural setting a picnic or backyard barbeque soundscape is created. A place of communal conversation, of reminiscence and laughter rather than the clinical and sanitized setting.

Nature

In our increasingly technological society many people are separating further and further from nature. This is exceptionally true for those in the hospital, though the need for sterility is understood. Surgical patients whose "rooms with windows looking out on a natural scene had shorter postoperative hospital stays, received fewer negative evaluative comments in nurses' notes, and took fewer potent analgesics than 23 matched patients in similar rooms facing a brick building wall." 11, p. 420 Nature art has also shown to reduce visible restlessness, noise level, staring and queries to the reception desk while increasing social interaction in hospital emergency waiting rooms. 12 Similarly patients supported by respirators and in mild comas (Glasgow Point 9 and above) showed and reported reduced anxiety, agitation and lower blood pressure when played nature sounds on headphones over a matching control group of no intervention. 13 The generative and rhythmic elements of nature and evolution as well as their effects on our health greatly inspired *[Personal Nature]*.

Music Therapy

Working with persons suffering IC and their loved ones is familiar ground for music therapy. From gathering loved ones to reminisce and write personalized versions of the affected individuals favorite song 3 to active adaptive music therapy sessions where the therapist plays an instrument and/or sings a song in response to the individuals heart and/or breath rate. 14 Throughout Leslie Bunt's book *Music Therapy: An Art Beyond Words* whistles which sound like birdsong appear always being linked to the feeling of freedom. 15 Music therapy techniques and methods greatly influenced the creation of *[Personal Nature]*.

Sonification Concrète

Applying Edgard Var se's concept of musique concr te to sonification Paul Vickers saw the need for a spectrum between concrete and abstract as well as scientific and artistic sonifications. 16 This created a space for a variety of scientific and artist sonifications within the same sphere allowing for a focus on listenability and aesthetics while still offering scientific material. John Neuhoff describes how evolution has affected our neurological and cognitive architecture making us exceptionally sensitive to real world sounds our brains process these sounds differently than erratic beeps and buzzes. 17 Often times we neglect how often we use our ears to measure. Think about boiling a teapot: listening to the level of the water as it reaches the top, the clicks and subsequent whoosh of the gas stove lighting, the groan as the boil begins and finally the whistle (or if you're like me the 'almost whistle'). By using real world sounds there is a chance to "tap into perceptual and 'meaning making' processes that cannot be accessed with sounds that are more artificial." 17, p. 80

Implementation

Data for this work was obtained through Thought Technology's Biofeedback system which includes non-invasive sensors for: heart pulse rate, breath rate, skin temperature

and galvanic skin response (GSR). I applied the sensors to my body gathering a baseline as well as emotionally stimulated (ouTube) data. This data was stored to a CSV file to be accessed in the prototype creation. *[Personal Nature]* is composed as follows:

Heart Rate – Birdsong/Children: Peaks in the heart rate data trigger a randomized clip of either birdsong or children playing/laughing. The greater the peaks distance from below zero (louder on the left side) and above zero (louder on the right side) this is to amplify the influx in the heart rate. Birdsongs are often considered auditory signifiers that all is well in the environment 8 , I believe that the sounds of playing children enhance this concept.

Breath Rate – Water: The breath rate controls the speed and volume of a looped audio recording of water gently lapping at the shore. As the breath quickens so does the pace of the water lapping at the shore which also becomes louder. Schafer is very explicit in his writings on the connection between waves and human breath 18 , one that I found pertinent for this project.

Skin Temperature – Wind: As the temperature rises and falls so does the volume and speed of looped recording of wind rustling leaves. A warm breeze or a cool wind can often affect our perception of temperature often bringing attention a change in weather.

GSR – Wind: Using a prebuilt open source wind generator the data from the GSR changes different aspects of the pitch and tone. The sound replicates wind as it moves past the ear. Similarly to skin temperature the moisture on our skin is often made apparent when a gusts of air flow over our bodies.

The system is built using Max 6 a visual node based programming platform. The values of the sensor data are highly manipulated as to scale them to useable values in the sonification process. This is a part of the amplification process as it is the fluctuation in values that are important not the specific numbers themselves.

Discussion

I am aware that this is an area of research full of ethical questions, ones that as an artist may require more scrutiny. I remain worried that some may question the artist's role in this sensitive situation that they might consider me all too hopeful. I understand that the patient may not have any response that it may not be interpreted clearly or *[Personal Nature]* may be more of a hindrance than help. et I feel compelled to try. For example take Thomas a child involved in the *biomusic* research at HB RH. His parent went from describing their interactions with him as this:

> "You're coming in [to the room] and you aren't really sure if they know that you're there (C2)" 1, p. 6

to then speak of him in this way:

> "It makes me feel like before [his disability] when he was very lively. It makes me think of the lively boy before. The sound represents his character… I would want to have it on. The sound keeps on it feels like my son still exists." 1, p. 6

It is this dramatic emotional shift that compels me.

My work process has changed drastically in the creation of *[Personal Nature]*. During different parts of this transdisciplinary project I have viewed it from many perspectives including artist, designer and technologist but also as patient, loved one and hospital staff. By employing different creative strategies I found that I was able to overcome many technical, psychological, theoretical and aesthetic issues.

This media calls for an artist's intervention, for artists' intervention. As someone who has spent countless hours confused at the side of a loved one I believe it is a media worth investigation. I believe I am able to help ease this disruption. I find inspiration and solace in the words of R. Murray Schafer: "The sense of hearing cannot be closed off at will. There are no earlids. When we go to sleep, our perception of sound is the last door to close and it is also the first to open when we awaken." 18, p. 11 *[Personal Nature]* may reach the person with IC and it may not either way it fills the silence 1 and could possibly complete the other side of a conversation for their loved ones at their side.

Conclusion and Future Work

This work aims not to heal in the traditional sense but to provide comfort and presence for often but not purposefully objectified persons, their caretakers and loved ones. As this is a media project the aim is to provide a means for communication no matter how minimal, a dialogue which offers a greater chance for connectedness. Considering Baumgarten's sensual aesthetics and the bodies reaction to human contact, the sensed beauty of a loved one speaking and touching us, exposed through the ANS. The automatic reaction invisible but now audibly represented though time. *[Personal Nature]* is really at the starting point at the moment. Currently sound is the major focus and offers a wide range of location options to replicate for instance beach or rainforest environments or even possibly replicating a home environment with all the hums of electronics and sounds of loved ones. However I see the chance for a full perceptualized experience. By this I mean I see room for visualization and haptic options. By doing this I believe there will be a more immersive experience allowing for an even deeper connection.

As sensor technology is continuing to mature and become more affordable I also see growth in mobile iterations of this project. By using Bluetooth and smartphone technology the options for gathering and interpreting data grow immensely. For example the current wearable sports and training technology is a market *[Personal Nature]* may add to among other novel possibilities.

Finally as an artist I see great potential for performative and installation iterations as well as the ability to explore a variety of emotions while recording the data. Being

able to create a space sonically, visually and haptically using such personal and raw expression excites me.

[Personal Nature] Example

A sample sonification can be found at this URL: https://soundcloud.com/davee d/personal-nature-examples

Author Biography

David Dowhaniuk is an artist, designer, technologist and theorist in the area of digital media. He has a Bachelor of Fine Arts from OCAD University and a Master of Science from the University of Bremen. Experimentation has always been a focus of his work, from the early year's double exposing film through the fast-paced visual effects industry to his current interest in patient/doctor communication and emotional aesthetics in the hospital. He draws much of his inspiration from spending time in nature often hiking, cycling. canoeing or tobogganing.

Abstract

The Pacific Northwest is a top region for innovators at the intersection of art and technology. This density of technology creatives – artists, programmers, technologists, designers, entrepreneurs – combined with the Pacific Northwest's uniquely community-oriented zeitgeist has had a meaningful impact on the local arts community, creating fertile ground for genres of interdisciplinary, technology-mediated art. In order to help foster this growing community of artists/technologists in pushing the bounds of what is possible in their work, we organized a workshop bringing together key stakeholders in the region. The workshop was structured as a focus group including a brief questionnaire to generate feedback for how to best support this community. The unique concerns and collective agenda of this interdisciplinary group are discussed as they would apply to broader contexts.

Keywords

Community development, community of practice, art and technology, new media art, focus group, interdisciplinary collaboration

Introduction

In the past decade, a growing, integrative genre of art has been taking root in the Pacific Northwest of the United States. In an area dominated by a thriving technology industry – including software giants such as Microsoft, Xbox, Amazon, and Adobe, and a very active startup culture – so too has the local arts culture become increasingly infused with technology as a medium for creative expression. These works often exceed the bounds of traditional exhibition spaces and thwart gallery space business models. Due to the affordances of the medium to sense people and respond, they also tend to be interactive and participatory with special space and maintenance requirements. Given the specialized skills typically required to implement these works, some of the most inspiring pieces tend to be interdisciplinary with hybrid collaborators including scientists, technologists, designers, and more traditional artists. Their interdisciplinary nature further points to the importance of developing a welcoming community of practice, where innovators may find each other, develop trust, collaborate, and through open sharing accelerate innovation.

Although there are a number of organizations and individuals practicing at this intersection of art, design, and technology in the Pacific Northwest, we see a need for more cross-organizational awareness and communication in order to nurture a thriving community of practice that works effectively together to achieve its goals. To help foster this growing community of artists and technologists, we organized a workshop bringing together key stakeholders in the region to map out the space, discuss a collective agenda as a community, and spark next steps for actively achieving these goals.

In this paper we:

1) Map out the community, defining its special characteristics.
2) Articulate and prioritize the community's common goals.
3) Propose a series of activities (e.g., knowledge sharing, events, and communication vehicles) as next steps toward fostering this and similar communities.

Definition & Historical Context

"Technology (from Greek τέχνη, techne, "art, skill, cunning of hand"; and -λογία, -logia[1]) refer to the collection of tools, including machinery, modifications, arrangements and procedures used by humans." — Wikipedia

Art and design are at the very root of technology. This paper is specifically looking at the forms of art that embrace the emerging technologies that open up new domains of artistic expression. Artists, designers and hybrid creatives that explore the immanent qualities of these many new technologies disrupt accepted conventions in order to forge a new language of creativity.

The exploration of modern technology for art has roots as early as the 1960's, when a group of avant-garde artists embarked on a series of collaborations with electrical engineers at Bell Telephone Laboratories (Bell Labs), known as Experiments in Art and Technology (E.A.T.). These performative experiments exploring emerging technologies for making art were considered the forerunners to current technological art collaborations.

"The 9 Evenings artists and engineers came from collaborative experimental subcultures with similar values and practices. These included open, egalitarian approaches to experimentation; discipline boundary-

crossing and respect for diversity; concern about technology as both a tool and a sociopolitical and cultural phenomenon; and a process-based approach to creative production influenced by new ideas that included cybernetics theory of man/machine communication systems." (Oppenheimer, 2013)

In the next wave of art/technology collaborations, technologists started actively developing creative tools in collaboration with artists. For example, Kenneth Knowlton, while at Bell Labs, wrote BEFLIX, a program developed for animation. More recently, Casey Reas and Ben Fry developed Processing, a programming language currently driving much of the computer-mediated visuals and data visualizations in the arts.

Concurrently, there was a rich precedence of art playing an important role in the technology innovation research process. Nam Jun Paik was interfering with electronics and pioneering video art and installations in the 1960's. The Xerox Palo Alto Research Center's Artist-in-Residence program (PAIR) was started in the early 1990's and continues to be an on-going research effort at Xerox Palo Alto Research Center. The program pairs artists and designers with research scientists and engineers who use similar media technology as a common language to push artistic and scientific innovation. More recently, the creation of the Internet provided another space for creative technological collaboration. Pioneers using the Internet include Roy Ascott's telematic art events linking artists and engineers around the world. Western Front, Vancouver and Pittsburgh's DAX group in the 1990s pioneered real-time global art events.

The range of artistic activity engaged with these distribution and experiential spaces transcend traditional artistic practices through the birth of new hybrid forms of technology creatives. Artist/programmer, designer/scientist, artist/filmmaker, social networker/artist, engineer/artist are hybrid creative identities that blur the boundaries between art and science and the ways in which art may be enmeshed within our culture. Mapping the community of current artistic collaborations between art and technology would include domains as diverse as social networking, bio systems, gaming, programming, film, media, apparel, mobile media, robotics, sound design, mediated performance, information science, data visualization, education, and government. Modern distribution opportunities continue to expand the impact of these works, including screen technologies (tablets, phones, computers, televisions, digital signage) and mass-produced objects.

Although we have observed a growing presence of these technology creatives in the Pacific Northwest, the question remains; who are the people and places that are engaged in this activity? How can the community be evolved in order to stimulate more activity and opportunity?

Why the Pacific Northwest

Seattle has long been heralded as *"the city the future"* (McGinn, 2012), and the Pacific Northwest has been at the center of the explosion of the new digital economy. Many of the technologies that drive the digital economy were developed in this area and have attracted technologists to the region from around the globe, including ecommerce and new media distributions such as Microsoft and Amazon. Due to this vibrant creative technology economy, in 2012 Seattle was rated #1 city for technology jobs by Forbes (Kotkin, 2012). Similarly, a report by Enterprise Seattle ranked the city as #6 in Interactive Media based on the concentration of those employed by the interactive games industry (Mefford, 2012).

"The Interactive Media industry is a high tech industry that blends art and technology for both entertainment and more serious or practical applications. The core of the industry is the development of digital content, driven by talented individuals with expertise in software and artistic development, including computer game enthusiasts." – Enterprise Seattle Interactive Media Industry Assessment, May 2012 (Prepared by CAI Community Attributes Inc., Commissioned by Enterprise Seattle)

As they further note, throughout their interviews, an important theme affecting growth in the Pacific Northwest is *"the quality of life and amenities that align with the Interactive Media workforce demographic."* (p. 31).

Alongside the commercial and industrial evolution of the region, there is a growing integrative genre of arts, design and technology.

"Today, Seattle's creative vitality is nearly three times the national average—among the highest in the nation. The arts not only inspire and fuel discovery – they improve our quality of life, create jobs, help attract and retain business, make our city a major destination for tourists and play an important role in the economic revitalization of our community." – Mike McGinn Arts and Economic Prosperity Report, 2012

In June of 2012, the Americans for the Arts, a national nonprofit arts advocacy group, released the most comprehensive economic impact study of the nonprofit arts and culture industry ever conducted in the United States (Arts and Economic Prosperity Report IV, 2012). According to their report Seattle has seen $447.6 million in annual economic activity from the nonprofit arts and culture industry, with 10,807 full-time equivalent jobs – almost three times that of similarly sized cities. As of January 2011, Seattle, WA is home to 4,571 arts-related businesses that employ 20,616 people. The confluence of thriving arts and technology communities in the Northwest has created a fertile ground for inspiring arts/tech collaborations.

A Community with an Innovation Culture

As we discuss how to foster a thriving community of practice at the intersection of art and technology, we may draw inspiration from past work (Wenger, 2000). To start, it has been well-established that conversation is the main activity

of any thriving community. While we need regulars to provide stability and historical knowledge, the conversation must be open and welcoming to all participants (Oldenburg, 1989). Members of an effective community can articulate their common goals, and the steps they are taking to accomplish them. In a thriving community people know each other and regularly interact with each other. We cannot emphasize enough the importance of helping people develop trusting relationships, where they have a feeling of identity and belonging toward the community and are willing to contribute time and energy toward these common goals. People develop these relationships not only through their collaborations, but also by having fun together.

As a community of practice, it is also important to develop a shared understanding of best practices within the field, and host repositories of knowledge and shared artefacts. When seeking to foster a culture of innovation, it is important to expect and reward change, to foster an openness to new ideas across social hierarchies, and to collaborate across organizations and disciplines (Bryant, 2014).

In organizing this workshop, we very much embraced these principles, seeking to include a diversity of voices, across roles and organizations. For example, in developing the workshop agenda and facilitating the workshop conversation, we welcomed the contributions and emerging leadership of any individual or organization in the space. We also sought to provide increased opportunities for conversation and to infuse that sense of play, by wrapping up the workshop with an art show.

Workshop

Broadly speaking, the goal of the workshop was to bring together diverse stakeholders in the ecosystem of the arts and technology worlds to discuss how to foster a community of innovators, increasing awareness, collaboration, and collective efficacy toward common goals. More specifically, the workshop agenda was to map out the space, identify core goals of the community, and develop concrete next steps toward fostering these goals. The workshop was structured as a four hour focus group including a) a brief questionnaire to generate individual feedback for how we should best support this community, b) introductions where participants described their own activities in the space and their own goals, c) breakout brainstorming discussions around emergent themes, and d) a discussion of concrete next steps. See Figure 1.

Workshop Participants

Participants were invited through two phases. We first generated a list of potential attendees known to the organizers who would reflect a diversity of roles and organizations in the community. In the process of inviting participants we asked whom else they believed should be attending. Names frequently mentioned or identified by community leaders were then invited in the second round of invitations.

Figure 1. The workshop was optimized for conversation.

41 people attended the workshop, 23 female, 18 male. Participants were asked to categorize themselves in the questionnaires in terms of what primary roles they play in the arts and technology community. Figure 2 below illustrates the breakdown of innovators (67%), educators (52%), advocates (50%), researchers (45%), organizers (30%), writers (30%) and curators (28%).

Figure 2. Participants represented a diversity of roles.

The term "innovator" was used to encompass artists and technologists who created new works. We further asked innovators to identify themselves according to following categories: artist, technologist, designer, maker, hacker or entrepreneur. Figure 3 shows the breakdown of innovators. It should be noted that many of the individuals in the room wore multiple hats, reflecting the interdisciplinary nature of the community even at the individual level – artists who were also entrepreneurs, hackers who were educators, and community organizers who were also designers.

> *"We had become interested in the process we were involved in, which was the meeting, marrying, and mating of artists and scientists that was a kind of coupling, some form of, hopefully, a synergistic new wrinkle in artistic thought and scientific thought. That they would repel each other, and attract each other in some strange*

dance, and we would get out of that the flowering, the explosion, the evolution of something for the future." (Steve Paxton, Open Score - 9 Evenings film by E.A.T., 1966/1997; from Oppenheimer, 2012)

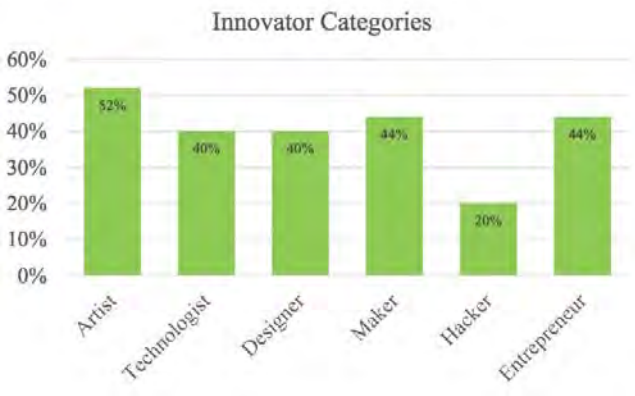

Figure 3. Attendees included many types of innovators.

Mapping the Community

A key goal of the workshop was to map out who were the organizations and people actively engaged at the intersection of art and technology. Through the process of generating the participant invitation list we first developed an initial list of categories, and then populated the list with prominent exemplars in each category. At the workshop, we asked our participants to further indicate those organizations, individuals, news sources, and so forth, that they keep track of or are most representative or influential in the arts/tech community.

Figure 4. Network map of workshop invitees, with their roles (orange), interests (blue), and organizations (green)

Across categories of educational groups, exhibitions spaces, maker spaces, companies, and social groups, we found there are few organizations devoted specifically to the arts and technology space. Rather, they tend to be only partially involved or have overlapping interests with the arts and technology space. For example, while exhibition spaces like the Henry Art Museum have art shows with technology-oriented art, not all of their exhibitions are focused on this area. The exception to this is in the maker spaces, which tend to be focused specifically on supporting technology as a creative medium. We similarly did not find that participants acquired information about activities at the intersection of art and technology from any one unified source.

When we asked participants to indicate how they kept up to date with information and events about the arts and technology community, they reported largely relying on social media and mailing lists. Few mentioned more traditional news sources. See Figure 5.

Facebook/Facebook Groups (9), group/organizational mailing list (8), Twitter (7), Wired(3), Internet(2), Rhizome(2), LinkedIn (1), email (1), ars electronica (1), NYTimes (1), Geekwire (1), The Verge(1), FastCompany(1), Skype (1), ITP (1), Omnivours (1), Leonardo(1), Word of Mouth (1), Stranger(1), Makerhaus(1), Zero1 (1), Blogs(1), Gizmodo(1), Engadget(1), Create Digital Music(1), Meetup(1).

Figure 5. How people keep up-to-date.

We asked the innovators a few questions to test our assumptions about the nature of their work. When we asked how they used technology as a creative medium, there were a wide variety of responses, with programming, physical computing, design, and rich media being the most prominent categories. See Figure 6.

Programming (10), Microcontrollers/Arduino(3), electronics(3), graphic design(3), fabrication (2), dance(2), Kinect(1), computer science (1), 3D imaging, digital mapping (1), response technology (1), math(1), logic(1), code(1), sensors(1), cameras(1), rapid prototyping tools(1), film(2), choreography(1) lighting(1), sound/music (1), Photo/video editing(1), metal work(1), word working(1), processing(1), openFrameworks(1), social media(1), CAD digital fabrication(1), visualization(1), web/app(1), Robotics(1).

Figure 6. Uses of technology as a creative medium.

We observed a dichotomy in how the innovators employed technology in their art. Many perceived their use of technology simply as a tool or means to an end.

> *"I use technology full stop. It is the set of tools I use to do what I do, it is the means not the end."*
> *"I use digital tech in my artwork whenever I need it to achieve my goals, for interactivity...also use those tools in creation of animation"*

Whereas for others, technology was an important theme integrated into their work.

> *"I use technology to enhance the way humans sense the world and to explore the intersection of the physical and digital worlds"*
> *"[technology is] "Instrinsic to the platform of the art"*

As expected, the majority (56%) of innovators reported all of their projects were collaborative, with another 38% reporting they had both solitary and collaborative projects. Only one person reported that her creative projects were only solitary. Collaborative projects ranged in size from 2 to 50 collaborators, with most being in the 3-5 person range. We also found that when people reported their projects were collaborative, they often sought out people with different skills as collaborators. Many of these cross-disciplinary collaborations combined technological skills such as programming or CAD fabrication, with more traditional artistic skills such as dance or design.

In terms of work spaces, people reported using a mix of their own studios, maker spaces, work sites, and online spaces.

> *"living room, backyard, café, bars, labs, maker spaces, Cornish residency"*

When seeking to learn skills, people reported a mix of a) finding information online, through search, Wikipedia, Youtube tutorials, and technology forums, b) through local universities, c) through the maker spaces, and d) by seeking people in their personal networks who have the desired knowledge and skill.

As illustrated by these survey responses, the innovators in this community actively used technology as a creative medium, sought out cross-disciplinary collaborators as a part of their work, worked together through a mix of personal and shared spaces, and engaged with ongoing learning around specialized skills through online resources, educational resources, and their personal networks.

Collective Goals

Perhaps the most important agenda for the workshop was to articulate the shared collective goals of this community of people at the intersection of art and technology. As organizers we had developed a preliminary list to inspire discussion, but also asked participants to describe their own agenda and what they hoped we might achieve. To start the conversation, we asked participants in our survey to rate the importance of possible goals.

As can be seen from Figure 8, most of the goals were rated fairly highly, with more diversity in perspectives, across gender, race, and socio-economic status, being rated the most highly. Following this, the desire for more exhibition spaces, increased educational opportunities, an improved sense of community and social support, fundraising opportunities, access to collaboration spaces, access to specialized tools and machinery, and better promotion of arts/tech related activities were all rated as equally important. Less important were networking events, an online directory of artists, or better collaboration tools.

In the second phase of the workshop, we reviewed people's introductions and their stated interests, and then we broke apart into four discussion groups around the four most prominent themes in the discussion: diversity, education, bridging communities, and the underlying philosophical perspective of technology as a medium of art. Further discussion of these and other emergent themes are below.

More Diversity

Given the specialized skills, educational resources, and funds required for works using technology as a creative medium, the population of those active in this space tends to be higher in socio-economic status. Furthermore, given the gender discrepancy of those in the technology industry, it also trends towards being more male. For those at the workshop, this was a great cause for concern. One element of low diversity is the perception in disadvantaged groups that this genre of art may not be for them, and a key issue is how to increase individual agency to leverage the resources available. In the discussion, attendees suggest a number of approaches to increasing the community's diversity, including a) mentorship programs between novices

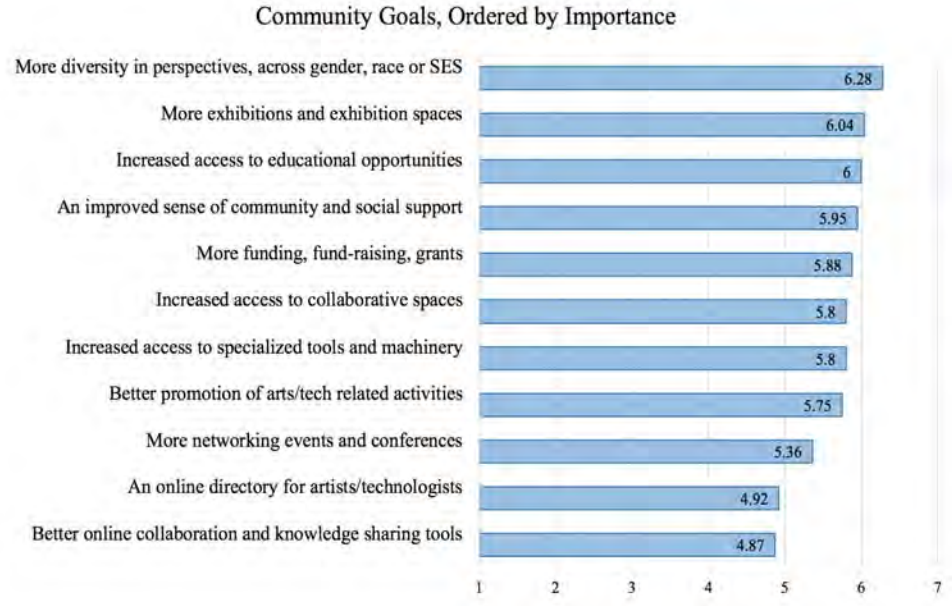

Figure 8. Average ratings of community goals

and experts, b) a sharing platform for sharing resources, c) educational programs such as ArtsCare and ReelGrrls, and d) increasing the prominence of role models in news and social media.

More Exhibition Space

> *"Consistent exhibition opportunities that are healthy in traffic online and in real time".*

Although the Pacific Northwest has a thriving technology industry, there are no dedicated places for exhibition of works at the intersection of art and technology. Participants agreed there is a potentially vast, virtually untapped market of patrons and buyers for interdisciplinary tech and art that needs to be engaged if we hope to finance growth in this field. The biggest issue with those spaces seemed to be a lack of sustainability. It is a major cost to our city if creative entrepreneurs spend years and thousands if not millions of dollars on under-supported ventures. So, as we look to encourage local artists we must also look to those space makers to learn from their experiences and improve access to financial supporters, community resources, and possibly more adaptive business models.

Workshop artists also expressed that they wanted accessible space that comes well-promoted to an audience who will show up and interact with the work, plus a robust online platform to share the work beyond our local market. One unique aspect of the technological art space is that it must extend gracefully into the ether. As such, ideal spaces need to be connected, and relevant to a wider audience.

Increased Access to Education and Makerspaces

> *"Education, diversity, and access are the biggest holes. Most of this has to do with affordability, and perhaps cultural exclusivity."*
> *"Education: more context for teaching/mentoring youth by art/tech professionals."*

Access to life-long educational opportunities emerged as important due to the ongoing need to maintain and learn new skills as new technologies evolve. There are many educational opportunities in the Pacific Northwest that include traditional educational institutions, online tutorials and courses, Meetups, conferences and events, as well other networking opportunities. Groups such as Dorkbot and the Seattle Robotics Society are largely structured around providing peer learning opportunities. That said, in the past decade makerspaces or hackerspaces have emerged as important community centers, with tools for turning data into 2D and 3D objects. They provide valuable resources for artists, designers, engineers and educators, including life-long learning opportunities. Educational institutions that do not have adequate funding or resources can use these types of public technology spaces to enhance and facilitate technology-focused art programs. Students can develop concepts and final designs in a classroom setting and cost effectively outsource the production. This coordination between institutional education and non-institutional production is becoming a model of technology education in the future.

Access to free or inexpensive education is also important because differential access to education decreases the diversity of the community. Although we are increasingly in a world where people may learn many new skills online – particularly skills around technology – many are not aware of said opportunities or do not feel empowered to seek them out. The success of maker spaces further illustrate the limitations of online learning, given the importance of hands-on access to specialized machinery and related skills training. Independent artists and designers often cobble together various combinations of resources to produce their projects. Complex projects may involve several types of expertise from quite different disciplines, and embedding projects in shared makerspaces provides serendipitous access to such cross-disciplinary knowledge.

Social Impact

An important emergent theme of the workshop was how should we use art as a tool for social impact – that is, not just as a vehicle for aesthetics and communication, but also for helping the world be a better place. To the extent that art can be perceived as shaping the nature of cultural conversations, how can it be used to impact culture, particularly given the affordances of technology-mediated art to reach broader audiences. This issue is related to that of diversity, in that if technology is being used as a means for artists to have a voice in shaping cultural change, it is important that a diversity of voices be participating in that conversation.

Bridging Communities

> *"Better bridging/defining of what is art to tech community"*

As illustrated by the number of groups and individuals engaged in this space, in one sense the Pacific Northwest already has a thriving arts and technology community. That said, there is no clear name for the community, no clear home or hub online, no one central place for people to convene, and no one communication channel for them to subscribe to. Because the community is inherently interdisciplinary, there will always remain the need for different organizations and individuals to support the specialized concerns of their constituents. For example, the Seattle Robotics Society and DXARTS at the University of Washington, while having some overlap in their missions and their people, also serve very distinct purposes. Consequently, an important theme that emerged from the workshop is the need to adopt more of a coalition model as we consider how to foster a growing interdisciplinary community – that is, we should work to build bridges across diverse communities around the common interest of innovating at the intersection of art and technology, rather than trying to

merge them. One such coalition approach, for example, might be to work together to host an event specifically designed to connect people from different disciplines or groups. Similarly, we might work together to more effectively help people find collaborators through online tools.

> *"Art and technology hackathon, w/peer mentoring, matching artists with engineer/ designer".*
> *"An easier way to discover compatible individuals and new projects/technologies".*

Financing Technology-based Art

> *"We have an Arts Incubation series for helping to generate new ideas but are very limited in terms of our digital technologies resources. So the best would be funding access to technology for artists to experiment."*
> *"A critical understanding of how to develop, market, and commerce relate to art based on technology".*

Traditional business models for gallery art do not easily apply to technology-based art. That is, consumers of such art are rarely in the position to purchase it for personal display at home, either because it would be too expensive considering the cost of actually implementing it, the art is too large, it is too ephemeral, or it is not sufficiently tangible. Given the high wage to be earned in the technology industry by those with specialized technology skills, few technology artists actually make a living from their art, but rather use their work wages to personally fund their art. Thus, when asking our workshop participants what resources they needed to reach their full potential in their creative projects "more time" was frequently mentioned.

Philosophical Substrate and Critical Voice

> *"Dedicated art/tech critic in the city".*
> *"The role of art as a form of research/interrogation as it relates to envisioning technology and how we understand our lives, and the ways in which we (as a community) can work together to intensify and externalize the A/T conversation, helping it feel relevant and accessible to no-traditional/non-"art" audiences."*

Whether technology is perceived as simply a tool for creative expression, or as an object of the conversation itself, the issue of how this community stands relative to other genres of art is an important one. It is only through a shared understanding of technology-based art as a genre that we may also develop a critical voice for identifying and promoting standards of excellence in the domain. However, while the term "technology-based art" brings to mind specific creative tools and artefacts such as programming languages, digital media, and electronics – the word technology itself is somewhat conflated with the meaning of word art. As noted by participants in the workshop, the meaning of the word technology is rooted in the greek word, tekhnologia merging art and skill.

> *"Technology, like art, is a soaring exercise of the human imagination. Art is the aesthetic ordering of experience to express meanings in symbolic terms, and the reordering of nature—the qualities of space and time—in new perceptual and material form. Art is an end in itself; its values are intrinsic. Technology is the instrumental ordering of human experience within a logic of efficient means, and the direction of nature to use its powers for material gain. But art and technology are not separate realms walled off from each other. Art employs techne, but for its own ends. Techne, too, is a form of art that bridges culture and social structure, and in the process reshapes both." -- Daniel Bell, "Technology, Nature, and Society," The Winding Passage, Abt Books (1980).*

How then, do we best argue that technology is a medium of art, a category in its own right equivalent to "visual art", "theatre", or "dance", or "music", which as a discipline should evolve its own best practices, and develop its own critical voice for excellence? Moreover, how can we blur the lines between technological envisioning and art (which relies heavily on design and other activities leveraging creative voice), in order to illuminate alternative, generative pathways for the creation of the technologies that will shape our lives in the future. Essentially, how can we embed artists into the technology process as an important means of discovery and innovation.

Next Steps: Community Building Activities

Having mapped the space and community goals, the next step for the workshop was to discuss concrete next steps toward achieving these goals, which fell into three main categories: documentation, communication, and events. In line with the "coalition model", we believe different people and organizations must take leadership, no one organization can complete the whole list of activities.

Documentation and Sharing

How do we develop a central repository for documenting who's who (organizations, projects, and people), best practices, knowledge sharing, digital assets, and so forth? The obvious solution to this is some form of website and/or social graph, but who should host this web site, and who would fund it? These questions require further conversation, however in the short term, we decided to create this summary report to share lessons learned, and have started exploring developing a social graph including individuals and organizations in this community.

Communication and Collaboration Channels

As discussed earlier, a primary requirement of any thriving community is an ongoing communication channel. To fa-

cilitate ongoing conversation and community updates, it is important to leverage existing communication channels, such as mailing lists, Twitter, and Facebook. For example, to help us more easily find each other on Twitter, we decided upon the"#ArtsTechNW" hashtag and created a related @artstechnw account.

Community Building Events

Events undoubtedly have a substantial impact in fostering a thriving community. The best mix includes a large number of intimate opportunities for individuals with specific commonalities to convene, with a few larger shows and parties to bring together the wider communities. In addition to producing our own events, however, it is most important to suffuse larger culture-building events with the thinkers and artists who represent the community and to assist in the promotion and attendance of those instances. One project we considered undertaking as a community would be to increase the technology/ interdisciplinary art presence at relevant local festivals and as programming at a range of venues. A consortium of art and technology organizations could coordinate speakers and shows featuring local innovators and visiting luminaries by noticing opportunities that already exist in our market. This kind of integration helps us build bridges into the larger cultural landscape while providing a new audience and potential resource pool to our members.

Another approach to is use regular meetups as a platform for investigating collaboration and experimentation in the arts, technology and design. For example, as a followup to our workshop, a group called ArtsTechSea will be organizing educational programs and social/networking events for individuals working at the intersection of art and tech to share ideas, strategies, successes, challenges and failures.

Coalition

Seattle has a strong creative community. However, in order to truly maximize the individual contributions of institutions, organizations, creative professionals, makerspaces, non-profits and individual agents-provocateurs, and take their work to the next level, the need for an interdisciplinary art and technology coalition arises. Through a coalition members from diverse groups and backgrounds may meet at regular intervals to share their work, calendar, methodologies and visions, with the ultimate goal of creating cross-institutional, cross-community work that leverages and expands on current assets towards the creation of a truly vibrant, globally relevant, creative culture.

Synthesis

In organizing the workshop, our goal was to bring people together to map out the community, clarify common goals, and initiate concrete next steps toward achieving these goals. Coming out of the workshop, we found our goals had broadened considerably relative to going in. Given the excitement of the people in the room and the expressed need for this community to grow, we elevated the conversation in how we define innovation to take leadership in community building and risk taking. As suggested by one of our participants, we decided to embrace *"Let's be dangerous thinkers"* as the motto. Creating an environment for interdisciplinary arts and technology collaboration requires special efforts in community organizing, including creating tools for knowledge repositories, leveraging social media, and organizing cross-organizational events. By sharing lessons learned we hope to support other community organizers with similar ambitions.

Acknowledgements

Thanks to our workshop participants and to Cornish College for the Arts for hosting the workshop.

Smash the Black Box – designing for creative mobile machinery

Anja Venter

Center in ICT4D, University of Cape Town
Cape Town, South Africa
anjaventer@gmail.com

Abstract

With the rise of the 'visual web' the visual design capabilities on feature- and smartphones are increasingly expanding. We investigate how young resource-constrained people in Cape Town, South Africa are using the free tools on their mobile phones to make instrumental visual designs. We suggest that an alternative space for production of, and learning about, electronic arts and design is offered by ubiquitous mobile phones among this group. We offer a discussion of this repertoire of tools in relation to 'professional' design software, such as Adobe Creative Suite - describing the need for software that blurs the distinctions between professional desktop tools and casual mobile tools. We relate experiences from the participatory design and development of an open-source design tool for mobile in response to such a need, and find that many of these design processes are, in turn, hampered by limited developer libraries for visual design on Android. We posit that, in order to promote cultural diversity within the public domain, and in mobile-centric young people's lived realities, it is becoming increasingly necessary to expand and democratize visual design tools for the mobile ecology, in order to explore local design needs and visual vernaculars.

Visual Design, smart phone, South Africa, mobile creativity, resource-constraints, DIY

Introduction

> *Computing is a structural enterprise, but we are not structural creatures. How do any of us create lives, our own rich lives, in the constant presence of the reductionist properties of the computer? In this sense, computation is a colonization that we all face.* [1]

Mobile phones have often been hailed as the device that will connect Africa to the global information economy. [2] Yet, they are currently predominantly described as a means to consume information, and not produce it. [3] Diverse and inclusive participation in the cultural production of visual online content, as with other cultural production, is crucial in promoting cultural diversity in an increasingly globalized world. [4] As smartphones are becoming affordable to a larger portion of the South African population, this might signal an increase in such visual cultural production – allowing a new generation of visual creatives a platform for networked artistic expression and instrumental visual design, a ticket to participation on the 'visual web'.

The creative capabilities of the average smart phone or tablet user to produce electronic arts have recently exploded: app markets are brimming with new tools that enable the production of visual creations. These 'consumer' tools exist within a certain genre of 'casual' mobile creativity, restricting the user in its use – often imposing a certain style or workflow. I discuss a case study that investigates the media ecologies of a group of aspiring designers who operate within this mobile-first paradigm. Many have hacked these informal tools to produce instrumental designs. However, the institutions where they are studying Extended Curriculum Programs in Visual Design do not expand on these 'mobile-first' [5] visual design literacies. These institutions, like the majority of design schools, promote the industry standard packages of desktop design software, namely the Adobe Creative Suite. Although Adobe has adapted many of their packages to function well on mobile devices, these are intended as "companion apps" to the primary desktop design environment, excluding many resource-constrained young people who are mobile-primary users from using these tools to their full capabilities.

Unpacking these issues, we introduce the context and method of our study by first offering a representative narrative based on the lived experience of a participant. Thereafter, we situate the need for the expansion of design capabilities on mobile phones towards fostering a more inclusive creative landscape, by giving a short overview of Cape Town's design industry as culturally non-representative. We then describe the establishment of Extended Curriculum Programs (ECPs) for visual design as contributing to growing the design industry, but due to capacity, only being partially successful in combating this hegemonic order.

Looking at mobile phone creativity, we offer a discussion that seeks to differentiate 'casual' creative tools, from 'legitimate' creative tools, as positioned by gatekeepers at these institutions. In response to this view of mobile tools as low-brow design tools, we discuss the development of *Molio: the mobile portfolio,* a creative app that attempts to blur these distinctions within the limiting affordances of the mobile phone. The app was ultimately deemed a failure, and was severely hampered by the embedded aesthetics of existing developer libraries for mobile design tools.

We argue that these developer buildings blocks can make it increasingly difficult for artists and designers to "open the black box" – as Bruno Latour would have described the "need to examine the practices whereby technologies and 'facts' are naturalized" [6] – on the tools that facilitate their creativity. In other words, students cannot see the inner workings or logic of creative tools beyond the mediated interfaces as authored by others – their creative tools are "black-boxed". This naturalization of pre-packaged digital arts tools can limit innovation and alternative modes of image making, and ultimately threaten to colonize the shape and nature of electronic visual creativity by imposing a globalized design vernacular. [7] Resisting the agencies and structures that perpetuate this, we posit that, it is not only necessary to disrupt the colonization of digital tools for visual creation, but also to "smash the black box" and allow for the cultivation of young creatives who can build their own creative digital tools, particularly on and for mobile.

Context

Akhona flips through the photographs on his Samsung Galaxy S III, a special gift from his grandmother on the eve of his first day at the University. He is the first of his family to attend a University, and she was very proud. Perched on his bed, hunched over the phone, he scrutinizes each image carefully. The photographs are mostly of his illustrations, 3 years' worth. He has to decide which picture he wants to use in a composition for his ad: he wants to advertise his services as a portraitist among his peers on Facebook. He desperately needs the extra money for materials; otherwise he might as well not bother with going to class at all. The lecturer gave him a final warning: he has to use gouache; he's not allowed to use the cheap powder paints he's been using as a substitute in class. He really hoped she wouldn't notice, but she did. He can't afford gouache at the moment, but he also can't afford another embarrassing moment like that.

The photos document three years of illustrations andrecent school projects. He laughs at an old portrait he did about a year ago – that was before he knew anything about drawing: the eyes look bewildered; the strokes are awkward and too carefully executed. Without a high school introduction to drawing and the arts, it was difficult to adjust, and he very nearly failed the June exams. For those first few months, he spent every moment he could on the computers next to their studio at the University, researching. Even those were hard to get used to – they didn't have any computers at his high school. He practically only ever accessed the Internet from his phone back then. Whenever he didn't know what the lecturers were talking about, he would run and Google it – there was lots to become acquainted with in this new world.

He lands on a photograph of a friend from class, Neo. She has long braids that are hanging over her face and wears a shirt designed by another friend of his, Sabelo. Sabelo has his own clothing brand called "Kasi-stylez" – 'Kasi' means 'the hood': the township. The graphic is of a breakdancer mid-spin, but he is clothed in traditional beaded Xhosa attire. Akhona breaks out his pencils and his drawing pad, for the next hour he whips his gaze between the small screen balanced on his left knee and a piece of white paper, fastened to a wooden clipboard pressed down on his other knee, carefully observing the lines so that he can copy them. Pausing occasionally to sharpen his pencil, he ponders the possibility of fitting a tiny desk in the already cramped three-people-per-room shack. When he finishes he switches the phone to camera, and takes a picture of his drawing. He opens the image in an app called PicsArt, pushes the contrast, ups the brightness, so you can't see the shadows on the paper. He crops the image slightly, so the composition is stronger. He uses his fingers to zoom in and then meticulously paints the word "AkhonArt", his latest design moniker, at the top. He saves it out, and Whatsapp's a copy to both Neo and Sabelo – they would appreciate it. Sabelo might even feature it on his brand's Facebook page. He closes the app, and opens another one called Studio Design, imports his picture. He adds text and social media icons to make it look 'legit' – "custom portaits between R50 – R300 ($4 - $25)*", "contact Akhona" – and lists his number next to the Whatsapp icon and his BBM (BlackBerry Messenger) pin next to the BBM icon. This takes a while: the app keeps crashing. He downloaded both icons from Google images to make the ad look more legit: hopefully that venture didn't eat too much data. He then taps the share button, selects Facebook, and sends – he silently prays he still has enough data left on his bundle to upload the image, but is relieved when the image appears on his timeline. He thinks for a moment, and then opens Whatsapp – he hates broadcast messages when other people send it, but this is an emergency – he broadcasts the image to a select group called "Frendz". Luckily he can Whatsapp for free with his service provider. He looks at his design again – if only he could be as quick in Photoshop already…*

Akhona is a 20-year-old aspiring graphic designer from the township of Gugulethu – he is a participant in my research project that revolves around young aspiring visual designers, enrolled in Extended Curriculum Programmes (ECPs) for Visual Design. Through a Participatory Action Research method, I have followed the trajectories of 60 students across two such courses, for little over a year. I have utilized ethnographic methods (including participant observation and in-depth interviews with 33 of the participants) three iterations of Participatory Design workshops (Figure 1), as well as two user-testing sessions to collect my data. I obtained formal ethical clearance and participants provided written consent on condition that all personal information would be presented anonymously.

These participants come from a variety of backgrounds, but a large portion hail from low-income, low-resourced

neighborhoods; have often had negligible exposure to the formal skills associated with visual arts prior to applying for these courses; and, for the majority of their lives, have accessed the web directly from their feature- or smart-phones.

Figure 1 Akhona demonstrates his method at a participatory design workshop, 8 September 2014

Akhona is a typical South African young person: his grandmother, their sole caretaker, earns around R2600 ($222) a month, working as a domestic worker for a family in one of the wealthier suburbs. This is slightly above the average median income for a single-income Black household which stands at R2 167 ($185) per month according to the most recently available statistics. [8] He went to school at an inner-city township-serving school where he wasn't able to take Information Technologies, nor Visual Arts, as school-leaving subjects – putting him among the 99% of secondary school-going children in South Africa who do not have formal exposure to these literacies and skills at school. [9]

South Africa celebrated 20 years of democracy in the year 2014, sharing a birthday with Akhona. Prior to this, the country had in place a system of *Apartheid*: legislation and reinforcement that curtailed the rights, associations and movements of the majority Black (under apartheid, Black people were broadly termed "non-white" and specifically classified as either 'black', 'coloured' or 'indian') inhabitants of South Africa. [10] In effect, this meant that racial groups were segregated in public spaces, education, medical care, and most all other aspects of everyday life. [11] During this time, the artistic and creative voices of the Black majority were systemically suppressed, manifested in a lack of arts education at school level and limited support for Black artists. [9,12]

The City of Cape Town, located at the most Southern tip of the African continent – the first point of colonization in South Africa – remains one of the most economically unequal cities in the country today. [11] Geographically, the city is still divided in racially, and economically segregated districts, despite the promise of integration that democracy held. In the Central Business District (CBD) lives the wealthy elite of whom the majority is White, and along the periphery of the city, in slums and government housing called "townships", live the Black working class.

World Design Capital For a Few

For the year 2014, the City of Cape Town was declared the *World Design Capital,* a title previously held by cities such as Helsinki and Seoul. According to the official press release, the *World Design Capital* is a "distinction awarded to cities which recognize design as a tool for social, cultural and economic development". [13] This precarious title has been met with skepticism from critics and activists throughout the year 2014, with one such critic bitingly writing: "Cape Town is a pretty city. It is also a city using art and design as a means of bullshitting its way through its social and racial inequality". [14] Many have had similar issues with what they perceive as a cultural and artistic palimpsest – ignoring the blaring absence of diversity in the Design industry, a "symbolic battlefield" reflecting an unequally designed social system. [15]

In a case study that perfectly demonstrates this "battlefield", art-activist group *Tokolos* defaced a Rayban-sponsored 'homage' to Nelson Mandela titled "Perceiving Freedom" [16] which was installed as an official World Design Capital event. The piece was a giant pair of steel Rayban spectacles resting on the Sea Point (a sea-front suburb on the Atlantic seaboard) promenade, framing the far-away view of Robben Island. Robben Island is where the late statesman spent 27 years of his life, incarcerated by the Apartheid government, for his involvement in the Freedom Struggle. *Tokolos* called the piece "myopic" – criticizing the artwork's representation of "freedom" as shortsighted – a commodity to be consumed. Their critique bit into Elion and Ray-ban's co-opting of the Mandela legacy, further drawing attention to the fact that this piece (like the majority of public artworks in the city) was produced by a White male artist. [17]

This controversy touches on the conflict between the social and political role of design as democratic, sustainable and transformational with the profit-driven cosmopolitan notions of visual design and art as distinct leisure activities of the upper classes. [18] Ideological conflicts in the matter of public art in general, and related to the World Design Capital in particular, has drawn a great deal of attention to the limited number of Black African voices in the creative fields – a direct result of a schooling system that neglects the creative and technical literacies and skills that are necessary for a tertiary education in visual design [12] beyond the basic introductions to often-stereotyped traditional 'cultural crafts'.

In *Arts Under Pressure* political scientist Joost Smiers draws attention to the importance of diversifying the perceived modes of legitimate creativity, naming cultural diversity in the arts as one of the pillars of a democratic society – "A characteristic of democracy is that many different voices can be heard and many different opinions expressed. The public domain in any democratic society is the mental and physical space in which the exchange of ideas and an open debate about all sorts of questions can take place without interference from state agents, who may

have their own agenda, or from commercial forces whose only purpose is to sell as much as they can." [4]
The ad-hoc creativity of young people like Akhona and his peers start revealing an alternative creative space - providing "novel means for civic engagement, bringing new voices into public debate" [6] through personal expression and visual creativity.

These specific young people have gained access to the courses that could potentially allow them passage into the exclusive inner circles of art and design; this in itself makes them exceptional. Yet such case studies allow us a means to re-evaluate the institutional training of these designers and the naturalization of their suggested tools.

The South African Mobile-First Generation

Although the South African Design industry places importance on formal degrees and accreditation, when we look elsewhere in the world these institutions of learning are being decentralized to online communities of practice and genres of participation. [6,19,20] They allow young people who have frequent online access, and access to communication technologies, to explore digital creativity in a casual capacity. To many of these young people, these creative activities offer a "first touch" [21] or introduction to instrumental (in other words, towards a productive or profitable goal) visual design, and possibly a means to leverage these literacies and familiarities into formal education. Customizing a WordPress blog can spark an interest in web design, Instagram can be a springboard into photography, and character customization in a free online game can cultivate an interest in digital game design or animation. For others, this informal skill development can offer a "Hackademia" allowing them a means to be functional, if not accredited, designers. [22]

In South Africa, the majority of young people access the Web from their mobile phones. [23,24] Few have frequent access to computers or stable Internet connections. But with increasingly quick and affordable online access from ever-cheapening smartphones, these young people are finding ways to participate in digital cultural production. [9] Kids like Akhona have made do with the technologies and resources at their disposal to familiarize themselves with these creative industries. They have also, often with great difficulty, managed to navigate the difficult application process and financial strain of formally obtaining a degree.

Extended Curriculum Programs: Gatekeepers addressing the Bottleneck

Akhona, like the other 60 participants in my research project, was enrolled in Foundation courses for Visual Design. These courses have appended a pre-first year to bring inexperienced and untrained young creatives up to speed with the formal skills deemed necessary to continue with the standard 3-year design course: serving both a diagnostic and remedial purpose. These courses are government-initiated and -funded, and specifically designed to offset the disadvantages of young people who have had negligible exposure to the skills and literacies that would allow for success in tertiary Visual Design education.

These programs have been met with varying degrees of success, despite compassionate course conveners who constantly work to evolve programs. At one of the field sites for this research, for example, the pass rate for 2013 was 10% - course conveners identified an external selection process as the main contributor to this staggeringly low pass rate.

In addition, students struggle with fees, transport, language of instruction, the foreign social and cultural environment, and gaining access to the epistemologies of their chosen programs. [25]

Hegemony in Visual Design Education

In the global North, studies conducted by researchers such as James Gee [26] and Brian Street [27] have suggested that academic success is to some extent related to enculturation earlier in students' lives – which in turn has direct connections to race and class identities, suggesting that "the university privileged some cultural ways of being and knowing over others". [25]

Within the Design courses I observed (which varied between the traditional visual design fields of Graphic Design, Industrial Design, Surface Design and Fashion Design), for example, the formal design principles as set out during the formation of the Bauhaus are taught and hailed as the benchmark for good, clean design. Theorists such as Victor Papanek took issue with this widespread Bauhaus-first influence over Design sensibilities in education. [28] For Papanek, the design student was a person with a unique set of skills and knowledge, which came from their situated lived experiences. Each design student would therefore be able to bring unique expertise toward designing solutions for their own local environment based on this situated and personal wealth of knowledge – formal education needed to compliment and naturally expand on what the student already knew. By assimilating all designers into an international school of design thought, or globalized parameters of legitimate design, we would be negating these valuable localized insights, dismissing unique cultural design vernaculars [28] and tools – reinforcing a hegemonic order for visual design where Northern tastes and aesthetics are seen as the ideal.

Figure 2 various examples of participants' mobile-produced and distributed content (c)

Very few ECP students complete the 4-year degree, and find work following their studies, indicating that these courses are only partially successful in allowing more young people access to the 'spaces of appearance' – as Hannah Arendt would have described "reality [as it] can be witnessed and its value judged by a 'plurality' of individuals who exchange the role of actor and spectator with each other" [29] – in design industry today. We suggest that an alternative space for production of, and learning about, electronic arts and design is offered by ubiquitous mobile phones among this group.

Casual versus Legitimate Design Tools

Although Akhona and his classmates are actively engaged in an emerging mobile-centric creativity, these modes of creativity are not recognized as legitimate forms of design. This dismissal is three-fold: firstly, with limits in processing power, mobile phones offer far less rendering "muscle" than their desktop counterparts. Secondly, the mobile platform is often seen as an accompaniment or an extension of the desktop environment in an ever-increasing convergence of computational technologies, not something that should be designed for, or on, as standalone platform; and thirdly, these tools are 'casual' by nature and do not contain the kind of customizability and uninhibited open creativity offered by material tools (such as pencils, paints and inks) and industry-standard design software such as Adobe PhotoShop or Illustrator.

PhotoShop and Illustrator offer maximum customizability, from canvass sizes and resolution, to which tools the user would like at hand at any given moment, and individual settings for each tool. For example, new brushes can be created, assigned properties and saved out for future use. Layers can be created, deleted, shuffled around, assigned effects, opacity, and assigned styles. Colour swatches can be picked from any image and saved out into a palette that can be named, additionally providing the user with the exact colour profile in a variety of industry mark-ups. Patterns can be created, defined and added to the library. Most aspects in the interface offer the user a way to edit, create, define, and save out their own personalized creative assets. These can then be saved out in working files, and any project can be picked up with the full scope of adjustments at a later stage. In addition, these programs have large online communities who provide each other with textures, fonts, brushes, elements and tutorials for sale or free download.

Mobile tools are usually intended as a means to publish on mobile, with few giving the user control over canvass size, resolution, or settings for print. Few offer the user access to the working files for later additions or editing. Creative tools for mobile are often connected with very specific brands with particular aesthetics – colours, filters, typefaces, shapes and elements are limited within each application. These are usually connected to a social network, where users rate these images within the paradigms provided by the brand. Some of these offer libraries (fonts, textures, frames, 'stickers', colour palettes, etc) that can be updated through the applications' official store, but these are all brand-sanctioned, and not user generated.

Studio Design, for example, offers a selected variety of typographic styles that are minimally customisable – rendering most photographs overlayed with these to look similar. *MyPicStory* gives users a variety of frames to place their photographs in, and although there are often new frames for download, this gives young creative people very little freedom in customizing or creating their own frames beyond editable phrases.

Furthermore, these tools are often separated into distinct categories – photographic apps (abundant), drawing apps (less so) and vector drawing or design apps (scarce). These separations can and do often dictate to the user what the purpose of the creative artifact should be – a photo app creates a decorated photo, a drawing app allows for finger painting, a vector app allows for quick sketches and trac-

ing. A stark contrast to the kind of unbridled creativity offered by desktop programs.

Molio – the Mobile Portfolio

The ubiquity of mobile phones in South Africa, along with their increasingly sophisticated capabilities and rapidly dropping prices, make them the ideal digital creative tool for young people who do not have access to the traditional tools for visual creativity, nor the opportunity to formally study visual design. *Molio* was conceptualized as a design project that would allow for sophisticated design capabilities within the parameters of constraints offered by the mobile platform, disrupting the notion of mobile phone as an exclusively 'casual' or 'accompaniment' tool.

Iketsetse – DIY in a mobile-first creative ecology

In order to start conceptualizing *Molio* we first explored the existing creativity that was happening on mobile phones through in-depth interviews and two preliminary mobile-making participatory design workshops.

We found that users, in this mobile-first ecology, were equipped with a toolbox consisting of mobile camera, physical materials (such as felt-tip markers, pencils and paper), design apps (including *MxPix, MyPicStory, Instagram, PicMix, Studio Design, Pixlr Express, VSCO Cam*, and *Android Photo Editor*, to name a few) and social networking apps (*Facebook, Whatsapp* and *Mxit*), and produced a wide range of visual artefacts (Figure 2) for a variety of purposes.

These ranged from personal advertisements, branding for grassroots organizations and labels, decorated selfies, fan images, humorous memes, event flyers and visuals for musical projects.

Describing this, one participant said: "It's 'iketsetse'…that's Xhosa for 'do-it-yourself'. We didn't have all the things, the computer and the money…but you still have the ideas, so you just make it with what's around." Below follows a brief overview of some of these creative artifacts.

Kasi clothing brands

The emergence of clothing brands, deeply entrenched in a local *kasi* habitus [30] and particularly influenced by local *Izikhotane*[1] and international hip-hop subcultures articulates a distinctive style, which plays on a visual bricolage of "bling", urban decay, and traditional African 'tribal' aesthetics. These items consist largely of t-shirts, hoodies, and caps. Young people come up with slogans or logos and sell them on a made-to-order basis. These are commonly run from Facebook, Black Berry Messenger or Whatsapp.

Selfie-expression

Decorated selfies allow young creatives to dialectically author and craft identities for themselves through symbolic embodiment in spaces of appearance – reflecting the view of the self that the author wants to project to their peers and the world. [31]

Phonefolios

In lieu of high-resolution digital cameras, computers and hard drives, mobile phones offer a way of documenting work. Participants back these images up directly onto *Facebook* through mobile upload, creating an ad-hoc cloud backup. These devices also allow for the carrying around of work as a means for display in co-located interactions.

Subcultures and visual vernaculars

Often images are authored as stand-alone electronic artworks, or visual poems, creating images that make sense of lived realities. Young people tell stories of crime, violence, poverty, love, hope, God, family, good, evil, and their everyday experiences which they share with friends over social networks or messaging services.

Yet, as discussed, many of these artifacts are severely limited in terms of available typefaces, colours, workflow, editing capabilities – curbing creativity on mobile platforms. Furthermore, many of these young people make their designs and artworks in relative isolation, where exposure is limited to their existing Facebook friends or Whatsapp contacts.

Participatory Design as Intervention

Borrowing from the Scandinavian tradition of Participatory Design [32], we looked toward uncovering local design vernaculars that originated on mobile phones in order to design a mobile exclusive, open source design tool in tandem with a larger social network that would enable sharing, mentorship, critique and community among young South Africans who were interested in the creative industries. The first tool would help with the creation of design artifacts, and the second would allow young people to network with these creations, find inspiration, and share ideas, resources and customized tools. This paper focuses on the development of this first application.

Prototypes and Collaboration within the academic space

Towards the development of the app I recruited a number of Honours Computer Science students and together hosted multiple workshops with participants. The result was the blueprint for an app which would include an integrated environment for both vector and raster editing; allow the user to prepare documents for print or web; include the option to produce custom libraries and save out custom tools, shapes, or textures; and work within a layered framework.

Molio – Another Black Box

By the end of the 2-month development period, the tool was a mutation of every other existing mobile visual editing app on Android, with added bugs. Multiple reasons contributed to this flop, but at the center of these awkward

[1] A local South African subculture where young people compete in displays of showmanship or dance battles as a display of wealth. Expensive material items are often destroyed during such displays to demonstrate the competitor's lack of concern for such possessions.

utilities, lay the building blocks of the Android libraries - intended as casual tools for casual design.

We developed the app for Android 4.4.4 KitKat, and the developers largely modified existing Android libraries to populate the app. There was the exception of the vector graphics editor, which was developed using the C language and required an interface to pull its functions into Android. This was done in lieu of any Android or JavaScript libraries that could produce SVG rendering to the full specification. A necessity for printed output, and a means for artists to edit individual nodes of vectors. The C library didn't have a touch interface, and had originally been designed for a desktop environment, which meant that the development team spent a large amount of time simply trying to make the tool respond in a mobile environment. These issues indicated the very limited development that was happening within the open source space for producing visual design on mobile. These limitations both indicate a gap to be filled by developers with dual interests in visual design and programming, and challenges for developers who rely on libraries to build their apps.

Smash the Black Box: A New Era of Mobile Creativity

In light of these troubling drawbacks, we advocate for a larger community of artists, developers, hackers and makers to produce alternative tools and open-source libraries, which break out of the linear, limiting vision of what is possible on mobile (for example, the processing power of a mid-level smartphone today offers roughly 2000 times the computational ability offered by the Macintosh computers that ran the first iterations of Illustrator '88).

Additionally, we believe that formal education should explore a larger repertoire of design tools, building on what young people are already using for artistic practice, and for their dominant modes of exhibition (social media). This will also possibly allow them to "smash open the black box" through exposure to programming languages such as Python, Java and PHP.

Among a mobile-primary generation of users, designing on mobile, for mobile, appears to be an emerging practice. For these young people, the development of local and custom built tools lies at the heart of finding and connecting with an online audience and expressing their voice in the public domain. The necessity to produce a design tool that allows for customization, crowd-contributions, and a natural evolution can take place 1.) Outside of the formal institutional aim to assimilate students into the traditional visual design principles and 2.) The commercial aims of profit within the mobile development sphere, remains critical.

Although formal design education offers a well-trodden path into formal design industry, the formal educational realm is increasingly struggling to keep up with the fast evolving technologies that enable the electronic arts [20]. This changing attitude toward the value of formal degrees might benefit young people who are already hacking the formal skills that could make them functional, if not accredited, designers. This is not to say that these courses do not have significant worth – but just that they do not have the capacity to assist the majority of aspiring young South African creatives who may benefit from a more casual, networked, mode of digital Do-it-Yourself cultural production.

Conclusion

Mobile phones offer a powerful tool for visual creativity, offering a "first touch" of instrumental design practices for a majority of young South Africans through photography, sharing practices and casual image editing and drawing. Yet development and recognition of this emerging creative tool remains underexplored outside of 'casual' apps and basic developer libraries.

The prolific 'hacking' of instrumental visual design that is happening on mobile phones among select students enrolled in Extended Curriculum Programs indicates a potential democratization of visual design skills outside of formal design education, without access to desktop computers and fast, stable internet connections.

These practices might also start indicating what differentiates these students from others who did not attain access to these courses, supporting the notion that casual exposure can be leveraged into formal skills.

These emerging forms of creativity need to be further developed, hacked, networked and expanded if they are to graduate beyond the current 'lo-fi' mobile aesthetics of casual use.

Toward this, we call on open source communities, artists and hackers to develop visual tools that "smash the black box" of mobile creativity, allowing young people to play with and customize the tools that allow for open-ended visual creativity on their mobile phones. We also advocate for a shift in formal education where educators explore existing creative ecologies and allow young people to "smash the black box" on the technologies that enable their creativity, by including app development languages such as Java, Python and PHP in their curriculums.

Acknowledgements

I would like to acknowledge the guidance and inspiration I received from the late Professor Gary Marsden while conducting this research, as well as the input of my supervisor Professor Marion Walton, and the members of the ICT4D lab at the University of Cape Town. A special thank you goes to the Molio participants for allowing me to publish their work anonymously.

Abstract

This paper presents the *Mandala*, a multimedia live performance piece that explores the use of body movement and virtual imaging to enrich musical expression. This project combines an interactive 3D bimanual interface with a computer imaging application designed to graphically render and physically simulate the interactive construction and deconstruction of the ancient Tibetan Buddhist sand arts, called *Mandala*. *Mandala*, an agent of ancient arts and philosophy, uses technology to lure the next generation into traditional cultural practices, disrupting the boundaries between ancient arts and leading-edge interactive imaging technologies.

Keywords

Tibetan mandala sand arts, multimedia live performance, CHAI3D, body motion, human computer interaction, augmented-reality, dynamic simulation.

Introduction

Human beings are deeply expressive. We use body language, and speech to communicate our thoughts and feelings to other individuals. During musical performances, audiences often connect to the performer and mentally model thoughts and feelings in the performers mind, in what is called emotional contagion (Hatfield et al., 1993). In addition, humans are highly skilled at reading bodies, and voices; this ability begins at infancy and is refined to an art by adulthood (Darwin, 1872). Body motion and gestures are natural artistic expression forms worthy of further study and implementation in live performance. The aspiration of the Mandala project is to capture the natural forms of human expression and embody them artistically in real-time by bringing an ancient art form of Tibetan Buddhism to the digital world.

As new technologies have appeared, inventors and artists have been driven to apply new concepts and ideas to improving multimedia live performance or creating entirely new means of controlling and generating dynamic sound and graphics. In the past two decades, with the explosion of digital technology, the computer has become an essential tool for creating, manipulating, and analyzing audio and visuals. Its precision, high computational performances and capacity to generate or simulate audio-visual signal make it a compelling platform for artistic expression and experimentation. Moreover, the availability of many new forms of human interfaces, ranging from camera trackers to tactile displays, offers an infinite spectrum of possibilities for developing new techniques that map human gestures on sophisticated audio-visual events. Although many approaches have been proposed to use body movement to drive interactive arts and musical instruments (Hunt et al., 2000; Knapp and Cook, 2005; Machover and Chung, 1989; Overholt, 2001; Wanderley et al., 2001; Winkler, 1998), to the best of our knowledge, few studies have explored the use of vocalists' digitalized body motion to simultaneously control real-time dynamic simulation and to enhance musical expression during multimedia live performance.

Related work

Previous work in movement tracking can be categorized in two groups: movement sensor-based and position tracking based. Movement sensor-based recognition is most suitable for mobile applications in which the user may traverse large workspaces. These systems typically rely on small accelerometers or joint sensors that capture the movements of the human body. Such systems have been mounted on instruments and used for musical performance conducting systems (Rekimoto, 2001). Furthermore, wearable devices such as glove-based interfaces designed for capturing sign language (Hideyuki and Hashimoto, 1998) have demonstrated the capacity to sense even subtle finger motions. Tsukuda and Yasumura (2002) introduced the Ubi-finger, a wearable device that uses acceleration, touch and bend sensors to capture a fixed set of hand gestures.

In contrast, position tracking based devices are used for stationary applications and generally require a tracker or camera to be set up, and often calibrated, at a fixed location. Iason et al. (2011) present different strategies for recovering and tracking the 3D position, orientation and full articulation of a human hand from marker-less visual observations obtained by 3D Kinect sensor. More advanced multi camera systems such as the Vicon 8 have also been used to capture human motion during large stage performances where optical occlusions may occur (Dobrian and Bevilacqua, 2003).

In the area of musical expression, systems for interactive control of sound and visuals in virtual reality can also be traced back to 1990s. Meskers et al. (1999) used the electromagnetic to track the "Flock of Birds" in shoulder motion research. Robyn et al. (2006) further explore the use of motion tracking techniques to extract musical data to gen-

erate responsive imagery. Through a series of his own work, Pritchard (2010) theoretically analyzed "the body as object", and how body, body motion and gesture can be used in both musical and visual expressions. Our research attempts to expand upon the musical applications of these technologies as well as the theoretical implications of gesture control in live, multimedia performance.

The Mandala

In Tibet, as part of a spiritual practice, monks create mandalas with colored sand (Bryant, 2003). The creation of a sand mandala may require days or weeks to complete. When finished, the monks gather in a colorful ceremony, chanting in deep tones (Tibetan throat singing) as they sweep their Mandala sand spirally back into nature. This symbolizes the impermanence of life.

In this project we strive to create an intriguing work that translates this ancient philosophy to an arts and cultural experience as spiritual expression through interactive multimedia art and music composition. As the engineer Richard Hamming pointed out (1997, cited by Roads 2015), it is insignificant if the novelty and innovation make no cultural impact on human history. Through this piece, we innovatively provide a quick, yet rich presentation to simulate the Tibetan Mandala sand arts with musical expression; we aesthetically explore the ancient Buddhist philosophy of impermanence; and we increase the visibility of traditional cultural practices to the "twitter generation", who has less patience to rediscover those transcendent human treasures.

Figure 1: Construction and destruction of a sand Mandala.

The Piece and the Performances

As part of a multimedia live performance created at Stanford University and an invited performance at the Third International Buddhist Youth Conference in the Hong Kong Institute of Education, an interactive display of sand Mandala was dynamically simulated and choreographed with the vocal and instrumental compositional-improvisation. The musical and visual expressions through body motion were further explored and documented. The first performance at Stanford University took place before an audience of engineers and young Silicon Valley entrepreneurs, while the second performance occurred in Hong Kong, before an eastern, Buddhist audience. Both audiences showed enthusiasm for the culture content, and the science and technologies behind the scene that creates the magic, both during and after the performances.

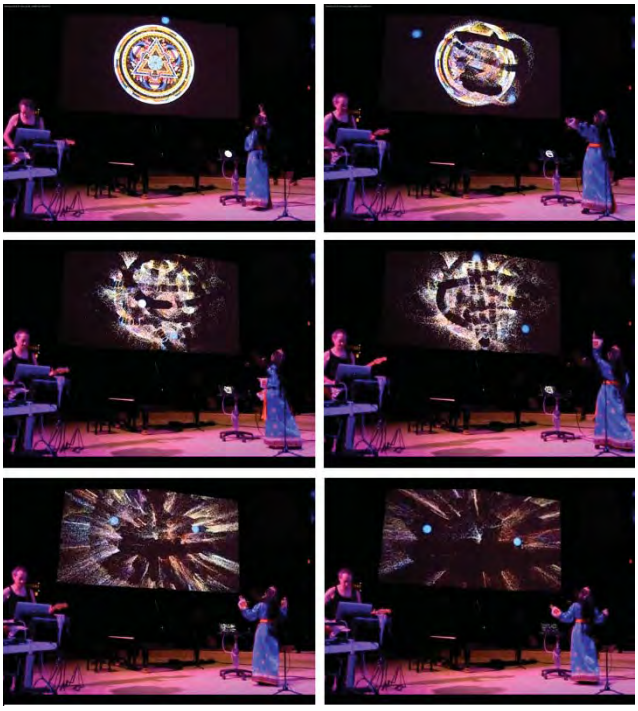

Figure 2: Live performance of the *Mandala*.

The proposed system is composed of two applications that operate on a single laptop computer and handle both the motion tracking and audio-visual processing events. The motion tracking application connects to the Hydra Razer interface and acquires the position, orientation, velocity and acceleration values of each input device at 100 times per second. Additionally, the states of the input switch and configuration of the miniature joysticks mounted at the extremities of both end-effectors are also retrieved. These measurements are then converted into events that are used to interact with the dynamic model of the virtual Mandala and real-time audio processing. The different parts of the systems are further developed in the following paragraphs.

The piece Mandala includes three movements: *Construction*, *Climax*, and *Destruction*. At the beginning of the piece, hand motions from the vocalist were directed to initiate the *Construction* of the virtual Mandala. Music composition for this part includes implementing additive synthesis and FM synthesis techniques (Chowning, 1977) to create an ocean-wave-like musical landscape with dynamic high pitch notes moving through the body movement. The backbone of the piece is made of rhythmic loops in Logic Pro with outputs and lives guitar processor inputs, routed through a Mark of the Unicorn 828mkII interface for 10 channels of spatialized output. Live guitar sounds are generated by a Fractal Audio AxeFX Ultra processor.

Mixed sounds of electronic guitar, rhythmic drumming, Buddhist chanting, synthesized sound waves and celleto start to create and build up an imaginary world from tran-

quility and emptiness to intense passion and complex glamour. During the *Climax*, musicians were focusing on musical improvisation while the virtual Mandala was self-directed and presenting animation, such as rotation, twisting and glitter effects. Granular synthesis, along with audio panning and spatialization techniques, are implemented to create bursts of variously-pitched pieces of sound fractions which, when put into interaction with experimental low-tone throat singing and explosions of violent soprano interjections, comes to symbolize the extreme conflicts and ecstasy in life, the extraordinary highs and lows, the sharp rises and falls of life as it is experienced, ending with a sharp fade out into the deconstruction of the mandala. The *Destruction*, which underscores the eternal nature of impermanence, occurs near the coda of the audio-visual piece through the hand motions from the singer.

A video of this multimedia live performance piece's premier can be viewed at: (http://tinyurl.com/ku5cg4f)

3D Human Interface

The vast majority of motion-controllers available today rely on small accelerometers that detect hand motions generated by the operator. Although such inertial sensors are used in almost any game controller or smart phone available today, their precision remains limited, and they lack the ability to track absolute positions in 3D space. For this project we selected a new type of interface called the Razer Hydra. As compared to accelerometer based, ultrasonic or camera driven motion sensors, the Razer Hydra uses magnetic motion sensing. Magnetic motion sensing enables this new interface to track in true 3D space for absolute position and orientation with its magnetic field. This technology also allows for full six degree-of-freedom movements tracking with sub millimeter accuracy, while eliminating the need for a line of sight to operate.

The user interface adopts a paired system, with a base station emitting a low energy magnetic field that both hand controllers record to estimate their precise position and orientation. The controllers and the base station each contain three magnetic coils. These coils work in tandem with the amplification circuitry, digital signal processor and positioning algorithm to translate field data into position and orientation data. The raw data are then processed using a first order filter and converted to a MIDI protocol before being broadcast to the audio stage.

The audio processing application, designed using the ChucK language (Wang and Cook, 2003, 2008), interprets MIDI signals from the motion-tracking module and activates a selection of audio filters and generators according to the desired musical expression. The application communicates all input and output audio signals by using the Unicorn 828mkII interface, which supports multiple channels that include both voice and electronic instruments.

Because of the real-time nature of the technology, the interface delivers near instant response between the hand motions generated by the operator and the actions commanded by the computer. An illustration of the device is presented in Figure 3.

Figure 3: The bimanual Razer Hydra interface

Dynamic Simulation

The virtual Mandala is composed of 4.5 million digitized sand particles that are physically modeled and updated 100 times a second. Force interactions are modeled in real-time by capturing the position of the performer's hands and by computing collision events with and between the individual sand particles. A graphic and dynamic modeling framework CHAI3D (Conti, 2003) is used to simulate in real-time the physical interaction between the captured hand motions of the performer and the small mass particles composing the virtual Mandala. The mapping between the hands of the performer and their models in the simulation is performed using a new mapping technique (Conti and Khatib. 2005) called *workspace expansion* that relies on progressively relocating the physical workspace of the devices mapped inside of the virtual environment towards the operator's area of activity without disturbing his or her perception of the environment. This approach allows the operator to interact with high accuracy in a very large virtual environment while moving his or her hands within a reasonably small workspace.

Conclusion

In this paper, we presented a human interactive simulation framework to explore the imaginative relationships between singing, dancing and natural emotional expression by using gestural and motion control to modulate and shape the texture and contour of sound and visuals. By demonstrating the motivation, compositional structure and methodology to achieve our aesthetics and technical goals of the multimedia live performance piece *Mandala*, we combined state-of-the-art technology in simulation and human interaction with ancient eastern philosophy and Tibetan Buddhist arts. Repeated performances of this piece with multiple audiences have confirmed not only the successful application of this technology, but also the ability of this technology to work with music to bring to life ancient art forms and philosophies for worldwide modern audiences. These preliminary results validated the intuitive design of our application and its capacity to respond with real-time audio-visual performances and confirmed our original idea toward exploring natural human motion and gesture as an effective way to instinctively enrich musical and artistic expression.

Authors Biographies

Jiayue Cecilia Wu: Originally from Beijing, Jiayue Cecilia Wu is a scholar, composer, multimedia performer, and audio engineer. Cecilia earned her Bachelors of Science degree in Fashion Design and Engineering in 2000. Upon winning the MTV Asian Beat contest, Universal Music identified her talent and signed her as a music producer in Hong Kong. In 2010, Cecilia produced her original album of spiritual electronic music, Clean Your Heart. In 2013, Cecilia obtained her Master’s degree in Music, Science and Technology at Center of Computer Research in Music and Acoustics at Stanford University, where she focused on computer-assisted composition and audio engineering. As an audio engineer, she received a graduate grant award from Audio Engineering Society. As a musician, she received an award from the California State Assembly for being a positive role model in sharing Chinese culture. Currently, she is pursuing her PhD in Media Arts and Technology at UC Santa Barbara.

François Conti: Originally from Switzerland, François Conti is a co-founder of Force Dimension, a company that has earned international recognition for designing and manufacturing high precision haptic interfaces that are used today in research, entertainment, and medical fields. François also leads the development of the CHAI3D open-source haptic visualization libraries and is a lecturer of the Experimental Haptics course at Stanford University. François holds a B.S., M.S. from the Swiss Federal Institute of Technology in Lausanne, and a PhD from Stanford University.

Can Art Save Hong Kong? - A Case Study of Preserving Hong Kong Cinema as an Intangible Cultural Heritage

Annie On Ni Wan

Hong Kong Baptist University
Hong Kong SAR, China
aonwan@hkbu.edu.hk

Abstract

In media arts discourse, the term post-digital describes art practices in relation to digital technologies. However, its concerns are humans and cultures rather than the technologies themselves, and the emphasis is on the aesthetics inherited through audience participation in artworks. This research project introduces a post-digital strategy for the preservation of local cinema and, at the conjunction of ubiquitous post-digital technologies, arts and the humanities, seeks to foster a new public awareness of the issues at stake in the city's most representative cultural industry. The aim of the project is to re-forge the severed link between citizens and the cinematic representation of their own living space in the post-digital era. It argues that in the years to come, Hong Kong's public cultural institutions should be able to conserve the city's technological edge while reaffirming its modern specificity; to create a renewed sense of its own identity; and ultimately to propose to the general public an innovative feature of heritage mediation.

Keywords

post-digital, augmented reality, Hong Kong cinema, intangible cultural heritage, local culture, ubiquitous technology

Introduction

At the crossroads of the arts, social sciences and ubiquitous technologies, this research project aims to explore, in the still broadly defined field of the digital humanities, new ways to create academic knowledge through a collective process. Therefore, a corpus of definitions is required to create a collective vision of how the consumption of Hong Kong cinema is evolving in the post-digital era. In the process of rethinking the use of cinema practitioners through participatory methods, the project will reassess the foundational position of Hong Kong cinema in Hong Kong's identity. The project will also develop a Participatory Action Research (PAR) plan to unite, drive and understand the many processes at stake in such an interdisciplinary project.

Historical Background

Hong Kong offers a unique case in world history, where a colonized space, once returned to sovereignty, had very little in common with its pre-colonial past. In the meantime, it has returned to a so called "motherland" that it ignores completely.[1] Furthermore, the lives of most of the Hong Kong population have been tempered in one way or another by the dramatic events that occurred during the difficult first decades of the People's Republic of China (PRC) and the throes of exile.[2] For these reasons, Hong Kong has created a very resilient and spirited way of doing things that is best illustrated in its unique cinematic production.

This very broad historical overview provides an understanding of the evanescence, the very fragility of self-representation, in a space and time borrowed from colonialism and exile. It also provides an important key to understanding the very peculiar importance of cinema as an identification tool within the *very* tight boundaries of the territory. In 1984, the already mature movie industry received a blow, along with the rest of the population, when Hong Kong learned that it would be handed back to the PRC in 1997. This decision created intense anxiety among Hongkongers and triggered intense reflections on the very existence of a rich and distinct Hong Kong Chinese culture and identity. Through this process, Hong Kong cinema encountered its most innovative momentum, as the only discursive medium able to interpret the depth of this introspective moment. This surge of imaginative talent gained international fame for the inventive skills and artistic achievements of Hong Kong cinema.

[1] Hong Kong was lost by the Manchu during the Qing Empire and returned to the Han Chinese People's Republic of China.

[2] Over a million mainland Chinese flooded into the city in 1949 alone, mainly businessmen, artists and writers, transforming it into an illegitimate daughter of twentieth century Chinese culture. Most of the movie industry in Shanghai settled in Hong Kong at that time.

Since the handover, the Hong Kong film industry has met the challenge of multiple crises that seem to have severed the link between the city, its inhabitants and their most representative creative industry. First, the global pursuit of the logic of (neo)liberal economics in creative spheres has resulted in a global "depoliticization" of issues that has flattened the realist and self-conscious outlook of the industry. Second, the PRC has recently emerged as a central actor in the entertainment business, both as a market and as a financial resource, under the conditionality of political correctness.

Since the beginning of the 1980s, the arts and cinema in Hong Kong have been haunted by reflections about the city's space and history, and by the search for an identity defined by local specificity, often reduced to fragile vestiges, or even to their absence (PERNIN, 2014, p. 659). The latest official research on the cinema industry suggests that the situation for Hong Kong's industry is "astounding" in terms of financial, technical and artistic collaboration with the outside world (mainly the PRC). Revenues are growing steadily under the auspices of the Closer Economic Partnership Arrangement signed in June 2003 (HKTDC, 2014). Nevertheless, reading a little further on the same official website, doubts seem to remain about the real potential of such an organization (SHACKELTON, 2014). The number of movies made in Hong Kong is decreasing steadily and Hong Kong's "starring role" in the movie business in China seems less evident or certain.

Finally, the ever-increasing rhythm of technological invention in recent years, combined with the ever-increasing number of images at our disposal, has changed the nature of film production, consumption and preservation, and has thus imposed a redefinition of the basic features of the cinema experience on the whole industry.

Pocket Cinema Hong Kong (PCHK)

The PCHK project was born from this array of complex but contiguous issues, with the modest conviction that if it could not answer those questions, it could at least create an innovative podium to further reflections on the central questions at stake, with the core idea that researching human experience through the arts makes complete sense to people. At the crossroads of the arts, social sciences and ubiquitous technologies, this research project aims to explore, in the still broadly defined field of the digital humanities, the triple direction at the core of the problem.

First, and most importantly, it is now officially recognized that the Hong Kong Chinese identity is problematic. The PCHK project, in fostering reflection on a creative industry located at the heart of its creative cultural distinctiveness, aims to contribute to the formulation of a singular global identity for Hong Kong, drawing on the possibility, the relevance and the legitimacy of a modern, cosmopolitan and legitimate Chinese ego that is at peace with itself and aware of what is at stake both inside and outside its own boundaries. Within this soul-searching effort might lie a free and open future for the Chinese identity in the contemporary world.

Second, using the latest ubiquitous post-digital technologies, the PCHK project aims to acknowledge the telescopic time-scale of contemporary obsolescence that seems to condemn, simultaneously, all of the past habits of our cinema practitioners. Indeed, regardless of their status, analog films, videos and DVDS, and even the Web, all seem to be dying in the face of the new needs and requirements of a borderless, individual, digital mobility that is urging us, as individuals and as a community, to re-think the modality of cinema to re-invent the extent of and dependence on technology. All of those essential questions for our time must nurture a global reflection on how cinema in general, and in terms of our interest, Hong Kong cinema in particular—as an art form and as a cultural assessment—needs to cope with evolution. This mandatory exercise imposed by the era is necessary to confirm and pursue the technological edge that Hong Kong has always had, and to reaffirm its pioneering role in scrutinizing the future. This epochal change should be seen not as an obstacle, but as an incentive to invent new means of survival and dissemination for Hong Kong's cinema heritage.

Third, regardless of how much it is transformed, caricatured, fabricated and sublimated, Hong Kong is the central actor in Hong Kong cinema. The city is a contender for the title of "cinema city" along with Rome, Paris or New-York. As such, the purpose of the PCHK project is to develop a coherent and innovative digital strategy for urban cultural development. The institutions involved in the artistic development of Hong Kong will be able to propose a cultural guided tour of the city through its memorable cinematic moments. In other words, as Vivian P.Y. Lee brilliantly put it, if cinema and heritage can be jointly defined as two modes of cultural production, the PCHK project needs to rethink heritage through cinema, and to rethink cinema through heritage. The PCHK argues that in the years to come, Hong Kong's cultural public institutions should be able to propose to the general public an innovative feature of film and urban heritage mediation in relation to the development of Web technology and digital services in mobile situations.

Research Methodology

By the very nature of the issues it tackles, the PCHK project can only be a collaborative undertaking. Combining the latest technologies in satellite localization (GPS) with nomadic application design, the PCHK project can be considered a post-digital undertaking because technology is not its end, but only a means to its end. It is much more concerned with humans and culture through a process in which art—both the film corpus and the application, a form of digital art—are the basis of the research. Methodological breakthroughs using art both as an end (cinema) and as a means (application) are needed to focus/foster/invent a community of practice. Therefore, an emphasis on the process rather than the method will allow an active space for participation that lies between existing disciplines and their methodologies while proposing the formation of new methodological criteria. It is this process space that alludes to the conditions for the research.

PCHK aims to penetrate the city, film and the public, and to question the symbiotic nature of those three elements (technology – humanities – art). The art of the arts-based researcher extends to the creation of a process of inquiry. In its eagerness to explore new ways to create academic knowledge through a collective process of urban development and cultural heritage, the need to involve the local public to feed and further our research creates the need for a participatory methodology, whereby public feedback can lead us to develop a more acute sense of our purpose. At the crossroads of Participatory Action Research (our method) and Art Based Research (our assessment), the project intends to reassess the foundational position of Hong Kong cinema in Hong Kong's identity.

Project Description

Imagine wandering through the urban setting of Hong Kong, where your steps are loosely driven by your own mobile device, through a game of digital image recognition that takes you through the different steps of a seminal movie abstract, filmed on the very same spot. You would, at the very same time, share the space with its cultural significance—a meaning probably unknown to others. A way to (re)create an intimacy with the evolving setting of Hong Kong's moving urban disposition and to (re)discover how much the city is a central part of its own representation.

Once the application is downloaded onto a mobile device, the public audience, transformed into a mediated *flâneur*, will be invited to join cultural tours in which they are free to stroll through the cultural identity of the territory and experience its intense physical heritage through its rich cinematographic legacy. The superimposition of dynamic data-dense spaces over physical ones ultimately creates a kind of aesthetic paradigm that questions how spectators can interact with a renewed experience of cinema and a renewed experience of the city. A constant engagement between the informational and the material space finally creates an informational continuum that informs the technological transformation of our relationship with urban spaces while simultaneously seeming to renew our experience of cultural heritage.

Figure 1. One of the tours with around 15 participants. ©Hong Kong Baptist University.

Ultimately, the potential extensions are limitless. Depending, of course, on the participation of private and institutional partners, one could develop the PCHK by movie genre, by actor, by director or by area, with each trail providing a different perspective on the city. The Web platform could help in planning the walks by providing information on the area, on the movies and its players. Participants could create their own stories about the city with their memories of films and/or places. Then, the PCHK could also be translated into different languages to deepen the understanding of visitors to Hong Kong by giving them deeper access to the city's intimacy more eloquently than the obsolete and speechless East/West binary cliché. It will allow a reinvention of Hong Kong's story by rewriting stories with insiders and outsiders. Official institutions that specialize in the preservation of cultural heritage (museums, archives, libraries) are well aware that making a heritage alive and meaningful to insiders and newcomers involves its usage and distribution through ubiquitous new media forms. Preservation today seems to turn to usage within the frames of nomadic consumption.

The application is now functional and, although it is

still only in a beta version, it is already advanced enough for us to use in practice. We organized 4 initial tours with our partners. We programmed 7 steps, each related to a place and a movie abstract from three films that were filmed on the available spots. Total number of 35 people was provided with information about both film and place to connect and react automatically to the digital location and to the image recognition device.

To conclude our first trial, we gave the audience a short questionnaire to collect some feedback on the experience. The answers were encouraging. The three questions regarding the fluidity of the application usage and the will to follow its development suggest a great deal of confidence. More remarkably, the process seemed to trigger the interest and the curiosity of a majority of participants in the pursuit of PCHK for Hong Kong cinema production. Finally, learning more about the films through this new application seemed to provoke a desire to further the experience with the prospect of seeing more local films in their home environment.

De-totalizing Capture: On Personal Recording and Archiving Practices

Jacek Smolicki
PhD candidate
School of Arts and Communication, Malmö University
Malmö, Sweden

jacek.smolicki@mah.se

Abstract

This paper serves as an overview of a part of the research conducted towards a PhD at the School of Arts and Communication, Malmö University in Sweden. In the context of the changing nature of the archive, big data exhaust and data surveillance, the research explores alternative and voluntary recording and archiving practices mapped among artists and media practitioners concerned with self-tracking and collecting personal data.

Today's media-scape presents recording and archiving as one of the major media practices performed by an increasingly growing number of people. Practically every personal digital device is equipped with some recording function allowing to capture and categorize texts, sound clips, images, video sequences, geographical location and increasingly bio-physiological processes. On the other hand, often without us being aware, the same technology passively tracks and records ever more detailed information about our behaviours, movements and decisions. As some scholars suggest, latest advancements in technology made the dreams of recording one's whole life come true. This total capture becomes a condition that calls for reaction. In this paper I interrogate the idea of a passive and automatized capturing by confronting it with a concept of a reflective and proactive recording practice. As an exemplification of the latter I introduce a set of artistic practices I have been performing regularly since 2009. These practices aim at constructing a record of my life and the space I find myself in. Contesting the enthusiasm around the technologically enabled possibility of recording entirety of one's life I argue that recording and archiving are generative and active processes requiring reflective and critical approach to media technologies that they inherently rely on.

Keywords

Recording, Archiving, Life-logging, Total Capture, Media Practices,

Introduction

The following three sections propose a critical and analytical perspective on different modalities of relating to recording and archiving media. In the context of the discussion, the term *media* ought to be seen not as representing material objects, tools or institutions, but as a constructive and vital process, an entanglement of media technologies and humans resulting in a conception of particular, media-aided practices of recording and archiving one's life.

Living *in* recording and archiving media

Marc Deuze suggests in his book Media Life that we no longer live merely *with*, but ever more often *in* media. Parts of our lives increasingly migrate, resettle and are exposed *in* media where they form realities that can be accessed, shaped and remixed, also by other people [1]. Christiane Paul describes contemporary, post 2.0 culture as characterized by a "fascination with visibility" where an increasing number of tracking technologies "enforce people's need to make the world aware of them and be observed by it" [2]. While this exteriorization of the self happens in relation to or as perhaps a dominant form of interaction with others, simultaneously a new form of self-witnessing emerges as Deuze describes it: "we have now entered a time in which we can see ourselves live" [3]. As Deuze elaborates further: we need to conceptualize strategies that would enable "to safely, authentically and ethically keep track of our lives in media" [4]. As he clarifies, such a survival technique requires a good degree of digital literacy and skills in using media as both producer and consumer [5].

Looking from a different perspective, Deuze's scenario of the proliferating settlement of life in media can be seen as a result of a somewhat neo-colonial expansion of mainstream media infrastructures, such as social media platforms or Google [6] into ever-larger (mental and geographical) territories of human activities. From such perspective, practices of recording and archiving appear as gradually becoming unified into the logic of so called 'pro-sumerism'. Coined by Alvin Toffler, the term 'prosumer' became characteristic for the Web 2.0 [7]. Applying this merge of two dominant forms of relating to media – producing and consuming – to the then new media landscape, was intended to demonstrate the more democratic and horizontal character of the Web 2.0 and subsequently social media, where everyone can be seen as both a producer and consumer. However as convincingly

argued by Edward Comor, practices of prosumers do not contribute to de-massification and de-hierarchization of media. Quite the opposite, prosumers "extend" and "revigorate" capitalism by "being involved in mostly entertainment and branding activities" [8]. In other words, seemingly immersed in individuation, self-realization and the projection of their uniqueness, prosumers remain in and contribute to the reproduction of commodity-driven relations. Consequently, personal recording and archiving practices in such light can be seen as being highly conditioned by two elements. Firstly, by the ontological substrate of the very media framework that these practices are bound to (e.g Facebook's chronology of the wall display, Instagram's nostalgic filters, etc.). Secondly, by the epistemic enclosure by which I mean an intensive circulation and replication of popular representations, themes and motives contaminating processes of personal enunciation and individuation[1].

To sum up, in the aforementioned scenario of living *in* media the formation of one's record (and hence the knowledge of oneself) happens extensively in relation to the pervasiveness of other media content and hence often as a mere response to its affective presence. The form that this response takes (the display of the recorded material) is determined by a rather inflexible architecture of the storing platform and its intrinsic mechanisms of hierarchization (e.g. Facebook). Moreover, this architecture predetermines the very formation of the record[2]; the decision of making a record (for instance snapping a picture) is a result of one's self-assurance that the particular situation, event or moment is aesthetically, formally but also socially appropriate enough to make a 'good' entry on a given social media platform (consider a growing popularity of phrases such as an *instagramable* or *facebookable* picture[3]). In other words, a condition of living *in* media, which paraphrasing Deuze can be equalled to 'living *in* the digital archive', implies a need to adapt to a set of socio-technological standards according to which one begins to perceive, structure, record and therefore experience his/her own life events. Such a record of life is readable only in the context of the socio-technological conditions that made the very record possible in the first place. In the 'living *in* recording and archiving media' scenario, as Brouwer and Mulder mark "there is no position outside of the (storing, linking, reprocessing, transforming and complexification of data) flows, an external position from which you can criticize or transcend the flows" [9].

[1] Although the number certainly differ today, in 2009 Manovich pointed out that only between 0.5 and 1.5 of Internet users were contributing with new content while the vast majority were primarily consumers, Manovich, L. (2009) *The Practice of Everyday (Media) Life*: *From Mass Consumption to Mass Cultural Production?* Critical Inquiry, Vol. 35, No. 2 pp. 319-331

[2] Consult Vilem Flusser' *Into the Universe of Technical Images* (2011, University of Minnesota) in which he argues that societies are ever more often being perceived, constructed and operate according to the rules imposed by technical images and apparatuses.

[3] Source: http://www.urbandictionary.com, accessed: 21.12.2014

Living *through* recording and archiving media

Although being highly predetermined, recording and archiving in the 'living *in* recording and archiving media' scenario allows for a certain degree of control by the subject. Generally speaking, taking a snapshot or pressing and holding a record button is a result of a conscious choice of the subject. However, latest developments of recording, sensing, tracking and storing technologies have given rise to ever more fully automated forms of logging one's life. As an effect, life-logging becomes one of the mainstream modern media practices.

As Kitchin and Dodge suggest in their often recurring definition: life-logging is "a form of pervasive computing, consisting of a unified digital record of the totality of an individual's experiences, captured in a multimodal way through digital sensors and stored permanently as a personal multimedia archive" [10]. What distinguishes life-logging from earlier forms of recording life is an increasingly automatic character of this process and consequently its wide scope that ambitiously aims to cover "a totality of an individual's experiences" [11]. Lifelogging as opposed to more active and voluntary forms of recording life such as through journaling or taking photographs, deliberately "operates in a passive manner" [12] Thus, allegedly active in lifelogging are only the moments of initiating and stopping the process of recording. What happens in-between is a "passive" and "unobtrusive" documentation of "'facts' around the episodes of our lives but not of their emotional interpretation"[13].

Life-logging is not concerned with collecting qualitative or semantic information. Rather, it increasingly prioritizes collection of quantifiable data that can be later utilized to devise pragmatic models for improving one's health, wellbeing or memory. The focus on quantification is what particularly draws attention of information technologists and computer scientists. In consequence, life-logging has been commonly debated as a domain of techno-enthusiast and developers operating much in the spirit of techno-determinism. We might argue that today, life-logging continuously misses critical and reflective attention from humanities and more specifically cultural and media, art and communication studies. The majority of debates on life-logging typically presents the idea of a total capture of one's life experiences as being rooted in Vannevar Bush's Memex- a technical device aiming to supplement the memory of a scientist. Consequently, stark attention is given to Microsoft researcher Gordon Bell and his project My Life Bits described as "a life story of everything" and a "fulfilment" of Bush's vision [14]. Assuming that the "total recall" [15] is technically possible, the majority of challenges in relation to life-logging are presented as being primarily of a technological nature: recording, storing and processing technologies have to be improved to allow ever more discrete, seamless and accurate capture, and what's becoming the most burning issue - a retrieval and comprehension of exponentially growing amounts of personal data.

Given a particular technological actuality in which life-logging happens, it captures or rather produces data that is technologically

Figure 1 Narrative clip, an automated life-logging device as attached to the shirt before starting a few month long comparative study of passive and active life-logging. January 1st 2015. Photo by the author.

'capturable' and 'producible' at a given time. Here Derrida's deconstruction of the archive as a neutral instrument of accumulating information can be once again recalled as a reminder: "the technical structure of the archiving archive also determines the structure of the archivable content even in its very coming into existence and in its relationship to the future. The archivization produces as much as it records the event" [16]. In this light, if as the earlier mentioned definition suggests life-logging is a form of personal archiving, then it produces as much as it captures one's experience. A life-log says as much about its subject as it does about the technological infrastructure *through* which the subject's life is being mediated and analysed. Proponents of automatic life-logging believe that in order to make life-logs really usable, and reach the potential of providing an objective record of one's life, there is a need to continuously perfect technologies so they can capture as much data as possible [17].

Despite some research proving that the focused and selective capture works better for supporting human memory[4], "the idea of 'total capture', sampling life experience in high fidelity is believed to provide for a more useful, future-proof and flexible lifelog" [18]. Gurrin and others further elaborate this statement arguing that: 'many of the computational techniques may not be known yet, so it is more useful to capture as much data as possible now. With total capture the "wouldn't it be great if I had a camera' moment will become a relic of the past" [19]. While making such a statement, they however seem to ignore the fact that while the future will certainly bring new, ground-breaking technique, it will simultaneously render some of the current ones obsolete. Many technologies used today for tracking, recording and analysing data will be out of date and replaced with more advanced versions or even completely new ones. Retrieving and utilising today's data and making sense of it when confronted with future ones might become problematic. Moreover, some methods of recording and inquiring data, prevalent and seen as highly accurate today, might even become entirely questioned and discredited in the future.

Life-logging, an automatized capture of the totality of one's life, appears as a return to the positivist idea of the archive; in this case however being personalized and distributed, as opposed to centralized and collectively relevant. In the positivist archive history is believed to be passively accumulating, "exactly in the manner in which the sediments of geological layers form, progressively, constantly" [20]. Just as in the 20th century, the alleged neutrality of the archive has been gradually demystified; the belief in the passiveness of automatic life-logging has to be further interrogated. The logic of seemingly passive operations of ubiquitous sensors, recording devices and algorithms that track one's life is founded as much on the third parties' decisions, political agendas and viewpoints, as on technological constraints and affordances that considering the current pace of developments might be operational only during a limited timespan. From the perspective of memory studies, automatic capture appears as an antidote to forgetting. Yet, there is an intrinsic paradox in such a position. If one does no longer have to remember to record (as recording takes place automatically), the effort to memorize becomes similarly redundant. We can hence argue that such devaluation of memorizing lead to an ignition of forgetfulness. Growing automation of recording practices dissociates the recording subject from his/her life. Life events are being fragmented, quantified and equalized by automatic procedures of capturing and, subsequently, recalled and analysed not by the associative and reflective capabilities of the subject, but *through* the appliance of quantitatively operating algorithms (consider life-logging applications quantifying stress levels or automatic photo-capturing wearable devices such as Narrative clip recording a unified stream of snapshots taken every 30 seconds [fig. 1]). In life-logging, it is the consultation not of one's own memory, but a memory of the tracking or storing device that gives rise to a recall of an event. Consequently the tracking and storing device might give priority to events that the subject himself/herself would not necessarily have been attentive to. Thus, the actions as recorded and presented to the 'automatic life-logger' are results of filtering his/her life *through* criteria deriving from what not he/she, but the life-logging technologies recognize and register as memories.

[4] Sellen and Whittaker (2010) suggest that rather than the over-ambitious goal of "logging everything," creators of life-logging systems would be better off directing their efforts at the kinds of data people find most valuable and the issues they find most problematic.

Living *with* recording and archiving media

Figure 2 A prototype of a self-designed wearable microphones embedded in gloves while being a student at Konstfack University of Arts, Craft and Design in Stockholm, 2008. Photo/illustration from the author's private archive.

The previous section describes recording and archiving practices as turning into ever more automatized processes eventually dissociating subjects from their own mnemonic capacities. Such a scenario recalls Stiegler's concerns with technological developments giving rise to what he calls *a dissociated milieu* [21] In the *dissociated milieu* the technological development contributes to the widening of the distance between humans and their memories, or more general their cognitive operations. In other words dissociation is a process where a know-how type of knowledge disappears in favour of technologized knowledge of which mechanisms are inaccessible to individuals for inspection and appropriation.[5]

It becomes harder, soon perhaps even unimaginable to lead life that takes shape apart from increasingly inescapable mechanisms of digital archiving, cataloguing and categorizing mechanisms that, metaphorically speaking, seem to constitute today 'backends', a sort of technical modus operandi of numerous social, cultural, professional or leisure-related practices we engage in on a daily basis when interacting with technologies. Since, to some extent we all have become micro-archivists every attempt to study this subject begins inherently from within the studied field. Thus, advocating for practical commitment to studying and reflecting on possibilities of personal archiving, in an autoethnographical manner, I bring in my own set of practices that in the light of the preceding discussion I perceive as personally tailored, an intentional disruption of the proliferation of automatic technologies for recording and archiving one's presence.

[5] Such mechanisms are often described in terms of a *black-box* – a technical instrument that facilitates processing of input data and production of an output information yet with no availability to inspect the very stage of processing data.

I propose to read them as practices accentuating the positive value of discipline, effort and attention that become jeopardized by the growing automation of personal recording, and archiving practices.

Figure 3 An illustration presenting the author and a set of recording devices he has been continuously applying and carrying with himself since the conception of the project

Since 2009 I have been systematically developing and implementing a number of media-aided practices aiming to record and archive different aspects of the surroundings I would find myself in. The concept of the On-Going Projects, as I refer to them, stemmed from one documentary practice I was working on in the summer 2008 while enrolled in the MFA programme in Experience Design at Konstfack University of Arts, Crafts and Design. In the project named Soundtracking I was experimenting with prototyping different technologies and performative techniques of interacting with, recording and mapping sounds of public places (for instance wearable gloves with little electret microphones installed on top of the fingers allowing to metaphorically grab sounds and shape them in hands [fig. 2]). These early experimentations with recording site specific sounds inspired other practices that deployed different existing media technologies to record selected aspects of my being in space. Affirming the obvious subjectivity characterizing decisions on what (and how) to record (and hence what to exclude), made me rethink the project as being a form of a cross-media journal reflecting the life of an individual in relation to the public space. Thus, the projects from an initial attempt to map my surroundings turned into a kind of sousveillance[6] - a set of self-tracking practices not solely pointing at the self or positioning it in the centre of interest, but rather

[6] Sousveillance, as the very term suggests (from French 'sous' meaning below, and veiller' meaning to guard, to look after, watch over) is a practice of watching that takes place below or under some other, dominant form of surveilling. The term was first introduced by Steve Mann et. al (2003) to describe a subversive practice of individuals closely monitoring operations conducted by authorities.

using it as a filter for reflecting on different aspects of the space it occupies and generates.
Ever since, I have been regularly using affordable and portable devices such as audio recorders, GPS watches or pocket size video cameras [fig. 3] to record sonic, visual, textual and spatial data reflecting on selected aspects of my presence in space. Gradually I have started introducing more discipline and consistency, which eventually led to a crystallization of a dozen of practices, each driven by its own, specific behavioural constitution, rhythm and a disciplined use of medium [table 1].

Name of the practice	Starting date and place	Short description of the practice	Medium used	Format of the collected data	Frequency of the practice
Acquainting	12.2010, Stockholm	Looking at teh society as being formed by professional profiles of people whose business cards I find and collect in public spaces	Scanning, text, processing software	Digital file, odt, jpeg	Each time the item is found in the public space
Facing	07.2012, Stockholm	Constructing a series of portraits of randomly encountered people in different means of public transportation	(digital) pen, paper, scanner	digital file, jpeg	Each time a trip using public transport is taken
Interpreting	10.2009, Krakow	Video recording and interpreting situations that inspire different associations.	video camera	video file, mp4 (10sec)	Each time when attracted by thought-inspiring circumstances
Minuting	07.2010, Jerusalem	Composing a sonic narrative reflecting my attentive presence in the public space and consisting of at least one 1 minute long sample to represent a day	audio recorder	audio file, mp3 (1min)	Everyday when attracted by an aural situation (Dependently, usually more than one sample a day is being collected)
Misquoting	04.2011, Stockholm	Constructing a collage-like memory-map made of daily news headlines and photographs from free newspapers and magazines	collage (paper, scissors, tape) scanner	digital image file jpeg	Once or twice a week, after picking up a free newspaper
Passing	10. 2011, Gdynia	Recording temporality of travelling between places by capturing a portion of the landscape each time when taking a long distance form of transportation	video camera	video file, mp4 (30 sec, 1 min, 1min30sec)	Each time when using long distance public transport
Scribbling	07.2011, Stockholm	Commenting on reality around me. through employment of an unbound writing triggered by an attentive observation of the surrounding and its actors as well as inclusion quotes and commentaries	smart phone, computer, text editor, Evernote application	text file, txt, odt	Each time when attracted by thought-inspiring circumstances
Self-tracking	08.2010, Stockholm	Recording and visualizing an architecture of my daily mobility in public space due to the appliance of the gps technology	GPS wrist watch, software GPS visualizer	GPS files, Gpx, kml, image files, jpeg	Continuously when in a freely accessible public zone
Sound-tracking	05.2008, Stockholm	Recording and geo-tagging urban and natural sonic phenomena characteristic for the encountered locations	audio recorder, GPS wrist watch, photo camera	audio file, mp3 (30sec), text file, image file, jpeg	Each time when attracted by a situated sound source
Street-sampling	07.2010, Haifa	Constructing a collection of ephemeral soundscapes created by street musicians performing in public spaces	audio recorder, photo camera	audio file, mp3 (1min), image file, jpeg	Each time when encountering a street musician in the public space
Reflecting	11.2012, Stockholm	Recording thoughts, naive observations and judgments triggered by the very situation while taking public transport	smart phone, text editor, evernote	text file, txt, odt	Each time in the public transportation when inspired by a combination of circumstances
Traversing	11.2009, Krakow	Building an open-ended repository of photographs of objects found during a weekly-executed walk	photo camera	Image file, jpeg	Every 8th day until 7 objects are found.

Table 1. A list and description of the majority of the On-Going projects.

For instance, every single day since July 2010, each time when attracted by a particular sonic atmosphere, I have been recording at least one, sixty-second long audio sample. For this purpose I have been using a portable Zoom H2 audio recorder and a pair of binaural microphones worn as regular earphones. Even though I capture preferably only one minute each day, being aware of the continuous character of the On-Going project makes me pay attention to soundscapes throughout the entire day. As opposed to automatic capturing described in previous paragraphs, On-Going projects require a certain amount of conscious gestures and effort. In the case of Minuting, as I call the one minute recording practice, these gestures include for instance reaching to the fanny pack where I carry my recording equipment or remaining particularly focused and preferably still while recording. Just as all the

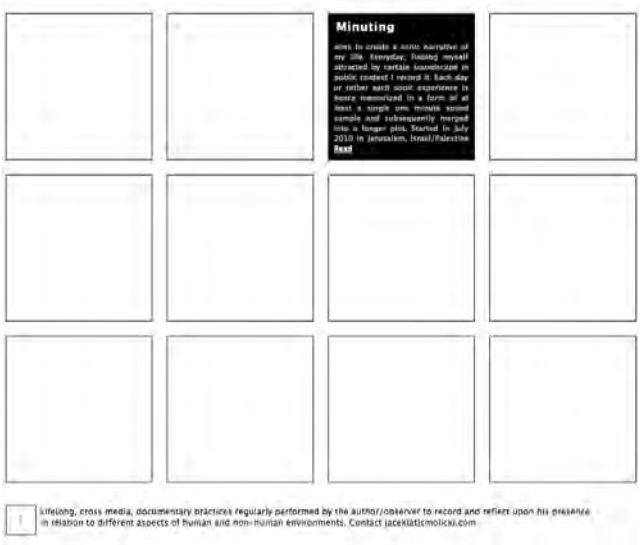

Figure 4 Screenshot of the self-developed website showcasing On-Going projects: www.on-going.net.

other practices within On-Going projects, I see Minuting as not being merely aimed at producing a record, a mediated impression for subsequent archivization, but primarily as a method of witnessing and being in the space more intensely. For instance while binaurally recording a minute I simultaneously listen to the amplified sounds of the surrounding. Through this technological amplification, my own sense of presence becomes amplified.

The On-Going projects are a highly idiosyncratic and subjective set of recording and archiving practices. This idiosyncrasy results from a highly personal array of conditions forming a unique kind of a conduct developed and applied by an individual to track, not all, but selected aspects of life. This idiosyncrasy of the digital record is also reinforced by the fact that the content is uploaded solely on a self-designed website which requires hard coding each time the data is being added [fig.4]. As both the front- and the back-end of the website are not inherited from any third party application or consumer-dedicated platform, the whole archive remains hardly informative and applicable for anyone else than the author. In other words, the possibility that the content becomes (ab-)used by some commercial entities, as it might easily happen with life-logs enabled by popular, consumer-dedicated online platforms and applications, in the case of the On-Going projects' website is drastically limited. While an important component of the content uploaded by people on popular social media is meta-data (contextual information assigned by the very users as well as the owners of the platforms controlling their back-ends and databases where users' data eventually end up), in On-Going projects the meta-data is often removed prior to the upload. For instance in a practice called Self-tracking I apply a GPS clock to record my daily itineraries. The watch is not connected to the cloud or any other external services. The data is downloaded locally and processed into graphical representations (a jpeg format). While for an external observer these representations most probably remain meaningless, for me perhaps not all, but many of them function as triggering images enabling a recall of particular moments and routes, as well as recognition of certain routines in my daily mobility [fig.5]. Thus, such a practice can be seen as a method of encrypting one's personal, bodily data in a way that it cannot be decrypted without the presence of the embedded memory of the very subject that generated the data in the first place.

The programmatic approach to documenting my life can be also seen as a way to counteract an excess of data produced through unstrained and undisciplined data collection practices characterizing modern of incorporating recording and archiving media into one's life.

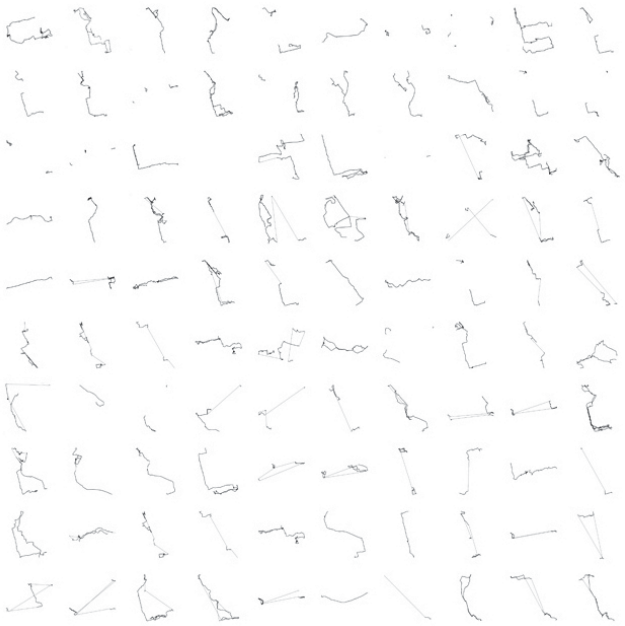

Figure 5 Self-tracking. A compilation visualizing one hundred days of GPS-tracked daily walks. The project has been initiated in August 21, 2010.

Summing up and concluding

Stiegler's study of memory, knowledge and their relation to technology as Mark Hansen suggests can be synthesized into an observation that "human evolves through exteriorizing itself in tools, artefacts, language and technical memory banks" [22]. The technology is not an autonomous addition to the human existence, but quite the opposite - it is its essential dimension. Human evolution does not happen merely in the biological sense, but rather above it, 'by means other than life'; in the dimension of exteriorized functions. In such light, the technology seen as exteriorisation of human functions does not interrupt or violate human evolution but rather intrinsically informs its progression. Similarly Flusser argues that since we rely more on learned than genetic information "the structure through which information is carried exerts a decisive influence on our lives"[23].

In this text I proposed a critical perspective on how we negotiate and articulate various grades of the entanglement with recording and archiving devices in the context of the latest proliferation of automated technologies of capture. As I argued, this very context requires critical, reflective and practical response, which I demonstrated by pointing at my own, life-long artistic project. I believe that the growing pessimism in relation to the direction that the development of media technologies seems to be taking (e.g. increasing data surveillance mechanisms, algorithmic analysis of human behaviours or increasing dominance over and colonization of the Internet conducted by ever fewer large corporations) can be addressed by recognizing, conceptualizing and shedding light on the potential that recording and archiving technologies might reveal if effortfully, attentively and reflectively entangled into individual tactics and practices. Seeing life as happening not *in* media or *through* media, but always already *with* media, let us avoid thinking of media as entrapping one into fixed and imposed relations. In contrast, extending and deepening the focus on *with*, both theoretically and practically, by for instance deploying artistic methodologies, allow more thorough and fruitful exploration of potentialities that reside in ever more easily accessible recording, tracking and archiving technologies of today.

Author Biography

Jacek Smolicki is an artist, designer and researcher currently undertaking PhD studies at the School of Arts and Communication at Malmö University in Sweden. In his research Smolicki explores recording practices conducted by individuals who creatively, subversively and reflectively deploy recording technologies to construct personal and site-specific archives. His interest encompasses practices of sousveillance, lifelogging and field recording studied in the context of the changing nature of the archive. Since 2009 Smolicki himself has been conducting a number of self-tracking practices utilizing variety of available recording media technologies (www.on-going.net).

Smolicki holds his master degrees from the Design Department of Krakow Art Academy, Interdisciplinary Studies at Konstfack University of Arts, Craft and Design as well as Sound Art from Stockholm Academy of Dramatic Arts. He actively engages in exhibiting, conducting workshops and leading seminars (e.g Madrid, Budapest, Krakow and Stockholm). More info: www.smolicki.com

Historical Residue, an Augmented Reality App and the Exploration of the Lost Town of New Philadelphia, Illinois

Jon Amakawa

Assistant Professor, Communications Media, Fitchburg State University
Fitchburg, Massachusetts, United States

jamakawa@fitchburgstate.edu

Abstract

The New Philadelphia AR Tour is an historical mobile app that uses Augmented Reality technology to present the lost 19th Century town of New Philadelphia, Illinois to visitors. New Philadelphia is a United States National Historic Landmark that is historically significant as the first town in the United States to be founded by an African American. After being abandoned in the early 20th Century, however, the site reverted to farmland. Today there are no visibly remaining buildings or artifacts. The app enables visitors to view 3D reconstructions of buildings overlaid onto the current landscape in their original locations. The historical buildings and artifacts are carefully reconstructed based on a collaboration between the author, the United States National Park Service's Network to Freedom Program and archaeologists from the Illinois State Museum. The project represents an innovative model for interpreting historical sites that have traditionally been challenging to interpret, particularly when there is an absence of remaining artifacts. The New Philadelphia AR Tour challenges the notion of what kind of historical site is worth interpreting and what value or historical residue remains when there seems to be little that visually remains. Moreover the project's use of Augmented Reality and its minimal footprint help to address the dilemma often faced by those managing historical sites of facilitating public access to a site at the risk of compromising site preservation.

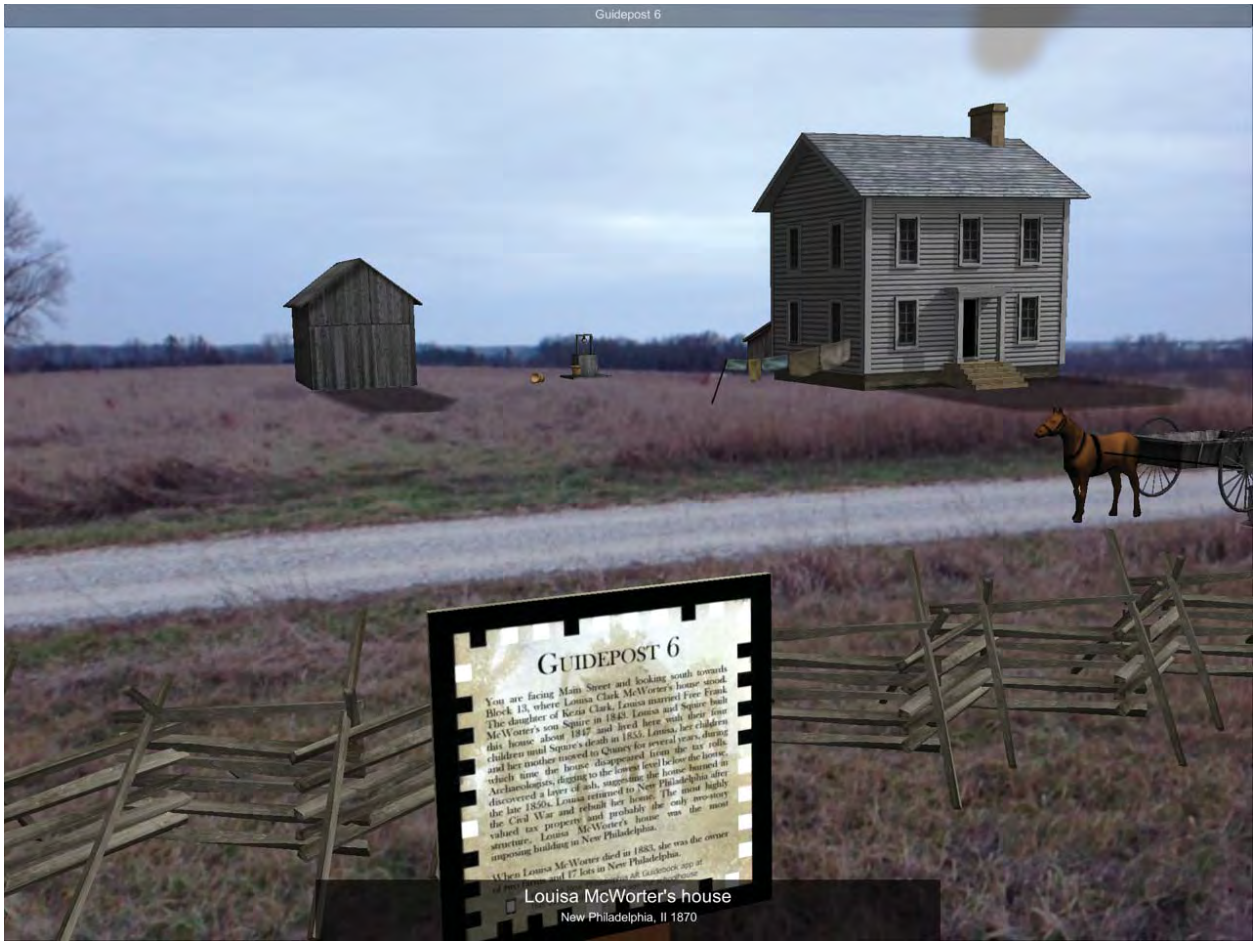
Augmented Reality, Virtual Reality, Games, History, 3D, New Philadelphia, United States National Park Service



Screenshot from mobile device during New Philadelphia App testing

Does an historical site lose its significance or become less worthy of interpretation if there are no surviving buildings? Can visual and multisensory representations give meaning to a bare landscape and ***disrupt*** our notion of which locations have historical value? As a serious game designer and Assistant Professor in Game Design at Fitchburg State University, I am seeking to address these questions through the medium of Augmented Reality in an ongoing project at the New Philadelphia National Historic site. The project involves a collaboration with the United States National Park Service's Network to Freedom Program, the Illinois State Museum and descendants of Free Frank McWorter to create an Augmented Reality app that allows visitors to walk through New Philadelphia, view reconstructed historical buildings placed in their original locations and learn about the history of a lost 19th Century American frontier community.

The story of New Philadelphia and its founder Free Frank McWorter is powerful, even biblical, in its narrative arc—encompassing major themes in United States history including slavery, the Underground Railroad, the American frontier and settlement of the West. In short, New Philadelphia is historically significant as the first town in the United States to be founded, platted and registered by an African American. The founder, Free Frank McWorter, was a slave who purchased his own freedom through money he had earned while being leased as a laborer. Free Frank moved west from Kentucky into Illinois and purchased land which he then surveyed and sold as lots, in the process founding the town of New Philadelphia. Free Frank used the proceeds from those lots to successively purchase the freedom of his wife and later his children and grandchildren, all of whom had remained enslaved in Kentucky.1 Over the course of the mid-19th century, New Philadelphia grew modestly in size as a multi-racial community of whites and blacks peaking around 1870, however, the town was eventually abandoned in the early 20th Century and reverted to farmland (Figure 1.).

The challenge today for historians and educators is how to interpret a site for visitors with little visibly remaining besides the landscape. As the developer of the New Philadelphia AR Tour, and in line with the ISEA Conference themes of ***Disruption*** and ***Residue***, I sought to leverage the historical ***residue*** in New Philadelphia--which in this case is the landscape and terrain. Visitors to present day New Philadelphia are confronted with an uninhabited landscape just as the community's first settler Free Frank. In many ways they are able to experience the site like Free Frank and imagine how they might build a new community. The app builds on that ***residue*** by reconstructing the town and presenting it virtually through Augmented Reality.

As an artist and designer who has dealt extensively with historical subject matter for museum installation-based exhibits (most recently for the Senator John Heinz History Center's semi-permanent exhibit *From Slavery to Freedom*), the New Philadelphia app was my first Augmented Reality project. The app builds on an emerging form of mobile app developed in the area of cultural heritage and digital humanities that enables visitors, to an historical landmark, to appreciate the existing environment while also accessing deeper location-specific historical and cultural information. A recent example of this includes *Ghosts in the Garden*, an audio and location-based interactive that presents the colorful social history of a Georgian Pleasure Garden in Bath, England.[2] Another example is *Jewish Time Jump: New York*, a mobile game that deals with Jewish labor activism in early 20th Century NY.[3] In both examples, users are able to explore both the location and information in a nonlinear manner. This was a feature that I planned to incorporate into the New Philadelphia app early on.

I created the app using the Unity Game Engine which affords all of the 3D interactive graphics capability of a 3D game. In addition, I used a Unity AR package called Vuforia by Qualcomm which enables the project's Augmented Reality feature through image recognition of precisely oriented marker signs. The app uses marker signs located at specific points within the site's visitor path to accurately place historical structures. When visitors view a sign through their mobile device, the app overlays 3D reconstructions of houses onto the current landscape (Figure 2.). The historical buildings and artifacts were carefully reconstructed based on a collaboration with archaeologists from the State Museum. Visitors also hear audio narration and sound effects which serve to recontextualize the existing landscape. A schoolhouse, for instance, echoes with the sound of children playing. As of May 2015, the app reconstructs half of the town and is in a testing phase. A beta version of the app is now available to the public for Android devices at Google Play[4]. An iOS version will be released in September of 2015.

The app also presents the site's less visible historical ***residue*** of archeological artifacts (many of which now reside at the Illinois State Museum in Springfield) buried or recently uncovered in excavations. Visitors can encounter virtual artifacts in the locations that they were found. These artifacts include a metal trivet, most likely created by one of the community's blacksmiths, a William Jennings Bryan campaign button, fragments of school slate boards and pencils, broken dolls and many other items.

One of the challenges in reconstructing a lost historical location like New Philadelphia for the purpose of historical interpretation, was in how to reimagine buildings and artifacts based on varying and limited information. Over the course of the project, I gained access to plat maps of property blocks and recent archeological survey maps (Figure 3.). The sources contained information on building locations and in some cases the building footprints. However, information on the buildings' exteriors varied from nonexistent to rough hand-sketches drawn from memory by previous inhabitants as was the case for case for the Louisa McWorter House (Figure 4.). As a result, in consultation with historians and archeologists from the Illinois State Museum, I

[4] https://play.google.com/store/apps/details?id=com.amakawa.newphiladelphia

decided to represent those buildings for which I had information on the exterior appearance in high detail. Other buildings that lacked information, but for which we knew existed in particular parcels, were represented with "graybox" house models. In this way, I devised a system for presenting historical artifacts in a way that reflected the veracity and degree of source information.

As an active archeological site, the New Philadelphia project seeks to address issues relating to historical preservation and interpretation that can apply to a number of other historically significant locations. For example, how can an historical site, in which archeological work is planned or ongoing be interpreted or presented to the public without damaging and compromising the site? The building of ghost structures (a proposal still being considered) has the potential to disturb the soil and destroy remaining artifacts. While sites like New Philadelphia can improve their funding prospects by expanding public access, the very means of historical interpretation can endanger or compromise the site itself. An augmented reality tour on the other hand can leave a minimal footprint as it requires small signs for positioning virtual buildings.

While New Philadelphia on the surface may appear to be an isolated rural landmark with limited appeal for visitors, it has the potential to connect 2 important historical sites--Hannibal, MO (the birthplace of Mark Twain) and Springfield, IL (the home of Abraham Lincoln). New Philadelphia is positioned between both locations on Illinois' Route 72. With adequate interpretation, New Philadelphia has the potential to help create a historical corridor for visitors both geographically and thematically given the significance of both Mark Twain and Abraham Lincoln to the African American experience.

Finally, as Frank McWorter's direct descendant Dr. Gerald McWorter, a Professor of African American Studies at the University of Illinois at Urbana–Champaign noted at a recent field test of the App, the history of New Philadelphia can serve as a beacon of hope for both African-Americans and Whites in its experience of peaceful co-existence and acceptance (Figure 5.). This is especially pertinent today in the wake of Michael Brown in Ferguson (less than a 2 hour drive away from the site) and Eric Garner in New York City.

Abstract

Ethnography is an inductive methodology that generates its own object of study through a series of encounters, while laying bare the modes of construction that are used to do so along the way. The result, the ethnographic media text, serves as the canvas for a subjective reflection on culture, but it is also often its own art piece that can take the form of a literary work, an illustrated catalogue, a collection of photographs, a video or an installation. What happens when ethnographic works are made with electronic media or when they are interactive? Does the use of digital research tools disrupt the making of ethnographies or does it trigger the emergence of new possibilities for ethnographers? Are some methodologies better suited to addressing the new ontological conditions of emerging digital-material research tools? By presenting three new media ethnographies that have been produced with a multi-sited design approach, our article suggests that this particular methodology might offer significant advantages when conducting ethnographic research involving new media technology. These examples of practice aim to show how the affordances of electronic art can better support an object of study that is complex in scale, multi-dimensional, shifting, and multiply situated.

Keywords

Multi-sited ethnography; research-creation; inductive approaches; digital cultural heritage; intangible heritage; Aboriginal research.

Introduction

As Tyler remarks, *in lieu* of providing scientific insights or political understandings, ethnography is a form of writing that engages in a process of negotiating and renewing ethical visions of the world. [1] Ethnographers achieve this by using three rhetorical strategies: *descriptive* (by presenting subjective observations on people and cultures), *interpretive* (by highlighting the relationships between these observations), and *reflexive* (by exposing the constructed nature of the relationship between the observer and the observed).

Ethnography is an inductive methodology that generates its own object of study through a series of encounters, while laying bare the modes of construction that are used to do so along the way. This implies that it is, as often as not, an open-ended exploration which consists of carefully documenting, not only a set of observations, but also a research process that will itself be submitted to scrutiny.

In cultural anthropology, the ethnographic text serves as the canvas for a subjective reflection on culture, but it is also often an art piece that can take the form of a literary work, an illustrated catalogue, a collection of photographs, a video or an installation; it has the dual status of research outcome and cultural product – *the research-creation*. As such, it can go beyond describing, interpreting, and reflecting on a given understanding of culture to provide valuable knowledge on the material practices of art-making. This implies that there may be a body of ethnographic inquiry that undertakes similar research objectives and strategies as do some research-creation methodologies in the arts.

But what happens when ethnographic works are made with new media technologies or when they are interactive? What are the ethical implications of such forms of artistic production? What opportunities and challenges arise when ethnography is practiced within the parameters of technical culture? Does the use of digital research tools disrupt the making of ethnographies or does it trigger the emergence of new possibilities for ethnographers? Are some methodologies better suited to addressing the new ontological conditions of emerging digital-material research tools? How could they best support new media creative practices?

Based on the assumption that some ethnographic texts may also be understood as research-creation projects, this paper suggests that a multi-sited design approach to making culture might offer significant advantages when conducting ethnographic research involving interactive new media technology. To support this claim, the first part of this paper will expound multi-sited design ethnography as a methodological tool recently introduced to the study of human-computer interaction (HCI), while the second part will provide three examples of practice in new media. The paper will conclude with a discussion on multi-sitedness.

A Multi-Sited Design Approach to New Media

All the authors of this paper are affiliated with the media anthropology lab of a HCI design department in which researchers conduct multi-sited design ethnographic research by building and maintaining *epistemic relationships* with informants encountered during fieldwork. Multi-sited design is a methodology recently introduced to the field of HCI by Dourish and other practitioners. [2]

This emerging HCI constructionist methodology combines two approaches: first, the practice of multi-sited ethnography as theorized by Marcus, [3] second, the tradition of participatory design that originated in Scandinavia. [4]

Multi-Sited Ethnography

Multi-sited ethnography is an interdisciplinary critical approach conducted in multiple, distributed, and shifting (micro) locales to later be analyzed against the contours of these sites' overarching (macro) context. [5]

While traditional ethnography typically sees one or sometimes several ethnographers describe a single, well-circumscribed site, in a multi-sited approach, one or more researchers can be sent to observe each of the fields in which stakeholders might play a role in the creation, production, distribution, and reception of a social structure.

Practically speaking, this means that fieldwork is conducted in a distributed environment made up of multiple sites. By moving in and out of these sites, the ethnographer can come to know the actors, customs, routines, practices, and idiosyncrasies tied to each one of these locales. This means that rather than studying a single location as the product of global phenomena, in a multi-sited approach:

> "*the researcher travels to multiple sites, following various pathways in order to assemble a narrative [which] is intended not to give the ethnographer more cases…but to expand a single case beyond its immediate location."* [6]

By documenting observations, reviewing them, culling them, and drawing them together, one can get a sense of how an overall cultural structure functions. Because the mode of construction is to follow a single thread across multiple sites, multi-sited ethnography ostensibly produces "a distinctly different sense of 'doing research'." [7]

Participatory Design, Participatory Development

While Participatory Design (PD) is a set of methods used in HCI to engage people within a workplace, organization or community of practice in order to participate in the design of the computer systems they use in the everyday, the related approach of Participatory Development more broadly aims to "involve local stakeholders in development projects", notably in developing regions or countries. [8]

Perhaps these two distinct approaches point to what some authors refer to as a "drift in focus from participation as the means to a political agenda to participation, as a means to a smooth development and implementation, or sometimes as an end in itself." [9] What they have in common, however, is that both are inherently about the politics of design. Who participates in the design process?

Anthropologists tend to be familiar with collaborative approaches. For instance, collaborative ethnography aims to go beyond the solipsistic bias of participant observation, [10] while participant-generated ethnography takes a pragmatic stance towards the problem of gathering data in large-scale systems by actively involving informants. [11] As a result, many ethnographers using new media technology share a similar set of concerns as designers using PD.

New Tools, New Platforms, New Ethnographies, New Research-Creation Practices

The work that has laid the foundation for multi-sited design argues that the transnational character of everyday life in today's world system presents designers with unique challenges when making interactive media artifacts. [12] Multi-sited design is thus proposed as a tool that can effectively meet the conditions of contemporary life whereby "technologies are appropriated into local cultures and yet shaped by transnational politics and negotiations". [13]

It is for this reason that this emergent methodology has proved particularly well-adapted for our research. Multi-sited design allows us to each construct our research field as its own network of sites. This configuration can include physical, virtual, and imagined sites of representation. [14]

Practically, this means being able to relate and simultaneously explain phenomena, which occur within the new experiences of time and space enabled by connectivity and human-computer interaction. Whether events take place in real time or asynchronously, and whether they are situated in the hyperlocal or are mobile in global networks, multi-sited design offers ethnographers new tools to describe and interpret. Furthermore, the extant literature argues in favor of making the act of design part of the investigation: multi-sited design is thus a research-creation methodology:

> *"we attempt to build a multisited analytical framing in which design is central to both our research method and analysis, with a commitment to positioning design and ethnographic writing purposefully against exocitization or center-periphery binaries and toward empathetic connection"* [15]

Producing ethnographies with multi-sited design gives researchers the flexibility to follow an object of study that is complex in scale, multi-dimensional, shifting, and multiply situated. Because our ethnographic texts are produced with interactive digital technologies, it also allows us to make better use of new media's specific affordances.

Three New Media Ethnographies

The following sections present three examples of practice that demonstrate how the multi-sited design approach can be applied to the production of new media ethnographies.

While in some cases, the sites may be multiply situated in terms of their geographical locations, in other cases, their multi-dimensionality may be manifest in how they assemble physical, virtual, and imagined sites of representation. For this reason, each of the three new media ethnography is described according to its genesis, its contribution to knowledge, its methodology, and its specific sites.

Appalachian Punks: A Multi-Sited Ethnography of Changing Traditions in the Era of the Interactive Documentary (Rachel Ward)

While folklore studies of Appalachia have typically focused on the documentation and archiving of traditional music, the first example of practice presented in this paper explores the global permutations and transformations of "traditional" culture as facilitated by new access to digital archives of cultural heritage. In this research-creation project, ethnographic inquiry is conducted through the parti-

Figure 1. *Performance by Appalachian "punk" band*, 2013, Rachel Ward, photograph, ©2013RachelWard.

cipatory development of an interactive documentary that will be produced through research and collaboration with the Smithsonian Centre for Folklife and Cultural Heritage, Library of Congress, interactive documentary producers, Canadian scholars and musicians, and community stakeholders from the northern Appalachian regions, specifically Pennsylvania, West Virginia, Pittsburgh and Brooklyn.

Genesis of the Research

In 2013-2014, Rachel Ward traveled throughout northern Appalachia filming a documentary short entitled "Appalachian Punks: A Resurgence of Tradition." This film explored the renegotiation of traditional mountain music from a young, contemporary punk aesthetic. A key component of this work is the in-depth interview that was conducted with Lester McCumbers, one of the last living traditional Appalachian fiddle players. During this interview, he explained that over 30 years ago, a man from the Library of Congress came to record him, but neither he nor his family had since been able to locate the recordings.

The Appalachian Punks research-creation project begins with the digital return of this "lost song", by tracing its beginnings from the instruments of West Africa and ancient European folk songs, to the archives in Washington D.C., to tape, CD, MP3, to the punk bands that are now performing these songs in Brooklyn and uploading their videos to YouTube™ as seen in Figure 1.

Research Contribution

From a theoretical standpoint, this project builds on scholarship exploring the implications of recent developments in the field of interactive documentaries and the UNESCO 2003 Convention for the Safeguarding of Intangible Cultural Heritage. It poses the question: how do interactive documentary projects create access to collections and help (or hinder) safeguarding intangible cultural heritage?

Although there is significant research in the realm of digital cultural preservation and visual documentation of Appalachian music, there is a gap in the literature that explores the use of new interactive documentary forms as tools in the dissemination and preservation of culture, or in the making of a collaborative, "public anthropology". As a platform that is becoming integral to our understanding of the documentary as a genre, interactive documentaries utilize "action and choice, immersion and enacted perception as ways to construct the real, rather than represent it" [17]. Importantly, from an interdisciplinary perspective, this project addresses the call for the use of Marcus's multi-sited method applied to the field of human-computer interaction design research. [18]

Research Methodology

Following her fieldwork in the Appalachian region, where struggles with poverty, illiteracy, and unemployment are pervasive, Rachel's dual roles as field-researcher and collaborative media producer have allowed her to identify community desires related to heritage preservation, technological training, and education. The culmination of her background and training in anthropology, new media, and film, in combination with her community connections in this geographic region, have uniquely positioned her to undertake an original research-creation project that is both culturally appropriate and accessible in collaboration with folklore scholars, curators, archivists, musicians, documentarians, archaeologists, historians, and local leaders.

Rachel is tracing the historical, transnational, and virtual flow of this music across global and digital borders using multi-sited ethnography. This approach calls for the "tracking" of a single object, metaphor or allegory across sites of interest. [19] In the context of this project, the path of one song is "tracked" across Scotland, Ireland, France, England, West Africa (Mali and Senegal), Canada, and the United States via archives, communities, and virtual/hybrid spaces. This music exists in distinctive styles throughout North America: the "Scottish" tradition of Nova Scotia, "prairie style" of Saskatchewan, French-Canadian sounds of Quebec, as well as the traditional Appalachian and Francophone Cajun in the southern USA.

The project explores regional variations based on European settlement and the syncretic blending with First Nations and African American styles. For instance, the signature "Red River Jig" dance of the Aboriginal Métis (residing in Canada and the northern United States) is clearly traceable to the fiddle music introduced by French fur traders in the 1600's and the pow wow dance tradition. [20] This data is then published in a web-based, user-navigable interactive documentary, in which the viewer can trace the movement of a song from its African/Aboriginal/European origins to a live-stream of Brooklyn bands uploading their "punk" reinterpretations on YouTube™. The user can pause at specific interactive nodes for an in-depth exploration of multimedia sites containing film clips, audio, interviews, photographs, and archival materials.

Research Sites

This interactive documentary combines theory and praxis as a visual representation of transdisciplinary research related to globalization, digital repatriation, intangible cul-

tural heritage, traditional knowledge (TK) transmission, and participant production as a research method.

Through collaborative research, Lester's "lost song" is traced as a metaphor for cultural knowledge and globalization, while addressing important (yet little known) African, First Nations and multi-cultural contributions. Distinct from folklore studies that focus solely on documentation, here, music is utilized "as a tool of discovery to question value systems – not just the differences between genres or subjects, but how the divides themselves are constructed and negotiated". [21] At the local level, this research will make a significant contribution to the creation of a digital resource that attends to local needs by focusing on the "value of meaningful community participation in efforts to safeguard their digital cultural heritage". [22] This type of methodological advance in the field of digital, participatory, and interactive documentation will reinforce the development of visual, collaborative, and interactive methodologies as novel fields of scholarship.

New Media and Intangible Cultural Heritage: Digitization, Documentation, and Circulation of Uyghur Dastan (Aynur Kadir)

The second example of practice presented in this paper is a media archive co-produced by the Making Culture Lab, the Xinjiang Folklore Research Center, Uyghur folk artists in Khotan Village, Xinjiang, and youth participants from the Uyghur community. Dubbed the *Digital Uyghur Dastan Archive Prototype*, the end product is to be designed in collaboration with community members through a slow, ongoing iterative design process. The purpose of this research-creation project is to use digital media to give tangible form to an intangible cultural heritage in China, which is increasingly endangered.

Genesis of the Research

China's vast northwest region, Xinjiang Uyghur Autonomous Region, has a rich and colorful history and has long been a unique blend of cultural influences. For hundreds of years, it was a vital link in the famous Silk Road, the overland trade route that connected China with Europe through Central Asia. Xinjiang's Uyghur people represent the easternmost expression of Turkic Islamic culture.

One of the largest traditions among Uyghurs includes *Dastan*, epic oral narratives which use both poetry and prose to dramatically recount events from the past. Dastan embrace a wide range of themes: not only the Uyghurs' ancient "heroic age", but also religious tales, love stories, and historical events like farmer revolts. Uyghur folk Dastan are of great length and complex subject matter, and are musically and instrumentally demanding. Dastan are played and performed by *Dastanchi*, skilled and specialized folk artists. They display their talents on market days and during traditional festivals. Dastanchi accompany themselves on traditional Uyghur instruments like the *rawap*, *dutar*, and *tembur*, while simultaneously adopting the roles of numerous characters during poetic and narrative Dastan verses.

However, as modernization continues to transform Xinjiang, Uyghur Dastan are rapidly vanishing from public view. Dastanchi, nearly all of them elderly, are now facing significant challenges to the sustainability of their ancient craft. In the past decade, researchers and students from Xinjiang Folklore Research Center collected an archive of over one hundred magnetic audiotape recordings and more than fifty videotapes of different sizes and formats documenting the Dastan. This collection needs proper organization and archiving in order to be digitized and returned to the community.

This project is especially urgent since only a dozen Dastanchis are still alive and available to record the most recent Dastan versions and to determine ethical treatments and cultural protocols for digital archiving. As a result, important questions regarding representation, copyright, intellectual property, ownership, and control of documentation and circulation in digital form must be addressed immediately for this knowledge to be transferred across time and space, for the benefit of future generations and publics around the world.

Research Contribution

The need to safeguard intangible cultural heritage around the world has garnered international awareness in recent years as a growing number of traditions have been deemed endangered. [23] This research focuses on the blending of theoretical, practical, and ethical issues in the collaborative design of a digital archive for intangible cultural heritage in order to assist in the safeguarding of Dastan.

The development of digital media technology has facilitated new ways of preserving and protecting such cultures. [24] For example, digital archiving and participatory filmmaking are seen as important tools for the documentation and revitalization of Aboriginal languages and cultural practices. [25] This nexus of culture and technology must take into account local cultural protocols for ownership and circulation, and Indigenous curatorial approaches. [26]

A number of media-specific questions arise from this research-creation project: How can digital knowledge sharing be facilitated through multi-sited ethnography and participatory design? How do existing cultural protocols and social, national concerns shape access and control of traditional knowledge in virtual space? What are the current protocols in which Uyghurs preserve and transmit their cultural heritage? How can we apply these understandings to represent intangible cultural heritage in a digital world while utilizing community-based approaches? What kind of challenges and opportunities are associated with media production, and archiving within the Uyghur context? What are the possible categorizations, meta-data standards, and technical treatments for media materials in the archiving process? What are the most appropriate ethical frameworks for the circulation of Uyghur digital heritage?

This research aims to explore emergent theoretical and practical issues regarding ownership chronologies, continu-

ity of traditions, repatriation potentialities, and to collaboratively negotiate opportunities and challenges associated with the digitization and return of cultural heritage. The outcome and level of access will be determined through collaboration process and will highlight usage of cultural protocols and national concerns as defining features of an interactive system. This research will draw attention to the importance of understanding traditional protocols for the handling and care of intangible culture, and how these may be adapted for use in preserving digital versions of culture.

Finally, this study expounds on how traditional cultural gatekeepers think and have functioned in the past and how their role may evolve in the future. The archive development process – understanding what a digital archive means at the community level – will make a significant contribution to research by addressing a gap in this area of research and by providing a platform with the potential to connect later generations with their culture in a sustainable way.

Research Methodology

As a media maker and Uyghur community member, Aynur Kadir is uniquely situated to undertake a research-creation project that involves developing and critically analyzing a digital archive prototype for the audio-visual materials of Uyghur Dastan. Her research plan begins with an investigation of the discourse surrounding the mobilization of Uyghur identity. It is to be conducted within the context of her role in the design and development of a community-based, sustainable web-based digital heritage prototype for and in collaboration with the Uyghur community.

The Digital Uyghur Dastan archive prototype is then to be designed through an iterative design process with community members using multi-sited ethnography and collaborative participatory design methods. These research strategies are needed because a single-sited ethnographic approach would not be a suitable tool to effectively produce and evaluate this collaborative digital archive system.

The reason for this is multifold. First, Aynur intends to conduct traditional anthropological fieldwork in different villages of Xinjiang region with collaboration with folk artists. Second, she will also categorize and organize physical/material archives in Xinjiang Folklore Research Center, China. And third, the post-production and media producing will take place in the Making Culture Lab, Canada.

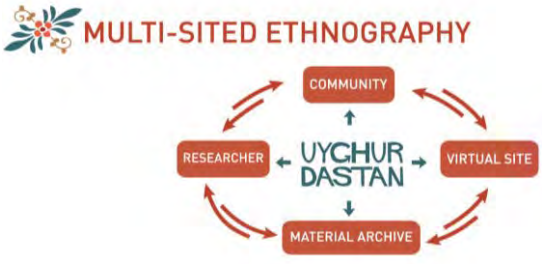

Figure 2. Diagram of the multi-sited design research model used in *Digital Uyghur Dastan Archive Prototype*, ©2013AynurKadir.

During the collaborative process, Aynur will create the digital archive virtual site, which is open to community and researchers to add continuous data/metadata of latest related Dastan materials. This virtual site will be another important "field site" that will be used to reproduce/represent traditional cultural knowledge. As represented in Figure 2, in this project, Uyghur Dastan is therefore the key location that connects different geographical communities, research labs, and virtual sites created by researchers and community together.

The interdisciplinary practice of multi-sited ethnography will allow Aynur to mobilize her cultural and academic identities and responsibilities during the research and production of this digital media research-creation project. In her quest to find answers to the ethical, practical, and theoretical questions raised by her research, she will also "follow" the Uyghur Dastan in different sites.

Based on collaborative participatory design experience and multi-sited ethnographic fieldwork, Aynur will trace representation, ownership, and intellectual property issues surrounding Uyghur digital cultural heritage. Not only will attention be drawn to the important role of digital technologies in the preservation and revitalization of culture but questions and concerns about how to best represent intangible expression in digital space and intellectual property issues in cultural heritage will also be explored. In summary, Aynur will set out to investigate both global and local theoretical, ethical, technical, and practical considerations for the Uyghur digital archive context.

ʔeləẃkʷ – Belongings: A Tangible Table in *c̓əsnaʔəm, the city before the city* at the Museum of Anthropology (Reese Muntean)

ʔeləẃkʷ – Belongings is an interactive tangible tabletop activating replicas of Musqueam belongings excavated from the *c̓əsnaʔəm* archaeological site along the banks of the Fraser River in what is now known as Vancouver, British Columbia. These ancestral belongings, along with contemporary objects of significance in Musqueam life, are placed on the tangible table to access cultural knowledge and stories about the First Nation's long history of fishing as well as its practice today. The table was designed by faculty and students at Simon Fraser University's School of Interactive Arts and Technology's Making Culture Lab and Tangible Computing Lab along with curators from the Museum of Anthropology (MOA). The table was installed in MOA as part of *c̓əsnaʔəm, the city before the city*, an exhibition hosted by three institutions (Musqueam Indian Band, the Museum of Vancouver, and MOA) in an exploration of one of largest ancient village sites on which Vancouver was built.

Genesis of the Research

Building on an existing research relationship with the Museum of Anthropology, The Making Culture Lab approached *c̓əsnaʔəm, the city before the city* curators Jordan Wilson and Sue Rowley about the possibility of contrib-

uting an interactive media-focused project to the exhibition. After consultation with the curators and representatives of the Musqueam Indian Band, an interest was confirmed in developing a tangible computing application to convey the complex significance of belongings—known by archaeologists as artifacts—for contemporary Musqueam people and their continuity with ongoing everyday practices. Making Culture Lab Researchers partnered with Dr. Alissa Antle's Tangible Computing Lab to begin an iterative co-design process with curators Rowley and Wilson that would merge interaction design research with critical museological approaches to representing archaeological collections and their contemporary lives as 'belongings'.

Research Contribution

This research builds on the movement of repatriation and digitization of cultural objects as well as the reviving, archiving, and again, digitizing, of intangible heritage. Processes and protocols are developing for sharing traditional knowledge digitally within a community while retaining the cultural customs around such knowledge, and institutions are opening their own archives for input and annotation from community members and local experts. [27] *ʔeləẃkʷ – Belongings* was similarly developed using values-led participatory design methods to highlight Musqueam values and voices along with the goals of the museum curators in the creation process. [28] This work further explores how interaction design and tangible user interfaces can be used to share cultural objects and intangible heritage with museum visitors as seen in Figure 3.

Research Methodology

ʔeləẃkʷ — Belongings represents a multi-sited approach to the collaborative design of an interactive media installation for a major Canadian museum. Reese Muntean from the Making Culture Lab was involved in the development of the tangible table as the project manager. By taking notes, documenting meetings, and overseeing the collaboration, she was able to observe the design process of the tangible table. From the overall goals of the project as expressed by the individual team members at the onset to the installation of the table in the exhibition, Reese was able to witness the entire design and document much of its process.

Reese is now part of a team who is studying the table in the museum and its reception by museum visitors. Visitor interviews and observations are being conducted to access the use of the tangible table technology in the museum setting and whether or not the visitors received the messages that the curators intended.

Research Sites

Reese's research sites can be understood as sites of "Belings" and sites of "Knowledge" (although these concepts are inseparable from one another). We begin by describing "Belonging Sites". *ʔeləẃkʷ — Belongings* uses physical replicas of both ancient belongings from the burial site at c̓əsnaʔəm as well as contemporary belongings to teach

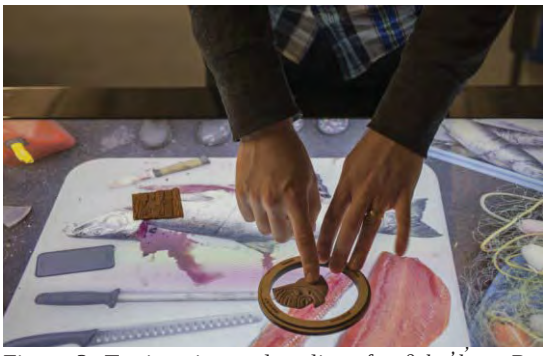

Figure 3. Testing ring and replicas for *ʔeləẃkʷ – Belongings*, 2014, Reese Muntean, Digital Photograph, ©2014ReeseMuntean.

museum visitors about the technological and traditional knowledge from Musqueam history and how that knowledge persists as part of the culture and day-to-day life.

The belongings embody a long history. For example, one of the replicas is cast from an original net weight housed in MOA as part of the Lab of Archeology's (LOA) collection from c̓əsnaʔəm. The net weight was originally used over one thousand years ago to place fishing nets. Excavations beginning in the late 1880s removed human remains and cultural objects from the village's burial site, and this net weight was one such item – along with hundreds of net weights – that ended up in the museum.

In 2010 MOA, Musqueam Indian Band, Stó:lō Nation/ Stó:lō Tribal Council, and U'mista Cultural Society launched the Reciprocal Research Network (RRN), partnering with other cultural institutions to bring the net weight and artifacts online and accessible to the community as well as researchers. Using the RRN website, collaborators can work together on projects, viewing, tagging, and commenting on items held by the partner institutions. The designer and curators of the tangible table used the RNN to access information about the net weight and other belongings, build prototypes, download images, and select final belongings from which to create molds for the replicas.

After viewing the original belongings in MOA and receiving permission from Musqueam, molds of the belongings were then made. Lastly, each belonging exists in the code of the table, and when museum visitors place the replicas on the table, that information is shared.

Other research sites can be called "Knowledge Sites". The traditional knowledge and intangible cultural heritage transmitted though the table was relayed to the design team from the Musqueam Indian Band through the MOA curators. Throughout the process, the designers made every attempt to implement and imbed the cultural values, as the designers understood them, into the design of the table, into the activity of designing the table, and all related documentation. Examples include the use of the term belong-

ing, earning knowledge, and the documentation and implementation of Musqueam's hən̓q̓əmin̓əm̓ language.

The term *belonging* was applied to all of the artifacts from c̓əsnaʔəm, as the Musqueam people still see the ownership of these items as remaining with the people who originally created them; these are the belongings of their ancestors. The term has been adopted by the design team and used in all discussions, meetings, and project-related writing and research.

Another example is the idea of earning knowledge. This concept was incorporated into the activity design of the table. For each of the twelve belongings, a visitor must learn about different aspects of the belonging, including basic information (what it is, what it does, and the name in hən̓q̓əmin̓əm̓), how it connects to Musqueam fishing technologies (incorporating the fish preparation image that is displayed on the table), and how it relates to contemporary issues in Musqeaum culture (which matches the ancient belonging to a contemporary).

Lastly, designers took care to ensure hən̓q̓əmin̓əm̓ terms and Musqueam language preferences were translated correctly into the digital form of the project and documentation. hən̓q̓əmin̓əm̓, traditionally a spoken language, uses the North American Phonetic Alphabet for writing which is often difficult to render properly on computers since many fonts do not include the necessary glyphs. Musqueam approved an abbreviation of c̓əsnaʔəm, which was used in standardizing file names for the digital archive of the project documents as well as in the code written by the tangible table programmer.

This constellation of sites – physical and virtual representations of belongings and knowledge – articulate the multi-sited collaborative interaction design process and its reception in a major cultural heritage institution.

Conclusion

After having expounded multi-sited design ethnography as a new methodology in HCI research, this article presented three new media ethnographic works that serve as contemporary explorations of multi-sited design. Each of them was described as its own research-creation process, which begins with a clear intention that becomes the trackable thread of the project and expands into multiple research sites. By doing so, this article set out to show that multi-sited ethnographers craft their sites as they go, guided by the encounters they make along the way. Tracing their object of study becomes a means to make and express the relationships between who and what they encounter.

In Rachel's ethnography, the multi-sited approach allowed her to describe the interplay between situated physical sites and online virtual sites of representation. In Aynur's project, since the archive has not yet been created and may never be created for political reasons, the sites are physical, virtual, and imagined; one could say the archive is a latent site. And finally, in Reese's work, the sites are both tangible (belonging sites) and intangible (knowledge sites). Here, the multi-sited design approach supports knowledge transfer by connecting these sites to one another, as well as through interactions between stakeholders.

All three of these projects highlight how multi-sited design uses digital-material research tools to engage in a narrative mode of knowledge production that experiments with today's augmented configurations of time and space. At a moment in which the majority of ethnographic documentation and representations are born digital and take on multiple lives and forms in virtual spaces [29], we view multi-sited design as a promising methodological direction for the creation and evaluation of these works. Further, as digital forms of ethnographic representation are increasingly intersecting with art and design initiatives – for example, see the work of the curatorial collective *Ethnographic Terminalia* [30] [31] – we aim to make a contribution to a growing movement in anthropology that values research-creation as scholarly praxis.

Author's Biographies

Dr. Kate Hennessy is an Assistant Professor specializing in Media Anthropology at Simon Fraser University's School of Interactive Arts and Technology (SIAT). Her research explores the role of digital technology in the documentation and safeguarding of cultural heritage, and its representation and exhibition in new forms. She is the Director of the Making Culture Lab at SIAT, where she oversees the research of the four graduate students who have co-authored this paper.

An interdisciplinary scholar, Claude Fortin is a doctoral candidate at SIAT. She applies a multi-sited design methodology to research that aims to help bridge the gap between the diverse stakeholders involved in the design of architectural-scale urban technologies.

Aynur Kadir is an ethnographic filmmaker and doctoral candidate at SIAT. She holds a Bachelor's degree in Education Technology from Xinjiang Normal University and a Master's degree in Folklore Studies from Xinjiang University.

After obtaining her undergraduate degree in Photography & Imaging and East Asian Studies at New York University, Reese Muntean is poised to complete her Master's degree at SIAT.

Now a doctoral student at SIAT, Rachel Ward completed her Master's degree in Social Anthropology at The London School of Economics in 2010 and a degree in Visual Anthropology at the Australian National University.

Abstract

Augmented Asbury Park is a free mobile experience created by the authors and their collaborative team, which involves the reconstructions of key historic landmarks in augmented reality on the Asbury Park boardwalk in Asbury Park, New Jersey, USA and off-site. The project invites people to disrupt their present experience by using their own mobile devices and locations to interact with digital representations of historic structures. *Augmented Asbury Park* superimposes interactive 3-D history on the present using augmented reality (AR) technologies, including both geolocation-based and vision-based technologies.

Keywords

Augmented reality, mobile technologies, GPS, locative media, community mapping, digital three-dimensional design, interactive design, virtual architectures, psychogeography, memory

Project Summary

How many times have you seen someone gesture at an empty space like a parking lot as a means to describe what was once there? *Augmented Asbury Park* is a free mobile experience involving the reconstructions of key historic landmarks in augmented reality (AR) on the Asbury Park boardwalk in New Jersey and off-site. The project empowers people to disrupt their present experience and connect it with the past by seeing digital 3-D models of past structures and buildings overlaid on top of their mobile device's camera screen. Frequent visitors to the boardwalk remember the old sites and have the opportunity to share their memories with new visitors. And new visitors have an innovative way of interacting with the history of the site.

One example of this is the digital 3-D model of the wreckage of S.S. Morro Castle from 1934 seen in Figure 1, which we reconstructed in a 3-D modeling environment using photographs provided to us from the archives of the Asbury Park Public Library. We used geolocation-based augmented reality to place the model where the wreckage was roughly located.

Asbury Park was one of the most prominent Jersey shore resorts from the late 1800s to the 1960s. It was a hub for Boardwalk entertainment and hundreds of hotels were frequently filled to capacity. All of this started to fade through 1970s leading to closure and dismantling of the majority of sites in the late 1990s and early 2000s, including two famous carousels. Guided by the community's sense of cultural loss and because we believed that, "AR can serve as a historic documentation…a reminder of people and culture of the past," we developed this collaborative project in 2013 with the intent of showing people what the Asbury Park boardwalk used to look like. [1]

We began by doing research on the history of the most famous locations by making connections with local historians and the Asbury Park public library.

Figure 1. Still image from camera of mobile device showing digital 3-D model of wreckage of S.S. Morro Castle from 1934 placed near Asbury Park beach in geolocation-based augmented reality.

After showcasing our initial explorations at World Maker Faire New York 2013, we ran a successful Kickstarter campaign. [2] Subsequently, we did more research, constructed and textured digital 3-D models with collected photographs, and using AR, we put a digital reconstruction of the boardwalk carousel back in the carousel house.

From the initial project success, we were invited to give a talk about the project at TEDxNavesink 2014. [3] Following the talk, we finished placing our digital 3-D assets on the Asbury Park boardwalk using geolocation-based AR. In addition, we provided on-site free tours over the summer of 2014 where people were able to experience these models through their mobile devices. The project is now available for free on-site and on the project website at www.augmentedasburypark.com. [4]

Inspiration

In today's society, there is a pervasive sense of cultural and historical loss. Our cities are sites of constant change. In the world where bottom-line seems to dictate what history and culture remains preserved, people often experience a sense of longing for what once was. In our interaction with Asbury Park residents and visitors, we listened to how important these places were to their collective memories.

We began by asking ourselves, "How can we help preserve these memories? And how can we use AR as a form of historic documentation that is directly related to the physical sites in which those memories were created?" As Dan Collins points out in his ISEA 2013 paper, "[Locative media] technology enables experiential mapping and geospatial annotation to produce online applications that support geographically 'located' communities." [5] Later in his paper, Collins states, "The strategy [of community mapping] can reveal the stories of a place that remain invisible to the casual observer." [6] We decided to explore using AR technologies and locative media, because of their abilities to disrupt the present by connecting people with meaningful information both spatially and geographically on a personal level.

Research Process

To begin our research, we drove to Hatfield, Pennsylvania to visit the Philadelphia Toboggan Company (PTC), the original manufacturer of Carousel No. 87, which has become known as the Asbury Park Casino Carousel. In 1932, PTC produced and delivered the carousel to the new Asbury Park Carousel House. The Carousel House was built between 1929 and 1930 as a part of a larger boardwalk redevelopment after the two devastating fires of 1927 and 1928. Warren and Wetmore, the two New York architects known for designing Grand Central Station, designed the Carousel House. [7] Built to fit exactly within Warren and Wetmore's new building, the PTC carousel was graced with masterfully carved wooden horses. In further research, we discovered that the Asbury Park Casino Carousel was moved from Asbury Park to Myrtle Beach, South Carolina in 1992. It is now in a small amusement park called "Family Kingdom." We drove to Myrtle Beach to shoot many photographs of the carousel, seen in Figure 3.

Figure 3. Photograph of Carousel No. 87 at Family Kingdom in Myrtle Beach, South Carolina.

Subsequently, our collaborative team constructed digital 3-D models of the carousel in a 3-D modeling environment and textured the models with the photographs collected from that trip as seen below. Each digital 3-D asset was

Figure 4. Image of digital 3-D model development of the Asbury Park Casino Carousel.

created in a very similar manner to a 3-D game design asset; each model consists of a series of triangulated polygons. We focused on reducing polygon count in order to decrease the load time of the experience on mobile devices. Also, we optimized the images that were applied to the 3-D models to decrease load time as well.

As seen in Figure 5, we placed a digital reconstruction of the Asbury Park Casino Carousel back inside the Carousel House using geolocation-based AR. Anyone with a smartphone and the free mobile app Junaio, created by software developer Metaio, can walk up to the Carousel House and see the model of the carousel in the space.

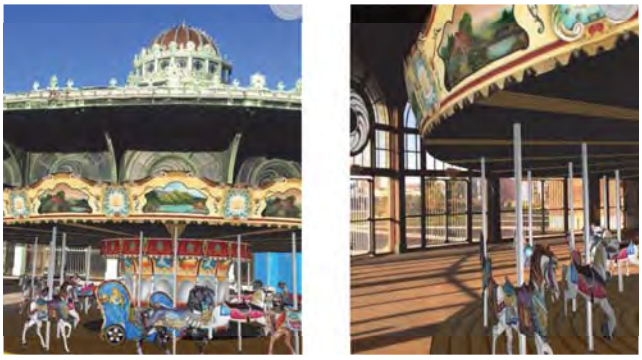

Figure 5. Images of digital 3-D model of Asbury Park Casino Carousel placed inside the Carousel House using AR.

With the help of the Asbury Park Public Library, we learned more about several other historic buildings and structures and were able to collect a large amount of visual references from the library's postcard collections. We created several other digital 3-D models of other buildings and structures on the Asbury Park boardwalk, and we placed those back on the boardwalk using AR as well.

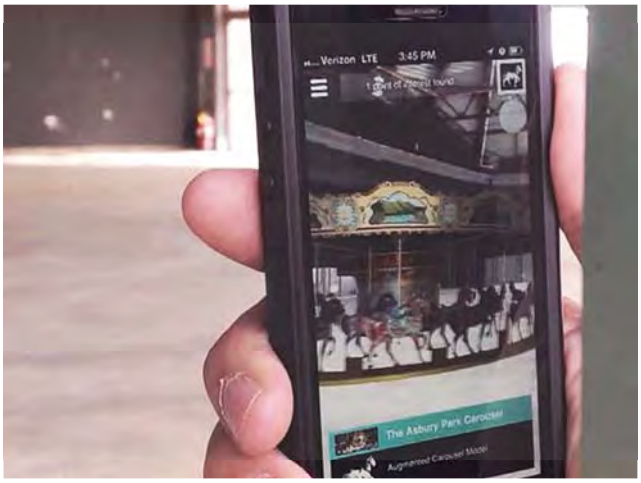

Figure 6. Photograph of camera phone interacting with the digital 3-D model of Asbury Park Casino Carousel placed inside the Carousel House using geolocation-based AR.

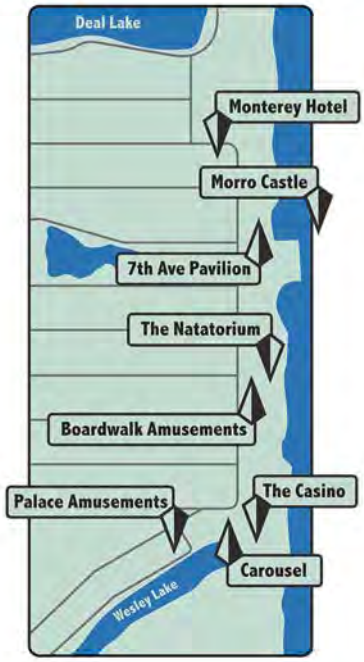

Figure 7. Map of AR assets on the Asbury Park boardwalk.

Here is a list of the completed assets from top to bottom:

- Monterey Hotel, built in 1912, demolished 1963
- Wreckage of S.S. Morro Castle, beached in 1934
- 7th Avenue Pavilion, built in 1905
- Original Boardwalk Casino, built 1903, destroyed by fire in 1928
- Natatorium, first built in 1912
- Skyride and Boardwalk Amusements
- New Boardwalk Casino, built in early 1930's and partially demolished in 2006
- Boardwalk Carousel, built in 1932 and dismantled and sold in 1992
- Palace Amusements, originally built in 1888, demolished in 2004

In addition to geolocation-based AR, we also used vision-based AR. This technology enabled our team to tag each model to a corresponding AR-enabled poster. We designed posters with illustrations and historical information about each building or structure. Now, when people scan one of the posters with their mobile devices, the digital 3-D content appears in front of the poster.

Project Impact

As we led our tours each Sunday in July, the significance of our project became clear. These tours coupled with the on-site AR content engaged the local community and provided opportunities for people to share their experiences and memories. On a perceptual level, it disrupted expected reality and activated it with superimposed, meaningful content. On a social level, the tours disrupted the expected

experience of casual beachgoers who decided to join in on the tour. People stopped and became engaged.

There are now permanent AR markers for visitors to experience on the Asbury Park boardwalk. Also, our project website provides free off-site methods for sharing and experiencing the project content. We are excited to continue offering these experiences and to find ways of growing these kinds of meaningful disruptions.

Author(s) Biography(ies)

Edward S. Johnston is an Assistant Professor in the Robert Busch School of Design at Kean University. He is a multimedia designer, artist, and educator working in a variety of contexts involving interactive design and three-dimensional digital technologies. Johnston has received numerous awards and grants including an Editor’s Choice Award, World Maker Faire New York 2013 (with Richison and Vujnovic), the YAP Grant from the D.C. Commission on the Arts and Humanities, partly funded by the National Endowment for the Arts, and others. Johnston’s creative works have been shown nationally and internationally, recently being included in the Lumen Prize Exhibition in Shanghai, Hong Kong, and the United Kingdom. Johnston’s work has been included in several publications including Olga Ast’s book *Infinite Instances: Studies and Images of Time*, KEM’s Norwegian publication SIRKEL, and several others.

Michael Richison is a Specialist Professor in the Department of Art and Design at Monmouth University. He is a multimedia artist who utilizes a variety of media and approaches including graphic design, video, sculpture, printmaking, drawing and installation. At Monmouth, he teaches Motion Graphics, History of Graphic Design and Typography. He has exhibited and performed at venues in New York, Philadelphia, Boston, Detroit, Los Angeles, and London. Richison has received multiple Grant-in-Aid for Creativity awards from Monmouth University.

Dr. Marina Vujnovic is an Associate Professor in the Department of Communication at Monmouth University. Vujnovic studies participatory journalism and new media, media history and gender, and political economy and cultural studies. Her interests focus on international communication and global flow of information, journalism studies and oral history; explorations of the historical, political-economic and cultural impact on media; gender, ethnicity, and media. In 2009, she published a book about Croatia’s first female journalist, and she frequently contributes to books dealing with journalism and media.

Cart(ont)ology: Mapping Self-as-Network in Three Carts

Jenny Filipetti

Emergent Digital Practices, University of Denver
Denver, USA
jenny.filipetti@gmail.com

Abstract

We live in a networked world to which we find ourselves entirely ill-adapted, clinging to outdated means of perceiving and understanding our environment. Part art intervention, part philosophical project, cart(ont)ology proposes the convergence of cartographic and ontological approaches to the question of being/becoming. It seeks to account for both individual entity and its networked presence in a single discursive movement. Through the development of three interwoven artworks – a pushcart, inventory-qua-cart, and PCBs-qua-cart – the author explores how we might engender a network sensibility in ourselves which encompasses our relations with not only people but also machines and objects, and which renders us better adapted to act within our networked existence. Embodied across these three scales, the physical carts created serve as abstractions through which to understand networked relations from the local context outwards. They are also a performative investigation into how we might engage in a radically active receptivity as a means of network-oriented perception, encounter, and exchange.

Keywords

research-creation, performance, complex systems, networks, semiotics, intervention, assemblage, ontology

A Crisis of Networks

Networks aren't what they used to be. Despite decades of post-structuralist semiotics, we remain uncomfortable with the privileging of process over object, and networks have been co-opted from the notion of a mutable set of relations to nothing more than a large and interconnected but fundamentally stable structure. Christopher Kelty writes:

> "At the time, the word network [...] clearly meant a series of transformations [...] which could not be captured by any of the traditional terms of social theory. With the new popularization of the network it now means transport without deformation, an instantaneous, unmediated access to every piece of information. That is exactly the opposite of what we meant." [1]

Of course this doesn't prevent us from living in them, and living in them seemingly well. We are not ignorant of the value of networks; rather, in the words of theorist Anna Munster, we suffer from "network anesthesia – a numbing of our perception that turns us away from their unevenness and from the varying qualities of their relationality." [2] We ignore the ever-changing forming and reforming of relations which make networks dynamic entities. [3] Above all, we neglect to address this dual-edged notion: it is the activity of their individual nodes that keeps networks in constant flux, and yet if the network around us is constantly changing, so must we be by extension, however still any of individually may be standing.

In her work Munster proposes how we might understand networks differently. My project is similar, but ontological in another sense as well: I suggest that to better understand and live within networks we also have to change how we think about and exist within ourselves. True we are already astute navigators of networks, albeit in particular of other human nodes within networks, and we are keen theorists of the powerful potentials of complex systems and networked life. Yet we recognize only insufficiently how deeply and perhaps existentially we are affected by our networks, and ignore how a network-level perception might radically change the scope of human and human-object relations. Our day-to-day encounters and existence are marked by the stilted continuation of a worldview in which there is us and then there is our surrounding network and environment of people and objects and machines, to be used or modified or displaced or engaged with as we see fit.

Towards a Cart Ontology

As a counterpoint to this state of affairs I propose a cart ontology: or, what it means to be a cart. Make no mistake: remove three letters (the "ont" of the individual, according to cell biology) and it serves as a kind of cartology, as well, an emphasis on what realities about larger systems might be expressed through the local; a complementary conceptual tool to deterritorialization. Cart(ont)ology as its awkward formulation suggests is a site of slippage between the well-traversed ideas of cartology and ontology.

Mine is as much philosophical project as it is performative experiment. I suspect that we are all carts of a sort – more likely we are several all at once – and research (surveyed briefly below) in genetics, parasite ecologies, and psychology is suggesting much the same thing.

So what is a cart? Well it is mobile. Carts are meant to move through space and time, and thus in our terminology, easily enter into and out of different assemblages and relations. Carts also exist, in-the-world, as a site of contact among people and objects. In contemporary art and architecture one must never take for granted the notion of something physically existing. This material existence is

crucial as well because it prohibits us from collapsing the notion of a cart into that of a vector, or some other immaterial means of transmission.

Yet more than most things we encounter, carts are defined by their relations. Just ask Google to show you a "shopping" versus a "gypsy" cart. At what point these relations become so central as to become part of the very identity of the cart is more than a question of worthwhile debate. It is the very crux of this project.

The premise of cart(ont)ology is not that we exist both as physical and networked individuals but rather that we exist simultaneously as both individuals and networks. It is an attempt to engender an understanding of this nature as concrete, experienced reality, not merely conceptually.

This is not just about the shopping and gypsy carts, of course. Everything and everyone may be characterized by a cart(ont)ology. Carts themselves – carrying pretzels or shawarma or medical equipment or toys or people – are the most basic exemplar and the abstraction through which we can begin conceptualizing this. As the capacities of an entity increase beyond those of carts as we typically know them, through sentience to movement to decision-making, the cartology of any network in any given instant becomes more complex. But this project exists especially for human beings in all their sentient, moving, desiring decision-making, as part of an equally desirous wish to better adapt us to our own networked existence.

Why Cart(ont)ology

In what ways can we be said to *be* (synonymous with our) networks? Deleuze and Guattari have already proposed multiplicity and molecular becoming as alternative ontologies; this project theorizes a similar understanding via our networked relations. Such a multiply defined existence is not a matter of conjecture; it is not even new, although its landscape is being shaped by contemporary technologies, surveillance tactics, and biological research.

Take for example the fact that researchers have found they can identify 95% of cellphone users based on four sole instances annually of knowing a user's location at a given time. [5]. Or the alarming accuracy to which our identities can be constructed and even future life events predicted as circumscribed by no more than Amazon purchase records, Google searches, online activity rhythms: in a word, datapoints, many of them, of all kinds. [6] Are these examples of our identity being externally assayed based on our networks, or ways in which our networked self is becoming equally or more our "actual" self?

What about research into how seasonal weather modifies human gene expression? [7] The way colour, sound, and sunlight almost universally affect our eating habits? [8] How parasites and bacteria alter animal behaviour? [9] How famine turns grasshoppers into locusts? [10]

What cart(ont)ology contributes to the theorizing of ontology is a reflexive gesture: remapping the self-as-network back onto the self-as-entity. It presumes that there is a direct relationship among nodes in an assemblage or network (insofar as the existence of relations is likely the criteria that compelled us to define some set of entities as a network to begin with). Let us also postulate that a network is characterized exclusively by the positioning of its nodes, albeit not necessarily their geographic or spatial positioning but rather any descriptor of its edges and relations that makes sense to apply. For our purposes there need not be any history to a network, other than the latent history which led to this configuration being precisely as it is now. The networks' possible future states are informed by its current configuration and the relatively imperceptible (virtual) capacities of each and every node.

From here, the experiential component of cart(ont)ology suggests that it is possible for each node, by virtue of its immediate access to its surroundings, to literally perceive, feel, or absorb information about the network's state, at potentially higher levels of abstraction than we traditionally attribute to perception (but ones which a few examples will show we do not typically exclude from it, either). This is perception, as Anna Munster describes it, as "a making of the world and of sensing itself, as we go." [11]. Anything existent within the immediate network is available to be perceived or acted upon, informing the actors' actions and the network's future. Likely much of it is already doing so, without the actor's realization, which is precisely why I suggest that beyond simply being in-a-network, a given entity *is*, in some ways, its network.

Also, because networks overlap, this perception may effectively extend beyond the immediate network insofar as each individual node exists at once as individual actor and an expression of (its own) network conditions.

It is crucial to note that cart(ont)ology is not restricted to human actors: networks conceived in this sense necessarily include people, objects, plants, machines, bacteria, etc. The individual-as-network aspect of cart(ont)ology is influenced by Jane Bennett's object vitalism, wherein "the concept of *agency* [...] becomes distributed across an ontologically heterogenous field, rather than being a capacity localized in a human body." [12]

At least in many circumstances, human nodes' capacities for action tend to outnumber those of their non-human network neighbors. Humans are also the only ones who might be reading this essay. Thus cart(ont)ology, despite urging a network-level perception and process of decision-making, is fundamentally human-centric in situating its impetus upon human actors. It inquires how we might act upon this object-oriented understanding to engender in ourselves alternative perceptive approaches that render us better adapted to life as networked beings. What precisely this might look like is the subject of my artistic research.

The Cart(s)

And so I am building a cart. Not one, but several carts! With a post-structuralist wolf in each. Many networks – and all self-organized critical systems – have the mathematical property of being scale-free, following a power law irrespective of their size or accretion. Well so do carts! Or, better said, so does the abstraction of a cart:

so does a cart ontology. To arbitrarily adopt the metric system as a means of illustration, entities that I would argue function like a cart at different scales might include:

- meteorites (kilocart)
- spaceships, urban plans (hectocarts)
- caravans and markets, airplanes (decacarts)
- my cabinet-of-curiosities street peddler cart (base)
- inventory (decicart)
- printed circuit boards (centicarts)
- altered genes (millicarts)

I am building three of these, from the street cart down. The contribution of my carts as physical objects is in the vein of art as research practice, as elaborated upon by Graeme Sullivan among others. [13] As such my philosophy of cart(ont)ology is still very much in process. At the time of writing I believe that each of these three objects already highlights different elements of cart(ont)ology; several rules will make these ramshackle real carts further exemplary of their cart abstraction.

First, the large street peddler cart (which houses the others) will not "know" or broadcast its location. This is an aesthetic not obligatory decision. It provides a space through which the networked reality of the cart can be emphasized over its physical one, since the latter of these is not about to be missed anytime soon, measuring about five feet long and three feet wide and set on rather prominent wheels. Furthermore, unlike its shop, food cart, and gallery brethren (especially mobile ones) it lacks an online presence of its own authorship and so can be experienced only through some degree of directly networked relations: through what I or its visitors have to say or show of it. There is also a mythology regarding the cart's inability to know its own location.

Speaking of which: fictions are an important aspect of my project because they expand one's understanding of the potentialities present in a given context. In the words of critic Steven Shaviro, writing on the philosophy of Alfred North Whitehead:

> "Whether true or false, delicious or repugnant, a proposition points to a *potentiality*. That is to say, propositions are neither actual nor fictive; they are 'the tales that might be told about particular actualities.'" [14]

In network terms, propositions (of which mythologies and fictions are instantiations) expand the (virtual) capacities to action of the node which has encountered them. How this affects and may be understood through cart(ont)ology is among the questions I will be exploring.

Second among my rules, the cart inventory must be continually updated, to the point of absurdity if possible. Everything *is* in fact always changing. If it is impossible enough to keep track of amidst our many trillion cells and surrounding molecules, it becomes downright inconceivable as soon as we remember we are an open not closed system and part of networks whose other components are also always changing. The absurdity of the inventory highlights the relative reasonableness of the proposition I am making: that we actively absorb these changes not through conscious observation and recording but rather as perceptions and affects, which may be acted upon through lived experienced.

Printed circuit boards, the centi-scale of the project, are already exemplary of a cart(ont)ology for the ways in which they house a regulated system but are designed to interface with the local environment through the input or output of signals. Their cart nature will be enhanced by making them mobile, by activating them atop small robots and through their sale as products.

Technically what else is on the cart makes little difference for my performative experiment, and indeed the most important feature is that these contents can change from day to day or even minute to minute. Nonetheless I have chosen the first collection of works quite specifically to highlight tensions between the physical and networked (virtual) body, whether these be of humans, objects, or locations. This is for two primary reasons. One, since I am situating this cart not only in the world but also in the context of "art", for the latter's sake the objects onboard might as well reflect the project's larger concept in the meta- approach of which contemporary art is so fond (and perhaps this also gives it a certain elegance). Two, I think I believe in cart(ont)ology and yet in my everyday existence I typically fail to feel like a cart. By exploring the tensions across the tripartite existence of biological/physical being, that of self-as-node-in-networks, and that of self-as-network, I hope to engender in myself the approach to networked existence I am propounding here.

One side of this largest of my carts is thus devoted to a project which collects breaths: both their forms, generated as a 3D model from sensor data, and then saved or 3D printed in ceramic, and the expired air, collected in small vials and labeled with name and mood data when granted. On the other side several works more directly juxtapose physical and virtual or networked bodies. Among these is a set of vessels, composed partially of local clays, whose shapes reflect the horizon line of the landscape where the material was collected. A separate series of prints compares the actual location of an entity (usually myself) to the location that would have been interpolated based on a triangulation of related data points. And so on.

Cartology Through Radical Receptivity

Thus far I have elaborated on the ways in which these three (or more) actualized cart forms represent and allow me to further investigate the idea of cart(ont)ology. They are all meant to change over time, to move or be moved to different settings, and to be encountered by different people: changing circumstances which I undertake as experiments into the nature of carts.

In addition to describing contemporary states of being/becoming, however, cart(ont)ology should propose an alternative means of being-in-the-world which takes optimal advantage of the peculiarities of the networked multiple self. The conceptual crux of cart(ont)ology as lived experience is a notion I refer to as radical receptivity. It owes much to Alfred North Whitehead's philosophy in

its conceptualization, again encapsulated here by Shaviro:

> "Activity, no less than passivity, is a dimension of receptivity itself. Every experience, every feeling, is at one and the same time an 'inheritance' from the past and a fresh creation. And both of these dimensions are contained within an open affectivity." [15]

Radical receptivity involves opening oneself to the network aspect of being. It urges us to recognize that we are constantly being affected by everything with which we are in direct contact whether the chemicals in our blood, the knickknacks on our desk, or the people we're communicating with. As suggested above, by extending this notion out through several degrees of overlapping networked relations, we may be said to be more or less directly affected by even non-local conditions.

Radical receptivity is necessary because complex circumstances increasingly render linear thinking and other historically useful approaches inadequate. This is an ontological problem, not one of a lack of data. Manuel DeLanda elaborates:

> "The reason why the properties of a whole cannot be reduced to those of its parts is that they are the result not of an aggregation of the components' own properties but of the actual exercise of their capacities." [16]

Capacities which are always in flux, whose precise outcome can never be known, merely statistically estimated. This may be sounding familiar. After all, a very basic observation of complex systems is that even deep knowledge about the workings of individual components is insufficient information to be able to predict the emergent properties of the system as a whole.

The privileging of man and his ability to impose his will on his environment is part of a distinctly western philosophy and worldview, if not also part homeostatic drive. [17] Yet now more than ever, man finds himself caught in the throes of enormous networks where it would be impossible to know all of the individual actors and nodes in most cases, let alone the landscape of an entire system. As non-omniscient human beings moreover with our own constellations of vested interests, we cannot effectively assess these systems in the ways heretofore favoured, much less make predictions about their futures or our futures within them. And yet much of human society is dedicated directly to these efforts. Cart(ont)ology and radical receptivity seek a way out by encompassing within ourselves our surrounding networks, in all their flux.

What does radical receptivity look like in action? This is where the philosophical project ends and the art-as-research-process begins. The streetcart I am constructing is a traveling incubator full of objects and fictions. As I reinvent the mythologies of the cart and objects onboard, as my collection of archived breaths grows, as I engage with the public about these projects and ideas, as I move to diverse locations: the introspectively performative aspect of my project is that I will be actively attempting all the while to engage in a praxis of radical receptivity. I hope to explore its contours, define its practice, map its limits, and suggest its potentials for a concretely networked existence.

Acknowledgements

The author would like to acknowledge the support of artist and professor Timothy Weaver in the development of this project.

Case Study: White Night Melbourne in 2013 and 2014 Disruption or Contribution Toward the Socially Engaged Public (Art)?

Yun Tae Nam

Monash University
Caulfield, Victoria, Australia
Yun.nam@monash.edu

Abstract

The purpose of this case study is to analyze the White Night arts festival as a form of public art using the frameworks of art as experience, art practice as cooperation and social objects. In 2013, Melbourne hosted more than 300,000 participants at its first White Night and in 2014 the number increased to 550,000. [1] The White Night started in Paris, 2002 influenced by the origin of Nuit Blanche, and is now held in more than 23 cities globally. [2] The various White Night events share a common objective, which is to celebrate and transform the city, as art and entertainment [3], into a free cultural event. The White Night festival features traditional and new media art in public spaces that promote social interaction and participation amongst large public groups. Three artworks are discussed as case studies using the conceptual frameworks to highlight the potential of the festival to build socially engaging and interactive public artworks. The case studies also reveal areas of focus that are unique to the festival, which could be leveraged to greater effect.

Keywords

Public Space, Public Art, White Night Melbourne, New Media Art, Social Objects, Audience Interaction, Participation, Cooperation, Co-creativity, Socially Engaged Art

Introduction

In 2013 and 2014 the White Night transformed part of the urban public environment in Melbourne, Australia into a cultural playground. Audience interaction and participation are significant components of the festival, and it brings digital media art projects directly into public view. Although the festival has a growing number of visitors and meaningful goals, it also raises questions of how the audience perceives the event and its larger influence on the urban environment in the city. Observers have viewed it as both a public disruption and contribution, suggesting lessons that can be learnt from the festival for exploring how digital media can provide a socially engaging and interactive experience for its audience.

As well as increased attendance, from 2013 to 2014 the White Night festival saw increased facilities for visitors and larger, more diverse area of involvement including the city center, railway stations, galleries, museums and laneways.

The White Night represents a growing international development that has brought public art to large audiences. The festival brings a concentrated collection of artworks and a unique scale of public involvement, making it a valuable event to analyze for its approach to public art. In this study the White Night is considered using established frameworks for interpreting public art projects, to find lessons that can be taken from the festival and also provide criticisms that can be used to develop it with increased social engagement and interactivity.

Methodology

Participatory new media installations in public spaces struggle in the intersection of political, cultural, social, educational, entertainment and economic fields. The fields have different operational logic and techniques that impose different demands for audience participation so the desired outcomes of public art in urban environments are diverse and sometimes conflicting.

This study is less concerned with political, educational and market aspects of the public art experience and focuses instead on experimental practices in new media participatory public art that has greater potential to build social interaction and participation. Art as experience, artifacts as social objects and art practice as cooperation are concepts that are relevant to the White Night festival and point to a discussion on how to develop socially engaged and interactive art practice. The concept of co-creativity forms the basis of an extension of this discussion.

Art as a tool for social transformation is not a new concept. It has a long history from religious paintings to new media participatory public art. However, recently the term ‘socially engaged art’ has arisen in many academic seminars and public discussions about contemporary art practices that focus on site-specificity [4], ‘new genre public art’ [5], participation [6], community [4, 5] and audience interaction, experience and cooperation. [7, 8]

The definition of ‘socially engaged art’ is ever evolving and has different connotations depending on context. This paper focuses on the underexplored potential that engaging the wider public as co-creators of interactive digital

experiences has to act as a catalyst for social awareness and change through positive experiences of cooperation.

Conceptual Frameworks

Social spaces can be defined by their physical properties, but also by conceptual properties. Public parks, shops, social networking sites and online games have their own social functions. Henri Lefebvre argues that space requires human social interaction and a cultural dimension of represented space. He states that all "space is social" and emphasizes the designing and planning of social space through the use of a 'social object', stating that "social space has thus always been a social product."[9]

Jyri Engestrom defines 'social objects', a concept he framed in 2005, as "the objects that mediate the ties between people" in the context of social networks and argued its fundamental basis to spark social interactions and build connections between users, leading to the success of the social network. [9] Karin Knorr Cetina had elaborated the concept more generally as 'Objectual Practice' four years earlier. [10]

This framework has been applied in different environments, such as the development of the iPhone, marketing and games. Nina Simon also applied it to museums. [11] These applications focus on elevating social objects as strong connections that bind people together, a connection of having something in common and new. These cases are based on social objects outside the social media paradigm.

Social objects can be everyday objects used in art or public works that result in human-human interactions. When a baby or animal is the centerpiece of a new interaction on the street, the baby or animal can be considered as social objects that play the role of promoting a new connection between people in a public environment.

One of the main objectives of the White Night festival is [re]connectivity between audiences through engaging in and with public environments such as Fiqure2. Dance Now. If an audience can identify new art objects that are social, transformative and playful in the White Night event it could lead to increased social interaction and participation, building a 'we-together' concept between social objects and audiences.

The concept of art as experience considers the way the viewer experiences the physical surroundings and other people when viewing art. The experience will differ from viewing the art alone at home, in an exhibitions or museums. The environment plays an important factor in facilitating active engagement, interaction and participation. By encouraging social engagement through artworks that require the audiences to interact with each other, a deeper experience can be created that is more dynamic and playful. [12]

The concept of co-creativity in art process and design is to have creative inputs from multiple individuals with shared goals in the output. This includes collective interaction and expressing shared values in public spaces. The artists and designers at White Night can facilitate audience members to participate and to become co-creators with positive social outcomes. White Night has a large audience and with it the potential to affect positive social change as a collective and cooperative movement.

Discussion

The reason for visiting White Night was to experience the art works as well as to explore Melbourne's laneways, which had been transformed by the event. White Night is as much an exploration of creativity as it is of the city and its people. People were as interested in the air of festivities as they were in the actual art works, but many visitors were there to witness the creativity and artistic expressions.

Some of the events were based on audience interaction. One particular event, "Dance Now", encouraged the participants to burst into a dance routine as soon as some music starts playing. This was a true example of playful participation and audience engagement and an embrace of art as experience.

Figure 1. *Dance Now*. Photo used with permission from Photographer Wayne Hawkins 2014.

The most notable displays involving new media were seen in Melbourne's Federation Square. The architectural light projections were vivid and stunning, as described by many viewers. These clearly highlighted peoples' interest in visually appealing media and the transformation of public spaces and architecture. The festival could build on the audiences' shared interest by accompanying visually engaging objects with viewing areas that encourage conversation amongst the viewers.

Socially Engaged Art Projects

Vladmaster is a handmade View-Master experience designed by Valadimir: A View-Master is a device to look at 3D color picture. It was widely used as a children's toy and for viewing tourist attractions. Viewmasters were in common use from the 1920s to the 1960s. It was interesting to see them in use during a contemporary arts festival, focussed on using the latest technologies. The physical interaction design was particularly interesting. An analogue touch based mechanism to navigate to the next scene with a pre-recorded narration. This unique involvement of a haptic (touch based) mechanism inspires design that encourages physical interaction and play.

Figure 3. *Vladmaster* performance at ACMI.
Photo by Yun Tae Nam 2014.

Purple Rain is an installation that uses sound and visual artwork to create an immersive experience. The name is a direct reference to the music of, and film featuring the performer Prince. It embraces the all night theme of White Night by using bright purple lights and showers of water to create a deep glowing effect that echoes the 1980s period that the film and music were made in. Audiences are given clear umbrellas so that they can get in underneath the artificial rain and see the light effects from various angles and music accompanies transitions in the light.

Figure 4. *Purple Rain*. Photo used with permission from
Photographer James Pang 2014.

This installation provides the audience with a unique sensory experience, not only through the effective use of visual content and sounds but also the audience engagements that create a starting point for interesting social interactions between audience-members in the installation environment. Taking pictures with each other or recording videos while the 'rain' is pouring down builds the feeling that they are sharing a common experience together. Smiling with each other, posing for the best pictures. They can also share the contents through social media as digital social objects that include the environment and audience interaction and participation as content.

The audiences are really participants and content generators because they also create sounds and scenes within the purple world. While holding umbrellas, or even without them, they freely play with the rain and generate sounds from their wet bodies. The combination of play and sharing a new world with other people can create an emotional experience and create new happy memories for the participants.

Bouquet Final 2 is a large metal structure that towers several meters high. From the top of the structure, liquid bubble foam begins to pour down and envelop the whole structure. The effect is temporary as the bubbles burst and the liquid drains down to the bottom of the structure. The artwork appears to grow and decay like an organic object.

The installation gives the audience a visual and haptic experience at the same time. The generated bubble foam creates an unpredictable sculpture in real time and the shapes are unique in every moment of time. Unlike many sculptures in a museum environment that are not permitted to be touched, *Bouquet Final 2* is a haptic experience. Audiences can freely touch and feel the foam which gives them a new experience they cannot typically find in galleries and museums. Audience members could be seen putting foam onto each other and laughing and playing with the bubbles like they might have done in their early childhood. This experience has the potential to induce a sense of nostalgia of happy childhood memories.

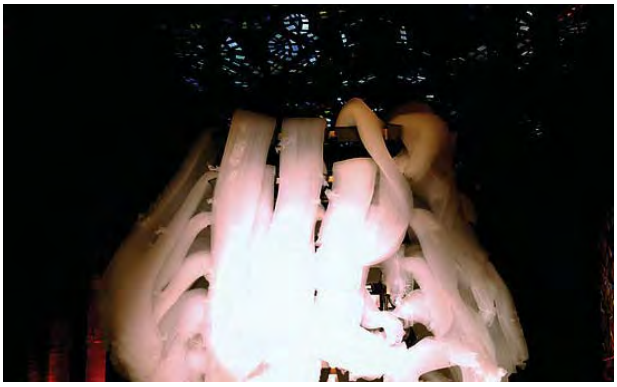

Figure 5. *Bouquet Final 2*. Photo by Yun Tae Nam 2013.

These three examples show successful applications of some of the conceptual frameworks of social objects, art as experience and art practice as cooperation. By embracing the freedoms of a short festival inside a public space, interesting experiences were created that facilitated play

and physical and social interactions. By having environments that can be enjoyed as a shared experience, participants were also inclined to take photos, which could act as social objects, expanding the reach and effect of the festival beyond its physical boundaries. Further exploration of these concepts at the White Night festival could continue to build the social function of the event and provide inspiration for public art in general.

Limitations

There were limitations in compiling a review of writings on the White Night in Melbourne.

- Lack of reviews by art critics and new media experts
- Limited sources of literature documenting specific individual events

Conclusion

At White Night in Melbourne there have been diverse artistic expressions using old and new media artworks. Each artwork has its own forms of interaction and meaning for socially engagement. They enabled social interactions and participation via multimedia installation forms that showed the potential of socially engaging because much of the presented works have been focused on participants-led. Art practices in public space such as the White Night are valuable events for seeing how the public perceives public art.

People often follow social conventions to guide their use of public spaces. Interactive digital technologies allow them to make non-destructive but stimulating visual, audial and tactile experiences of their own design. The new use and conceptual image of that space changes their personal and social experience. By using frameworks that consider both artist-led and participant-led artwork that embrace co-creativity, a unique, socially engaging experience can be created that has ongoing social effects.

Many artists, organizers and community groups are trying to encourage social transformation through events that run for even just one night, such as White Night, by temporarily transforming the city into a part of art and entertainment. This event can be considered as a social-cultural playground with further potential for the pubic to experience art in a meaningful way for our society.

Disrupting Conventional Boundaries of Public Art In Urban Space

Laura Lee Coles, MA
Artist-in-Resident
Vancouver Park Board – Aberthau Mansion
Vancouver, British Columbia, Canada

coleslauralee@gmail.com

Abstract

In contrast to the spectacle of large-scale projections onto urban architecture, digital eco-art offers intimate experiences in reciprocity with the largeness of the sensorial realm of nature. Digital eco-artists position work in natural settings for the exhibition of interactive computer generative sound and visual installation works. In doing so, they push traditional boundaries of urban public art to be more socially interactive, immersive, and inclusive of place they offer a means for re-visioning urban natural green space.

Keywords

LocoMotoArt, place, digital eco-art, technologically mediated experiences, urban environment

Introduction

"Space and place" are components of the living world, which have biological connections that can be mapped, measured, calculated, and used via the experiential. Within this concept of space and place, we find that both resonate multiple qualities, meanings and mediated symbolism, which we often take for granted. [1] We can also consider that space is a "sphere" consisting of multiple trajectories, more specifically that the sphere is comprised of "coexisting heterogentity…without space, no multiplicity and without multiplicity no space." [2] In this point of view, there is an inseparable character of space and place. Sampson reminds us, "a meaningful sense of place has four primary dimensions – emotional/affective, spatial/geographic, ecological/interconnection and temporal/historical. A true sense of place includes the intertwining of all four." [3] Lefebvre defined the concept of 'representational space' as spaces of imagination, complex embodiment and coded symbolism. A conceptual triad, representational space is considered the "most evocative" and according to Lefebvre, linked to "the underground side of social life as also to art," which he referred to as a "code of representational space." [4]

Use of space embraces a multitude of competing trajectories, which are interrelated. Contributing to these intertwined boundaries, we find that physical space and place are deeply embedded with technology and thus, electronic space and place is as much a part of space and place as buildings, parks and plazas. As Amen and Thrift note this has "crucial consequences" because "the technical is not seen as separate from the social or the natural," [5]. I consider space and place to be intertwined, ever changing, steeped in complex fluctuating intricacies and temporal changes.

In response to the awareness of the oscillation between physical and electronic space and place, electronic artists seek to interrupt the everyday and transplant human activities through the ubiquitous and sensorial aspects of digital technologies. These artists move towards unconventional use and repurposing of urban natural space. In doing so, a means for local place making and exhibiting public art emerges that disrupts conventional and traditional boundaries of the space and appeals to the imagination more intimately. Traditionally outdoor spaces are used for concerts in parks, parades, street parties, and festivals. Digital eco-art, emphasizes electronic and physical space and place by oscillating between perceived realms.

In "Digital eco-art: transformative possibilities," co-author Philippe Pasquier and I observe, "We must consider that there are many interactional experiences and relationships that exist in both natural settings and digital technology. It is generally understood that our ability to connect with nature is accomplished by way of direct sensuous engagement. Because digital devices and sensor technologies provide enhanced experience by augmenting human sensorial awareness within auditory, visual and haptic experiences, we can also be sensuously and immediately engaged through such technologies. By combining these multisensory augmentations with the experience of natural setting, the two blend, resurrecting our cultural connection to the natural realm…" [6]

Digital eco-artists use this sense of oscillation to push traditional boundaries of urban public art to be more socially interactive, immersive, and inclusive of place as a vehicle for re-visioning of urban natural green space. Drawing upon five years of arts based research and the work of LocoMotoArt, a multi-disciplinary media arts group, I report on a digital eco-art event, *LocoMotoArt @ Queen Elizabeth Park* in Vancouver, British Columbia. This paper does not provide the opportunity for lengthy discussion, therefore I describe briefly some of the works from the exhibition which played upon the oscillation of place, space, locale, memory, the uncanny, fusions of nature myths, the geological history and the convergence of the colonial ramifications found within Nature, cultural traditions and society as related to this specific urban space and place.

Disrupting Conventional Boundaries

A more traditional use of urban space by electronic artists involves the creation and exhibition of works for spectators to experience a distanced *engrandized* representation with sensations engendered by the sheer largeness of the spectacle of urban projection. During the 1980s and 1990s the "provocative spectacle" emerged as seen in the work of artist Krzysztof Wodiczko, who in the mid-1980s projected gigantic "40 foot" images of objects and body parts onto the facades of public buildings and monuments. In her paper *Urban Disturbances,* Ewa Lajer-Burcharth concluded that Wodicczko's projections, "…indicate and use the contradictions of specific social space … and in doing so open them to reinterpretation." [7] Large-scale projection utilizes architecture for screening surfaces, for staging striking visual displays for immense crowds of people who are assembled together in an urban area. It is axiomatic that urban ecological sounds, (sirens, horns, motorized traffic, air and land), as well as metaphors and symbols of human history and the architecture used, begin to merge into the viewing experience.

In contrast, digital eco-art engages the spectator with the interaction and intimate experience of both nature and technology. Digital eco-artists strive to use all attributes of natural settings such as forests, beaches, caves, lakes, or stream banks for example. Screening surfaces are found within the contours of the landscape, and incorporate natural aspects such as steep inclines, uneven ground, sand, or rocks. Another contributing aspect is that of existing ecological soundscapes, such as waves, birdsong, or wind. These add to the artist's work in ways that differ from large-scale urban projection or indoor gallery settings. Digital eco-art is the temporary occupation of natural urban place; it is small-scale and positioned in dialogue with natural settings, or as specific intervention. It engenders a sense of intimate connection to and the understanding of natural environment and its restorative properties. [8]

Aesthetics of Digital Eco-Art

The term aesthetics is commonly associated with the senses, art, and the value of appreciation of the beauty of art. The etymology of the term is "to perceive with the senses", so it is possible to consider "all experience as fundamentally aesthetic." [9] When considering the aesthetics of digital eco-art, we must acknowledge that we are corporeally connected to landscape, and that our senses hearken back millennia to a time when the experience of interconnectedness was synonymous with survival and our understanding of the world. Humans were so deeply embedded within a sustenance relationship that a sense of reciprocity with the natural world was embedded in human existence and culture.

Electronic space, or virtual space, is similar to natural spaces in that sensuous qualities such as texture, form, colour, light, scale and movement, sensation of sound may also be present. When we consider digital eco-art placed in natural settings, we must also consider interconnected aspects of these. Digital technologies provide multiple sensory and interactive experiences and augment the senses in ways that could be considered similar to the sense of arousal one can experience in nature settings. Within the human sensory-perceptual system we have the capacity to interpret, or internalize cognitively that, which is perceived. Internal and external perceptions are produced at the same time, and they are not separate; "in our experience we never find them disjoined" [10]

Re-visioning Urban Natural Space

As an emerging genre, digital eco-art provides an intimate, heightened sense of aesthetic engagement among humans, technology and nature, and disrupts pre-conceived cultural notions of the separation of the three. Similar to the influence of Joseph Beuys on social sculpture and environmental art, digital eco-art and its use of public natural space, history and memory also responds to the need for generating discourse related to ecological issues. These types of "art agendas" involve traditional as well as activist practices, and all have a role in raising awareness of ecological issues. The ubiquity of digital media in our lives can make them seem at times more familiar than nature. Digital eco-art re-visions the park or natural green areas of a city and provides a means for the repatriation of the inhabitant with his or her environment. As electronic space interacts with the physical urban public space, it becomes a transformative experience. [11]

Social Interaction and Digital Eco-Art

During five years of field study with LocoMotoArt, spectators repeatedly commented that the sense of stimulation provided by the experience of digital eco-art led to feelings that were "pleasant," arousing a sense of "being in love", or "uncontrolled excitement," or "intense uncontrolled curiosity" when experiencing electronic art installations *in situ*. Several spectators commented they had feelings of a sense of "intimacy" and that the technology and art all felt "absorbed" "connected" and not separate. In further findings participants spoke of feeling a momentary sense of human, technology, nature interconnectedness. This moment of bridging of the lacuna of the separation of all three – human, technology, and nature awareness – and the experience that all three are absorbed as one – the HTN Triad Relationship – may act as a conduit, or a potential sensorial pathway (intermediate agent). [12] Pursuant to research studies, there are associated cognitive and health benefits related to exposure to nature as well as "technological nature." [13][14] For complete details related to the research study, I refer the reader to "LocoMotoArt: Digital Art in Natural Settings," published in Volume 10 Issue 1 of the *International Journal of New Media, Technology and the Arts*, and other references listed related to LocoMotoArt.

LocoMotoArt

The multi-disciplined group of electronic artists also

called LocoMotoArt, re-vision natural settings for use in performance, participatory walk-based GPS enabled works, and interactive and computer generative sound and video installations. They are currently artists-in- residence with the Vancouver Park Board Arts, Culture and Engagement Division with studio space at the historic Aberthau Mansion in West Point Grey (2013-2016). It is the vision of the group to address the importance of our environment by offering audiences collaborative new forms of engagement through digital multi-media works comprised of sound, live movement, performance, storytelling, and participatory interaction with outdoor natural settings. [15]

LocoMotoArt @ Queen Elizabeth Park

Queen Elizabeth Park is a large world famous arboretum with a vista point from where tourists come and view the City of Vancouver. The park itself is an extinct volcano, and ex-industrial site. The former crater, previously a rock quarry, is now a showcase garden. Primarily a daytime park, at night the lower quarry garden is closed to the public. The garden became the site for the exhibition of twelve sound, visual and interactive installations created by artists: Jamie Griffiths, Miles Thorogood, Sebnem Ozpeta, Rob Scharein, Dave Leith, Laura Lee Coles, Merlyn Chipman, Mark Nazemi, Maryam Mobini, Wynne Palmer, Bobbi Kozinuk and an excerpt from *Coyote X* by the late First Nation media artist Terry Haines, presented by Aaron Rice.

Over 500 participants of varying ages, cultures and backgrounds enjoyed a rare opportunity to be a part of using the park in a non-traditional way during an untraditional time. To enter the installation area they had to descend a series of dimly lit stairways. Once at the bottom, the installations were viewed by walking the entire pathway, which snaked about through various levels encircling the large garden. The artworks could be experienced from afar, or up close – "in" the installation itself.

The members of LocomotoArt dedicated the exhibition to the memory of multi-disciplinary artist Terry Haines, of *Secwepemc*, Welsh, French and and *Tsilhquot'n* ancestry. A short segment of the late Haines' monumental four-channel video installation, *Coyote X,* was screened on the large rock face situated next to a fast moving waterfall that dropped forty feet over a granite rock wall. Viewers had to reach this area by walking over a bridge and pond. They could first see glimpses of the movement of light, with splashes of red, blue, turquoise, purple and patterns through the trees, but once at a designated place, they gazed upon the single channel video by standing next to the falls witnessing the Coyote emerging in and out of the brick poetry of *graffiti*. Haines wrote of his work that *Coyote X* mirrors human actions of adaptation and survival, "Standing like us in the shadow of a dominant society, amid urban sprawls, colonial ramifications and realities of expansion…[T]he contingent environment Coyote inhabits echoes our society's precarious tense on occupied traditional territories. The serene forest, Coyote's sanctum, has become a place of chaotic discord and unimaginable transition." [16].

beginning re-creation, was a multi-channel soundscape installation reminiscent of the former rock quarry of 1911. Presented by Miles Thorogood, whose work encompasses memory and imagination; the soundscape was generated using the *Audio Metaphor* system developed by Thorogood and Pasquier. "The composition module creates a layered two-channel soundscape composition by processing and combining classified audio segments. Each layer in the composition consists of processed background, foreground, and background with foreground sound recordings."[17] Thorogood placed eight small hand-made speakers into the landscape, challenging the participant to enter a dimly lit secluded path off the main walkway, surrounded by lush greenery on each side. As the participant explored this environment, they walked up several stairs to reach the top of a 20-foot lava rock mound. As they traversed this steep incline they experienced sounds of the derelict quarry, shifting back and forth with sounds from current place and time, that is, sounds recorded from the current botanical garden's acoustic ecology. To get closer to the final sound zone, the viewer had to step close to the edge of the 20-foot drop. The tension further augmented the participant's sense of memory, place and space as they heard clicking of metal tools and grinding of mechanized quarry work oscillate with the natural sounds of birds.

Vancouver based media artist Sarah Shamash presented her dual projection video installation *"D" for Diorama."* Shamash projected images of animals (tigers, gorillas, zebras, and rhinos) she photographed of the New York Natural Museum dioramas and alternated them with moving images of animals she videotaped at the Bronx Zoo. The installation was projected onto an 8-foot tall by 18-foot wide manicured Yew hedge. The alternation of uncanny dioramas with that of living animals that have been captured and removed from their natural settings – animals who in real life would never be found roaming the garden – invited the viewer to deliberate on the complex relationships among the animal kingdom, nature, and technology.

Interdisciplinary artist Jamie Griffiths employed a small-scale video pico projection accompanied by amplified audio for an isolated rock located off the main pathway, and found up a more secluded path with a slight incline. *BOTANICUS* discretely offered the visuals and sounds of people walking through Kew Gardens in London, UK (established in 1759 by British Royalty) and transplanted them into a public garden in Vancouver, BC. As the viewer climbed the small incline, the soundscape of Kews oscillated with the sounds of the present botanical garden. Through this alternating sense of presence of place, this meshing of locale, the conversations and species sounds intertwined to the point where sense of location was disrupted.

Conveyance[S] by Laura Lee Coles drew upon the geological history of the site known locally as "Little Mountain". Coles used the symbolism of fire to stimulate thoughts of the primordial beginning, *Conveyance[S]* invited viewers to reflect on the presence and absence of the former volcano by experiencing different forms and pat-

terns of flowing molten lava. Projected onto the rock face of hardened volcanic rock and framed by hanging tree branches, viewers glimpsed into the past made present, as if an eye or a ball of fire existed in the corner of the site looking back at them

Conclusion

In contrast to large-scale urban projection, the digital eco-art genre re-defines the role of technology and at the same time is reshaping public sphere *because it intervenes and exists* between experiences of electronic space/place and physical place/space *intimately*. As artists utilize the intimacy of the multi-sensorial realm of work *in situ* in natural spaces, meaningful implications may be observed for contemporary society as the work provides for shared social interaction and personalizes the sensorial connection with place and technology. The practice also changes the art experience from a contemplative one to a living experience by stimulating the human pre-disposition for affinity with natural space known as "biophilia", or "topophilia." [18] [19].

It is through lived and living experience that socio, cultural and ecological processes, the human connections to natural places, are both transformed and reinforced. There is great value in the re-visioning of public natural space through associations of cultural and environmental aesthetics, which reinforce connection and in turn may lead to enhanced aesthetic appreciation for the environment. [20] "The more hi-tech we become, the more nature we need." [21]

Acknowledgements

I would like to thank all of the artists of LocoMotoArt who have contributed to my research pursuits related to human, technology, nature interaction as well the various grant funders and sponsors for their continued support.

Disruptive Strategies in the Post-Digital City

Sandra Álvaro Sánchez

PhD candidate, Universitat Aut noma de Barcelona
Barcelona, Spain
sandraalvaro@enlaciutat.es

Abstract

The development of the sociotechnical apparatus shaping our Post-Digital space and culture ran simultaneously with the conception of a relational and processual reality and the development of computation and networks, which are becoming ubiquitous. These technologies have embedded in our physical space, giving birth to a fuzzy system that struggles between the opportunities for collective engagement, offered by the networked communication, and the capacity of control of a pervasive and opaque system. Art has been experimenting with these new technologies from its inception thus assuming the aesthetical and political commitment to develop strategies capable of disrupting the codes of domination and promoting a collective and constructive appropriation of space. These strategies refer to practices of embodiment and encounter, capable of promoting new assemblages towards the accomplishment of the Right to the City, the new citizenship proposed in the theories by Lefebvre and the actions of the Situationists.

Keywords

Post-Digital Space, Right to the City, Hardware Criticism, Appropriation.

Introduction

The city is the place of togetherness. It is the space of sociability and politics, as well as the ecological environment of our affordances and a collectively constructed form. This space is practiced and conceived according to an apparatus that codifies it the set of relations, discourses, institutions, laws, police measures and philosophical propositions supported by certain forms of knowledge and supporting the relations of power a space dominated and segregated in static functional parts. 1 However, at the same time it is the lived space, appropriated by its inhabitants and the rhythms of their moving bodies. 2 The body is not a substance but a producer of differences, that becomes understandable only when is considered conjointly with its medium. It became engaged with the reality around, interchanging information, starting new rhythms that produce resonances able to create new assemblages. Deleuze identifies this poetic activity with the ecological capacity of art. 3 The capacity to render the space expressive and give birth to the territory or inhabited space, where the process of subjectivation is possible. There is not subjectivation without the production of an appropriated space. It is a continual revolutionary activity, deterritorializing the codified towards the production of new assemblages.

The ongoing of capitalism and gentrification leads to a homogenization and fragmentation of space. The places of experience and identity vanish and the Dissolving City only endures as a museum or spectacle. 4 Later on, Castells attributes this dissolution of places to the rising of the space of fluxes. 5 The space of power, that organizes production in a global space thanks to the use of networked media. Territorialization and subjectivation become impossible in the fluid space and a new way of delocalized and diffused control appears. The Control Society, where individuals are always objects of information but never subjects of communication. 6 However, in his recent study about networked social movements Castells points to the possibility of appropriating the networks. 7 The net could become a place for encounter, a public sphere, where new social movements can begin. These movements are able to reach the street and produce social and spatial changes.

Lefebvre identifies the appropriation of the space with the “jouissance”, a way of enjoyment not related to non-work more than to productivism, to excess rather than to accumulation, to gift rather than to exchange. 8 In terms of space, it relates to the use as usufruct, the right to benefit from, use and enjoy something that is held in common ownership, as long as it is not damaged or destroyed common space that Agamben proposes as a result of the profanation, it being a way to challenge the apparatus that produces the dominated space, a form of use freed of goals, able to liberate the mediums, to return the spaces confiscated by power, and open it to the creative energies of the collective. 9 Both concepts refer to practices of embodiment and encounter, producers of disruptive situations where a liberated body moves and acts across the common space and oversteps the borders that fragments it in functional divisions. The appropriation is a poetic practice that renders the space intensive, where molecular bodies capture the noise and indeterminacy to start new interactions, the activation of non-actualized intensities capable of resonating towards the creation of new assemblages and territories.

The commitment to the aesthetic and political appropriation of the virtual and physical space has led to the development of strategies that materializes, firstly, as building blueprints then, as spatialized metaphors on the net, and finally, as embodied practices in the Post-Digital space. These are

raised from different fields that share a critical and productive attitude, increasing the capacities of the collective to interact and actualize the intensive matter and which applied to the common space are able to activate its collective production, the Right to the City.

The Architecture of "jouissance" or the mechanization of leisure: New Babylon vs Fun Palace

The playful appropriation of the space proposed by Lefebvre was practiced by the Situationists giving birth to practices such as the *dérive* (drifting), and the construction of situations. These are poetic actions involving the construction of environments that must be both the products and the instruments of new forms of behavior directed to revolutionize everyday life. New Babylon (1959-74) by Constant Nieuwenhuys was the project aiming to be the architectural space of these practices. 10 Conceived as a social space with movable articulations it was the playground of Homo Ludens, the new citizen with energy for becoming involved in the creative construction of a new environment and way of life after being liberated from work. It was an intensive space where physical dimensions were shaped by the actions of its inhabitants, made intensive by the use of technology as a tool for realizing experimental collectivism, by means of the promotion of communication. This labyrinthine city was never constructed Babylon must be the work of New Babylonians, for their creators it was only a model of reflection and play, an instrument to develop a new conception of social space.

In 1964, the architect Cedric Price, commissioned by Joan Littlewood and advised by a cybernetic committee directed by Gordon Pask, started another unrealized project. Fun Palace had to be a transformable building that emerged as a conversational process of the interactions among its occupants. 11 This building-sized transformable machine abandons the Situationist revolutionary goal of transforming life to become a space for leisure and the education of the masses. The authors of this building-toy responded to a different concept of human nature. The Homo Ludens is considered as a subject of learning and control, leisure is no more a chance for the freedom of creativity but an opportunity to educate the new specialized workers of the industrial era. Contrasting with the participatory architecture, the space collectively created by the inhabitants of New Babylon, Fun Palace is a responsive architecture, where technology is not an intensification of space, but a cybernetic machine that tracks and calculates the spontaneous movements and behaviors of its occupants an interactive construct that responds to the actions of the people within it while at the same time shaping them and their behavior. The architect becomes the engineer of social space, and their creation a concrete machine for techno-social construction.

International City Stand: Dematerialized metaphor on the Net

In 1990, Internet became accessible to humans through the interface, a virtual environment that spatializes information following familiar metaphors. This new medium for networked communication was soon considered as a new public sphere the anonymous, open, Agora, not hierarchized and freely accessible for the making of a new democracy. Amsterdam City was one of the first experiments for the collective appropriation of this new medium. It appeared as a free services provider in 1993, and was shaped as a city.

The Digital City was an interface built around the notion of square. In it, the city was used as a metaphor to show the culture-in-the-making resulting from the interaction between complex community spaces and the conceptual diversity and assembly that we can find in an open medium for general-purpose. 12 The Digital City closed in 2003. Nowadays social networks have substituted these services.

Social Networks are platforms for sharing and self-promoting driven by software, a social space where the architecture of participation encounters with algorithmic control. In it, our behavior leaves traces, data, retrieved and processed by the algorithms of artificial intelligence. The self-aware collective creation of space that characterized new Babylon shifts to the control driven by the non-transparent processes of a modular system that shapes our relations, a space where our choices are computed to capture our desire.

Software is not a neutral tool it shapes our relations and processes of involvement and determines ways of seeing and knowing. Software becomes a producer of culture and space. Matthew Fuller analyses how software criticism can foster disruptive interventions in the modular and in continuous variation control systems that are shaping our society, strategies that arise looking behind the software events. These are interpretive and reductive operations carried out according to the implicit politics of the dominant apparatus and with aesthetic capacities towards forms of control and production. Software criticism analyzes the indeterminacy of these events to propose new couplings towards unexpected results. 13

Fuller points to three strategies observed in different projects. Critical Software, consisting of the creation of pieces of software designed to open the black box of computerized processes, making explicit the protocols, statements dynamics and sequences of normalized software. Social Software, software produced, changed and developed as a result of an ongoing sociability between users and programmers. Free-software creates its own culture. Finally, Speculative Software, which takes advantage of the abstraction of hardware resources led by the process of virtualization to explore the potentiality of all possibilities, introducing creation and the possibility of change. It explores the capacity of software to foster transversal forms of connection, encounter the noise, and make the ordering of data categories or subjects spam out of control, leading to the possibility of a mutant epistemology and creative intervention.

The Post-Digital Space

Nowadays, computation is becoming ubiquitous. It is embedding the algorithmic processes of software into physical reality and reaching all the fields of our daily lives. The information becomes pervasive and the networked devices of the internet of things become new mediators of our relations with our world, which reduces everything to data, everything becomes normalized, stored, processed and retrieved towards a traceable and responsive space.

Post-Digital research is involved in the study of the development of this new responsive space. It is a reflexive criticism addressed to understanding the epistemology and ontology that this situation is producing towards a productive engagement with the new non-human agents that are populating our environment. Considering urbanism, it concerns the construction of the programmable space, not as unrooted, homogenized and fragmented no-where, jeopardized by the fuzzy relational systems of an imperceptible apparatus, but as a transactional environment populated by human and non-human agents, a space rooted in the specifics of the local and able to embrace difference a space populated by open systems that foster participation, empowering citizens, that can be appropriated for new uses and where everybody can be engaged in its social production.

Disruptive Strategies in the Post-Digital City

Post-Digital strategies challenge the Apparatus that produces and maintains our contemporary space. These strategies start in a reflexive analysis encompassing not only the devices and their functioning but also the processes, social relations and politics in which they are merged. With this aim, their practitioners refuse general standardized solutions to focus on situated issues arising from local communities. They do not accept information as a fact to be consumed passively and appropriate the spaces of knowledge and production for the common space. These strategies arise from research as production and are aimed at producing things that embody information and its processes, objects capable of invading the public space producing unexpected results and transforming the programmable space in writable information, where it becomes an interpretative experience open for creative intervention.

These strategies will be presented in three differentiated groups. The first are strategies making information tangible, directed at challenging the models implied on the production of cartographies of our space. The second considers the strategies that embody new social relations fostering new ways of social gathering and participation inherited from the traditions of FLOSS and DI . The third includes strategies directed at the intensification of space and the speculative production, introducing new non-human agents on the space able of promoting new intensities and affects towards the production of new assemblages exploring new possibilities.

Embodied interfaces

All our actions in the urban space are tracked producing data that are gathered and mined without our knowledge. The processing of all this data has led to a new form of cartography showed in well-known projects such as the Senseable City Lab's Real-Time Rome, Preemptive Media's Air, or Stamets' Crimespotting. Real-time visualizations that are aggregated in complex models, interactive dashboards as the IBM's City Forward. These models are used to redesign our environment towards an increasing efficiency and sustainability. However, they operate at an abstract level, disembodied from the reality that produces this data they normalize people, reduce differences, discriminate parts of the reality, and support concrete institutional frameworks and kinds of knowledge. Opposing these models we can find projects that produce new ways of interfacing information, making it tangible towards an increasing of our awareness and literacy of the communication process we are immersed in.

The projects produced by Julian Oliver consist of new objects produced to disrupt the automated systems and communication infrastructures producing our environment, thus resulting in the extension of our knowledge and capacity of intervention in these systems. In this way, the Transparency Grenade (2012-14) detonates leaking the information around. It captures all the traffic at the site and securely and anonymously streams it to a dedicated server where it is mined for information. Border Bumping (2012) is a work of dislocative media, an app that situates cellular telecommunication infrastructures and redraws national borders according to the disparities between virtual and political territories. 14

Embodiment of new social processes

Following the tradition of Free and Open Source Software, we find collective projects that engage people in the remixing, production and sharing of things. The open hardware connects with social processes such as the Do it oursSelf and Do it with Others, fostering new ways of sociability and reuniting people around the experimentation with the engineered objects interfacing our reality. These new local communities emerge in places such as Hacker spaces and City Labs confronting situational issues and the collective management of them. Projects such as Pachube are digitally-enabled places for the encounter of these communities. These are platforms allowing people to collect their own data that are shared in an open public network, free to interpret and reuse. 15 Other related projects extend towards the production of their own devices for data sourcing. This is the case of the Sense your City or the Data Citizen Driven City. 16 17 When people produce their own sensing devices in a shared and open way, they promote the awareness of how things work and how to engage in the production of the ecologies where they interact. They boost new epistemologies engaged in the appropriation of the spaces of knowledge and production towards a collective production and engagement in our environment.

Intensive space and speculative production

Finally, we find projects that use technologies to make the space intensive, by means of exploring the capacity of virtualization to create encounters between different realities.

Speculative production consists of the exploration of all the possibilities of space. It produces new things with new powers of assembly, where the noise produced by the playful actions of people is transformed into signals interacting in an open communication system towards the emergence of unexpected assemblages a poetics of connectivity that occupies the space with ephemeral or more stable unexpected structures. As an example, the DI City 0.01a (2012) is a prototype for a future mass-participation performance. In the project, the very streets themselves, and the buildings that look upon them, become the canvas for an urban-scale three-dimensional projection, a graphical environmental wiki that gathers the desires and expectations of a collective towards the production of urban space. 18

Conclusion

In our Post-Digital situation, the apparatus mediating our relations and producing our space have become a pervasive system where the mechanized processes of computation are reaching all the fields of our existence. They are determining forms of knowledge and production towards a functionalized reality in which we are immersed without being real users. For an effective territorialization of this reality that allows the process of subjectivation, an appropriation of these technologies is needed that allows information to become experienced in a public space. The examples studied here, are proposals that engage people in the participative production of the things mediating our reality. This playful appropriation increases our knowledge and awareness of the process producing our lived space, allowing our intervention and productive engagement. It boosts the profanation that challenges the dominated space of control producing a space open for productive disruptions towards an increment of our affordances. These practices are fostering new ways of collective engagement in the production of space, proposals that germinate new productive forms to the accomplishment of the Right to the City.

O'megaville: Excursions in Planetary Urbanism

Michael Hornblow

Post-Doctoral Fellow, Concordia University
Montreal, Canada
michaelhornblow@gmail.com

Abstract

Four decades ago Henri Lefebvre anticipated the complete urbanization of the planet, which no longer sounds so strange. Radical shifts seem to appear in our experience of the city, through dislocations of self and body, the World and the Earth. This paper explores a range of concerns underpinning a media performance project – *O'megaVille* – using Google Street View as a platform for critical approaches to planetary urbanism. This has involved dance workshops in Mexico, mobile media actions and video installation in Montreal and New York, and a performance-lecture in Toronto, amongst other events.

In this paper I'll use Google Street View (GSV) to think about how media assemblages play an enactive role in the speculative nature of experience. How may GSV be seen to illustrate what I see as an emerging urban condition that is simultaneously planetary and embodied? What may be at stake here for bodies (broadly defined) that operate within a distributed field of forces – in part nonhuman, often inhuman? And how may these disruptions in the fabric of experience call for a speculative response? Linked to a separate Artist Poster session at ISEA, this paper offers a series of conceptual and theoretical sketches for surveying the ruptured cohesion of Google Street View.

Keywords

Planetary Urbanism, Google Street View, Infrathin, Mondialisation, Cine-philosophy, User navigation, Faciality, Algorithmic intelligence, Image flatness

Introduction

It's not my intention to give an Artist talk here, for this occurs elsewhere, but rather to explore the broader conceptual implications of the project, so these might shift across conference formats in ways that invite disruption. It's also not my intention to comment on the work of other Artists who use Google Street View. Many of these reframe documentary photography in new ways – notably the work of Doug Rickard, Jon Rafman, Michael Wolf, and Mishka Henner. Others offer performative reconstructions of GSV, such as Ben Kinsley and Robin Hewletts' *Street With a View*, or Paolo Cirio's *Street Ghosts*. I'm interested in a more speculative approach for this paper, sketching a broad set of concerns that may find critical and poetic refraction in looking through the lens of Google Street View as a planetary image machine.

I'll focus on several features within GSV user navigation: first, finding three anomalies, or what I call a Stretch of the Imagination. These will be seen to offer a speculative reading for the future of planetary urbanism, drawing on Marcel Duchamp's concept of the infrathin, Jean Luc Nancy's approach to mondialisation, and Gilles Deleuze's cinephilosophy. Here I hope to locate a grey area for entering the Earth through a geological turn of the image. I'll go on to find what I call three Sites of Dis/Appearance, where Street View feels like the naked stumbling of early cinema, towards something new – taking us through cracks of continuity and smudgings of the subject, to become orbital in orientation. I'll conclude with a speculative proposition for excursions in planetary urbanism, with reference to my Poster session at ISEA where I offer a disruption for entering *O'megaVille*.

A Stretch of the Imagination

Extensive Surface: Google Street View gives us an image of the world as an extensive surface that seems to stretch and tear as we move across it, with each click smudging us further along our way. It's as if the stretch continues to the ends of the earth, or at least a kind of planetary continuation given by the image database. Even though incomplete in reach, it gives us the schema of a terrestrial flattening into the beyond – a stretch of the imagination.

If as Spinoza suggests, the imagination concerns affections of the body implicated with external bodies, present to us as images of things, [1] the question may become, how do digital geographies of this kind effect the way we situate ourselves in the world?

Geo-Presence: there is a sense of 'being there' enacted by Street View user-navigation, through the flattening and repetition of territory in the continuation of surfaces. A new Flat Earth phenomenon appears – especially when we use Street View to arrive somewhere physically, as if falling off the edge through a strange schism.

Historical Displacement: the feeling of geo-presence is nonetheless not quite Now, only until the last update on the image database. In some places we find local anomalies like this village in Sendai, Japan (Figure 1) – not updated since July 2011, soon after the Tohoku Tsunami. A few hundred meters away – on all sides – the reconstruction of

the region is virtually complete in a 2013 update.

Figure 1. Google Street View: Sendai, Japan. © Google

It's an historical displacement that feels somehow continuous with the movement of the world via the flat earth effect of GSV. (Or where the History View function also allows users to move back in time). These disruptions are especially uncanny here in Sendai as an echo of the devastation that was felt at the time – with the sweeping helicopter shots on News media and the invisible catastrophe that followed with Fukushima; to be felt everywhere as something planetary and embodied at an inexplicable rupture of scale.

An Infinite Now: for the purposes of user navigation its as if captured time becomes an enacted moment that repeats itself endlessly, giving us a fractured duration held somewhere between the image database and the act of arriving. A real place and a singular moment, but always there, pregiven and extensive, both untimely and enactive.

Planetary Urbanism

This inexplicable folding of a planetary surface opens in real terms to the kind of space-time disruptions we may see occurring in the experiential fabric of the City. In the 1960's Henri Lefebvre foretold the total urbanization of the planet. [2] But was this ever going to proceed as an even wave? Contemporary permutations of planetary urbanism are characterized by an uneven totality – a full datum of singular events within a complex whole, one in which the social tissue of experience is mutually affected by the built fabric and its surface distributions.

Black Hole Cities: Lets take Moscow for example. Moscow journalist, Ellen Barry, explores the involution of rural areas towards the urban metropolis. She says:

> "…the death of a village is a slow process. A geographer, Tatiana Nefyodova, calls them "black holes," and estimates that they make up 70 to 80 percent of Russia's northwest, where Moscow and St. Petersburg act as giant vacuum cleaners, sucking people and capital from the rest of the country" [3]

Or is it Moscow that's the black hole – a dynamic collapsing mass that pulls everything into its event horizon? And then at its core we pass into a parallel universe shared by Global cities the world over, where territorial abstractions acquire the floating density of integrated capitalism. It's as if we were to suddenly pop out the other side to find ourselves in New York, Tokyo or London, more so than any native country.

Topological Density: There are limits to the metaphor. But perhaps we can say that all are drawn along a strange horizon where uneven urban densities are distributed across the surface of the earth, subjecting all entities at whatever scale or category of existence to disruptions of an experiential fabric as much as a built one. An uneven topological field unfolding in and upon itself, through the systemic self-regulation of cities and their effects on all entities invested in the urban milieu.

We can see it in the trans-local evolution of global cities, transnational corporations and consumer products; we see it in the folding of reverse migration, or the donut effects of gentrification and economic polarization. We can almost feel it as a change in atmosphere as we move through the city. What I'm proposing here is that these contemporary permutations of planetary urbanism articulate an affective area beyond or further to normal space-time parameters, at a level that is simultaneously worldwide and embodied.

Entering the Infrathin

So how can we imagine such an area? Marcel Duchamp offers a useful conceptual figure for thinking about such a space – the infrathin. Not an actual space *per se*, but more of an abstract relation wedged in the concreteness of things. Donald Kunze defines the infrathin as "any delay between a conventional meaning and a further-on meaning." [4] Duchamp refused its definition, preferring to give examples: "The thickness of a shadow, the difference between two objects cast in the same mold..." [5] In Landscape Design Mary Kate O'Brien sees it in "...the thinness that separates artifact and site, the frame from the view, surface from depth, the distance between one moment and the next." [6]

These are all very instructive for GSV. The infrathin is that moment of the stretch, delimited by an extensive planetary surface; between navigation and being there; or of something having been there, now here. It's the strange fringe horizon of historical displacement, geopresence, and an infinite now; shifting points of disruption subtended by the full datum.

A World Without Another: If the infrathin helps to locate an image for this abstract relation, what is at stake here for planetary bodies, including our own, and how do we proceed? With globalization the World seems to have reached a territorial limit, to fold back through many black hole

scenarios, expanding and contracting, inventing new spaces for occupation. How do we renew our belief in the World when it brings us to a point of exhaustion?

As Jean Luc Nancy suggests, the World reaches an external limit as a transcendent ideal following historical vectors – Church, State, God, Empire, even Capital. [7] To find a 'world without another' we become earthbound, mondial or worldwide – in the sense of relating to or involving the whole World at once. We have already fallen off the edge of that other World - to find that this edge is in fact a crack taking us into a different flatness; a continuous surface where differential limits fold and spike across ruptures of scale.

A Different Flatness

There are always infrathin areas that escape capture, when we take time to pause, veer off and zoom into the fabric, to find an enactive depth within an event.

Figure 2. Google Street View: Moscow, Russia. © Google

There's something quite cinematic about Street View, when we reselect what has been randomly captured. Returning to Moscow, here's a young man walking down the street (Figure 2). Zooming in we find a different navigation and a different flatness – off track, at the limit of the image. Here depth-of-field is so shallow that everything seems to sit on the same plane – intersecting lines, dissolving colors, bleeding contours and textural artifacts – all coexisting on the surface with a painterly flatness. Then there's the way this young man raises his foot or holds his head with a pensive quality at the point of capture. It all indicates a life in motion – held for a moment – not just his life, or even a human one, but a life of intersection; an event ecology. The still image becomes cinematic in the way it singularizes a world, delimiting an expanded field of relations.

Cinematic Singularities: In his Cinema books Gilles Deleuze finds something unbearable in the World – in the limit of thought and the weight of time, where microintervals of experience shift within a given milieu. [8] In Cinema he also finds reasons for believing in the World once more, in its singular construction of 'a' world. Two useful concepts here are 'camera consciousness' and a 'filmic subject'. The way the camera moves around a scene gives us a nonhuman or more-than-human perception, letting us see and feel things beyond selective consciousness and subjective perception. The kind of subject this enables is not just one of human agency, but the film itself as a broader process of individuation.

Cinema constructs a singular world without another, while making possible modes of perception that may take on the World all at once. Movement and time enter disruptive delays and relays, through circuits of perception, affection and relation, giving the image an enactive plasticity in the event. We see this for example in the suture of cinematic montage, with the fullness or fracture that results when Film directors manipulate gaps and elisions, to elicit affective shifts in the spectator.

Google Street View has its own scopic specificity, but cinematic parallels become useful for the way these contemporary permutations of planetary urbanism may generate disruptive and productive contrasts with singular aesthetic worlds. As we've seen, strange hybrids of movement and time appear in the Street View image – geo-presence, historical displacement, the infinite now – mediated as a full datum. (Or at least, via the scopic assemblage of user navigation, image database, algorithmic intelligence, and satellite array).

Sites of Dis/Appearance

Moving towards a kind of Conclusion, I'd like to revisit a Stretch of the Imagination by locating what I call Sites of Dis/Appearance; where people seem to fall into the Earth – through the image – at the limit of the World.

Differential Flatness: The first of these is our young guy in Moscow, where a world appears just as the subject disappears into it – a different flatness becoming differential at its limit.

Scene: In terms of montage, there are about 4 or 5 image captures taken by the 9-Eyed camera of the Google car before it moves on. If we follow our guy we get a sense of moving around a scene, like a series of jump cuts, with all the gaps in continuity dropping us into a wider plenitude: the machinic vision of a planetary assemblage.

Stitch & Fray: As we move around the scene, the stretch from point to point reveals the way it's all stitched together. People seem to disappear when we try to follow the thread of the montage, especially at traffic intersections. This is because the Google car follows an economy of movement, cutting the city grid in lines – this way and that. On the database the temporal disjunction is stitched together to give the illusion of spatial continuity. At intersections you will often pass through these temporal dislocations, where people seem to appear and disappear as if through a crack.

Blur: Yet another flatness, and this time where the subject really disappears – into the scopic assemblage and out to a different milieu. Our man in Moscow has his face blurred to satisfy privacy concerns, as does everyone in the Street View world. It's a neat paradox – privacy is protected just as the public is privatized. Google owns the image, as if removing us from public space in a twofold pincer move. Or perhaps this is just another fold in the surface of planetary urbanism. Our faces are erased rather than identified – but the effect is the same, through face recognition software. In a reciprocal overcoding of power and overdetermination of desire we allow ourselves to be profiled, simultaneously fixing and mobilizing the subject within the computational agency of self-as-world.

Smudge: White Wall / Black Hole

For Deleuze and Guattari the notion of faciality operates as a grid of power - the White Wall of the face and its Black Hole orifices become a machinic configuration of signifiance and subjectification. [9] Street View blurs the two in a single smudge, making something inhuman of the face, and beyond it something strangely nonhuman.

An algorithmic intelligence saturates the scene, extending the smudge of signifiance and subjectification across each and every locale – including linguistic identifiers such as street signs and number plates. Anexact in measure, it accidently overreaches its protocol to find faciality traits in the pattern of leaves on a tree, or an arrangement of trash. It de/faces each location to excess, just to be sure, so all sorts of things get caught up in the strange horizon of the White Wall / Black Hole system.

Gridlock: Face recognition software calculates variations on a grid – mouth-line and eye-line across the bridge of the nose. Its not much of a stretch to see how the Grid as a primary urban condition allows an extensive surface for the White Wall, with all its ruptures of scale through the Black Holes of planetary urbanism; more-or-less human / more-AND-less human.

But lets not fall into an easy dystopian critique. Deleuze and Guattari saw the potential for defacializing the face with the notion of Probe Heads – the invention of new Black Hole / White Wall configurations; faciality machines that multiply and transform traits, becoming abstract to excess – something animal, botanical, architectural perhaps.

Conclusion: A Proposition

For *O'megaVille* I'm interested in tracing a migration of faciality traits within a given location, plunging through the face to find other smudgings across the scene. Here I aim to take this paper through a speculative segue as a practice-based research project. I'm also presenting an ISEA Poster session using a Google Cardboard VR headpiece for building Probe Heads out of things found on the street. I'm curious as to how Cardboard VR recalls early 3D Cinema glasses taken into the mobile-media space, where the flatness of Street View may acquire an orbital dimension for the cinematic futurity of planetary urbanism.

I want to hang this out there as a teaser, offering it as a proposition rather than a conclusion. Where this paper cross-links may be an opportunity for disruption, and for further excursions into planetary urbanism. I invite you to join these forays, from the flatness of this paper to embodied dislocations in the orientation of theory and practice.

3x4: Exploring metaspace platforms for inclusive future cities

Prof. Paul Sermon, Dr Claire McAndrew, Swati Janu, Vivek Muthuramalingam

Abstract

In megacities such as Delhi and Mumbai - and within one of the fastest growing cities within the world, Ahmedabad - more than 50% of the population live in informal urban settlements. 3x4 metres is the plot size seen to be provided in some resettlement colonies, a government initiative which relocates people within informal inner-city settlements to vacant land on the periphery. In a collaboration between Professor Paul Sermon at the University of Brighton, Dr Claire McAndrew at The Bartlett, UCL, Swati Janu a Delhi-based Architect and photographer Vivek Muthuramalingam from Bangalore, 3x4 looks at informal settlements differently where informality is not viewed as a problem, but a promising new model of urbanism for the global south. 3x4 uses an immersive telematic networked environment to provide a playful, sensorial exploration of new hybrids of digital space. Merging two 3x4 metre room installations in Delhi and London through mixed-reality, this transnational dialogue intends to set an aspiration for developing metaspace platforms in megacities of the global south. It builds upon practice-based research conducted as UnBox LABS 2014 Fellows in Ahmedabad, India; which used an immersive installation to explore the qualities and values built through self-organised communities that are lost in the resettlement process.

Informality, metaspace, telematic, resettlement, communities, videoconference, urbanism, population, India, cities.

Introduction to UnBox LABS

3x4 is an AHRC funded research project that seeks to identify a future cities *metaspace*, with a view to connecting communities and contributing to dialogue on informality in the global south; 'informality' in the context of this project refers to anything that does not fall within the purview and planning of the civic authorities. It is the component of the city that is not formal i.e. organized and planned, and consequently considered illegal. The project offers an alternative way of seeing informal settlements that prefaces their ingenuity in the face of adversity, over their illegitimate status. Such a perspective becomes necessary as informality gives rise to a new type of urbanism, one that is fuelling the growth of megacities in the global south and redefining temporal narratives of progress.

With an interdisciplinary team of researchers and creative practitioners, 3x4 seeks to embrace the informality of the global south and re-imagine new hybrid platforms. Through creative practice we have used the 3x4 metre resettlement plot size as an interface to identify an alternative *metaspace* platform. This initial 3x4 project concept was arrived at through our collaborative participation at the UnBox LABS Future Cities workshop at the National Institute of Design in Ahmedabad, March 2014. [1] Our interdisciplinary range of subject specialisms and practices were first brought together and explored in a scoping project that culminated in the development of a prototype video installation, consisting of a 3x4 metre muslin-covered bamboo structure (see fig. 1) exhibited at UnBox LABS. [2] This installation incorporated video projections of images and quotes sourced directly from informal settlements and their inhabitants, focusing on the role of networked technologies within these communities. The combination of the 3x4 plot size and verbatim comments clarified an opportune sense of informality and signalled the need to further explore new systems of communication within future cities of the global south.

3x4 Research Context

We now stand at the fulcrum of urbanisation with 55% of India's population expected to be living in cities by 2050. [3] Millions in the global south are leaving their rural homes in a mass movement toward the cities as they hope for a better life. [4] As cities swell under this surge of migration, informal settlements are proliferating to accommodate for the large numbers that are unable to find affordable housing. Viewing them as eyesores without

understanding the predicament of the inhabitants, the civic authorities have been seen to raze such settlements, sometimes leaving thousands homeless overnight. [5]

In a drive for 'beautification' of the city, those that are evicted are forced to resettlement colonies at the periphery of the city, with little or no infrastructure and in plots of land as small as 3x4 metres. Fast-tracking the creation of 'slum-free' cities and without addressing the larger issues at hand, the authorities in Delhi have started relocating people into high-rise buildings within the city. [6] The failure of such experiments in the West are many, from the Pruitt Igoe housing in St. Louis to the Aylesbury Estate in London. Without learning from the mistakes of the global north, Indian cities, like many other cities in the global south, aspire to be 'world class' cities such as New York or Dubai, overriding the requirements of a majority of their populations.

What is lost in this process is the strong sense of community and qualities that make informal settlements a productive and integral part of the city. These settlements need not be viewed as eyesores or problems within a city, but as self-made solutions by communities. It is arguably the DIY nature of such settlements that have helped communities survive in the face of government apathy. This iterative quality of informal urban settlements is necessary for empowering people to make their rightful claim to the city and bring about development. It seems the global north has much to gain from dialogue with its southern counterparts, with the conceptual development of 3x4 metre solutions as a sustainable and affordable solution to UK housing. [7] 3x4 provides a new way of viewing informality and our relationship to megacities as we envision the Future City.

Figure 2. Chroma-keying process used in 3x4 installation to composite images from Delhi and London together with computer generated background. ©Sermon, P., McAndrew, C., Janu, S.

3x4 Research Project

This next iteration of 3x4 contributed to the UnBox Festival in Delhi, 12 to 14 December 2014. [8] Using a live telematic videoconference connection, the installation functioned between two geographically distant audiences located in separate 3x4 metre blue-box room installations at Khoj International Artists Association in Delhi and Southbank Centre, London. The audience groups in these two blue-box spaces were captured on camera and brought together through a system of live chroma-keying (see fig. 2) and were placed onto a computer-generated background image. The complete composited image was then displayed simultaneously on large LCD video screens in both locations. As the merged audiences started to explore this shared telepresent space they encountered the digital background environment they now both coexisted within. These background scenes were co-created by online participants in London, Delhi and across the globe via a 3x4 project web portal and shared Google drive. [9] By uploading an image or downloading other people's contributions and using elements of them in their own, they created the environments displayed within these rooms, whatever they imagine that to be, directly referencing their combined social setting, ranging from informal settlement dwellings and Delhi environments to contemporary compact interior designs, micro living solutions and virtual worlds; asking what does a co-created 3x4 metre London/Delhi living space look like? In addition to occupying digital 3D models and photographed living spaces audiences were provided with chroma-key blue fabric and invited to bring objects and props into the 3x4 room to further explore their telepresent coexistence in this new *metaspace* platform.

The 3x4 installation in Delhi was located in Khirkee urban village at Khoj International Artists Association and opened directly onto a busy street (see fig. 3) within reach of a broad audience demographic, providing equal access to all local community participants, ranging from the inhabitants of informal settlements and urban villages to residential home owners and commercial businesses. The connected 3x4 installation at Southbank Centre London was equally situated in a public space, located in Festival Village at street level it also encountered a broad cross-section of public that inhabit and pass through the space daily. Spanning five time zones, the installation was connected six hours a day from 10.00am to 4.00pm in London and 3.30pm to 9.30pm in Delhi, combining two cities not just spatially but temporally, from the start of one person's day to the end of another's. The opportunity for the audience participants in Delhi to decorate and customise the interior of their 3x4 space played a pivotal role within the installation. Items of furniture, domestic objects and a means of self-construction were introduced and made available to explore how subjective design interventions influence the user experience and their creation of multidimensional spaces.

The networked convergence of these two physical 3x4 metre structures and their urban locations allowed these diverse public audiences the opportunity to explore networked spaces as new mixed-reality hybrid environments. It made it possible to experience, not only the presence of geographically distant participants, but also

a sense of coexistence with them. Using the embodied platform of open interaction as an alternative networked communications protocol, enabled them to define the context and narrative of what followed. Both audiences responded enthusiastically through their interactions with the installation, particularly in Delhi, with over 500 participants and return visits over three days the intervention made a significant and memorable impact on the community.

Figure 3. 3x4 at Khoj Studios, Khirkee village, Delhi. Dec 2014. ©Sermon, P., McAndrew, C., Janu, S., Muthuramalingam, V.

Through the design of 3x4, its methods of connection and representation, the layering of London over New Delhi provided comment on the domination of the global north and rising of the global south. And yet, the co-creation of built and imagined landscapes offered opportunity to redefine collective futures, a critical visual commentary on living spaces, racial segregation, informality, underground culture and contemplative fantasies. Occupying a part-demolished building via 3x4, took the matters of informalising architecture, contested space and merciless destruction to a global audience (see fig. 4). Not just imaginings, 3x4 also morphed into a playground of spontaneous and undirected play. Children, for whom the street and the objects it contain form a recreational landscape, shifted their space of play to this metaspace. Using their bodies as an interface, they even shared a digital chair – emblematic perhaps, of this approaching inversion and shared digital future. 'Playing the city' it seems, can bring built and imagined spaces closer together, creating new typologies of architectural space that shape lived experience in novel ways.

Play is in the eye of the beholder

3x4 is a temporal and spatial timecode; reduced to its ephemeral elements it consists of 18 hours of memories and reflections in the minds and collective recollections of those who participated in it, played out over three days on 12, 13 and 14 December 2014 from 10:00-16:00 GMT / 15:30-21:30 IST daily. Ultimately what remains as its legacy is a story told in and between two cities consisting of human encounters and events that unfolded in a state of flux between London and Delhi. Whilst every effort was made to document this transitory happening through photographs and video footage the single most important recording was from the line out video feed (see fig. 4); the final composited or chroma-keyed image of the audience participants displayed within the installation itself. When watching this recording we are taking up the position of the persons within it; we are looking directly at the very same image that caused the effect we are now contemplating for ourselves.

From beginning to end, the entire recording represents a 1080-minute data stream upon which we can now study and apply our own minute-by-minute layer of metadata based on observations, reflections and analysis, as we look the participant in the eye through this 'two-way mirror' recording. This video contains memorable moments upon which we can now reflect, such as when a young boy in Delhi enters the space and initially waves to participants in London, staying for over an hour perfecting his interactions and gestures as he invents and plays new games. Or when three ladies in Delhi enter with two babies greeted by participants in London eager to hold and play with them, who appear to be memorized by this lacanian moment of realization as the babies stare into the screen (mirror) [10].

Figure 4. Video still from line out recording of interaction in 3x4 installation. Dec 2014. ©Sermon, P., McAndrew, C., Janu, S.

Impact and Legacy

This public legacy represents a pathway to future cultural, social and economic impact that goes beyond its academic context, and has the opportunity to help shape the future cities of the global south. This legacy pathway draws on an analogy with other examples of significant research impact that have helped create the networked communities and technology industries of the United States west coast. This impact has resulted from the legacy of pioneering interactive media artworks and public interventions from the 1970s and 80s. Including seminal artworks such as *Hole-in-Space* by Kit Galloway and Sherrie Rabinowitz from 1980 [11] that linked live public

audiences in Los Angeles and New York, the *WELL* (Whole Earth 'Lectronic Link, 1985) network which was one of the earliest independent virtual communities based in San Francisco, [12] and pioneering projects such as *Send/Receive* by Liza Bear and Sharon Grace in 1977 involving public participation in some of the first interactive satellite art events. [13] These are among many examples of networked interventions and happenings that are often cited as the beginnings of the Internet and set a stage for the continued influence of the United States west coast today. In the same way, the 3x4 installation in Delhi and London aims to capture the collective imagination of its public audience to create its own legacy and similar level of impact albeit in relation to the inclusive needs of future cities in the global south.

In the context of informal settlements in megacities of the global south, the 3x4 installation provided many public participants with their first encounter of a networked platform. Through this unique engagement public audiences acquire new knowledge through their lived experiences that present a possible vision of a future city *metaspace*. These first time encounters and experiences can be used by the participants to influence future projects, define methods for using this new knowledge to inform themselves, who in turn tell their family, friends and colleagues of this new experience, motivating others to engage in similar experiences in future projects. The intention of this legacy is to inform a critical public community that impact on future network protocols appropriate to the needs and requirements of a future cities *metaspace*. At the same time it seeks to identify its relevance in the global north. The dialogue between Delhi and London is a critical pathway in connecting communities and contributing to dialogue on informality in the global south and its symbiotic relation to future cities in the global north.

The success of the 3x4 has led to the Southbank Centre London inviting the installation back for inclusion in Alchemy Festival from 15 to 25 May 2015 and Web We Want Festival from 28 to 31 May 2015, linking the Royal Festival Hall in London and India Habitat Centre in Delhi.

Paul Sermon (http://www.paulsermon.org) is Professor of Visual Communication at the University of Brighton. He has worked for over twenty years as an active academic researcher and creative practitioner, primarily in the field of telematic arts. Having worked under the visionary cybernetic artist Professor Roy Ascott as an undergraduate Fine Art student, Paul Sermon went on to establish himself as a leading pioneer of interactive media art, winning the prestigious Prix Ars Electronica Golden Nica in Linz, Austria, shortly after completing his MFA at the University of Reading in 1991. An accolade that took Paul to Finland in the early 1990s to develop one of the most groundbreaking works of his career Telematic Dreaming in 1992.

Dr Claire McAndrew is a Research Associate and Chartered Psychologist (CPsychol) at the Institute for Environmental Design and Engineering, The Bartlett UCL's Faculty of the Built Environment. Combining social science insight with design-led thinking, she is interested in the possibilities of design and digital technologies to facilitate connections between people through urban space for transformative effect. Her research since 2008 has focused on the embedding of design interventions in public spaces to shape cognition and behavior in the contexts of human wellbeing, security and resilience, and future workplaces as they extend beyond buildings into the fabric of the city.

Designing Interfaces to Experience Interactive Installations Together

Claude Fortin and Kate Hennessy

Abstract

Researchers at the *Making Culture Lab* use ethnographic methods to study how interactive technology supports digital practices in diverse cultural environments. This paper reports on how certain design aspects of display systems implemented in public space can induce social encounters and awareness. Field observations made since 2012 show that interface design may be a key factor in structuring such shared experiences. In 2014, HCI researchers introduced the Social Natural User Interfaces (Social NUIs) analytical framework to help HCI practitioners design interfaces that better support collaboration and cooperation in co-located multi-user interaction scenarios. This study describes four interactive media façades deployed in Montréal's Quartier des Spectacles to suggest that electronic artists intuitively anticipated the Social NUIs relational approach to interface design. Analyses highlight how the artists used crossmodal interfaces – also based on intuitive modes of interaction such as gesture, touch, and speech – to design interactive installations that engage people beyond the ubiquitous single-user "social cocooning" interaction scenario. The aim of this research is to illustrate how artistic architectural-scale digital public display installations has the potential to parallel, drive, and contribute to, socially concerned design thinking.

Keywords

Interface design; interactive displays; crossmodality; natural user interfaces (NUIs); Social NUIs; public space; urban interventions.

Introduction

While Huhtamo traces the history of public media displays to Ancient Rome, he further claims that it is the invention of electricity that saw dynamic displays and media façades make their appearance in public outdoor space. As far back as the nineteenth century, incandescent bulbs were used to illuminate advertising billboards while magic lanterns were used to project images on screen surfaces, walls, and public monuments. [1] Although today, these media platforms are electronically engineered, they often tend to serve similar purposes; typically, they are used to publicize commercial content, news, and location-relevant information.

Likewise, Manovich argues that digital technology has borrowed from older traditional forms – such as print and cinema – to remediate new media objects into *cultural interfaces*, a concept he defines as computerized screens that encode culture in digital form. [2] Because digital screens can now be used to mediate action and control, the design of cultural interfaces presents significant challenges with all new implications that reach far beyond issues of representation. [3] A case in point is how unleashing their interactive potential at the scale of the built environment might redefine people's everyday experience of the city.

Relatedly, contemporary artists are using the *crossmodal* properties of new media to experiment with large display installations as a media platform that can transform perceptions from one sensory modality to another. [4] For instance, *MindWind* uses ambient traffic noise (audio input) to trigger movement in an architectural-scale video projection (visual output). [5] The artist's stated intention is to use "elements that are part of our everyday environment to reconnect people to their sense of place." [6] Mediating one sense-impression into another also evokes an invisible link between the natural world and the transcendental.

Since 2012, the *Making Culture Lab* has been investigating such creative uses of dynamic digital displays in public space with a focus on understanding how new media artists are harnessing the interactive medium-specific potentials of screen-based systems to induce new forms of encounters and awareness. Field findings show that interface design may be a key factor in structuring such shared experiences.

Recently, the *Social Natural User Interfaces* (Social NUIs) analytical framework was introduced to the field of human-computer interaction (HCI) to help practitioners design interfaces that better support collaboration and cooperation in co-located multi-user interaction scenarios. [7] Social NUIs support a relational approach to interface design against the deeply ingrained technocentric orientations that have largely driven this research in past decades.

This case study describes four interactive media façades deployed in Montréal's Quartier des Spectacles to suggest that new media artists anticipated the Social NUIs relational approach to interface design in their screen-based artwork. In so doing, they may have paralleled, driven, and contributed to socially concerned design thinking by conceiving crossmodal interfaces that invite and engage people to experience interactive installations together.

Qualitative Field Study

Since 2012, we have been applying a multi-sited approach to the study of interactive media in public space with a focus on investigating the creative uses of dynamic digital displays. Our objective is to gather field data that will help

generate design knowledge on interactive display-centric technology deployed in urban environments. The following describes the research methods applied in this field study.

Methodology: Multi-Sited Design

The research methods used in this empirical study are derived from multi-sited design, an approach that draws from HCI, the social sciences, and the humanities. This emerging constructionist methodology is rooted in Scandinavian practices of participatory design as well as in multi-sited ethnography. [8] Participatory Design is a set of methods used in HCI to engage people in collectively participating in the design of the computer systems they use in the everyday. [9] Multi-sited ethnography is an interdisciplinary critical approach, which consists in conducting research in multiple, distributed, and shifting (micro) locales to later be analyzed against the contours of the overarching (macro) context that comprises all of the sites under study. [10]

Multi-sited design is a research strategy that can support thinking through making within the rapidly shifting socio-economic global context in which art and technology are being produced today. While traditional ethnography typically sees one or sometimes several ethnographers describe a single, well-circumscribed site, in a multi-sited approach, many researchers can be sent to collect data in multiple sites. [11] These sites are not only defined by their physical locations. They can be events, artifacts, narratives or even stakeholders. Further, such a method can allow researchers to compare the shifting and multiple virtual sites of representation that exist in online environments to situated sites.

By triangulating this data, a researcher sets out to sketch a broad picture or narrative, which exposes the web of complex relationships needed to create conditions conducive to the emergence of artistic creations or advances in art, science, and technology. In our research, the sites under study were made up of four art installations analyzed as situated events, which served as the locus of interactions between concerned stakeholders. By tracing connections between these sites, we attempted to identify design trends.

In this particular field study, data was collected while conducting non-participant observations of several interactive art installations deployed on some of the nine media façades of Montréal's Quartier des Spectacles, including first-hand field observations and notes, interviews with stakeholders involved in these projects; and a survey of the audio-visual materials that documented these artworks. In its broader context, this study was the exploratory phase of a latitudinous research that relied on participant observation and involved other places, stakeholders, artifacts, and events unified under a common thread: design knowledge.

Meta-Site: Montréal's Quartier des Spectacles

The past decades has seen major urban renewal projects undertaken all around the world to potentiate the new knowledge economy's "creative cities" by rebranding them as attractive and innovative cultural metropoles. [12] It is in this context that Montréal's Quartier des Spectacles came to operate nine media façades, wired connections, and a free wireless network within the boundaries of their one square-kilometer district. This permanent digital infrastructure enables artists to explore ways to catalyse public interaction and showcase their interactive public art pieces.

The deployment of such electronic artifacts is facilitated by ten kilometers of fiber-optic cables laid out underground to connect the master control room to strategic emplacements throughout the Quartier des Spectacles. Because this robust setup can support the real time transfer of massive data flows, it ostensibly encourages artistic experimentations in public space. Indeed, the Quartier des Spectacles announced in 2014 their intention to activate their nine outdoor media façades as a *digital urban laboratory*. [13]

Our field study considers some of the more interesting innovations that took place around the first instantiation of the *Digital Pathway*, a digital arts event during which interactive display artifacts were simultaneously deployed on some of the Quartier des Spectacles's nine media façades.

Key Approaches to Interface Design

While the last part of this study presents a detailed description of each of the four architectural-scale electronic art installations selected for analysis, the following section expounds the theory that guided our *post hoc* analysis of these artworks. Accordingly, it offers a selective overview of HCI approaches and concepts related to interface design to inform our discussion on interfacing devices used in digital art installations that include public media displays.

Crossmodal Experiences and the Digital Arts

While it can be said that each media technology offers its own ways to extend or compress the way we perceive, experience, and act within the matrix of time and space, it remains that today's screen technology comes with an unprecedented affordance. [14] Because it takes the form of digital data, it is now possible to transform media content into other media types, forms, and sensory modalities. [15]

Rendered possible by electrons – the very substance that digital information is made up of – this phenomenon is known as *transduction*, a three-step process which consists of, first, capturing raw data in the form of input; second, processing this data according to a set of prescribed protocols; and third, outputting it into an altered state. [16] Insofar as this characteristic of new media enables the conversion of one sense impression into another, digital art can be said to be a medium that supports crossmodal interaction.

But is this crossing over of sensory perception a novel phenomenon in people's experience of art? Merleau-Ponty claimed that everyone has a "synaesthetic perception" of their environment [17]. Notwithstanding that at any given moment, some sensory impression may overpower others, he purported that perception occurs through a "phenomenal field" in which different sensory modalities intermingle and mutually resonate with one another as sensory impres-

sions are experienced. [18] For instance, we can feel the softness of a fabric without touching it or hear the thump of a falling body even when it is observed without sound.

Many works of art defy Aristotle's concept of sensory discreteness, which suggests that we perceive an object according to the sum of the discrete sensory modalities it stimulates: its edges appeal to our sense of vision *and* its sound to our sense of hearing, *and* its texture to our sense of touch. [19] Not only does the experience of art tend to confound sensory modalities, but many artists have learned to use materials, colors, forms, and aesthetic strategies to produce artwork that stimulate perception across several senses or indirectly awaken one sense through another as when a sound is heard, or imagined to be heard, in response to a visual stimulus. With most media, this effect is achieved by association, metaphors, and evocative designs.

Artists working in new media, however, can use the principle of transduction to draw attention to how sensory impressions mutate into one another or trigger percepts across modalities. In fact, the science of electronics allows today's artist to expose this process in material form. In this sense, digital media lays bare the mysterious connection between the intangible and the tangible, the invisible and the visible, or the imagined and the experienced. Insofar as new media interfaces can make manifest how senses interact with one another, creating crossmodal interactions can become a means to expose these poetic relationships.

Further, because new media makes it possible to hypostasize crossmodality in works of art and because electronic artworks are conceived around this affordance, one could say that transduction constitutes a medium-specific property of digital art. [20] Indeed, most of the large-scale display installations described in this study proposed interactive experiences that remediated inputs across sensory modalities. In truth, this design feature has become so pervasive in the objects we use in everyday life that we rarely give it a second thought. Seeing, hearing, and feeling are now routinely combined in one of the world's most ubiquitous devices: the portable phone. [21] This becomes evident when it lights up, plays a tune or vibrates to alert users that there is an incoming call or a given location is close. [22]

This not only suggests that input and output are to digital art what brushstroke, color, and surface are to painting, or what light and contrast are to photography, it also implies that *interface design* constitutes a key factor in how new media objects shape aesthetic experiences. Interfacing devices are the membrane through which input and output are expressed and modulated – and although sensor and actuator technologies make up their nuts and bolts, in the end, user experiences are structured by interfacing strategies.

The field research we conducted on interactive display installations in Montréal's Quartier des Spectacles suggests that electronic artists often accidentally stumble upon unusual and innovative interfacing strategies in their creative work. Our review of the literature also shows that as far back as the early seventies, artists such as Peter Campus, Vito Acconci, and Bruce Nauman pioneered large-screen interfacing strategies by experimenting with human-scale video art installations. [23] The work of these legends and many lesser known artists arguably anticipated interface design thinking. The next section examines scientific trends in this area. This overview of the literature will be used to frame our discussion on examples of practice in art.

Natural User Interfaces (NUIs)

One of the major research trends in HCI is driven by the concept of *Natural User Interfaces* (NUIs), which proposes to rethink interface devices so they are responsive to "more natural forms of interaction such as touch, speech, gestures, handwriting, and vision" [24]. The assumption that underlies this approach to interaction design is that NUIs are said to be more intuitive and usable because they are arguably better adapted to everyday human actions, and thus more natural and easier to use. NUI advocates believe that developing interactions around a wider range of input modalities will enhance interactants' sense of power, offer better opportunities to design new forms of interactions, and more holistically blend users' actions with technology.

Because every new human-computer interface typically presents its own set of challenges and learning curves, Norman argues that natural user interfaces are not inherently natural, but certainly useful in enriching the existing repertoire of interaction techniques by adding more touch-based, gesture-based, and speech-based interaction to the existing arsenal. [25] In the same line of thinking, Wigdor and Wixon argue that adopting a NUI approach effectively multiplies expressive capabilities. [26] These remarks speak to the fact that interface design is not only a determining factor in what is *vs.* was is not possible in the realm of human-computer interaction, but also in that of art.

Design Approaches for Large Display Interfaces

In relation to screen technology in particular, Müller et al. offer a detailed taxonomy of design factors that support interaction including cognitive factors, interaction phases, interaction modalities, and mental models such as conceiving public displays either as posters, mirrors, windows or overlays. [27] Others metaphors that have been proposed to conceptualize the design of interactive public displays include *public notice areas* [28]; *community gardens* [29]; *theatrical stages* [30]; and *digital soapboxes* [31].

Beyond these dimensions, there are two aspects of large public displays that define them as a distinct type of interface: first, they can and are often used by more than one person, and second, they are deployed in a public context. Accordingly, design concepts and frameworks that place an emphasis on these seem particularly well-suited to developing the interactive potential of displays. This is the case, for instance, with the concept of *Shared Encounters* defined as spontaneous forms of communication and interaction that can take place in public places through technology [32]. More to the point, *shareability* is a concept that proves useful in operationalizing interaction in terms of entry points and access points in multi-user interfaces. [33]

The past few years, however, have seen a new approach emerge that is premised on this very idea of shareability in conjunction with that of natural user interfaces. Known under the moniker of *Social NUI*, it aims to facilitate thinking about multi-user interface design at an abstract level.

Social NUIs

Several HCI researchers have been concerned with the idea that NUIs are too focused on the single user's relationship with the interface and by extension, the system. Many of the researchers that have developed this framework are from the field of computer-supported cooperative work (CSCW), which is concerned with how people use technological systems to communicate, collaborate, and coordinate their activities. [34] Some felt that the concept of NUIs needed to be reframed into a model that could support these interactions. They describe Social NUIs as interfaces that "facilitate new forms of social interaction, participation and collaboration – how we communicate with each other, play together, learn together, and collaboratively work together through these technologies." [35]

Social NUIs place the focus on the relational aspects rather than the mechanics of interfacing devices. For this reason, it is an approach that arguably places greater focus on meaning and values because it encourages designers to:

> *"…extend the broader set of analytical concerns around NUI technologies to consider the meaning and values of these technologies as they are enacted in context..."* [36]

Given that most large interactive media displays are deployed in a public context, this study contends that the Social NUIs framework may be well-suited for this type of platform. To illustrate the forms Social NUIs could take in relation to dynamic digital displays, the following looks at four digital artworks that relied on custom-made interfaces specifically designed to engage users to experience the installations together as interactants *or* audience members.

Field Study: Four Interactive Art Installations

For a number of years and until recently, many of the HCI practitioners developing applications to interact with digital public displays used small, ubiquitous, portable devices such as cell phones or smartphones as their interface of choice. Although this trend was largely spearheaded by engineers, many artists followed suit by using this interaction strategy to conceive their own digital art installation. Figure 1, for instance, shows Yan Breuleux's *Tempêtes*, a media façade deployed in the Quartier des Spectacles that allowed people to post comments using text messaging.

Interface Size Matters: The *TRAME* Project

Our first case study offers a better example of how interaction with a media façade can afford greater shareability. Like the interactive video projection in Figure 1, *TRAME* sourced user input from people's personal portable devices, but its application called for more screen real estate.

TRAME is an interactive architectural lighting installation

Figure 1. *Tempêtes*, 2012, Yan Breuleux, video projection. ©2012MartineDoyon.

deployed in February 2011 on the media façade of a church located next to the downtown campus of Université du Québec à Montréal (UQAM). Born of an initiative instigated by NFB Interactive, the Rendez-vous du Cinéma Québécois and the Quartier des Spectacles Partnership, it was produced by Antoine Goudreault in collaboration with undergraduate students from l'*École des medias interactifs*.

In 2010, the Quartier des Spectacles hired the Montréal-based *VYV* firm to create detailed architectural mappings of their permanent media façades targeted by video projectors. VYV's signature *Photon* software has since been used by many artists to design media façades on the site. Given that each mapping carefully integrates the specific architectural elements of every building's façade, it becomes a tool that can be used to produce site-specific content that takes into account a media façade's peculiar shapes and textures.

TRAME was one of the first art projects to make use of VYV's custom-made software, which provided artists with a precise template of the intricate projection areas of UQAM's bell tower. Its video projections were made up of "episodes" each based on celebrated NFB animation films made by local artists in the past 75 year. Each episode paid homage to a key figure in the history of film animation.

In 2010-2011, UQAM students spent over seven months designing an application that could run on an iPod Touch, any smart phone, or an electronic tablet of variable size. During the deployment, anyone with a personal mobile device could download this application from the *TRAME* website to interact with an episode projected on the bell tower while it was being rendered live. Through simple touch screen commands, people could affect the music, and the speed or designs of dynamic visual motifs in real time.

Although the size of the input interface depended on whether people used their smart phone or a tablet, it would significantly change how people interacted. While smart phone screen size tends to encourage social cocooning, the increased visibility afforded by the oversized screen real estate of tablets made it possible for more than one person to watch a touch-based interaction. By including observers in the input process, here, interface size created conditions for socializing and thus for being involved in interactions.

Figure 2. *By Means of a Sigh*, 2012, Jean Dubois and Chloé Lefebvre, interactive video art installation. ©2012MartineDoyon.

Rewarding Group Interaction *By Means of a Sigh*

Another interactive display-based artwork that relied on the use of personal mobile devices for input is Jean Dubois and Chloé Lefebvre's *By Means of a Sigh*. Featured in the context of the first edition of the Quartier des Spectacles's *Digital Pathway* urban interventions in Spring 2012, this interactive video was showcased on an oversized digital display located outside the Place des Arts building on Ste-Catherine Street, near Jeanne-Mance. This was one of the rare *Digital Pathway* deployments designed for an actual LED screen rather than for a video projection on a façade.

Dubois has often used an anemometer to design interactions around his art installations. These devices measure the force emitted by wind or air pressure to generate data. In Dubois's *Brainstorm*, for instance, when someone blows into the anemometer, the words projected on the screen begin to move faster and away from one another, creating the illusion that one's breathing can disperse them.

By Means of a Sigh similarly uses breathing as the input signal that triggers interactivity. Filmed and edited prior to deployment, this artwork simply consists of a video loop of a lateral view of a woman and a man facing each other as they each blow bubble gum. As the size of their bubble increases, their thinning walls touch and eventually burst.

Interactants can help blow the bubbles by calling a telephone number that connects them to the screen. Figure 2 shows how they can then gather around the screen and exhale into their mobile phone to move the video projection forward at a speed consistent with the intensity of their breathing. If no one blows air into their mobile phone, the playback slows down or almost stalls, creating the impression that the balloon is deflating. If many people blow intensely and steadily, the balloon inflates fast until it bursts, causing the video to loop back to the beginning again.

Practically, this means that when people work together, they can synergetically influence the outcome. Although the input interface is small in that it is typically the size of a mobile phone, the application has been fine-tuned so that when the number of people who blow increases, the interaction appears more effective, and thus visually rewarding.

The artists's stated intention was to tie the intimacy of embodied experience to the art installation [37]:

> *"Being able to use one's breath to modify a big image, much larger in scale than one's own body, is a sensory experience that can give people a feeling of personal empowerment. We were concerned with finding ways of making interactive works that include interactants' bodies as part of the art piece because when we interact with an artwork, we become a part of it. Interactive public art is a tool that can activate public space and create conditions that connect people to it and each other".*

Although here, the art seems to be more about a process than an object, the physical and conceptual design of the interface determines the experience and value of the interactions. In this sense, the artwork attends to similar goals as Social NUIs by refocusing interactions on collaboration, play and meaning: it takes a village to burst these bubbles.

Interfacing Around a Campfire for *Bla Bla*

A few streets away, in front of a media façade deployed outside the Saint-Laurent subway station, an input interface that rekindled the age-old campfire metaphor offers yet a third perspective on how new media artists have been anticipating Social NUIs. Custom-designed for a public space installation that was co-produced by the National Film Board of Canada and the Quartier des Spectacles, the luminous podium seen in Figure 3 was the interactive portal of entry into the world of Vincent Morisset's *Bla Bla*.

Originally only available online, this interactive hand-drawn animation film was transformed into an interactive human-scale media façade on the occasion of the *Digital Pathway* in spring 2012. As was the case with the previous examples of practice, crossmodal interaction was triggered by touch-based input. Here, however, personal portable devices were replaced by a simple trackpad mounted on top of the stationary luminous plinth seen in Figure 3.

The input interface functioned much like the standard trackpads found on most laptop computers today. Indeed, hidden beneath the clean modernist lines and illuminated surfaces of the projecting base was a MACBOOK PRO™ connected to the fiber-optic cable infrastructure that leads

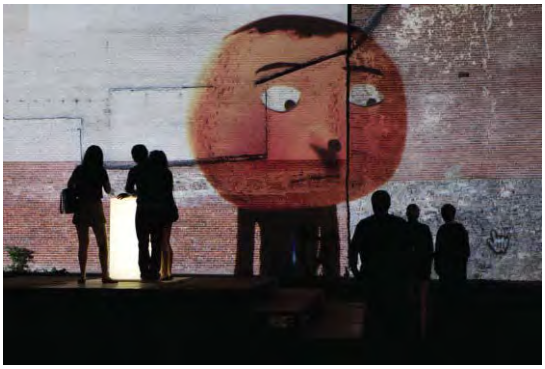

Figure 3. *Bla Bla*, 2012, Vincent Morisset, interactive animated video projection. ©2012MartineDoyon.

Figure 5. *Twenty-One Obstacles* powered by *21 Swings*, 2012, Daily Tous Les Jours. ©2012MartineDoyon.

to the Quartier des Spectacles's master control-room. This economic lo-fi setup was, in effect, all that was needed to run *Bla Bla*'s entire interactive program every day from 9 pm to 2 am for the full eighteen nights of the deployment.

Although the basic interaction script consisted of interventions upon the animated images projected on the media façade, it is noteworthy that the device used to achieve this also responded to user input: the luminous intensity and color schemes of the plinth varied and flickered in response to how users touched the trackpad. As a result, *Bla Bla* highlights two interactive objects: the video projection and a site-specifically designed new media urban furniture.

Further, three form factors of this artifact evoke a campfire scene. First, the fact that the luminous plinth is fixed means that users must go to it, rather than freely move around as one would when using a mobile phone to interact. Second, its shape and size, not only enable, but also invite people to gather around it. Third, its luminosity is an entry point since it captures attention and draws us in. [38]

This leads us to say that *Bla Bla*'s input interface creates favorable conditions for people to socially interact and possibly eventually cooperate as well. As a kind of electronic campfire, it has much in common with Social NUIs.

Twenty-One Obstacles Set in Motion by *21 Swings*

Using accent lighting to single out the input interface of a display-based installation was a design strategy also used in the *21 Swings* luminous seats seen in Figures 4 and 5. Conceived by two Montréal-based interaction designers, Daily Tous les Jours's Mouna Andraos and Melissa Mongiat, this project is arguably one of the Quartier des Spectacles's most popular deployments. Located in front of the Place-des-Arts subway station public transportation hub, the swings were often used by people waiting for the bus.

Each swing was programmed to emit its own distinctive note. Whenever more than one swing was being used, different notes would be generated to create layers of sound. As a result, unique musical compositions would be produced each time there were multiple users. Further, if the vertical coordinates of at least two of the swings perfectly synchronized, a special tune would play over the musical composition to reward interactants for swinging together.

When the *21 Swings* were deployed during the *Digital Pathway* in 2012, the designers connected them to the monumental *21 Obstacles* media façade in order to provide more possibilities for human-computer interaction: swing motion would then generate both audio output (music) and visual output (moving objects on the façade). Much like with a pinball machine, the colorful, geometric obstacles could be seen to chaotically collide into one other on the monumental media façade of UQAM's President-Kennedy building when graphics were powered by people's swinging. At times harmonious and at times cacophonic, *21 Swings* was a musical instrument that provoked and proposed new forms of social intercourse in public space.

Interactants seldom talked, but they did collaboratively make music together. Once, we observed a homeless man swinging next to young people; he was enjoying himself so much that he began to enthusiastically improvise his own melody over the musical notes played by the swings. He sang completely out-of-tune with the melody played by the installation. People lining up for the bus seemed bemused, but there was a sense of civic life, of people sharing a space and a moment that was just about being there and being part of something together. Something that was what it was. If interactive public space technology could enable more playful and respectful public interaction, might we see changes in how people relate to one another socially? Might the relational qualities of these works even play a role in meaningful social change beyond this public space?

Towards a Social Affordances Framework

These four examples of practice trace the evolution of some of the interfacing devices that supported interaction with artistic architectural-scale digital public display installations deployed within the perimeter of the Quartier des Spectacles from 2011 to 2012. In doing so, it highlights the idea that interactive installations deployed in outdoor settings might call for new frameworks that rethink interface design in terms of the peculiar context of public space.

On the face of it, the Social NUI framework seems to be addressing this challenge, but in fact, it is not specific to public space. Researchers have applied it to many domains that have been indoors or outdoors, private or public, and across domestic, leisure or work environments. Indeed, it was first developed around scenarios where technology was used to interact around the dining table at home; in surgical settings that required sterile practices; in relation to MOOCs and educational purposes; in family gaming events designed around brain-computer interactions; and to support cooperation and socializing in the workplace. [39]

There are other conceptual frameworks that – much like the Social NUI approach – could be applied to interaction in public space or with large display-based systems. However, none of them are specific to the former *and* the latter. For instance, Greenberg's *proxemics interaction* and Vogel and Balakrishnan's *spatial interaction* framework for ambient displays are display specific, but they are mainly applicable to spatial engineering in the context of a lab setting. [40] In the past, we published two frameworks that attempt to bridge the challenges of designing interactions for public space with those of designing for display-based systems, but neither placed social concerns at its core. [41]

Based on our field findings in the Quartier des Spectacles, it seems clear that the social dimension of public space should be a fundamental principle in any framework that aims to inform interface design for interactive public displays. While it appears that our study focuses on ergonomic design factors such as the screen real estate size of an interface, its location within an installation, its ability to entice and accommodate as many users as possible, and how this interface rewards co-locatedness and cooperation, it is, in fact, human factors – such as the public context of these interfaces and the relationship between people that results from this – that structure these physical affordances.

As far back as 2003, a study by Brignull and Rogers proposed a *public interaction flow model* and two concepts that have become foundational to our research on displays, namely *public interaction* and *social affordances*. [42]

> *"For public interaction to become a more acceptable mode of social activity requires the purpose behind it and how it is manifested around and at the display to have strong physical and social affordances, that people can easily and unambiguously pick up on."* [43]

While Brignull and Rogers set out to achieve this by focusing on ways of reducing social embarrassment, raising awareness, and encouraging people to engage with displays in semi-private setting such as parties and intimate gatherings, our research embraces a social perspective that focuses its lens on relational aspects in public space. [44] In this sense, it straddles their model, the Social NUI approach, and prior work referenced above. What this study found is that interactive public installations by electronic artists often intuitively anticipate, and even paramount, social interface design thinking. For this reason, we believe that they might be regarded as best-practice examples in this area of study, suggesting that still today, blending art and science may provide more fertile grounds for research.

Conclusion

Using a multi-sited design approach, this qualitative field study investigated locations, events, artifacts, and stakeholders as distinct sites of representation to produce design knowledge in relation to interactive digital public displays. By presenting examples of practice, we aimed to show that ergonomic form factors can serve as entry points and social affordances that invite encounters and collaborations around an input interface. We also highlighted how new media artists use touch-based and gesture-based input, as well as crossmodal interaction to bring to bear the relationship between the digital and the material, the intangible and the tangible, the invisible and the visible world.

Like Social NUI advocates, we believe that by developing interfaces from a relational perspective that takes into account collaboration, meaning, value, and context, other ways can be found to design interactive digital public displays that might foster more rewarding forms of civic interactions, and possibly propose unprecedented manners of public interaction – itself a concept that, with smart cities on the radar, will likely gain traction in the years to come.

Abstract

This paper examines the cultural and political implications of and for the proliferation of public urban screens appearing in cities around the world. Through a contextual and cultural study of cities and urban communities, informed by the work of Richard Sennett, Lucy Lippard and Scott McQuire et al., the paper asks what the opportunities are for creativity, intervention and public cohesion through these screens? This paper presents a case study of the authors/artist's practice-based research project "Occupy the Screen" 2014 for Connecting Cities Berlin and Riga 2014 European Capital of Culture. Using a practice-based methodology the authors utilise a method which maps the five elements of play, as defined by Hans Scheuerl in 1965 to measure open and closed systems in order to develop a framework for artists and curators to maximise engagement with public audiences through play.

Keywords

Telematic, urban-screen, intervention, ludic, participatory art, play telepresent, performance, interaction, networked.

Introduction

Our cities are networked; the screen allows the constant transmission of the latest information and communication. We are connected to a global digital infrastructure with mobile devices, GPS, Internet. Observed by surveillance cameras, our personal data can be stored and tracked, as can our geographical movements. Urban Screens take many formats to include large urban screens, handheld devices and architectural facades; they can be DIY, temporary, or part of the permanent architecture of the city. Urban Screens have been used to relay news, information sport and advertising, as well as cultural events and transmit 24hrs a day across cities globally. Through this practice-based research project we look at how artists can harness this digital network to offer audience agency, using Browning's definition (Browning 1964) as opportunity for creativity and making real choices, to promote sociability and play through participatory art works.

Networked Cities

Today's media cities are made up of many communities, which are multicultural, multilingual, and multi-faith, a multiple of strangers are brought together at close proximity. Richard Sennett sites Aristotle as the first to identify the city as a "synoikismos" or made up of diverse tribes and identifies contemporary cities as sharing a similarly tribal composition, arguing that it is important to respect these cultural complexities. Sennett promotes the idea of engaging beyond the divisive "us" and "them" attitude of a society defined by difference towards a "skilled co-operation" working together through craft skills. (Sennett, R. 2013, p4) The idea of multiplicity as beneficial to a community adding to the cultural richness, was shared by Georg Simmel a century earlier, in his 1903 essay on the city where he identified the demographics of a cultural mix as more enriching than the small close-knit communities of "Germeinschaft". (Sennett, R. 2013, p38) Richard Sennett suggests that contemporary society necessarily involves flux and shift in demographics. (Sennett, R. 2013 p4)

Through this research project we explore the historical and cultural context of our telematic artwork "Occupy the Screen" (Sermon, P. Gould, C. 2014) and the role it can play in connecting communities; to engage with the public and to offer audiences opportunity for agency and sociability through play, creating new narratives establishing new legacies, through public accounts stories and memories, grounded in the media arts context. Scott McQuire argues that artistic practice and research can potentially change and enhance the way that we experience the urban environment and the way that we relate to each other. (McQuire, S. 2008)

Community

Richard Sennett promotes the idea that sociability and community engagement need to be actively worked upon, and do not happen automatically. In a multicultural society, difference defines us and Sennett proposes that the aim should be a sociability that embraces tolerance as opposed to attempts to achieve consensus. In a contemporary society in which religion and material production play a reduced role in everyday life, Sennett advocates craft and ritual as well as informal discussion and social groupings as potential methods to bring people together as a support network, promoting empathy and tolerance as opposed to sympathy and condescension. He highlights the importance of all participants taking an active role in forging

institutions or community groups as opposed to an impinged "top down" approach. From this perspective the passive audience observes the spectacle promoting the idea that proactive engagement with culture is empowering to the public.

"…when ritual turns into spectacle something happens to communities and to individuals. Spectacle turns community into a hierarchy in which those at the bottom observe and serve but do not participate as individuals with self-standing worth". (Sennett, R. 2013, p108)

This image of a contemporary city as increasingly characterised by marginalisation and isolation is reflected in Robert Putman's study on social cohesion. He found that people keep away from those who are different, that passive participation now marks civic society. (Putman, R. 2001) George Simmel (1858-1918) had identified the inhabitants of the city of the early twentieth century as suffering from "stranger shock". He identified a universal pleasure in pursuing other's company in German known as "geselligkeit" and was optimistic about the opportunities posed by the larger urban communities as promoting "sociality".

Urban Screens

Urban Screens have been set up across the globe, including in twenty-two cities in the UK often used for news, information and sport, some exclusively for cultural purposes such as in Linz and São Paulo. The position of the screens offers huge opportunity for potential to engage with a broad demographic. Freud documents an early experience of an urban screen, in a letter to his family in 1907 from a Piazza in Rome in which he describes being transfixed by the repetition of images and isolated from the crowd. This passive consumption of images and expressed sense of alienation is implicit in the notion of specular culture as presented by Debord. (Debord, G. 1967) Further, the presence of large urban screens could connote an Orwellian image of surveillance and control. Nam June Paik responded to dystopian fears with his "Good Morning Mr Orwell" as part of the New Year celebrations in 1984. He highlighted the importance of video and satellite television as liberating as long as it is used interactively. *"Orwell only emphasized the negative part, the one way communication. I see video not as a dictatorial medium, but as a liberating one. That's what this show is about, to be a symbol of how satellite television can cross international borders and bridge enormous cultural gaps…the best way to safeguard against the world of Orwell is to make this medium interactive so it can represent the spirit of democracy not dictatorship"* (Paik, N. J. 1984)

Art as Intervention

Brecht drew attention to the increased disempowerment of the audience since the development of the radio, *"Let the listener speak as well as hear…bring him into a relationship instead of isolating him"* (Brecht, B. 1986)

Benjamin highlighted the importance of a proactive relationship between audience and producer *"What matters, therefore, is the exemplary character of production, which is able first to induce other producers to produce, and second to put an improved apparatus at their disposal. And this apparatus is better the more consumers it is able to turn into producers_ that is readers or spectators into collaborators…"* (Benjamin, W. 1978)

Others highlighted the implicit dynamism between audience and artist in the development of artworks. Philosopher John Dewey in 'Art as Experience" (Dewey, J. 1934) underlined the audience's role in the interpretation of meaning in art. Marcel Duchamp that the interpretation of artworks involves creativity,*"The creative act is not performed by the artist alone; the spectator brings the work in contact with the external world…and thus his contribution to the creative act"*. (Kepes, G. 1960 p111-112) This was reaffirmed by Roland Barthe's assertion that the work of art is a dual process between writer and reader, and that authorship involves multiple input. *"We know that to restore writing to it's future, we must reverse it's myth: the birth of the reader must be ransomed by the death of the author"*. (Barthes, R. 1977 p142-148) The concentration here is on the relationship between the artist, the environment and the audience and the interplay that takes place.

This is a huge leap from the renaissance philosophy of one worldview, truth and divine-right and Henri Lefevre identifies the period from 1910 as a time where all that was taken for granted in the classical world became shifted as developments in technology, philosophy, science, engineering and mass production, had a profound impact on our understanding and experience of the world, the very structure of the city had changed, expanding the way that we inhabit the world into the sky and deep below the earth with high-rise buildings reaching skyward whilst trams are tunnelling underground.

"The fact is around 1910 a certain space was shattered. It was the space of common sense, of knowledge (savoir), of social practice, of political power, a space hitherto enshrined in everyday discourse just as in abstract thought, as the environment of and channel for communications; the space too of classical perspective and geometry, developed from the Renaissance onwards on the basis of Greek tradition (Euclid, logic) and bodies forth in Western art and philosophy, as in the form of the city and the town." (Lefevre, H. 1991, p25)

The new philosophies impacted on our interpretation of art, the avant-garde questioned the very institution of art. Futurist artist Luggio Russolo explored manipulating the senses through cataloguing the sound types brought about

through industrialisation using the street as his instrument. The Surrealists were very interested in the street as a creative starting point, and in-particularly Paris. Surrealist poet Louis Aragon celebrated the urban environment as having "the wonderful sense of the everyday".

Söke Dinkla identifies the movement away from the traditional gallery setting from the early twentieth century and at the same time a development of interaction within artistic practice from the object as art towards performance and interactivity as a prelude to media art. From this perspective the move away from the traditional gallery and the interest in artist and audience interaction went hand in hand. This also suggests that the movement away from the art establishment towards public engagement was empowering. (Dinkla, S. 1996, p279) Art works moved from the gallery to the theatre exploring active interaction between artist and viewer through typography, performance and sound. Filippo Tommaso Marinetti in the manifesto "Variety Theatre" commented:

"The Variety Theatre is alone in seeking audience's collaboration. It doesn't remain static like a stupid voyeur, but joins noisily in the action, in the singing, accompanying the orchestra, communicating with the actors in bizarre dialogues". (Marinetti, F. T. 1913)

Lucy Lippard identifies a move during the fifties and sixties away from the fetishisation of the object and the "dematerialisation of the art object" (Lippard, L. 1997), towards audience participation, interaction and performance from the Situationist movement, to Fluxus, which often took place on a stage like venue and Happenings events, taking art events out of the traditional gallery and into the streets, with a sense of theatre and an interplay between audience and performer.

Play and Ludic Interfaces

Richard Sennett underlines the importance of role-play in society and argues that the modern being's search for "true" or "authentic" character as a result of capitalism and secularization has lead to a "crisis of public life". (Sennett, R. 1986 p27) In the eighteenth century role-play was an expected part of polite society. *"… in a period like the 18th Century, actor and stranger would be judged on the same terms, and what one could learn from the one in the domain of art, one could learn or apply to the other in the special domain of impersonal life. And therefore in a very real sense, art could be a teacher about life; the imaginative limits of a person's consciousness were expanded, just as in an age in which putting other on, posing, and the like seem morally inauthentic, these limits are contracted"*. (Sennett, R. 1986 p41)

Viewed from this perspective art can teach and inform us about life and can offer the opportunity for imagination and creativity. Sennett argues that the pre-industrial city offered the opportunity to engage with theatricality as part of life. Henry Fielding in 1749 spoke of the street and the theatre as "literally" intermixed and no longer a metaphor. Sennett suggests that without the opportunity for play, we are bereft of a basic perquisite to a full life, underlining creativity as key to this. *"It is robbed of the expression of certain creative powers which all human being possess potentially- the powers of play- but which require a milieu at a distance from the self for their realisation"*. (Sennett, R. 1986, p264)

The importance and conventions of play was being asserted and reassessed at this time. Jean Jacques Rousseau referred to play as an essential learning tool in "Émile", or "On Education" (Rousseau, J. 1762) and it was during this period, in 1793, that Friedrich Schiller, in a letter to his sponsor defined a new meaning for "play". He said that it could express the simplest to the most complicated of ideas from: *"…the aesthetic state", "a state of the highest reality so far as the absence of all limits is concerned" where we can experience a "unity of human nature. "* (Schiller, F. 1962 p607) Schiller believed that play draws together the objective with the subjective to create culture. Karl Groos had identified a potential for impact of play on culture and on promoting creativity, he also highlighted an "aesthetic presence" in play. (Groos, K. 1901) Schiller, who also identified a beauty in play, reaffirmed this. Huizinga looked to trace all forms of culture back to play; he saw play as a need to create order, therefore as potentially beautiful. (Huizinga, J. 1938, 2008) Friedrick Buytendijk further aligned play to the creative act, describing the play object as figurative, defining play as stimulative and unpredictable, and with the potential to open up opportunities for fantasy, lending it's self to interpretation and association. (Buytendijk, F. J. J. 1932) Scheuerl made an association of art and play, and saw the relationship as that between process and form, both of which are accomplished in the moment. (Scheuerl, H. 1965)

Johan Huizinga defined play as an activity external to everyday life, but totally absorbing and thereby suggesting a liberating quality, "Summing up the formal characteristics of play, we might call it a free activity standing quite consciously outside "ordinary" life as being "not serious", but at the same time absorbing the player intensively and utterly." (Huizinga, J. 1938, 2008)

Roger Caillois identified limitations to this definition as this excludes gambling from the definition of play but also notes that while mystery can be part of play is not a necessary component to make it part of the definition and conversely that mystery can be revealed through the nature of play. (Caillois, R. first published 1958) Caillois identified six elements, which defined play as *"Free", "Separate", "Uncertain", "Unproductive", "Governed by rules" and "Make believe"*. (Caillois, R. first published 1958, p128)

Claus Pias identifies a need to make a distinction between play and games*"…not about games (Spiele) but rather about play (Spiele), about a playful attitude"* (Pias, C. 2011, p164) and notes that the German word for 'play' and 'game' is the same, 'spiele'. Hans Scheuerl defined

games as having five attributes; (i) "freedom", no goal outside it's self. (ii) "Inerfinitude" with no preconceived ending, (iii) "closeness of the game" the rules or defined area of play, (iv) "ambivalence", movement between rule and chance, serious and fun, impulse and cognition, immersion and reflection, (v) "virtuality", separate from "real life" and the self. (Scheuerl, H. 1965, p607)

This definition maps on to Caillois method, however provides a little more distinction than Caillois' definition of play, which tallies to the characteristics of open systems, specifically the idea of "infinitude", in some closed systems there are only one of two possible endings, and the concept of "ambivalence" how far unexpected outcomes are possible, or the potential for rule-breaking, or using chance to impact on outcomes.

For the purposes of this study we have used Scheuerl's definition of play and games as a method to create a framework for the observations of user interactions in the installation "Occupy the Screen" referred to later in this paper. The framework was used to evidence observations, recording participants reactions, their time spent in the installation, and engagement with the screen and other participants.

Systems of Interaction

"All arts can be considered interactive if we consider viewing and interpreting work as a kind of participation". (Sakane, I. 1989 p3 in Rokeby, D. 1995 p134)

Whist this acknowledges a relationship between artist and viewer in the construction of meaning, as discussed above, theorists such as Benjamin have promoted a much more proactive relationship between artist and audience, making a distinction between "producers" and "consumers" identifying the former as active and the later as passive. (Benjamin, W. 1978 p101-120)

Lev Manovich states that by definition the computer interface (HCI) is interactive, but that it is a mistake to identify all art that uses computing as interactive. (Manovich, L. 2005) Sometimes interactive works appear to offer the audience creative opportunity, through an interface that provides choices, however point and click and motion tracking can often disguise nothing more than a series of choices made by the artist. Sharon Daniel argues that the collaborative aim of media arts focuses on the potential to create new experiences and exchange revealing new insights, but can be overshadowed by the appearance of audience autonomy and choice, disguised by the physical function of the interface. (Daniel, S. 2011, p74) Jane Kelly reaffirms this.

"Real Collaboration is often undermined by the authority of the artist, who retains control of the technology. The apparent autonomy given to a participating spectator is often a false front, simply a product of digital technology's ability to offer more varied, but still strictly controlled routes through a closed set of prescribed material" (Kelly, J. 1997)

Sharon Daniel goes further making a distinction between interactivity and collaboration, and sees the former as a passive user experience. (Daniel, S. 2011, p74) Margot Lovejoy, however argues that interactivity can be divided into two approaches the "monologic" (point and click) and the "dialogic" approach which enables a collaborative exchange between artists and potentially multiple participants provided by *"telecommunications that interactively make use of global network connectivity"* (Lovejoy, M. 2011, p14) which Margot Lovejoy describes as *"open"*.

Jeffery Shaw and Peter Weibel identify three narrative types of interactive works, *"transcriptive forms"*, multi-layered narratives, and "*recombinary permutation"* involving an element of chance with random programming and *"distributed forms"* which offer open systems for multi-direction communications to take place. (Lovejoy, M. 2011 p18) These definitions suggest a continuum between open and closed systems; "distributed forms" at the open end and "transcriptive forms" at the closed, with "recombinary permutation" in the middle.

Roy Ascott identifies a focus in interactive art on *"whole systems, that is systems in which a viewer plays an active part in an artwork's definition and evolution"*. (Ascott, R. 1999, p67) Ascott proposes that the removal of the 'second observer' or 'phantom audience' is a necessary precursor to the truly "whole system", so all participants are fully active in the outcomes and the potential for spectacle is removed, in order to achieve *"an open ended evolution of meanings and the closure of an autonomous frame of consciousness"*. (Ascott, R. 1999, p70)

Stiles and Shanken also identify "agency" as an important factor in interactive systems. Meaning and intention as well as effective communication to an audience are important. They argue that artworks *"must activate semiotic signification that is literally full of meaning"* (Stiles, K. and Shanken, E. 2011, p35), potentially changing audience understanding through *"agency"*. They refer to Douglas Browning's definition of agency, *"The concept of the agent is required in order to allow for the possibility of freedom, communication, comprehension and mystery. "Culture in general…rests upon…agency"*. (Browning, D. 1964)

Stiles and Shanken argue that interactive works should offer the audience "agency"; a proactive role, with freedom to make decisions and be creative, offering opportunity to change and influence society. *"Agency involves the freedom to create, change, and influence institutions and events, or act as a proxy on behalf of someone else. In both cases agency is measured by the ability and the responsibility to have a meaningful effect in a real-world, inter-subjective social conscience."*. (Stiles, K., Shanken, E. 2011, p36)

Occupy the Screen

"Occupy The Screen" (Sermon, P. Gould C. 2014) was a site-specific work commissioned by Public Art Lab Berlin for the Connecting Cities Festival event "Urban Reflections" from 11 to 13 September 2014, linking audiences at Supermarkt Gallery Berlin and Riga European Capital of Culture 2014. This installation builds on our practice-based research and development of previous interactive works for large format urban screens such as "Picnic on the Screen", originally developed for the BBC Public Video Screen at the Glastonbury Festival in 2009. Connecting Cities was a EU consortium involving big screen curators and artists who initially came together for a workshop as part of the Transmediale Festival 2014 in Berlin. Through our presentation of research findings to date the initial workshop considered what the essential criteria were for future urban screen interventions.

This new installation pushed the playful, social and public engagement aspects of the work into new cultural and political realms in an attempt to 'reclaim the urban screens' through developments in ludic interaction and internet based high-definition videoconferencing. Through the use of illustrated references to site-specific landmarks of Berlin and Riga, audiences were invited to "Occupy the Screen" by climbing the statues in both cities, with scenes reminiscent of the crowds claiming the Brandenburg Gate after the fall of the Berlin Wall in 1989. The concept development of "Occupy the Screen" was inspired in part by 3D street art as a DIY tradition, referencing the subversive language of graffiti. The interface borrows from the "topoi" of the computer game, as a means to navigate the environment; once within the frame the audience becomes a character immersed within the environment.

"Occupy the Screen" linked two geographically distant audiences using a telematics technique; the installation takes live oblique camera shots from above the screen of each of these two audience groups, located on a large 50 square metre blue ground sheet and combines them on screen in a single composited image. As the merged audiences start to explore this collaborative, shared ludic interface, they discover the ground beneath them, as it appears on screen as a digital backdrop, locates them in a variety of surprising and intriguing anamorphic environments (see fig. 1).

"Occupy the Screen" aimed to include the widest range of urban participation possible and aligns to a Fluxus "Happening" in a move away from the object as art towards the street environment and the "every day" experience. It also borrows from a tradition of early 20th century media developments where audiences were transfixed by the magic of being transported to alternative realities though early film at the traveling fairs. Lumière contemporaries, Mitchell and Kenyon, whose films of public crowds in the 1900's present a striking similarity to the way audiences react and respond to "Occupy the Screen". These pioneering fairground screenings of audiences filmed earlier the same day possess all the traits of live telepresent interaction, albeit the latency in processing, whereby the audience play directly to the camera and occupy this new public space by performing to themselves and others when screened later.

Figure 1. "Occupy the Screen". Audience participants in Riga interacting with the screen. 11 Sept. 2014 ©Sermon, P., Gould, C.

The position of the urban screen as street furniture is ideally suited to engage with people going about their everyday life, and often the most interesting outcomes are discovered through the ways that the public interprets and re-appropriates culture through "users tactics". (Certeau, M. 1980, p480) The interaction is an open system aiming to offer the audience a means of agency, defined as "freedom" to be creative and make individual decisions.

As part of the project development, workshops were held with the local community in Wedding-Moabit, Berlin, a multicultural demographic including various migrant communities. We were keen to ensure that all aspects of the community were represented in the development of content for the work and to find ways of engaging the audience in the installation, reflecting richer layers of experience relating to place through "hybrid nonlinear stories" rather than reflecting a "homogenous view",. (Lippard, L. 1997, p24)

The workshop participants identified personal landmarks and discussed their experience in the local environment, their history and cultural references, also their idea of tourist routes through that part of the city. In this way the public were able to advise the development of the work through their feedback and ideas to inform the content of the environment. We developed the landmarks suggested as well as artefacts relevant to the local and migrant communities, at the same time representing both of the cities involved, including cultural motifs as well as references to the county of origin. This follows the tradition of dialectic art as an intervention (Kester, R. 2004) and supports Roy Ascots proposal that with his definition of a "whole system" "a viewer plays an active part in an artwork's definition and evolution". (Ascott, R. 1999, p67) The installation further offered opportunity for

collaboration between audience and artist through an inclusive approach to creativity and sociability employing the “ludic”, nonsensical, and “phantasmagoria” of free play. (Sutton-Smith, B. 1999)

Our method of evaluation referred to earlier involved audience observation, both during the event and via line-out video recordings (see fig. 2) directly from the installation. The latter provided us with the most accurate record of audience engagement allowing us to observe the participants and their interactions through the very same image they caused and reacted upon. We also had local assistants to support the work and talk with audience participants in a familiar context and language.

Figure 2. “Occupy the Screen”. Line-out video of participants in Riga and Berlin. 13 Sept. 2014 ©Sermon, P., Gould, C.

The outcomes from both the observations and the line-out video were then plotted on a data map using a y-axis informed by Hans Scheuerl’s definition of games; from “freedom”, “inerfinitude” and “closeness of the game”, to “ambivalence” and “virtuality”. (Scheuerl, H. 1965, p607) Against an x-axis aligning to open and closed systems.

Drawn from a 31:44 minute line-out extracted video recording (Sermon, P. Gould, C. 2014) the following edited observations and analysis, using the Open/Closed matrix based on Scheuerl’s definition of games: “Freedom” to respond to each other at times negating the suggested environment is evidenced at 06:10 when a boy break dances across the floor, while a woman reaches forward to get into the bath. Examples of “virtuality” include instances of ludic play where people engage in nonsensical activities such at 08:45 two men (late teens) in Riga flap their arms as if to fly, another lifts his arms as if to glide. Imaginary play and narrative sequences emerge through participant’s interactions drawing other participants into the scene including at 04:18 a man (20s) in Riga shuffles from side to side while children in Berlin chase behind. There are many instances of “mimicry” across age groups and locations such as at 02:02 two women (in their 40s Riga) enter the screen and hold out their hands to rescue a boy and a man both in Berlin. Examples of “visual trickery” centered on the joining together in the two locations include at 07:45 three men (20s) in Riga, and two women (20s) in Berlin form a line and dance.

Instances that fit into the category of “closeness of the game” happen when participants remain faithful to the environments, and do not diverge from the suggested scenes, such as at 09:13 a man and woman in Berlin (20s) balance on a plank across a hole, a man in Riga (20s) steps in and gestures a wobble as if to almost fall.

Instances of “infinitude”, take place when the ending is unpredictable, they are situations that were unexpected so often have elements of the ludic which is closely aligned to “virtuality” such as at 11:07 a boy jumps from the quay into the boat, joining the boy in Berlin, while a woman in Berlin stands on the quay.

Instances of “ambivalence” or the movement between rule and chance, occur when people respond to the environments, often with unexpected outcomes such as at 06:55, three woman, two in Berlin and one in Riga (20s) sit on chairs at the table while a man in Riga (20s) stands on the table. At 07:00 the woman in Riga moves to stand on the table then jumps to the floor, the women (20s) in Berlin move their hands to spur her on. In the next frame 07:11 the woman in Riga (20s) moves back on to table top, the man (20s) in Riga moves to crouch in front of the table, all three woman stroke his head. The unpredictability of the actions are encouraged through the changing interface and in the next scene at 07:24 two men in Riga and a man and woman in Berlin stand on the floating cube of turf, while a woman holds the ankles of a man in Berlin.

Through this research we found that the environment and timing have a large impact on the way that an audience responds to an interactive work. Participants were at liberty to decide whether to engage with “Occupy the Screen”, and as soon as we turned the installation on even for testing people were keen to participate within the work, aligning with the notion and criteria of “freedom”. Having no goal outside it’s self; the environment was available for people to engage with as they wished. The inspiration was drawn both from the cities of Riga and Berlin, with input from the communities, but also from the idea of street interventions such as anamorphic pavement art where from a particular position the characters can look as if in a precarious situation.

In “Occupy the Screen” this included suspended on a plank high above a lake, or on an over sized wooden bridge. The installation was designed for the audience to engage in an intuitive way and there was no preconceived ending, in-keeping with the characteristic of “Infinitude”. The area of play was clearly demarked as a space via a blue box groundsheet in both Berlin and in Riga identifying a theatre of play, once in the space the participant engages as they wish. The environment may suggest activities or events but the audience is free to respond as they choose so that rules are limited and focus on the defined area of play in relation to the category of “closeness of the game”. This also meant that

"ambivalence", movement between rule and chance, serious and fun, impulse and cognition, immersion and reflection, were constant and in flux throughout engagement with the work. It is this fluidity, which is key to the characteristic of an open work, that there is much opportunity for the unexpected and that chance encounters can change the direction of a narrative that is unfolding.

We used our experience of previous installations to inform elements of the design to include objects that people can engage with, but also playing with perception of vision and illusion. This included a Pop-Art inspired tunnel, which participants intuitively jumped into, and steps which disappear into an underground bunker. There were also other events staged in Riga's Esplanade Park, with loud pop music playing through out each night, which initially seemed a little intrusive, but in actuality contributed to the work. From our observations optical illusions acted as a signifier of play, people inherently recognised the environment as playful, this may have been successful particularly because it represented "virtuality", a space separate from "real life".

We also used the notion of the computer game as a design reference, inspiring a child in the audience at one point to shout "Wow Supermario". We incorporated references such as box hedges suspended in space, which participants recognised as a game platform to jump on and between. The environments often implied a physical response such as jumping, diving or climbing, including a swimming pool to dive into, coloured boxes to climb across and a bridge to jump off. This may have contributed to the active approach that the majority of the participants took. This may have been further enhanced by the music, and many people engaged with the environment through dance. One woman stayed for several hours at the installation dancing and interacting with the other participants, returning the next night to do the same.

Figure 3. "Occupy the Screen". Audience participants in Berlin interacting with props. 12 Sept. 2014 ©Sermon, P., Gould, C.

The night-time showing of the piece, further added to a sense of playfulness, as people walked through the park on their way out and back from bars and clubs. The installation ran each night until 1pm to co-inside with the Berlin festival. We introduced ludic or nonsensical elements at times such as a boat (see fig. 3), which people responded to immediately by jumping into it.

People of all ages took part and adults were as likely as children to engage, particularly because of the late showing. We observed an uninhibited willingness to play from children. One girl played for hours engaging with the set, pretending to sit at the table, jumping into the tunnel, walking the plank etc. She engaged in a very performative way, with confidence and exaggerated movements. We also observed this enhanced ability to perform in some adults as well as responding to the environments they tended to engage with others from Berlin, pretending to scratch someone's head, or hold hands in order to jump into the tunnel, or lift someone up from the pool. The remoteness of the installations appeared to give confidence to cross into personal space that might otherwise be seen as a physical invasion of space. In many ways "Occupy the Screen" broke down cultural and social barriers, both in the local communities, but also between two cities, Berlin and Riga, where new collocated spaces and creative encounters could be founded and occupied.

Through this research project, we have developed a framework for open participatory artworks for urban screens to maximise audience agency through play, engaging the public in new ways in the urban environment, offering the public agency and developing events that create memory. Levels of openness were measured through a data map, from which we were able to define key characteristics, to provide a framework for open interactive systems for urban screens.

Authors Biographies

Charlotte Gould (http://www.charlottegould.org) has developed a number of interactive environments for urban screens. She is currently developing location specific work in which the user becomes an active participant in the narrative and explores methods of user driven content. She graduated with a BA Honours Degree in Graphic Design from Chelsea School of Art in 1990 and was awarded an MA in Creative Technology from the University of Salford in 2003. Charlotte Gould is a Principle Lecturer and Academic Programme Leader for Visual Communication at the University of Brighton.

Paul Sermon (http://www.paulsermon.org) is Professor of Visual Communication at the University of Brighton. He has worked for over twenty years as an active academic researcher and creative practitioner, primarily in the field of telematic arts. Having worked under the visionary cybernetic artist Professor Roy Ascott as an undergraduate Fine Art student, Paul Sermon went on to establish himself as a leading pioneer of interactive media art, winning the prestigious Prix Ars Electronica Golden Nica in Linz, Austria, shortly after completing his MFA at the University of Reading in 1991. An accolade that took Paul to Finland in the early 1990s to develop one of the most groundbreaking works of his career Telematic Dreaming in 1992.

Abstract

City to City is an interactive artwork that visualizes the geography of the internet, from place to place, and allows individuals to see their own unique participation in it. Users conduct their online activities and observe their own inquiries, distinguished by color graphics and sound, as messages travel from their points of origin to their destinations. Participants are able to see the visible and distinctive paths that compose the larger, collective global internet. *City to City*'s visualizations reveal the map of online traffic along with our dependency upon the invisible infrastructure of place to place connections; this infrastructure forms the foundation for all of our daily online activity.

Keywords

Visualization, Mapping, Internet, Interactive, Public Space

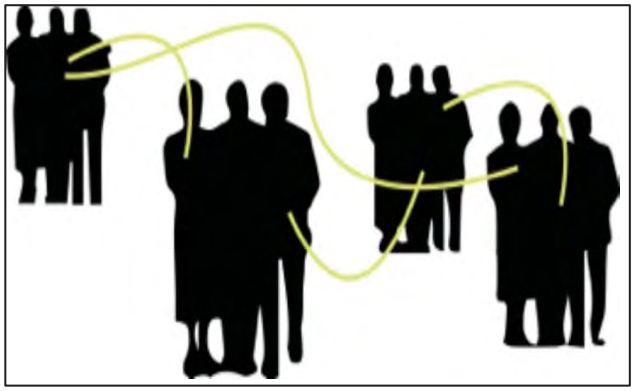

Figure 1: *City to City*, poster excerpt, January, 2014

Introduction

City to City maps the invisible geography of internet traffic, using graphics and sound to visualize and animate paths of online activity from their points of origin to their final destinations. A large map of the world is projected on a wall. Viewers of the installation opt-in as participants and carry out their online activities. Each individual is identified by color and sound; s/he can see her/his own distinct presence on the projected map of the world. Visitors see themselves become part of a growing network of other local users, all of whom are physically present in the same space. [Figures 2, 3, 4]

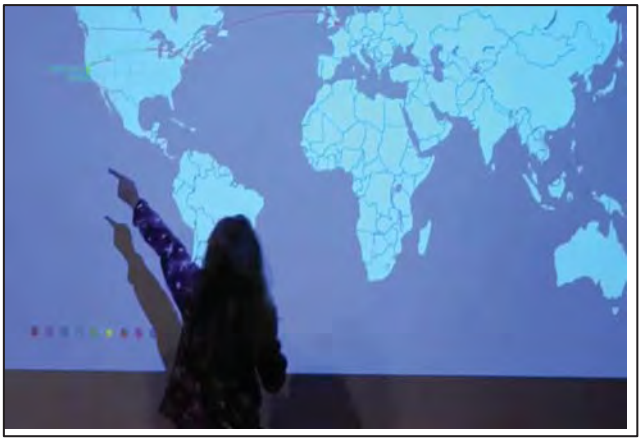

Figure 2: *City to City* installation view, Zero1 Garage, San Jose, CA, February, 2014

Figure 3: *City to City* installation view, Zero1 Garage, San Jose, CA, February, 2014

Figure 4: *City to City* installation view, Zero1 Garage, San Jose, CA, February 2014

As the map of visible and audible trajectories grows larger, and as each trajectory traverses across the globe, the routes connect city to city on the way to their destinations (Figure 4). In effect, this growing pattern of trajectories forms an overlaying second map which represents the hidden global interdependency of place to place, and metaphorically an emerging global intimacy, of which we are all a part.

Related Work

There is a growing body of works that create new cartographies outside of conventional Cartesian space through data visualization and use of the World Wide Web, and other locative media tools or systems. Some examples are listed here.

*Kit Galloway and Sherrie Rabinowitz's Hole in Space (*1980) is a seminal work using emerging satellite technologies linking two sites-- Lincoln Center for Performing Arts in New York City and *The Broadway* department store in the Century City Mall in Los Angeles. Cameras at both sites transmitted live feeds via satellites allowing passersby to see and hear each other. While *Hole in Space* enabled both visual and auditory connection and ours does not, both works enabled viewers to see themselves radically differently in relationship to the larger, invisible global network system and extend their perceptions of themselves beyond local.[1]

Like *City to City, The Virtual Dinner Guest* uses networks to create a site of social engagement the extends beyond the local, with a view to global community building. *The Virtual Dinner Guest* organizes dinners using video conferencing bringing people from different cultures, politics and geographic locations together to share a meal and conversation. Rooted in peace-building and conflict resolution, Eric Maddox, the project's founder, has held dinners in thirteen countries and across four continents.
(See: http://www.virtualdinnerguest.com).

Stamen Design, founded by Eric Rodenbeck in 2001, is a San Francisco based research studio using data visualization and interactive design to produce stunning, innovative maps. Using the map as an interface, the range and depth of their work are examples of the scope and aesthetics now possible thanks to emerging cartographic and analytical tools. (See: http://stamen.com)

The Satellite Sentinel Project uses satellite imagery to track evidence of atrocities on the ground in Sudan. Founded by George Clooney and John Prendergast in 2010, the project monitors changes on the ground and alerts policymakers, new organizations and activists to activate a global networked alarm system. *The Satellite Sentinel Project* fosters a new brand of global witnesses. (See: http://www.satsentinel.org/).

Background

City to City was the culminating project of a 2013-14 Fellowship which Zero1[2] and Google awarded to Paula Levine. The call was to develop an artwork that served to "interpret or illuminate the current state of difficulty associated with molding cultural policy so that it conforms to the reality of a society that is more connected with, and dependent on technology than ever before.[3]"

Levine's fellowship proposal was situated at the intersection of mapping and empathy, exploring implications of how interconnected and interdependent networks were changing and reshaping our daily lives. Her recent projects visualized the impact of distant geo-political events by transposing them upon areas otherwise untouched by those circumstances (TheWall, 2006, http://*thewall.name*; TheWallTheWorld, 2011, http://*thewalltheworld.net*; SanFrancisco-Bagdad,2004, http://*shadowsfromanotherplace.net*.).[4] In effect, these works aimed to conceptually collapse geographical space so that the impact of an event could be simultaneously viewed on both familiar and unfamiliar ground.

[1] Galloway and Rabinowitz were pioneers in early Satellite Arts and founders of the Electronic Cafe (1984) which preceded current projects using satellite and web technologies to bridge borders and boundaries. (See: http://www.ecafe.com).

[2] *Zero1: The Art & Technology Network*, is a Silicon Valley arts organization that sponsors a wide range of art, technology and science programs bringing together corporations, community and artists for project development, incubation of ideas and community collaborations. http://zero1.org.

[3] From the Zero1 Fellowship call for submissions, July, 2012. The residency ran between January, 2013-May, 2014.

[4] See: http://paulalevine.net for detailed project descriptions.

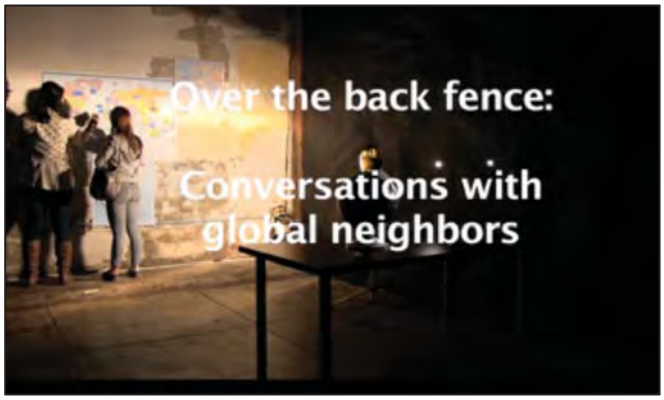

Figure 5: *First Friday*, Installation by Paula Levine, March, 2013,

Bridging between previous work and the Zero1/Google fellowship, Levine's initial plan was to design a platform that would, in effect, collapse the distance between local public space and public spaces elsewhere. This would allow participants to create and participate in a web of global communities that built upon the already existing place to place system of global internet connections.

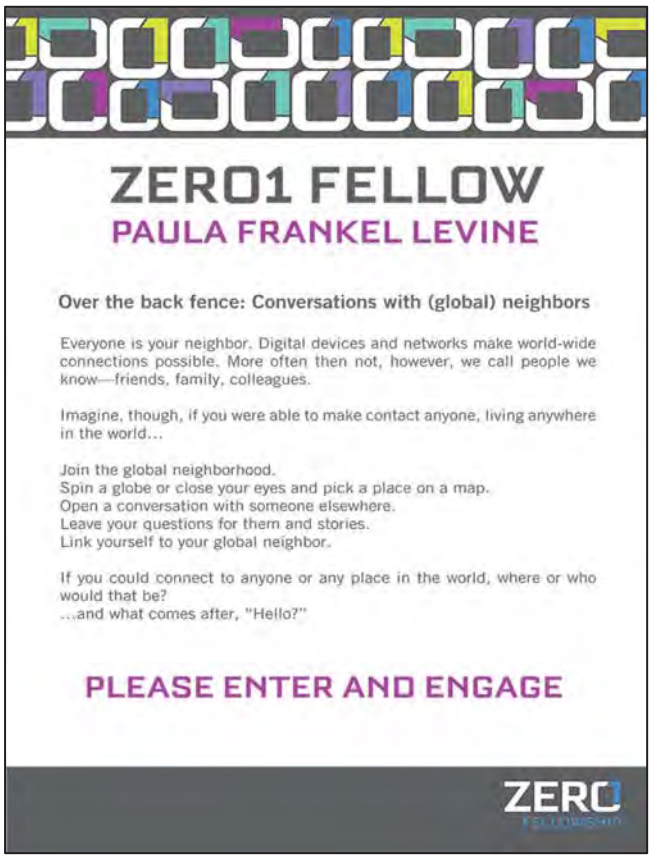

Figure 6: *First Friday*, Installation poster detail, March, 2013, Zero1 Garage, San Jose, CA

Process

Zero1 hosted the community of San Jose during the city's monthly *First Friday* events, which were described as when "street meets geek." (Figure 5). Galleries in San Jose's South First Area, including Zero1, could draw over 700 visitors to view art and participate in various cultural events and activities. Zero1 opened their Garage gallery space to visitors to view works in progress by current fellows and provide opportunity for the public to engage in conversations with them about their work.

Levine used the *First Friday* events in 2013 (Figures 5-7) as opportunities to conduct qualitative research focusing on visitors' use and understandings of the global internet system: how users spent their time online, their estimates of time allocated among work, research or entertainment, the places they would connect to over the course of a day, and their conceptual understandings of their own presence within the larger internet system. Through conversations, interviews and questionnaires, she consulted with about 100 participants and gathered data on patterns of use, expectations, as well as on visitors' impressions of themselves as part of the internet. Levine's goal was to formulate ideas for new designs that fostered place-based connections, such as a community-based system of networks bridging public space to public space, creating a more public global common ground for crowd-sourced global exchanges.

She discovered from research results that people thought in terms of person to person (peer to peer) rather than place to place connections. When asked about the value of place to place connections to support community building through, for example, open public platforms connecting one city or town's public space to another for networked collaborative events or message boards, participants hadn't considered such models of connections and questioned their use, application and value. Many participants expressed beliefs that diverse geographic locations already existed through multiplayer online gaming or group platforms like Google Hangout or Skype. Few could see how networked locations might function, or what they might be used for.

As the result of these conversations, it became apparent that we might focus on two initial objectives: first, to change people's perception of the World Wide Web by reflecting their own place and participation within it; second, to reveal the place-based system of connections in existence that sustained online user activities before considering ways to bridge between locations and build global community.

Our challenges became:
1. How to create an experience that would allow the public to envision themselves as a part of the global network as

active participants, indeed contributing shapers of the network itself?

2. How to make the public more aware of the invisible presence of the place to place infrastructure that was already in place, that supported and sustained their daily online lives?

Figure 7: *First Friday*, Installation detail. March, 2013, Zero1 Garage, San Jose, CA

Figure 8: *City to City*, Interactive installation, Zero1 Garage, San Jose, CA. January-May, 2014

City to City

Implementation

The web is a system of interconnected devices, and we, as users, are rarely aware of the physical locations of these devices or the paths that on-line inquiries take to travel from their point of origin to their destinations. *City to City*, as an interactive installation, addresses both--the reality of the physical devices located at various points in the network, and the paths that connect origins and destinations.

City to City opened at Zero1 Garage in San Jose on January 22, 2014, and was on view through May, 2014. (See Figures 2, 3, 4, and 8 for exhibition documentation). A large map of the world is projected on the gallery wall. *City to City* provides a wireless access local hub for visitors to Zero1 Garage to log into and access websites. The network traffic passing through the hub is captured, traced, geolocated, and displayed on the map.

When a user visits a website, s/he is usually only aware of the two endpoints of source and destination. The messages generated by a website visit may actually pass through many intermediate routing devices, located in different time zones, geopolitical regions, and continents. In *City to* City, the physical paths traversed by viewers' traffic, as they surf the World Wide Web, are interactively displayed on the map, making visible the intermediate place to place connections that enable the illusion of direct peer to peer user experiences.

In addition, as each animated network path passes through intermediate locations, pitched sounds are played on the *City to City* sound system. Pitches are selected based on the distance between the source (San Jose, for the opening at Zero1 Garage) and the intermediate network nodes. The result is a visually and aurally interesting display of the selected internet traffic travelling through the *City to City* wireless hub.

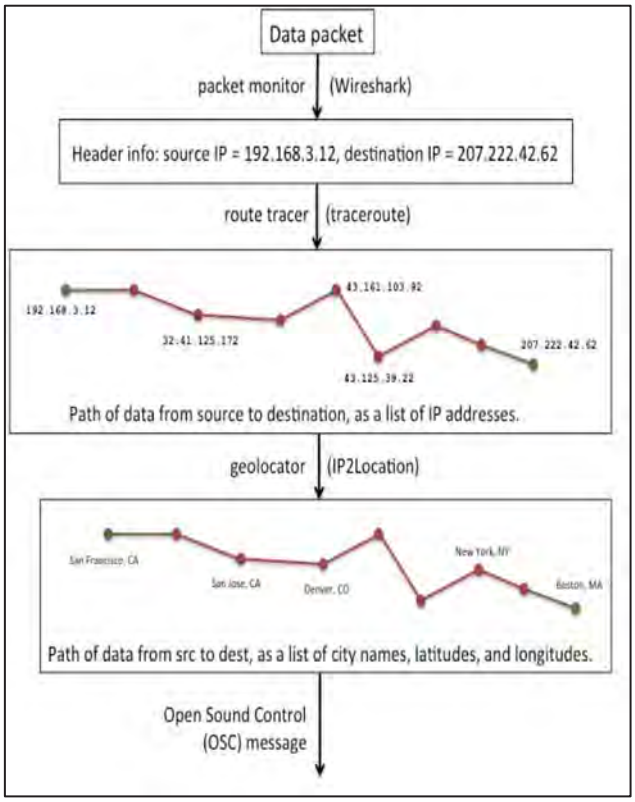

Figure 9: *City to City* software block diagram

Technical Details

The internet is a massive network of *nodes* with each node identified by a unique number--the *Internet Protocol (IP) address*. For example, when a user at the *City to City* installation site in San Jose, California, makes a connection to a website hosted in Berlin, Germany, the access follows a path consisting of a number of nodes, from San Jose to Berlin. To trace and display an internet access made by a user, the *City to City* software system goes through the following main steps:

1) Data packets using the *City to City* wireless hub are detected by the *Wireshark* packet monitor. (https://www.wireshark.org).

2) The IP addresses of the source (always Zero1 Garage) and destination are extracted from each packet.

3) The *traceroute* utility, found in most Unix and other common operating systems, is used to find all network nodes in the path taken by the packet, from source to destination.

4) The *IP2 Location* geolocator[5] looks up the location (i.e., name, latitude and longitude) of each node, based on its IP address. The path taken by the user's internet access is traced on the projected map. In addition, the node location data is mapped to pitches based on distance. This sonification is rendered as the path is traced on the map.

Each viewer's internet access is processed on-the-fly by *City to City*'s software system, as the outgoing message packets of an access are detected by Wireshark. Traceroute and geolocation sometimes require a few seconds to deliver their results; hence, there is a slight delay from the moment a viewer initiates her/his access, to the display of the path on the projected map.

Project Outcome

Through the opening of *City to City* in January, 2014, and on various subsequent First Friday events at Zero! Garage, , we observed that visitors were quickly drawn to the map of internet trajectories. They seemed to understand quickly and intuitively the main operations of the installation. This was verified in conversations with participants. While many were creating internet accesses and obseving their trajectories on the map, others observed the results of the participant's engagements. (See: Figures 2,3,4,8).

City to City exposes the unexpected. For example, shortest or most direct routes are not always ones taken. Instead, network messages may take paths of least resistance in situations where high traffic demands are an issue.

The project also makes visible a daily worldwide system of mutual dependency within a borderless world. *City to City's* map, of seemingly frictionless connections over huge distances, appears in striking contrast to daily realities on the ground—ones of daily struggles, skirmishes and territorial conflicts over international and regional borders and boundaries.

Conclusion

We have come close to a system of networks that Leonard Kleinrock described in 2001 as one that serves "nomads as they move from place to place in a way that is transparent, integrated, convenient and adaptive." (as cited in William J. Mitchell's *The Cyborg Self and the Networked City,* 2003). It appears that another model is emerging--one of a rapid globalization that is bringing people in closer proximity to each other than ever before. It is a world that, according to Jeremy Rifken, is becoming "transformed into a university public square."

> While the backlash of globalization--the xenophobia, political populism, and terrorist activity--is widely reported, far less attention has been paid to the growing empathic extension, as hundreds of millions of people come in contact with diverse others.

City to City connects participants to their online activities and reveals the presence of the hidden infrastructure of place to place connections that makes online lives possible. There are many leaps from an awareness of the hidden place to place connections, to networked communities and a transformation from nomad to global citizen. The first step, however, is envisioning more innovative platforms using existing network infrastructures to foster bridges between and among people, in order to empathically connect local needs and global actions, as well as local actions and global needs.

DaDa Visualisation

Dr Geoff Hinchcliffe

Centre for Creative & Cultural Research, University of Canberra
Canberra, Australia
Geoff.Hinchcliffe@canberra.edu.au

Abstract

Inspired by Tristan Tzara's DaDa poetry, in which the words of a newspaper article are randomly reassembled to create an original poem, DaDa Visualisation is a whimsical interactive artwork producing dynamic generative visualisations based on a catalogue of poems. This paper outlines the work and examines the key issues and ideas to which it responds. It defines data visualisation as a lens that is increasingly applied to all aspects of our lives, and while typically heralded as a revelatory scientific instrument it shows data-vis as a creative cultural form. Fundamentally, DaDa Visualisation is an irreverent celebration of our fascination with data and data graphics but also provides a valuable critical perspective, reminding us that data visualisations are neither benign nor impartial but the product of authorial agency.

Keywords

data, visualisation, generative, art, poetry

Introduction

A common mantra of today's networked society is that we are drowning in an ever increasing sea of data and the way to bring order and sense to this otherwise incomprehensible volume of information is through data visualisation. The mantra has evolved for good reason; the scale and rate of data generation is estimated at 2.5 quintillion bytes of data daily with over 90% of the world's data generated in the last two years. [1] The issue is not only quantity but the fact that much of the data is illegible in its raw state; our only way of appraising these data sources is through some kind of representation. Consequently, and as importantly, the rise in data production has seen a reciprocal increase in the incidence of data graphics, with data visualisation earning a privileged status in our data-centric culture. And as we become more familiar and literate with data and its graphical representation we are examining every aspect of our daily lives through the data lens. The rise of personal analytics and with it personal tracking devices, services and apps is just the latest example of our growing fascination with data collection and representation. It is from within this context that DaDa Visualisation emerges and it is to our insatiable appetite for data visualisation that it responds.

DaDa Visualisation

The title of the work is inspired by Tristan Tzara's DaDa poetry, in which the words of a newspaper article are randomly reassembled to create an original poem. Rather than newspaper articles, DaDa Visualisation treats poetry as a dataset for dynamic generative visualisations. The work consists of two distinct parts; the physical and the virtual. The physical component is a simple thermal receipt printer situated on a slender white plinth. [Fig.1] The virtual component is a web catalogue customised for mobile devices and presenting a series of poems contributed by notable Australian authors; Paul Hetherington, Lucy Dougan, Ross Gibson, and Jen Webb. [Fig.2] An audience member can peruse the poems, make a selection and see it transformed into a series of data graphics via the thermal printer.

Figure 1. The title to DaDa Visualisation's catalogue of poems, designed for viewing on mobile devices.

The website is a modest production; the poems are laid out simply as per the authors' original compositions, the bold title typography and minimal colour scheme providing visual character - a direct reference to Tristian Tzara's "Bulletin DADA" of 1920 [2]. [Fig.3] Each poem is accompanied by a "DaDa Visify" icon which, when tapped/clicked, brings the thermal printer to life. After a moment's hesitation, the printer spews out a print 7cm wide and between 40-70cm in length. [Fig.1] Below a cryptic re-worded title at the top of the page, the print features a stream of graphics separated into vertical blocks by thin horizontal borders. [Fig.4] The blocks offer an assortment of different graphical approaches, most accompanied by a succinct descriptive label. The "Word Length" and "Vowel Frequency" blocks are the most recognisable as conventional graphs; Word Length is a simple bar chart and Vowel Frequency is a regular line graph. "Letter Count" is also of the graph variety but offers a less typical rendering with tonal density indicating the total count of each letter. A number of bold typographic blocks provide statistical summaries such as the total number of characters, words, and lines, as well as the most popular letter, punctuation and word. "Char : Space : Punc" indicates the relational ratios of characters, spaces, and punctuation. Finally, two pattern blocks are untitled and unexplained but their layout and spacing suggests a connection to the visual composition of the original text.

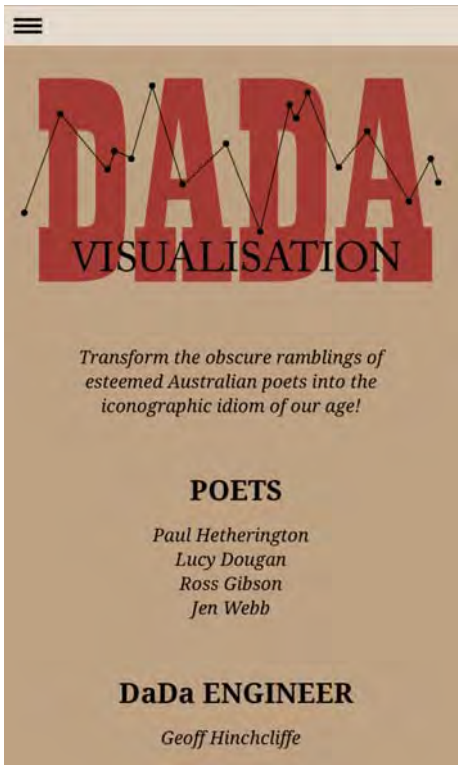

Figure 2. A poem in the process of being output from the thermal receipt printer.

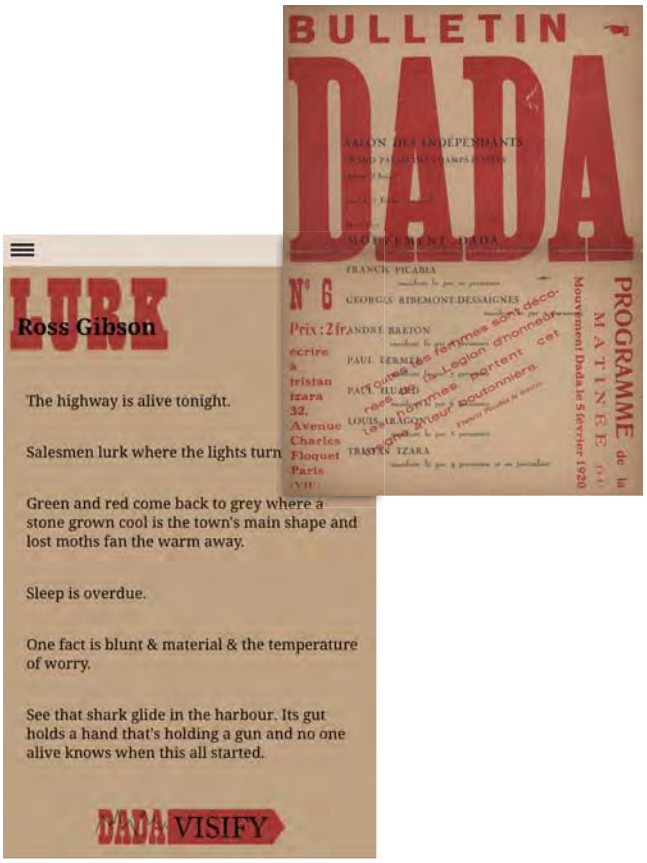

Figure 3. Bottom left: "Lurk" by Ross Gibson displayed in the mobile web interface. Top right: "Bulletin DADA" by Tristian Tzara, 1920.

There is a playful enquiry driving the different graphical representations and a clear concern for the visual aesthetics: the banality of a letter count is converted into a beautiful mosaic of tonal discs; the irrelevant measure of vowel frequency is painted as an elegant intertwining structure of ligaments and joints; the abstract patterns of illegible letters and word blocks create stark graphic compositions revealing incidental rhythms of the original text. [Fig.5] But the most remarkable characteristic of the work is its subject-matter; written poems are an unlikely source for a data visualisation. In treating written poems as a data source DaDa Visualisation foregrounds our fetishistic relationship with data and its representation; its logic seems to be that if we can use data-vis to reveal new meaning about "big data" (the human genome, global warming, national census data), why not use its revelatory powers on poetry? Here data visualisation is a lens that can be applied to any source and increasingly the purpose of that application is aesthetic rather than practical. In this regard, DaDa Visualisation joins a rapidly expanding field of practice concerned with data visualisation as an aesthetic creative medium.

The field is represented by sites such as infosthetics.com and flowingdata.com, both of which use a blog format to report on works and events related to visualisation as a creative form and practice. It should be emphasised that the examples celebrated in sites such as these are firmly grounded in the science of data analysis as well as its aesthetic representation. Perhaps more than any other practitioner, Nicholas Felton has driven the development of data visualisation as an aesthetic lens. His "Feltron Annual Report" series, which present his own, often banal, personal data as beautifully crafted data graphics today exist as a distinct genre of infographic visualisation. [3] The significance of the works, initially viewed as humorous curiosities, continues to increase particularly with the immense growth in "personal analytics" and the "internet of things" - both of which are notable for their presence in our everyday lives. The everyday is a complex cultural context and one that demands very different aesthetic approaches to the office, lab or work site. [4]

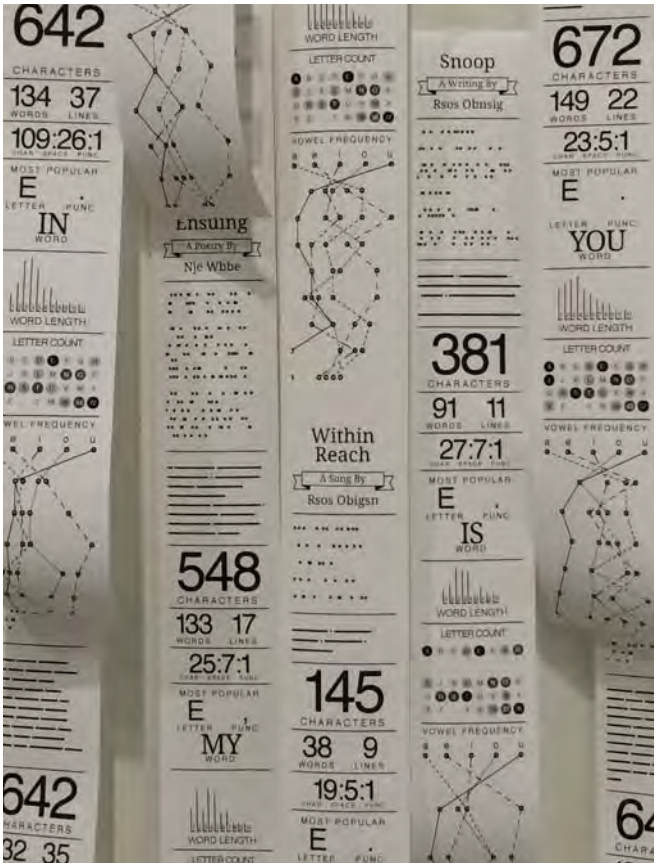

Figure 4. A collection of visualised poems.

Like others from this emerging field, DaDa Visualisation celebrates data-vis as a creative form but through its absurd production of charting written poems [Fig.4,5] it speaks to our obsession with data and to our fascination with seeing our reality quantified and charted. The dislocation between the screen-based text and the thermal printed graphics emphasises the black-box nature of data visualisation: data goes in, magic happens, and visualisations emerge. There is no option to interact or even witness the visualisation process. While somewhat oblique, the graphics are also entirely "accurate". They remind us that data visualisation is not an impartial scientific instrument but a complex cultural form; a form that we typically afford an abnormal authority.

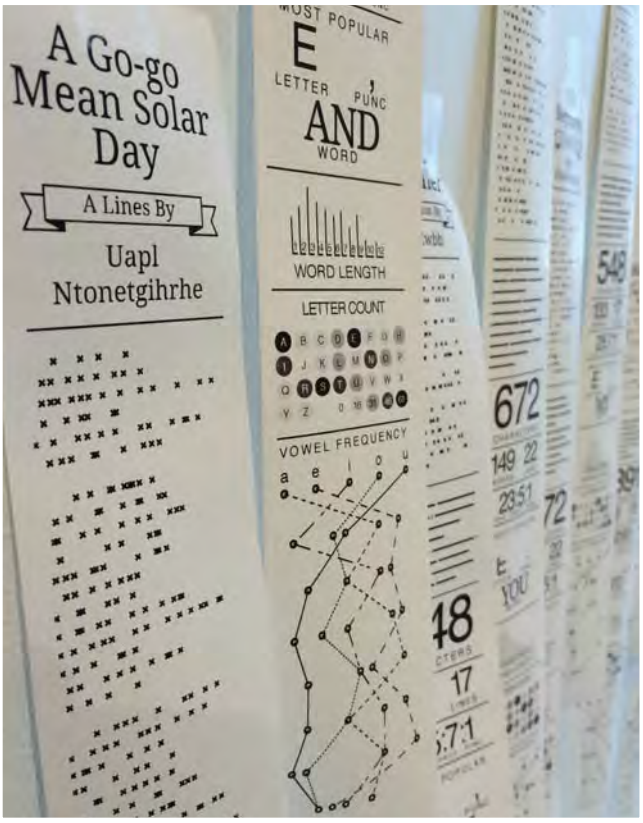

Figure 5. The title in the foreground is generated by replacing the original words with similar terms. The letters of the author are randomly reorganised to form the nonsensical name.

Data scientist, Pete Warden, draws our attention to this implicit trust stating that the *"wonderful thing about being a data scientist is that I get all of the credibility of genuine science, with none of the irritating peer review or reproducibility worries"*. [5] In the same post Warden cites various cases in which his own work has been used by journalists and social groups to substantiate spurious claims with no understanding of the quality of the data or process that generated the visualisation. Guardian data-journalist John Burn-Murdoch echoes Warden's concerns, citing the case of the Washington Post's *"Map of the world's most and least racially tolerant countries"* which enjoyed viral social media exposure and syndication by dozens of large media sites despite criticism from qualified experts regarding the methodology and data upon which the map was based. [6] Burn-Murdoch notes that comparatively, the criticisms had less than 1% of the social media exposure of the data map.

These examples point not only to the potential misuse of data visualisation but also to its persuasive power and our propensity to trust graphics without the same scrutiny we apply to text. Burn-Murdoch posits that this critical inability stems from education - while we are taught to critique text, *"data visualisations are overwhelmingly used simply as a medium of displaying final results"*. [7] With its "before and after" view of a poem, DaDa Visualisation questions the conclusivity of data charts and makes apparent the violence involved in the transformation of data to graphic form. It shows that all data graphics (accurate or not) are an abstraction, a performance of an original "text". And with its cryptic and poetic graphical renderings, DaDa Visualisation's approach to the performative is intentionally provocative, challenging common conceptions that utility and legibility should be prioritised over all other aesthetic concerns [8]. It ignores such obligations to a legible truth, instead focusing on visualisation as a medium that can question and entertain as well as inform.

Conclusion

While conventionally viewed as an instrumental form, data visualisation is increasingly being explored as a creative medium; a lens that can be applied to all manner of data and information. In its bid to render the poems of four notable Australian poets as data graphics, DaDa Visualisation reveals the absurdity of our efforts to see all aspects of our lives quantified and visualised. It reminds us that data visualisations are neither benign nor impartial, and are far from conclusive; they are products of an authorial process which is as much about the ingenuity of adaptation as it is about the accuracy of the form.

Living Mandala: The Cosmic of Being

Jing Zhou

Monmouth University
New Jersey, USA
jzstudio@yahoo.com

Abstract

This paper presents the motivation, background, and implementation of *Living Mandala: The Cosmic of Being*, an interactive graphics installation that combines real-time data, multi-cultural mandalas, scientific imagery, cosmological symbols, and sound. Built with an open source programming language and environment, this living contemporary symbol is an exploration into uncharted territories of the human soul sculpted by our present time. Its interactive revolving graphical system visualizes our perceptions of life (microcosm) and the universe (macrocosm), our connections to ancient mythology, cosmology, and cultural heritage, and the relationships among humankind, science, technology, and nature in a globalized society. Merging cultural traces—art, history, science, and technology—this living organism alters every moment, responding to the movement, color, light, sound, and temperature of its surroundings. Following ancient quests, it separates indigenous mandalas from traditional cultural context to build one that is contemporary and universal.

Introduction

What is Mandala?

> The vegetative universe opens like a flower from the earth's centre,
> In which is eternity.
>
> William Blake [1]

In Sanskrit, mandala means secret circle and center—the symbol of the cosmos in its entirety, while the square is the symbol of the Earth and human-made world. Its traditional design hence often consists of a series of concentric forms, suggestive of a passage between different dimensions. In this essence, it pertains not only to the Earth but also to the macrocosm and microcosm, the largest structural processes as well as the smallest. It is the gatepost between the two. Thereby the mandala is a living structural matrix subjected to the infinite processes of growth and transformation by the virtue of the ever-changing relationships both internal and external to its basic structure. [2] The center is the beginning of the mandala, the origin of all forms and processes, and ultimately the eternal potential. The center of the mandala is not only the external space but also of time. The center of time is *now*. [3] When living in the present, one's physical existence and position in consciousness unfold like a mandala at the center of one's own compass, awareness, and experiences. Expanding from its center, mandala is a manifestation reflecting human consciousness and perception of the universe in their present time, which continually appeared in rituals and art forms throughout history.

Digital Artworks Inspired by Mandala

Although the roots of digital art are ancient and varied, digital art came into existence shortly after the development of the computer, which emerged in its modern form in the 1940s. [4] During the six decades of human-computer interaction and computer graphics development, mandala and its abstract symbolic form have continuously influenced artists to explore and create new artworks digitally. James Whitney's astounding analog film, "Yantra," (1957) anticipates the digital visual effects of brother John Whitney's "Catalog" (1961) and mandala-like symmetry of James' "Lapis" (1966). In the tradition of cymatics, pioneered by physicist Ernst Chladni in the late-eighteenth century, "Protrude/Flow" (2001) by Sachiko Kodama and Minako Takeno interactively transforms three-dimensional patterns in black magnetic fluid to stimulate viewers' most primitive emotions, which appears to be choreographed to its sonic environment. [5] "Nanomandala" (2003) is an installation by media artist Victoria Vesna, in collaboration with nanoscience pioneer James Gimzewski. It projects images in evolving scale from the molecular structure of a single grain of sand to the recognizable image of the complete mandala, and then back again. Inspired by Buddhist and Islamic art, Anne Spalter manipulates city footages around the world to develop patterned compositions that explore the concept of "modern landscape" in her works such as "Meditations" (2014).

Rationale and Objective

> Where is the Life we have lost in living?
> Where is the wisdom we have lost in knowledge?
> Where is the knowledge we have lost in information?
>
> T.S. Eliot [6]

As a Chinese artist living in the Western world who continuously explores visual art and cultures, it is astonishing

for her to realize that certain universal symbols appear in different cultures and represent eternity, divinity, and harmony. One of those is mandala, the symbol of the round of life and death, of the cosmic procession of beings, planets and stars, of earthly seasons and galactic cycles. [7] Whether it is the Chinese I-Ching, Navajo ceremonial sandpainting, Tibetan meditation sandpainting, or Aztec calendar, mandalas present views of humankind as the microcosm through their own compasses. Since our world has dramatically transformed in the past two hundred years and the stages of human development remain the same as they were in the ancient times, the artist's intuition led her to wonder what a contemporary mandala would be, for which this project was created.

Digital media provides a means for artwork to consist of motion, time, light, data, sound, and interactivity, which serve artists to envision and represent the complex message of their work. *Living Mandala: The Cosmic of Being* is a new approach to visualize mandala, an ancient art form, in a contemporary context using digital technology.

The three components of this project present three different timeframes:

- The thirty-six colorful mandalas from sixteen cultures on the bottom layer represent the past five millennia;
- The fifteen white semi-transparent graphics of human studies on the middle layer represent the past five hundred years;
- The real-time computer generated interactive graphic system on the top layer represent *now*, the center of time.

When the three images from each group overlap representing different times and human consciousness simultaneously, *Living Mandala* is born, which connects art, culture, science, information, and technology from the past to the present in a harmonious and meditative unity (Figure 1).

In his most influential theological work *Pensées*, Pascal said, "Man is but a reed, the most feeble thing in nature; but he is a thinking reed… All our dignity consists, then, in thought. By it we must elevate ourselves, and not by space and time which we cannot fill." [8] The multicultural mandalas and graphics of human studies on the bottom and middle layers are the visual representations of human thoughts in various fields including cosmology, mythology, mathematics, physics, chemistry, and more. These fine images are as if the atoms of an intellectual sphere coming out of our past. When this beautiful sphere blends with real-time interactive graphics representing *now*, this marriage signifies human cognition as a whole through a condensed timeline. Such sophisticated and universal visual experience with appropriate sound effects could communicate with the audience from various backgrounds at mental, spiritual, sensory, and emotional levels. This experience might lead to deeper contemplations among the viewers, so that the seeds of knowledge could be sowed in accordance with each viewer's inner compass.

Living Mandala: The Cosmic of Being not only reflects our present awareness and perceptions of the universe, but also investigates the changing relationship between humankind and its environment since the Industrial Revolution. The objective of this work is to expand aesthetic experience and enhance human perceptions of the rapidly changing global environment, the universe, and the center of being. Enriched by profound cultural heritage, this dynamic and symbolic graphical system bridges ancient mandalas, cosmological icons, scientific and technological studies, nature elements, and real-time interactive graphics, through which new meanings and imaginations emerge.

Making of This Mandala

Using known technology, this project was built with Processing (an open source programming language) and Arduino (an open source hardware).

Edward Tufte, a pioneer in information design and data visualization, stated that among the most powerful devices for reducing noise and enriching the content of displays is the technique of layering and separation, visually stratifying various aspects of the data. [9] With complex graphics throughout human history and intricate interactivity, the system consists of three overlapping layers each representing a different timeframe, shown in Figure 2. The bottom layer contains multicultural mandalas in five thousand years of history; the imagery on the middle layer shows human researches in the past half millennium; the top layer generates real-time interactive graphics responding to the movement, color, light, sound, and temperature of its surroundings.

The Bottom Layer

On this layer is a looping animation of thirty-six mandalas and cosmological circular imagery collected from sixteen

cultures in five millennia. The image changes calmly every five seconds.

In order to make a diverse and balanced mandala collection from world cultures as many as the artist could find, the searching and selection process is both time-consuming and rewarding, because some ethnic groups created many more mandalas than others.

The sequence of the thirty-six mandalas was organized in accordance with the aesthetic quality and cultural diversity, which the artist intended to present in the project. Mandalas were often used in rituals and ceremonies of many spiritual traditions for focusing attention, meditation, and establishing a sacred space, so it is important to inherit such aesthetic, meditative, and integrative qualities in this digital mandala, which would bring a sense of beauty, tranquility, and relaxation to the audience. As a result, in order to ensure smooth transitions from one mandala to the next, the image sequence was carefully arranged to harmonize the changes of colors and symbols from each mandala to the next. Meanwhile, this interactive mandala was designed to reflect our contemporary consciousness and perceptions. As the Internet and air travel enable millions of people today to experience different cultures with great speed, not showing two mandalas from a similar culture in a successive order is more suitable to visualize this concept than grouping mandalas by regions or cultures. Therefore, this seemly random sequence of mandalas indicates a dynamic and globalized society in which we live.

Here are the thirty-six mandalas divided into twelve groups in alphabetical order.

Africa
- African Bwa Sun Mask

Australia
- Aboriginal Painting (20th Cent.)

Central Eurasia
- Scythian Kelermes Mirror (6th Cent. BC)

Far East
- Chinese I-Ching and Zodiac (30th Cent. BC)
- Chinese Zodiac Bronze Mirror (7th Cent.)
- Chinese Cosmological Mandala (12th Cent.)
- Chinese 100 Longevity Characters
- Japanese Mandala (17th Cent.)

Hinduism
- Hindu Chakra
- Indian Sri Yantra
- Jain Meditational Yantra (17th Cent.)

Judaism
- Jewish Merkabah Mysticism
- Jewish Sepher Yetzirah Wheel

Middle East/Mughal Empire
- Arabic Miniature (16th Cent.)
- Egyptian Zodiac (50 BC)
- Islamic Mosque Ceiling, Tr (15th Cent.)
- Mughal Emperor Shamsa (17th Cent.)

Multiple cultures
- Aztec, Greek, and Egyptian Ouroboros

North America
- Diegueño Ceremonial Sandpainting
- Navajo Ceremonial Sandpainting 1
- Navajo Ceremonial Sandpainting 2

South America
- Aztec Calendar
- Maya Calendar

Tibet
- Tibetan Mandala
- Tibetan Sandpainting 1
- Tibetan Sandpainting 2
- Tibetan White Tara Mandala

Western Europe
- Byzantine Art and Zodiac (13th Cent.)
- Celtic Bronze Disc (500BC–500AD)
- Celtic Cross
- Chartres Cathedral Labyrinth, Fr (12th Cent.)
- Christian Celestial Maps (18th Cent.)

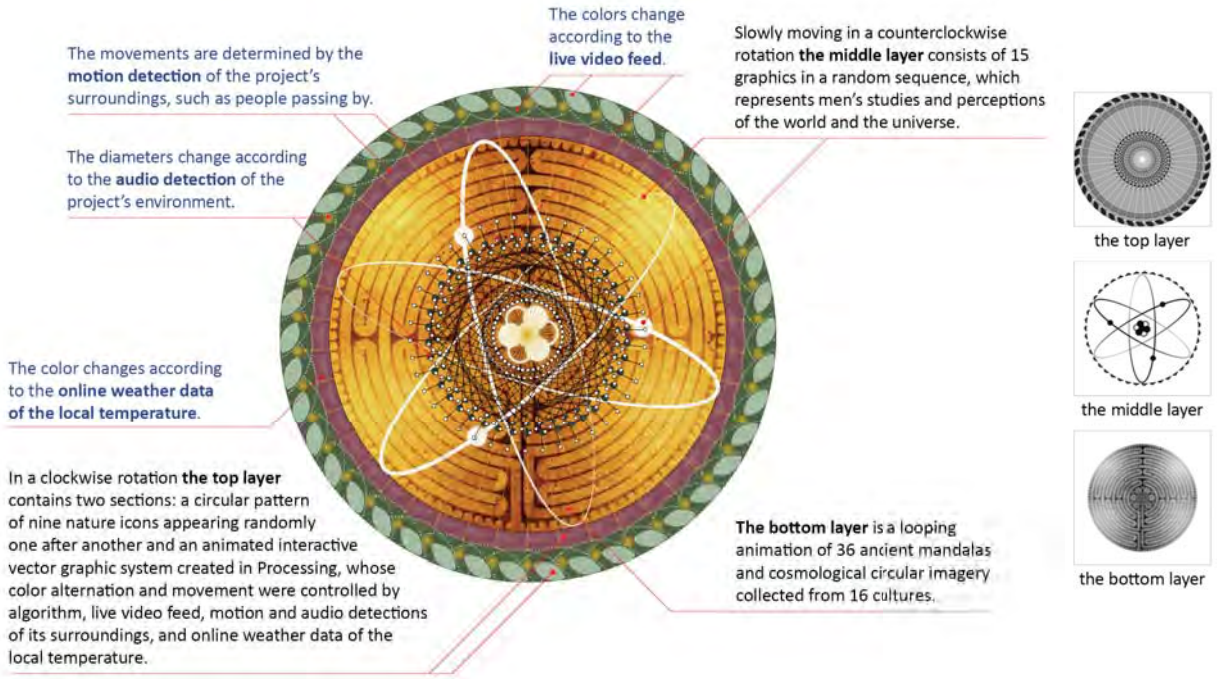

Figure 2. Diagram of *Living Mandala*. © Jing Zhou.

- Greek Phaistos Disc (20th Cent. BC)
- Strasbourg Cathedral Rose Window, Fr (15th Cent.)

The Middle Layer

Slowly moving in a counterclockwise rotation the middle layer consists of fifteen white semitransparent circular graphics, carefully selected by the artist, in a random sequence indicating the dynamic of change in the past five centuries. Every graphic image was either designed by the artist or recreated digitally based on a public domain image. Those images represent human studies and perceptions of the world and the universe, among which are the Vitruvian Man, the path of Venus relative to the Earth over eight Earth years, the constellations, the golden ratio pentagram, the planetary orbital paths, phyllotaxis patterns, the Seed of Life, Galactic Geometry, the Platonic solid – dodecahedron, GPS satellite constellation, atom diagram, and the illustrations representing Industrial Revolution, information technology, sound waves, and the electric field.

The Top Layer

In a clockwise rotation the top layer representing *now* contains two sections: a circular pattern of nine nature icons appearing randomly one after another and an animated interactive vector graphic system programmed in Processing.

Albert Einstein wrote, "A human being is part of a whole, called by us 'Universe,' a part limited in time and space". [10] Although this art project bridges many aspects of humankind in art, history, culture, mythology, cosmology, science, technology, anthropology, etc., it is equally important to combine classical elements and basic components from the natural world, which are part of the universe. For instance, in classical thought the four elements earth, water, air, and fire frequently occur in ancient Greece, China, and India. Thus the following nature icons were created by the artist for this project: water, fire, mountains (earth), stars, leaves (wood), wind (air), feathers, shells, and animal tracks.

This interactive vector graphic system was designed to be able to see, hear, feel, and think, as if it was a creature, shown in Figure 2. The live video feed and motion detection allow it to see; the audio detection makes it sensitive to sound; the changing colors synchronizing with online weather data of the local temperature indicates how it feels; the color alternation and movement determined by algorithm enable it to think.

The Installation

Living Mandala: The Cosmic of Being can be presented on monitors and projection screens. All external hardware devices are packed in a custom-made black acrylic box. The background sound is a combination of meditation music and chanting from different cultures. However, this project could also be shown in silence or with white noise.

The Conclusion

The interactive graphics installation presented in this chapter connects the potential of digital technologies with traditional art, culture, mythology, and scientific studies, in order to create aesthetic and meaningful experiences for diverse viewers. *Living Mandala: The Cosmic of Being* is much more than an animated interactive infographic. It transcends the concept of mandala and touches the core components that matter today: mixing multiple data streams in a single platform; building an environment for consideration of data in cultural and temporal realms; presenting a framework in the context of human history; and packing striking and universal visual components and conceptual thinking into a limited presentation space. Furthermore, it translates the dynamic contemporary cultural landscape—a modern approach to an ancient quest—to enhance human cognitions and perceptions of the universe and humanity in our time.

Reopening the inscription
Rodrigo Arteaga, from the inscription to the phenomenon

Yara Guasque

Independent Artist and Researcher

Florianópolis, Brasil

yaraguasque@gmail.com

Abstract

Maps are a key element in the practices of Rodrigo Arteaga and of Fitz Roy, despite the different backgrounds, and the interval of centuries. Fitz Roy is the commander of *Beagle* and *Adventure* who explored the Chilean landscape cut by the oceanographic topography, channels, rivers and capes from Patagonia to the Antarctic Continent in the nineteenth century. Rodrigo Arteaga is the young Chilean artist, in exhibition since 2009, whose work deals with expanded cartographies like hydrographic basin, astronomy and others. In *Libros Abiertos* a series from 2012, Arteaga juxtaposes pages taken from old volumes of anatomy, botany, astrology, maps of the watershed. The capillarity of rivers and tributaries are displayed next to scientific images of arterial anatomy and membrane fragments suggesting what, in a way, resembles calligraphies to be interpreted. We know that for the observed phenomena to be transcribed into a flat topography, various tools and much knowledge are needed. And yet the transcription should be intelligible in the Knowledge Network. This is exactly what Fitz Roy wanted from the phenomenon transformed into a readable abstract inscription. Rodrigo Arteaga predicts that the inscription is reversible and can be reopened into the observed phenomenon again.

Keywords

Maps; abstract inscription; phenomenon; Knowledge Network.

The narrative of Fitz Roy's travel attempts to account for a variety of natural phenomena that influenced the navigability in the southern hemisphere. His purpose, in addition to following instructions bound by the economic and political interests of the English Crown when exploring the passage from the Atlantic to the Pacific, was to improve the navigation charts by providing updated information. Winds and sea currents, water and weather temperatures, earthquakes, climate changes are described just as well as the recognition of flora and fauna and of the society under development in such an inhospitable land: the shock of the settlers with the natives, the adaptation of foreigners and the survival of the natives and their social system, used to few resources and hard weather, facing the presence of missionaries and explorers who docked on their land. The details of his daily records on the tides and winds were useful to reconfigure the old Spanish maps of the coast and rivers. Furthermore, as a good surveyor and meteorologist observing on the spot, Fitz Roy was able to realize how these data influenced the navigation. [1]

Travelers and shipwrecked, helped each other sharing information and supplements as they could. They formed a network, which can be exemplified in the fact that they used one of the small islands as a place to exchange their correspondence, in the Post-Office Bay, so named because it was where sailors sought for received letters and other letters for which the addressee was at a location on their route (ROY, 2013, p. 420). The Beagle and Adventure ships under Fitz Roy's command could be considered mobile laboratories. The surveys made in those days are comparable to projects of environmental census nowadays, with their measurements, charts and graphs, with data collected in different languages and formats. The Beagle became famous in history for having for five years a renowned researcher on board, Charles Darwin who was part of the group of 74 members, most of them sailors. According to Fitz Roy's remarks the young biologist could contribute more than the surgeon in charge of the health of seafarers, who in his spare time would be also responsible for taking notes on the specimens collected during the trip. Charles Darwin, during the voyage, kept constant correspondence with his former teacher John Stevens Henslow. Despite the distance and the difficulty of communication, the collaboration between the two narrowed. Henslow in England was Darwin's advisor, guiding Darwin, through letters, as to how he could continue his research. It was he who received the boxes with the assessment of the surveyed specimens from the southern hemisphere. The task of scientists is only effective through networks, technoscientific networks, if we are to use Latour's term. And we see Charles Darwin implied in two networks that led him to the southern hemisphere: still young when he left as a research biologist at the Beagle, led by Fitz Roy (1831- 1836), and then in his maturity when he had Fritz Müller as his collaborator making remarks in the open (a friendship kept over the years, from 1861, when Fritz Müller read *On The Origin of Species* until 1882, date of Charles Darwin's death). Fitz Roy and Charles Darwin and / or Fritz Müller and Charles Darwin characterize cartographies of knowledge, or Knowledge Networks according to Latour. Knowledge Networks nourish the Calculation Centers with the mobilization of scientists going abroad to exotic places first, and then in their return, comparing the new data and species that were brought from the peripheries with the ones of the collections. The species away from their places of origin, inside a collection - data centers where the capitalization of knowledge happens - are transformed into abstract entries that are comparable within the collection, and so universal.

Knowledge Networks

Knowledge Networks are nourished with the movement between the periphery and the center. Taking and bringing specimens within scientific expeditions has mainly two different purposes: when moved to the peripheries for cultivation aiming the survival of sailors, as the case of shipwrecks from exploratory trips, or when they are brought to the Centers for study means, drawn or as dried specimens, exsiccates, and inserted in the collections and herbariums spread in Europe, such as Kew Royal

Botanic Gardens in London, to where several examples of South American flora were brought. [2]

Figure 1. Tillandsia tenuifolia var. surinamensis, one of the specimens collected in Brazil and sent to Europe by Fritz Müller, that today is part of the collection of Kew's Herbarium, Royal Botanic Gardens as a dried plant. [3]

The parameters of Natural Sciences were present in the practices of Fitz Roy and of the naturalist Fritz Müller while they were exploring the southern hemisphere in the nineteenth century, *i.e.* the *in loco* observation phenomenon; the inventory in the open; and the conceptual instrumental able to interpret the data. In the case of Charles Darwin, who followed Fitz Roy to the southern hemisphere at a very young age, we can only speak of representing phenomena out of his reach when he was already ill and settled in his native country, continuing with his search through collaborators.

The network of Charles Darwin and Fritz Müller materialized through letters. Fritz Müller was the naturalist researching the Atlantic Forest under demand. Charles Darwin now repeating the role of his former teacher John Stevens Henslow. was the older scientist giving the guidelines for the research to be undertaken in the forests of the southern hemisphere, which became foreign publications from the Calculation Centers, legitimized by the circle of renowned scientists. "Many instructions are to be given to those sent around the world on how to stuff animals, how to dry up plants, how to label all specimens, how to name them, how to pin down butterflies, how to paint drawings of the animals and trees no one can yet bring back and domesticate ". But it is important to set the same coefficients, the same parameters, in order to have instrumental knowledge. [4]

The technosciences are carried out through complex networks, not homogeneous, either knowledge or financing networks, and through the use of specific instruments such as "templates, graphics totals, tables, lists" allowing us to link many disciplines. The purpose of technosciences is action and control from a distance. "Going from 'science' to 'technology' is not going from a paper world to a messy, greasy, concrete world. It is going from paperwork to still more paperwork, from one centre of calculation to another which gathers and handles more calculations of still more heterogeneous origins". [4]

Not only the climate conditions, the study of hydrography, geology are implied in the map, but also the engineering of boats and navigation instruments, political and economic trends. We could consider that every work that collects environmental data and places it "into the paper world," tries to encompass a fleeting and transient reality, - for the monitoring of the environment would have for purpose the capacity to predict changes and disasters, to facilitate access to unknown regions and, in short, one day being able to reconstruct the phenomenal world from the information gathered and preserved in the form of abstract inscription. However neither the water temperature, nor the height and frequency of the waves collected, for example, as measured in 2005 by the buoy Station 31201 in Florianopolis coastline, in a survey undertaken by the Universities UFSC and USDC, was able to predict such a rare hurricane in southern Brazil. And neither the prevailing currents nor the winds at the Strait of Magalhães and Beagle Channel, as reported by Fitz Roy, reconstitute the phenomenon of the sea itself, even though they assist new navigators entering these waters.

Abstract inscriptions and living organism overlap one another and take turns in the work of Rodrigo Arteaga. Such detail can be seen in *Convergence,* from 2013, in which the artist, after researching in the microbiology laboratory of San Joaquin Medical Center, grew colonies of filamentous fungus on glass slides to populate his maps thus giving the heraldic inscriptions an organic quality. Another installation displayed by the artist in October 2014 in the Gallery *Afa Arte Contemporaneo*, in Santiago, Chile, shows a plant that survives on a thin layer of soil on an old volume of a botanical treatise. [5] This encourages us to travel the technoscience networks described by Bruno Latour in *Science in Action* (1987/2011). These are the technoscience networks for which the trip captained by Fitz Roy bringing the young scientist Charles Darwin to the southern hemisphere could come as an example. But Arteaga recreates, in an exemplary way and with great sensitivity and precision, the link connecting the inscription in the book of botany to the plant in the world, and from this back to the graphic inscription on the botanic book. The plant springs from the book, so to speak, and builds this bridge, as an example of connection between the living species and the abstract inscription, such as the scientific illustration and the data in the book of botany. [6] Were the works by Arteaga and other artists who make environmental census, aestheticizing or fictionalizing science?

Reversely, searching for an inscription in the correspondence between the naturalists on expedition and the scientists in the study centers, or in their published data, can also be an investigation of artistic value. [7] Reopening the "inscriptions" gives rise to the collaboration network that allowed the storage of collected information, and brings to light various instruments, such as maps, tables, several studies even of economic and political decisions involved in the expeditions. [8]

Too Big To See: The Need for Design Strategies to Visualize Multiple Spatiotemporal Datasets

Scott Hessels

The School of Creative Media,
Hong Kong
shessels@cityu.edu.hk www.scotthessels.com

Abstract

Tracking software paired with 3D modeling now provides animations of movement in nearly every context of our highly sensed world. However, few visualizations exist that show adjacent systems, usually because of wildly divergent data. One such spatiotemporal adjacency is crucial to our safety – our increasingly cluttered skies rapidly filling with drones, budget airlines, helicopters, weather collection sensors and Asian satellites. The scale, number, tiered altitudes and variant speeds of aerial hardware are a physical reality that can only be understood through the moving image. However, no visual model exists to reveal all the machines when stratified causing our culture to lack an understanding of the expanding system. Can stratified aerial traffic be represented through a hybrid of informative data visualization and evocative information arts? What are semiotic strategies and taxonomic delineations that can merge into a visual language understandable across the growing number of cultures now involved in aerial movement and its dangers? This paper will present a creative context to explore visual strategies for better cognitive and perceptual understanding of multi-tiered, spatiotemporal data. Creative design tools will provide insight into finding meaning in dynamic data and may lead to advances in understanding other sets of Big Data.

Keywords

4D Data Visualization; Information Arts; Strategic Design; Spatiotemporal Semiotics.

Introduction

With multiple launches across several nations, Asia's aggressive entry into the space race is quickly adding to the proliferation of hardware in each layer of airspace. The systems above require great cultural, economic, and political coordination yet there seems to be no singular control. In addition, they are separately represented through disparate spatiotemporal animations that are becoming increasingly important as tools of prediction. Individual aeronautic and aerospace software only visualize the assets within their industry, treating altitude layers as lanes of traffic.

As early as 1978, NASA predicted that satellite collisions would increase the amount of debris to a point where a permanent junk belt around the earth could make space flight too dangerous. The invisible borders between altitudes are disappearing and 2009 marked the first space disaster caused by sheer numbers as two communications satellites collided, scattering deadly debris across low earth orbit. Weapons to destroy surveillance satellites were deployed by China in 2007 and 2010, creating debris that classify as the planet's largest environmental disaster and causing further collisions. Current spatiotemporal tracking visualizations failed to predict any of these occurrences. An improved visual model of aerial strata movement is crucial for safety, public understanding, global policy, environmental discussion, artistic resource, and political and economic clarity.

Starting From The Ground Up

Although these animation models can be perceived as technical or scientific visualization, they also closely tie to digital humanities as the resulting tools are often used to inform in cultural and social contexts. The social impact of this design problem can be seen in the ugly racist slurs towards the Chinese in the comments section on NASA's space debris visualization on YouTube. [1] An effective visualization can enhance a cross-culturally shared understanding of aerospace utilization. Finding a solution is both challenging and beneficial due to its interdisciplinary approach but it must begin by looking at research trajectories through data visualization, motion graphics, information arts, big data, art+sci collaborations and media philosophy.

In Data Visualization

Cartography has stretched to consider 4D data visualization semiotics from many perspectives including perceptual psychology, effective design and color strategy, interactivity, and realism vs. abstraction. Temporal visualizations within cartography were pioneered in the 1960's with the work of Torsten Hägerstrand who developed a time-based model for understanding human migration. Hagerstrand's space-time path illustrated navigation through an environment in a new way and affected the development of geographic information systems that visualize movement data. More recent researchers expanding the diversity of ways to present complex spatiotemporal datasets for better understanding include Menno-Jan Kraak and laboratories and research centers like The Bartlett Center for Advanced

Spatial Analysis at UCL and MIT's Senseable City Lab which both focus on large scale temporal visualizations in mostly urban contexts.

Research in computer graphics has focused on generating increasingly realistic displays; the successful abstraction found and accepted in cartography pre-computer has not carried over to the computer age. Recent research suggests however, that we are beginning to see a return to symbolization systems and map-type taxonomies. The deluge of temporal data and advances in technology are allowing for more thematic portrayals. In addition, the modes of design - color, font, layout, metaphor – are recognized to have distinct cultural meaning in data visualization. These cultural implications appear in the research of Mei-Po Kwan who juxtaposes visualization strategies of temporal datasets created in China and the U.S. She highlights the differences between Eastern/Western visualizations, stating that "Chinese and U.S. terminology and approaches to space and time concepts and their integration in GIScience research draw from distinct deeply established cultural, historical, religious, and scientific traditions and foundations." [2] She argues that we must find a shared language regarding complex concepts related to space-time integration research.

Information sets that are too large and complex for database management tools to negotiate is appearing in nearly every discipline. In addition, computational sensing is finding new patterns and shifts that were once indiscernible. Machine learning real-world applications have flourished over the last two decades. Theorist Lev Manovich outlines three trends in information display: designers and scientists are trying to show more data, represent relationships between more dimensions of data, and break from the ideological paradigm of simpler, reductionist approaches that may not apply to the current evolution of complexity. Properly visualizing scale and recognizing the abstract feelings associated with Big Data may help understand it.

In Motion Graphics

Two examples from media history, one mechanical and one on film, are still effective spatiotemporal displays. Orreries were antique mechanical models of the solar system not used for scale or prediction but holistic understanding of multiple objects travelling at multiple speeds across multiple layers. Charles and Ray Eames' "Powers of Ten" was a 1977 film commissioned by IBM to show the relative scale of the entire universe. The image advances on the 'y-axis' from a frozen moment in a Chicago park by zooming to limits of the observable universe and then back to the limits of known atomic structure. In this, it provides a profound historical example of strata visualization within one holistic semiotic language. Government and scientific communities are developing powerful software to model, simulate, visualize and analyze dynamic aerial systems. However, like lanes on a highway, each industry stays within a specific band of vertical space. There is no collective system that combines these animations. MIT's Ben Fry posits that "there is a space of highly complex systems for which we lack deep understanding because few techniques exist for visualization of data whose structure and content are undergoing continuous change." [3]

In Information Arts

Data Visualization embraces clarity yet the emerging field of Information Arts favors evocation placing Cartography in a tug-of-war between them. Many within the visualization community consider adding artistry a reduction in precision to reach a broader public; art and visualization have distinct functions and "in the case of Information Visualization, Form follows Revelation." [4] However, others argue that the era of a single minded pursuit of clarity will be replaced by the importance of engagement, that visualization is becoming a mass medium. "By recognizing that being expressive and engaging doesn't mean giving up clarity, we will have fulfilled the promise of visualization." [5] Still others insist that due to massive new data, art's abstraction and aesthetic skills are now required in information display, as science "ha(s) no photo-realist technologies to fall back on." [6] And finally, some believe that the best direction is a hybrid of both objective and subjective strategies, joining to form new insight.

In Art + Science Collaboration

The Data Visualization/Information Arts dichotomy is contrary to visionaries in both science and the humanities working to form research partnerships. There is much extant research by scholars who acknowledge the value of art/sci collaborations in moving knowledge forward, partially driven by the humanities now being confronted with large datasets themselves and having to "create practices that incorporate their own disciplinary values and ethics." [7] In a personal communication, leading nano-physicist Dr. James Gimzewski explained, "Science tends to be, in my opinion, too reductionist… and increasingly in science we're more and more aware of complexity, that we can't isolate something. An artists' natural way to work is non-reductionist; it's the opposite. They can look at very complex problems in a way that we are trying to learn."

In Media Philosophy

By presenting the hovering hardware as a system outside the context of human perception, alternative display may connect to metaphysical movements in Object Oriented Ontology and speculative realism. Researchers like Timothy Morton and Ian Bogost argue that philosophy should encounter non-living things and objects. Object-oriented Ontology (OOO) questions Kant's view that objects find their existence through our subjective perception of them and insists on objects existing and relating independent of us. Once we accept an object as a being, we can speculate on a larger range of interactions. Even if only metaphorically, a better visualization of a network of object-object relationships interacting above us, eerily independent from

our perception or consciousness, comments on the equality of object relations.

Beyond the Skies

Such a diverse background suggests that resolving this design problem requires a holistic approach, one often found in creative strategies. Indeed, arts-inflected methodology is offering new signification approaches in scientific visualization. NASA's recent ocean current animation was created by their 'van Gogh' team, designers who used brushstroke techniques from art history. As large quantities of data increases, effective visualization draws increasingly greater attention from researchers as well as practitioners in many fields, including science, education, engineering, interactive multimedia, medicine, etc. Finding the best possible visual strategy for explaining complex datasets is an important field for artists and sciences to create new knowledge and contribute to a richer understanding of the creative methods for spatiotemporal visualization and the mechanisms of the aesthetic components (e.g., sensory functioning, semiotics, animation, narrative, and cinema).

In addition, conceptualizing and measuring those components may reveal interdisciplinary approaches that integrate technology, media arts, and human cognition to enhance understanding. The repercussion of using new media art as a tool for elucidation of Big Data can be applied to a wide range of industries and sciences that have interests in utilizing their Big Data for enhancing user engagement (e.g., marketing), learning (e.g., education), and pattern prediction (e.g., transportation). The long-term impact affects science and art intersections exploring the problems of representing large-scale, complex and evolving systems.

Esolangs as Experiential Art

Daniel Temkin

New ork, N
daniel@danieltemkin.com

Abstract

Esolangs (for "esoteric programming languages") are a class of languages made by programmers at play, not intended for practical use. Ben Olmstead (creator of the *Malbolge* language) describes them as "pushing the boundaries of programming, but not in useful directions." [1] This paper looks at how these strange languages function as experiential art pieces, with similarities to Oulipean systems and Fluxus event scores.

Keywords

Esolangs, Esoteric Programming Languages, Language, Concept Art, Fluxus, Ouipo, Code Art

Introduction

Esolangs have been described as jokes, parodies, impractical research, scenarios of the improbable, or what can only be defined as programming languages by butchering the very definition of a programming language. 2

Figure 1. *Hello World* in INTERCAL (author unknown)

There are three strategies esolangs commonly take to express an idea. The first, and perhaps more obvious given that most code is a form of text, is through their vocabulary. The other two we can think of as logic-oriented esolangs and concept languages.

Languages like *LOLCODE* and *INTERCAL* both make strange use of keywords, although with very different approaches. INTERCAL, created in 1972 (and generally considered the first esolang), functions as a parody of languages of the time. It asks the programmer to beg and plead with the machine, personifying the compiler as a capricious autocrat who allows programs to compile or not based on how much groveling is done. Its language is cryptic and confusing, a puzzle for the programmer. 3

```
HAI
CAN HAS STDIO?
VISIBLE "HAI WORLD!"
KTHXBYE
```

Figure 2. *Hello World* in LOLCODE (Adam Lindsay)

LOLCODE (Adam Lindsay, 2007) personifies the "lolcats" meme. Starting every program with "HAI" and ending with " THXB E", the script in between is full of the familiar mix of baby talk and internet slang of lolcats. 4 These languages ridicule the authority of the machine through the actual text of the programs created within them. However, the code is still intuitive: using "visible" for "print" and "kthxbye" for "exit." The lolcats concept is added to the code without obscuring the code's function.

Programming languages are formal systems they are self-contained and closed, apart from references to computer operations. They are made up of commands which must compile down to machine code, a purely denotative space with no place for nuance: when we communicate with the machine, we can't insinuate or gesture; any ambiguity in the language is wiped out. Both these languages use elements of human language and expression to add back some of that gesture and nuance at the top level, even if it is stripped away in its conversion to machine instructions. Where commands in INTERCAL are confusing, they are only confusing to us, not the machine likewise, at the machine level, LOLCODE commands are the same as in many other imperative, procedural languages.

Befunge and brainfuck

Although nearly all esolangs rely on vocabulary as part of their method of expression, many esolangs are less vocabulary-oriented than those two examples. In 1993, Wouter van Oortmerssen designed *FALSE*, a language for the Amiga. The objective of FALSE was to support the smallest possible compiler (written in assembler, it was 1024 bytes). To reach this objective, Wouter used single letters for commands. 5

This obfuscated syntax was then picked up by two other languages the same year, both also written for the Amiga and using single-letter commands: *brainfuck* (usually spelled lower-case) and *Befunge*. Where FALSE was essentially a tiny version of the Forth language, brainfuck and Befunge began to explore the programming language space as systems of thought. These languages rely on logic more than vocabulary.

```
>                  v
v  ,,,,,"Hello"<
>48*,              v
v,,,,,,"World!"<
>25*,@
```

Figure 3. *Hello World* in Befunge (author unknown)

Brainfuck (Urban Müller, 1993) is Turing Complete, meaning that it can theoretically be used to write programs to do anything that can be written in, say, C++, only it is even tinier than FALSE, consisting of eight punctuation marks alone (resulting in a 240 byte compiler). In brainfuck, we can t write code that looks like "let x = 36" because all of those characters, from the word "let", to the spaces between words, are ignored. *X* means nothing to the language, and neither does 3 or 6. Instead, we move back and forth through memory using the angle brackets (< and >) until we get to a place we might think of as *x*, followed by 36 plus signs, each incrementing that memory cell from zero.

A more succinct alternative is to loop six times through the operation of adding six, like so:

```
++++++  ++++++ -
```

Alternately, one could count down from zero, as in 8-bit brainfuck, subtracting one from zero gives you 255. Or one could use nested loops to reach any number which, modulus 256, leaves 36. There are a great many ways of producing that single number, and choosing one over another becomes a matter of personal style or a chance to find a clever solution. 6

The complexity of brainfuck does not arise artificially each brainfuck command maps directly to a command in assembly code, the substrate of most languages. Rather than making these commands more human-friendly (like how, say, the C compiler does), it refuses to ease the translation, both with its odd syntax and its tiny selection of choices, thereby directly exposing the conflict between human thinking and computer logic.

Figure 4. *Hello World* in Piet (James Dessart)

Befunge (Chris Pressey, 1993), similarly, builds on complexity that arises from a simple idea. It uses 2D code rather than the ordinary formatted strings of text. Befunge programs run up and down the page (or screen), crossing itself in horizontal and vertical lines, like a maze. Because of its snaking structure, the same command can be read multiple times in different directs, in completely different contexts and with different results. Also, it ignores any code which is not in its execution path, meaning comments and non-executed code can appear amongst real code, making it hard to differentiate what is or is not part of the program.

Building on the 2D design of Befunge, *Piet* (David Morgan-Marr, 2001) gets rid of characters entirely, using images as source code. The compiler takes a similarly serpentine path through the image, only here the change in color from one

group of pixels to the next determine commands. Both changes in hue and in lightness have meaning; because it's delta-based (the change rather than symbol itself is the signifier), correcting a mistake in the code means rewriting all the pixels that fall after it. The language was named for Mondrian, and so much of the source code mimics Mondrian s aesthetic, although the rules of the language favor a shattered and sometimes lumpy, pixelated look.

Piet unifies the vocabulary-oriented impulse with logic-oriented code. Like INTERCAL, Piet creates a space between the look of the code and its actual function, making language visible in a way it isn't in traditional languages (which opt for clarity of style to emphasize code's function over its appearance). Where INTERCAL brings in an overflow of human expression that ordinarily has little place in code, Piet encodes it into an entirely different system with its own signifiers and style, whether it's used for simple abstractions or representational images. However, Piet also has the strange logic borrowed from Befunge like the logic-oriented languages, it is experiential in nature, a challenge for the programmers using it. This impulse to mix systems is reiterated in other work of David Morgan-Marr's, such as his language *Chef*, which uses (often extremely odd) recipes as code.

Esolangs as Performance Scores

It is tempting to compare Piet programs with Generative works, as some have a similar appearance to computer-generated images. Only here the look of the image is determined by rules which run on the *programmer*, not the machine. Geoff Cox, in his *Speaking Code*, looked at running code as performative. He sees it as a special type of performance, in that the machine always "performs" the same piece of code the same way: the speaking of the code and performance of it become flattened. 7 We can contrast this with work such as the Fluxus event scores, which leave enormous space for interpretation. Yoko Ono's *Fly Piece* (with the single instruction "Fly"), evokes many different things, leaving nothing specific for the "performer" of the score — that performer might be a reader, for whom an imaginary flight is invoked, or perhaps someone actually trying to physically interpret it. 8

Esolangs in the tradition of brainfuck and Befunge however, re-open this possibility in the score. Because they are open-ended systems, the writing of programs within the language becomes the space for this interpretation. They are experiential — you have to program in a language in order to understand it, it's not to be passively received. And even in brainfuck, code by different programmers may feel very different. An esolang with no esoprogrammers is a sad thing, a score with no performer. A language is a prompt.

The esolanger ais523, who co-runs the esolangs.org wiki, puts it this way: "it's much more interesting if the point of view of the language is one that you can think in independently." Ais523 singles out LOLCODE as falling short of this:

> I should also mention LOLcode, which has become pretty relevant as an esolang in the non-esolang community recently, much to the annoyance of most actual esolangers. It doesn't have much intrinsic interest for most of the reasons people are interested in esolangs, being mostly a simple imperative language derivative with the keywords swapped out... However, it appeals for things like its visual appearance and general attitude, which although are IMO the least important aspect of an esolang, are one of the most immediately noticeable. 9

To actually code in such a language does not lead to a greater understanding of its system we essentially get LOLCODE by looking at sample code. Richer languages, even vocabulary-oriented ones, may reveal more interesting ideas about language and code.

Conceptual Languages

Before a compiler builds a program, it has to parse the code. Some languages focus on this step. Like unperformable Fluxus scores, they produce no functional programs at all, serving only to verify source code, turning a language into a system of inclusion or exclusion.

The compiler for the language *Unnecessary* (eymaker, 2005), when run on any file at all, fails with an error message. An empty document, an image, a Word document, each is rejected as not Unnecessary. Only a file which can't be found succeeds in compilation—and it succeeds in creating an empty program, one which simply opens and closes. A single instruction—NOP (pronounced "no op" for "no operation") is the whole of the program. As Keymaker puts it:

> The main idea was that the language could not have programs, other than the kind that don't exist. (Can it have those then if they don't exist?) Then I noticed that every valid program (whatever that is) is a/the null-quine but that was more of a by-product of the main idea. Fitting nonetheless 10

A quine is a program which prints its own source code to the screen. The null-quine is a program with empty source code that prints its source (which is nothing) to the screen, producing no output. Unnecessary is a language with no keywords, no input, that can only make empty programs.

Is it possible to have esolangs that go even further than Unneccesary, requiring no machine to run? Chris Pressey, creator of Befunge and creator of the mailing list where much of the early esolang discussions took place sees it this way:

> [T]hey're made up of concepts, and these concepts would exist even if our computing equipment wasn't electronic, or wasn't digital, or if we didn't have computing equipment at all. It's just that having computing equipment makes it a lot easier to design and experience these programming languages. 11

A language is just a set of rules for symbols and their behavior. In a sense, they are an even more immaterial form than software more like fields of possibility for potential software. Making this field narrow enough, we can get languages that have no usability, like Unnecessary. Even with Turing Complete languages like brainfuck, the practical use of the language is never the point: they are designed for the experience of digesting their rules. What makes an esolang interesting is that it rewards this investment of thought.

While these three strategies are distinct, they are often mixed together, as in Piet (and, to some degree, INTERCAL), and in hundreds of others which have been written since that time. Each of these three approaches makes language visible in making programmers type strange things, or think through irrational logic systems. At their best, they create a space for human impulses of communication to overflow constraints of logic.

Steep (I): a digital poetry of gold nanoparticles

Abstract

Gold exists simultaneously as reality and myth in a kind of superposition (a term from quantum mechanics referring to the ability to simultaneously occupy two positions such as yes/no or one/zero). In ancient times, ings Croesus and Midas were real life, historical figures that exist in contemporary life primarily as myths/metaphors referencing gold. More recent stories such as those of the londike and other gold rushes reinforce gold's position in the imagination as an object of desire promising untold wealth and/or misery.

There is another level where gold exists: as a material at the nanoscale, a nanoparticle. At this level, gold inhabits another superposition of sorts where it is inference (we can't see at the nanoscale) but equipment which can sense nanoparticles renders the information visually to us as an object.

Steep, a gold nanoparticle collaboration between Raewyn Turner, Brian Harris, Mark Wiesner, and Maryse de la Giroday along with a rotating list of collaborators is a multi-year, multi-disciplinary, and multi-installation project exploring the superposition (mythic and real) posed by gold nanoparticles. *Steep (I): digital poetry of gold nanoparticles*, the subject of this proposal and the first of the collaborations, is an artistic/poetic exploration of how these mythic/real particles may be affecting, changing, and disrupting the understandings we have of ourselves and our environments.

Keywords

nanotechnology, gold, nanoparticles, myth, metaphor, nanoscale, macroscale, environment, art/science, poetry

Introduction

There are many, many types of nanoparticles including gold, silver, aluminum, carbon, plastic, silicon, copper, and more. They are not new we have been producing, inadvertently, various nanoparticles for millennia. Examples of 'ancient' nanoparticle-enhanced materials include the Lycurgus Cup (gold and silver nanoparticles, 4th century CE, Late Roman), the red colouring in medieval stained glass windows (gold nanoparticles), and Damascus steel blades (carbon nanotubes found in the blades which were produced until 1700 when production ceased). 1

More recently (in the last 20 – 25 years) we have begun to manufacture all manner of nanoparticles, including gold nanoparticles, purposefully. The belief is that nanotechnology along with a set of associated emerging technologies such as robotics, synthetic biology, and artificial intelligence will have an impact equal to or even more disruptive than the Industrial Revolution's effects on agriculture, transportation, medicine, the arts, work, and all manner of existence.

Addressing some of the changes, issues, and ideas arising from nanotechnology and an associated set of emerging technologies is a grand task and *Steep (I): a digital poetry of gold nanoparticles* is, proportionately speaking, the equivalent of offering a single nanoparticle's worth (one billionth of a metre) as party to the endeavour.

Golden histories

Gold, despite modern challenges from platinum and palladium, has been and remains the most prized metal across cultures and throughout history.

King Croesus's name has been a synonym for wealth for centuries,

"… [John Gower] in Confessio amantis (1390):

> That if the tresor of Cresus
>
> And al the gold Octovien,
> Forth with the richesse ndien
> Of Perles and of riche stones,
> Were al togedre myn at ones…"

Croesus was ing of Lydia (560 -547 BCE) and is credited as being the first to produce and use gold coins as a means of exchange. 2 As for the other 'King' myth, there were at least three individuals named ing Midas but the one who survives best is the mythological entity turning everything his hand touched to gold. 3

In real life, the Lycurgus Cup (4th century CE Rome) is an outstanding example of how gold can play multiple roles. It is a cage cup made of gold extracted from the earth and beaten and heated for shaping. This cage holds a second cup, one made of glass and fashioned with gold and silver nanoparticles which endow it with extraordinary optical effects. It glows red (Figure 1) or green (Figure 2) depending on how the light shines on it. 4

The 'Cup' is an iconic nanotechnology image gracing the cover of the British Society's 2004 report "Nanoscience and nanotechnologies: opportunities and

uncertainties," which was written in response to concerns from Prince Charles about nanotechnology and a 'goo' scenario (the possibility that nanoscale devices, self-assemblers, would begin to self-assemble uncontrollably and ceaselessly snatching atoms from everything they came in contact with resulting in a denuded world of 'goo'). 5, 6 Feelings have calmed since that time, possibly due to the Lycurgus Cup itself, which demonstrates a benign and beautiful use of nanotechnology.

Figure 1. Lycurgus Cup (owned by the British Museum) glows red when backlit. Credit: Johnbod, 2010, no flash. Image is licensed under the Creative Commons Attribution-Share Alike 3.0 Unported license. Downloaded from http://commons.wikimedia.org/wiki/File:Brit Mus 13sept10 bro oches etc 046.jpg

Medieval glass windows in European churches with ruby red panes coloured by gold nanoparticles are thought to do more than look beautiful,

> "Professor Zhu said numerous church windows across Europe were decorated with glass coloured in gold nanoparticles.
>
> "For centuries people appreciated only the beautiful works of art, and long life of the colours, but little did they realise that these works of art are also, in modern language, photocatalytic air purifier with nanostructured gold catalyst," Professor Zhu said. 7

Zhu Huai ong is a professor at ueensland University of Technology in Australia whose expertise includes the direct photocatalysis of metal nanoparticles.

Moving beyond Europe, researchers found layers of gold foil beaten to a thickness of 100 nanometres when examining Namban screens from Japan's Edo period (1603 – 1868) which they reported in a 2014 paper. 8

Gold at the nanoscale has been part of our existence since before we had a means of describing it.

Figure 2. Lycurgus Cup (owned by the British Museum) appears green when frontlit. Credit: Johnbod, 2010, with flash. This file is licensed under the Creative Commons Attribution-Share Alike 3.0 Unported license. Downloaded from http://commons.wikimedia.org/wiki/File:Green Lycurgus Cup.jpg

Engineered nanoparticles, gold and otherwise

More recently, we have been exploring the use of materials measured at the nanoscale with a view to exploiting the properties associated with quantum mechanics. The US National Nanotechnology Initiative (NNI) has invested over 21B since the program's inception in 2001. [9 The European Union, the U , China, Japan, Canada, and Iran are only a few of the other jurisdictions which have invested untold amounts into exploring the quantum properties of nanoscale materials such as gold nanoparticles, carbon nanotubes, etc., with a view to enjoying economic glory as a direct consequence. Businesses too such as IBM, HP

Labs, Intel, L'Oréal, and more have invested extensively in nanotechnology.

Mark Wiesner (Professor of Civil and Environmental Engineering and Director, Center for the Environmental Implications of NanoTechnology CEINT at Duke University, North Carolina, US), notes informally there is more than one process for producing/manufacturing gold nanoparticles but this one is in common use today,

> "Gold nanoparticles are made about the same way as silver- you start with a solution of the metal salt and add a reducing agent. ou might also include some organic compounds that give the resulting particles a charge that prevents it from forming clusters with other particles. Maybe the most common method is to start with a solution of gold salt like HAuCl4 aka, Gold Chloride, Hydrogen Tetrachloro Aurate (III), Chloroauric Acid, or Gold Acid Chloride and use citrate both as the reducing agent and to create negatively charged functional groups on the surface that stabilize the particle against cluster formation." 10

Irrespective of production techniques, gold nanoparticles have proven to be of tremendous interest in health and medical applications, and in electronics, sensors, etc., and, to a lesser extent, in its use as a catalyst. 11, 12

While gold nanoparticle-enabled applications are currently coming to market with more being developed every day, there are studies into the risks associated with these materials. The nanoparticles, themselves, have not occasioned the levels of concern aroused by silver nanoparticles and long carbon nanotubes but there are issues. A research team at Stony Brook University (New ork state) published a 2013 paper detailing a study which suggested gold nanoparticles could cause cellular toxicity, specifically in certain types of adult stem cells. 13, 14]

Steep collaborative project

Figure 3. Raewyn Turner's hand covered in gold. Raewyn Turner, 2014.

As more gold nanoparticles are manufactured and 'pumped' into our air, our water, and our soil, we are becoming 'steeped' in gold as Figure 3 fancifully demonstrates.

This art/science project, initially conceived as a single cross-disciplinary art project invoking the notion of being steeped in something invisible which is both new (nanoscale) and familiar to us over thousands of years (macroscale), was developed by Raewyn Turner (artist) and Brian Harris (electronics designer for film and video). The project was expanded to include Mark Wiesner (previously mentioned Professor at Duke University, North Carolina, US), as a science consultant/collaborator and Maryse de la Giroday (writer) and has been reconceived as a series of virtual and/or physical installations with a rotating cast of collaborators.

One of the challenges of a cross-disciplinary project, including this specific poetry video/animation installation, is integrating the principals' (Maryse de la Giroday and Raewyn Turner) differing and, at times, opposing perspectives on representing gold nanoparticles in digital poetry form. Issues over language be it written, verbal, or visual and attempts to avoid dichotomies, for example, words vs. pictures, have required significant investments of time and effort to reframe the discussion and the approach to creating an installation which represents an emerging science (nanotechnology) and its uncertainties.

Steep (I): a digital poetry of gold nanoparticles

The first installation in the reconceived *Steep* series is *Steep (I): a digital poetry of gold nanoparticles*, and is designed as a poetic trilogy realized through onscreen animation and, in future, as a real life video installation. This trilogy, an onscreen piece, is a 'research work in progress' as poem, as animation, and as science communication. The visuals and language are metaphoric as informed by the science.

Yearning, the first part of the trilogy, focuses on gold and its role as a metal of desire. It takes inspiration from terms such as golden opportunity, golden rule, golden ratio, and others. References to its pursuit (inspired by Shakespeare's, "such stuff as dreams are made on") during the Klondike gold rush (taking place in the Yukon, a Canadian territory lying north of British Columbia and adjacent to the US state of Alaska) will act as metaphor for all the gold rushes. [15] *Yearning*, intended to convey how thoroughly gold permeates our culture and history, will also touch on the process of extracting gold from the earth.

Light/Shadow, the middle part of the trilogy, reviews our current understanding of the metal in its particle form. In effect, making the invisible, visible by proxy emulating how scientists view nanoparticles. (The process most commonly requires a scanning probe microscope of some kind where the probe's tip has been dragged across a substrate, sensing the particles by touch, recording the information as data, and sending the data to a software program, which then represents the data visually.)

More specifically *Light/Shadow*, will reference the optical effects made possible by the particles and seen, for example, in the Lycurgus Cup (previously mentioned) and in a 'golden fleece' developed in New Zealand.

> A gold nanoparticle infused yarn developed by Kiwi scientists is expected to be sold to wealthy buyers of luxury carpets, rugs and furnishings. Unlike the 'golden fleece' of Greek mythology the yarn and completed woollen products will not have a golden colour at this stage.
>
> The Aulana-branded wool has been developed by Professor Jim Johnston and Dr Kerstin Lucas of Victoria University after $3 million of research and development.
>
> A tiny amount of pure gold is combined with wool and the chemistry between the two causes it to bond and produce the colours of purple, grey and blue. [16]

Gold's new found role as a catalyst for chemical reactions, and its more common uses in medical applications are more examples of 'light' while the possibilities of toxicity, 'shadow', will also be represented in word and form. [17, 18, 19, 20, 21, 22, 23]

Finally, *Discovery*, the last part of the trilogy, is a meditation on the worlds represented by the atoms present in gold nanoparticles. Drawing on the notion of Erwin Schrödinger's cloud model of atoms rather than the more commonly taught planetary model (the Bohr Model named after Danish physicist Niels Bohr) and referencing William Wordsworth's 'I Wandered Lonely as a Cloud', also known as, 'Daffodils', *Discovery* hints at how little we know and the volatile state of the research and the knowledge. [24, 25, 26] For example, researchers in Finland published papers in July 2014 and in February 2015 where they noted that gold nanoparticles of 144 atoms behave like gold metal at the macroscale while gold nanoparticles of 102 atoms behave like a giant molecule. Meanwhile, researchers Carnegie Mellon University (in the US) noted in a March 2015 paper that gold nanoparticles of 133 atoms were not yet metallic. [27]

Animating Steep (I)

Yearning's opening visual sequence starts with a distant shot of the planet earth and a descent, drawing closer to show the tops of houses (which resemble nanorods from a certain distance). This sequence and subsequent visual imaging convey the 'yearning' for beauty, riches, and spirit. The visual style changes from one part of the trilogy to the next signifying the shifts in theme while retaining overall cohesiveness. *Light/Shadow's* visual design emphasizes the interplay between light and shadow, with work seen in shadow and gradually revealed. It parallels how bits of scientific information are acquired. Specifically, we are slowly learning about gold nanoparticles, for example, there was the realization that the Lycurgus Cup's optical properties are due to gold and silver nanoparticles. *Discovery* is the most conceptual section using images of gold nanoparticles taken with a specialized microscope to convey the ideas and science underlying the poetry and the notion of being 'steeped in gold'.

The serendipitously named 'particle system technique' produces an effect where visuals dissolve into particles. In this case, the plan is to use the effect so we can represent gold nanoparticles which then reconstitute themselves as new words and/or images. This proposed 'cloud' of gold nanoparticles and text is intended to signify Schr dinger's atomic model and Wordsworth's 'cloud' blending science and poetry with attention being paid to not being overly literal. Animation tools under consideration include After Effects, Maya, Vectorian Giotto, and/or Blender.

A current sample animation (working title: animated words video), included with this submission, features a high resolution aerial photograph of the hills of Hawkes Bay, New Zealand and 'words' (symbols used as placeholders for words) accompanied by music, a Jesse Cooper remix (Ben Sage). Final Cut Pro was used to create the work in progress.

Conclusion

Steep is an international art/science research project examining the impact gold and gold nanoparticles have had in the past and could have in the future. Designed as a multi-year, multidisciplinary project with a rotating cast of collaborators, *Steep* is based on the current state of scientific research and its flexibility as a project reflects the uncertain and disruptive state of nanoscience and nanotechnology (as they are sometimes referred to).

Steep (I) a digital poetry of gold nanoparticles, our first piece, is largely concerned with the elements of air, water, and earth or, more fancifully, gold in all its forms: myth, metaphor, and reality as it transitions visibly and invisibly throughout our environment.

The co-leads (Maryse de la Giroday and Raewyn Turner) for Steep (1) have artistic practices that while grounded in various disciplines exploit the state of 'not knowing'. This requires spontaneity and openness to a state of uncertainty. The following trilogy and video sample accompanying this submission are works in progress and are emblematic not only of the co-leads' artistic practices but of the uncertainties associated with nanotechnology and its disruptive impact (for good and/or ill) socially and environmentally.

a digital poetry of gold nanoparticles

Yearning

shards of sun
hidden in the river s silted bed
buried beneath the earth s skin

a beautiful killing
in the cold, cold river
in the darkness underground

opportunities made of gold
wealth beyond Croesus' and Midas' imaginings
shining brightest

londike calls
El Dorado beckons
siren songs of:

safe passage through this vale of tears
alchemical transformation from fear to joy
power over life and death
pleasure unending and unimaginable

kings and paupers answer
build empires
strive for godhood

Buddha, Jesus, Ganesha
and the others
sitting golden in their temples waiting tribute

flesh and spirit
striving towards
a beautiful eternity

Light/Shadow

golden cage
holding
the Romans' particulate offering
two-colour glass rainbow glowing red/green

wounded cerebrum
made whole
nanoporous gold-plated electrodes
electrifying neurons

New Zealand's woolen fleece
economy wrapped in gold
gleaming lavender

stromal cells
collecting
gold ceaselessly
until
a failure
to regenerate

European cathedrals paned in
photocatalytic purifiers made of gold particles
blazing red

mining nanogold in
sewers
deposits richer than the earth

harvesting the sun
with a fishnet made of gold
Au 144

poisonous nonpoison circulating
the air
the earth
the sea

Discovery

wandering lonely as cloud
a host of golden nanoparticles
rains down on earth

superpositioned quantum world
dead/alive
metal/molecule

classical physics
dead or alive
metal or molecule

simultaneous and incompatible truths
for now

metal particles—144 atoms of gold—Au_{144}
molecular particles —133 atoms of gold—Au_{133}
transmutation of Au particles from metal to molecule and back

Nature's alchemy
breathing them
eating them
drinking them
we become gold
discovering what we are

Author Biographies

Maryse de la Giroday, independent scholar, writer, and science blogger received her BA in communication from Simon Fraser University (Burnaby, British Columbia, Canada) and was awarded an MA in creative writing and new media from De Montfort University (Leicester, U). Her BA honours project resulted in a video, "Bridging the Cultural Gap" on intercultural communication used as a teaching tool in Canada and the U.S. Her MA pro-

ject, “The Nanotech Mysteries: An Initiation into the Science and the Technology wiki” is mentioned in the 3rd edition (May 2014), “Digital Storytelling: A creator s guide to interactive entertainment” by Carolyn Handler Miller. Since 2008, she has written extensively about nanotechnology on her *FrogHeart* blog and has presented on the topic at regional, national and international conferences. During the 2014 autumn semester, she taught two courses, “Bioelectronics, Medical Imaging and Our Bodies” and “Nanotechnology: The Next Big Idea,” at SFU in the Continuing Studies program.

Raewyn Turner’s work is concerned with cross-sensory perception and the uncharted territories of the senses. She works with video, interactive installations and performances, painting and sculpture, working solo and in collaboration with artists, musicians, architects, dancers, performers and academics on installations, theatre performances, exhibitions and screenings. She is also a concept and design theatre artist and lighting designer and operator in large scale international performance in stadiums and theatres, for contemporary music and dance. She has worked in collaboration with Dr Richard Newcomb, molecular biologist, NZ. In 2011 she was recipient of a Fulbright Travel Grant for an artist’s residency at Monell Chemical Senses Center, Philadelphia. Her works have been shown in numerous national and international exhibitions and performances, including ISEA2013, Museum of Contemporary Art, LA, Parque de las Ciencias, Granada, Spain, 11th Prague uadrennial of Scenography and Theatre Architecture 2007, Prumyslovy Palace, Prague, Argentina, Georges Pompidou Center, and elsewhere.

The Scroll Unfurled - Ancient to "Vanguard"

Leslie C. Nobler

William Paterson University
New Jersey, USA
noblerl@wpunj.edu

Abstract

An historical understanding of the scroll is useful for creating within new textual genres. Books and text art-forms are destabilizing, energizing future possibilities. Yet we must look backward to the reasons this first information technology existed, as I do in my digital scrolls that report, communicate, purge, and narrate. In light of our changing "book landscape," we combine heirlooms, maps and artifacts with rounded and striped visual structures expressing the rich aesthetic of a *fading* old (slow) format. Where will the new and fast electronic formats lead our culture?

Keywords

Text, Scroll, Book, E-book, Digital Art, Artist's Books, Textile

Introduction

I use history, and books, intensively in my work in the realm of the artist's book – both the tangible and electronic. But I always use the newest digital tools and materials - so I had to ponder if there is a connection between the oldest form of information-recording and what is happening today. Out of concern about the possible demise of the physical book, I was compelled to explore its earliest roots.

There are a wealth of "connections" between the scroll– the oldest known book format, and present-day electronic books. Scrolls and hard drives and CDs are rounded - they spin and roll. We ***scroll*** on our electronic devices. We only read on one side of them; they are literally illuminated. Scrolls were one-sided – and were *artistically* illuminated.

Uses for, or the purposes of, scrolls over centuries of history have also informed my digital scroll-making. Like those before me, I dealt with human relationships in these scrolls. An early digital scroll expressed my search for strength during divorce, and in *Partners* the opposite is explored. Scrolls of the past recorded important life events. My *Fly to Safed* marks the occasion of a long awaited journey. *Flow* [below], combining transfer and direct ink-jet printing, is an imaginary, electronically-generated *picto*-graphic, "letter" of sorts that I wrote to my ancestors, honoring the important use of the scroll format for interpersonal communication.

Figure 1. *Flow;* Copyright, the author/artist

Destabilization

In *The Realm of the Circuit*, Charles Traub and Jonathan Lipkin posit that books are repositories for thought, and therefore power – the power to spread ideas and knowledge, which in the final analysis leads to profit. Over time, they became more and more portable and easier to reproduce; the digital download-able book is just the next phase in this process. The authors argue that in the traditional scroll, and book, content is FROZEN. [1] It was made and scribed, or printed, and could not change. This is not true with artist's books and scrolls, at least those that are designed to change/morph physically and interactively, and certainly not true with e-books.

Books traveled – first along trade routes – and slowly. Now they can travel at the speed of light. And with such massive changes is this dynamic, like those that we see today, things can become "destabilized."

There is a cultural rupture created by the possible (even presumed), slow and deliberate disappearance of the physical book. But the artist can help society confront this by a provocative analysis of 1000's of years of text, and by crossing from literature into other expressive spheres. As I use text, code, and relief picture-making, I have been investigating contemporary aesthetics within bookforms, recently the **scroll**, created both by hand and machine, and various hybrid techniques.

Scrolls as Fodder

This pivotal change and void (rupture?) moving from paper and print to ephemeral media is currently examined throughout the art world; many, like myself, use history to ground their analyses. Using new technology to make "old technology," – **the book**, among the oldest technology, I focus on sacred and ritual books. The earliest sacred books were typically in the form of a scroll, and they shape the basis of my exploration. The scroll is round, fluid and continuous, and must be unfurled. It is also (oddly) quite linear – often stripped together, and "striped" also, hence I design imagery that goes *around* and/or emphasizes striping and concentric lines. Sacred scrolls were richly ornamented; their protection was critical so they were bound, buckled and enrobed in beautiful containers.

The scroll was our original format of choice - a long rolled piece of parchment, paper, silk, etc. One gradually unrolled it, exposing one section at a time. Coiled into a round tube when closed, it worked "in-the-round," not unlike our vinyl records, CDs, DVDs and spinning hard drives. In today's world of iPads, e-readers, e-books and laptops, it feels like we've returned to yesterday. We read on only one side of a screen. We scroll through everything digital. Authoring, publishing, designing, and illustrating software all work on the premise of streams of information ~ upon which pages are IMPOSED, rectangles forced onto a flowing continuum (pagination). Using "forced" pages, new media/electronic artist Seth Ellis builds *flowing* scrolls bringing stories from the past to light. Ellis writes "My work is about finding new ways to tell stories – by making them site-specific, by creating them with randomizing programs, by asking other people living and dead for input. I'm interested in active, experiential reading." [2]

Elements in my scrolls derive from 19th and 20th century ceremonial and everyday objects and texts. Vintage papers, lace, maps, and odd relics are utilized or referenced. Interested in using modern technology to reincarnate symbolically rich, historic art and artisanry, I mine visuals with ritual, religious or mystical significance, and symbolic heirlooms. Akin to Ellis, exploring historical, mythical and ethnic stories through the digital lens of today, combining hand with byte, is the heart of my studio practice.

The Narrative

The yellow round form in *Flow* is based on the filigree top of a Sabbath spice box from the 18th century, near the area in central Europe from which my great-grandparents emigrated; as I constructed this imaginary painterly scroll-letter to those ancestors, I found it important to layer many softly printed phrases and circular elements. Half-real scenarios evolve in my mind, related to journeys I take. For example, *Caves and Flickers* [below] is about a house of worship in an embattled town, and a downhearted man thinking of entering its doors for a "flicker" of hope.

Figure 2. *Caves and Flickers;* Copyright, the author/artist

In other works I may simply journal my travels, as I learn about distant places, their arts, culture, history, and social issues. In *Open the Floe-gates*, to the right, note the maps, suitcase and sense of antiquity. It also questions the future of the narrative on *paper*. So precarious is the future of the physical book, that *Floe* is apt for its title – a floating sheet of ice – ready to melt, crack or self-destruct, disrupt!

The Rolling, Scrolling "Book"

The scroll's beginnings and its amazing connections to the book of today were a far bigger "concept" than I would have ever thought. A large part of the reason for that is how much book arts today – both digital and tangible – actually harks back to, or relies upon, the legacy of the scroll. I got caught up in this thought when I first saw Anselm Keifer's life-sized work in the book and scroll art forms.

Viewers of Keifer's art interact with his huge sculptural books made of the most unique and unexpected materials. They are both light and leaden, furling and rigid, or frozen, perhaps as Traub and Lipkin propose. [3] Yet they had (and have) a beautiful and weathered lyricism to them, as they "rolled" through space at the Smithsonian.

Exploring history – through art history – and its social structures (with all their social inequities), and its ethnic "stories," through the digital lens of today – with its evolving democratic global community, is essential to this body of work. Past cultures' stories, adapted digitally, wind

Figure 3. *Open the Floe-gates;* Copyright, the author/artist

through the coiled multi-substrate surfaces of my scrolls, Keifer's (though not digitally), and a group of like-minded artists that I identified and curated into two recent new technology art exhibitions. What will an unrolled scroll, scribed with leading edge tools, reveal? In the end, it is the story, concept, interactivity, and overall aesthetic experience that most matters.

The New Scroll – Group Exhibition

The show was titled **The New Scroll – an old technology reinterpreted.** Its first venue was the Hamilton Street Gallery, a pristine storefront gallery in Bound Brook, NJ. After that came Arts Guild New Jersey, an exhibition space and cultural center in a town aiming to become the regional arts district. With a little funding, a student-intern and two venues in place, I began carefully selecting art that made the right statement. I had previously searched all over, in various ways, to identify art-makers. Now this grouping of their works had to come together – and interrelate.

The gallerist and I wanted to show a broad range of materials and techniques, with an intensive focus on those with *unusual* contemporary twists on modern technology. The artwork had to have a visual narrative and/or use text. The list of those that work electronically comprised myself, Suzanne Stokes, Haley Nagy and Joohyun Pyune. Stokes is a (shadow-art) performance artist and printmaker, who expertly uses Photoshop to create serigraphs based on the performances – always with a richly choreographed story told in a vertical flow. Nagy is a book artist who uses electronically-controlled knitting to literally knit (revised) biblical words into her extra-long scroll installations. Pyune is a digital textile-print artist who uses all the art software and printing technology she possibly can to heat-transfer print sheer horizontal overlays that tell a story in three dimensions. All are interested in blending the old sources and techniques of their art with the newest ideas and processes in making their scrolls.

Bookforms and Possibilities

"Analog" book and scroll artist, Aimee Lee, states "I have adapted ancient techniques and materials in my art to revive and update tradition, and encourage the survival and evolution of the old ways, while adding layers of meaning to my practice." [4] Using digital tools to respect the vast knowledge of times past, making it relevant and accessible, is a common objective. Linking the past to the present intensifies the content, as seen in *Flagging Helicopters* [below], a scroll/work in progress. The story of a search for lost passengers from a voyage or flight that got inverted (note my upside-down triangular Dutch row-house roof-tops) is told through the use of "mined" metaphorical scenes and symbols.[1] Often looking backwards, revisiting your roots, drawing from the depth of the past, is the optimal way to grow, using this future-minded medium. Here, vintage-style memorial flower wreaths and *wedding band* quilt patterns are rich symbols for *all* times.

Figure 4. *Flagging Helicopters 1;* Copyright, the author/artist

1 Part of participatory group art project done with the Book Arts Roundtable (NJ, USA); to become an electronic scrolling book.

After looking at the literary and pictorial heritage of the scroll, along with some strong artistic interpretations, one cannot help but question how that early technology will continue to influence the computer scroll-like products of today and tomorrow. Hopefully the viewer will consider how *scrolls* can *now* be made and *rolled out*/distributed – perhaps "democratically" worldwide, and definitely at the speed of light. *Light* itself, or its meaning of expanding knowledge [enlightenment], even tells a story; below left a detail of a collaged scroll combining an illuminated manuscript and an x-ray style photograph and right is section of a scroll using a still from illuminated light/shadow theater.

Stories about centuries-old ceremonies celebrating a new life, such as in the piece below left, can easily unfurl in a nanosecond. It continues that scrolls, such as these, can be experienced as non-linear in much the same way we/our youth adapt to/evolve new computing. The horizontal units of the pieces can rearrange, sometimes three-dimensionally. Then the layers of meaning might change too.

Figure 5. Left: detail from *Dutch Lace on Sabbath*; Copyright the author/artist. Right: detail from *Ascend (scroll)*; Copyright Suzanne Stokes

Scrolls Abroad

It is important to note that there are other attitudes about the contemporary *scroll-as-art* experience in different cultures. Chinese, Korean and Japanese artists still today use the beautiful silk scroll formats from long ago; many artists offer provocative, unusual new interpretations. On a recent research trip to Oslo, Norway I studied the work of digitally invested textile and book artists, all makers of scrolls, up close. Galleri Format, a leading Norwegian venue, was vey informative in this regard.

There, I became versed in the work of Kari Dyrdal, who describes her encounter with digital tools as rich,

investigative, *disruptive* and constructive – all rather apt adjectives. Her work involves an intensive background in art traditions, yet it is innovative in its use of digital technology. While conceptual, it also strongly refers to substance and technique, which connects to a deep cultural appreciation for the heritage of the process, craft and its materials. The detail of a three-part scroll below, left, is especially rich in its use of fiber and computer printer-dyes, while quite changeable – even destabilized – in terms of the position each unit holds both vertically (according to its state of "unroll") and horizontally. It contains fairly illegible text as well. Notice its similarities to the piece on the right by Korean-born Joohyun Pyune, which also shows subtle symmetry within a transient sense of time and light. The digital medium is "perfect to visualize the ambiguity of the life experience." [5] Once posted, these

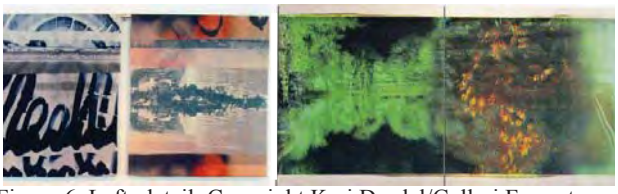

Figure 6. Left: detail; Copyright Kari Dyrdal/Galleri Format. Right: detail from *Five Seasons*; Copyright Joohyun Pyune

scrolls reach an internet audience in almost no time, and make an immediate, if not powerful, optical impression on the visitors at the public spaces in which they hang.

It is hard to discuss the modern scroll experience without including the ancient Jewish scroll, the Torah. It remains a vital part of the spiritual, literary, and aesthetic aspect of Judaic practice, comprising all elements of its crafting – the calligraphy, stitching, woodwork and ornamentation along with its musicality. Marvell Ginsburg writes that old Torahs that were dressed in jewel-toned mantles, topped by silver crowns, "looked like kings and queens," [6] placing an anthropomorphic spin on the sacred book. Interestingly, they become damaged by NOT being unrolled for many years, as happened when the Nazis confiscated and warehoused them. It is as if a Torah can only remain functional through the very act of repetitive interactive scrolling.

Yet, one can also wonder if there is another, radical, slower, more expansive or more *illuminating* way to "scroll" in future centuries. Should scrolling be more – or – less iterative? One or two-sided, or multilayered? What might electronic or analog scrolling look like decades from now? How shall that quickly-fading first information technology inform us? Meditative concentration is required to truly "read" or discern the scrolls of **The New Scroll.** Focus is necessary to grasp the art. But when we only scroll faster and faster – where will that ultimately lead us?

Author Biography

Leslie Nobler is a digital artist, creating artist's books, surface design, and monoprints. Her recent work *reinvents* sacred books and ritual artifacts using alternative digital printmaking. Exhibitions internationally include New Jersey State, Noyes and Montclair Art Museums (NJ), Old-Main Art Museum (AZ), Athenaeum Museum (PA), Kemper Museum of Art (MO), Afri*graphics* Pretoria, and Digital Art Awards/Australia and China. Nobler has had multiple inclusions in SIGGRAPH Art Galleries. She is an Art Professor at William Paterson University (NJ) and curator/ lecturer at universities, museums and alternative spaces. Her work is represented internationally in museum and university art/book collections, such as Sheffield University, UK. A recipient of Surface Design Association and Puffin Artist's Grants, among others, she earned her BFA at University of Michigan, Stamps School of Art, MA at New York Institute of Technology and MFA at City University of New York - Hunter College.

'Twitter': Practice in Writing
A recipe for Creativity & Creative Interpretation

Janis Jefferies, Anastasios Maragiannis,

Goldsmiths, University of London, University of Greenwich,
London, United Kingdom
j.jefferies@gold.ac.uk A.maragiannis@gre.ac.uk

Abstract

This paper will explore how the way we read on the screen can create new forms of collaborative writing online. With reference to our 'Twitter: Practice in Writing' workshops in London 2014 and Vancouver 2015. As a younger generation move swiftly from print to pixel, reading no longer becomes deliberate and concentrated but rather a scan for information as our eyes follow an F-shaped pattern. Screen-reading encourages rapid pattern-making, provoking action, whereby words are merged with images. From scroll to moveable type, will twitter 'novels' give rise to twitter brains? How does it affect what we read and write? Has this change been recognized in the publishing industry?

Keywords

Screen; Reading, Writing, Graphics, Twitter, Novels; Brains: Technology; Type;

Introduction

In order to understand how screen writing and screen reading have evolved, a series of 'Twitter: a practice in writing' workshops were devised in London 2014. The first steps of this workshop devised ways for dismantling the most obvious and accepted of connections, be they between words, colours, shapes, or ideas. Then brought these elements together, in ways that have never been linked before. The critical issue here is that the new combination of colours/words/ideas must trigger new extensive connections and 'meaningful' associations in both the creator and ideally others. Mere linkages between disparate themes and concepts are insufficient, as witnessed in many drug-takers' meaningless ramblings or schizophrenics neologisms, creating only nonsense words.

We see the world, thanks to the creation in a new way because the extensive and therefore 'meaningful' associations have formed in our brains, previously triggered by these novel juxtapositions of previously disparate elements [3].

This changes clearly develops through our younger generations. Young people moved from print to pixel, today some 4.5 billion digital screens illuminate our lives. Words have migrated from wood pulp to pixels on computers, laptops, tablets and phones, with *our"…digital screens illuminate our lives... Letters are no longer fixed in black ink on paper, but flitter on a glass surface in a rainbow of colors as fast as our eyes can blink…We are now people of the screen…these newly ubiquitous screens have changed how we read and write." Kevin Kelly 2010*

Writing does not come naturally

The 2014 workshop was the starting point to illustrate the development of a framework that analyzed the use and production of typographic forms and text, which were influenced by the media-specific potentials of emerging technologies. The process aided design practitioners in their creative thinking and writing. The purpose of the workshop was to obtain a clearer understanding of opinions held by participants on the application and role of screen based text. By identifying the different natures of the interactive screen, media practitioners were able to experiment with creative methodologies. The workshop was designed to function as an ongoing series of experiments to further our understanding the nature of writing, and captured something of the elusive moment when thoughts turn into words. Moreover, the workshop explored how new media affects established design processes in terms of clarity of communication. If one is to achieve an understanding on the unique potentials of the development of typographic form, it is important to bear in mind the conditions in which the new media and new technologies influence the designing process.

The workshop outcome was informed by an understanding of the creative process as a holistic action with the capacity to simultaneously achieve both epistemological and ontological shifts. Furthermore it provided educators, researchers and students the opportunity to challenge the most obvious and accepted of connections, creatively, be they between a variety of words, that affected by colors, created by unique and experimental shapes, or innovative ideas. Whilst it became clear that they were not reading on line in the traditional sense, they were engaging in what is termed "power browsing' through links, blogs and all forms of social media. This is supported by the British Library's report (2008) where researchers found that everyone, *"exhibits a bouncing/flickering behavior, which sees them searching horizontally rather than vertically… Users are*

promiscuous, diverse and volatile." They navigate, they skim, and they pick out only key words.

Mass production

Despite the concerns raised in the previous paragraph, the usability of webpage's does allow for new forms of writing to emerge. These forms are based on interaction and dependent on the feedback of others through the unique meshing of graphics and words. It also rewards participation and performance rather than more contemplative behavior that print literacy has exhibited for generations. After all, post Gutenberg mass-produced books in the 15th century changed the way people read and wrote so that the technology of printing expanded the number of words available (from about 50,000 words in Old English to over a million today). More word choices enlarged what could be communicated but in contemporary society, less is more.

Using thumbs instead of pens, it appears that young people collectively write over 12 million tweets that comprise no more than 140 characters, per day from their phone. In terms of issues in contemporary writing, Jennifer Egan's Pulitzer Prize winning novel, A Visit from the Goon Squad *"an inventive investigation of growing up and growing old in the digital age, displaying a big-hearted curiosity about cultural change at warp speed*" [4], is an exemplar of what is happening. In her follow up work, *Black Box* propels a character from A Visit From the Goon Squad into the 2030s and a world of citizen espionage. But Black Box is only available as an eBook, and The New Yorker, on Twitter, first disseminated it. The tweets ran one a minute for an hour each evening, over ten days, starting on 24 May 2012.

So what do you do if *you* have a novel to write and you are not a Pulitzer Prize winner but you have something to say about your world and want to do this by creative participation? Artist Cory Arcangel's new book is a compilation of those who couldn't resist tweeting the words "working on my novel". Working On My Novel [2]. It's a compilation of tweets, found on twitter by searching for the phrase "working on my novel", and re tweeted by Arcangel's account of the same name. This is but one example, but as the artistic boundaries, in some cases, between producer and consumer in increasingly blurred; the relative ease of digital creation through twitter novels for example and online distribution and feedback may lead to production by the masses that rival production for the masses. The distinction between the producer of culture and the consumer of it is blurred. This is the one of the findings from the Twitter: Practice In Writing workshops from June 2014.

Publishing Industry

Drawing on debates informed by a series of roundtables at the Guardian newspaper (2013, London, UK) and the National Endowment for Science, Arts and Technology (2014, London, UK), writers, lawyers, publishers and economists explored the issues that are impacting on the global publishing industry. Whilst much of the debate tends to focus on digitization and on the transformation of products (books to e-readers, paper to screen) and the developments - called "social creativity"- there appears to be an unlimited source of innovation for social and economic aims. The value of alternative working as well as business models including the formation of new publishing consortia, new cooperative and participatory practices were acknowledged. This has led to the emergence of new economic models that challenge the boundaries between what we have traditionally considered to be the public, private and common realms [7]

For example, there are many small presses in the UK that bridge the gap between writers, new writing and industry, seeking experimentation and innovation where the question of nurturing relationships and collaboration is the primary concern. Smaller presses like SALT, INFLUX or Gallery Beggar Press in the UK ('high class boutique' presses) who publish up to 12 title a year (SALT) or 4 (INFLUX) but the same challenges are face large or small, risk versus money, good editors as good readers and no book sells itself, authors are always key. CompletelyNovel [5] is a self-publishing platform and book community, specializing in print-on-demand publishing which hosts an eclectic mix of authors writing across a whole spectrum of fiction and non-fiction.

What is a Book? What is a Novel?

"Siri write me a novel…"It's pretty easy to make 50k words of nonsense…we want to see is code that produces alien novels that astound us with their sheer alienness. Computers writing novels for computers, in a sense." Stephen Fortune, 2014 [fig 1].

So what is a book or indeed what is a novel? " Ulises Carrion (1985) poses such a question in his essay, '*The New Art of Making Books'* [1]. A book is a sequence of spaces and since each of these is perceived at a different moment, a book is also a sequence of moments; it is an autonomous space-time sequence. The content of a book is contained within the volume of the book. Elements or blocks of the content – both identical with the elements of the book and independent of it and from them texts, images- are organised within the space of the book.

The relationships between them are spatial rather than linear. Whilst the content of the book is organised and

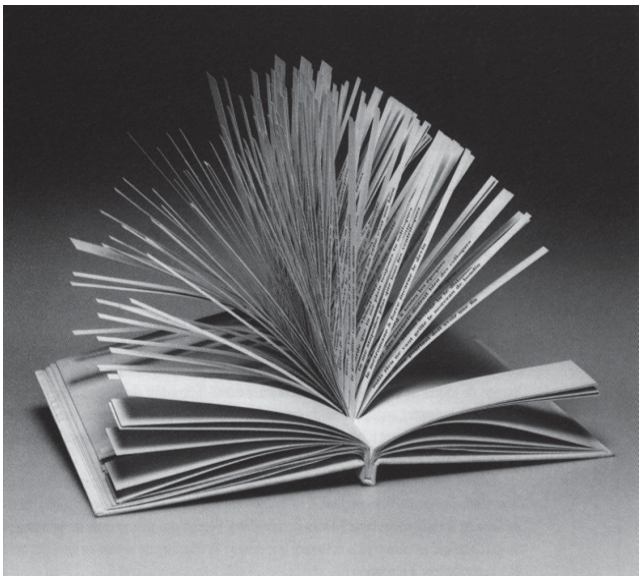

Figure 1. Raymond Queneau's One Hundred Trillion Sonnets

structured simultaneously in space, it is perceived consecutively in time and the time sequence only realised in the process of reading.

It is the reader who chooses where to start in the process of reading, where to stop, how and what to read, how fast, how slow and how attentively. Another example is the "A Thousand Plateaus" written in a non-linear fashion, and the reader is invited to move among plateaux in any order . It shows how such distinctions are operations on the surface of a deeper pasture with further complicated dynamics [8]

These stylistic choices are entangled in the book's content, as made apparent in the introductory section on "rhizomes"." Furthermore experimental approaches in writing also appears in Katherine_Hayles book 'Writing Machines' and in Tom Philips "A Humament" where both are exploring alternative techniques of the words through painting, collage and cut-up practices to create an entirely new version of existing writing.

Readers, while welcoming the new generation of electronic reading devices, still buy predominantly paper copies of books. Time and again the conversation leads to blanket statements about 'the end of books' where little attention is paid to the vast potential for new hybrid forms of text, and the fundamental shifts in the writing-reader axis that the new technologies are enabling. Attributing too much agency to technology is often tantamount to the abdication of responsibility, and we are concerned with broadening the discussion toward notions of ethics, collaboration, property and creativity. Is it possible that there is a potential transformation in the *relations* rather than *objects* (books, devices) that characterise the publishing industry?

You turn the page and guided or confronted by its structure, you manipulate the book – and through the interaction between book and reader something is revealed. Sven Birkerts (1946) in The Gutenberg Elegies: The Fate of Reading in the Electronic Age calls this 'deep reading' because we, the reader, are free to "indulge our subjective associative impulses; we dream our lives in their vicinity" and we hear "in the theatre of our auditory inwardness, voices that we conjure as our own as a sound print of the self." (ibid:146)

Birketts has a pessimistic perspective on reading in the electronic age since the printed page and the circuit driven, emerging (defined as information) technologies are not 'kindred' but are staged in opposition, undermining, what he states in his introduction as 'the once stable reader-writer' exchange. In Maryanne Wool's words (2008) "How much syntax is lost. Where is the "slow reading" movement? Will we become Twitter brains?" The brain, after all, is as plastic as words; writing can be as collaborative and social as individually conceived. In fact, as Woolf argues the brain was not designed for reading, as there are no genes involved as there are for language and vision.

The brain has adapted to read, so for one of the authors, my brain has to learn shortcuts to deal with one form of non-linear reading (there are exceptions of course).

Was this ever so? Lawrence Stern's cult classic novel,

The Life and Times of Tristram Shandy, written in the mid 1700s, is a rambling mock autobiography packed with eccentric characters, elaborate wordplay and lots of typographical and diagrammatic interaction. In attempting to tell the story of his life, Shandy goes back in time trying to explain to his readers what has shaped him, frequently digressing from his tale according to whatever interesting subject appears to him. He does not even get to the part where he is born until volume three.

An experimental book, hardly neither linear in time nor chronological in structure, is now considered a postmodern tour de force, visually exploiting the resources of print so that the physical shape of the book is expressive to touch and sight concurrently. Chapters are misplaced only to reappear later, out of sequence and out of time. Fragments of learning and intellectual scholarship are peppered with doodles, blank pages and distinctive punctuation that is almost captured in the film 'Cock and Bull' (taken from Tristram Shandy's last sentence) a cinematic labyrinthine directed by Michael Winterbottom in 2005.

Digital thinking

As leading author and developer Dean Johnson ('https://twitter.com/activrightbrain' and author of *#1 Design iBook 'Digital Publishing: The Next Steps'*) has noted, designers, working across platforms, need to re-examine usability. Often rarely an issue for simple print formats with centuries of familiarity, usability now needs to be a major consideration. Today, digital skills – and, even more importantly, a digital mind–set, a willingness to engage

creatively with the new possibilities digital formats create – are a vital part of every publishing department, graphics design school or thinking about writing a collective Twitter novel as we are exploring in our workshops A project that can include writing techniques in collaboration of different mediums, such us interaction, animation and sound. . But, stop for a moment and just look at Twitter and its brisk 140-character declarative sentences.

Creativity and Innovation are supposed and proposed to be key drivers of the UK economy particularly when subsumed under the 'creative industries' label. Can new forms of technology contribute (alongside the old forms of technology) to the re-prioritisation of relations between writers and readers, designers and prosumers, publishers and technology developers, industrialists and inventors? Our twitter workshops and CREATe roundtables suggest that they can. The merging of text and technology (as in YourFry) is but one commercial example [10]. Stephen Fry and Penguin's *YourFry* project has been created to ask questions about the nature of how we create and publish autobiography in the digital environment. The web is responsive, interactive and chaotic – what if the conventional autobiography is thrown open to the web? What might the results look like, what form might they take?

So what do you do if you have a novel to write? Go to Twitter, and tweet about the work you're not doing, of course, Maybe record it, annotate it, use a picture to describe it further, print it record it again, post it and so on…

Aesthetic Experience by Proxy: Science Description and Science Fiction in New Art Practices

Lotte Philipsen

Aarhus Institute of Advanced Studies
Aarhus, Denmark
lottephilipsen@aias.au.dk

Abstract

The claim of the paper is that in many cases new artforms that make use of new, advanced science and technology, paradoxically, prompt aesthetic experience by means of simple text. The paper investigates the difference between the technical media of, for instance, works of bio-art, and the concrete material that the audience of such works encounter in the gallery. In relation to new artforms, the 'simple' paratextual descriptions of the works' technical media take on a significantly different role compared to the paratexts accompanying traditional artforms. While the paratexts' primary purpose is one of simply conveying information on the works' technical media (such as DNA-material, brain cells, digital software etc.), which are often hidden from the human sensory apparatus, in reality the paratexts simultaneously take on a second, but more important function: that of being the prime catalyst of aesthetic experience – thus substituting the work itself. The paper analyses the mechanisms of this new role of the paratexts accompanying scientifically advanced art and concludes that an important component is the conceptual character of allographic, informational paratexts. Curiously, this conceptual character is also a key feature of the advanced science at work in the new artforms.

Keywords

Aesthetic experience, paratext, bio-art, new media art, science, conceptual art, fiction, narration.

Introduction

How is aesthetic experience prompted by works of art that make use of advanced technology? What is it that makes such works aesthetically intriguing? One explanation that is often offered is that – compared to traditional art media – recently developed, advanced scientific procedures and technologies provide the works with new possibilities and dimensions, and as a result the new technologies themselves are at the focus of attention when critics and theorists analyse works said to belong to new genres like, for instance, bio-art, computer art, or nano-art. While fully acknowledging the importance of new technologies in works of art, this paper demonstrates a different approach: Instead of investigating technology and science in itself as the hotbed for the aesthetic potential of such works, the paper claims that what really acts as a catalyst for aesthetic experience in the audience encountering such works is good, old-fashioned text. Specifically, the texts that give rise to aesthetic experience are the paratexts that accompany and guide the reading of the 'real' texts. In this paper the texts are the works of art that make use of advanced science, and the paratexts investigated are wall labels, captions, or catalogue listings that describe the material of these works of art.

How this aesthetic experience arises is demonstrated by analysing the role of paratexts with the help of theory deriving from classic aesthetics (Immanuel Kant), literary theory (Gérard Genette), and art theory (Nelson Goodman, Dominic McIver Lopes, and Diarmuid Costello).

The two overall claims of this paper are: That simple, descriptive paratexts play a different role when they describe works of art that make use of advanced technology – these paratexts simply function differently than paratexts that describe more traditional artforms. And second: that, because of that different role, the paratexts in question actually take the place of the physical work of art as catalyst of the viewer's potential aesthetic experience.

The (new) role of paratextual description

In his book on paratexts from 1987 Gérard Genette made a thorough analysis of the diverse functions of paratexts. Working in the field of literary theory Genette's primary examples of 'texts' are novels, and the concrete paratexts he takes under consideration are: prefaces, covers, title pages, postscripts, critics' reviews, etc. The purpose of the book was to investigate paratextual messages according to their:

"[S]patial, temporal, substantial, pragmatic, and functional characteristics. More concretely: defining a paratextual element consists of determining its location (the question *where?*); the date of appearance, and if need be, its disappearance (*when?*); its mode of existence, verbal or other (*how?*); the characteristics of its situation of communication – its sender and addressee (*from whom? to whom?*); and the functions that its message aims to fulfil (*to do what?*)." (Genette 1997a, 4)

Illustration 1. David Hockney: *Mr and Mrs Clark and Percy*, 1970-1,The Tate Collection, London. ©David Hockney.

Out of the very elaborate system that Genette presents in his book, this paper focuses on the relationship between the two latter – the 'pragmatic' and the 'functional' – aspects of the paratextual messages.

At this stage it is of relevance to look at and compare three different paratexts that each describe the technical medium of different works of art. The term 'technical media' here refers to the way Lars Elleström uses the notion to describe 'the *actual* material medium, the "form", that realizes and manifests the latent properties of media, the "content"' – regardless of what that content might be (Elleström 2010, 17). The first paratextual example accompanies a work by David Hockney, *Mr and Mrs Clark and Percy* (illustration 1), and reads: "acrylic paint on canvas" (tate.org.uk). The technical medium of the second work, *Pancreas* (illustration 2), created by Thomas Feuerstein and Thomas Seppi, is communicated by this text: "glass, metal, plastic, technical equipment, brain cells, bacteria" (Wipplinger 2012, 224). Finally, the text that describes the technical medium of a work by Charlotte Jarvis, *Music of the Spheres,* (partly represented in illustration 3, next page) goes like this:

"1. Jarvis enlists British composer Mira Calix to write an original piece of music – she does this, inspired by the hum of the huge data storage machines in the server room at EMBL–EBI [European Molecular Biology Laboratory – European Bioinformatics Institute].
2. The music is recorded and encoded in a form that could be represented by the letters of DNA. That DNA was then synthesised and infused into liquid soap.
3. Calix's music is performed on stage by an orchestra. Bubbles of the DNA-infused soap will be blown about during the performance, filling the air with miniscule copies of the original composition.
4. As the bubbles float through the air, the musicians fall silent. The bubbles become the only physical manifestation of the music.

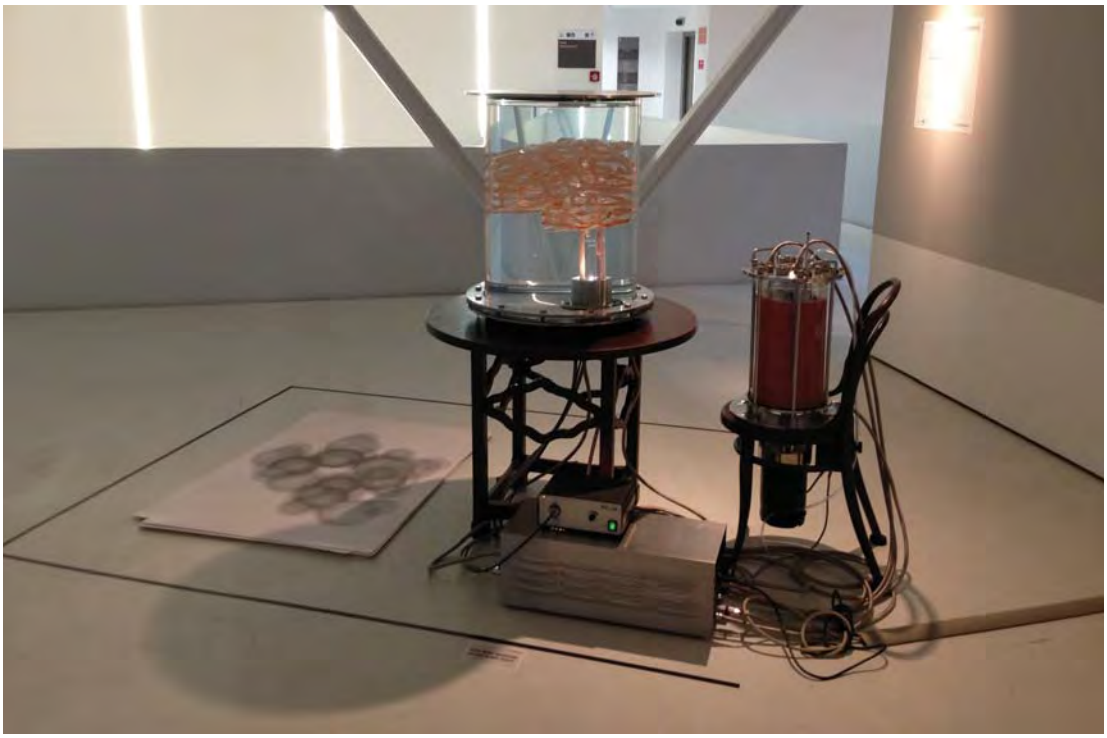

Illustration 2. Thomas Feuerstein and Thomas Seppi: *Pancreas*, 2012. Exhibition view: Ars Electronica 2013.

5. After the performance, the soap mixture is offered to audience members as they leave. Theoretically, they could have the soap sequenced, whereupon a digital file detailing the sequence of the DNA fragments would be sent to them.
6. Then, using instructions online and some smart computer programming, they can decode the fragments to recreate the music file." (Brownell 2014, 13)

The fact that the last paratext – even though it still only describes the technical media of a work of art – is considerably longer than the first two is understandable insofar as, in this case, the scientific procedures that make up the technical media are much more complicated and inaccessible to layman, and therefore in need of much more description.

The claim in the following, however, is that the paratexts above illustrate a tendency: Whereas traditionally there is a difference between what Genette terms informational and interpretative paratexts, these two types merge in the texts that accompany new works of art (like *Pancreas* and *Music of the Spheres*).

Informational and Interpretative Paratexts

Despite the different length of the three paratexts, and the fact that they describe the technical media of three very different works of art, they are of a similar pragmatic character insofar as they are all of the same type of, with Genette's term, illocutionary force. According to Genette, the illocutionary force, or the purpose, of paratexts may be that of communicating, for instance, 'sheer information', 'intention', 'interpretation', 'a decision', 'a command' of a work/text. (Genette, 1997a, p. 11). The illocutionary force of all three paratexts quoted above is that of conveying information on the technical medium of the works in question. In most traditional art forms, such information on the technical media is of little, if any, relevance to a hermeneutic interpretation of the work in the sense that to most viewers (experts or conservators excepted) it would not alter their aesthetic experience of *Mr and Mrs Clark and Percy*, if the textual information on the technical media read, for instance, 'oil paint on plywood' instead of 'acrylic paint on canvas'.

An example of a paratext that is not of informational but of interpretative illocutionary force could be this one, which invites us to consider the subject matter of David Hockney's painting in more detail:

Illustration 3 (right). Charlotte Jarvis and Nick Goldman: *Music of the Spheres*, 2013-. Photo: James Read

> "Close to her and therefore, perhaps, associated with her are the lilies, traditionally a symbol of the Annunciation and feminine purity. Likewise, the cat on Ozzie's lap carries symbolic resonances of the libertine and somebody who disregards rules and does as they please. Viewed in this way, *Mr and Mrs Clark and Percy* recalls the famous portrait of a married couple, *The Arnolfini Marriage* 1434 (National Gallery, London) by Flemish renaissance painter Jan van Eyck." (excerpt from longer text at tate.org.uk)

What this text offers is a different look at the scene depicted in the painting that transforms what we see from being merely an everyday interior with two figures to a symbolically loaded scene of tension in the relationship between two different characters – a scene that possesses numerous potential narratives on what is going on in the marriage, what happened earlier and what will happen in the future. Compared to the informational paratexts, "acrylic paint on canvas", it seems that interpretative paratexts like this one are much more hermeneutically relevant and carry a greater potential to directly affect viewers' aesthetic experience of the work. In other words: whereas the informational paratexts on the technical media reveal only what we can already see and/or expect, 'this is paint on a flat surface', the interpretive paratext above, to most viewers, reveals a surprisingly new (but not exhaustive) interpretation, which sparks our imagination and expands the scope of the work beyond its technical material.

As Genette himself points out, however, even if the illocutionary force of a paratext in theory is informational (like an unknown author's name) it may have an interpretive *function*. If, for instance, the name reveals the author's sex it "may have crucial thematic relevance". (Genette 1997a, 40). And it is exactly the *function* of the, in theory, purely descriptive and informational paratext accompanying new art forms that differs from its presumable function. Traditionally, as in the case of the two paratexts quoted that relate to the Hockney painting, concurrence exists between the implied illocutionary force and the function of each paratext: 'Acrylic paint on canvas' is meant to account for the technical medium and this is what it does – nothing more, nothing less – whereas the implied illocutionary force of the paratext that compares Hockney's painting with that of Jan van Eyck is one of hermeneutic interpretation and that is also its actual function. As we shall see in a moment, a similar neat distribution of roles between different types of paratexts is not at work in relation to *Music of the Spheres*.

The paratext describing *Pancreas*, however, holds a position between those of *Mr and Mrs Clark and Percy* and *Music of the Spheres*, insofar as the informational paratext comes in two versions in the catalogue in which the work is described: The short text ("glass, metal, plastic, technical equipment, brain cells, bacteria") is immediately followed by a longer text that elaborates on the items listed in the short one:

> "The processual sculpture PANCREAS transforms books into sugar (glucose) that feeds human brain cells. The books' paper is shredded, soaked in water, and pressed into an artificial intestine (fermenter), in which bacteria break the cellulose down into glucose. After filtering and purifying, the glucose is fed to the cells growing inside a glass tank (brain in a vat). The feeding of the artificial brain follows a strict diet: the brain food consists exclusively of Hegel's 'Phenomenology of Spirit'. PANCREAS is a pataphysical machine that uses biotechnologies in order to translate language and books, that is symbols and data, into matter and flesh. Glucose, as a universal fuel of life, which all cells, especially brain cells, feed from, becomes the artistic material for PANCREAS (Gr. pánkreas, pán = "all", kréas = "flesh")." (Wipplinger 2012, 224)

The short text briefly hints at the fact that 'invisible' material ("brain cells, bacteria") plays an artistic role. By elaborating on the technical medium briefly listed in the short text, the longer text reveals information on the technical medium that bears significant relevance to the aesthetic potential of the work, and which we will never be able to learn by use of the human sensory apparatus – no matter how much time we spend looking, smelling, listing to, touching or tasting the technical media – and which, most importantly, surprises us: The paratext mentions Hegel's philosophical masterpiece, *The Phenomenology of Spirit*, which argues for a teleological, historical move towards the conscious self-realization of the absolute spirit transcending material matter. Learning, from the paratext, that Hegel's work is used as simple, material fodder for brain cells (and thus fulfils a kind of homecoming that Hegel himself most likely did not anticipate) potentially prompts intriguing, yet undetermined and disinterested, activity – aesthetic experience – in the mind of the viewer/reader.

Thus, a difference is at work in the long *Pancreas* text between its illocutionary force (of conveying information of the work's technical media) and its function (of potentially prompting aesthetic experience, because the information conveyed about the technical media is so unexpected and surprising). The long informational paratext, which reveals the details of *Pancreas'* technical media, does not have the same illocutionary force as the interpretative paratext accompanying *Mr and Mrs Clark and Percy* even though it, in reality, may have an interpretative function. Instead, *Pancreas'* paratexts equivalent to the Hockney painting's interpretative paratext are the catalogue texts, written by different scholars and curators, that elaborate, for instance, on the meaning of recurring motifs in Thomas Feuerstein's oeuvre. Despite its length, the long informational paratext is 'only' a descriptive caption and not a reading of *Pancreas*.

In the case of *Music of the Spheres*, the merging between descriptive and interpretative paratexts goes even further, insofar as very little is (yet) written on the more traditional symbolic dimensions of the work (for instance references in the work's title to Pythagoras or other com-

positions bearing the same title). Instead, the technical dimensions of the work are often thoroughly explained while, to my knowledge, there is no official equivalent to the short texts of purely informational function, which accompany the other two works (see Higgins 2013, Brownell 2014).

Just like the aesthetic potential of the interpretive paratext related to the Hockney painting arose from the suggestion of elements that reaches beyond the scope of what is strictly visibly in the painting, the description of *Music of the Spheres* tells us that there is much more to the work, than what we (can possibly) see. Now, we are used to interpretative readings of works – whether they stem from art critics or children – and in that sense the possibility of adding new interpretations of a work of art never comes to an end. What is different in the case of *Music of the Spheres* is the fact that the paratext does not add a new *symbolic* reading to the work; instead it alters the character of the *physical material* in front of us in a very surprising manner. By means only of simple informational paratext, a container of childish soap bubbles is magically transformed into a DNA-material that contains a MP3-code with a piece of music. A fictive equivalent would be if the informational paratext describing the technical media of *Mr and Mrs Clark and Percy* did not read 'acrylic paint on canvas' but instead: 'all red colours in the painting consist of blood from a dead cat.'

Hence the first claim of this paper: The paratexts related to contemporary art that makes use of advanced science often take on a different, additional role in which seemingly simple descriptions in reality function as radical revelation in the minds of the audience. To some extent art has always incorporated science and new technology – from mathematical calculations of the linear perspective in a renaissance painting to Nam June Paik's experiments with magnetic manipulation of electronic TV-signals to music in DNA or brain cells in an installation – and since all these works of art presumably have informational paratexts describing their technical medium, neither the paratexts or the role they play are really new. But they play a different role from the presumed, simple, descriptive one. What I hope to have demonstrated is that such paratexts' also play a paramount role in the aesthetic experience of the works. The remaining part of the paper analyses a peculiar implication of this fact: that the paratexts in question take the place traditionally occupied by the 'text' (the physical work of art), and become the actual catalysts of potential aesthetic experience in the viewer.

From Science Description to Science Fiction

As demonstrated above the paratext describing the technical medium of *Music of the Spheres* holds a greater aesthetic potential than the physical work that we can approach by use of our sensorium. One significant reason for this is that *Music of the Spheres* does not exist as one physically coherent work – and not just because many of the elements are so small or abstract that we humans cannot sense them; after all, even DNA very much exists. More importantly, the elaborate technical and scientific mechanisms of the work (made known to us only through the informational paratext) are combined in ways that are new, not only to the artworld but also to the field of science (see Goldman et al. 2013), not to speak of the perspective of the layman. It is for this reason that, throughout this paper, I have made use of the unidiomatic notion 'works of art that make use of science and new technology', and refrained from using terms like 'digital art', 'bio-art', or 'new media art'.

Admittedly, it would be easier to refer to a work like *Pancreas* as, for instance, 'bio-art' in order to quickly give a rough hint to readers or potential viewers about what to expect when experiencing the work (see Lopes on appreciation in art and aesthetics (2010, chapter 4; 2014, chapter 9)). However, as the description above indicates, *Pancreas* could also be considered 'sculpture' (Feuerstein's own words), 'performance' (due to the processing of paper and the 'live-ness' of the brain cells), 'installation' (as suggested by the way it is exhibited in the gallery), 'scientific experiment' (what kind of paper is best suited?), 'critical reading/reverse engineering of Hegel', just to mention some of the more or less established categories that would fit such a work. None of these different labels fully capture all aspects of *Pancreas*, but they each suggest different ways of categorizing and hence interpreting the work, at the same time as they preclude the others.

Similarly, it would seem reductive to label *Music of the Spheres* according to a specific artform label. It can be considered 'music' (composition/performance), 'bio-art' (DNA-encoded material), 'software-art' (the music is embedded in the DNA in MP3-format), 'multiples' (the audience each gets a soap bubble container), 'scientific experiment' (new method in molecular biology is applied to the field of art), etc. None of the suggested categories, however, would be able to grasp the trans-categorial character of the work, just like none of the physical dimensions or stages of the work could represent all the work's technical media.

The soap bubble device depicted in illustration 3 represents only the visual dimension of a fragment of the technical media accounted for in the informational paratext. The photo is taken from Charlotte Jarvis' website's description of *Music of the Spheres*, which also contains photos that depict the server room at EMBL and people with protective rubber gloves who handle pipettes and fluids ('Art for eating' website). No single photo represents the work better than the others. Even if we were present at the live concert, mentioned in point 3-4 of the paratext, would we have a clue about the work, had we not read the informational paratext. Instead of *a* physical entity or object, *Music of the Spheres* is an abstract idea consisting of numerous different concrete, physical objects and actions that cannot be physically combined in the same space. In fact, the only thing that provides the audience/viewers with a

sense of the work's form (that is, its spatial and temporal extensions and limits) is the informational paratext.

Allographic, conceptual reduction

A significant feature of the informational paratext is that it is, what Nelson Goodman terms 'allographic' which means that it cannot be forged because it consists in a 'numeric' score. Literature is an allographic art because, in the case of, for instance, Thomas Grey's poem *Elegy* "any sequence – even a forgery of the author's manuscript or of a given edition – that corresponds to a correct copy is itself correct, and nothing is more the original work than is such a correct copy." (Goodman 1976, 115-116). *Elegy* is *Elegy* regardless of whether it is printed in a hardback or handwritten on paper napkins, as long as the words and syntax are combined so that they spell Grey's *Elegy*.

In the case of the informational paratexts accompanying works of art that make use of advanced science and technology, the allographic character, contrary to the one of a poem or a novel, consists not in correct spelling or grammar, or even in the use of a certain syntax or language. What must be conveyed very precisely is not letters or words but the *essential content* of what makes up the technical media of a work. The aesthetic potential arises from the so-called 'raw' information (on the technical media) that the paratext reveals. The exact manner in which this raw information is delivered is not crucial as long as the essential message is received. Hence, a traditional equivalent to the informational paratext would be the oral narrative, which relates to the (unwritten) tale in the same way as the paratext relates to the inaccessible work of art. Or, to be more precise, the written informational paratext functions as a physical manifestation of the work, which in itself is what Genette refers to as "an ideal object of immanence" (Genette 1997b).

In his elaboration on Goodman, Genette states that:

> "The allographic work […] exhibits the paradox (and practical inconvenience) of being entirely itself only in the ideal object it immanates in; but this object, because it is ideal, is physically imperceptible, so that there exists, even for the mind, nothing more than a vanishing point that can be defined but not observed." (Genette 1997b, 125)

The fact that some of the most important material dimensions of a work like *Music of the Spheres* are inaccessible to human perception poses some interesting questions to our understanding of the mechanisms of aesthetic experience. Immanuel Kant's distinction between cognitive faculties and sensory experience seems to be challenged here, since, traditionally, sensory experience is considered to be a necessary foundation for aesthetic experience in art. However, the reading of Kant's aesthetic judgement as governed by perceptual or formalist dimensions in a narrow 'Greenbergian' sense has been convincingly contested by professor of philosophy Diarmuid Costello, who suggests that

> "the default understanding of Kant's formalism should be the 'expansive' formalism that Kant operates with throughout the *Critique*. […] it is the unified organization of aesthetic attributes required to present an idea that constitutes the work's form" (Costello 2013, 294).

Costello specifically investigates how Kantian theory allows aesthetic judgement to arise on the basis of conceptual art in the strong sense – that is works of art that belong to the institutionalised domain of visual art but which have no perceptual features at all. His core example is Robert Berry's work *All the things I know of but of which I am not at the moment thinking: 1.36pm; June 15, 1969*, which consists 'only' in the title that is perceptually allographic in the sense that it does not matter which font, size or colour is used when writing the title. The reason that such works are still able to evoke aesthetic judgement in the subject is that they refer to an idea rather than to a concept, and hence they are judged freely. With reference to Kant, Costello argues that the aesthetic idea in the work of conceptual art does not depend on perceptible features, in the same manner as the aesthetic idea of a literary work does not rely on perceptible features like words or syntax which is proved by the fact that the aesthetic idea of the literary work remains unchanged even if the work is judged by reading it in a translation to a different language (Costello 2013, 296).

Does this mean that *Music of the Spheres* is to be considered a conceptual work of art? One thing that could, wrongly, lead to such a conclusion is that Genette – with reference to Husserl's phenomenology – accounts for the mechanism of conceptual reduction as a characteristic of allographic works of art (Genette 1997a). Transferred to the context of this paper: If we have ten different informational paratexts describing the technical media of a work – some handwritten, some narrated orally, some in German, some using a higher readability index than others – the reduction consists in studying the different versions (of which none can ever be 'complete') so as to subtract all insignificant features, to condensate the paratexts, in order to value only their essential elements. This allographic reduction strips the work to its conceptual core, and this is actually the function of the informational paratexts accompanying *Music of the Spheres*.

The paratexts related to *Music of the Spheres*, however, despite being just as allographic as *All the things I know of but of which I am not at the moment thinking: 1.36pm; June 15, 1969*, are not meant to evoke the work's aesthetic idea – 'only' its technical media. In principle the informational paratexts under scrutiny in this paper serve merely as a communicative service that conveys practical information on the advanced technical media of work; they are meant to evoke judgement of the work's aesthetic idea no

more that 'acrylic on canvas' is meant to when applied to a Hockney-painting. Similarities have been suggested between conceptual art and technologically advanced art, for instance due to the fact that both "interrogate the conventional materiality and semiotic complexity of art objects" (Shanken 2002, 438), but the focus of this paper has been on the effect of the informational paratexts, and not the works of art – conceptual or not – in themselves. And this investigation has shown that the actual *function* of these paratexts is potentially highly aesthetic. In effect these paratexts – which, due to their informational character, tend to fly below the radar of new media art scholars – play a performative role that is similar to the role played by conceptual art paratexts that constitute the aesthetic idea of a work.

The traditional roles of text and paratext are potentially reversed: A consequence of the aesthetic function of the informational paratexts is that the physical objects that we encounter in the gallery – the objects that we think of as the work of art itself – are not necessarily the primary source of aesthetic experience. Instead the work – which we traditionally presume to be the text in Genette's sense – in effect functions like the supplement, the paratexts, while the informational wall label or the trivial caption, functions as the very text. The physical objects and acts in the exhibition space serve as mere exchangeable props that do not in themselves act as catalysts for aesthetic valuation of the overall work, but strongly depend on informational paratexts to reveal to the audience what the work consists of. The work of art – even if it is a huge installation like, for instance, Wim Delvoye's *Cloaca* (2000-2010) – is invisible without the descriptive paratexts. We are thus dealing with aesthetic experience by proxy. This may sound rather depressing, but the aesthetic experience of conceptual works of art may be every bit as rewarding as that which is prompted by an autographic, sensuously accessible work of art.

An even more ultimate, and theoretical, consequence is that the work's advanced technical media, pointed to by the paratext, does not even need to exist in order to generate aesthetic experience. Instead of highly advanced soap bubbles with DNA-code/MP3-file there need only be ordinary soap bubbles. If the informational paratexts are able to convincingly persuade the audience that the phenomenon in front of them is soap bubbles containing MP3-files encoded in synthetic DNA-material, then the aesthetic implications are the same whether this is actually true or not. Even if the paratext was science fiction instead of science description, it would possess the performative power of evoking aesthetic experience – as long as the audience reads it as a simple, valid description of a highly advanced and intriguing work of art.

Comparing Two Sound Design Styles: Between Determinism Emergence And Interactivity

Abstract

In the design process of sound installations, the composer designs his sound for a real or a virtual space according to the listener's walking path. One way to design this walk is to allow the listener to interact with the system via Non-Player Characters[1]. For a given piece, the creator affords the interactor a certain amount of freedom; and the system, according to its level of self-sufficiency, a certain amount of autonomy. We assume that these choices are directly related to design styles: the "scripting style" and the "emergent style". In the scripting style, the designer takes the point of view of the interactor, who becomes the narrator. In the emergent style, the designer takes the point of view of Non-Player Characters. We have designed two versions, composed in each style, of the same interactive sound installation *The Listening Walker*. This paper is mainly devoted to a comparative analysis of the sound design styles experienced, and to the presentation of the two artistic and development experiences.

Keywords

Emergence, Interactivity, Narration, Sound Installations, Video Games

Introduction

One of the authors of this paper has worked as a composer on numerous sound walk art installations [1]. During the last decade, her work has been influenced by the design methods used in video games, leading to interactive pieces. In the design process of such pieces, as compared with interactive music works, the composer conceives his spatial sound design in a real or a virtual space according to the listener's walk path. Such an installation shows the evolution of the composer's role from a deterministic creation to a non-deterministic one [8]. For a given piece, the composer affords the interactor a certain amount of freedom; and to the system, according to its level, a certain amount of autonomy. According to these two parameters each art piece can be positioned somewhere within the DIS triangle (Figure 1), the vertices of which represent the Designer, the Interactor and the System. In [2] and [3] a set of interactive pieces are analyzed in order to place these works within the DIS triangle.

[1]A Non Player Character (NPC) in a video game is a character controlled by the game as opposed to the avatar controlled by the player.

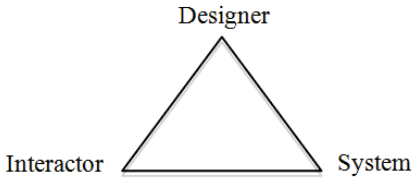

Figure 1: The DIS triangle

In this triangle, the designer has a very particular role: he is the decider. He may choose to create a piece for which execution is perfectly controlled, near the D position. He can decide to design his composition as a generative and emergent art system, near the S position. He can also afford the Interactor a high degree of freedom - collaboration in the execution of the piece. Of course, any mixture of these three positions can be considered and has been experienced by artist and designers.

Our research attempts to investigate conceptual and practical tools that allow the sound designer to understand and choose his position within the DIS triangle. We assume that this choice can be directly related to a choice of designing style. We designed two versions of the same interactive sound installation *The Listening Walker*. First, we present the concept of the sound installation *The Listening Walker* and the two design styles. Next, we present a set of criteria with which to compare the two styles. Finally, we explain our experimentation and development process. To conclude, we pose questions relative to the artistic consequences flowing from these two design styles and present our future work.

The Listening Walker

The Listening Walker is an artwork produced as part of the Terra Dynamica project, funded by the French government. The purpose of this project was to bring to life Terra Numerica, a static virtual city [4]. The production of an artwork, the scripted version of *The Listening Walker*, using the Terra Dynamica technology, was one of the tasks assigned to the CNAM. The title of this piece comes from a book by Michel Chion [5]. The installation was created in Paris during the "Futur en Seine" festival in June 2013.

The goal of this sound walk is to discover a virtual district of Paris around the Pantheon. The interactor walks around this part of the city wearing headphones with personal binaural sound rendering. The experiment takes about ten minutes. This installation is designed as a video game with different levels of exploration. The interactor's reward is the discovery of the city mainly via sound. Success depends on his listening behavior: NPCs surroud him, interpreting his moves, the direction he takes and the time spend listening to particular sounds. Depending on the listener's attitude, each NPC has his own reaction, such as running away, getting closer to the listener, ignoring him or helping him to discover secret areas. The listening walker must be aware and must try to understand these NPCs.

The Two Design Styles

The Scripting Style

An interactive narration is written according to the scripting style if it takes the interactor's point of view. He is the narrator of an interactive scenario, written in a procedural form. The rules are contextual and related to a relative chronological order determined by the path the interactor follows. So any variability inside the narration is linked to the interactor's previous experience, and in particular, his trajectory. Each NPC's behavior is described in relation to this experience at a given point and time of the interactor's path.

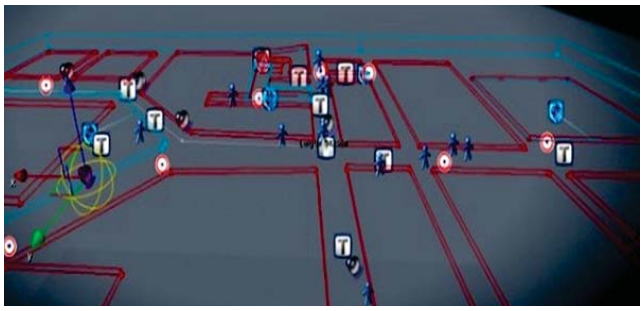

Figure 2: City 4 map in the CryEngine editor

As an example, consider the City 4 version of *The Listening Walker*. City 4 is a constrained itinerary in which the interactor, hearing a sound, starts from an empty space and gradually builds the city. Invisible barriers are set up in the space as interaction spots. These set off events when the interactor enters their influence area. A trigger can set off a sound, create a new road or a new building. The triggers are also logically ordered. Some of them can only be activated if the interactor has come across previous ones. This logical scripting ensures that the events occur in a non-anarchic way as well as ensuring the consistency of the itinerary.

The Emergent Style

An interactive narration written according to the emergent style takes the point of view of each NPC as a potential narrator. It has its own perception and memory, which influences its behavior, described in a generic (non-contextual) way.

As the player appears at the intersection of rue Saint-Jacques and rue Soufflot,
A sound hidden in rue Saint-Jacques 2 is activated;
When the player arrives over there,
A part of the urban outline of a district becomes visible;
(see FlowGraph /entities/FloorAppear :FloorSoufflotPantheon).
The sound of rue Saint-Jacques 2 deactivated
and a bass tone comes up rue d'Ulm;
An NPC – Le Chevalier – appears visually, read a text and heads towards the back of the Pantheon following a given path;
If the player follows him, he triggers a sound moving around him;
If the player stays longer enough listening the moving sound, two more sound entities are triggered;
If the player tries to catch them at the intersection of rue Clotaire and place du Pantheon, they vanish;
NPC Bakal appears place du Pantheon, talking to himself.

Figure 3: Example of City 4 map scripting

For example, City 5 is an open itinerary. The interactor travels on the map from one area to another. Each area is controlled by an NPC. Its main goal is to follow and memorize the movements of all characters (avatar of the player and NPCs) that are or have been located in the controlled area. So a trigger, like an invisible barrier, is no longer a mechanism associated with the interactor's avatar, as in the scripting style, but part of an NPC's perception system. Global geographical zones, like districts, become themselves interaction controllers. This is also mostly the case when each NPC perceives the interactor in its own area. This determines the elements of the city (sounds, lights, outlines, buildings) that the NPCs will reveal at a given time and a given point of the listener's experience.

Bakal's control a zone situated between rue Soufflot, rue Le Goff and rue Saint-Jacques 1. His main personality is to be fearful.
Bakal's behaviour :
Each time someone enters my zone,
I activate a given set of sounds and lights
I identify the intruder.
I increase the visit count of the given intruder.
If an intruder is present in my zone and if it is a player and if it is his first visit,
I speak to the player.
If an intruder is present in my zone and if it is a player and if it is his second visit,
I appear, silent, in front of and at a given distance from the player.
If the player comes too close of me, I run away.

Figure 4: Informal specification of Bakal, a fearful NPC.

A First Comparison of the Two Styles

A Game Design Point of View

In the context of creating an interactive walk installation like *The Listening Walker*, an object-based methodology inspired by Game Design is certainly applicable and, from our point of view, efficient.

The scripting style of design has been, until recent years, the main one used in the game industry. Such an approach has some clear advantages. On the one hand, it is a subjective narrator-driven interactive storytelling style, which is rather easy to understand. Its validation, which uses program tests, is "classical". On the other hand, this method relies on describing a universe as a kind of egocentric, centralized simulation. As a consequence, describing autonomous NPC behavior is difficult, or even impossible. The development of evolving games (Massively Multi-player Online Role-Playing Games, Facebook games, games based on physics...) pushes the emergent design style.

According to Jesper Juul's classification of games [9], the scripting style leads to "games of progression", that is to say games in which rules are contextual. The emergent style leads to "games of emergence", in which rules are relevant in all situations. From the designer's and hence the composer's point of view, the scripting style of design leads naturally to a branched approach of interactive narration and, therefore, to "progression-style" game types rather than to "sandbox-style" ones[2].

The Narrator and the Memory

The scripted design writes the story from the point of view of the interactor's avatar. This is the method; the universe and the events exist only when they have been or are perceived by the interactor. In this way he is the narrator and he holds in his memory the events involved in his narration. In the emergent approach, each NPC has its own memories thanks to its own perception system. For example, Bakal has the memory of each intruder in his zone. The story is described with respect to what has been perceived and remembered by each actor (avatar and NPCs). In both cases, it is possible, from a narrative point of view, to simulate a universal narrator who has knowledge of events that no or not all actors have seen or heard.

Finding a Place in the D.I.S Triangle

Returning to the introduction of this paper, the main open question is: how much freedom and knowledge is the listener afforded?

From the point of view of an electroacoustic composer working on spatial sound installations, most of our work was created for a given indoor or outdoor area using a set of speakers adapted to the chosen space. In such artworks, the sound and the spatial sound rendering are synchronously controlled. Each piece has a beginning and an end, and a given duration. The freedom of the listener consists of being able to walk, wait, sit or lie down somewhere within the performance space. A previous work on interactive soundscapes, *Listen Lisboa*, produced at IRCAM [6], used the same approach. The listener is walking through a physical empty space hearing sounds through geo-localized headphones. According to his trajectory, the listener is able to hear different versions of the same soundscape, without having real control over it. As a consequence the writing of *Listen Lisboa* relies on the scripting style.

In this current research, the composer is moving towards more open works. The goal is to give the interactor a more potentially accessible and comprehensive interpretation of the piece, which is constructed as an emergent composition through the use of intelligent agents.

Using the scripting style leads to design a piece in a constrained space (a progression in a corridor). The designer may open the map, giving the interactor more choices, with an understanding of the consequences of his decisions. The piece will be designed as a walk in an open space and a local and implicit description of the NPC's behavior, using the emergent style.

In this way, a controlled composition of the two styles and the structure of the map are a way to design and implement a piece at a defined position in the DIS triangle.

The Two Versions of the Listening Walker

Aspects of the development process of the scripted version

This development is part of the OCTAVIA[3] project. The scripted version was designed using a method strongly inspired by the level design of adventure games, as well as the maze principle [7]. The interactor's avatar appears at a given initial point of an empty map. Invisible barriers and their associated triggers are placed according to the possible paths of the interactor's avatar. The paths and the triggers are partially ordered to create sound events and the revealing of roads and buildings. Triggers are also used to guide the interactor: they lead to sound events located within the space. NPCs, according to scripted behavior, try to seduce or intrigue the interactor. As the city is progressively revealed, the path of the avatar becomes more and more constrained by the walls of the buildings. The story ends when the last trigger is activated, revealing the Pantheon. The mapping between triggers, events and NPCs behavior is written using Flowgraph, the graphical programming language of a game engine (CryEngine[4]).

Aspects of the development of the emergent version

The main principle here is that any action is decided and executed by a Non-Player Character using its own perceptions, decisions and actions. Its behavior relies only on the events that it has been able to observe and memorize. The empathic relationship between the player and the NPC are the same on both versions. However, the corresponding actions and rules are non-contextual. For example, a rule for Bakal, in the scripted version is written as follows:

"When I (the interactor's avatar) arrive at the crossroad, Bakal appears.

If I move too close to him, Bakal runs away".

[2] "A sandbox is a style of game in which minimal character limitations are placed on the gamer, allowing the gamer to roam and change a virtual world at will. In contrast to a progression-style game, a sandbox game emphasizes roaming and allows a gamer to select tasks." http://www.techopedia.com

[3] Tool for Creating and Testing Atmosphere Life Interactive and Autonomous. http://www.masagroup.net/products/innovation

[4] http://www.crytek.com/cryengine

In the emergent version, the behavior of Bakal is described as a finite state machine, and the same rule becomes:

"Each time I (Bakal) perceive somebody near me,
I identify him
If it is the first time I see him and he comes too close to me,
I run away"

Therefore Bakal is defined by:

- His perception: Bakal can see in front of him (180 degrees), hear all around him without any distance limit, and receive messages from all other NPCs.
- His possible actions: Bakal can walk, run, speak a set of given sentences, sing a set of music, can be visible or invisible, and send messages to all other NPCs.

To summarize, the design process follows these steps:

- Structure the map into districts.
- Choose the set of NPCs.
- For each NPC define his perception, decision-making and action system.
- Specify all messages exchanged by NPCs.
- Define the NPCs' finite state machines.

Conclusion and Future Work

Comparing the two styles

The use of video games tools is probably a good choice as they are designed to support both styles. But, in both cases, the translation of an informal specification into a formal one is a complex task.

From an artistic point of view, the possibilities opened up by the emergent style are very promising. But this way of thinking about an artwork as a set of localized and dynamic pieces is a break with the habits of music composers. The scripted style is a much more comfortable way to think and develop an interactive sound walk. To summarize, based on the results of our experiment, it is easier to write a story, even an interactive one, than to design an open world. The artist gives up control of space, time, and progression in a story and then takes as a designer a new position. So the most interesting artistic challenge is to design an evolving process, an open combination, rather than a final, fixed object.

Our comparative analysis takes the point of view of the designer, and, more specifically, that of one of the authors of this paper. As a consequence, it cannot be directly generalized. With the help of the sociology department, we arranged interviews with seven well-known artists and designers from various fields. Eric Viennot, the Game Designer of *In Memoriam*, one of the first Alternate Reality Games, summarizes the result of our study:

"At a given time, as a designer, we are creating a universe where some emerging part of the story may appear. It is something that we did not really forecast. It is really interesting and I call it emergent narration...

I like to master the time when the player feels a given emotion. I think that we must find in some way a mixed solution: too open works lack artistic dimension."

Future Work

The comparison of the two versions of *The Listening Walker* takes only the point of view of the composer. Up until now, only the scripted version has been exhibited. As the two versions are developed, it is possible, by conducting a public survey, to have the point of view of the interactor. Of course the scope of the results is limited to this piece but it is probably a unique experiment as the same piece is rarely developed twice.

We are working on sound walks in a real city, using an augmented reality 3D sound system. As a consequence, we will try to specify and prototype efficient authoring tools.

Printed Radicality

Alessandro Ludovico

Academy of Fine Arts, Carrara
Carrara, Italy
a.ludovico@neural.it

Abstract

The static and unchangeable printed page seems to be hardly considered in years 2010s as a key tool for political and radical strategies, as human beings are constantly looking at a few personal screen-based devices, most of them updated in real time. But there are a few cultural elements in traditional media, which are still playing a decisive role in the circulation of culture. Among them the recognition of their aesthetic "forms," even if digitised in both design and content. The familiarity with those forms is based on metabolised "interfaces" (we're all culturally "natives" when it comes to radio, TV, and print) that makes them almost invisible, especially when translated for the digital realm, delivering the content in a more direct way. And since we recognise those forms instinctively, we "trust" them, and so we trust their content.

Keywords

print, publishing, fake, library, digitalisation, plagiarism, wikipedia

Newspaper as (fake) political imaginary

The form of the newspaper is still one of the most recognisable. What we can consider as the modern form of newspapers has only slightly changed since the 19th Century (except for the inclusion of pictures and colours), becoming a daily medium for quite a few generations, establishing itself as an aesthetic standard and a defined cultural object with its specific interface. That's why artists and activists have often used newspapers as an identifiable information environment and a daily object at the same time. From Andy Warhol's "Headlines" series [1], with huge reproductions of particularly dramatic front pages as frozen in time, to "Modern History" series by Sarah Charlesworth [2], tracking the use of the same picture on different front pages. But a specific conceptual manipulation of newspapers (and the conventional ecosystem surrounding them) has been employed by artists and activists to foster specific ideas. The "fake" newspaper, or accurately reproducing a real newspaper arbitrarily changing its content, has always been able to question the instinctive trust we have in this medium. If making fake copies and freely distributing them in order to attract public's attention (but then revealing as mere advertising flyers) is a remarkably old practice, dating back to the end of 19th century [3], the conscious use of those fakes as a political medium is more recent. In this respect, there are a few effective examples emerging especially in the 1970s. "Il Male" [4], for example, stemmed during the rise of leftist political movements in Italy, and especially the "Creative Autonomism" student movement in 1977. It conducted a few campaigns through fake journalistic "scoops" (all being simultaneously plausible and surrealistic) rendered in major Italian newspapers layouts and attached next to newsstands, generating sometimes quite harsh reactions and a lot of discussions in the streets. In the same years another two actions (officially anonymous) were accomplished. In 1979 in Poland, a fake of the major propaganda newspaper Trybuna Ludu was distributed during Pope John Paul II (Karol Wojtyla)'s visit to his homeland, sporting the banner headline "Government Resigns, Wojtyla Crowned King."[5] And in France, in 1977, a fake Le Monde Diplomatique was anonymously distributed to a certain number of subscribers, featuring very satirical comments on the Rote Armee Fraktion's Stammheim Prison bloodbath [6]. Thirty years later an impressive fake newspaper distributed in several thousand copies invaded the streets in New York City, on November 12, 2008: "The New York Times special edition" by The Yes Men in collaboration with Steve Lambert and The Anti-Advertising Agency, and anonymously sponsored. [7] It was set in the near future (July 4, 2009), featuring only positive news, briefly plausible after Barack Obama's election as U.S. President. The New York Times layout, fonts and graphic design were painstakingly reproduced (including the usual advertisements, satirically changed as well), so the majority of the public was easily fooled. A large network of volunteers distributed it for free in the city, even in front of the New York Times headquarters, without any legal repercussion. What was embodied here was the public imaginary, the articulated hope this historical event generated, historicised then altogether in a stable and recognisable format, without the daily compromises of major media. The group produced another few fakes, one of them in the form of the International Herald Tribune. Italian artist Paolo Cirio, instead, made a project composed by a web application, a workshop and an action in 2011, called in Veritas, It is centred on Italian newspapers, inviting people to invent their own story that can be composed as a headline sheet with the newspaper logo of choice, through the project's website. Then it's fairly easy to print it out and attach it (during the night) close to local

newsstands. [8] The use of fake newspapers in political campaigns has proven not to be a thing of the past. The classic strategy of purchasing a full front page ad, designed to look just like the real front page has been used many times. The Liberal Party in British Columbia did it in 2013, disguising the ad as "official" information, and so generating a whole national media case with polarised reactions about the Party ethics and the high risk of misleading the readers. [8] Even more, in 2011 there was a more direct political newspaper scam, when police identified a network of infringers who had been illegally producing and distributing fake copies of Ziarul de Garda and Timpul, two of Moldova's leading newspapers, trying to manipulate the public opinion ahead of elections by publishing negative articles about the pro-Western ruling coalition. [9]

Plagiarism (from print to digital and vice-versa)

Newspaper fakes incorporate some forms of "plagiarism", mostly related to misusing a "standardised" visual form. This has been technically feasible since the mechanical reproduction of print, and even more with the lightning-fast speed and accuracy of digital (re)production. But the plagiarism of content is much older, and the very concept of plagiarism dates back to the Roman Empire. It was used for the first time by Roman poet Martial, complaining that another poet was "kidnapping" his verses, so he called him "plagiarius", which literally means "kidnapper." These were the verses he used to express his feelings:

Fama refert nostros te, Fidentine, libellos
non aliter populo quam recitare tuos.
si mea vis dici, gratis tibi carmina mittam:
si dici tua vis, hoc eme, ne mea sint.

(Fame has it that you, Fidentinus,
recite my books to the crowd as if none other than your own.
If you're willing that they be called mine, I'll send you the poems for free.
If you want them to be called yours, buy this one, so that they won't be mine.) [11]

There are plenty of more or less famous cases of literary plagiarism in history, but only some of them were publicly admitted (like the script of the TV series Roots, admittedly plagiarised by his author in some passages from the novel "The African," published nine years before). In contemporaneity, plagiarism seems easier than ever, especially taking advantage from "big data" sophisticated sources like Wikipedia, and so a few critical artworks have been developed consequently. Belgian artist Stéphanie Vilayphiou investigates how free software can deeply question the fixity of the printed page once it's digitised, and how the defensive copyright practices, historically consolidated can be challenged. In particular she writes various transformative software to create controversial versions of literature classics. Specifically, in her net art piece "La carte ou le territoire (The map or the territory)" [12] she selected a controversial book, Michel Houellebecq's "The map and the territory", which became renown and discussed in France for its evident quotes from Wikipedia, never acknowledged by the author nor by the publisher. She retrieved the book's digitised text and then wrote a software filter which parses it in sentences (or part of it) looking for them in the millions of digitised texts contained in Google Books, eventually finding the same sequence of words in any other books. The results are rendered then in their original typefaces, and the parts matching Houellebecq's book are highlighted in yellow. Visually the book is entirely transformed in a sequential digital collage of quotations (whose original authoritative printed context is still maintained in the background), definitively loosing even the last bit of originality. Vilayphiou ultimately questions originality and authorship through software automatisms, turning them into trackable

and technically demonstrable collective thinking. Another example of artistic practice deliberately using other people's writings in a specific context is Traumawien's "Ghostwriter" [13] series. The Viennese group performed a virtual "action" with their own software robots compiling and uploading hundreds of e-books on Amazon.com with text directly stolen from YouTube videos' comments, as if they were abstract dialogues. They have defined it an "auto-cannibalistic" model, and these e-books sport a very classic paperback layout as spontaneous instant books, redirecting the endless flow of comments in a specific form and freezing them in time. This action is obviously re-contextualising the original meanings, setting them in a new scenario and in a new literary form: from personal notes not necessarily relating each other, into a single continuous and sometimes surreal dialogue. What happens in the passage from one medium to another, is that the original spontaneousness and sometimes naïveté of the text once rendered as a book assumes the formal character of the adopted layout. The paradigm of access to "big data" is embedded in practices like the above mentioned, and the software programmer's vision is the only limit to what kind of results and new (digital and printed) forms can consequently be created.

Printing as a risky strategy

In the end of years 2000s there has been a few famous and dramatic cases of sensitive information leaks: Wikileaks and its small galaxy of information-wants-to-be-free "heroes" (Julian Assange, Bradley Manning, Edward Snowden) publishing secret or classified information from anonymous sources, and Aaron Swartz and his brave act of freeing the copyrighted academic knowledge of JSTOR [14] (Swartz committed suicide in 2013). The leaks' transmission and acquisition has been totally digital, but then traditional media has been deeply involved to make this information "public" (and implicitly to somehow certify the scale of the action with their innate "authority",) including printed ones, mainly newspapers. At a smaller scale, there are other cases using print as a tool for liberating secret information. Carl Malamud, for example, an activist dealing with the fact that vital parts of US law are secret and that you're allowed to read them only paying a quite high amount of money, has founded Public.Resource.Org [15] organisation, which digitises, and eventually re-publishes public domain materials. He has scanned, OCRed and re-published in print, codes like the "Public safety codes of California" or the "District of Columbia Official Code" including in the print a statement that says "being law, any claim about their copyright by the authorities is "null and void."" Answering the question "why print copies?" Malamud says that the print edition limits distribution with no "side effect of infinite copy" that scares standard and legal people, so making his efforts somehow still acceptable. In this case print is turned into a legally strategic medium of distribution, because of its slow duplication standards, as newspapers have been equally strategic for Wikileaks, being part of a clever tactic that considers the different role and weight of the respective medium, in order to seamlessly accomplish an effective distribution of the content.

The library, ultimate cultural centre vs. big data repository

"(Libraries) are nerve centres of intellectual energy [...] knowledge is power [...] and that power should be disseminated and not centralised."
Robert Darnton, Harvard University library director [16]

The physical library is one of the crucial spaces where the discourse about the new relationships between traditional and digital publishing is taking place. On one side the "global virtual library" is closer than ever with Google investments worth millions of dollars to digitise millions of books, and with plenty of other similar efforts at different scale, including some remarkably vast, independent and shared. On the other end the physical library's historically values as meeting and research space for citizens are simultaneously reclaimed and challenged. Funding cuts and innuendos about its obsolescence in the digital era, are dramatically permeating both common sense and institutional policies. Some libraries are reinforcing their role through digital initiatives, like the Toronto Public Library, which launched a Fahrenheit 451-themed alternate reality game, where people where invited to play it in the

city through telephone calls with the motto "Join the literary resistance." [17]

And the push on libraries to "reinvent themselves" can effectively be rethought taking the exchange of physical books as a starting point to expand the knowledge in new directions, creating less conventional models for that. So beyond platforms like BookCrossing [18], using a web-based platform and a simple social mechanism to share books in public places, the main question seems to be about which social role the exchange of knowledge can implement. For example there are different efforts in building what could be defined as "spontaneous citizen library". There are attempts on a small scale like the Little Free Libraries [19], a few thousands wood boxes scattered around the world where people can take or leave books, or Ourshelves [20], a San Francisco lending library open to everyone, with almost 300 members and 3.000 volumes, built around its community, planning to replicate around the city [21]. And if we take into account that Wikipedia has specific templates to add information in its pages about the availability of related content in local libraries [22], spontaneous social mechanisms connected to a self-managed physical exchange can be easily enabled. These kind of initiatives can question the library as a centralised facility, reconfiguring it as the outcome of a community, opening new possibilities. Teaching how to digitise books, for example, for example, could dramatically expand access, especially to forgotten titles which Google Books won't include or give access to for different reasons. Then involved people should assume their own responsibility in scanning and sharing, on a personal and independent level in building their own cultural history, preserving (physically) and sharing (digitally) all the knowledge that they think it's worth, as it has been done with music since the early 2000s.

Conclusions.

The historical importance of the printed page as a medium has still a great influence in cultural dynamics, and it can be used to trigger innovative and radical processes when approached with the new opportunities offered by digital technologies. Active and critical strategies can be then developed using the combined qualities of those two media. The most effective radical efforts has been historically supported by an innovative use of media and technologies, which has grounded the vision of new social and cultural models. The re-appropriation of public imaginary through printed fakes, the plagiarised use of online content on print, the ability to create social libraries, and the sharing of digitalised content, can structurally redefine the printed medium, turning it into a crucial opportunity to rethink our relationship with knowledge, both in contemporary and historical perspective.

The Digital Diasthima: Time-Lapse Reading Digital Poetry

Álvaro Seiça

PhD Fellow, University of Bergen
Bergen, Norway
alvaro.seica@lle.uib.no

Abstract

In moving texts, such as digital kinetic poetry, the reader-user might no longer control the duration of their reading, unlike the traditional and static nature of printed texts. The user deals with readable time versus executable time, the human time-line versus the machine time-line. By having an imposed and fixed number of milliseconds to perceive the text on the screen, the user might find themselves completing or imagining the unread text, following the dynamic forms with an imposed dynamic content. Yet, to understand the shifting reading patterns of digital poems, one has to consider another methods or tools that may complement traditional models. Therefore, performing a critical approach solely based in close reading methods might not accomplish a fully comprehensible reading of digital poetry. In this sense, following upon methods taken from other areas, e.g. time-lapse photography and R. Luke DuBois's concept of "time-lapse phonography" (2011), I introduce the notion of time-lapse reading as a complementary layer in order to close read disruptions in reading processes that demand a set 'experiencing' time when letters, words, lines or stanzas are replaced, with a case study on Philippe Castellin's *çacocophonie* (2013).

Keywords

Electronic Literature; Digital Poetry; Digital Diasthima, Time-Lapse Reading; Philippe Castellin.

Introduction

I am taking into consideration a critical reading of kinetic text, namely kinetic digital poetry. Kinetic digital poems are *performed* with time-based media as both a creative and a critical practice, e.g. onscreen running piece and live performance. In this paper, I am focusing on the critical *performance* executed when reading onscreen pieces, but also how its live performance might affect the very reading process. Time-based parameters operate as functions in diverse programming languages, allowing for a text or poem to run human language and/or code onscreen with a temporal interval determined by a precise number of milliseconds. Therefore, coding these functions helps creating dynamic text which, in turn, might result in diverse nuclei of creative practice: generative text, fiction and poetry, Flash-based or animated/kinetic poetry using other software, distributed/hybrid piece/practice, installation, site-specific installation, performance, real-time sensor-actuator work, and so forth.

Interactivity, Generation and Time-Lapses in Kinetic Digital Poems

One of the complex issues of close reading poetic text in motion is precisely and, first of all, 'just' reading. There are though two main modes underlying this issue: interactivity and non-interactivity. Interactive kinetic poetry often employs a degree of user participation or interaction, by means of mouse movement, keyboard input, joystick, haptic peripheral, touch-screen, sound or movement input captured by sensors (micro, camera, etc.), if one thinks of gallery-mounted pieces, database-pulling interference, etc. Nonetheless, interactive poetry might use several of these features and/or simply contain a speed controller, e.g. Rui Torres's *Mar de Sophia* (2005), Stephanie Strickland, Cynthia Lawson Jaramillo and Paul Ryan's *slippingglimpse* (2006) or Johannes Heldén and Håkon Jonson's *Evolution* (2013), which allows readers/users to change the speed at which the poem runs onscreen, in order to fully read the lines. [1] [2] [3] Hence, one is able to accelerate, slow down and sometimes even pause the unfolding poem. Non-interactive kinetic poetry presents no controller and, therefore, the reader/user might not be able to fully read the lines or words on the surface/onscreen level, if the running time is programmed to be quicker than human reading perception/cognition's skills – e.g. Philippe Castellin's *çacocophonie* (2013), Pär Thörn's *I Am* (2011), Scott Rettberg's *Frequency* poems (2009) and Young-Hae Chang Heavy Industries' *The Lovers of Beaubourg* (2007). So, if the reader is not able to fully read, how can they even close read? [4] [5] [6] [7]

Before replying to this question, there is another important distinction to be made, between generative and non-generative kinetic poems. Generative kinetic poems instigate a type of time-lapse, let us say, time-lapse α, which resides in the fact that the poem one reads or tries to read can always be different from screening to screening or, simply, if one refreshes the browser. Time-lapse α might then carry two problems: 1) one does not have sufficient time to apprehend the poem; 2) one tries to apprehend something always divergent. As of problem 2 some writers would vindicate that their pieces are intended to be conceptual, and, therefore, their argument relies mainly in the process, rather than in the output, which some would expect to count the most. However, other writers would advocate for the process as well as the degree of craft

achieved in the difficult task of creating poetic output out of a limited or unlimited pool of data, e.g. words. Non-generative kinetic poems, thus, might prompt a type of time-lapse β, which is precisely that of the above-mentioned problem 1: textual replacement might occur at a speed rate difficult for our (still) biologic eyes to cope with. Consequently, and returning to our question, how can one read something not totally readable, slightly readable or unreadable? Shall one create screenshots of parts of a poem evolving over time? Shall one screencast a complete running cycle of the poem? Yes, we can adopt one of these strategies. Yet, isn't this method – as Patricia Tomaszek (2013) referred – going against the very motional property of the poem? [8] Let me reformulate it, does one try to critique a poem's intrinsic dynamic and unfolding nature with a static and print-based reading paradigm? And, more, what if we consider a generative poem supposed to run over 2 x 60 minutes, 24 x 60 minutes, 1 year, 4 years, 23 years, 1000 years, n^x years? Can one actually critically perform close readings based on screenshots, lest to say, screencasts or video recordings? No, one cannot. So, I shall argue here, as I did before (2013), that generative art (visual, sound, textual, performative) is meant to be partially read, that is to say, insofar as one needs to extract a sample or pattern as a representation of totality. And that should be generally accepted, since the process fierce fully needs to be stressed. You wouldn't want to be in front of a machine neither for 4 years in a row, nor 1 week, so that you could experience a work of art, would you?

The Digital Diasthima: 7 Proposals to Approach Time-Lapse Reading

It is exactly at this point that time-lapse emerges as a significant reading method. In fact, one needs to acknowledge that same impossibility in non-controllable kinetic poems and allow for a meaningful time-lapse experience to fully flow within its creative matrix. That said, an interval or disruption is created when reading – what I have been defining as digital *διάστημα*, or *diasthima*, that is, a spatial or timely extension, dimension, interval, gap. The digital *diasthima* is a void, a blank moment in time and space, forcing a quicker human reading, which often ends/begins as a creative process itself by way of incomplete association, metonymy, and metaphor. If we can't read everything, what do we read then? We read what our brain selects and, if we start running the poem several times, we can then begin to read other paths as well. To sum up, I would pinpoint a time-lapse reading approach in these terms:

1. Don't be afraid of not reading everything.

2. Engage with the interface and reject frustration.

3. Be open to discomfort and don't skip the poem.

4. Avoid extracting meaning by merely considering static strategies.

5. Read the source code.

6. Read the surface(s).

7. Allow for *diasthimas* to performing a relevant role in your reading.

Time-Lapse Pho(n/t)ography Informs Time-Lapse Reading

Two good examples of a certain kind of *diasthima* are time-lapse photography and comic strips. One watches a movement scene evolving over time but one does not exactly know what happens in-between moments – it is unknown and uncertain, therefore requiring a shift in perception that erects meaning by association, either narrative thread, metaphoric denotation or synecdoche. And yet, the moments are static. Now, if one has *diasthimas* evolving with dynamic moments, the problem of reading becomes even more complex. Taking a different framework, but nonetheless relevant to our purpose, R. Luke DuBois's (2011) notion of 'time-lapse phonography' deals with "computing the spectral average of a sound over time" to achieve a system, or "temporal momentum," but also a transcoded reading (listening), in order to appropriate their sense of totality with partial episodes:

> How about if you've ever skipped to the next song on an album because you don't like the one playing. Even if you do like the song, do you always listen to the end?
> Like so much else these days, our listening experiences are becoming increasingly under siege by the funny feeling in the back of our minds that we don't have time to waste listening to things we don't necessarily want to hear. So we switch stations, skip to the next track, and cut off the song after the second chorus because, to paraphrase Gordon Gano, the third verse is usually the same as the first, more or less. (DuBois 2011: 248) [9]

If we consider non-controllable kinetic poems, in which the reader has no possibility to interfere with the reading duration, such as Young-Hae Chang Heavy Industries' *The Lovers of Beaubourg* (2007), a Flash-based poem, Scott Rettberg's *Frequency* poems (2009), a poetry generator created with Ruby, Pär Thörn's *I Am* (2011), a poem pulling real-time lines from Twitter Search API with the expression "I am," or Philippe Castellin's *çacocophonie* (2013), we can conceive, for now, a particular kind of reading experience that comprises time-lapses as necessary for close reading the work.

Figure 1. Philippe Castellin, *çacocophonie*, 2013 (screenshot).

Time-Lapse Reading Philippe Castellin's *çacocophonie*

I will thus focus on Philippe Castellin's *çacocophonie* (2013), presented on September 23, 2013, at the Centre Pompidou's BPI in Paris as a "lecture assistée par ordinateur" [computer-assisted reading], during the festival "Chercher Le Texte." Throughout the debate, Castellin showed how reading the same work (Figure 1), or, to be more precise, the same source text, varies depending on the speed and coding parameters attributed, whose outcomes are, in fact, different works, or different speed variations/versions of the same work.

Initially, with a word processor, the author read a static and plain text version of *çacocophonie*, pausing and performing, on a human readable level, the effects of a cacophonic dialogue poem between two characters. The work's utterance disclosed a strong sound poem, with the alliteration on "ça," "ce," "s," "ss," which stresses another thematic disclosure – that of a parody of an episodic conflict between "je" [I] and "tu" [you]. Moreover, the interplay between "ça" [this, it] and "là" [there] helped creating an atmosphere of resembling and opponent forces, which addresses the absurd construction of everyday love conflicts over small things. Now, the second stage of the computer-assisted reading comprised a dynamic and rich text version of the work. Built with Processing, the poem was animated in order to perform lines at a given on-screen speed. Whilst being machine readable, the execution of the code entailed still a fairly human readable experience, in which certain portions of the first version were visually and cognitively dismissed and others highlighted, by force of human brain selection. Finally, the third stage of this event used exactly the same process, although now the speed of each line appearance was drastically accelerated. By reducing a simple parameter, such as the number of milliseconds for line display, this time-based poem displayed on the Web is still readable by the machine. However, it stops being human readable, or on the verge of non-human cognition, as the speed rate allows only for certain words to emerge as meaningful, at least, at the conscious level. Even if this version does not use sound, all the different crafts around code, moving text and image create a synesthetic awareness. The quick juxtapositions of kinetic text displayed via software, hardware and network remain tacit features as if to understand that such poetic and reading interplay needs to be addressed in a different way.

Conclusion

Digital poems often bridge visual, sonic, and literary content. More, their *performance* is often an instantiation and extension of their distributed materiality. On some occasions, digging into the source code might provide new insights, comments (in *çacocophonie* there are only some indications about optimized browsers), that is, language or artwork which is still part of the code – some works have other works hidden in the source code, ASCII art, etc. – but not machine readable, and the discovery of codework, that is, creative and critical code that is manipulated in order: 1) not to be executed by the machine but to be read by hu-

mans; 2) not to be executed by the machine nor to be read by humans; 3) to be executed by the machine and to be read by humans. On other occasions, database aesthetics forecast the ground for input from real-time data sensors, SNSs APIs, user's input, and/or blended databases.

As evidence shows, digital works cannot be analyzed with the same critical tools as non-digital works. Therefore, it is imperative to research new models and methods, and to engage with discourses pertaining to the scope of works one is set to critique.

Biography

Álvaro Seiça (b. 1983, Aveiro, Portugal) is a writer, editor and researcher. He published four poetry books, the most recent being *Ö* (2014) and *permafrost: 20+1 zeptopoemas sms* (2012). He holds a MA in Contemporary American Literature, with the thesis "Transduction: Transfer Processes in Digital Literature and Art" (University of Évora, 2011), winner of the Moser Prize 2013. Seiça has published several poems and essays on different journals. In 2007, he co-founded Bypass (http://bypass.bigcartel.com), a nomadic editorial and curatorial project. He currently lives in Bergen, Norway, where he is a PhD fellow in Digital Culture at the University of Bergen, Humanities Faculty, Department of Linguistic, Literary and Aesthetic Studies.

Seiça is a researcher on electronic literature and digital art at the Bergen Electronic Literature Research Group and editor of the ELMCIP KB (http://elmcip.net). His PhD project focus on digital poetry and how time and space relate to digital kinetic poetics.

The *Suplemento Dominical do Jornal do Brasil*: Art, Poetry, and Media Design in Yellowed Newspapers and Digital Archives

Simone Osthoff

Pennsylvania State University
United States
sosthoff@psu.edu

Abstract

This paper focuses on a Brazilian newspaper archive from the 1950s—the *Suplemento Dominical do Jornal do Brasil*—usually considered as the vehicle for the neoconcrete movement. It argues that the artists and poets working in this six-year publication increasingly engaged this media as a medium. It further raises methodology and historiography questions regarding the status of documents and digital archives. And, hopefully, it helps disrupt established narratives with fresh transnational histories crafted through comparisons between a couple of artworks published in this cultural supplement and related examples from the New York based *Art Forum* magazine in the 1960s and 70s.

Keywords

Suplemento Dominical do Jornal do Brasil, archive, documentation, neoconcretism, site-specificity, tactical media, Ferreira Gullar, Robert Smithson, *Art Forum*, graphic design.

Introduction

This short paper focuses upon an under-examined Brazilian newspaper archive— the *Suplemento Dominical do Jornal do Brasil* [*SDJB*]—a cultural supplement published in Rio de Janeiro between 1956 and 1961. Central to the debates of the concrete and neoconcrete movements in Brazil of the 1950s, this publication articulated original relations between art, poetry and design, clearly expressed in the innovative layout of this newspaper. I have been exploring this archive for a few years now, first for its content, as the documents of an important developmental era; second, beyond documentation, examining methodology and historiography; and third, by creating a few experimental collaborations that explore the generative potential that will be opened up by the digitalization of this material. In the next paragraphs, however, I will discuss one specific aspect of the *SDJB*: its use as a site-specific medium by the neoconcrete poets and artists who worked on this publication.

It is well known that the *SDJB* became a vehicle for the neoconcrete movement. But the *SDJB* was also a site-specific space, given that its newsroom was, at times, used as a gallery. And furthermore, we can argue that the graphic design revolution of this newspaper, which reflected ideas from concrete and neoconcrete movements and influenced news media design for years to come, in addition to the publication of a few artworks which were never built or no longer exist, suggest that the *SDJB* can be seen in terms of media intervention, and therefore constitute a pioneer example of tactical media.

Born in the cultural effervescent 1950s, as part of Brazil's developmental era that aimed at modernizing the country by leaping ahead "fifty years in five"—as the president's motto insisted—, like other concrete avant-gardes in São Paulo and elsewhere internationally, the Rio de Janeiro-based neoconcrete movement emphasized non-metaphorical and non-representational forms that sought to create their own concrete reality by eliminating fictional and symbolic references. Despite their goals and efforts, however, fiction and non-fiction remain inseparable in Modern or Contemporary Art.

The newspaper archive as document: local and transnational comparisons

On a local level, comparisons can easily be made between neoconcrete artworks and the participatory creations that followed it. Neoconcrete artworks that were destroyed or never built, such as Ferreira Gullar's architectural poem, *Poema Enterrado* [Buried Poem] and Reynaldo Jardim's *Teatro Integral* [Total Theater][1] were important precursors

[1] Ferreira Gullar's *Poema Enterrado* [Buried Poem] was built in an underground brick and mortar room and later abandoned after

to, and the actual "prototypes" of the more famous participatory works of Lygia Clark, Hélio Oiticica, and Lygia Pape of the 1960s and 70s.

Transnationally, comparisons between the *SDJB* and art publications elsewhere in the world open up interesting questions. For instance, the publication of images and blueprints of neoconcrete "non-objects" on the pages of the *SDJB* echo similar media interventions, such as the ones in the pages of the New York based *Art Forum* magazine in 1969 and 1974 respectively.

Beyond Documentation: Engaging the Media As Medium

The *SDJB* is certainly an archive of documents from six years of experimental thinking (beginning with poetry and the visual arts, and increasingly discussing all the arts as well as architecture), which articulated the various dimensions of art and poetry, including visual and verbal spaces, static and dynamic forms. While there are some similarities, for instance, between Gullar's *Buried Poem*, 1961, and earthworks, such as Robert Smithson's *Partially Buried Woodshed*, 1970, I want to suggest that the *SDJB* also has a site-specific dimension by comparing it with the publication of a Smithson essay in *Art Forum*. One of that magazine's former editors, Phillip Leider, argued that the publication of a Smithson essay about his *Yucatan Mirror Displacements* in *Art Forum* in 1969, was a *new* thing, in that it became one of the versions of Smithson's work:

> The best examples, I'd say, are the "mirror displacements." That essay is one of the forms that that work takes. The nine photos are another form. The actual work in Mexico was another form. But that essay is a form of that work of art. That was one of its manifestations. And that was a whole new thing.[2]

A similar argument can be made about Linda Benglis's famous "center-fold" ad published in *Art Forum* in the November 1974 issue (in which she poses nude in pornographic fashion, wearing sun glasses and displaying a large dildo). It was not simply an exhibition ad, but arguably a tactical media intervention that subverted traditional hierarchies between art and advertising, artwork and documentation, gallery and media exhibition sites. It certainly triggered a heated controversy among the magazine's editors and contributors (a few of them left the publication to start *October*), not to mention within the feminist movement and throughout the art world. Benglis work asks us to consider the difference between the documentation of art and a site-specific media performance. And I believe that the publication of artworks such as Gullar's *Buried Poem* and Reynaldo Jardim's *Teatro Integral* [Total Theater] on the pages of the *SDJB* can be also approached as site-specific, and as examples of tactical media, as much as they are documentation of art projects, and they are the only version of those artworks that have survived.

Digitalization of Archives: Questions and Disruptions

There is great cultural value in old newspapers, but journals are also used "to wrap fish the next day." Material loss, disaster, and failure haunt history and memory, and this loss of physicality is increasingly true, as newspapers become extinct by moving to digital platforms. An important aspect of digital archives is also their generative and recombinant potential, which in the case of the *SDJB* includes the material and methodological possibilities opened up by the digitalization of about 2750 newspaper pages. This generative potential poses further questions about how we engage history *as* a medium, and calls attention to how technology influences the dynamics between visual and verbal languages. How does the transformation of a collection of yellowed newspaper pages into a database constrain and expand research, as well as our understanding of historical events? Before approaching documents as evidence, what are the relationships between archive and method? And even though an archive of artifacts can also function as a database—for instance, when artworks never built during an artist's lifetime are created by curators from drawings, or when multiple copies of interactive artworks are recreated for different exhibitions without an original—a digital archive's generative potential grows exponentially by enabling new translations among objects, images, texts, and sounds.[3]

---

a pre-inauguration flood; Reynaldo Jardim's *Teatro Integral* [Total Theater] is a multimedia installation room, which only exists as a full page drawing on the pages of the *SDJB*.

[2] Phillip Leider, in Amy Newman's *Challenging Art: Art Forum 1962-1974* (New York, Soho Press), 250-251.

[3] I have created a three-minute video analysis of the graphic design evolution of the *SDJB* in collaboration with Candice Ng: http://vimeo.com/46111510 (password SDJB). See also the sound-based collaborative performance *Playing the Archive*: http://playingthearchive.com/

Among the questions and disturbances this research produces, are the histories that position "Latin American art" as derivative of Euro-American pioneer accomplishments. [4] A transnational perspective builds networks and often disrupts traditional narratives, while producing more nuanced, critical, and relational media histories.

Participatory (Counter-) Surveillance and the Internet

Annina Rüst

Department of Transmedia
Syracuse University
Syracuse, NY, United States of America
arust@syr.edu

Abstract

This is a text about Internet art projects dealing with Internet surveillance. In the paragraphs below, I will describe a web service that floods the Internet with fake websites, another web project that allows users to create email accounts in the names of villains that send conspiratorial emails to each other, and a solar-powered disco ball on which YouTube dance videos are projected. What connects these seemingly disparate projects? It may sound absurd, but these projects may help us understand our complicated existence as surveillant and surveillee within networked communications. Since the projects described in the text were made over more than a decade, the article may also reveal some aspects of how the Internet has changed over time.

Keywords

Internet, Internet art, surveillance, participatory, countersurveillance, detournement, humor, hacking.

Introduction

Internet surveillance is complicated. Digital pessimists tell us that surveillance is always negative, because it violates our right to privacy, free speech, etc. And yes, it does (no need for the pitchforks to be raised)! However, there are a lot of gray zones and relationships to consider. Anders Albrechtslund explains in his article "Social Networking as Participatory Surveillance" that people actively construct an identity as they share information with others in Social Networks. They are therefore not powerless subjects of a hierarchical surveillance apparatus but actively participating in mutual surveillance by exchanging information about themselves with others. This subjectivity-building activity therefore is empowering and not disempowering. [1] Albrechtslund's text gives us a glimpse into how complex Internet surveillance is. However, beyond participatory surveillance in Social Networks, there are many more surveillance relationships that we need to consider: People spy on one another using search tools, private companies spy on consumers, government agencies spy on people, and those same government agencies spy on one another. In the following, I describe electronic art projects that question Internet surveillance and shed light on the nature of surveillance relationships. These projects were made by me alone or with collaborators over roughly 10 years. I see these projects as participatory countersurveillance. As I describe the projects in the paragraphs below, I will be building a loose definition of the term.

Participatory Countersurveillance

To begin, I look back to 2001-2002. Compared to today, the Internet at the time seemed like a public park. [3] Nostalgia aside, even at the time, crucial wayfinding went through companies like Google: Then, as today, the most popular search algorithm belonged to the aforementioned company. The term algorithm is used in the context of computer programming to describe step-by-step procedures in automated reasoning and data processing. [4] The Google search algorithm determines how web content is prioritized and in what context it is shown. At the time, the basic algorithm was fairly simple: Pages with lots of links from other pages pointing to them were shown first. [5] The search engine was in the process of becoming the research tool of choice for the majority of Internet users. Thus, the verb "to google" was coined.

Search engines enable a special kind of research: spying on others. But what if you do not want to be found? As part of the group LAN based in Zürich, I created the project *Tracenoizer – Disinformation on Demand* in 2001 [6] (figure 1) to provide a tool for people who did not want personal data to be found by users of search engines. I am writing about this project in the past tense because at the time of writing the project is available as an archived version on my website, but is no longer functional. This is a fate that is typical for Internet art projects that use extensive server-side scripting.

When we created the project, we realized that all the data traces associated with a person constitute a databody. This databody consists of all the data traces associated with with a person, irrespective of whether the person has produced the data themselves or if it was produced by somebody else. We created a service to "clone" one's databody and therefore cloud one's identity. Users could enter their name and *TraceNoizer* would do a search using Google, Yahoo, Altavista, or whatever search engine was not blocking us at the time.

Figure 1. The *TraceNoizer* website © LAN

TraceNoizer would download the search results and run a statistical text classification using the Rainbow text classification library [7] on the data to organize the downloaded text into statistically related groups.

Using these organized groups of text, the program created a home page with thematically organized subpages. The website was then uploaded to a public webserver. Following this, *TraceNoizer* would run another search based on the previous search and make another slightly different website. Websites were linked to each other so that in the eyes of the Google indexing algorithm, their "importance" was increased. As a result, the sites created by *Tracenoizer* would show up in the search result when people searched for a person's name. The idea behind *TraceNoizer* was to create a cloud of disinformation so that nobody doing personal research could tell real from fake information and the original databody of a person would disappear.

Maintaining one's own databody and spying on others via search engines can be described as a sort of participatory surveillance in that the surveillee is participating in their own surveillance while surveilling others. TraceNoizer is a participatory countersurveillance tool in that it uses the mechanisms of participatory surveillance (search engines) to counter participatory surveillance.

Participatory Countersurveillance

More than a decade ago, in October 2001, the Swiss parliament issued a decree that mandates Internet service providers to retain metadata for six months [8]. This means that law enforcement agencies can reconstruct a person's social network because they have access to email and phone data. Proponents of this type of legislation tend to cite terrorism as a justification [9]. So far, no terrorists have been caught as a result of the Swiss legislation: A study by researchers at the Max Planck Institute found no statistical indication that data retention increases the efficiency of law enforcement. [10] Besides being ineffective, data retention also does not conform to the presumption of innocence, a fundamental right in a democracy.

When mandatory data retention in Switzerland was instituted in 2002, I responded by making the project *SuPerVillainzer – Conspiracy Client* [11] (figure 2). It is a webproject and the website itself still exists but like *TraceNoize*r, I no longer maintain it – one of the problems of preserving digital art. *SuPerVillainzer – Conspiracy Client* is a website that looks like a program for sending and receiving email. However, instead of facilitating the typical functions of an email client, it allows users to create email conspiracies. Users can enter a conspiracy name and a select a set of villain profiles (figure 3). Then they can press a button labeled "create conspiracy" and email addresses will be created for the selected conspiracy on a Swiss server. These email addresses will then automatically start sending each other conspiratorial emails. These emails have subject headers such as "NSA ALERT!" The body of the email will have ostentatiously conspiratorial text such as: "The informer we have inside the Secret Service says they are planning to sell details of the updated AFIWC COMPUSEC plans to the Dallas diplomat in Bern just as everybody is sitting down for Christmas dinner." Other emails look like they are encrypted. In the years when I actively maintained the service, thousands of villains were created. They had the names of the people who created them, but villains were also named after politicians, military officials, scapegoats, etc. Users created

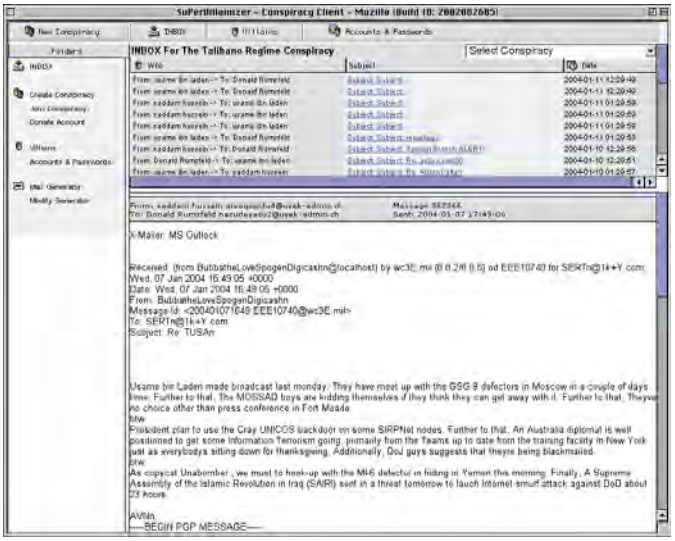

Figure 1. The *SuPerVillainzer* website © Annina Rüst

Conspiracies with names such as "Operation Blue Phoenix", "Tomorrow at 6:00:00", "The Mustafa Connection", and many thousands more.

The project was motivated by my interest in terrorist communication. I wondered, how can one tell what a conspiracy looks like? What constitutes terrorist communication? And finally: Who decides who is terrorist and who is not? How is an "enemy" profiled within a load of metadata?

Sunrise, the Swiss Internet service provider on whose servers I automatically created email accounts eventually found out about my activities. I think that the project appeared on the radar of their legal department only when print newspapers started writing about it. They sent me a letter ordering me to stop my activities and turn over passwords and usernames for the email accounts I had generated. Of course I complied and I did not hear from Sunrise's legal department ever again. The project however continued: I set up my own server where I continued to generate email accounts.

In 2005, I created a sequel to *SuPerVillainizer*, called *Sinister Social Network* [12], a project similar to *SuPerVillainizer* in that it constituted a participatory, speculative approach to Internet surveillance. However, this project specifically focused on surveillance algorithms, specifically on programs that identify suspicious activity.

These algorithms exist. One such algorithm was outlined in a paper presented in 2004 at the 2nd NSF/NIJ Symposium on Intelligence and Security Informatics. The paper explains the rules that allow researchers to search through data from chat rooms and distinguish malicious communications patterns over benign ones. For example: "Normal communications in the network are voluntary and 'random' however a hidden group communicates because it has to communicate (for planning or coordination)." [13] (Baumes, Goldberg, Magdon, Ismail, Wallace 1). No examples of actual observed terrorist communications are given but the rules outlined by the researchers show what stereotypical "criminal" behavior would look like. The researchers are therefore building a hypothetical profile based on speculation. In his book, *The Simulation of Surveillance: Hypercontrol in Telematic Societies* William Bogard calls this kind profiling "surveillance in advance of surveillance". [14]

Like *SuPerVillainizer*, the project *Sinister Social Network* existed mainly on the Internet. I populated IRC chat channels with villains and charted their activities in a social network graph. I displayed the IRC conversations on a website and asked viewers to speculate what kinds of sinister things were going on in the chat channel.

Like *TraceNoizer*, the projects *SuPerVillainizer* and *Sinister Social Network* are participatory counter-surveillance environments. However, the approach here is speculative: Users of both websites can create speculations about who the enemy could be and whom they are conspiring with. The projects explicitly question power: I am using the projects to raise the question of who is allowed to collect and analyze communications data and according to what criteria.

Participatory Surveillance and Empowerment

In his article about Participatory Surveillance in social networks, Anders Albrechtslund says that social surveillance practices are at the heart of social networking. Albrechtslund writes that as users share information about themselves with others they build identity and subjectivity online. He sees this surveillance practice as empowering. [15]

One such example of online identity building is a genre of web video where people film themselves while dancing. On the popular social networking site YouTube, the type of video where people film them themselves has become a widespread phenomenon. Countless people are recording themselves dancing and sharing these clips through YouTube and other social media platforms. This form of online identity building differs from the online identity building that LAN addressed in the early 2000s with *TraceNoizer – Disinformation on Demand*. Today, online identity is not mainly expressed in the form of a home page on a server. Rather, it is distributed over social networking sites owned by companies such as Facebook, Google, Yahoo, and Twitter. Communication on the web today is much more widespread, visual, and exhibitionist than it was in 2001. It is still consumed in the form of text but mostly through images and videos. The following section of the paper is therefore not a departure from the topic. On the contrary, it takes into account surveillance relating to online identity building enabled by social media platforms like YouTube.

In 2012, Amy Alexander and I created the performance project *Discotrope: The secret nightlife of solar cells* [16] (figure 5), which examines the genre of the YouTube dance video. The performance features a solar powered disco ball. We project dance videos against it. In the performance we trace the genre of the YouTube dance video back throughout film history. We found that the sense of intimacy and immediacy between performer and audience that characterizes the YouTube performances was popular in early silent films and Hollywood musicals, where models for performance were drawn more from vaudeville than from theatrical narrative. An example for this is the silent film "Annabelle – Serpentine Dance" [17] shot as one of the first films in 1894 at Thomas Edison's film studio. In this clip, the dancer performs directly "at" the camera. Like in YouTube dance videos, the performer looks directly into the camera. Theresa Rizzo describes this type of cinematic performance as an "exhibitionist cinema where the spectator is overtly acknowledged and invited to look" [18]. There is an element of voyeurism and exhibitionism that can be found both in early cinema and later on in YouTube clips. We have found that this direct-to-audience style continued on to the musical films of the 1940s for example in the films featuring Ginger Rogers and Fred Astaire. Later on, films were shot in such a way where the audience takes a "fly-on-the-wall" perspective. An example for this style is the film "Dirty Dancing" where no direct-to-audience dancing takes place

and the actors stay in character throughout the film. Exhibitionistic cinema has only recently come back in the genre of the YouTube dance video. This type of video is typically shot with a webcam on a computer and oftentimes in an intimate setting such as a living room, a garage, backyard, or in a bedroom. Like in the Annabelle clip from 1984, the YouTube dancer acknowledges the camera.

During the Discotrope show we project this historical trajectory onto a disco ball where mirrors have been replaced with solar cells. This creates a mosaic-like projection against the walls. When enough light hits the ball, the ball rotates and the projection rotates along with it. We perform the ball live, adding color and light to the video projections, improvising layering and mixing to create visually rhythmic stream-of-consciousness juxtapositions. The changes in imagery vary the light to the solar cells, which changes the speed of the ball's rotation, allowing us to "choreograph" the movement of the projected visuals. Accompanying the performance is an algorithmic sound design by composer Cristyn Magnus. Sound is generated and mixed in real time from the audio tracks of the projected videos, creating a seamless, danceable connection between audio and visual.

In the performance we examine how today's YouTube dancers represent themselves. We reveal contrasts and connections over cinema history. Those include characteristics such as gender and body expectations, implications of aforementioned voyeurism and exhibition. We have found that although YouTube performers are self-directed, liberated and empowered, many still will enact gender stereotypes and conform to body expectations. Dancers that successfully defy gender stereotypes such as an obese man in a leotard dancing to Beyonce's hit song "Single Ladies" [19] are few and far between. So while participatory surveillance as described by Albrechtslund might be empowering in that it helps to build online identity, the cultural context where it happens still needs to evolve so that the promises held by the concept of participatory surveillance can actually be realized.

Conclusion

I hope to have demonstrated that Internet surveillance is as multi-faceted as a solar-powered disco ball. The projects I have described above are participatory countersurveillance environments. They challenge forces that attempt to exert power through Internet surveillance. Those entities include (but are not limited to) governmental agencies, corporate (search engine) algorithms, as well as societal expectations more broadly. As an artist, it is my job to create environments where participatory countersurveillance can happen.

Author Biography

Annina Rüst produces electronic objects and software art. She creates technologies that are artistically and socially motivated. Her projects happen at the intersection of activism, algorithm, data, electricity, humor, politics, and pop culture. Her work has been reviewed in publications such as Wired and the New York Times Magazine. The Huffington Post called her recent robotics work a "Badass Feminist Robot". Annina's projects have been shown internationally in galleries, museums, and festivals such as Zero1 Biennial and Critical Make, as well as at the Edith Russ Haus for Media Art in Oldenburg, Germany. In 2014, she received an Art+Technology Lab grant from the Los Angeles County Museum of Art (LACMA). She has a Diploma from the University of the Arts in Zürich, an MFA from UC San Diego, and an MS from the MIT Media Lab. Annina has worked at Syracuse University since 2009. She has worked at Syracuse as Assistant Professor since 2009.

Remote and Embodied Sensing: Observations on Interactive Art and Politically Engaged Practice

Margaret Seymour

Sydney College of the Arts, University of Sydney
Rozelle, NSW, 2039, Australia
margaret.seymour@sydney.edu.au

Abstract

Remote Sensing is an interactive artwork that previewed during *The Image in Question* conference at the University of Sydney in August 2014. Making the work led me to ask, "Why has interactive art been sidelined in recent publications about participatory art and politically engaged practice?" In this paper I discuss recent theoretical perspectives on participatory art and interactive art and the sociopolitical and cultural contexts for my work *Remote Sensing*, which seeks to raise awareness about surveillance. As a vehicle for social and political comment, interactive art objects might not have the 'hit-and-run' appeal of tactical media and augmented reality projects but as divisions between art forms become increasingly blurred perhaps it is time to rethink interactive art, which engages the user in embodied actions.

Keywords

Interactive art, participatory art, politically engaged art, digital art, new media art, surveillance, embodiment, interactivity.

Introduction

Interactive artworks by their nature involve users in various forms of participation. Depending on the artwork the interaction can be either predictable or full of surprises. Interactive artworks can be found online and in public spaces, but my concern here is primarily with interactive artworks presented in galleries or museums. By encouraging viewers to physically engage with the work, interactive artworks challenge the established viewing conventions of the 'white cube'.

Over the last two decades there has been a lot of interest in various forms of participatory artwork. Works with a dialogic or collaborative element have increasingly been presented in museums and in major art exhibitions. These works have also found strong support in key publications, including Claire Bishop's book *Artificial Hell*s. But Bishop chooses to leave interactive art out of her discussions perhaps because she sees it as a sub-category of 'new media art' rather than 'participatory art' even though it combines aspects of both. In this paper I examine the changing nature of participation and the discourses that have grown up around digital art, participatory practice, politically engaged practice and interactive art, before discussing how my own work, *Remote Sensing*, is positioned at the interface between these discourses.

The Changing Nature of Participation

In her 2012 book *Artificial Hells: participatory art and the politics of spectatorship* Claire Bishop notes that since the 1990s there has been a "surge of artistic interest in participation and collaboration." [1] She names the following art forms as examples: socially engaged art, community-based art, experimental communities, dialogic art, littoral art, interventionist art, participatory art, collaborative art, contextual art, and social practice. [2] Interactive art and other digital art forms are conspicuously absent from her book. Bishop justifies the omission saying that participatory art involves many people "as opposed to the one-to-one relationship of 'interactivity,'" [3] and that according to her definition of participation "people constitute the central artistic medium and material." [4] However, not all interactive art is made for a single user. For example, augmented reality art projects allow multiple users to interact online and in public spaces. Interactive projects made for public spaces, for example Rafael Lozano-Hemmer's *Under Scan*, also often involve multiple users who can collaborate to deepen their experience of the work. What is clear is that digital media open up new forms of participatory interaction. Internet forums and social media give new importance to the practice of 'sharing' as a form of participation. Online campaign groups like GetUp! in Australia, the global organisation Avaaz and MoveOn in the US, inspire users to 'take action' online and in the physical world. Like life, which today involves both digital and embodied interactions, participation often straddles Bishop's so-called 'digital divide'.

Heralded as a democratic space by many, it seemed in the 90s that the internet might eclipse the elitist and commercial models that operate in the art world. But artists and theorists have long recognized the benefits of occupying the physical as well as the digital realms. Back in 1997 when they published *The ABC of Tactical Media*, Geert Lovink and David Garcia accepted "the paradox of *centers* of tactical media." [5] They argued that, "As well as castles in the air, we need fortresses of bricks and mortar, to resist a world of unconstrained nomadic capital." [6] Deterritorialisation is not empowering in itself; it is in

fact a characteristic of capital. As "flexible media tacticians," they were also happy to adopt 'strategies' of power when needed, specifically a physical base in the centre of Amsterdam where they could consolidate their efforts. [7] A space to "plan not just improvise." [8]

This is a theme that Garcia takes up again in 2014 in *From Tactical Media to the Neo-pragmatists of the Web.* [9] Here he argues that "despite the powerful forces seeking to domesticate the internet" it is still a powerful platform for political activism. [10] Partly this is because of the way online activists have sought to negotiate and perhaps embrace their own contradictions. According to Garcia, organisations like Avaaz have "the vision to step out of the established conception of how to do politics and into the new hybrid spaces that combine the virtual and the street." [11] Garcia argues that rather than clinging to "avant-garde rituals and tribal affiliations", the corporate look and feel of groups like Avaaz is a form of neo-pragmatism. He argues that Avaaz, and organisations like them, engage with the mainstream while acknowledging the risk and contradictions that entails.

In a similar way, media artists who previously shunned mainstream art institutions are now included in major exhibitions and festivals. Perhaps it is therefore time to rethink the tactical advantages of interactive art, which often combines digital and physical elements and can more easily penetrate the elitist art world. Conscious of Bishop's criticism that art institutions often co-opt participatory art practices by marketing them as enjoyable museum experiences, how might interactive artists maintain their political punch? Can limiting the interactive aspects of an artwork help focus attention on the meaning of the work?

Interactive Art and Participatory Art Practice

An interactive artwork is not an object in the traditional sense but a 'system' that works in concert with its users. It is often evaluated according to how much freedom the user has and how responsive the system is. For example, Beryl Graham in her chapter *What Kind of Participatory System? Critical vocabularies from new media art* says that very little new media art is actually interactive. She says that more often artworks are reactive; they respond to the viewers' actions but do not "physically act upon the audience in return." [12] The binary of interaction versus reaction perhaps grew out of criticisms of the hyperbole that surrounded early screen-based interactive works. Many were sceptical of the claim that these works give the user freedom to create his or her own experience or narrative because even though the user can chose a pathway through the material, the pathways themselves are predetermined by the programmer. However, the concept of participation itself is not static. As Graham notes, the critical vocabularies that have grown up around participatory systems are informed by the histories of previous art movements. [13] Allan Kaprow's *Happenings* in the 50s and 60s built upon but also challenged strategies developed by Dada artists who aimed to break the passivity of the audience, usually by confronting them with unexpected actions. However, Kaprow argued that to "assemble people unprepared for an event and say that they are 'participating' if apples are thrown at them or they are herded about is to ask very little of the whole notion of participation." [14] Kaprow sought to involve participants in a more democratic way: "I think that it is a mark of mutual respect that all persons involved in a happening will be willing and committed participants." [15] The rhetoric of human empowerment and democratic decision-making has become strongly associated with participatory art today.

In her book *The 'do-it-yourself' artwork* Anna Dezeuze notes that participatory works are often "premised on the belief that participation will encourage individuals and groups to take control of their own social and political existence." [16] But participation is not always liberating. Artist Bruce Nauman was reportedly very sceptical about user participation; Janet Kraynak in her perceptive analysis of Nauman's work *Dependent Participation: Bruce Nauman's Environments,* quotes him saying, "I mistrust audience participation. That's why I try to make these works as limiting as possible." [17] Kraynak argues that participation is "a historical rather than a static concept." [18] She places Nauman's work in the context of the technocratic space that developed in the 1960s, which was characterized not simply by media culture and technological developments like television and computers, but by the "increasingly administrative order" that accompanied these changes. [19] The limited audience interaction that Nauman stages in works like *Going Around the Corner Piece* mirrors the Kafkaesque feeling of being stuck in a bureaucratic cycle.

Surveillance and Secrecy

Today we have a new 'administrative order', one that also encourages and has perhaps refined participation as a form of social control. The networks that provide ready access to information and communication are also used to capture and store information about us. The legality of mass surveillance has been hotly debated, not only in the US but also around the world, but the extent of its reach and operational details are often shrouded in secrecy. Even so, most would be unwilling to give up access to the internet. We depend on it to receive and share information, yet while we 'participate' we are also giving up information, the metadata which internet and telephone companies are required to store. Civil libertarians argue that mass surveillance violates the right to privacy. Others argue that these powers are needed to protect citizens and infrastructure from non-state actors who are using the internet to recruit followers and plan attacks. It is not within the scope of this paper to weigh arguments for individual freedom against national security. My interest is in how art can reframe ethico-political questions, not only in my own work but also in the work of others.

In November 2013 artist Trevor Paglen photographed three intelligence agencies in the US: the National Security Agency (NSA), the National Reconnaissance Office (NRO) in Chantilly, Virginia and the National Geospatial-

Intelligence Agency (NGA) in Springfield, Virginia. Challenging the secrecy surrounding mass surveillance, Paglen posted the three images online saying they could "be used by anyone for any purpose whatsoever, with or without attribution." [20] Prior to this, the most commonly used photograph of the NSA facility appears to have been taken in the 1970s. It shows a corporate-looking building photographed on a clear day. In contrast, Paglen's new image shows the NSA facility at night, which gives it a slightly sinister feeling. The largely empty car park is bathed in orange light. The main building itself seems to have undergone little change since the 70s, but thanks to whistleblower Edward Snowden we know a little more about the way surveillance has changed.

Paglen hopes his images of these facilities help people to think about what these institutions do and about the effects they have on the society around them. [21] Images capture the public imagination and have the ability to shift public perceptions. But unlike images in the past, which were distributed through more traditional channels, today images are instantly uploaded and available globally. Paglen has posted his photographs of the NSA, NRO and NGA online with a creative commons licence that allows others to use them with or without attribution. This not only ensures a wider audience for the original images but also facilitates creative reinterpretations of his work.

Remote Sensing

My work *Remote Sensing* (Figure 1) incorporates Paglen's photograph of the NSA facility and its surrounding car park. The work comprises a small trolley on wheels that users push around the gallery. A computer screen embedded in the trolley's top surface displays a small section of Paglen's image. As the user manipulates the trolley left, right, forward or backward, the screen updates to show contiguous parts of the image. If the trolley swivels on an angle, so does the onscreen image. For all intents and purposes, it is as if a large virtual image was mapped onto the floor of the gallery but viewers can only see a small part of it on the trolley's screen. In order to see more of the image, the user pushes the trolley towards the corresponding section of the floor. It's a form of 'blinkered' vision. The user is unable to see the whole image simultaneously.

Fabricated in unpainted galvanised steel and supported on industrial swivel castors, the trolley object appears old-fashioned, though its bent acrylic hood gives a nod to the sleek and sexy mobile devices used today. Artist, writer and curator Wes Hill argues that the renewed interest in obsolete technologies in art today is partly due to digital artists trying to overcome the speed with which their own works become out-dated. [22] However, my interest in obsolete technologies goes hand in hand with my interest in physical interaction. Both strategies are used in order to give physical form to contemporary issues, many of which, like surveillance, are dematerialised and/or disembodied. The action of 'scanning' the floor to reveal Paglen's image of the NSA is a bit like searching a microfiche library catalogue. A transitional technology between paper cards and

Figure 1. *Remote Sensing* (2014). Steel, acrylic, castor wheels, electronics. Programming by Dr. Andrew Burrell. Image courtesy of the artist. ©Margaret Seymour.

computer catalogue, microfiche miniaturised the catalogue, thereby compressing the catalogue into a smaller physical area. The user navigated the tiny text records by winding a film spool or sliding a film cradle to the desired magnification point. Today computers have changed the way we store and access information, allowing ever increasing quantities of data to be captured and searched.

The image on the horizontal screen of *Remote Sensing* is also a bit like augmented reality in that a virtual image is overlaid onto real space. Unlike most augmented reality works, however, the screen shows a 2D image that 'replaces' the floor rather than producing a composite of floor and image. In *Remote Sensing* the horizontal orientation of the image echoes Borges' story about the cartographers who make a map the size of the empire that replaces the empire point for point. [23] And perhaps one day the vast repositories of data amassed by governments, internet and phone companies will face the same fate as Borges' map:

> *The following Generations, who were not so fond of the Study of Cartography as their Forebears had been, saw that that vast Map was Useless, and not without some Pitilessness was it, that they delivered it up to the Inclemencies of Sun and Winters. In the Deserts of the West, still today, there are Tattered Ruins of that Map, inhabited by Animals and Beggars; in all the Land there is no other Relic of the Disciplines of Geography.*
>
> Jorge Luis Borges, *On Exactitude in Science*

Like Nauman's tactic of limiting the actions available to viewers of his works, *Remote Sensing* also allows only a limited range of user interaction. If the user moves the trolley outside the area marked up on the floor, the image is replaced by static, as if an analogue signal has been lost. This is suggestive of the fact that online we have the freedom to explore a vast network of information and to engage and maintain contact with others who have similar interests, but only within given parameters and technical constraints.

I chose Paglen's image because I wanted to contrast the secrecy surrounding surveillance with the philosophy of open access to information in the digital commons. I was struck by this contrast during the debate about privacy versus security in the US, but also particularly because of the conservatism of the debate in Australia. In October 2014, the Australian government introduced legislation that mandates data retention for two years. The government, with the support of the opposition, has also passed new anti-whistleblower legislation. The National Security Legislation Amendment Bill "increases the penalty for disclosing information about a special intelligence operation to a maximum of five years imprisonment, and 10 years if the person intended to endanger someone." [24] These are worrying developments, especially for journalists who are rightly concerned about protecting their sources. Rather than opening up a conversation about individual freedom and national security the Australian government seems determined to place tighter regulations on the digital realm.

Remote Sensing aims to extend and amplify the conversation about surveillance by engaging the viewer in embodied actions. The work slows viewing down to walking pace in order to allow time for contemplation. The act of revealing one part of the image necessarily conceals another part; but after spending some time with the work, the viewer might recognize the whole image, which was taken by Paglen from a helicopter. Although the camera's point of view doesn't match the horizontality of the screen exactly, both the camera and the trolley place the viewer above the object of interest and looking down. The trolley has a handle that viewers must bend down to reach. This action focuses attention on the screen beneath, so that the rest of the gallery tends to drop out of the user's field of view. This ungainly pose can make the user feel self-conscious, concerned perhaps about other gallery visitors who may be watching them and whom they cannot see with their head down. The image is not immediately present for the viewer but has to be assembled piece by piece in his or her mind through a process of gradual revelation. In the act of revealing the image the viewer is also observed by a small web camera (attached to one of the roof beams above the work) and by other people in the gallery, thereby inverting the spectatorial power dynamic in the gallery. The viewer is both surveyor and surveyed.

Consciousness of being under surveillance prompts in the viewer a mix of anxiety, self-censorship and caution. Some users reported feeling nervous about using the device and asked if their actions were being recorded. They wanted to know how the onscreen image was being updated. Only a few noticed the web camera. Perhaps the hazard tape marking out the boundaries of the virtual image on the floor also made people feel self-conscious. In a gallery or workshop, markup tape on the floor usually indicates danger and shows how far the viewer should stand from an artwork or a piece of machinery. Also, without a sign saying 'please interact with the work', some people were naturally wary. These responses confirm that physical engagement with interactive works of art can produce affective responses, in this case curiosity and anxiety.

Conclusion

If, as Bishop states, the most striking participatory projects "unseat all of the polarities on which this discourse is founded (individual/collective, author/spectator, active/passive, real life/art)," perhaps it is time to unseat another polarity, the one Bishop identifies in her article the *Digital Divide*. [25] When Bishop's article was published in 2012, it prompted a lively outpouring of criticism from academics and artists. Her characterization of new media as a 'specialised' discipline seemed to sum up the longstanding neglect with which it had been met by major art institutions. It is not my intention to revisit the criticisms of Bishop's *Digital Divide*. [26] Digital works can be critically evaluated according to the discourse that has grown up around them, but they also challenge existing criteria and push art discourse in new directions. Rather than looking for ways to transplant the digital into physical space, many artists are already blurring the boundaries across the digital divide. With a stake in both the digital and the physical world, interactive works can engage the user in contemplation *and* participation – in remote and embodied sensing.

Towards an Autopoiesis of Surveillance

Tom Kohut

Winnipeg, Canada
thenewennui@gmail.com

Abstract

Surveillance has now become a ubiquitous phenomenon that envelops the globe in an uneven and non-transparent manner. While the work of Foucault (the panopticon and the administration of subjectivities) and Deleuze (the control society with its reliance on communication and marketing) provides powerful tools for understanding the surveillance apparatus, closer attention to its digitally networked nature must be given. To this end, the work of Nancy Paterson's *IXMaps* and Julian Oliver and Danja Vasiliev's *PRISM: The Beacon Frame* provide morphological samples of the autopoiesis of surveillance. Autopoiesis, a concept related to cybernetics and developed by Humberto R. Maturana and Francisco J. Valera, posits the existence of self-sustaining and regenerating unified systems of relations that are indifferent to their components. Autopoiesis, they argue, is a necessary and sufficient condition to consider a particular system living or otherwise. We speculate at the end of this paper the degree to which the global surveillance apparatus might be considered a living organism, albeit one of our own accidental design, and what the possible implications might be.
.

Keywords

Surveillance; autopoiesis; networks; new media art; Foucault; Deleuze; Maturana & Varela; cybernetics; protocol

One of the many uncanny aspects of the Edward Snowden revelations is the fact that the extent of the NSA's bulk surveillance program – according to Glenn Greenwald, data from 97 billion emails and 124 billion telephone calls was collected in the course of just thirty days in 2013 – seems both appalling and banal. [1] Appalling: what used to be considered as a "reasonable expectation of privacy" can no longer be reasonably expected. Telephone and mobile conversations, email and text messages, Internet browsing histories, social media activity, credit card purchases, national and international travel, etc., are all potentially subject to collection and analysis. Banal: the automated nature of the technology behind bulk metadata collection means that the strategy (collection of relevant information) should far exceed its purpose (national security) and go too far.

Certainly, a ubiquitous surveillance apparatus is hardly a recent development, of which the top-down model associated with George Orwell's 1984 (i.e., secret police, a centralized panoptic state control over a population, surveillance activities directed towards a specific enemy group or activity, etc.) is foremost in the popular imaginary. However, and while it is certainly true that there are numerous places in the world where this centralized model of surveillance is violently active, the activities of the surveillance apparatuses of not just the NSA but also CSIS (Canada), GCHQ (the UK), CNCTR (France) and the BND (Germany) – to name a few examples – indicate that centralized surveillance is merely one model among others: or, more specifically, one network morphology linked to a wider, more flexible and robust system of networks. One indication of this is the degree to which surveillance is no longer an exclusive concern of a state apparatus; as the example of Facebook or Amazon's continual negotiations with their users' patience indicates, capitalist interests have invested in and adopted surveillance technologies in order to develop and expand their market interests, while routine monitoring is a feature of the contemporary workplace (e.g., timed toilet breaks in call centres and retain service industries, monitored Internet usage, etc.). Indeed, it is from an analysis of the sociology of workplace surveillance that the ubiquity of the surveillance apparatuses is foregrounded:

> Surveillance is (1) an ubiquitous feature of human societies and is found in both the political (public) and civil (private) spheres of society; (2) associated with governance and management; (3) endemic to large-scale organizations; (4) constituitive of the subject and has a corporeal aspect to it; (5) disabling as well as enabling and is "productive" in Foucault's sense; (6) understood in terms of distanciation, i.e., control of space and time; (7) becoming increasingly implicated in a system of assemblage which brings together diverse control technologies; and (8) rhizomatic, as evident in the ability of convergent technologies to capture and assemble inordinate amounts of information from various sources. [2]

There are several things noteworthy about this description. For one thing, the ubiquity of surveillance is related to its generalized function as mode of "governance and management," or, to use a vocabulary drawn from cybernetics, command and control. Further, there are the references to the work of Foucault and Deleuze – in particular, Foucault's move from the postulation of the disciplinary society in which "prisons resemble factories, schools, barracks, hospitals, which all resemble prisons" [3] to an absubjective apparatus of surveillance based on "and environmental type of intervention instead of the internal subjugation of individuals." [4] Developing this in his 1990 text "Postscript on Control Societies," Deleuze notes that prison incarceration has increasingly been

replaced with electronic tagging, psychiatric hospitals with outpatient health-risk management – more often than not involving medications – and the Fordist factory replaced with the forced dissolution of trade unionism and info-capitalism: "marketing is now the instrument of social control." [5] As Deleuze notes, this mode of control operates not as much through the allocation of bodies in space as it does by means of transmission and access to

Deleuze's emphasis on the "digital language of control," that is "codes" of "information" alludes to an important feature that cannot fail to escape the notice is the importance of communication technologies in the contemporary surveillance apparatus. The pluralized, nonhierarchical networks alluded to by Foucault and Deleuze and stated specifically in the sociological definition depend less on particular human agencies, such as the secret police structures of "totalitarianism." than they do on the technological servo-mechanisms of data mining and extraction in order to monitor the unprecedented levels of communication flows currently in operation. These servo-mechanisms are able to operate in the way they do because they share the same substrate as the flows they monitor: data. Lev Manovich, in his book *Software Takes Command* , has noted that data accessed and shaped by software is the noumena of the contemporary socio-cultural-political-economic order; a heterogeneity of artistic, economic, personal, etc., transmissions are reliant on a stratum of collectible and quantifiable informatemes. [7] This noumenal homogeneity – data, whether it be financial information, financial records or personal trivia, necessarily is translated into binary code – makes control over the heterogeneity of networks possible by modulating control and access to this data.

Before we describe how these networks are controlled, or, to be more precise, how the communication networks have been imbricated into the surveillance network as a control mechanism, some attention must be paid to how these networks function. This is a question of morphology as much as technodynamics, one directly addressed by Canadian artist Nancy Paterson's ongoing (2008–the present) project *IXmaps*. (See fig. 1). With a consortium of students and faculty at the Department of Information, University of Toronto, *Ixmaps* is an online "interactive tool that enables Internet users and researchers to study the route(s) that data packets take across the Internet, with surveillance and other 'interesting' sites highlighted along the way." [8] *Ixmaps* functions as an art project but also as an act of intervention in the politics of network surveillance; in addition to data visualization (effectively, a vectoral map of North America), the group produce an annual report *Keeping Users in the Dark or In the Know: Report on Data Privacy Transparency of Canadian Internet Service Providers*, providing policy recommendations to ISPs, privacy officers and the Canadian government along with ratings of the main ISPs used by Canadians in terms of their commitment to informing customers about external data requests, storage or routing of data packets in and through the United States, transparency about their operations regarding personal information, advocacy for privacy rights, etc. this information: "in control societies, […] the key thing is no longer a signature or a number, " which would mark a particular subject, e.g., "Jane Doe," with a particular bank account number, social insurance number, credit rating, date of birth etc., "but a code: codes are passwords […]. The digital language of control is made up of codes indicating whether access to some information should be allowed or denied." [6]

is not to produce a consumer report, but to address the problem of uneven network transparency – that is, access to information about the form and function of the surveillance network itself.

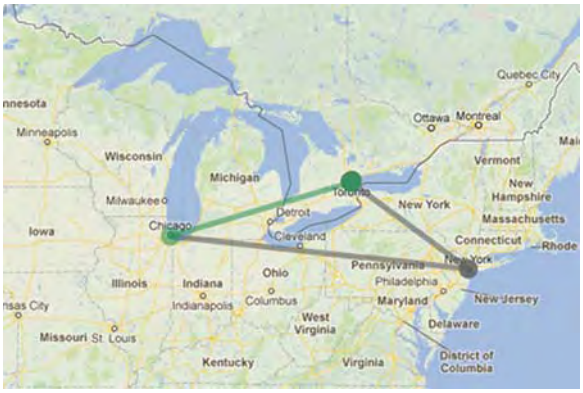

Figure 1. Nancy Paterson, *IXmaps*. An email sent from Toronto to Chicago is routed through New York. © Nancy Paterson

As David Lyon notes: "As the details of our daily lives become more transparent to the organization surveilling us, their own activities become less and less easy to discern." [9] This critique of uneven transparency has been one of the key areas of political contestation in recent years, from Wikileaks to Edward Snowden's desperate exile. Indeed, as it is often the case that one can observe the efficacy of one's political strategy from the violence of the reaction it raises in the dominant social vectors, one might point to a similar exploration of data network transparency in the case of Julian Oliver and Danja Vasiliev's *PRISM: The Beacon Frame* at Transmediale, Berlin, January 2014. (See fig. 2). Oliver and Vasiliev describe this project as "a speculative, functional response to the general absence of information as to what NSA PRISM equipment actually looks like." (PRISM was the name of the NSA program for the collection of private communications from such companies as Facebook, Google, etc.). Originally produced for the ArtHackDay 2013 event in Berlin, Oliver and Vasiliev further elaborate:

> This [2014] iteration of the project is a field deployable wireless surveillance and GSM interception unit comprising a robust tripod, large glass prism, nano computer, nano projector, GSM antenna and cellular communications base station (also with a computer).
>
> It employs the same techniques of wireless (WiFi) device localization and mapping, cellular network hijacking and wireless packet inspection known to be in use by state

sanctioned surveillance agencies such as GCHQ (UK) and NSA (USA).
When activated, the computer scans for local cell towers owned by mobile service providers [...], building a list of their unique properties. The prism then begins rotating, and one by one each cell provider is impersonated by the PRISM tower. Activated mobile phones in the presence of the tower will hop onto the rogue network, "recognizing" its properties and believing it to be trustworthy.
At that point, they are sent SMSs of a troubling, humorous and/or sardonic nature. Data corresponding to these events are projected through the prism, in turn showered onto the walls in a rich and exploitative light show. [10]

Figure 2: Oliver and Vasiliev's *PRISM: The Beacon Frame* before being disconnected at Transmediale, Berline, 2014. © Julian Oliver, Danja Vasiliev

The SMS messages sent were along the lines of "Welcome from your new NSA friends" and the like, of which over 1000 were sent to mobile devices during the exhibition opening and the following day, at which time, a curious incident occurred. Without the artists' consent, members of Transmediale's staff disabled the device, and the artists were advised that Transmediale would be unable to cover their (the organization's and the artists') legal expenses if official complaint were made to the authorities. In response to this, Olivier and Vasiliev chose to discontinue the project. [11]
As with *IXmaps*, *PRISM* challenges, albeit in a more confrontational, spectacular manner, the uneven transparency of surveillance networks by making them palpable and visible. In the case of the former, participants are able to visualize the path a particular data packet travels through the communications networks and to mark where these paths are transected by NSA and other data collection nodes. In the case of *PRISM*, Oliver and Vasiliev offer a performative example of State surveillance interference not only through the shock tactic of receiving the alarming SMS message on one's mobile, but also through the projection of the gallery audience's ISP addresses and other data on the gallery walls. What these two projects have in common is their exploration of the automated, absubjective nature of the contemporary surveillance network. While it is doubtless true, as David Lyon's work in surveillance studies makes clear, that contemporary surveillance often operates in terms of a "social sorting" of the general populace into gradations of desirability and undesirability, this activity of social sorting is still largely done not by subjects but by impersonal processes, the servo-mechanisms of control. [12]

In their book *The Exploit: A Theory of Networks*, Alexander Galloway and Eugene Thacker refer to this impersonal control process as "protocol," which they define as "a horizontal, distributed control apparatus that guides both the technical and political formulation of computer networks, biological systems and other media" [13], a definition they elaborate thusly: "*protocol is a technology that regulates flow, directs netspace, codes relationships and directs lifeforms*." [14] Galloway and Thacker's theory of "protocological networks" is useful to the present study of surveillance in a number of ways. For one thing, they emphasize that network control "is not an exercise of power 'from above,'" but "[r]ather, protocol is an immanent expression of control. Heterogeneous, distributed power relations are the absolute essence of the Internet network or the genome network, not their fetters. Thus the relation between protocol and power is somewhat inverted: the greater the distributed nature of the network, the greater the number of insider-out controls that enable the network to function as a network." [15] Two points should be made here: networks function as informatic, as we have noted, and thus transect biological and well as electronic communications systems. (Hence the privileged examples of networks in *The Exploit* are the Internet and DNA). Secondly, the immanence of protocol means that network control is constituitive of the morphology of the network themselves; in this sense, they are self-generating.

Automation and the circular causality that allows a network to form and regulate itself, of course, brings to mind Norbert Wiener's cybernetics (again, command and control), which began with the question of how systems can self-determine in order to perform their tasks more efficiently and to anticipate environmental or situational changes that may require corrective action on the part of these systems. The Chilean biologists Humberto R. Maturana and Francsico J. Valera further developed the evolution and behaviour of these systems through their notion of autopoiesis. Autopoiesis is characteristic of "machines, living or otherwise," a machine in this case constituting a unity determined by a particular dynamic organization (set of relations). Autopoietic machines are:

> *a network of processes of production (transformation and destruction of components) that produces the components which: (i) through their interactions and transformations continuously regenerate and realize the network of processes (relations) that produced them; and (ii) constitute it (the machine) as a concrete unity in the space in which they (the components) exist by specifying the topological*

> *domain of its realization as such a network.* It follows that an autopoietic machine continuously generates and specifies its own organization through its operation as a system of its own components, and does this in an endless turnover of components under conditions of continuous perturbations and compensations of perturbations. Therefore, an autopoietic machine is a homeostatic (or rather, relations-static) system which has its own organization (defining network of relations) as the fundamental variable which remains constant.[16]

Autopoietic machines are cybernetic networks with the added feature of self-replication; these machines generate the conditions of their own continuance in a particular space, and this space, along with the network of relations, constitute the unity of these machines. They are autotelic and can interlock with other systems, autopoietic and otherwise, to generate second and third order autopoietic systems.

It is possible at this point to imbricate the notion of autopoiesis and protocological networks in an autopoiesis of surveillance. Surveillance systems, as with autopoietic and protocological systems, are circularly causal and immanent to their own networks. Their autotelos generates their own components and relations; this is the sense in which surveillance is not merely productive of subjects to surveillance, but also productive of its own network morphology. A further development may be added at this point. Monika Vrečar, in her essay "Art in the New Media Environment" notes that the automated risk management associated with the contemporary surveillance apparatus operates by cycling through all possible combinations until the "risk" behaviours it is set to discover are realized. [17] Or, to put it in the terms we have been using, the protocological nature of surveillance as autopoietic system is defined by its components or nodes as being subjects of/to surveillance and its relations one of regulation, direction and production; surveillance thus maintains a homeostatic equilibrium that enables it to withstand and even predict internal and external perturbations. This is the socially pervasive double-bind caused by such organizations like the NSA; as Glenn Greenwald notes, *it is the "desire" of surveillance to "collect it all" that generates the need for surveillance.* [18] Put more simply: if you are looking for threats to the stability of the government, a rise in iPhone usage or particular trends in sopping articulated along gendered continua, you will certainly find them eventually.

It must be admitted that there are two possible objections that might be made as to the characterization of surveillance as a fully autopoietic system. The first concerns the degree to which surveillance can be said to have a unified topology that Maturana and Valera stipulate as characteristic of autopoiesis. Here, we return to the two artworks under consideration. In Paterson's *IXmaps*, and Oliver & Vasiliev's *PRISM* project, we have two works that explicitly explore the spatial unity of the surveillance network apparatus, but it is a unity that is produced through its system of relations between components. Galloway and Thacker discuss this unity in terms of internal and external individuation: "The first type of individuation is that of the macroidentification of the network as a cohesive whole. This is [...] a paradoxical move, since the key property of any network is its heterogeneity. Hence, the first type of individuation is in tension with the second type of individuation in networks, the individuation of all the nodes [components] and edges [relations] that constitute the system." [19] The immanent self-organization of the network posits itself as a unity *qua* network; however distributed and transnational, the surveillance network necessarily individuates itself as an individuated entity. One might further add that the transcoding of heterogeneity into the homogeneity of Deleuze's "digital language of control" further enables the macroindividuation necessary for the unification of the network as network.

This brings us to the second objection, which concerns a trickier set of problems – that autopoiesis is characteristic of *living systems*. Maturana and Varela state that: "the notion of *autopoiesis is necessary and sufficient to characterize the organization of living systems*." [20] Only living systems, such as cells or the nervous system, can be described as autopoietic. In this context, the question becomes: To what degree is surveillance a living system? At the earliest stages of the twentieth century's accelerated technological development, Marshall McLuhan argued that media is fundamentally prosthetic: the wheel is an extension of the foot, the book an extension of the eye, etc. But he also noted, not without ambivalence, that "after more than a century of electric technology, we have extended our central nervous system itself in a global embrace, abolishing both space and time as far as our planet is concerned." [21] (It is in this context that it should be remembered that Maturana and Valera produce an appendix to "Autopoiesis: The Organization of the Living" devoted to the technical analysis of the nervous system as autopoietic). If the emphasis has hitherto been on the technological prosthetic as an extension of the human body, we might say (with McLuhan, in fact!) that there has been a characteristic figure-ground reversal and that technological systems now use humans beings as their prosthesis rather than vice versa: in effect, an extension of what is understood as "living organism" to include the "moist" (Roy Ascott: "between the dry world of virtuality and the wet world of biology lies a moist domain"). [22]

There is a further detail regarding surveillance as (semi-)living organism, which follows from René Thom's mathematical analysis of complex (including organic) systems in *Structural Stability and Morphogenesis*. Concerning himself with sudden transformations in organic systems (through the development of chaos theory), Thom sought to provide models for understanding these topological transformations. It is clear that our present situation in which the autopoietic surveillance network of protocological control is not necessarily in our favour, but it may be that the work of people like Paterson, Oliver and Vasiliev can provide us with important topological models as well by means of their transversal cuts through the contours of the surveillance networks

(akin to biopsies performed on cancerous cells). The generation of these topological models would allow us to understand better this new organism, and give us greater insight into the nature of our relationship with it – which would include a greater understanding of the future relationship with surveillance that we would like to have. As it stands, the surveillance apparatus appears to function in a parasitic manner, feeding off the data it transcodes from the communication networks it has come to inhabit as it runs through its algorithmic computations and providing, for those in need of it (i.e., state disciplinary apparatuses), justifications for the continuation of this parasitic relationship. Perhaps it is necessary to rethink what sort of networks we would care to inhabit and what sort of protocols should be installed so that we might decide the fate of this organism that we have, albeit inadvertently, allowed to grow on and in us.

URME Surveillance: Analyzing Viral Face-crime

Leonardo Selvaggio

Chicago, IL, USA
Leo.Selvaggio@gmail.com

Abstract

This self-reflective art paper examines my position within the ecology of surveillance art focused around facial recognition. *URME Surveillance*, transforms my identity into a defense technology for the public's protection against facial recognition software. This project encourages the public to substitute their identity for my own by wearing a 3d printed prosthetic mask made in my likeness.

This paper will begin by examining our relationship to surveillance and identity by discussing the surveillance system in Chicago as a case study. I will then discuss the work of Adam Harvey and Zac Blas as two contemporary artists working with identity recognition technologies. I will then use their work as a jumping off point for my own, discussing the strategies that lead me to *URME Surveillance* including an overview of its successes and failures.

Keywords

Surveillance, Subversion, Identity, Performance, Facial-Recognition, Data, Power structure, Prejudice, Prosthetic

It was terribly dangerous to let your thoughts wander when you were in any public place or within range of a telescreen. The smallest thing could give you away… In any case to wear an improper expression on your face was itself a punishable offense. There was even a word for it in Newspeak: facecrime [1] *-George Orwell, 1984*

Considering the quote above, I am struck by the Newspeak word, "facecrime". Its implication is disturbing: that the part of the body most indicative of an individual could perpetrate a crime. This link between face, or identity, and crime is not as unfamiliar as Orwell's futuristic novel would have us believe. One example in the United states of this is the notion of Shopping while Black. The United States has a myriad of these examples: post 9-11 profiling of Arab Americans, immigration practices on the Mexican border, Japanese internment camps in World War II, etc. While these examples may be construed as racial rather than facial, the genetics that make up race have a circumscriptive determination on our facial features as well, such as eye shape and color, cheek bone height, nose width, lip size, etc. Perhaps we should translate "facecrime" into a relatively new English term from our own technological era: facial recognition.

Facial recognition software has been one of the most developed surveillance technologies of the last 10 years and it is an arms race to apply facial recognition to as many contexts as possible. For example Mark Zuckerberg, creator of Facebook, has invested in a multi-million dollar recognition program known as "Deep-Face" which can identify a face regardless of the angle the image is taken from with 97.2% accuracy: the equivalent accuracy of a human being [2]. This investment reflects Zuckerberg's interest in improving the photo tagging experience on Facebook.

The embedding of facial recognition within social media is indicative of another shift within the last 10 years: the digitization of accessible personal information, which I would argue is the most prevalent form of identity formation and expression today. In the sci-fi television show Caprica, a grieving father attempts to resurrect his daughter by downloading all the public information about her into a robot body. His rationale is that all her preferences, experiences, memories, and accomplishments in one way or another have been archived online through photos, videos, posts, articles, etc, and that these are the relevant components of who his daughter was. Research scientists working at the intersection of social media and marketing share this idea. In a 2013 study from Cambridge University, a group of researchers developed a method of constructing an identity profile of a person based solely on what someone "likes" on Facebook. They claimed that with access to this information, it was possible to accurately determine a person's gender, age, race, religion, sexual orientation, political stance, socio-economic class, whether they are an only child or not, and consumer behavior to name a few [3].

Facebook, and other social media platforms use this information to sell marketing profiles about its users to advertisers based on our perceived identity. This external creation of identity through interpreted data collected by others, along with the global reach and ubiquitous nature of social media, threatens each of our own authorships over our individual identities. When this data is combined with facial recognition surveillance systems the potential to tag this data to a physical body in the world arises. Most importantly, what will happen when this "data" is used to profile potential criminal behavior: facecrime.

Enter real world surveillance systems, such as Chicago's own "Virtual Shield". Known as the most widely surveilled city in the nation, Virtual Shield houses over

25,000 federated cameras, including blue-light cameras, cameras in public school, traffic cams, and those on busses and trains. What makes Chicago frighteningly special is that it is also the national leader in fiber-optic systems, meaning that all 25,000 government cameras are networked together, moving thousands of surveillance images into one centralized hub [4]. Housed in the 911 Emergency Response Center, Virtual Shield also has some of the most sophisticated facial recognition software anywhere in the country, and with each camera having a known corresponding physical location, Virtual Shield has the potential to track an individual's movements throughout Chicago, using their face as the trigger.

The inclusion of facial recognition in surveillance practices has had a profound effect on the way artists engage with the subject of surveillance. Though there are examples in art concerning our relationship to surveillance and identity dating back several decades, such as Bruce Nauman's *Video Corridor* (1970), several contemporary artists have shifted their strategies to include the face as a sight for intervention. Two such artists are Adam Harvey and Zach Blas, both of whom have been integral to the formation of my own work on the subject.

In 2013, Adam Harvey created *CV Dazzle*, a method that uses makeup to confound facial recognition software. Facial recognition works based on feature detection, such as analyzing the distance between each eye, or the size of a person's chin. Harvey is able to successfully change how these features appear by using makeup to alter the image the camera system sees to the point that most surveillance systems can't even detect a face let alone identify it. Harvey's work has enjoyed considerable attention and has been emulated and practiced by several groups such as the "Anti-Surveillance Feminist Poet Hair & Make Up Party," a Tumblr blog that catalogues women using makeup as a subversion tactic [5].

Similarly Zach Blas has been working on his *Facial Weaponization Suites* since 2011. His project consists of a series of prosthetic masks made from distorted 3d models of amalgamated faces. Arguable the most famous of these *Suites* is "FagFace" which is a model comprised of several queer men's faces. These faces, as with all of his *Suites*, are collected through a series of community-based workshops. The faces are scanned and then turned into 3d models. Afterwards, the models are meshed together and distorted using 3d modeling software and then fabricated into a wearable mask. Because of the distorted features of these masks, when worn, they successfully hide the wearer's face from biometric scans and other forms of facial recognition.

While having considerably different aesthetics and systems of distribution, these two projects fundamentally share the same strategy: protect the individual by hiding or occluding their face from security cameras. This idea of "hiding" is in fact the most prevalent strategy both in and out of the art community offered to the public. The majority of Youtube videos on the subject of anti-surveillance include how-to videos involving the use of ski masks, hoodies, and the hat/sunglasses combo. Unfortunately, these strategies of hiding often draw suspicion from onlookers and tend to be associated with criminality, which can have deadly repercussions. One recent example is the tragic case of Trayvon Martin, a Black teen whose death was blamed on his concealing his identity with a hoodie, rather than being the victim of a murder with serious racial undertones. In the case of Harvey and Blas, each of their projects have considerably extreme aesthetics which as a form of cultural expression make them successful as bold, overt, and public visual statements of resistance. However these aesthetics, by their very nature, will likely draw more attention to the user than is useful for a practical anti-surveillance intervention.

As a result, when considering how I might add to the ecology of art concerned with facial recognition, my goals became to address this prevailing strategy of "hiding" through an artistic intervention that underlined real world function with an emphasis on subversion and avoiding detection by surveillance as opposed to the important, yet overt, public visual statments made by Harvey and Blas. I aimed to produce something others could potentially use without drawing unwanted attention to themselves.

Thus when considering both Harvey and Blas' work, along with the majority of information provided to the public, I came to two conclusions. The first was that I needed to create a new strategy if I wanted results that did not immediately associate the wearer as suspicious or criminal. Simply continuing to hide a face with new aesthetics would not suffice. The second conclusion was that in addition to facial recognition systems, I had to consider the role of the general public as agents of surveillance as well. I required a strategy that would protect the user from being identified by cameras in the way that Harvey and Blas work does, but, aesthetically speaking, would pass inconspicuously in a crowd of people as well.

These two conclusions led me to the strategy that would launch URME Surveillance: rather than hide a face, substitute it. Show the camera and the public a face, but not the actual user's face. Having already opened up my identity for others to use in YouAreMe.Net, an interactive web project that provided open access to various aspects of my cyber identity to visitors, using my own face was a natural choice. Though I considered creating a fictional face, I decided that this would defeat the long-term purpose of my strategy. With facial recognition systems having the potential to access not only our public records, but also searchable information on social media, it would only be a matter of time until the face was found to be a fraud with the most likely scenario being that anyone using that face after a certain amount of time would be tagged as suspicious or perhaps even criminal. There was also the ethical concern that the face I created may inadvertently resemble an actual person who would be affected by a kind of identity fraud. Thus my face was easily accessible, attached to real world data, and ethically speaking, it was the only identity I was willing to put at risk.

URME Surveillance primarily consists of two anti-surveillance devices, each using my face as its primary material: the URME Surveillance Identity Prosthetic, and the URME Paper Mask. The prosthetic came first conceptually, and based on the criteria used in analyzing Blas and Harvey's work, is the more successful of the two. The prosthetic is a photo-realistic, hard resin, 3d printed rendering of my face made by my partners at ThatsMyFace.com, a company with a proprietary technology that enables them to first create a 3d model of a person's face from a single image, and then print that face as a wearable mask.

Unlike other options such as latex prosthetics, the photo realism doesn't come from air brushing over the prosthetic, but rather the color is injected directly into the material, like an ink-jet print. This results in the inside of the prosthetic, or the side of that touches the wearer's face, having all the photo-realistic features found on the outside, creating the illusion that one is putting on another person's skin when wearing the device. While the prosthetic has boundaries, such as the top of the brow, side of the face, and the under part of the chin, that are detectable to the human eye upon inspection, normally expected elements such as hair, a scarf or a hat, dramatically increase its ability to pass undetected in a crowd of people. In addition, because most surveillance cameras operate at a significantly lower resolution than the human eye, the prosthetic blends seamlessly to all but HD cameras. This is important because up until now we have ignored the human element, such as a security officer, in surveillance systems. Though both Blas and Harvey's work thwart facial recognition, they offer little to prevent a human from tracking the user from camera to camera, a task easily accomplished on a network such as Chicago's Virtual Shield. The conspicuous nature of their aesthetics- pink blob, and futuristic warrior paint- as with the majority of other strategies discusse, make it easy for a human to spot on a monitor, even on low-resolution cameras.

The URME prosthetic turns the weaknesses of these low resolution cameras into one of the project's strengths. As mentioned above, the lower the resolution of the camera the higher the chance the prosthetic has to pass undetected to a human watching a monitor because the edges appear to blend seamlessly into the rest of the face. In contrast, on higher resolution systems those edges may be more visible to the human eye due to the larger amount of visual information available. Thus there is a direct correlation between low image resolution cameras, which most surveillance systems use, and the prosthetic's ability to "pass" as a real face on a set of surveillance monitors. In this way, a security officer or other human element will continue to track the prosthetic with conviction, believing that they are in fact seeing the person presented to them on camera, "Leo Selvaggio". Furthermore, as *URME*'s strategy is not to hide but rather substitute, it is simultaneously important that the camera recognize an identifiable face. The prosthetic was designed with all the same features that trigger facial recognition and so cameras detect it immediately as a face. In other words, the prosthetic works on two levels as a kind of recognition/misrecognition duality. The camera recognizes a face while the human does not recognize the face as a prosthetic. In this way, the URME Surveillance Identity Prosthetic falsifies the documentation created by surveillance convincingly, thus subverting a system into attributing the user's actions as my own

Proof of this has already occurred on a rather large surveillance system known as Facebook photo-tagging. As previously mentioned, Facebook has invested in some of the most sophisticated facial recognition software anywhere in private sector. While several of the images on Facebook are not convincing to the human eye due to the extremely high resolution photographs, the system still successfully and automatically tags all new images of the prosthetic and its users as me.

However, as with all projects, the prosthetic is not free of problems. The first and most obvious concern is the rigidity of the resin. Its lack of flexibility does not allow for the emulation of facial expression the way some high-end latex prosthetics do. This is further compounded by its muffling of the human voice due again to the fact that the mouth does not move. Thus, any direct interaction with a human, will lead to immediate detection of the prosthetic which limits the contexts in which the prosthetic is viable.

The rigidity also presents another problem. Because the prosthetic is a 3d rendering of my face, it has its own unique set of contours and variables, such as the depth of my eye-sockets, or width of my chin. As such, not everyone is genetically compatible with it. For example, it has been known to cause injury in some by digging into the eyes of the wearer whose eyes protrude farther than own. Yet on others, it fits flawlessly. I have had successful and unsuccessful fittings on members of various races, ethnicities, and both genders. That being said, differences in skin pigmentation can present a problem. While the addition of scarves and gloves can help, their use in certain climates would draw suspicion. A atex prosthetic would correct several of these physical limitations, however the need for the prosthetic to be as democratic as possible outweighed the advantages latex would provide. The average price of a custom, Hollywood-grade latex mask is anywhere from eight to twelve hundred dollars each. The URME Surveillance Identity Prosthetic can be purchased directly from ThatsMyFace.com for two-hundred dollars. Because it is considerably less expensive than the alternatives to make, it has the potential to be more widely used. When compared to the availability of makeup in Harvey's work however, the prosthetic is still an economically privileged device, only available to those with a certain amount of disposable income.

This fact led me to the creation of a second URME device in the form of an economical paper mask. The URME Paper Mask takes the form of a DIY kit that I have manufactured. By having the buyer make the mask, the initial costs go down significantly. They are also light and very inexpensive to ship. Furthermore because they are flat

they are extremely portable. The total cost spent to make each kit, which includes the price of ink, cardstock paper, mask fastners, and bubble mailer, comes out to a little under a $1.00, which is also the price it will sell for. All URME devices are sold at cost to maximize potential use by the public.

However, like the prosthetic, the mask suffers from several problems as well. First, though it will identify the wearer as me via facial recognition, it is not passable to human eye. In order to acknowledge this flaw, I shifted the proposed purpose of the masks into a device used by those who may want a low level of protection but are comfortable asserting themselves in public space, such as in Blas and Harvey's work. When sold in packages of 12 or 24, the paper masks have been rebranded as Community Development Hacktivist Kits. Rather than try and pass inconspicuously, the goal of these kits are to make a strong unified statement about the group's right to assert itself in public space. The kits also are quite apt at producing a sense of spectacle. Photographed for the first time in downtown Chicago, the small group of 10 volunteers wearing these masks drew crowds, stares, and cameras. People were interested by this strange phenomena taking place on the street: a cluster of pedestrians all wearing the same face. The interest of the people I talked to while photographing this spectacle led me to produce other work in public, such as conducting workshops and guided walks with the paper masks. The utility of the paper mask has shifted the original goals of URME Surveillance to include civic engagement in public spaces.

While developing this project, it became clear that there were also several sociological and ethical concerns that needed to be examined. Foremost amongst these is that the URME Surveillance is asking others to present themselves in public as a White man within the context of a surveillance culture. This of course brings about questions of race, gender expression, and nationalism to name a few What does it mean to ask a Latin immigrant male to present as a Caucasian man, or a Black woman to do the same? What would it mean to any Transgender individual to become me? In addition to these questions of identity, there are also questions about the historical use of surveillance as a component of institutional racism in the form of pervasive profiling, disproportionate incarceration of non-White citizens, and the suppression of cultural and political expression in public spaces.

Though it is beyond the scope of this paper to properly survey the entanglement of racial and gender politics within surveillance practice, the most important conversation that URME Surveillance can contribute to, even more than the right to privacy, is discussion of white male privilege in public space. URME Surveillance asserts the utopian ideal that everyone could and should benefit from the same privilege that White men do, which is to simply be themselves and valued for it despite their behavior, criminal or otherwise.

The URME Surveillance Prosthetic, if undetected, allows for an individual to temporarily experience and consequently perform White male privilege in public space, while at the same time drawing attention to the very nature of privilege as a component of a patriarchal power structure that excludes the majority of Americans. It is not the goal of URME Surveillance to transform everyone into White men. I reject that notion of milky homogenization. However, by engaging the idea that white male privilege could somehow be shared and distributed to others, then as a metaphor, URME Surveillance has the potential to become a platform to examine questions of race, class, nationality, gender, sexual orientation and expression, and other factors that circumscribe our freedoms in public space.

Surveillance is a system based on fear that offers us the illusion of safety by sacrificing freedom. The source of this fear comes from the very questions stated above. That fear has lead us to build an architecture of prejudice that acts against the democratic ideals of the United States. This power structure prejudices women, prejudices minorities, and prejudices the lower class and old age. It fears Arab Americans post 9-11 and Mexican immigrants at the border the same way we once feared the Japanese we interned. Surveillance in a product of an American culture that fears Black people who shop and only finds safety in Whiteness. Want to be invisible to surveillance? Be a White man in a suite. No prosthetic needed. What is at stake is nothing short of our freedom to express and explore the very nature of our individual identities. The *URME Surveillance Identity Prosthetic* may never allow the user to be who they really are in public space, but neither does the current state of Surveillance. We are fundamentally changed when we are watched. We perform prescribed acceptable versions of ourselves rather than simply be. So be me instead. URME.

An Aesthetic Reading of Online Artivist Projects

Tuğçe OKLAY

University of Paris VIII (Vincennes – Saint-Denis) PhD Candidate
Saint-Denis, France
tugceoklay@gmail.com

Abstract

This article is an essay for a theoretical reading of the contemporary online contents in light of the contemporary aesthetic theories. It focuses on online *artivist* productions and website projects which are related to the resistance movement in Turkey, just before, during and after the Gezi movement period (June 2013). This paper tries to analyze some of the online projects and to discover creative aspects and new trends in internet aesthetics. It also observes participatory quality of online artivist projects and common language in those projects.

Keywords

Artivisim, net art, activism, occupy movements, Gezi, language, information age, and aesthetic experience.

Introduction

Our research aims to establish a theoretical reading of the contemporary online contents in light of the contemporary aesthetic theories. We focus on online *artivist* productions and website projects as contemporary online contents, which are related to resistance movements since 2008 (the great recession) to 2014.

There is a wide range of aesthetic theories in the literature. In our text we will ground on the 'aesthetic experience' notion as it provides us a revisited understanding of aesthetics, arts and their relationship to daily life. According to Dewey, the experience plays an important role in artistic creation. The fundamental element of the process of artistic expression is no longer the material work of art but rather the development of an experience. For Dewey, there is also an aesthetic aspect in 'non-aesthetic' productions and relations. An aesthetic experience cannot be held separate from everyday life experiences and the purpose of the aesthetics is to ensure the continuity between the refined art experience and daily life experience. [1] For Rancière an aesthetic experience is "a reconfiguration of the forms of visibility and intelligibility of artistic practice and its reception." [2] An artwork is "given in a specific experience, which suspends the ordinary connections, not only between appearance and reality, but also between form and matter, activity and passivity, understanding and sensibility." [3] Dewey's and Rancière's writings give us a new perspective on the relation between daily life, aesthetics and art; and enable us to reestablish this relation in today's productions. We also aim to investigate what these artistic and 'non artistic' productions tell about our political and social spaces and lives, as well as our intellectual practices.

This research also investigates the notion of language in online activist artists; training and uses of language as an artistic material and as a message. In our work, we investigate the language as a tool (material) and as a message. Computer codes, acts of hacking or electronic sit-ins represent altogether the material; whereas the written content or shared images represent the message. Our work proposes a comparative approach between different web projects that include pieces recognized as artworks and also popular projects on online social networks. We construct our theoretical reading in three main sections. First, we will analyze the political and social background. Then, we will identify contemporary *artivist* projects (from Turkey). Finally, we will explore the online content producers and their organization behind the projects.

Social and Political Background

We have been witnessing a transformation from industrial to post-industrial society: the change of societal organization as a result of subordination of the materials (raw materials, machinery) to intangibles (knowledge and information). Developments in digital technology have brought a significant change especially in the field of communication and media, but also in professional and social life. Before then, the communication paradigm was "one-to-many"; after the (r)evolution of the media this paradigm has been replaced by "many-to-many". This change refers to the passage from a mass society to a networked society. [4] Although there are still regional inequalities to access to new technologies and to new media content; the 'new medias' are altering the sense of geographical distance, increasing the communication volume, allowing numerous channels for the flow of information, providing an opportunity to increase communication speed and for interactive communication, and finally maintaining the possibility to ensure interconnection between the different forms of communication. [5]

Along with those changes in economic and sociocultural production there have been riots in several countries in the world. The causes and consequences of those riots are differentiated by countries but there are unignorable similarities that we are interested to discover: the resistance movements built a new language and created intelli-

gent and ironic web projects which are related to creative productions on the streets. We affirm that those web projects and online productions offer us aesthetic experiences in Rancière's and Dewey's terms.

The Projects

In the 1990s in Europe, especially in Eastern Europe and Italy, we encounter activist artistic projects which interrogate notions of information, reality, and perception. These projects were influenced mainly by the writings of William S. Burroughs and Hakim Bey on the media and the manipulation of information. [6] Both authors proposed to 'hack' Medias (tools of communication). Hacktivists created pirate radios and TVs, fanzines, fake personalities, etc. We realize that similar projects appeared in Turkey within the period since the second part of the 2000s to 2014, densely just before, during and after the Gezi movement period (June 2013).

We also observe blending of 'virtual life' and 'real life' experiences, transitions between the streets and the internet. It might be necessary to mention that the relationship between the streets and the internet is a question of power struggle; here we refer to Henri Lefebvre to understand this conflict, the characters of those two spaces and their importance in the resistance movements. [7] Both the streets and the internet are social spaces and they are subject to the social movements as social products, where we may observe control, domination, and power struggles between the people and the political authority. Two remarkable examples of the transition from the Gezi movement: Standing Man and Rainbow Stairs were civil disobedience acts which are reproduced afterwards in several cities, and images from all over the country had been circulated on the internet.

Hoax News Websites

One of the projects that we observe is hoax news website *Zaytung*. *Zaytung* questions the 'realities' of everyday life and politics. It interrogates the media's attitude in disinformation and also truthfulness of the news broadcasted by mass media organs. We also observe similar websites in other countries: The Onion (USA), Le Gorafi (France), News That Matters Not (India), El Koshary Today (Egypt), etc. [8]

We examined that in the hoax news websites; articles are about current events, politics and politicians, but also the lifestyle which is presented as *American Dream* for the middle class workers, especially for whom working in *Bullshit Jobs* (referring to the jobs in the service sector which do not lead to a real production) in Graeber's words. [9] Visually hoax news websites look like the websites of the 'real' newspapers; they also have weekly magazines where the authors criticize the content of such magazines. For example in the mass media, we usually notice articles entitled "Where to eat this weekend?" That's how they make publicity of the restaurants, and also a specific way of life, amazing holidays, etc. The hoax news websites transform or *detourne* those articles with humor, as International Situationists would do. [10] For example, in the satirical newspaper article, the writer claims to be invited to a student's place in the weekend, and writes that there was only pasta to eat in order to underline the reality in contrast to the constructed image by the mass media. They also prefer to use the mass media's language, to mock, as it was an article in *The Wall Street Journal* or *Le Monde.*

We claim that their production can be seen as awakeners, the content offers us a moment of alienation (a disruption point) in Brechtian way (*distancing effect* or *estrangement effect*). We may read their work by Dadaists' claim: "*Art, should not be an escape from daily events, but should instead make visible the violence, chaos and hypocrisies of contemporary life.*" As Hugo Ball also says: "*For us, art is not an end in itself [...] but it is an opportunity for true perception and criticism of the time we live in.*".

Fake Personalities

Especially in 1990s fake personality phenomenon was common: *Luther Blissett, Darko Maver* (one of the projects of 0100101110101101.org), *Harry Kipper* were already known with their mystified histories. *Yes Men* of RTMark is also one of the well-known examples of spoof characters: Two activists, Jacques Servin and Igor Vamos (alias Andy Bichlbaum and Mike Bonanno) who mock liberalism and criticize the liberal economic system satirically by making presentations on behalf of the World Trade Organization (WTO) and in the name of Dow Chemicals (widely protested multinational company of chemicals). *Yes Men* built fake sites that gather the originals (the one for G.W. Bush is no more available, but the fake WTO website is still accessible). *Yes Men* also distributed fake copies of New York Times with the title "War in Iraq is over" in 2008. In their projects, we observe a criticism of the political and economical system but also the media and the information sources of the society. Obviously they were not the first who created fake personalities or fake satirical newspapers; here we should mention Mark Twain's satirical newspaper articles and Orson Welles' film *F for Fake* and his radio show *War of the Worlds*.

In Turkey, a fake personality was created as *Şafak Başgan* following the Gezi movement (affected summer of 2013). During local elections in March 2014, there was a candidate named *Şafak Başgan* who lead an alternative campaign by creating a satirical personality, especially using the social media, Facebook and Twitter. [11] His Facebook page got 10720 likes and he has 5600 followers on Twitter (May 2015). His project was born as a reaction to gentrification politics of the city of Istanbul and the *crazy projects* of the Turkish government. [12] (Figure 1)

His campaign's visuals, videos and language are worth to analyze because again we can read those materials as *awakeners* and *détournements*. His campaign was criticizing political scene, existing parties, and neoliberal politics applied by the government and the mayor of Istanbul. His campaign was claiming that none of the candidates (includ-

ing the opposition) are worth to vote for. Some people were not supporting his choice of mocking political scene, but his campaign forced people to think about it.

Figure 1. On the left, Safak Basgan "Vision 1963: We will take Istanbul back to 60s!" On the right, ex PM Erdogan "Vision 2023, Turkey is Ready!" (2023 is the 100th anniversary of Turkish Republic)

Hacking – Code Writing

Hacking is also another example of aesthetic experience as a performance and also as a creative act. In Turkey, we observe electronic sit-ins like the *Electronic Disturbance Theater*'s performances especially when the society was discussing the new internet law and censorship in 2011. *RedHack* (*Anonymous* like hacker group, active since 2005) took down some governmental websites and leaked information in several operations. A virtual protest was also organized via Google Maps which gathered thousands of people at Taksim square on Google Maps. [13] (Figure 2)

Figure 2. Protest on Google Maps, 25 January 2010.

Figure 3. RedHack's hack on public buses, Istanbul, 2013.

In 2013, during the Gezi resistance, RedHack hacked the screens inside the public transport services (public buses in Istanbul), to say that the resistance will continue as they wrote "Durak yok, yola devam" which means "No station, keep going on" where it should be written "will stop in the next station". This was a clear allusion to the slogan of the government party (AKP) "Don't Stop, Keep Going On!". (Figure 3)

Photoshopped Posters and *Caps/Memes*

We've noticed *photoshopped* posters and captures as well. Due to the 2.0 version of internet and the simplification of interfaces, computer and internet users had the possibility to create or manipulate images. As a simple internet user, anybody has an access to huge amount of data to use to reproduce, to manipulate; and these users also have possibility to diffuse their productions online. (Figure 4)

Bobiler is an alternative online platform where the users may share the *caps*, videos, or images they created or manipulated. As we already mentioned for other projects, in this website and those productions we may observe a common language as well. [14] Here we analyze the *Bobiler* community and we realized that even if such platform

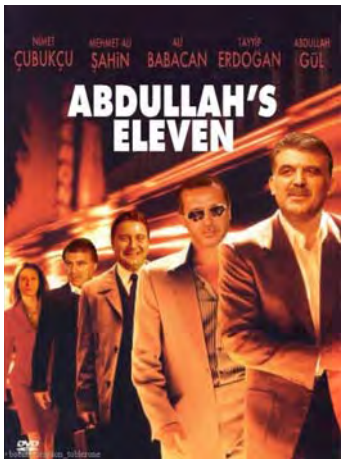

Figure 4. A *photoshopped* (manipulated) movie poster

does not exist in other countries, the practice of photoshopped images and caps/memes was observed. (Figure 5)

Those productions are driving us to reconsider our daily and political lives, with a sense of humor and intelligence. Depending their qualities, they attract much or less attention.

Who produces those projects?

Content producers are observed to be generally between 20 and 30 years old young students or workers in several examples according to our interviews with the initiators. We see that those who filled the streets intersect at a very large proportion with those who produce and consume on the internet. The youngsters bring a dynamic aspect and perpetuity to the movements and to the online projects.

The production process is collective and participative. In general, these projects are the products of network communities composed of individuals from different social

Figure 5. A *caps(meme)*, Obama: "No, you first."

backgrounds (majorly middle-upper class, mostly leftists); with a group of editors in charge (see Zaytung, Bobiler, Ekşi Sözlük, etc.). The content creators have pseudonyms which are also part of the satirical content. In hacking activities the participants are anonymous and they also act collectively. We observe that both users and visitors are especially from the big cities, Istanbul in the first place, Ankara, and Izmir then the rest of the country; similar to the number of internet users across the country.

On collective production of the content or an action, we may refer to the notion of *social sculpture*, attributed to Beuys, it is not required being a geek, an expert or a member of an artistic community to create and share satirical texts or artistic productions. Walter Benjamin's listener participative radio idea also corresponds to the idea of collective production of individuals.

Conclusion

In this article we analyze contemporary online contents in light of the contemporary aesthetic theories. We focus on online artivist productions and website projects which are related to the resistance movement in Turkey. We discover the disruptive and creative forces of the analyzed projects, and investigate new trends in internet aesthetics, observe participatory cultures of online *artivist* projects and the importance of language in those projects. We observe that they create an aesthetic experience and an occasion for alienation both for users and visitors.

We can state that it is necessary to broaden our research to the other countries and constitute a comparative approach between these countries where different resistance or Occupy movements occurred, such as Greece, United States, Egypt and Tunisia.

Finally, as the resistance notion became a popular 'image' and 'trend', it turned into an object of consumption for different social groups. So, it will be interesting as well to question the role of the *artivist* projects in the market as new intellectual merchandises.

Geopolitical Subjectivity

Tomas Laurenzo

School of Creative Media
City University of Hong Kong

tomas@laurenzo.net

Abstract

Rhetorics conceived in geopolitically powerful contexts fail in allowing for the different relationships between art and politics that appear in the periphery. This paper analyzes this from a framework of cognitive capitalism. We identify a need for a sociopolitical vocabulary in new media art rhetoric that takes into account the geopolitical context. By reproducing the center–periphery model, peripheral art is reduced to a dichotomy proper of the modernizing discourse and to the arduous task of developing a replacement of the stories that constitute "the other". Nevertheless, we argue that it is possible to assert the existence of both a distinct reality and the parallel construction of a language that transcends the re-reading of international tendencies from a local or "localist" perspective.

Keywords

New media, new media art, aesthetics, geopolitics, politics.

Introduction

Politics is aesthetics in that it makes visible what had been excluded from a perceptual field, and that it makes audible what had been inaudible.

Jacques Rancière, 2004

In order to analyze a cultural phenomenon it is needed to take into consideration its historical, social, and political contexts. However, art's relationship with politics is extremely complex and admits a wide plurality of views.

Rancière's quote casts a first conceptual light onto this relationship: there is an immanent artistic characteristic in politics, for its verbalization of societal processes is inherent aesthetic. Coherently, Luis Camnitzer argues that the Tupamaros – the 1970's leftist Uruguayan guerilla movement – embodies Latin American conceptualism's most authentic and relevant artwork. According to Camnitzer's argument, there is an undeniable aesthetic quality in, for example, the Tupamaros's military actions, such as the *Toma de Pando*[1].

The sociopolitical context has always been a "central aspect" of artistic production, although it "long remained inconspicuous, or even invisible". According to Friesinger, "It took the great exertions of the context-oriented methods of modernism to return it to the field of view, from which it was hidden, for the most part, by the tendency of bourgeois art appreciation to oversee the social and historical embeddedness of an artifact or an aesthetic approach."[10] It is not, still, until the avant-gardes, that appears what Peter Bürger calls "a new art-based praxis for life", a reaction to the identification of art being the objectification of the self-understanding of the bourgeoisie [4].

Even if we assume the immanence of the political context in art production, the characteristic of this relationship is still unspecified. Kenning argues that art betrays itself if it is too direct in its opinion, especially in its political opinion, while Rancière states that "an art is emancipated and emancipating when it renounces the authority of the imposed message, the target audience, and the univocal mode of explicating the world, when, in other words, it stops wanting to emancipate us." [15]

As Steve Klee notes, this discussion on the ambiguity of art does not include explicitly political art in what constitutes an unforgivable reductionist blindness: "If all art that incorporates clear political slogans and demands is dismissed as authoritarian because of its univocality then we will misrecognize those moments when these slogans actually introduce ambiguity into the social by forcing a split in the distribution of the sensible." [15]

This blindness is not explained by, but resonates with the hegemonic centrism of the art discourse analysis. Political art seems to be more common and more easily co-opted by the peripheral artworld.

Coincidentally, Buckley argues that "as a political mode of knowledge, art is powerful precisely for the ways in which it can disarticulate those received or existing forms of political and disciplinary subjectivities (that which Rancière has called the 'regimes of perception')." [3]

Furthermore, the dismissal of political art neglects activism. The militant practice of artists who reclaim certain media, languages, processes, or contexts as their

[1] An episode framed in the Tupamaros's guerrilla warfare in the 1960s. On October 8, 1969, several members of the Tupamaros took by assault the police station, fire station, the telephone exchange and several banks in the city of Pando, 32 kilometers from Uruguay's capital city, Montevideo.

own. Activist art has played a significant role in creating appropriation techniques and in creating and enabling spaces that, in subsequent stages, permitted artistic appropriation.

New media art, in particular, offers a tremendously rich and effective field for activist art. The somewhat recently coined term *hacktivism* stands for the blending of conceptually subversive new media ("hacking") practices and politically subversive ones.

According to Blais and Ippolito, the executable nature of new media art – in particular where mass digital media are appropriated – constitutes its differential and more powerful characteristic, since it allows for concrete, active, influence on the world.

In their own words: "Executability has given hacktivists not only an arsenal of new tools but a much wider arena in which to exercise these new powers. Because computers are now linked via a global network, code that affects a single operating system can be redirected to execute on computers around the world. No longer confined to the sanctuaries of gallery and museum, digital work has been executed in government-agency databases, in corporate Web ad banners, and on the hard drives of private citizens."[2] However, art, activism, or "hacktivism", by no means emerged with digitality. As Neumark affirms, speaking about Fluxus's Mail Art: "They not only expanded the boundaries of art, media, and communication, they defi(n)ed them. They traveled not as vehicles, but as meaningful cultural and artistic objects, while shifting the meanings of culture, communication, and art objects in their journeys. The journeys of Mail Art marked a particular configuration of geography and social, economic, and cultural relations; they contributed to a remapping of the relation between art and everyday life." [7]

This early example of media appropriation showcases the re-configuration that political art may provide: an informed, critic dialogue with the sociopolitical context of the art practice's cultural artifacts and societal inscription. Such dialogs are transversal to the specifics of the art practices, or, as Matthew Fuller puts it, the specific "art methodology" [11].

The need for context analysis is rooted in the intrinsic dialectical nature of art. In effect, all art is political, for, as Ricœur notes, "praxis incorporates an ideological layer; this layer may become distorted, but it is a component of praxis itself." [11]

Even if every art production undeniably entails an ideological standing, we do not pose that there are no differences between political and apolitical art, or, we could say, between explicitly and implicitly political arts. A parallel can be traced with interaction: even if every artwork can be deemed interactive, there is a distinctive aesthetic quality in interactive art that should not be left unconsidered.

It is, however, necessary to broaden our scope and discuss some concepts that allow us to introduce some political notions into our new media art analysis discourse. We identify a need for a sociopolitical vocabulary in art's (and very especially new media art's) rhetoric.

General Intellect and Cognitive Capitalism

A useful model to start tackling the dialectal relationship between art and context is provided by the concept of "general intellect"[2], first presented in Marx's Grundrisse in a section entitled 'Fragment on Machines' (written 1857–8, first published 1939) [16].

The general intellect describes an increasing involvement and relevance of the human knowledge in the work process, and the understanding that "wealth is no longer the immediate work of the individual, but a general productivity of the social body that utilizes both workers and technologies". [16] The notion of general intellect makes available a political understanding of aesthetics, language, and society by addressing that information – embodied in technical expertise and social knowledge – became a crucial force of production.

Ultimately, the general intellect "is a measure or description of 'how general social knowledge becomes a direct force of production'." [11]

In Paolo Virno's terms, the general intellect is the linguistic cognitive faculties common to the species, which constitutes a new kind of richness: *cognitive wealth* [27].

This cognitive wealth is not synonym with dematerialization. Even, if as Lazzaratto notes, "Immaterial labor finds itself at the crossroads (or rather, it is the interface) of a new relationship between production and consumption. The activation, both of productive cooperation and of the social relationship with the consumer, is materialized within and by the process of communication." [18] It can be understood that "capitalism informational economies tend to involve more materialization and commodification of knowledge and, contra the thesis of dematerialization, increased consumption of what is classically termed as matter (oil, paper, aluminum, heavy metals and plastics)." [13]

General intellect, as a model, leads to the analysis of art's role as a means of knowledge production, that is, wealth creation, and the dialectal relationship that this has with said artistic processes.

The operation of the general intellect within the society is aptly seen via the thesis of cognitive capitalism. Indeed, since the crisis of Fordism, capitalism has seen the more and more central role that knowledge plays, and the rise of the cognitive dimensions of labor.

As Vercellone notes, "this is not to say that the centrality of knowledge to capitalism is new per se. Rather, the question we must ask is to what extent we can speak of a new role for knowledge and, more importantly, its

[2] Although there are related concepts, such as Spinoza's "Common Notion", or social brain, the General Intellect proves to be especially apt, if only thanks to its framing within Marxism and capitalism theory.

relationship with transformations in the capital/labor relation." [26]

Cognitive capitalism differs from traditional capitalism in that – as Talankin once said in order to attack Vygotski – it "virtualizes" the concept of tool or that of labor, and allows for mental factors such as culture to be determinations, rather than strict economic factors. [29]

It is indeed striking how Marx's works and contributions still apply after the crisis of Fordism and Taylorism. In the cognitive capitalism, the valorization of knowledge leads to a new form of capitalism; this valorization operates with knowledge not as a common good, a human acquis, and instead treats it as commodity, as an article of trade or commerce.

Cognitive capitalism is, then, a new stage of capitalism after industrial capitalism, which does not have to rely on the affluence of digital technologies, but, instead, relies on the creation of knowledge and on the economic return of the cognitive dimension of work.

This new stage is built upon a crisis of the labor theory of value. Effectively, the labor theory of value shows how – in the industrial capitalism – the capital appropriated the production and abstracts itself from labor. Labor is operated by the capital in such ways that allow for its commoditization. Thus, division of labor and serialization are instrumented, permitting to measure labor in simple unqualified work units.

In cognitive capitalism this, however, does not apply directly, as the general intellect adopts a "diffuse intelligence" where capital does not seem to play a necessary nor defining role in its creation. Ownership of the means of production is relegated to the background and knowledge becomes central. Knowledge that transcends the expertise in operation of new technologies but instead also involves the ownership of the social processes of creation of new knowledge.

In order to satisfy capitalism's need of commoditization, *cognitive capitalism is built on artificial scarcity*. This commoditization operates on things (knowledge) that are not commodities, thus, it requires the private appropriation of knowledge.

This artificial scarcity is created by fencing knowledge. This way, knowledge is not set free in the society but, instead, is bounded by intellectual property laws, patents, and secrecy policies that keep it in the private sphere.

It is particularly interesting the role that tertiary education (which is based on public funding) plays in cognitive capitalism. Universities educate cognitive workers to operate in the private sector, applying their education on the creation of value that stays within the companies and does not return to society.

There is an underlying scission between what is *public* and what is *common*. Artificial means of scarcity divide them and prevent knowledge to be set as part of the common; instead, cognitive value returns to the society as the result of a choreographed production, as knowledge–artifacts and not as knowledge (in Flusser terms: applied scientific text). In this way, knowledge remains in the Marxian reign of need without being able to reach the reign of liberty.

New media art and politics

> *Pop culture and the mass media are subject to the production, reproduction and transformation of hegemony through the institution of civil society which cover the areas of cultural production and consumption. Hegemony operates culturally and ideologically through the institutions of civil society which characterizes mature liberal–democratic, capitalist societies. These institutions include education, the family, the church, the mass media, popular culture, etc.*
>
> Dominic Strinati, 1995. [25]

As we mentioned, new media art's potential executability has allowed for hacktivism strategies that foster the perennial dialogue between art and politics.

Art is intrinsically deregulatory: it exists – or may exist – on its own epistemological framework, or, we could instead say, on its own ontological universe. However, new media art's relationship with technology situates it on a peculiar situation, with a unique position to reflect on contemporary political issues.

The interplay between art and the political significance of its materiality is not new. The Italian Arte Povera, for example, was "seen by some as radically political in the late 1960s", as a direct result of their use of *poor materials*, which "opposed not only the industrial aesthetic of American pop and minimalism, but also all forms of systematic, and hence authoritarian, thinking, celebrating instead individual, lived experience through a 'new humanism'" [14].

As well as the political quality of Arte Povera resides on, or emerges from, the relationship with the material substratum, new media art's media appropriation carries a political art discourse.

If we are to discuss new media art's *politicality*, it is necessary to consider the politics of the appropriation process and not only the specific artistic activities (or methodologies) that this appropriation enables. In this way, while tempting, the discourse of executability or the analysis of affordability, should be postponed.

As Christiane Paul states, "art has always employed and critically examined the technology of its time" [21]. However it is new media art's appropriation what distinguishes it as a genre [17].

It is no accident that new media art co-exists with cognitive capitalism: both are result of the valorization of knowledge. What capitalism does in terms of commoditization, art does in terms of re-definition and re-edition of its own praxis, and it is in this duality where the dialectal relationship new media art–politics exists: in the orthogonal (if not antagonistic) approaches to knowledge creation and societal administration.

In this analysis it becomes necessary to understand that cognitive capitalism's relation with knowledge is not emergent but politically designed, and in this environment the art practice exists and is adopted and co–opted.

New media art's systematic appropriation – that we call media appropriation – [17], though, is intrinsically and unavoidably political, for it undermines the basic underlying process of cognitive capitalism. It is more probable that it is this ontological antagonism what lies behind new media artworks having "gradually formed a common practice whose objectives allude to utopian theories of social organization lying closer to certain visions of communism, direct democracy and anarchism, rather than to the realities of neoliberal capitalism within which new media are produced and predominantly operate" [24], instead of previous discourses of mere opportunity, exposure, and scope.

Perceptual capitalism

New media art often proposes a systematic logic of dematerialization, as a natural result of the immanence of the digital. Accordingly, a relatively recent term has come into use in the analysis of digital artistic practice: post-digital [6]; although loosely defined, it makes explicit the pervasiveness of the digital realm into cultural production, and effectively states that its omnipresence implies a qualitative change of both the production and its consumption: its appreciation, valuation, and eventual conversion into economic goods no longer depends on, or is related to, its digital quality.

This is often seen as a move towards a more human-centered evaluation of culture, which is, by no means, a requisite, and therefore, a naïve reduction. Instead, post-digital refers to the standardization of the digital in all the aspects of human culture, rendering its digital quality meaningless if considered separately from other values, aesthetical, social, or functional.

This immanence of the digital reminds us of the triumph of capitalism. Žižek recounts an anecdote where an editor asks a journalist (Marco Cicala) to replace "capitalism" with a synonym, like "economy" [30]. This rendering of capitalism as not only the ultimate, but also the *only* socio-political and economic arrangement of society attempts to remove from the framework of analysis the very components of capitalism. *It attempts to establish a post-capitalist discourse.*

We need to be aware of the ubiquity described by these two "posts", while focusing on (at least some of) the implicit socio-political discourses that these hegemonies carry.

Geopolitical subjectivity

The digital revolution is over.

Nicholas Negroponte, 1998. [6]

However prevalent the forces of globalization are, the automatic translation of centrally[3] conceived models, interpretations, and practices, constitutes an eminently political act. Besides the linear acknowledgement of a debatable necessity of historical and context rooting, the construction of a centrally conceived rhetoric is never innocuous.

Postcolonial theory has traditionally recognized the center–periphery asymmetries in the construction of knowledge, with an explicit intention of reclaiming histories that have been neglected by dominant historical narratives. However, postcolonial studies "have been notoriously absent from electronic media theory, and criticism", being somewhat stuck in an inebriated recognition of "the potential of new technology". [9]

New media art, meanwhile, poses again a rather unique perspective within the arts for its inherent technical requirements locates it on an axis of usefulness usually alien to the art discourse. Especially when, according to Raunig, activist practices are allowed only if they are "purged of their radical aspects, appropriated and coopted into the machines of the spectacle." This becomes apparent in "mainstream media, which invariably reproduce only two patterns in reference to insurrection: the mantle of silence or the spectacularizing and scandalizing of protest." [23]

Where the real world changes into simple images, the simple images become real beings and effective motivations of hypnotic behavior. The spectacle, as a tendency to make one see the world by means of various specialized mediations (it can no longer be grasped directly), naturally finds vision to be the privileged human sense which the sense of touch was for other epochs; the most abstract, the most mystifiable sense corresponds to the generalized abstraction of present–day society.

Guy Debord, 1977. [8]

It is under this framework that the need of a geopolitical view of new media art appears. As Garcia Canclini notes, geopolitics refers to large global structures and implies cultural or symbolic power in knowledge practices. It is then a problematic field, a descriptive tool that incorporates a certain asepsis product of its own conscience [12]. Geopolitics can be seen as a tool for uncertainty, as an admission of the Kantian nature of models.

Nevertheless, this pretense for asepsis should not be understood as lack of involvement, for our conceptualization is one of resistance. As Lazzarato states, "to say no is the minimum form of resistance". Our resistance

[3] Central, as opposed to peripheral, originating in the core countries. Anew, within world systems, dependency, and post-colonial theories.

must open a creative process, a process of transformation, of active participation. [19]

The very first "no" that we must say, our first form of resistance, consists on acknowledging that the artistic historical narrative of media arts and its analysis of context interrelation is constructed from within a central perspective. Even the general intellect, as introduced, does not allow for a characterization of the geographical distribution of the social worker, nor it reflects on the implications of such distribution and the relation with the centers of power.

New media art in the periphery cannot be apolitical, for the very appropriation of technology is a political event: *it implies surrendering to an applied scientific text that has been written in the center*.

As art history is written in, from, and for the cultural centers, the characteristics of peripheral art in general, and peripheral new media art in particular have not been analyzed or, at best, have been inscribed on a centrally conceptualized narrative, carrier of colonialist granting of meaning. A narrative that fails, for example, to understand how political art naturally and systematically appears in the periphery (very specifically in Latin America) without creating much (or any) of the ontological tensions that appear in central narratives due the lack of ambiguity.

Camnitzer, in his book "Conceptualism in Latin American Art: Didactics of Liberation" proposes "conceptualism" as the original process of conceptual and political art [5].

Latin American conceptualism composes an original artistic movement that appeared and expressed itself with its own language, in parallel to central artistic processes.

Yet, as Camnitzer shrewdly points out, "art history is written in the cultural centers" and so, any difference between conceptual art and conceptualism has not been analyzed.

Artistic discourses that emerge outside of the cultural centers of the world, according to Camnitzer, have their own roots and its understanding requires an appropriate historical framework. However, the label "Latin American conceptualism" clearly is "a concession to the hegemonic taxonomy" [5].

In this paper, we do not aim at discussing, or finding, the artistic languages that emerge from the geopolitical periphery, but we rather work in understanding that the sociopolitical and economical contexts always play a defining role in the construction of the (commodifiable) knowledge, the worldview.

If new media art is always conceptual, [17] then the sociopolitical dimension adopts a very particular role. It is in new media art's relationship with technology where we are to focus; not in the construction of a "purely artistic" language, but in the differencing components of new media art. If we identify media appropriation as the defining path of new media art, and explicitation as it's most transversal aesthetic quality, [17] which differences in them appear in the periphery, specifically, in Latin America? Or, what conceptualist new media art entails?

By reproducing the center–periphery model, Latin American art is reduced to a dichotomy proper of the modernizing discourse and to the arduous task of developing a replacement of these peripheral stories that constitute "the other".

We should reflect on whether the idea of "Latin American art" responds to specific contexts where each region contributes from their cultural and symbolic horizons, or if it is structured according a universal reference frame that contains the concepts of modernity, avant-garde, and progress [22].

Nevertheless, we argue that it is possible to assert the existence of both a distinct reality and the parallel construction of a language that transcends, at least in some cases, the re-reading of international tendencies from a local or "localist" perspective.

The simultaneous appearance in Latin America, of processes that restructure the relationship of art with its materiality, should not be seen as a prefiguration (nor re-edition) of the Italian Arte Povera but, instead, as a genuine instrument for probing reality and for the construction of an autonomous poetic.

In this context we can talk about Latin American conceptualism as a *strategy* instead of a *style*. Even if the style is influenced by the center, the periphery historically has not cared about stylistic nuances and produced conceptualist strategies that focused on communication [22] [5].

In analyzing peripheral new media art, it becomes essential to understand how it calls into question an *arrangement of power* constructed from a hegemonic canon centered on Europe and the USA, that operates as an articulatory axis for interpretation. Specifically, an axis that has to prevent us from the perennial risk of exoticism, a risk always present in centrally constructed art narratives.

Media appropriation in the periphery

We are annoyingly citing facts of the same species, and doing by imitation what others did in ignorance, to prove that we have studied the lesson.
Imitate originality, as you imitate everything.

Simón Rodríguez, 1828. [5]

In the periphery, with its contextual conditioning, the *necessity* for originality seems evident. In Simón Rodríguez terms, "we invent or we are mistaken".

From the assumption of the need of a peripheral new media art constructed from a non-hegemonic discourse we can state that the traversing of the axis technology consumer–technology producer cannot be performed in the same way that it occurs in the center, for the rela-

tionship with technology and its societal inscription are radically different.

Arte Povera proposed the liberation that arises from renunciation, stating – among other things – that art can (re) emerge from a tabula rasa of materiality. Similarly, conceptual art appropriated the meaning and use of tools, of apparatuses produced by technology.

Both strategies implemented an appropriation of the *poetic dimension* of these apparatuses; however, they did not appropriate their *technological dimension*, technology is taken as contextual, as something given. It appears for art to reinterpret, remix, and adopt it.

New media art proposes this technological dimension as part of the sensible, it inscribes the reason, purpose and technicality of the tools into the art practice, "fractalizing" the technology and its products: each change creates new tools and new possible changes, it systematizes serendipity.

It is natural that in a society of knowledge an art language is created from within this knowledge; therefore, it is in the differences of the relation with knowledge where a big part of the need for a peripheral, conceptualist, new media art, resides.

In fact, what is needed is a meta-appropriation: the sociopolitical appropriation of the context that would allow for original new media art, that is, *the appropriation of the processes of construction of knowledge.*

Camnitzer's aforementioned attempt to inscribe the Tupamaros's guerilla into an artistic discourse becomes, under this light, more sensible: in the periphery, the political dimension is inseparable from the conceptualist art practice.

As Chomsky stated: "'Globalization' is used within the doctrinal system to refer to a very specific form of international economic integration designed in meticulous detail by a network of closely interconnected concentrations of power: multinational corporations, financial institutions, the few powerful states with which they are closely linked, and their international economic institutions (IMF, World Bank, WTO, etc.). Not surprisingly, this form of 'globalization' is designed to serve the interests of the designers." [20]

Coherently, Thomas "argues for an approach which is far more alert to the historically specific forms which it adopted in different periods and places, as well as to the various strategies employed by colonial projects, their discursive successes and existential failures." [28]

As Alonso states, in his "praise of low tech", it is fallacious to think that only from the technical possession a critic discourse can be created. [1] What is needed is the creation of differential strategies in the relationship with technology. "Strategies", as systematization of a "problematic insertion" in the relationship with applied knowledge.

Many of such strategies are possible, from a technical postmodern Arte Povera (both as a reclaim of the low tech and as the proposal of a ground zero for the appearance of new aesthetics) to actively working on the creation of processes of meta-appropriation.

What remain fundamental are the identification of these strategies and, very especially, the understanding of the political stance that they inevitably entail.

Nicholas Negroponte is quoted saying that the Digital Revolution is over; we cannot help but hope that it is just starting.

Scambaiters, Human Flesh Search Engine, Perverted justice, and Internet Haganah: Villains, Avengers, or Saviors on the Internet?

Andreas Zingerle

University of Art and Design
Linz, Austria

andreas.zingerle@ufg.ac.at

Abstract

In recent years, Internet users have been increasingly participating in so called digilantes or cyber-vigilante communities, becoming self-appointed avengers of justice who wade through the Internet to hunt down unlawful netizens. These groups see the legal mechanisms for criminal punishment as ineffective and use social networks to crowd-source both the prosecution and the execution of punishment. I conducted an experimental investigation into these justice-seeking activist groups to compare the 'scambaiting' anti-fraud movement and their methods and similar web-formations like 'Perverted justice', 'Human Flesh Search Engine' and 'Internet Haganah'. Each group's motives are presented with recent examples, and parallels are drawn to similar projects carried out by journalists, artists or activists. Mass mediated prosecutions entertain popular culture and are used to regulate social norms. It was found that vigilante communities use congruent techniques in gathering intelligence and use comparable prosecution methods like shaming, humiliation, cyber bullying, or doxing. Furthermore, moral concerns of these deviant actions and possibilities of governmentality are discussed.

Keywords

Vigilante online communities, digilantism, hacktivism.

Introduction

Vigilantes are self-appointed citizens who take the law in their own hands, when law enforcement is inefficient or not present. In 17th and 18th century feudal societies, personal vengeance was exacted through duels using swords or pistols. The two opponents agreed on matching weapons and to obey certain rules. In Western cultural traditions, the vigilante has been romanticized as the dissatisfied moral avenger: Robin Hood and his fellow outlaws fight the rich and share the booty with those in need. [7] During the Gold Rush in the 19th century, vigilante committees were formed in mining communities to deal with the rising crime rates and the lack of legal institutions. [18]

Nowadays, vigilante communities are seen as community service, like the national neighborhood watch groups 'USAonwatch' or 'Guardian Angels' in the United States or the 'Ourwatch' community in the United Kingdom. Often, members of these groups have difficult relationships with the police and prefer to take justice into their own hands and deal with the criminal themselves. In California, the Minuteman project is an activist group, which uses a network of webcams to patrol the US-Mexico border and monitor the influx of illegal immigrants. It describes itself as a 'neighborhood watch' on the borders. Volunteers report undocumented immigrants and smugglers to the Border Patrol. However, there have also been cases reported, where rights of Mexican citizens have been violated by shaming and humiliating them.

In one report, Bryan Barton caught a Mexican citizen crossing the border illegally, detained him and forced him to pose with a t-shirt saying: 'Bryan Barton caught an illegal alien and all I got was this lousy T-shirt'. [4] After the incident, the Border Patrol and the Mexican Consul agreed that no crime had been committed, but the Mexican immigrant was still publicly humiliated. When the Minutemen are not patrolling the border, they erect fences along the US-Mexican border.

Since the late 70s, groups of 'Real-life Superheroes' (RLSH) patrol cities. Inspired by their fictional archetypes like Batman, Guy Fawkes-masked V or the Watchmen group, they hide their identity by wearing masks and dress up in costumes to fight crime or perform public services, just like their comic book heroes. [31] Across the globe there are more than 200 registered RLSH that can be grouped into 'social workers with capes' and 'radical activists'. [19]

With the advent of mass-mediated online communication, vigilante groups establish themselves in web forums, discussion sites and Social Media platforms to express alternative public opinions on these new frontiers of the Web 2.0. Their actions have many names, 'DIY-justice', 'e-vigilantism', 'civilian policing', 'digilantism' or 'cyber-vigilantism', but in this article I will use the most commonly used name 'Internet vigilantism'.

Although a number of studies have examined vigilante communities like the 'Scambaiters' [38, 27, 32], 'Perverted justice' [12, 14], 'Human Flesh Search Engine' [37, 8] or 'Internet Haganah' [35, 9], a review of the literature indicates that there has not been a focus on mapping out parallels between those communities. With this paper I want to provide additional insights into the similarities in the use of tools and techniques and comparable prosecution methods used by these vigilante groups.

The paper is composed of four themed chapters:

- The first section of this article examines the scambaiting community 'Artists Against 419' (AA419) and outlines their prosecution tool 'Lad Vampire'.
- Chapter Two explains the 'Negobot' and 'Chatcoder' tools that the 'Perverted Justice' (PJ) movement uses.

- The third chapter is concerned with the 'Human Flesh Search Engine' (HFSE) and lays out their recent activities.
- The fourth section presents the findings of the research, focusing on the 'Internet Haganah' (IH) movement.

Finally, the conclusion gives a brief summary and critique of the moral and ethical issues concerning these groups and the government's proper role in online governance.

Crowdsourced Online Justice

Tatiana Bazzichelli states in her book *Networked Disruption* that artists, hackers and activist groups (AHA groups) use disruptive techniques of networking in the framework of Social Media and web-based services to generate new modalities for using technology, which in some cases are unpredictable and critical. This two way strategy in networking contexts can be used as a practice for generating criticism and can serve as a methodology for business innovation. These 'AHA groups' critically rethink interventions in hacking culture, art and technology; they accept that they must act from within the market scenario in order to change it, while ironically deconstructing it at the same time. This way, the goal is not to oppose frontally, but to trick them by becoming them and creating disruptive and ironic camouflages. [5] Similar tactics can be observed when investigating vigilante online communities and their practices. In recent publications, I mapped out vernacular tools used by scambaiters or how they use social engineering practices when communicating with Internet scammers. [39]

For this experimental investigation, I conducted autoethnographic research on different vigilante communities and documented the parallels to artistic and journalistic practices to map out correlations of their usage of technology and working practices. The 'Scambaiting' community is a global movement, which contacts Internet fraudsters in order to document their practice or jam their workflow. I observed the group very critically after conducting a 'scambait' myself without knowing of the existence of such an active online community. My initial intentions were based on curiosity, and the communication with the scammers gave me an opportunity to understand and document their working practices. By participating in scambaiting forums I encountered several subgroups, each following their own agenda ranging from wasting a scammer's time and humiliating them online to tech savvy activists who shut down fake websites, monitor scammers' email accounts or track down online groomers and romance scammers. [29] Members of these different subgroups were also involved in other vigilante communities: the 'Perverted Justice' movement, mass-mediated actions of the 'Human Flesh Search Engine' and the 'Internet Haganah' group, as well as their tools and techniques for obtaining background checks on website administrators. In the following paragraphs I want to introduce these communities and take a closer look at their methods and practices with the help of several case studies.

Scambaiting Communities Against Online Fraud

Scambaiters are online communities that take action against online advance fee fraud. They actively report scam emails to email providers, collect phone numbers or track IP-addresses of the senders and publish them on platforms to warn other Internet users. In order to be able to process a large number of emails, general warning platforms like scamwarners.com are assisted by more specialized forums that only document specific scam scripts, e.g. romance or employment scams or forums that document scam tactics like phone scams.

Some scambaiters create fake characters with email addresses and social media profiles and use these virtual personas to contact scammers. Often they act like gullible victims to give the scammer the feeling of an easy prey. Once the scammer takes the bait, the scambaiters document the scammer's working practice, for example by collecting identity cards and bank information, in order to document and jam the scammer's workflow. Some scambaiters specialize in reporting bank accounts or warning hosting providers about fake websites on their servers. In some cases, scambaiters manipulate scammers to leave their place of work and travel to remote areas, thereby actively jamming the scammers' workflow and making the travel as long and tedious as possible. [38]

Scambaiters use social engineering methods and several vernacular online tools to create trustworthy characters and believable storylines. Online tools like name-generators help to create fake characters with believable names and existing street addresses. When using VoIP telephony to be in direct contact with the scammers, they use voice morphers to pitch their voices or webcam add-ons to use pre-recorded videos that mimic live video feed. The scambaiters often ask for photographs of the scammers and ask them to pose with obscure signs or in humiliating poses. These photos are collected on online forums like the 'Hall of Shame', where they become memes or are virally shared with the public. Several forums document scambaits where users can comment on the stories and share tips on how to make them more humiliating and hilarious. [27] Forums like 419eater.com or thescambaiters.com specifically distance themselves from racist actions and claim to ban such users from their forums. Within the forum communities the members often challenge each other to submit photos of scammers in more and more hilarious positions. This is to prove to the community that the scambaiter has talent in persuading the scammer to believe their ridiculous stories. Therefore each forum member maintains a posting signature that is added to every posted message. Icons and animated gifs indicate their achievements: pigs indicate closed bank accounts, country flags represent shut down websites, hats for sucessfully sending a scammer on a travel.

Scambaiters try to unveil the real identities of the scammers and expose them to their friends and families. In order to do this, they request the scammers to submit scanned ID's or other documents and images to prove their authenticity. Images that come in the .jpg or .tiff format carry metadata that is stored as 'Exchangeable image file format' data (short Exif-data). When taking a photo, metadata like date, time and camera settings (e.g. camera model, aperture, shutter speed, focal length),

GPS location information and a thumbnail of the image is saved and embedded within the image file itself. This is mostly done by default without the camera owner's knowledge. Scambaiters analyze the Exif-data and see whether a photo has been edited or when and where it was taken. This can often serve as additional information to prove the authenticity of a story.

There are reports where the scambaiters provided enough evidence to successfully catch the scammer, but most times people just laugh at the scammers and feel superior to the petty criminals. Within these different motives and subgroups of scambaiters, the next paragraph is dedicated to the 'Artists Against 419' group and highlights some of their working tools.

The 'Artists Against 419' (AA419) is an international community that documents fake websites and tries to educate the public on how dangerous it can be to trust companies' online representations. Scammers often use fake websites and top-level domains like .com, .co.uk, or .net addresses to add credibility to their stories. AA419 started out by reporting fake bank sites that were used for phishing attacks. This was done by cross-checking the companies' websites with local regulator's lists. Back in 2003, a small group of net activists started using custom software to take down fake bank websites. They called these acts 'virtual flash mobs' and their programs were called 'Mugu Marauder', 'Muguito' or 'Lad Vampire'. [1] These programs repeatedly downloaded images from the fraudulent website until the bandwidth limit was exceeded and the hosting provider blocked the public access to the website for the rest of the month. This action can be considered as 'bandwidth hogging' and enabled the vigilante group to block access to fraudulent websites, if the hosting provider didn't react to their written complaints. The act of 'bandwith hogging' is often miscredited as a Distributed Denial-of-service attack (DDoS), but a DDoS attack targets the whole server, where normally several other websites are hosted and not just a single website. [24] The group provoked a lot of discussions and controversy with these illegal virtual flash mobs, so they discontinued the development of those particular software programs after September 14th, 2007. Since then their main focus is on writing complaint letters to hosting providers and establishing a reliable alliance with them.

Through a public database they publish fraudulent websites and link these entries to publicly available 'Domain Name Server' (DNS) entries. This DNS information shows the hosting provider's name and address, the date of registration or when the website was updated last. Besides banks they document all sorts of online businesses; international couriers, escrow services, insurance companies, online shops, construction companies, trading agencies, job or travel platforms. So far, the AA419 lists the biggest collection of fake websites, and the community actively maintains international relations with law enforcement, web hosting companies and domain registrars to get fraudulent websites removed from the Internet.

Hunting Online Pedophiles – The 'Perverted Justice Movement'

Perverted-Justice (PJ) is a civilian watchdog group and online community that tries to expose adult predators trying to contact minors through online chat rooms. [14] They setup sting operations by their members, who create fake profiles and pose as young teenagers, and log in to chat rooms and forums to make contact with predators. They document the chat transcripts and analyze the chat messages. Similar approaches include automatized software programs like 'ChatCoder' or 'Negobot' that analyze chat transcripts for inappropriate language. [21] Once a chat partner is unmasked as a predator, they play along and document the conversation. The chat message logs, phone conversations and real life meetings become part of the evidence to convict the predators. Since June 2002, over 588 predators have been convicted of abduction and molestation. Several members also regularly monitor social media platforms, like Facebook or Myspace, and actively report suspected profiles to the platform administrators.

Since Nov 2004 the Perverted-Justice community has become widely known due to their participation in the Dateline NBC investigative news program 'To Catch a Predator'. In this reality show, sting operations were set up to expose, humiliate, and arrest online predators. Members of the vigilante online community lured predators through online chat forums by setting up decoys. Once the decoys gained the predator's trust, they sent them to an empty house, where another young girl and the host of the show, Chris Hanson, questioned the suspects before investigators arrested them. Between November 2004 and December 2007 twelve such sting operations were carried out, over 286 people were arrested, and 103 (36%) were pronounced guilty. However, in the case of 150 incidents (52%) charges were dropped due to lack of evidence. The payments made by NBC to Perverted Justice created conflicts of interest within the online community. Also, local police departments criticized the vigilante working methods of the television show, which transformed from 'news reporting' to a 'news-making' agency.

In Nov. 2006 district attorney Louis W. Conradt was suspected of being a child molester. According to Perverted-Justice's documented message log files, Conradt, posing as a 19-year-old university student, engaged in sexually charged online chats with a person using the alias of a fictional 13-year-old named Luke. [29] Conradt persuaded Luke to exchange nude photos and after two weeks of ongoing file exchanges, the NBC team brought in an actor to play the fictional character Luke over the phone. After one phone call Conradt stopped responding to attempts to get in touch with him, leading the producers of the show to call in the local police. The producers and local law enforcement raided Conradt's house, where Conradt shot himself. Patricia Conradt, sister of the deceased Louis Conradt, sued the NBC network. The case was resolved amicably in June 2008. Due to this incident, there was heavy criticism of the producers' methods – public shaming, punishment, and social control as media entertainment.

Human Flesh Search Engine - Identifying and Exposing Individuals

The movement called 'Human Flesh Search Engine' (HFSE) originated in China with early incidents dating back to 2006. [34] The term was translated from the Chinese words 人肉搜尋 (Ren Rou Sou Suo), which broadly refers to 'an act of researching information about individuals or any subjects through the often viral

and impulsive online collaboration of multiple users'. [36] Actual people, rather than computer-driven online searches, demonstrating citizen empowerment and civil participation, power the massive collaborations. Through the use of social media platforms, the wider public is involved in the fight against illegal behavior. By using progressive and interconnected search methods the knowledge of thousands of humans is used to uncover 'the truth' and identify any illegal behavior on the part of an individual or a company. In China netizens of the human flesh search movement are also tagged as 'Red Guards 2.0'. [23]

Once the angry mob is released, the exploitation of private information or the leaking of classified information about the accused individual is impossible to avoid, due to the large number of people involved. This information is based on speculation or other low quality information, resulting in wrong accusations, flaming, cyber-bullying or even issuing death threats to innocent people by a crowd-sourced justice-seeking cyber-mob. Most outcomes include public shaming, exposing private information like home and work address, personal photos or video files, DDOS attacks, shutdown of personal websites, unemployment, fines or arrest.

Recent incidents include accusing and casting suspicion on innocent people after the Boston marathon bombings. 4chan and reddit users created 'photo think tanks' and crawled through the photos that were released by the FBI. The FBI planned to crowdsource to be able to gather more photo and video material from the incident. This worked out well and thousands of photographs were submitted to the FBI. In a second step, the 'crowd' was asked to identify the suspects, but the crowd already started their own investigations: a whole subreddit called 'FindBostonBombers' was dedicated to finding the suspects (see Fig. 1).

Figure 1. Photo posted on Reddit showing potential suspects in the Boston bombing

The crowd used several online tools to compare images. They used the 'Exif-Data' provided by many files to locate the exact camera position when the image was taken. Normally law enforcement use software tools like 'CrowdOptic' to carry out this kind of mass image recognition.

Another way to test the authenticity of an image is to use 'reverse image search' engines, which specifically search for matching images rather than finding content according to keywords, metadata or watermarks. When an image is submitted, a digital fingerprint is created that is compared to every other indexed image. The accuracy of different engines and plugins varies, from finding exact matches to similar images, including those that have been cropped, modified, or resized.

The findings of the analyzed images were published and discussed in subreddits like 'FindBostonBombers' and others.

The description of the subreddit stated:
'This subreddit is a place for people to post images, links, and thoughts about the potential identities of those responsible for the bombing. HOWEVER, please keep in mind that most or all of the 'suspects' being discussed are innocent people.'

The crowd fueled rumours and speculations and targeted people carrying backpacks – non-white, innocent people like Salah Barroom or Sunil Tripathi, amongst others, were accused and became public enemies. Some social media accounts of potential terrorists were leaked, and the innocent suspects received threatening calls. Different news stations contradicted the 'online witch hunt' and other news reports in order to bring the angry mob under control. Still, people were afraid to go on the streets. [22]

When the police reported the Dzahar brothers to be the suspects, news media also reported private information like their Amazon wish list and their favorite videos from YouTube. [30]

Internet Haganah – Confronting Islamists and their Supporters

'Internet Haganah' (IH) is a 'global open-source intelligence network' and web platform dedicated to confronting 'Internet activities by Islamists and their supporters, enablers and apologists'. Haganah, meaning 'defence' in Hebrew, was also the name of the early Israel Defence Forces who protected Jewish settlers in Palestine. Back in 2003 Adam Weisburd started blogging about offensive and dangerous sites and founded the organization. Over the years, the community has managed to shut down several thousands of radical websites. [6] On their website, they provide forums covering several issues, where community members post and discuss their collected intelligence on topics such as Reds in China, Russia, North Korea, Left/Right or Nihilist Wingnuts, Global Islamic Revolution, Islamists, Hamastan or Israel. [35]

Once a suspected website is found, it is posted on the Internet Haganah forum, where its relevance is then discussed by the forum members. The group uses online translation tools to translate the website's content. Offline versions and screenshots of the website are archived and used as evidence. Online archives like the 'Waybackmachine' are used to see the website's history. This way, they can create a timeline of the website and see the past publications and latest updates.

Furthermore, background data like the 'Domain Registry Information' is acquired to contact US-based hosting providers of jihad-supporting websites. If the hosting provider refuses to take down the website from their servers, they file further reports to U.S. National Defense Complaint Centers and provide information in the form of press releases and news articles to their media network. Within the network, cases are

documented where hosting providers wouldn't cooperate and take the websites off their servers. In one case volunteers from the Haganah community figured out the hosting provider's administrator's private cell phone number and started to call his phone and put additional pressure on him until he took the site down. [6] In summer 2014 their website www.internet-haganah.com went offline. Parts of the forum can still be accessed by the Internet archives 'Waybackmachine'.

Projects from Journalism, Art and Activism

The following section presents four projects from the fields of art and journalism that use disruptive techniques and other hacktivist methods to communicate their political messages. The different projects, a net-art performance, political activism, video installtion and subversive journalism, were selected because they use disruptive methods and software tools similar to those also used by the various vigilante communities. In 2011, Ian Paul created 'Borderhaunt', a net performance piece, where he cross-references a surveillance network database with a border deaths dataset to create a haunted commentary on the US-Mexican border situation. Electronic Disturbance Theater is a cyber-activist group using different software tools to shut down banks or governmental institution websites. The video installation Password:****** leaks email passwords of Internet scammers and shows how social engineering tactics can be applied to 'deceive the human' rather than 'hacking the system'. The last project is by Mads Brugger, who documented his investigative journalistic approach to uncover diplomatic corruption in the central African state of Congo.

Borderhaunt - Cross-checking Databases for an Artistic Net Performance

The artist and theorist Ian Paul created a net-art performance called 'Borderhaunt – A Border Database Collision' [28]. The online performance took place on July 15, 2011 and was an attempt to merge two different databases associated with the U.S.-Mexican border. 667 participants from over 28 countries collected entries from the database that holds the names and descriptions of people who died trying to cross the border territory. This database is initiated by the Arizona Daily Star, who started compiling border deaths that were recorded by medical examiners in an effort to present an accurate number of people who died in the course of their attempts to cross into the United States illegally through Southern Arizona. These deaths are either caused by extreme weather conditions, violence of vigilantes, or abusive law enforcement officiers. [4] These entries were then sent to a database of the blueservo network, a private service company contracted by the Texas Sherriff's Border Coalition which crowdsources surveillance of the Texas-Mexico border, creating reports of 'suspected' undocumented border crossings. Volunteer users of the database watch livestreams of the border and submit 'suspicious activity' once they see an illegal immigrant crossing the border. For this the Department of Homeland Security installed 25m tall observation towers equipped with long-range radar, high-resolution cameras and an underground sensor network. One observation tower can detect the slightest movement in a 10km range along the Mexican border. [20] As a result of the performance, the border was symbolically haunted for the duration of the one-day action as the border police received over 1,000 reports of deceased immigrants attempting to cross the border.

The action was conceptualized as a kind of collective online performance and intervention for one day by cross-referencing the 'Border deaths database' and the 'Blueservo surveillance network', which reflected on border crossing deaths as well as disrupting the surveillance technologies used in the border territory (see Fig. 2).

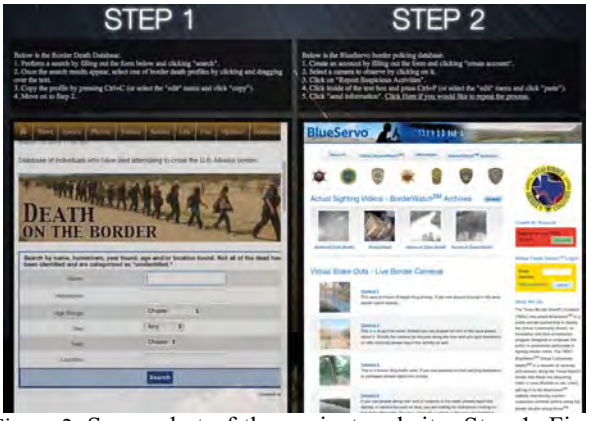

Figure 2. Screenshot of the project website: Step 1: Find a dead person in the database, Step 2: Report a suspicious activity in the Blueservo border policing database

Virtual Sit-ins: the Electronic Disturbance Theater

The Electronic Disturbance Theater (EDT) is a small group created by Ricardo Dominguez, Carmin Karasic, Brett Stalbaum, and Stefan Wray. These cyber activists and artists engaged in developing the theory and practice of 'Electronic Civil Disobedience'. One of their software tools is called 'Flood Net', which is a URL-based software tool used to flood and block an opponent's web site, enabling users to participate in collective electronic civil disobedience in solidarity with the Zapatista rebels of Chiapas (Mexico), a revolutionary group of indigenous people who were fighting against government oppression. [10] With these virtual sit-ins, members of the EDT slow down a website's performance and drain the web server's bandwidth until the website is extremely slowed down or even unreachable. [11] On April 10, 1998, they released a java applet called 'FloodNet' and performed non-violent actions against the Mexican president Zedillo's website ('98 and '99), several Mexican banks, the Frankfurt stock exchange, the U.S. Government and the Pentagon. The users were asked to create 'bad URLs', web addresses of nonexistent web pages at targeted sites, e.g. URLs that consisted of names of Zapatistas killed by the Mexican army. Each time such an website was requested, it was inscribed in the server's error log. The Department of Justice counterattacked the EDT and destabilized the group's infrastructure. Ricardo Dominguez, driving force behind the EDT group, claims that their actions are artistic experiments in 'electronic civil disobedience' rather than true acts of sabotage. By adopting the civil rights movement methods of 'sit-ins' to blockade the entrance of public buildings to block the Internet, they

experimented with new ways to protest through the use of digital media. [13] In 1999, the group released the software to the public as part of the 'Zapatista Disturbance Developer's Kit'.

The Video Installation 'Passwords: ******'

The artist collective kairus.org referenced a scambaiting database, where activists publish scammers' usernames and passwords for their email accounts, and visualized popular passwords in a 6-channel videoinstallation. This sensitive data is gathered by using social engineering methods to persuade the scammers to share their login information. This can be done through the use of fake forms where the scambaiters ask for sensitive information that can reveal the scammer's email security questions, e.g. mother's maiden name or street adresses. Another method the scambaiters use is to offer a supposedly free web service to scammers. It is specifically advertised as a 'trusted and reliable infrastructure' that scammers can use for their businesses. The scambaiter sends out email formats of bulk messages in order to attract the interest of scammers to sign up for this service. During the application process, the scammer has to provide several alternative email addresses and a selection of passwords. Scammers who use several fake identities often use same or similar passwords for their email accounts. Once the scammer logs in to the newly generated account and tries to use the service for fraudulent activity, the email and password details are stored in a database. This database is shared amongst the scambaiting community to crowd-source the high number of scammers' account details. Scambaiters are asked to log in to the scammers accounts and to document criminal evidence. Often you can find fake documents, login information for other online services or gang communications. Scambaiters read through the emails and warn potential victims not to believe the rogue business and to stop communicating with the scammer. They continue monitoring the scammers account until the scammer loses interest and abandons the account. This makes it possible to learn from the scammers' practices and demoralize their attempts to gain any money from people who are ready to pay. The illegal act of accessing another person's account is justified by the efficiency of warning victims and collecting intelligence by accessing a criminal's 'virtual desktop', where important documents or passwords for other services can be found.

While looking at and experiencing the 6-channel video installation, the visitor reflects on issues of online security and questions one's personal password usage (see Fig. 3). The artwork stresses the 'online common sense' that passwords can be hacked as a result of security flaws like 'Heartbleed'; they can also be obtained by social engineering techniques. Securing personal data online with a strong password and constant security updates to avoid exploits is essential. However, people are still lax when it comes to securing their passwords and not sharing them with others. [39]

Figure 3. Exhibition setup 'Passwords:******'

Performative Journalism: Mads Brugger

In his documentary film 'The Ambassador', Danish provocateur, journalist and filmmaker Mads Brugger impersonates a Liberian ambassador called 'Mr. Cortzen', who goes to the Central African Republic of Congo to expand diplomatic relations. He is able to buy a valid diplomatic passport from the state of Liberia over the Internet. Under his new name 'Mr. Cortzen', he is able to enter Liberia and establish diplomatic relations with other state diplomats. [15] His official agenda is to represent the state of Liberia, with a fake diplomatic passport, and set up businesses as a cover story, e.g. a match factory to employ a local tribe of pygmies. His second agenda is to provide an insight into corrupt politicians and to uncover the ongoing blood diamond trade. With hidden cameras he documents how he bribes his way up the social ladder and engages with government officials and other diplomats. Over-exposing his superior status as a white, ginger-bearded foreigner in a postcolonial outfit, Mads Brugger sees his production as 'performative journalism', uncovering the criminal potentials diplomatic immunity provides. In a fragile state like the Central African Republic of Congo, most white men have several hidden agendas, so he could avoid being questioned why he, as a white man, represents another African state. Because of the film, the Liberian press identified eight Mr. Cortzen-like diplomats in their corps. Today in many countries like Russia or China it is extremely dangerous for journalists to work and report from. Mads thinks it is necessary for journalists to use a new set of tools to research and report in such countries. [15] [17]

Discussion

There is an ongoing debate about the benefits these vigilante communities bring to net societies and law enforcement. Differences in the training of volunteers, the various state legislations and divergent sets of resources will undermine the communication process between the involved parties.

Vigilante groups invest a lot of time and commitment to their act of civil service. Members are often tech savvy and are open to sharing their findings with potential victims or law enforcement.

Could these vigilantes be used as a resource in the fight against cybercrime? Could a training by the police set certain standards and enhance the cooperation?

Since 1996 NGO's such as 'Ultrascan Advanced Global Investigations' (UAGI) operates by identifying, analyzing and predicting perpetrators of cross-border

fraud and the communications and support of terrorism from local or international religious extremists. [33] They offer a six-phase volunteering program, where helpers are coordinated to warn scam victims (phase 1), help them to file complaints (phase 2), visit working offices of scammers (phase 3), collect sensitive information (phase 4), report to the police (phase 5), and collect intelligence to get the scammers arrested (phase 6). Similar attempts to include civilians and private organisations to cooperate with law enforcement in the fight against cybercrime are undertaken by NC4 Cybercop or Project Vigilant. [2] [16] Such programs distribute the duty of policing and empower citizens to fight Internet crime.

Conclusion

By observing the working practices of the different online vigilante communities it is possible to map their working practices and the tool-sets they use that empower them to prosecute their 'opponents'. In general, these vigilante communities are very concerned about their anonymity and use fake profiles to camouflage their digital identities. Digital identity can be simply defined as the digital information that creates the image of an individually identifiable person. The groups use and misuse various vernacular online tools to gather intelligence. In the last few years, more and more artists have used net-activist tools for producing their artworks. This merges the activists, hackers and media-art movements into new genres, often referred to as tactical artists, hacktivists (hacker and activist) or artivists (artist and activist) cultures.

'Scambaiters' and members of the 'Internet Haganah' group use common practices to obtain background checks on the hosted websites to figure out their registration date, track down the administrators and get a physical address and phone number of the webmaster. Also, that way it is possible to obtain information regarding who the hosting provider of the website is and if local state laws or the hosting companies' 'Terms & Conditions' can be applied to the case in order to force the hosting provider to take the website off their servers. The activists use social media platforms, blogs and press releases to inform the public about their ongoing investigations and try to draw the public's attention to the case. They often cooperate with local NGO's that warn potential victims and extend their outreach.

Members of the 'Scambaiting' community use several online tools to create fake characters, track email IP-addresses or use image analyzers to extract Exif metadata from images. Software tools like 'Muguito' or 'Lad Vampire' are used for 'bandwidth hogging', reducing the server's capacity and limiting access to the website for potential victims. 'Scambaiters' and 'Perverted-Justice' communities use fake profiles to hide their identities and create 'honeypots' for online criminals and groomers. By using special software tools like 'ChatCoder' or 'Negobot' they can analyze chat transcripts for predatory language and distinguish faster between a potential criminal and a regular chat-forum user. The 'Human Flesh Search Engine' and the 'Internet Haganah' are heavily crowd-sourced sting operations, where lots of members are engaged in a single case, e.g. identifying suspects in the Boston Bombings or collecting evidence to shut down Jihadist websites. This massive user-driven approach to data gathering, analyzing and filtering information is discussed in forums where adaptive prosecution methods are also evaluated. In this process ethical discussions are often forgotten, and no ethical group guidelines are defined; common moral sense is thrown overboard. The act of online humiliation through offensive text messages or photo-collages and exposing sensitive data like phone numbers, private address, or occupation is a common form of self-justice. The viral prosecution can result in cyber-bullying, prank calls, physical harassment, and death threats, often also targeting the accused's friends, family members, or co-workers. These kinds of harassment and the pressure of increased media attention have also sometimes led to the loss of social status, e.g. study status or employment. As social media profiles are shut down in order to not provide a platform for harassment and bullying, individuals often find it impossible to give a statement in their defense. Once the Internet has found a victim, it becomes hard to counter any false accusations.

Collected evidence that is gathered through background checks or by documenting communication with the victim could be tainted and become unusable in court, or targets could be condemned as guilty when innocent, said Paul Kurtz, the executive director of the Cyber Security Industry Alliance, a coalition of chief executives of tech companies. 'When we all become "law enforcement officers", justice becomes very blurry.' Individuals and U.S. officials think that they can learn more about online criminals or terrorist operations by monitoring suspicious sites, which are operational. They can obtain background information that law enforcement cannot gather. Often, evidence is either gathered illegally or by morally questionable acts like hacking or social engineering. Nevertheless, every case has to be analyzed separately: how the provided evidence is gathered, whether it can be evaluated by law enforcement, or if it just interferes with their investigations.

Authors Biography

Andreas Zingerle is a media artist from Austria. He works as a research assistant and PhD candidate at the 'Time-based and Interactive Media Department' at the University of Art and Design in Linz, Austria. He is researching anti-fraud strategies and demonstrates how they work in interactive narratives, artistic installations and creative media workshops. In the past he worked on art installations exploring creative misuse of technology and alternative ways of Human Computer Interaction. Since 2004 he takes part in international conferences and exhibitions, among others Ars Electronica, ISEA, Siggraph, Japan Media Arts Festival, File, WRO Biennale. Together with his partner Linda Kronman he started an artistic collaboration called 'Kairus'. More info: andreaszingerle.com, kairus.org.

The Aesthetics of Activism: See-through Effect

1st Vicki Moulder and 2nd Michael Heidt

[1]Simon Fraser University, Canada, vmoulder@sfu.ca,
[2]Chemnitz University of Technology, Germany, michael.heidt@cs.tu-chemnitz.de

Abstract

For this demonstration the authors intend to present the *Aesthetics of Activism* as a work-in-progress. This interactive artwork explores the nature both of audience engagement as well as the interdisciplinary conditions of its making. The work is designed to visually represent an assemblage driven by people's bodies that are tracked and translated into interactive collage elements via motion sensors. Images projected are composed from a mixture of algorithmically scavenged social web resources and artistically curated and altered videos. The demonstration will present a new interactivity feature that continuously tracks a body, coupling it with a distinct eyehole (a region distributing transparency), allowing one of the composition s retrial layers to be viewed. The experience provided points towards the ways technological advances transform and shape public spaces, thereby subverting familiar strategies of activist practice while rendering possible new forms of aesthetic resistance.

Keywords

Interactive Art Aesthetics Code Literacy Activism.

Introduction

The *Aesthetics of Activism*[1] is an interactive work-in-progress designed to facilitate aggregation of visual material from social networks to form themed compositions that can be explored jointly within a shared interactive space. It seeks to combine reflection on the algorithmic conditions of contemporary digital attention economies with an awareness of the interdisciplinary circumstances of technology production. To this end, aesthetic principles underlying human-made visual compositions are translated into algorithm. Generated and curated content is combined within interactive collages exhibiting a multi-layered structure. The work is part of a larger research study that investigates the broader context of social, digital, and cultural production 3 .

For this demonstration, we worked with social web resources related to Canada's Kinder Morgan protest[2] to present a new feature that couples every tracked body with an eyehole shaped lens that allows one of the composition s retrial layers to be viewed. As seen in Figure 1 each time a new body enters the interactive zone a distinct eyehole transition (i.e. region redistributing transparency) is created. Each tracked body is coupled with a distinct eyehole such that a different layer becomes accessible to the respective audience. When more bodies enter the interactive zone, more layers are partially revealed. The exact configuration and structure of visibility thus depends both on the number of present bodies as well as their collocation.

Whenever no people are present within the interactive zone, the system slowly cycles through available compositions as seen in Figure 2. The nature of the composition is a variable that rests on the described 'see-through' effect, revealing additional content or creating a thematically motivated contrast. Depending on the site of demonstration the work illuminates glimpses of hidden layers or invites sustained exploration amongst people interested in the retrial layers.

Figure 1. This illustration demonstrates the effects of four people collocated within an interactive zone.

Figure 2. This illustration demonstrates the effects of the system generating image composition without people present. As time lapses the image layers thin until they fade completely.

[1] Aesthetics of Activism documentation: interactionart.org
[2] David Suzuki Foundation's blog on Kinder Morgan's Trans Mountain pipeline project: http://davidsuzuki.org/blogs/panther-lounge/2012/07/we-are-the-kalamazoo/

Layered images are seldom exported to visual 'consumers'. By exhibiting a multi-layered surface the piece hints towards the interdisciplinary circumstances that produced the artwork. Our goal is to demonstrate how traditions both from the visual arts such as assemblage making [1], as well as, digital practices such as interactive collage [2] can be used to make statements about real-life events.

The proposed demonstration as illustrated in Figure 3 can be projected onto a white wall, projection screen or, ideally, a glass surface for rear projection (e.g. a store front window). The generative part of the composition is created from aggregated social web resources as displayed in Figure 4. As seen in Figure 5 the installation requires reduced lighting and an unobstructed interactive zone infront of the display surface.

Figure 3. Aesthetics of Activism work-in-progress projected onto the Surrey Central Library, BC, Canada

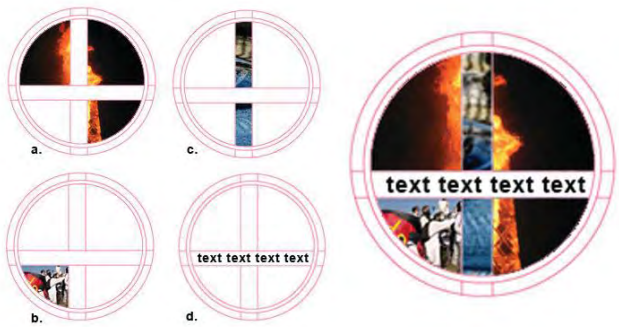

Figure 4. This illustration maps the generative composition aggregated from social web resources. The placement of each layer represents: a) context, b) contrast, c) people protesting, and d) text related to theme.

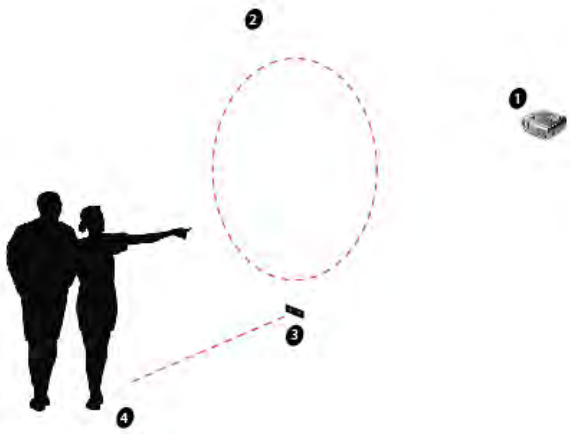

Figure 5. This illustration shows the general set-up: 1) Projector and Laptop computer, 2) Screen, 3) inect sensor, and 4) Interactive zone in front of the projected images.

Conclusion

In this submission we have briefly introduced the *Aesthetics of Activism* as a work-in-progress investigating the broader context of social, digital, and cultural production. Our proposed demonstration intends to invite conference attendees to experience our new interactive feature that couples every tracked body with an eyehole shaped lens activating the retrial layers of the artwork as seen in Figures 1 and 2. Our future work will continue to explore the creation and detection of social media patterns and interactivity as a mode of cultural production combining formal and non-formal aspects of aesthetic phenomena such as painting, nature, or mathematics.

Abstract

In this research, we studied the disruptive aesthetics of interactive artwork based on the activity theory. The audience engages in interactive artwork not only for the pleasure of participation but also for the disruptive aesthetics of social values in the organization of human life. We analyzed audience activity in interactive artwork using the activity theory and created a framework with a basic structure for a disruptive aesthetics of interactive artwork. The audience engaged in interactive artwork and overthrew the social structure in three categories: disruptive rule, disruptive community, and disruptive role. Through the framework, artist will create a disruptive interactive artwork, and the audience will enjoy the interactive artwork as part of disruptive aesthetics.

Interactive Artwork, Digital Art, Activity Theory, Disruptive Aesthetics, Interactive Framework

Introduction

Background and Motivation

Disruptive aesthetics is a term already being used in the analysis of artworks. [1, 2] This paper refers to this term, which means changes in interactive artworks' factors and structures.

Disruptive aesthetics challenges society's previous view of artworks and overthrows the old concepts. The interpretation of artworks today is a paradigm shift in art history. This paper proposes this paradigm shift in four categories: from a cultural approach, a functionalist approach, an experience-based approach, and a techno-futurist approach. [3]
Modern art: Readymades by Marcel Duchamp, "*Happening*" by Fluxus, John Cage's music, interactive artwork by Jeffrey Shaw, and Bio Art by Eduardo Kac have changed social values and created resistance through disruptive aesthetics.
Today, many digital artworks or bio-artworks have challenged authority. The content of a work might pleasurably subvert a meaning, thing, or relationship from real life. Participants might also feel subversive pleasure simply from behaving in ways they perceive to be "against the rules" of the world set up by a work. [4]
Digital art is media art based on digital technologies. Has digital technology strengthened disruptive aesthetics features in art? With the digital age, a variety of positions have emerged on the interpretation of the correlation between the aesthetic object and the aesthetic experience, resulting in a blurred picture of the field. [3] The possibility of complex interaction in digital art goes far beyond the simple "pointing and clicking" that offers nothing more than a sophisticated way of looking at a work, or the type of interactivity where a user's act triggers one specific response. [5]

What are disruptive aesthetics in digital art? They are special features. Various papers and books refer to the following five features. [5, 6, 7, 8]
1) Expanded human creativity mediated by digital technologies
2) Audience participating in the artwork and real-time feedback system
3) Global communication based on a networked system
4) Virtual reality or augmented reality - digital human customizing and agent system
5) Bio-artwork based on human body, organization, or DNA

These features give the audience disruption based on digital technologies, unlike previous artwork. However, we should make new digital works with not only these new features but also those that contain meaning and value - disruptive aesthetic of contents.

Does digital interactive artwork contain disruptive aesthetics in terms of the continuity aesthetics of art? Interactive art gives pleasure to the participating audience. Subversion is the pleasure of breaking rules or of seeing others break them. It is also the pleasure of subverting or twisting the meaning of something or of seeing someone else do so. [4] These interactions are disruptive values of digital art in view of audience participation and real-time feedback by digital technologies. [5, 6] Many researchers want the audience to participate in interactive art in various ways, with the art concentrating on the audience's experience. [9, 10, 11, 12] In this situation, the audience performs easily and intuitively. This participation is fun and interesting, akin to an interactive game. [10, 13, 14] However, the artist and research also consider the meaning of the artwork's contents in terms of defiance. The audience directly performs the interactive artwork installation and affects its contents. The audience is essentially a disruptive aesthetic of trigger in an artwork via its own activities.

The Aim of This Research

The aim of this research is to create a framework for analyzing or producing a disruptive aesthetics of an interactive artwork based on the activity theory.
The process of the research is as follows
1) Analysis of aesthetics of interactive artwork
2) Making a new framework via application of the activity theory
3) Analysis of interactive artwork based on the framework
4) Proposing a disruptive aesthetic result based on the analysis

Case Studies

Art History for Disruptive Aesthetics

This research studied a history of art for disruptive aesthetics. [5, 6, 7, 8] Marcel Duchamp's concept overthrew the stereotype of artworks being made creatively only by artists. His images moved on the canvas so that audiences "performed" his installations, which meant the images were kinetic art and not interactive art because they were not mediated by digital technologies. This artwork with a rotary plate was the first artwork in history to enable the audience to participate through their own actions. Duchamp proposed a paradigm shift in artwork by breaking down the stereotypes of artwork.
The Fluxus "*Happening*" performance overthrew the stereotype that an artist produces an artwork for his own meaning. The unintended result of the actions of Fluxus members was that they created performance artwork through their physical movements. They resisted worthy activities based on rationality in their artwork. They broke down the aesthetic standards and proposed the message that the human body is the best interface for artwork. They deconstructed the metaphysical philosophy of Western ideas and morals with their uncanny gestures. The audience viewing the performances became co-workers of the Fluxus members.
In addition, musicians have been performing directly and playing tunes. However, John Cage overthrew this stereotype and discovered the delicate noises that audiences make. The music of *4'33"* was made both by Cage and by his audience. This was not only the discovery silence but also a musical collaboration between the audience and participants. Cage found his artworks' contents by coincidence. His performances (or his audiences' performances) disrupted the relationship between the artist and the audience, whether intended or unintended.

Here, we briefly explore modern artworks' history in view of disruptive aesthetics. Artwork consists of form and content based on overthrowing the previous society and structures of artworks. A paradigm shift is needed for the artists and the audience because people enjoy new artwork concepts that change the world and society's structure. Disruptive aesthetics have the strongest and most powerful effect on a paradigm shift. Through disruptive aesthetics, people expand their imagination and creativity, and they challenge society's structure in order to enhance the value of humanity. Beyond playfulness and fun, interactive artworks have meaningful values for proposing a new paradigm in order to enhance humanity. This enhanced humanity comes from an innovation-related resistance to renewing and overthrowing the social order. The disruptive aesthetics will let the audience change society with regard to its views about artwork. We analyze the disruptive aesthetics via the audiences' experiences with interactive artwork.
In view of being formative, interactive artwork is a challenge to overthrow. However, interactive artwork is needed by disruptive aesthetics in view of its contents. It is also needed as a method to enhance the values of humanity through the disruption of an oppressive society, which is different from playing interactive games. The main issue is the embodiment of interactive artwork from audiences' actions mediated by the installation through digital technologies. The embodiment is how artists express their perspectives on aesthetics and produce their artworks' contents. The embodiment of the artwork contents is related to disruptive aesthetics, which means overthrowing the stereotypes and social limitations. This disruptive aesthetics enhances and expands the artworks' contents.

Interactive Artwork Applied by Activity Theory

The core meaning of interactive art is the direct activity of the audience and the triggering of contents. The direct effects are factors of the disruptive aesthetics of artwork contents. The audience activity could expand the real social world beyond the interactive artwork environment. In interactive artwork, the audience performs its own actions out of desire, and the actions are represented by social symbols.

We first analyze audience activity in interactive artwork. The activity theory is an essential analysis method for human activity. This research applied the theory to create a basic framework for interactive art in view of aesthetics. [15, 16] The following is a basic production framework for interactive art based on the activity theory. [17]

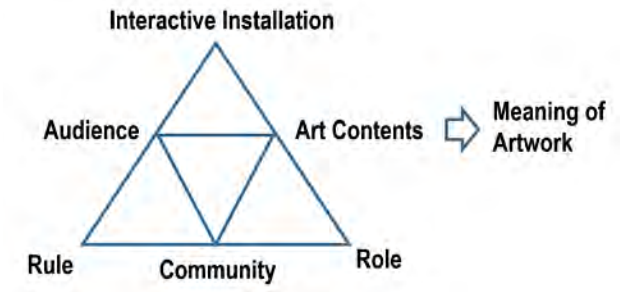

Figure 1. Framework Model of Interactive Artwork Created by Applying Activity Theory [17]

Analysis on Interactive Artworks Based on New Model

Based on a new framework for the meaning of interactive artwork created by applying the activity theory, we analyzed three pieces of interactive artwork.

- *Legible City* by Jeffrey Shaw (1989)

In The *Legible City*, the visitor was able to ride a stationary bicycle through a simulation of a city. [18] This artwork overthrew the meaning of the city as a social construction for human residence. This artwork proposed an audience's travel in a virtual environment using textual images. The audience had an adventure of new meaning within the virtual city, which broke down the symbol of the text buildings and human architecture.

Figure 2. *Legible City*

- *Text Rain* by Camille Utterback & Romy Achituv (1999)

Word text refers to written symbols for words. Humans have long used text to communicate with one another and to keep data in books or materials. [19] In this artwork, the audience members used their bodies to perform in front of a screen and play text images that fell like rain. This artwork overthrew the meaning of the text stemming from social rules created by humans. The artwork proposed disruptive play in order to change the meaning of the text.

Figure 3. *Text Rain*

- *Be Your Own Souvenir* by blablabLAB (2011)

In this work, the audience became the producer as well as the consumer through a system that invited its members to perform as human statues, with a free personal souvenir as a reward. [20] This artwork overthrew the role of humans themselves. The humans did not think of themselves as souvenirs. However, this artwork proposed this concept by playfully encouraging them to strike enjoyable poses. The audience members became creators and models through their own poses and gestures.

Figure 4. *Be Your Own Souvenir*

Disruptive Aesthetics of Interactive Artwork

Audience members had a disruptive experience in the interactive artworks based on their own activity. The term disruptive aesthetics is defined as breaking the form of society and proposing a new form. Therefore, this research proposed a new framework for interactive art in order to overturn the basic factors of the previous framework. Through interactive art, the audience overthrew the previous activity content through its own activity: rule, community, and role. This research proposed three categories on opposing sides of the previous framework: disruptive rule, disruptive community, and disruptive role.

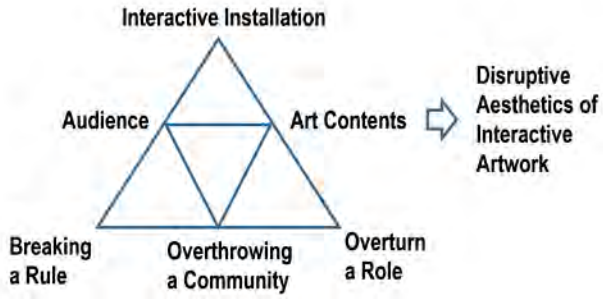

Figure 5. Framework for Disruptive Aesthetics of Interactive Artwork

1) Disruptive Rule of Interactive Artwork

Audience members performed interactive art and overthrew the social order by participating in the interactive artworks. Disruptive aesthetics not only means breaking down the rules but also reforming the rules. This expands the range of the rules. People have made various rules for keeping the systems of society. Rules comprise symbols, regulations, laws, principles, and morals. People live to uphold various rules for themselves or for their communities. Breaking the rules means a new way of looking at basic rules for extended human cognition and physical activities. The process of disruptive rule enhances the value of human regulations.

2) Disruptive Community of Interactive Artwork
Audience members performed interactive art and overthrew the social community by participating in the interactive artworks. People have developed various communities in order to keep living or to have a stake in the outcome. Communities comprise families, groups, schools, armies, nations, nongovernmental organizations, and cyber communities. Communities are made by humans and are disbanded if this is the communities' objective. People want to both belong to communities and escape from them. This is the destiny of people, either to be together or to be alone. Overthrowing communities does not mean breaking them down but expanding them. This is not anarchy for a society but rather a renewal of that society. The process of disruptive community enhances the value of human groups and defamiliarization about organizations made by humans in order to discover the value of human relationships.

3) Disruptive Role of Interactive Artwork
Audience members performed interactive art and overthrew social roles by participating in the interactive artwork. Humans have performed roles for their own sake and to maintain society. Private people assume roles that are satisfactory for themselves or to get close to people in interest groups. Overturning a role not only means the destruction of the role but also an extension of the private role for the discovery of one's own values. Also, this does not mean moral action or the destruction of the organization or the system. This is a creative renewal that works to make a new paradigm in sociology. The process of disruptive roles enhances the value of human performance and of finding new abilities.

In these ways, audience members in the interactive artworks performed their own activities and overthrew the three social values: rule, community, or role. These are the disruptive aesthetics in an interactive artwork.

Conclusion

We researched an interactive artwork in view of disruptive aesthetics. The audience members directly performed in interactive artwork and overthrew the social structure in three categories: disruptive rule, disruptive community, and disruptive role. We analyzed interactive artworks based on the framework and proposed factors in the disruptive interactive artwork.

Producing interactive artwork through disruptive aesthetics gives pleasure in different forms from other interactive installations or interactive games. These are the aesthetics of intrinsic, disruptive, interactive artwork. Art overthrows the framework in order to create more art.

Research through Design, Documentation, Annotation, and Curation

Aisling Kelliher and Daragh Byrne

Carnegie Mellon University
Pittsburgh, PA, USA
aislingk@andrew.cmu.edu, daraghb@andrew.cmu.edu

Abstract

The practice of research through art and design can pose challenges in terms of evaluating contributions, formalizing methodologies and generating extensible principles. Creating a middle layer of critique and interpretation between the generated artifacts of research through art and design and the foundation of general theory provides a viable space for exploration. We propose integrating artifact description, process documentation and participatory annotation as a useful approach in this intermediate critical area. We introduce a multimodal documentation framework for capturing, annotating and presenting the activities, processes and generated artifacts of research through art and design practice. We describe findings from our experience documenting a series of research through design workshops, and illustrate our annotation and presentation approach in the form of a curated exhibition.

Keywords

Documentation, research through art, research through design, experience design, exhibition

Introduction

The practice of *research through art and design* extends beyond the creative arts and is becoming an established presence in fields such as planning and human-computer interaction. With this development, thorny questions arise about measuring impact, understanding contributions to different disciplines, and developing a coherent theoretical and critical interpretive framework. As researchers working across disciplines (design, art, HCI and computer science) our praxis approach produces multiple outcomes including methodologies, installations, online applications and scholarly texts. A recent proposal for presenting such outcomes is an 'annotated portfolio', a term used to describe a collective body of work assembled into a considered and 'marked up' whole, which is encountered in such diverse forms as monographs, exhibitions, digital archives and performances [8]. The selected works and their accompanying annotations can be understood as occupying a middle or intermediate generalizable ground between the discrete originating design or art artifact(s) and a formalized, extensible theory [13].

The conceptualization of annotated portfolios to date relies primarily on retrospective annotation of artifacts from a relatively singular perspective. Integrating a documentation approach throughout the entire creative process provides an opportunity to combine the production and consideration of knowledge into an accessible and comparable set of research practices evolving over time. Opening this reflective documentation process to a diversity of participants (e.g. team members, external experts, clients, students, general public etc.) further allows for the broader type of sensemaking and connectivity referenced in [13]. Supporting this type of research practice requires the development of comprehensive documentation protocols and a flexible computational framework structuring the storage, annotation and presentation of collected material.

A series of design workshops held during the 3-day international *Emerge* symposium hosted at Arizona State University in 2012 provided us with the opportunity to develop and put into practice our own multimodal documentation framework. The symposium brought together theorists, practitioners and researchers from the arts, design, sciences and humanities to create and reflect upon "what it means to be human in today's world" [3]. Working closely with the symposium organizers and the nine workshop leaders, we developed a documentation approach appropriate for the planned activities and the 250 invited participants. The workshop organizers anticipated using a variety of design methods including speculative strategies such as *design fiction, sci-fi prototyping,* and *scenario planning.* The goal of our documentation approach was both to support the presentation of the workshop outcomes during the symposium, and to create an open, 'intermediate level' annotated record of the event activities for broader participants and audiences.

In this paper we present our hybrid multimodal framework for capturing, annotating and presenting the activities, processes and generated artifacts of research through design practice. After surveying prior work, we describe the implementation of our data collection and presentation approach during the Emerge symposium, and the subsequent integration of the captured content into a 3-month participatory exhibition at the ASU Art Museum in Phoenix, Arizona.

Prior Work

Research through art and design

Art and design research explorations within technological and scientific domains have generated a rich understanding of 21st century contemporary aesthetics [16]. A growing body of work across multiple disciplines extends the integration of art and design techniques with established research practice, towards a comprehensive formalization of *research through design* as a discrete endeavor in and of itself. Building on Christopher Frayling's inquiry based distinction between research *into*, *through*, and *for* art and design, practitioners and researchers to date have primarily focused their efforts on exploring the realm of research through art and design [5]. This approach is particularly evident within academia in the UK, Europe, and Australia/New Zealand, where there is a strong tradition of practice based research in the arts and design [15], in addition to a substantial body of work aimed at analyzing, evaluating and understanding such practices [2].

The primary contributions of research through design approaches are typically encountered as artifacts or systems that seek to encapsulate the thinking and ideas of the production team within their material form [7]. From the manifestos of the Critical Engineers [10] to the speculative design work of Dunne and Raby [4] or the design fiction practice of the NearFutureLaboratory [1], the past 15 years have witnessed a growing body of provocative work aimed at instigating broad social discourse. While this is of course valuable, much less attention has been directed in describing the *process* by which these future-oriented artifacts are conceived and created. This lack of documentation, highlighted by Zimmerman et al. [17], makes it difficult to formally compare and evaluate the diverse outcomes generated by research through design. There remains a relative lack of formalized procedures or systems for capturing the tacit knowledge evident outside of the presented artifacts themselves. The recent proposal for "annotated portfolios" provides a framework for coherently presenting a collection of artifacts as "a systematic body of work", annotated according to a variety of features such as perspectives, relationships and implication shaping [13].

Our work seeks to extend the notion of annotated portfolios by creating a hybrid physical/digital documentation framework for capturing, annotating and presenting both the *products and the process* of research through art and design initiatives. Presented as an integration of mediated experience capture and management, our approach is guided by insights gained from analog and digital documentation and presentation methods.

Event Documentation and Presentation

Pioneering documentary filmmaker Ricky Leacock described his filmmaking practice as 'the search for the feeling of being there' [12]. For Leacock, significant moments are captured for later arranging as meaningful audiovisual sequences running after one another. From this realm of professional documentary making, we now have a multitude of integrated capture devices and representation media enabling us to record, summarize and share significant events. Documenting the 'feeling of being there' no longer just encompasses a singular team capturing physical presence. It now involves distributed individuals and groups generating and sharing content, together with a dynamic set of virtual activities associated with 'being there'.

This new era of documentation is ripe for tackling the mediated complexity of contemporary art exhibitions, international conferences, biennial expositions and summer festivals. In addition to professionally produced content (e.g. the large archive of TED talks), there are growing collections of captured amateur and social media content expanding event representation on outlets such as Twitter, Flickr, Facebook and Pinterest. Creating an integrated and diverse record of an event allows for the emergence of multiple perspectives and enriches the potential for the continuation of post-event discourse.

Museums and galleries have been at the forefront in adopting new technologies and tools for archiving, presenting and navigating exhibitions. Mobile applications and adaptive guides have proved useful in personalizing experiences for visitors [11]. Attempts have also been made to motivate reflection on exhibits and encourage communication both between visitors and with the host institution [9]. Our approach is to marry findings from the above in creating a hybrid physical/digital exhibition that encourages conversation and contribution in a playful, creative, and research-focused environment.

Documentation Capture Framework

Building on this prior work, our multidimensional documentation framework was developed in collaboration with the overall event organizers to minimize disruption and ensure that the presence of recording instruments and documentation team members was integrated as well as possible into the planned workshop activities. Our framework provided a distribution of capture techniques ranging from passive to interrogative, public to private, analog to digital, and situated to online. Details of the integration of content captured by social media activities, passive recording devices, a custom design probative installation and a trained documentation team are described below.

Passive Capture

To gain an overall sense of general participant movement and collaborative group interactions during the workshops, we installed passive web-cameras in all nine internal workshop locations and at several key outdoor locations. Imagery from these cameras was collected at a rate of one image per second, capturing general activity in the space from

preparation, through the event, and subsequent tear down. Image data from these spaces was streamed in real-time to a custom-designed application displayed on a screen in an entrance hallway to the main presentation spaces.

Social Media

Prior to the event, we established groups on Flickr and Vimeo and promoted their use to all upcoming participants. During the symposium we prominently displayed information promoting use of these platforms for casually collecting media. We also invited all participants to use the Twitter platform as a commentary space and encouraged the use of the event hashtag. For participants either unfamiliar with or non-users of Twitter, we modified a Twitter public display application previously developed by the authors. This application provided attendees with a dynamic glanceable interface displaying tweets annotated with the event hashtag and encouragement to contribute.

Design Probes

Traditional documentation techniques emphasize the role of third parties in preserving a record of proceedings. However, attendees at events are increasingly key to its communication and curation, particularly through social channels. As part of the experimental approach, we sought to engage attendees in actively contributing to the documentary effort. The first was a variation of Gaver's cultural probes [6] designed to enable the participants to document how their workshop unfolded. Each symposium workshop was provided with a kit containing a variety of artifacts to facilitate first-person documentation (e.g. two disposable cameras; a USB drive; sketch sheets; and a series of comment postcards. As many of the workshops would mix both discussion with digital production, the USB drive not only facilitated the exchange of digital content within the workshop, but also provided us a record of that content. When the workshop was completed, the artifacts were returned to the probe kit and collected.

Figure 1. The exterior of the *Probotron.*

In addition to examining the in-the-moment evolution of the workshop through collective curation by its participants, we developed a second capture method that explored the individual participant experience from a broader frame. An installation, named the *Probotron*, was created and situated in the primary venue of the symposium (see Figure 1). Appearing similar to a photo booth, the Probotron blends technology and a large physical structure to deliver a space for reflective contribution. Each visitor to the booth was asked to choose one question from a larger set of future-themed prompts developed by the event organizers and record a short one-minute response. Questions included: "What kind of future do you want to make?"; "What is going on in your workshop at the moment?"; and "How can innovation be responsible?" This offered participants an opportunity to record their personal perspective on the proceedings, or provide a reflection on the significance of the event as whole.

Documentation Teams

Documentation teams were formed from the student cohort of a 7-week course (co-developed by the authors and two anthropologists) for social science and digital culture students. The students received training in ethnographic methods and observational media documentation, logging and annotation. Each workshop was assigned two dedicated documenters who captured events using hand written field notes, digital photos, digital movies and audio recordings.

Emerge Symposium and Workshops

The Emerge symposium was focused around the topic of artists and scientists redesigning the future. The nine event workshops focused on different themes, led by experts in areas such as design fiction, sci-fi prototyping, archaeology, the arts, gaming, and technology studies, Each workshop had between 20 – 25 registered participants, with a relatively even distribution of theorists, designers, artists, makers, scientists and engineers per grouping. Over the course of two days, the workshops would engage participants in a variety of activities including - writing letters to their future selves, sculpting and 3D printing futuristic artifacts, fabricating material evidence of a former civilization, envisioning possible energy scenarios, and writing and producing a design fiction movie.

At the beginning of the workshops, the documentation teams introduced themselves to the participants and invited them to open and examine the documentation probe toolkit. The team also directed attention to the *Probotron* and the variety of associated social media platforms available for sharing and tagging content. At the end of each day, the documentation team members met to transfer material to a main server and lightly annotate the content using categories such a location, participant names and activity type.

The final day of the symposium was open to the general public and included presentations from the workshop leaders as well as keynotes by speakers such as Bruce Sterling, Neal Stephenson and Stewart Brand. The event finally concluded with an hour-long immersive outdoor performance piece. The performance included 3D video projections across multiple buildings, with an immersive 3D audio environment triggered by the movement of the audience. Improvising actors moved through the crowd enticing the audience to engage with interactive sculptures and animations. Three interactive installations were thematically related about the idea of a futuristic circus, with novel takes on fortunetelling, magic mirrors and a carnival organ. The documentation teams spent the day in designated locations capturing all of these events using Flip cameras and still image cameras.

Figure 2. Actor interacting with the crowd during the final performance. Photo by Robbie McCarthy.

Data and Annotation

The documentation team produced over 1 TB of audiovisual data, including 1,173 photos and 1,498 videos. Ninety usable video clips were created in the *Probotron*, while the documentation kits were used extensively by two workshop groups, and in particular one group who spent a whole day collecting material for their presentation on the USB stick. Building on the rudimentary metadata associated with the captured media content during the event, we expanded our annotation framework to specifically encompass features related to design activities and practice. These categories included: Discussion; Research; Planning/Strategy; Introductions; Summarizing or Conclusions; Argue/Debate; Analysis; Synthesis; Making; Prototyping; Refining. In addition, during this primary stage of analysis, all recorded content was annotated according to its level of fidelity (i.e. poor quality/unusable; reasonable quality; high quality). Content of the highest quality from each of the workshop categories was selected by the authors for richer description, whereby annotation of participants, locations, summary details or thematic labels was attached. This data was derived from the public schedule, review of the captured data and in consultation with the documentation team members assigned to each workshop.

Exhibition as Annotated Portfolio

The purpose of designing a curated exhibition using the event findings and outcomes was multifold. Together with the symposium and workshop organizers, we were interested in exposing the foundational ideas, methods and practices engaged in by the invited participants to a more general public audience. While the final workshop presentations were attended by approximately 300 members of the public, and edited online videos of the presentations garnered several hundred views, creating a more refined and accessible presentation format had the potential to greatly extend the reach of the work. In addition, we wanted the exhibition to be both an encounter with this form of design research and a direct invitation to participate.

Working closely with the symposium organizers and the curators of the ASU Art Museum, we developed a multilevel annotation and summarization schema identifying common representative themes and features across the collected data. While some of the generated artifacts were obvious and self-explanatory (e.g. well edited movie), others required a more nuanced, translational or indeed transformative approach in developing an appropriate surrounding context. We also identified key workshop activities (e.g. writing letters to the future, sculpting futuristic objects, contributing video responses) that translated well to a conception of an exhibition space as open, participatory and inclusive.

Figure 3. The main exhibit room containing the View-Masters, iBook, 3D printed objects, letter writing station and comic. Photo by Craig Smith.

Reeves et al. proposes a taxonomy for spectator experience design that accounts for the relationship between visitor as performer and observer [14]. Our target audience would include regular visits by mid-size groups (10 – 30 people), which necessitates consideration of processes such as turn-taking, waiting and public performance. The interactive installations created for the original public event contained both 'secretive strategies' such as the *Probotron* where the input and feedback interaction takes place in private, and 'expressive', such as the fortune telling *FutureSphere* (see Fig.11 later), where performers and spectators alike are privy to all aspects of the interaction. Our intent was to build on these different experience modes by

creating exhibit elements for private/public use and for individual/collaborative interaction in order to maximize engagement and reflection. The overall framing of the exhibition was categorized as "Redesigning *the future",* within which audiences could view, contribute and annotate three curated content collections (see Fig. 3 for photograph of the main exhibit room).

General commentary

To introduce exhibit attendees to some of the primary content themes and design practices of the event, we presented a variety of quotations at the main exhibit entrance (Fig 4). To select the quotes, we both mined the event tagged Twitter data for evidence of quoted phrases from the keynote speeches that the original audience tweeted about, and also searched through the video content for ideas and phrases that propagated from speaker to speaker throughout the event. Using the quoting and re-commenting features of social media data functions helpfully as an initial filtering mechanism for ascertaining selective public interest in a dataset.

Figure 4. Introductory panel displaying significant quotations from the design symposium speakers. Photo by Craig Smith.

Workshop Summaries

We categorized the workshop documentation and outcomes into three collections based on their inter-related themes and topics: *Embody the Future; Envision the Future;* and *Design the Future*.

The *Embody the Future* collection was the smallest in scope (photos and a large infographic, see infographic in Fig. 5) as it represented 3 workshops that were primarily discursive and ended rather inconclusively. As a result, we focused mainly on expanding the aim and reach of the tangible insights gained from the other more design-oriented workshops. The two resulting collections contained multiple activity sites inviting visitor contribution, annotation and commentary and demonstrate use of a range of summarization approaches at varying levels of abstraction.

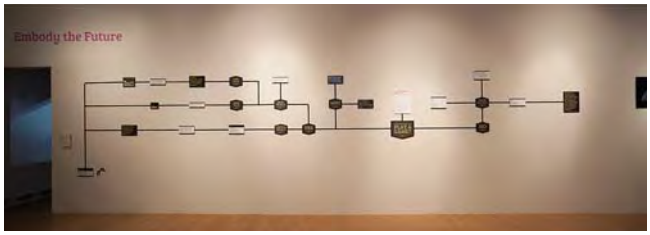

Figure 5. The infographic wall. Photo by Craig Smith.

The *Envision the Future* collection presented visitors with both designed artifacts and a window into the design process behind their creation. A bound book of annotated imaginary artifacts was presented as a form of future history book. The genesis of this artifact was introduced through a series of framed 'letters to the future' written by the workshop participants. Attendees were invited to write and contribute their own letters to the future at a nearby writing desk. This open-ended, long-form activity was complimented with a more constrained platform for contribution at the sci-fi prototyping workshop installation. Here the workshop participants had used storyboarding as a method for considering future health scenarios. We selected one of these scenarios and produced a graphic comic, with a final blank whiteboard panel for participants to complete (see Fig. 6). A time-lapse camera was placed above the exhibit to capture the creation, removal and re-creation of multiple possible endings. This form of quick, directed annotation provided visitors with a less time consuming way to contribute, and proved popular with children.

Figure 6. A child contributes an ending to the comic panels.

A workshop on future energy solutions produced a relatively dense final Powerpoint presentation requiring considerable expert or insider knowledge to decipher. In this instance, our curatorial approach was to depict the findings through various levels of mediated abstraction. First we created simplified short story statements representing each of the proposed energy scenarios (e.g. "Green Silicon Valley" or "Hippies and Cowboys"). We then illustrated these

stories using images mined from the Flickr creative commons archive. These images were accessed using a fun and familiar analog View-Master device (one device and set of 7 images for each story), and visitors were invited to contribute pithy responses on post-its for posting around the View-Master stand (see Fig. 7).

Figure 7. A child engages with the View-Masters, in the background contributed suggestions are seen on the wall.

This particular facet of the exhibition could be viewed as almost entirely an annotation in itself, as little of the originally produced material was used to illustrate the workshop event. The various presented components functioned more as indexes soliciting further high level 'tag' annotation.

The *Design the Future* collection presented artifacts and documentation from the three workshops that addressed design fiction directly. One workshop produced a high-quality movie about the convenience store of the future, which was directly presented in the exhibit, along with a curated selection of the fake future products (e.g. panda jerky) featured in the movie. The creation of the artifacts could be understood by examining them to hand, while the short 5-minute movie demonstrated their use in context, thus requiring little additional description. A workshop focused on 'archeology from the future' resulted in the creation of clay and 3D printed future objects, which were inspired by the development of imaginative personal narratives by workshop participants.

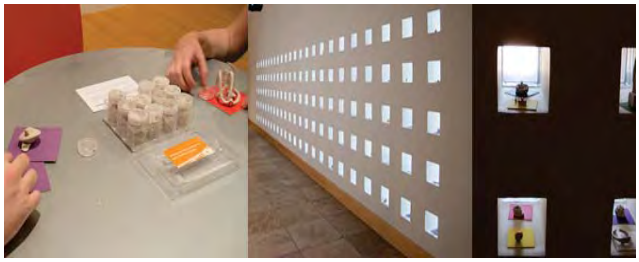

Figure 8. Attendees create future oriented clay objects and then leave them for display at the museum.

We selected four of these clay/3D model sets for inclusion, annotated with a summarized text version of their original inspirational story. In addition, we created a collaborative clay making and display space for attendees to *contribute and annotate* sculptural contributions to the archive, by creating their own future objects annotated with descriptions (Fig. 8).

One of the workshops adopted a highly improvisational design approach, punctuated and directed by multiple episodes of collaborative group decision-making. The group created two large-scale outdoor sculptures, and gathered a rich collection of media materials for their final presentation, which illustrated (falsely) how these sculptures came into being.

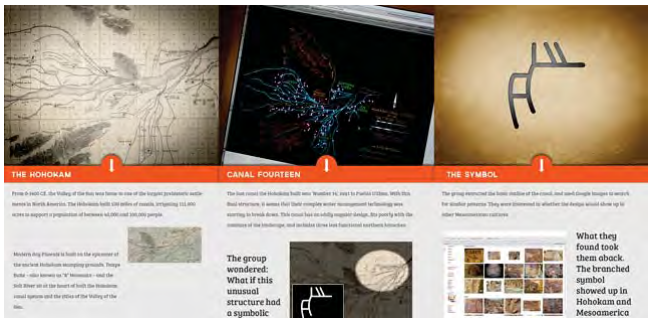

Figure 9. A reduced excerpt from the digital book.

Beginning with materials culled from the documentation kit USB drive, we created a chronological mediated story in close collaboration with the original workshop leads. Presented as an interactive iPad book, this exhibit sought to reveal the process behind-the-scenes while maintaining the integrity of the original subterfuge intent (Fig. 9).

Performing the Future

The second room of the exhibit aimed to summarize the immersive festival performance on the last night of the event.

Figure 10. The performance space included projected footage from the event, costumes and two interactive installations

We selected three costume heads from the animator performers and installed two of the interactive exhibits, one a take on futuristic magic mirrors and the other a future fortuneteller. We also created an edited 9-minute video of the one-hour performance that was projected on one entire wall of the exhibition space (Fig. 10)

Exhibition Outcomes and analysis

The gallery hosted over 20,000 visitors during the 3 months of the exhibition which was well trafficked and drew a large and diverse audience. In particular it attracted many school tour groups. In one special family day alone, over 2,500 children visited the gallery and a comparable number of students from local schools visited the exhibition. To ascertain the efficacy of the 'exhibition as research' approach we reviewed the contributed content (e.g. over 500 *Probotron* videos, 700+ objects, letters and post-it comments), and consulted with the museum's knowledgeable staff and curators. Given the high volume of tour groups, we conducted an in-depth interview with the education curator responsible for these visits. We now outline four primary findings highlighted by the curator.

Duality of Interactivity

Within the exhibition, the most popular elements were those that were interactive and tangible (the marble voting, the *Probotron* and the *FutureSphere*). Higher levels of interactivity seemed strongly coupled with popularity and appeal, particularly with tour groups. While this does appear to enhance engagement with the content there is a duality to this.

The level of interactivity on entry was immediately distracting for the younger audiences. "*I had to get them away from the opportunities to engage before they understood what they were looking at,*" explained the curator, who ultimately found that introducing the exhibition prior to arriving in the space was the best way to mitigate against this. Engagement was at times a barrier to fully understanding not just the themes present within the exhibition, but also within the installations and areas it contained. High levels of interaction led occasionally to playful exploration rather than deep consideration. On some level, and particularly for younger audiences, it may be more important to give them a compelling experience that engages and excites, rather than ensuring the completeness and coverage of their understanding. As the curator noted: "*do they really need to understand the scientific basis for everything, sometimes magic is awesome!"*

Catalyzing interaction

Only a small number of visitors were initially bounded by *"traditional gallery behavior"*, and students were reported to immediately engage with the rich space. Many of the exhibits needed no explanation, such as the *FutureSphere*, however others required an individual to initiate the group to converge upon it and catalyze others to participate (Fig 9). The *Probotron* was designed to be a private, reflective space where activities occurred behind a closed curtain. As a result, its function or appeal was not immediately evident. The curator explained that once one person explored it, and they deemed it to be *'cool'* or fun, it became of immediate appeal to the others in the group. Similarly it was noted that the infographic "*had limited appeal*" but "*once someone engaged with it they did start to interact with it more*." Given that contribution may be affected if interaction is not catalyzed, it is necessary to afford opportunity for that process to be initiated.

Mixed opportunities for engagement

Within the tour groups, marked differences were observed between the children and those supervising them. The adults were seen to gravitate towards the more involved, complex content, such as the infographic, avoiding heavily interactive pieces. The curator explained that this was not because this content appealed more to the older audience, but instead, teachers and chaperones wanted to "*make sure the kids had a really good experience, so they would go look at the things the kids weren't as fascinated with*".
Interplays between non-interactive and interactive components of the exhibition were also noted in the performance area. The *FutureSphere* (shown in Fig. 11) was extremely popular within this space, often having considerable lines. The presence of the projected performance movie offered them an alternative attraction, which could be readily consumed while maintaining their position in line. The exhibits 'cooperated' in this way.

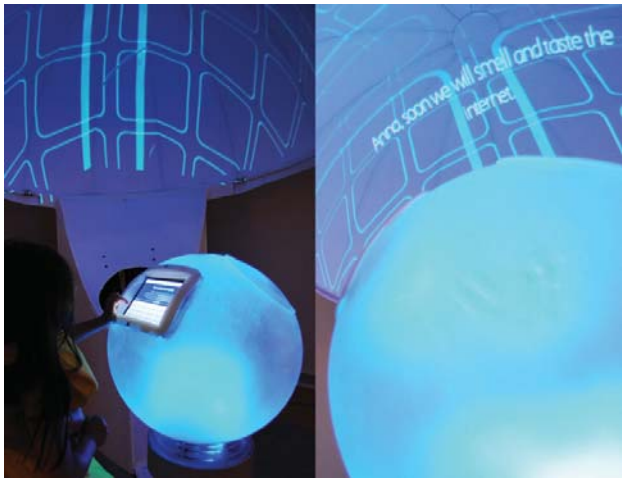

Figure 11. The *FutureSphere* in use

Both observations reveal that opportunities for engagement may be encouraged in how complex and lightweight, interactive and non-interactive elements are situated and juxtaposed with one another. Leveraging such interplays in representing experiential content appears particularly fruitful in designing for diverse audiences.

Involvement & Contribution

When introducing the exhibition, the museum guides also took particular care to explain that it represented on-going research into design fictions of the future, and that they would have the opportunity to contribute to these investigations. The curator commented that this was an exciting prospect as *"everyone likes to become part of the research."* This interest in contributing to research was evi-

dent in the effort invested in the contributions created. The activities individuals engaged with in this regard varied. The greatest number of contributions (over 500) were seen with the production of future objects activity. The creation of the clay objects was particularly popular with the children who visited and the curator noted that many of them invested a great deal of time in considering and producing these: "*I saw people spending 20-30 minutes working on their objects."* It was casual visitors who most deeply engaged with the more contemplative letter-writing task. Several individuals were remarked to have spent in excess of 45 minutes giving these compositions highly considered production.

"Everyone loved the concept of leaving an object in the Museum… Especially with the children, a lot of kids like to take things home. We gave them the option to leave it here or you can take it home. It's up to them. We were all astonished at the number of kids who decided that it was better to leave their art in the museum… Usually the majority take it home, but not on this project, even really little ones…Everyone who heard that this was part of research, really wanted to help the researchers... I think that was really appealing"

Overwhelmingly, visitors opted to leave contributions. The premise of their created work being incorporated and considered in a much broader effort was particularly compelling. In choosing to contribute in this way, it gave visitors agency and involvement in a much broader discussion and this considerably changed the relationship between them and the ephemera they produced.

Conclusions

Our work extends the concept of an annotated portfolio to propose the use of a considered documentation approach throughout the design process. Of particular value for capturing, organizing and annotating the artifacts and practices of research through design, our framework adopts an open contribution and annotation model to include diverse curatorial perspectives. Explored through a curated exhibit and developed as an online platform, our approach supports the presentation and dynamic re-presentation of annotated content at both personal and community filtered scales. Conceived to illuminate the methodologies and processes of research through design, our work has impacted the original event participants, our own design practice and the exhibition visitors. Our ongoing and future research includes creating an open source version of the online portfolio platform to support design researchers, practitioners and audiences in presenting, interpreting and validating diverse design contributions.

Researchify: Artists' Research as Disruption

Donna Szoke

Brock University
St. Catharines, ON, Canada
dszoke@brocku.ca

Abstract

My practice-based research explores what is invisible in the visual realm in order to investigate immanence, haptic perception, and non-visual knowledge. I approach the non-visible realm through video, animation, writing, installation, experimental collaboration, and drawing. Through this context, I ask: what is at stake in the recent shift in Canadian academic institutions for artists to define their work as artist-researchers? While this shift does suit the practice of many artists (myself included) it also carries a dangerous edge, a subtle implication that applying 'research' to art practice entails a more rational, articulable, or self apparent explanation of the function and value of art. The coined term "researchify" exemplifies this erroneous rational order. I argue that this urge to "researchify" is a dangerous tendency, and artists must protect the unutterable lacuna within their process. The leap of perception in the art experience remains fundamentally within experiencing the art itself. Art is an encounter that exists through the act of making and/or through the viewer's experience, accessible through phenomenological investigation. I apply the basic tenets of Gilles Deleuze's fold, Giorgio Agamben's lacuna, and Laura U. Mark's immanence of irreversible time to eschew rational over-determination.

Keywords

Artists' research; immanence; encounter; phenomenology; Deleuze; Agamben; lacuna; Laura U. Marks.

Introduction: The Limits of Reason

As a contemporary interdisciplinary artist I use video, new media, animation, writing, installation, experimental collaboration, and drawing to investigate immanence, haptic perception, and non-visual knowledge. I have been drawn towards animation for its inherent ability to suggest the flight of the imagination, and to irritate the rupture between what is actual and what can be represented. Throughout my art practice I have been drawn to implicating what is non-visible in the visual realm. The unseen yet apparent is often the driving force in my work, and it manifests in different forms. My recent research *Invisible Histories* explores the unseen through site-specific media art in public venues. [1] I create interfaces, artworks and situations in which the public can engage with new media that addresses their physical place in the world.

This way of working allows me to connect an art experience to emergent technologies, and our very localized, specific, sensory ways of being in the world. People, technology, and the landscape combine in magical surprises.

The catchphrase 'artist researcher' fits my practice as my body of work has arisen through a critical engagement and theoretical reflection that results in the production of artworks. The thinking and making are inextricably linked by "research in and through art." [2] As the term 'artist researcher' becomes a burgeoning category within academia, I am drawn to questioning the basic tenets of this shift. What fuels the expectation that artists can or must 'researchify' their practice? The term 'researchify' playfully and sardonically prods the question of how art is legitimized within academia. [3]

With the concept of 'researchify' I am referring specifically to a relatively recent shift (in Canada) in standards placed on artists teaching in universities to 'researchify' their practice. Artist research can be defined as both "research *for* art" (the range of practices that both inform and constitute artistic production) or "research *through* art" (where artistic practice becomes a vehicle for producing and presenting new knowledge)." [4] I am interested in the political stakes at play in the insistence to 'researchify.' Through this poetic reflection I aim to embrace, decry and celebrate the contradictions and complexities of artistic research methodologies. How does individual artists' creative research play a role within this larger debate?

'Researchify' implies a rational order by which we justify creative outcomes. *reasonable & senseless* is the title of my twenty-channel video installation. [5] Each video channel shows footage of an historic, human made, disaster with an animated letter superimposed upon the footage. When the animated letters are read across the twenty channels they spell the title of the work. The phrase *reasonable & senseless* implies that pure reason itself is a senseless force exemplified in the human made technical disaster. This type of disaster is not an accident, but more of an inevitable conclusion to a series of steps. Given the limits of reason, and its senselessness, how might we articulate the way individual processes emerge through studio practice? Besides an imaginative intellect, what other types of knowledge are at play for artist researchers?

The Cult Of Efficiency

The shift from art practice to practice based scholarship suggests that to 'researchify' art making entails an attendant shift to a more linear or rational process. In the Massey Lecture, *The Cult of Efficiency*, Janice Gross Stein observes that our current time is steeped in the cult of efficiency to such a degree we lose sight of the difference between what is efficient, what is efficacious, and what has lasting effect. [6] The act of creative making is not entirely knowable, and to present this process as fully articulable is to grossly misrepresent it. As an artist, my work is rooted in the traditionally poetic, and as David Jhave Johnston notes, this entails vulnerability, uncertainty, and epiphanies. [7] Embracing the irrational in art making takes us to surprising connections, linkages, and insights. To embrace the creative process, and to do it justice in writing, we cannot just blindly defend it, or attempt to fully define it but must cleave to a process that remains fundamentally outside of language. From my current experience within academia, I witness this uneven terrain between the cliché of inarticulate irrational genius, and extreme formal analysis, thus I am striving to define a more nuanced middle ground. Writing alongside my creative process demands poetic devices to articulate its terrain with any degree of precision. How do we bridge this space between the nuanced processes of sense making in practice with an entirely proscriptive act of telling? It is of utmost political importance for artist-researchers to privilege their ever emergent shifting studio work as a *lacuna* within the fixity of language, as a creative process that cannot fully enter into verbal coherence. The artistic medium of a works' realization is its most precise articulation and cannot be simply transcribed into words.

My interactive video installation, *and all watched over by machines of loving grace*, is a collaborative work created with artist Ricarda McDonald. [8] The title is from a 1967 Richard Brautigan poem that suggests a loving, caring machine gaze watching over humanity. In the gallery two enormous video eyes follow the visitor as they enter the installation. The work questions the uncontrollable growth of surveillance by machine networks and the values of those systems. The installation confronts the viewer with a silent system of dominance, and hopefully, attains this with some absurd humour. This work exemplifies a recurrent idea in much of my artwork: the power of what is omitted, elided, invisible, or unutterable. Language, or rather, absent language, is often the driving force in my work. It is precisely this crux of what is un-representable that my creative process springs from. When I create absence as presence in my work, what is this elusive thing I attempt to locate?

Absence As Presence

In the exhibition announcement for *Making is Thinking*, at Witte de With Contemporary Art, curator Zoe Gray states that the process of thinking cannot and should not be fully stripped away from the process of making: "An increasing division between making and thinking has marked European society since the Industrial Revolution." [9] If we refuse these binary ideologies such as concept and form we come to more productive outlooks. One such perspective is that there is a form of thinking inherent in making which can never be fully stripped from object-hood. The art object isn't just a thing, it is a thing in flux. At times it is merely an expensive object, and at others, a deeply affective en-

counter charged with meaning, and most often, both at once. My consideration of both the act of making and our critical reflection must lead me to privilege the making or encountering the art object, not to abstractions such as merely reducing the logic of the object to its market value, literary condensation, or other mediations. We can't sell, speak, or write away the art.

What might some productive models outside a division between making and thinking look like? What art making strategies encapsulate an intertwining of experience and modality? How might we be speaking within the synchronous mode of making? New forms begin to assert themselves such as simultaneous creation, exhibition, and discussion. In 2012 I was invited to present at an art lab by the hosts BADco, at Klub Mama, Multimedia Institute, in Zagreb, Croatia. [10] The BADco collective is comprised of five performers, dancers, choreographers, two dramaturges, and one philosopher. The central exploration for our gathering was the intersection between the agency of images, the performance of the body, and the apparatus of seeing. In the art lab model, the exhibition of work in progress is presented alongside the written and verbal considerations of the work. This conjoining allows for a phenomenological opportunity for investigating and negotiating layered meanings together. [11] It creates an open arena in which the improvisational and the written are equally present. As a group of experienced creators, we conjointly confront creative struggles in a shared encounter. In opening to each other's unfurling work we engage in a phenomenological co-creative trajectory. In this model, making and thinking are coterminous, integrating both critical and creative processes. In these shared encounters, openness is crucial.

Lacuna

Dahlberg typifies this aspect of openness as key to phenomenological research: "Openness is the mark of a true willingness to listen, see, and understand. It involves respect, and certain humility toward the phenomenon, as well as sensitivity and flexibility." [12] The aim is to allow the phenomenon to present itself to us instead of us imposing preconceived ideas on it. As Finlay notes, this openness needs to be maintained throughout the entire research process not just at the start. [13] Furthermore, in teaching the process of studio research this openness must also be maintained. Perhaps co-creating the moment of research becomes the only ethical way in which we can teach that moment of creative unfurling, as it is as we encounter it in the studio: uncertain, barely perceived, in error, in omission, repressed, or barely visible and limping. Like other forms of phenomenological research, studio work cannot be simplified of its multivalent possibilities. Dahlberg notes "the best phenomenology highlights the complexity, ambiguity, and ambivalence of the participants' experiences…. researchers need to be "careful not to make definite what is indefinite." [14]

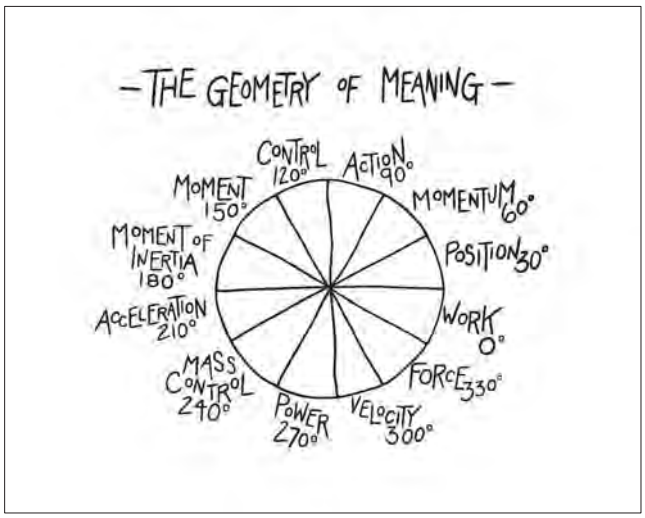
To 'researchify' is to deny the complexity in which we are deeply embedded: as subjects we are never separate from the object of our creative study. As we near the object of our study, our process entails an inherent, inarticulate interface that is in fact our own lacuna, our own pre-cultural, pre-lingual selves, indivisible from its enmeshment with the world. Giorgio Agamben articulates this idea of the lacuna when he writes about the impossibility of testimony. For what testimony reveals at its core is "the non-language to which language answers, in which language is born." [15] I press up against experience, against making, precisely because I cannot utter experience any more than I can utter what resides in my own non-language. The impossibility of mediating experience is the central idea in my single channel video *the bell*. [16] The work has a short, subtitled narrative that conveys the idea that although the nature of experience cannot be fully articulated, it sings out in our silence. The narrative revolves upon a song that is almost impossible to listen to, and yet the song moves towards articulation despite the impossibility of becoming fully divulged in that process. Perhaps the song is the very impulse to make art, to push up against the limits of representational systems.

Flow

Emphasizing the gap between representation and what cannot be articulated is a strategy to highlight our nature as a human subject, as a Deleuzian fold of "the outside folded in" and hence, "an immanently political, social, embedded subject." [17] In this complexity our apprehension is also inherently misapprehension, and slippage is always entailed in the process of articulation, or art making. Here is where sense making in the studio exists, where creative bifurcations improvise previously unforeseen outcomes.

In *Enfoldment and Infinity* Laura U. Marks states that our primary relationship to perception is not to "measured time, but to lived, irreversible time" and that this relationship constitutes "a 're-enchantment of the world.' This is true immanence. If time is irreversible, no law can predict the outcome of an experiment (such as life); instead, things in their particularity, and people too, bring about new states that could never have been imagined." [18]

To 'researchify' is to artificially slash apart the myriad complexities of the creative process. The urge to 're-searchify' is borne of an industrial model that has clear political agendas in the separation of concept and form. To cleave to the immanent is to refuse this separation between concept and form, to refuse an institutionalization of formal analysis that results in the dematerialization of the art object, the art form and the art process. The ink drawing, *The Geometry of Meaning*, clearly spoofs the ideological function of extreme formal analysis. [19] In a similar vein, Fredric Jameson notes a similar institutional "irrepressible urge to identify all thoughts with a named source." [20]



When I bring my own strategies as an artist into the pedagogical process, I am challenged to sustain the gap between representation and what is unknowable. To sustain the lacuna, gaps, and slippage in the studio process is to present it whole. Otherwise I am locked into an artificial rank-structure as an expert who produces knowledge workers rather than being one of a collective in a creative response to the learning studio situation. I'd like to highlight this strategy, that of the collective creative response, as I see it as exemplary of the type of integrated approach I am urging as an ethical response for the framing of artistic research and the teaching of art. It suggests a shift, from knowing to doing, from visuality to haptic engagement, from expertise to creatively exploring our collective not-knowing. This process, this shared flow, stands in contradistinction from the urge to 'researchify', which is essentially stratification. Perhaps this is what 'researchify' best exemplifies: that institutions can tend towards stratification. As artists, we are within the institution to challenge stratification through he reinvigoration of forms, of understandings, of practices, of definitions, of languages. We inhabit the creative response manifested through research, and are part of the process of ushering in new forms of research within the institution. It is our creative bifurcations that accompany this shift from stratification to flow.

Chair de lumière by Marjolaine Béland: How Disruptive Conditions and Mimicry Capture Attention and Favor Empathetic Resonances

Louise Boisclair

Abstract

This paper examines the experience of *Chair de lumière*, an artwork by media artist Marjolaine Béland, that aims to create conditions of the apparition of the double, our double of light. By analyzing the disruptive conditions of illusions and performances that the artist orchestrates, we come to understand how cumulative effects –the architectural components and accessories, the involved audio and video technologies, the infiltration of two performers in the space and the interplays with light, transparency and reflection– build an aesthetic event in five different Times. The key factors of the aesthetic event are the mimetic human or non-human performances. The resulting empathetic experience with projections/reflections/refractions and the performing bodies induces ambiguous and tense sensations. Then the phenomena of mirror neurons contribute to clarify these ambiguous feelings, by distinguishing the visuomotor and the visual aspects that are entangled. Finally, the miming gestures of the participant and one performer and vice versa are exemplary of an intense affective moment constructed by micro-disruptions and resonating in the suspended Time.

Keywords

Apparition, double, light, mimicry, movement, empathy, mirror-neurons, performance, reflection, projection.

Disruptive Conditions in Actual Art

In actual art creators use many disruptions, be it scenographic, choreographic or technological, to divert habits of the participants and create singular conditions for building an event.

To start, there is often a blurring of the perception to destabilize the body, to alert its presence and to capture its attention and orient it. The inaugural disruption may be brutal (stroboscopic lights, extremely loud sounds, even conditions of vertigo), but the rupture of convention can also be incremental with tenuous disruptions as with the performative and immersive installation *Chair de lumière* by media artist Marjolaine Béland. With the participation of two performers, her main objective is to create the conditions for the participant-spectator to be present to the apparition of his or her double. This double of the body is provoked by variations of light, as captured and projected through a technical apparatus that she tries to make disappear in order to create room for the phenomena of appearance and vanishing and also by the powerful amplified sounds that subliminally affect the balance of the body in acting on the vestibular system.

In September 2013, Béland invited the public to three Evenings-Events at La Chaufferie, au Cœur des sciences de l'UQAM, in Montréal on Thursday September 12th starting at 6:26 PM, Saturday the 14th starting at 6:22 PM, and Sunday the15th starting at 6:20 PM. Personally, I participated in the September 14th event, which started a few minutes late for final adjustment to be done. Before opening the doors, she asked us to wait in the park while the sunlight was decreasing. These three Evenings-Events constitute the creative portion of Béland's doctoral research and thesis that she just completed.

Chair de lumière: General Description

A brief description of the event found in its invitation states: "*Chair de lumière* is an immaterial and impalpable work whose form is on the border of media arts, film and performing arts, and where the 'faire œuvre' of the phenomena of appearance is based on the ephemeral, the improbable and the fugitive, on the nebulous, the vague and the uncertain, on the nonlinearity and the unexpected, on the imperceptible sensory impression of the viewer.'' [1]

In other words, *Chair de lumière* proposes to the 'participant-spectator' an experience where he or she, while remaining themselves, becomes the actant of the experience going through a quest of indexes. It goes from exploring the architectural space and listening to sounds, to looking at the screens and window reflections, to observing the effects of a light projector and of a kinect capturing movements that are superposed to the seeing of performers walking outside and, at some other time, to the performers playing with a veil before final mimicry with one participant.

In front of the entrance, a laptop screen on a pedestal shows five chronometers with citations in the margin. Attracted by the screen, participants-spectators star at these chronometers, trying to figure out what dimension of time the first one is calculating while the others, indicating a specific duration, are waiting for their unknown cue.

A few moments later, the four speakers start to emit more and more amplified and transformed recorded envi-

ronment sounds, interfering with the physical sounds of the locus and its occupants. Gradually the external environment filled with anonymous people is doubled by the projection on the south wall screen provoking illusion and distorsion. The performers discreetly stroll outside, visible from the mural windows west to east and vice versa, while their duplication on the south wall screen opposes the other portable screen on the north side of the room.

First dilemma: is it in real time or in delayed time or both? Hard to say, maybe a mixture of both.

Second dilemma: by watching one screen, what do we miss that is being shown on the opposite one, the same thing by concentrating on a direction east or west or a specific portion of the room or the accessory of the veil?

All of these conditions with the deployment of the performance live and captured create five different phases of a new spectatorship. As Béland writes, they are:

- Time0: time prior… 22 minutes;
- Time1: time of exploration and immersion. 13 minutes ;
- Time2: time of illusion. 10 minutes ;
- Time3: time chiasmus. 30 minutes ;
- Time4: time of suspended work (…). [2]

As I experienced, this spectatorial investment evolves from Time0, observing artificial light taking place and searching for indexes, to Time1, from peripheral spatial attention to intensive immersion, to Time2, engaging an encounter with things invested by the performers and movements generating reflections, to Time3, movements of performers and engaging mimicry with participant-spectator before capturing somebody else, to Time4, dissolution of illusions, movements and projections.

Béland's installation integrates different qualities and intensities of light (daylight, light from the screens, the projector, filters, etc.), various form of movement (walking, dancing, playing and fighting with the veil, etc.) and of their double (projected, captured, lighted, reflected and transformed). First, she invites us implicitly to attune with the end of the day outside. Second, once having entered into the room, she slowly captures our attention, playing with duration through the sound projection and she mobilizes our expectation with the chronometers. Third, she coordinates the superposition of the recorded sources of images and sounds with the performance live *in situ*.

Immersed in a monumental space with big fenestrations on the west and east side, the set up built a continuous and changing effect of doubling things and humans, with increasing illusion up to engaging our body in mimicry.

From disruptive conditions to illusion

Béland's technoartistic 'mise en phase', different than 'mise en scène' more stage oriented, crosses disruptive conditions from the architecture (whistles from heaters, pipes noise, heat from radiators), from the use of accessories (lines of red paper pasted on the windows, white veil on the windowsill), from a mixture of devices and softwares (wall giant screen, computer screen on a pedestal, kinect, projector, four speakers) and from the participation of two professional performers infiltrating the inner and the outer space, and eventually transforming us in mimetic performers.

The scenography induces:

- a rupture from accelerated urban life to a slowness of waiting;
- a delay while watching the twilight;
- a gradual pulse taking of the place in tune with the descending darkness and the increasing artificial light;
- a transitive passage from individual presence to collective state;
- a plurality of projections/reflections/refractions transforming the doubles;
- five phases building a dynamic field for mimetic human and non-human performances;
- resulting in an empathetic experiencing disrupted by tensions.

Parasite Issues before Integration of Meaning

The slowness is disruptive to urban life of Montréal's downtown. First of all, the waiting awakens our perception and stimulates compensatory repositories while various questions parasitize or divert our attention.

Why starting at a specific time related to the decline of daylight and its shadows?

What do the five chronometers refer to?

Why is there a veil on the windowsill? What narrative function does it assume? Is it a micro-event metaphor of the global event?

Are the bizarre noises from the pipes and the hot air coming from the radiators conditions included in the scenography?

Are the red lines taped on the window there to capture a specific area, if so where is the camera? Is it for filming what has been done before or will be done?

Are the people traveling in the east and west sidewalks part of the event?

What is the significance of the capturing of a participant by a performer that mimics the movement she leads?

What happens to the body with these multi-layers effects affecting the individual and collective presence?

Progressively, as the magic begins to operate, the questioning proportionally vanishes as the body crosses and the bodies cross various states and feelings.

Body, Embody, Perform

"Our own bodies form lenses of experience, perception, cognition and disruption.'' [3] More and more immersed in *Chair de lumière*, the body feels, the bodies perform and embody variations of doubles. To perform here is a complex ongoing process, becoming to per-form in the words of Nathaniel Stern:

> The conception of a continuous embodiment, however, allows us to rethink bodies as formed through how we

> move in, and relate to, our surroundings. Embodiment, I contend, is not a pre-formed thing, but incipient and per-formed. [4]

Per-formed is to be underlined here in many ways. To begin, the waiting body, then, the alert body. With the intensification of the presence. The broadcasted mimetic body, the flesh in the Merleau-Pontian sense of this term in the encounter with images and others. The sensitive/emotional/mobile body. The inanimate and animate bodies, the physical and projected bodies in the space. Throughout the postdisciplinary per-formance orchestrated by the 'metteure en phase', the bodies of humans or non-humans participate in the illusion. The 'effets de présence' build an event of appearance and disappearance. As Pitozzi proposes:

> The effect of presence manifests the passage of a "body" that fits and takes place into the reception of the viewer: the trace of a movement, an image or a sound that is not there and at the same has been there, but that is no longer there now. [...] The effect, as a product of presence, corresponds to a combination of sensations that the presence induces and inscribes on the sensitive plate of the viewer's brain to produce a resonance in his muscles, in a shared dimension of empathy. [5]

It is about apparition and its modalities in the interval just before and after the illusion. It is an epiphany that induces empathy.

Affective forces that vary from one participant to another (the weight of expectation and the sensory exacerbation, the search for meaning and the plus or less easy integration of resonances, the cuts from one direction to another, etc.) and various emotional tones (the esthetic delight of some images, the joy or interest of movement mimicry, the magical effect of illusions, etc.) modulate attention and enlarge the depth of immersion.

By orchestrating the technoartistic phases with the performance of actors and their contamination of the spectators, Béland questions the political context of the accelerated speed, the virtual temporal components of urban life. By interweaving the virtual and the actual, in the Deleuzian sense of these terms, she invests spatiotemporal dimensions. Illusions open the ability of the body to feel the action seen and heard 'as if', things and beings carried out internally but externally inhibited and disinhibited. This feeling of doubling or being doubled introduces an empathetic bodily experience. Mimicry induces connection with the other. Our double? But also it provokes ambiguous feelings by seeing the performances or by feeling them as if we were doing them ourselves.

Empathy is central to understand how performance, human or non-human, is a conscious and unconscious source of mimicry. This emotional and motivational matrix influences constantly, and is also influenced by, our aesthetic experience and its multiple variations, not to say disruptions, and the ambiguous tensions that they provoke. In order to clarify what is happening, neurophysiology of empathy and mirror neurons can add some inspiring clarifications.

Empathy and Mime in the Light of Mirror Neurons

During the evening-event, the many unexpected lighting and reflecting micro-events intensify our resonance, we become empathetic with the performers, the others and their doubles.

According to neurophysiologist Alain Berthoz, empathy requires a change of point of view or of perspective. It consists of looking in our own way but within the extension of another's perspective. To do this, it relies on the memory of the past, while being oriented towards the future. Our memory has built a vocabulary of actions, intentions and related consequences that are used for anticipating situations that we encounter. [6] When we empathize, we feel what we see with an ambiguous tension. May be this tension is related with seeing only and with seeing as if doing.

These empathetic tensions gain light here with the phenomena of the mirror neurons described by Rizollatti and Sinigaglia. [7] After the discovery of mirror neurons in the macaques' brain, other studies have examined their role in action recognition and imitation in human brain.

Movements that we see have resonance in a certain zone of our own brain, as if we were doing them ourselves. Then movements from other entities penetrate our corporeity as if we had performed them ourselves, but only if we have similar movements in our vocabulary. Mimicry between the two performers that we look at and between one performer and ourself and so on, invades our individual and collective consciousness field. It has a visuomotor component that corresponds 'as if we would do it' if we have the vocabulary and, if not, only a visual component. Rizzolatti and Sinigaglia explain that, without any visuomotor resonance, it can be called following James, 'cold' or 'neutral' perception, which is devoid of any emotional colouring. [8] Nevertheless it still penetrates our body. I propose that these distinctions explain subtle feelings related to the empathetic experiencing. Neurophysiology adds neural information to diffuse experienced feelings.

So the contrast between the waiting and the incremental intensification brings at the forefront some of the conditions that otherwise we incorporate without acknowledging them. The perceived movement around us appears 'as if' they were lived in our own mirror. In fact, they are seen *in situ*, they are reflected in window and projected on screens. Mimicry reverses the inhibition of the body by unfolding its potential with our visual and/or motor connection with others. For example, in the fifth phase before ending, after the mimicry between the two performers, each performer mimics a selected participant.

When I am captured by the performer, I move in a certain way, to see to what extent she can imitate. What a surprise, her movement is very similar, except for small interruptions. As Massumi has discussed about the politici-

zation of the power of mime conducted by former United States president Ronald Reagan, "That power is in interruption. A mime decomposes movement, cuts its continuity into a potentially infinite series of submovements punctuated by jerks.'' [9] The effect of mime is immediate and affective. It carries an excess of intensity. It makes you the center of the interconnection, even more when you see your doubling on the screen and in the window. As Massumi highlights:

> The affective "atoms'' that overfill the jerk of the power-mime are monads, inductive/transductive virtual perspectives fading out in all directions to infinity, separated from one another by dynamic thresholds. [10]

In *Chair de lumière*, with the suspension of disbelief, a kind of magic settles. Through ninety minutes of passing-dynamic thresholds, a close relationship with doublings inaugurates a mimetic circuit between action, reflection and sensation. Progressively the hunt for causes fades until more complete immersive feeling prevails. In this suspended time modalities of illusions and sensorimotor modalities of tensions are subsumed by the contentment of an empathetic event and its waves of empathetic feelings.

Acknowledgements

The preparation of this article was facilitated by the postdoctoral research grant (2014-2016) from the FRQSC. Thanks also to my supervisor Brian Massumi, to the artist Marjolaine Béland and to my readers Enrico Pitozzi and Troy Rhoades.

Alea (iacta est) – Dance of Presence

Abstract

In this paper, I present an overview of the notion of presence in dance works. I give an analysis of the dance piece *Alea (iacta est) – the die has been cast* created by the Italian choreographer Simona Bertozzi, then follow with a comparison of dance productions that utilize motion capture.

In my analysis I define, or perhaps redefine, the concept of presence in performance within technology and human interaction, specifically Mo-Cap. The definition of presence that I propose is related to the notions of intention, attention and memory of the performers, as well as their relationship with space. The phenomenon of presence can be defined as an expansion of the body, rather than an overlapping of it; hence, my argument is that presence requires a physical body as a starting point. To be present means to maintain a certain degree of tension between the dancer's body, his or her intention and the performance space.

The research is driven by several theoretical and methodological approaches, such as: phenomenology of Maurice Merleau-Ponty, historical explorations, and my own experience as a dancer.

Keywords

presence, dance, phenomenology, choreography, awareness, Simona Bertozzi, performance methods, motion capture, interactive media arts, Alea (iacta est), Homo Ludens

Introduction

'Presence' is a controversial and multifaceted term that cannot easily be defined since it has been used in a wide variety of disciplines, such as theatre, cinema and dance. I claim that the phenomenon of presence, in dance and performance, occurs when dancers/performers have a clear intention and a strong attention that allows them to become aware of the space through their bodies. This awareness creates a relationship between time, space, body and audience.

The rising trend of the use of technology in dance and performance has changed the way we conceptualize liveness and, consequently, presence. Since I argue that to be present means to maintain a certain degree of tension between the projection of movements and their actualization in the space, I pose the question: Is the physical presence of a body necessary in order for presence to be manifested? If so, how can the notion of presence be redefined in an interactive media-art performance?

In the first section of this article, I investigate the dance piece *Alea (iacta est)*, third episode of the project *Homo Ludens* created by the Italians Simona Bertozzi and Marcello Briguglio. *Alea (iacta est)* exemplifies what I intend as the phenomenon of presence, defined from a phenomenological perspective, in a non-technological dance piece.

I then investigate the same phenomenon in interactive media-art performances, specifically in pieces that use the motion capture (Mo-Cap) system. I argue that *presence* can be defined as the expansion or the projection of the body into space. This definition allows the use of the concept of presence in a technological environment because it considers presence as exceeding of the body rather than an overlapping of it.

Alea (iacta est) and dance productions utilizing motion capture produce different results in the manifestation of the dancers' presence, but they share the same principles: strong intentions and attention of movements. To conclude, I argue that in order to create the phenomenon of presence, defined from a phenomenological perspective, a physical body is always necessary as a starting point.

Alea (iacta est) – Dance of Presence

In colloquial language, 'presence' defines someone or something that is in a specific time and place. Usually, the word 'presence' is linked with the idea of 'liveness' and of the presence of a physical body. However, in the field of art, especially in disciplines like theatre and dance, this term usually describes the characteristic of a performer being present on stage and being open to an audience. This implies that performers must have an awareness of the intention of the movements and be conscious of the relationship between their bodies and the space. According to the phenomenology of the French philosopher Maurice Merleau-Ponty (1908 – 1961), the body has a tendency to exit and open up to the world. This inclination is comparable to the projection I indicate as the source of presence.

The phenomenological approach of Merleau-Ponty can be seen as an attempt to explain how the intention of an artist (the invisible) becomes visible in a work of art. Merleau-Ponty describes the invisible not as "the contradictory of the visible"; instead he states: "the visible itself has an invisible inner framework (*membrure*), and the in-visible is the secret counterpart of the visible, [appearing] only within it."[1] From this perspective, the

notion of presence represents neither the physical body nor the feelings of the performer; rather it is an expansion of body into space. Presence does not overlap the physical body; instead it transcends it. As Merleau-Ponty describes it, presence is the invisible.

The definition of presence that I propose is related to notions of intention, attention and memory of performers because "presence implies temporality, too – a fulcrum of presence is tense and the relationship between past and present."[2]

Based on these premises, we can make an analysis of the notion of presence in the dance piece *Alea (iacta est)* (2010-11). *Alea (iacta est)* is the third episode of the project *Homo Ludens* (2009-2012) choreographed by the Italian dancer and choreographer Simona Bertozzi. This project consists of four dance pieces, each dedicated to a different character, which refer to the categories of play as defined by Roger Caillois in his work *Les jeux et les homes* (1958), based upon the book of the same name written by Johan Huizinga in 1938.

The first piece, titled *Ilynx* (2009), represents ecstasy, vertigo and the idea of the vacuum; the second is *Agon* (2010), where Bertozzi examines competition and challenge in sports; in *Alea (iacta est),* the third episode, Bertozzi investigates gambling and games in which everything is left to fortune; and in the last piece, *Mimicry* (2012), she focuses on mimesis and fantasy.

Alea (iacta est) is a duet, originally created in collaboration with the English dancer and choreographer Robert Clark, then interpreted by the Italian dancer Manfredi Perego. The piece clarifies the important role of intention, attention and memory; it also exemplifies what I defineas "invisible dance".

Bertozzi considers the body as an instrument that is always collocated in a specific time and space. The body is open to an environment and inhabits movements; therefore it becomes a witness of the space. In other words, there is an intertwining between the inside and the outside of the body; there is an exchange between the space and the performer. Dancers' actions find space both inside and around their bodies; presence cannot be seen outside the dialectic between the projection of movement and the reiteration of the bodies' action. It is in the subtle space between the visible and the invisible, between the movement and its projection, that the phenomenon of presence becomes visible.

In *Alea*, the audience sees wandering bodies moving into space, leaving their movements' marks on the stage. As Bertozzi writes:

> Starting to move only some parts of the body slowly so as to avoid leaving a deep mark into the space; it is necessary to feel its organic nature. To cut through it by connections, by casting lines between the various points of its material consistency, so as not to seal it inside a choice of physical depiction that is aesthetically pre-established.[3]

Let us consider the moment where the two dancers, Bertozzi and Perego, blindfold their eyes with their own hands. They explore the space as if it were the first time they had entered it. They constantly change levels, from standing vertical to lying on the ground; these transformations leave traces of movement that create geometries of space. Dancers construct the space through the signs of their movements; this allows the storage of gestures into the memory of spectators. Bertozzi states:

> Gestures are actions of the body that fuse a before and an after […] I experience movement as a multiplicity of figurations and possible events with the intention of generating a dialogue between the visible material and its corresponding element in absence. Presence and ghosts. Gesture and movement, thus enacted, measure themselves against a perception of time based on quality. [4]

An analysis of *Alea* allows us to reflect upon human behavior because the two dancers become participants in a play in which they are deeply involved. The play evolves as a dialogue between their bodies until it dictates the rules of the choreography.

The awareness of body and space is such an important feature of Bertozzi's aesthetic that it also inspires her teaching methodology. Her dance workshops focus on the intention and attention of the dancers using different strategies, such as somatic practices, clear thinking, and the dancers' ability to put thoughts into words. Using the information that she gives, dancers can expand their imagined, dilated bodies. Bertozzi usually asks her dancers and students to imagine their bodies and to visualize their anatomies projected into space before the movement takes action in the tangible world.

This process generates what I define as the phenomenon of presence. Presence in dance is an ability to project movements and bodies into space in order to create a tension - between projected bodies, actual bodies, and movements - which makes the phenomenon of presence visible.

Interactive media technology

I would now like to introduce and discuss the definition of presence as it relates to performances that include interactions with technology, specifically motion capture. The integration of multi-media technologies into dance and performing art requires a redefinition of the concept of presence because the use of motion captures, as well as of digital projections, has transformed our understanding of the notion of presence.

As discussed previously, the phenomenon of presence in dance means a tension between an actual movement and its projection, as well as between a physical body and its dilation in space. The definition of presence that I presented oversteps the physical body; therefore it allows the term to be applied to a technological environment. I argue, however, that the phenomenon of presence always requires a physical body as a starting point.

The use of Mo-Cap makes it possible to receive information regarding performers' movements that would otherwise be impossible to reveal; for example, a virtual movement can be read as a trace, a phantom, or as presence - as defined it in the previous paragraphs. The use of digital supports makes it possible to explore new paths, to open the field of the possible without restricting or binding the body to a predetermined order.

First of all, it is important to emphasize, as the performer and philosopher Susan Kozel notes, that there is a distortion of the term virtual. It can occur as something "embedded within the virtual-real duality and used to qualify an action, object, space or emotion that is distinguished from the real." [5] In this case, the term virtual is used to highlight the dichotomy with reality. On the contrary, when I argued that the notion of presence does not overlap the physical bodies of dancers, but concerns their virtual bodies, I was referring to a dilated body, which is an expansion or an image of the physical one. The virtual body, both reproduced by movement sensors and intended as dilated, does not identify with the physicality of the dancer; rather, what is created is a dilation of it that opens up new horizons and possibilities of movement.

In an interactive media environment, the 'physical presence' of the performer can be replaced with its virtual reproduction. Giulia Tonucci explains that, in this situation, two different processes are ongoing: the "doubling of presence" and the "amplification of presence". The former is referred to as a scission between the physical presence and its digital double; the latter is defined as "the movements captured, elaborated and then digitalized and amplified, in real time or in post-production." [6]

Tonucci's clarification is useful for analyzing creative practices, as the introduction of technologies has changed the manner in which choreographers and artists compose. The scenic composition, as Tonucci claims, becomes a new environment: new technologies offer new tools to analyze and compose it. Nevertheless, I disagree with her definition of presence because I believe that what she defines as "amplification of presence" has nothing to do with presence; rather, what she describes is the power of new technologies, considered as an instrument for learning about movements and for breaking down dancers and choreographers' habits.

On the same topic, in her book *Closer* (2007), Kozel states:

> When I encounter my digital self I discover that it is not simply me. […] The figure with which I perform is always at the same time both my own body and another body; […] If we follow Merleau-Ponty, perception is more than just the neurophysiological mechanism by which I apprehend the world. Perception is constitutive of who and what I am.[7]

In other words, the digital body is not the double of the body; it is not a different and separate entity. The digital body is the materialization of presence, interpreted as an expansion and a projection of the body and its movement. It is evident that in order to talk about the phenomenon of presence, the physical body is necessary.

However, if we consider Bill T. Jones' piece *Ghost-catching* (1999), I suggest that, in this case, the digital body can be considered as a double of the physical one because the performer was not on stage. In this digital art installation, created in collaboration with Paul Kaiser and Shelley Eshkar, the dancer's physical body is separated from its movement; movement is withdrawn from Jones' body.

The use of motion capture changes the relationship between the performer and his or her body. The description of Kozel's experience as a dancer in the event *Real Gestures, Virtual Environments* (1998) reveals similarities and differences with Bertozzi's aesthetic. Although Kozel interacted with visualized data, whereas Bertozzi established a dialogue with mental images, she performed "with visual movement data projected in real time on a surface adjacent to the performance space […] so that the visualized data becomes a partner in the space." [8] In a similar way, Bertozzi danced with space, creating imaginary shapes into it and transformed the projection of her own body into a partner.

Conclusion

This article has presented the notion of presence through the lens of dance studies and an analysis of the dance piece *Alea (iacta est)* choreographed by the Italian artist Simona Bertozzi.

I have presented a definition of presence that does not overlap the physical body, but rather oversteps it. From this perspective, presence is the invisible as Merleau-Ponty defines it; it is the ability to project dancers' movements and bodies into space. In other words, the phenomenon of presence is made visible on stage by the tension that dancers create between their actual movements and their intentions or, in the case of productions that utilize motion capture, by the digital/virtual body.

My argument is that Bertozzi can be considered new and innovative, even though she does not use any kind of technology in her works; instead she uses dance as an image-making technology. She creates and composes with mental

images in dialogue with the body and the space. Although there is no use of technology in her dance pieces, the intentions of her movements are extremely clear so that we can see the expanded/dilated body moving in space. In both Bertozzi's works and those of interactive technologies, presence transcends the actual dancing body and becomes 'visible' on stage.

Through the strong focus and attention that Bertozzi places on movements, spectators can recognize traces and signatures of her dancing body without the aid of technologies, as if her pieces were interactive media-art works where virtual figures can be perceived, touched or felt as if they were projections of dancers. The phenomenon of presence exceeds, or at least corresponds with, the performers' bodies.

Abstract

This body of work explores the transformation of the human body, both physically and mentally as increased reliance upon electronic technology forces conditions of artificial that replace the "natural". This Fundamental shift in stimuli becomes a tipping point in evolution.

Keywords

Evolution, Artificial Selection, Interactive Installation, Telepresence.

Post-Body

From the beginning of human existence there has been an innate desire to control and shape both our world and ourselves. The construction of primitive tools from bone has accelerated into a dramatic shift in the evolutionary process of the human species. As the tool making species increases its reliance upon its own constructs, many residual effects work to alter its progress. Throughout time there is, and arguably always will be a universal struggle for existence, but in today's technological society the factors that dictate survival have shifted to a rupture point where the velocity of human modification of the environment is out pacing our evolutionary adaptation. The basis for natural selection put forth by Charles Darwin, states that 'through competition, generations of a species will transform or adapt itself with those qualities' [1]. By the simplest of genetic distortion, the 'fittest' will survive longer, enabling them to reproduce more often and hence contribute more of their genetic character to the species as a whole. Today, however, due to the increased reliance upon electronic technology and biomechanical engineering, the gene pool itself is shifting in a contradictory direction. The traits once considered assets for survival are now obstacles. As technology further augments the 'natural' with the artificial, the more the 'weaker' traits of the species will prevail, further perpetuating the reliance upon the artificial for increased productivity. The tools the human species makes in turn make them. Contemporary adaptation is increasingly transformed into an artificial process driven by a social collective, which seeks survival through technology.

The tools created to control the environment are now controlling us, both in how we individually function and collectively as a species. Genetic alterations are shaping our species by this very technology. Those who cannot exist or reproduce naturally are now, through the advent of technological means, living longer and reproducing more. The natural genes, which enabled their dependency upon technology is being passed through generations in an increasing abundance fostering a deeper reliance upon the artificial. Systematic cultural design is transforming the interface we use to know the world, while internally the mind is processing and absorbing a world not based upon natural stimuli passing through the body, but understanding itself from the artificial.

Biomechanical technology seeks to alter the physical body through artificial selection. From the advent of external limbs through the recent development of genetic engineering, a progressive restructuring of the physical body is occurring. Almost all cultures, both past and present, practice some from of body modification. The oldest human remains found to date, the five thousand year old mummified body of a man frozen in the ice of what is now the Italian Alps, had tattoos. However palatable the current trends of body modifications are, the future offers more exaggerated displacements of the current body image, encouraging a deeper rift between the natural and the artificial.

As an artist, I am concerned with the impact technology has over our collective development and how it further embeds itself inside of us. The notion of socially directed body modification dates back thousands of years, the Greek "super-anatomical" sculptures helped to invent the ideal form, the 19th century development of moving pictures illustrated the behavior and movement of that form, but it wasn't until the technological development of "X-Rays" that the real notion of the body changed. Today, through physical examination and reliance upon machines, we can communicate directly with the body. What the patient know is untrustworthy; what the machine knows is reliable, and those machines are shifting.

Technology is not just a tool. It is information, in that it shapes how we think and in the absence of an alternative reality (i.e. nature) what we think about and know.

Black Lung, (figure 1) an interactive sculpture, responds directly to the technological restructuring of the body. This piece consists of a compressor and a motor driven valve system, which allows the artifice to simulate a working lung in the human body. Additionally, a motion detector is added to the compressor to emphasize the need for social approval in order for the machinery to successfully augment the body. This motion detector is hooked solely to the

Figure 1: Black Lung, Interactive Installation, Bill Hill

compressor so that without the reinforcement of an audience (the masses) the machinery continues to control the physical body but grinds away unproductively. The single lung expands and contracts inside a human rib cage, pointing to the simplification of the current biological system. The entire work is mounted to the exterior of a steel box, a sign of the industrial revolution. The body becomes the skin of the machine controlled unknowingly by a passive community.

The metal box acts as an artistic reference to the pedestal of "High" art, which seeks to elevate the work from the grounding of functionality. Here the use of steel is a direct reference to the manmade alloy that serves as armor to protect the body, but ironically is functioning inversely. Similarly the organs of the body are presented outside and exposed along side the gears of the machine that is controlling the body; nothing is hidden. Aside from the literal interpretation of the need for machine to control the body and the need for other to control the machine, this work seeks to examine the very need of a body at all in a post digital world. Conceptually, Black Lung refers to pneumoconiosis developed from inhalation of coal dust that destroys the body's ability to regulation oxygen; the natural is harvested to the increased reliance on the processed. The individual is disrupted to provide for the collective, the destruction of the one body for the machine.

Conversely, *Belay* (figure 2) consists of 21 handholds attached to a wall that is 24 feet in height. Positioned at the top corner of the wall is an organically suspended sculpture with a video viewer. There is a direct reference to the human anatomy through the abstraction of the esophagus form and the video loop with resembles the view of an endoscope inserted down the throat.

Using mechanical spring contacts that compress with weight the piece tracks the users progress and rate of ascent, which then sets the frame rate of the video once all holds, have been used. Conceptually this work examines the parallel structure of control placed on exploration. Whether it is the biological investigation of the human body or the human exploration of the natural world, both are limited by the constructs of the system.

In examining the physical and social aspect of interaction, this piece seeks to engage the audience through a direct and overt methodology. Simultaneously it seeks to look inside the body both physically and emotionally with a direct reference to physicality and biology.

As our collective culture and our physical bodies coalesce with technology there is an essential and traumatic remapping of our physical and psychological networks. These electronic works are concerned with the transformation of the human species, specifically its biological components and it behavioral characteristics. This transformation or evolution is an environmental reaction to the manifestations of science and technology. These works examine the need to address the physical body and how the action of users needs to be interconnected with the interface and content of an interactive piece. From the development of opaque sculptural input devices to the use of transparent technologies these interactive works seeks to examine the process of conditioning users; their predetermined interaction and the physicality of computing.

Figure 2: Belay, Interactive Installation, Bill Hill

Electronic technology not only invades and alters the body but it fundamentally reforms the cognitive process of the mind. As the computer becomes more integrated with the developing mind, especially as an interface with knowledge, it shapes not only our understanding, but also ourselves. We are becoming a hybrid of the machines we use. By its very nature, Machines replace the activity done by humans, to displace the labor and the interaction with the natural. Additionally, in an effort for immortality, we develop machines to foster an illusion that our body and mind are separate. But when the receptors of knowing

Figure 3: Nomadic Dominion, Interactive Installation, Bill Hill

change so do our understanding and we can never return to Plato's cave. This not only impacts the function of the body, but the environment in which the human interacts and knows.

Michael Foucault, in his text *The Order of Things*, refers to these spaces that disrupt conventions of order as "heterotopia". Heterotopic sites seem familiar, as they are subsumed within a society's conventional ordering system that links them to other sites, yet they are unfamiliar in that they simultaneously contradict the premises by which these relationships are sustained.[2] Therefore the complexity of these machines destabilize the seemingly straightforward transcription of real space and create not only an inverted but parallel space. We know ourselves and our word thru mediated experiences with a disrupted reality, or to use Foucault's word an *aemulatio*; the idea that patterns of resemblance can occur between things despite the spatial distance separating them: "There is something in emulation of the reflection of the mirror: it is the means whereby things scattered through the universe can answer one another." Of course, the problem is which is the reflection and which the reality? Foucault responds by stating that "emulation is a sort of natural kinship existing in things; it arises from a fold in being, two sides of which stand immediately opposite to one another." [3] As a result, multiple 'realities' are juxtaposed. It is even more intriguing to consider the mediate experience as unique sites in which the fictive space of utopias and the real space of heterotopias converge. The "mirror" is a utopia in the sense that it projects a virtual space behind its surface, a space in which the observer is misperceived as being present.[4] Conversely, the mediate space is also heterotopic due to the oblique manner in which it affirms the observer's position in real space: "it makes this place that I occupy at the moment when I look at myself in the glass at once absolutely real, connected with all the space that surrounds it, and absolutely unreal, since in order to be perceived it has to pass through this virtual point which is over there." [5]

In our contemporary post-industrial information society the machine is not only eliminating the human factor in the work environment but is affecting communicative behavior and interpersonal relationships. Virtual interaction is generating a nomadic citizen increasingly identified with abstract and distant symbols offered by electronic culture. *Nomadic Dominion* is a projected immersive interactive environment, with a mixture of photo-based panoramas and computer generated environments and objects. Users wearing red/blue stereo glyph glasses navigate through a hyper-real simulated world using didgeridoos to guide them.

Nomadic Dominion (figure 3) is using telepresence to allow a person to feel as if they were present, to give the appearance of being present. It is focusing on the environment as a metaphor for the artificial dependency, which is inherent in our species. We tend to force external changes rather than internal. The land is modified. As soon as we put down roots and begin agriculture we start the process of modification. This environment is the predecessor of virtual reality. We don't follow food; we manufacture it. We edge our lawns, plant crops in rows, reroute rivers, and use pesticides, all to reshape the natural into the artificial.

As Eduardo Kac states in his article on *Telepresence Art*, "at its best, interactive art implies less stress on form (composition) and more emphasis on behavior (choice, action), negotiation of meanings, and the foregrounding of the public who, now transformed into "participants," acquire a prominent and active role in shaping their own field of experiences. The role of the artist in interactive art is not to encode messages unidirectionally but to define the parameters of the open-ended context in which experiences will unfold." [6]

While Foucault challenges the mediated space as an alternate structure that stand in binary opposition to the "real", Jacques Lacan finds the reflective other as both external and affirming. In his theory of the mirror stage, a child encountering a mirror realizes that he or she has an external appearance. From a psychoanalytical perspective prior to this recognition the "I" of identity is a primordial form, but afterward it is objectified in the dialectic of identification with the other. From here language works to restore them into one universal subject. At this moment in a child's development, they recognize themselves as a uni-

fied image, as a whole self. Once this occurs the child will no longer see the reflection as projected other, but rather it projects consciousness into the image and transforms it into "self". Arguably this is one of the first independent actions of a child, while still nursing, unable to walk, and prior to language; they place consciousness into an external image that they control and see it as perfection. Later this ideal will add tension to the self as something that can never be matched, a fiction to be lived up to, while creating a desire to be whole with the other. Although we sometimes feel alienated from our "self" we see in the reflection a unified whole.

Contemporary reflections of self and the other are mass-produced and distributed through various projected means along an electronic umbilical cord feeding our conscious and subconscious selves. The blending of this artifice within the make up of the self is wholly infused with identity and is widespread. This is evident in the pervasive use of social media and digital recordings to document ones tangible existence through virtual means, #selfie. But it also transfers into mass consciousness as the ideal is mass-produced and disseminated into a world where the physical is becoming increasingly blurred into a virtual understanding of self. We are increasingly faced with an integrated dialectic that conflicts with traditional views of identity and relies upon simulated projections detached from and isolated in time and space.

As Émile Littré once stated "Whoever fakes an illness can simply stay in bed and make everyone believe he is ill. Whoever simulates an illness produces in himself some of the symptoms." [7] Art of the new media can be seen in binary approaches with the human body; ***robotic*** in the sense of augmenting or replacing the action of the physical or ***telepresent*** in the sense of bypassing the physical receptors. In both they strive to construct symptoms though a simulation of something that can no longer be considered real.

Similarly *The UnCultured Pearl* (figure 4) is an interactive video that has a direct one to one relationship with the viewer. Using a video-tracking camera mounted on the ceiling. The work tracks the users proximity to the video screen. As the user approaches the screen the figure treading water on the screen submerges. The closer the viewer comes to the screen the deeper the virtual figure descends.

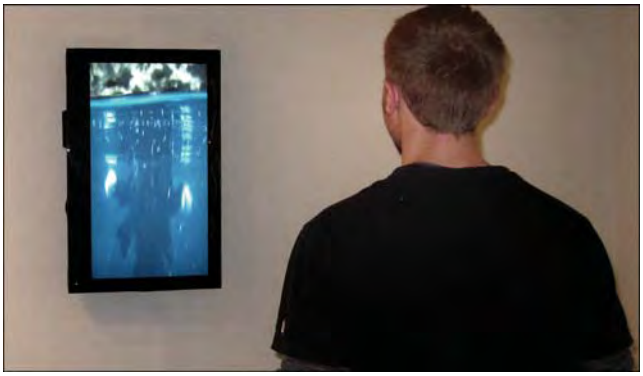

Figure 4: The UnCultured Pearl, Interactive Installation, Bill Hill

Conversely, as the viewer moves away from the screen the virtual swimmer ascends to take another breath. Conceptually this work examines the parallel structure of control placed on exploration. Whether it is the biological investigation of the human body or the human exploration of the natural world, both are limited by the constructs of the system. Using the metaphor of a *Bow and Arrow*, the more one pulls inward, the further out they can thrust themselves. Here the audience is forcing the figure to submerge while at the same time they come closer to examine the details. Time slows to a stand still as the two are at the closest points. This submerged figure acts as a digital mirror of the collective self.

Here the work is less about the developing the illusion of an open-ended experience, but to restore a Brechtian perspective in the audience and reconnect to the limitations of both simulation and the body. Building upon this physical interaction, the work explores the transcendental spectacle that is secondary improvisational theatre. The audience is both participant and performer creating a secondary performance for others. Similar to the early *flaneur*, who would stroll down avenues people watching or gazing at merchandise of a consumer dream world but today's digital world shifts the purpose and function of the body.

Abstract

The present work looks into the place the body occupies within interactive experiences. Firstly, we explore the nature of the machine in its corporeal dimension, and the human body in the digital representation process. Then, a classification is proposed for the modes of articulation of the participant's body in interactivity, following various analytic frameworks. Finally, we analyze the difference between the physical bodies within an experience and the construction of the bodies present in the artwork, outlining the dialogue between technical engineering and the symbolic dimension.

Keywords

Body – Interactivity – Interfaces – Representations - New Media.

Introduction

"An interactive work challenges one to undergo a transformation from an onlooker to an "interactor", an active agent. A peculiar kind of dialogue develops. In addition to mental interaction that is a precondition to the reception of art in general, physical, bodily action –one that involves more than just movement of the eyes-takes place".

Erkki Huhtamo

Interactive Art shakes the spectatorial tradition, and invites bodies to get up from their exclusively receptive position and assume an active role within the artwork territory.

If we look closely at an interactive work, we will see bodies in motion, exploring, communicating, and relating sensorially to the work. Through direct observation, they will appear as whole bodies. However, there is a difference that often goes unnoticed between the interactor body in the installation space and the body that is integrated into the interactive experience, and through which the public interacts. The physical bodies in the installation space differ from the bodies perceived by the interactive system and the interacting bodies, but still all of them fold and converge into the subject who converses with the artwork.

As Caroline Jones (2005) states, mediations in human sensoriality have greatly intensified.

The physical body of the public who is immersed into the artistic experience shares the space with the mechanical body of the artwork. When they meet, they define a semantic universe which reconfigures the relationship among objects, subjects, and environments.

The Mechanical Body and its Senses

"Today, we are transferring what we know about machines into living organisms, and vice versa. For this reason, we sometimes refer to bodies as machines, and to machines—or technical processes in general—as a kind of life (artificial life)."

Arlindo Machado

Just as the interactor is a kind of mind-body unit, the computing device may be understood as an artificial mind-body configuration. The *hardware-software* pair which makes up chips in action suggests the idea of a physical dimension (*hardware*) and an intangible dimension, similar to mental processes (*software*). Considering the pair as a whole, *hardware* could be thought of as the interactive system body.

In this context, *sensors* in a machine would be equivalent to *senses* in human bodies: bridges between the inside and outside, a means of information exchange, points where receptivity from the outside and exteriorization of internal processes are articulated. The lexical connection between the word *sensor* and the word *sense* points to the underlying analogies regarding the constitution of machine devices. In this sense, *sensors*, like windows to the world, allow the system to *perceive* and establish a relationship with the environment.

The human body may also be thought of as an organic interface. David Rokeby outlines a comparison showing the difference between our body and the interfaces:
'Our "organic" interface is extraordinarily complex and massively parallel. Our sensing system involves an enormous number of simultaneously active sensors, and we act on the world through an even larger number of individual points of physical contact. In contrast, our artificial interfaces are remarkably narrow and serial…' (Rokeby: 1990)
Given the diversity in sensors, there are several senses that may be built into the *hardware.* The machine body is, by definition, a polymorphic body. Its senses and thresholds are defined by algorithms, and are subject to processing speeds. The characteristics it assumes in each artwork will, in turn, define what dimensions of reality it will be able to

perceive and which bodies in the audience it will be capable of conversing with.

The Organic Body and its Representations

"Far away from the mechanical logic and inserted into the new digital regime, modern bodies act as processing systems for data, codes, encrypted profiles, information banks. Thrown into the pace of technoscience, the human body seems to have lost its classical definition and its analogical integrity; within the digital plane, it becomes permeable, projectable, programmable".

Paula Sibilia

The physical body of the public in contact with the interactive work turns into another body's framework: the represented, virtualized body; the body that is perceived by the artwork. These two bodies may coincide or differ considerably. The following sections present -using a taxonomic approach- different modes in which the body becomes integrated into interactive works.

The Body as a Unit

In some artworks, interaction is based on actions from a unified body. Generally, these are works that use movement in space as the variable for interactivity. A work like «*Rain Room*» (2012), by Random International, invites the user to experience a curious situation: walking in the rain without getting wet. In order to achieve this, the heavy rain falling within the room will open special hiatuses at the exact point where the body is located. Bodies circulate and go around the space enabling, as they move, rainless patches that make them waterproof, shielding the skin from humidity. Thus, the body acts as a unit during the experience.

The body is conceived as a unit that stimulates the artwork, and triggers the transformation of the shape.

The Partial Body

In various interactive works, the body stops being a compact unit, and is reinterpreted and partially incorporated into the artwork. In the same way as, in movie productions, an actor's entire body at the stage is analyzed and visually cut when captured in a close-up, in many interactive works, the body is fragmented, keeping the physical component as a material framework for the interaction, and trimming certain senses, limbs or organs that form part of the interacting body in the artwork. We will establish three main analytical spheres for partial bodies.

1- Senses

"If the mission of 20th century art was to make the invisible visible, 21st century artists will be concerned with finding ways to allow us to sense the invisible in the visible. The ratio of the senses may shift, and new perceptual modes may be uncovered."

Roy Ascott

Various artworks build their interactive mechanism based on a particular *sense*.

A) Sight - Eyes

One of the emblematic works using this approach is «*Zerseher*» (1991) by Joachim Sauter. In an art gallery setting, the one-time spectator stands before a painting when something unusual occurs: his or her glace starts to deconstruct the image. This work fully addresses the classical issue of spectating as a passive phenomenon, and the interactivity derived from interactive aesthetics.

In this artwork, the main point of contact in the interactive activity is the eye and, more precisely, eye movement.

B) Hearing - Ear

Due to its receptive nature, hearing is not a sense that usually generates stimuli for artwork input; nonetheless, it may be observed that, in some works, it plays a main role in terms of the connection between the body and the work. This variety includes the project «*Hot and Cold Whisperer*» (2009) by Ebru Kurbak and Jona Hoier, which emulates children's "hot or cold' game. The interface consists of a headset the user needs to wear. In cities, Wi-Fi signals are an invisible and intangible presence. The headset works as a signal detector. A voice whispers 'hot', 'warm' or 'cold' into the user's ear announcing the proximity of a Wi-Fi signal while the user wanders round the installation space.

C) Taste - Tongue / Smell - Nose

Taste—together with smell—is probably one of the least explored senses in interactive works. However, a few examples do exist. We might mention the work entitled «Mate Parlante» ('Talking Mate') (2013) developed in the UNA Multimedia Art course of studies (in Argentina) by Mariano Ferle, Azucena Lozana and Sebastián Caiafa. This work invites the user to sit down and drink mate. A thermos with water allows the user to pour this liquid into the mate containing yerba mate, and acts as the interface. Once the user pours the liquid, he or she can drink it through the straw. With this gesture, while the user drinks, the mate will tell a story related with the tradition of this infusion, exploring a founding ritual for River Plate idiosyncrasy. The artwork content is accessed through the physical action of drinking.

D) Touch - Skin

The introduction of the sense of touch is probably the main innovation brought by Interactive Art in terms of the artwork sensorial dimension. As Erkki Huhtamo (2007) states, Interactive Art is bound to the touching action, and this generates important conceptual changes in the field of artistic experience.

The work «*Delicate Boundaries*» (2007) by Chris Sugrue is based on the sense of touch, in several ways. Virtual organisms contained within a screen move into the physical space, travelling on the user's hand, and can go

around his or her upper limbs surface; skin is where the body and the image meet.
In the work *«Touch Me»* (2004) by the Dutch group Blendid, integrated by David Kousemaker and Tim Olden, users must press their body on a frosted glass surface to leave an impression of themselves. Almost emulating a large-scale scanner, participants put themselves against the glass in various manners while a light scans the surface and prints the body; the visual result resembles drawings made in caves 10,000 years ago. A great number of modern interactive works include touch in same way.

2. Limbs

Another possible criterion is thinking about the body in terms of its parts or limbs. This classification overlaps with the senses, but, essentially, the purpose of the approach is based on the perspective that some configurations do not seem to be mainly related to the senses, even though they may include them.

A) Hands
«*Mobile Feelings*» (2002), a work by Christa Sommerer and Laurent Mignonneau, focuses on the hand as point of interaction. Through a tangible interface, a pumpkin-shaped object, two users can feel the vital parameters (heart rate and breathing) of the other person. As a result, this work generates a non-verbal, bodily and intuitive communication between remote people.
We may even go into more detail and observe some cases where only part of a hand can become the acting body in the artwork. In the work «*Pulse Index*» (2010) by Rafael Lozano Hemmer, a finger is the point of contact between the public and the artwork. The user is invited to introduce a finger into a wall cavity. The interface captures an optical image of the fingerprints, which are projected, amplified, on screens around the exhibition space. At the same time, the interface senses heart rate and prints images at a speed that is analogous to the user's pulse.

B) Head
The Australian artist George Khut created «*Wee Leaf*» (2009) within the framework of the residency entitled «*Thinking through the body: Sensorium Gymnasium*», where various artists explored the potentiality of movement, touch and proprioception. In this work, a tree leaf hangs from the ceiling, at a person's head level. This work invites users to stand on a platform capable of sensing body balance, and induces them to touch the leaf with their face and cause movements. The swinging of the leaf in space, and the balancing are translated into sounds, in a situation that proposes an experience for the body that is unusual in interactive works: interaction is mainly achieved through the face; interactive action occurs in the head as a whole.

C) Vocal Tract
«*Universal Whistling Machine*» (2004) by Marc Böhlen and JT Rinker addresses the topic of language universality, and resorts to whistling, which is common to all cultures (and several species), as a communication code. Thus, participants face a system that can engage in a dialogue with them. They are invited to whistle, and then that whistle is reproduced by the machine in a sound mimicry act. In this case, as we can see, the *interacting* body is the vocal tract (and the lungs providing air for the whistling sound to be created). In reference to the perceptive thresholds described in previous sections, this work is only sensible to whistling, not to words. That is, if the user pronounces verbal language, the work remains immutable; this action falls outside the perceptive ranges of the work.

3. Organs

> *The body and the outside universe have exchanged places; the new adventure is not to discover new lands or planets but to see and map the inside of the body.*
>
> Lev Manovich

The third segmentation is based on the body and its integration through the organs. This category implies traveling beyond the dermis into the body's inner core. Bodies become reversible, folded, to reverse the relationship and put the inside on the edge, in contact with the outside world.

A) Heart
We can find a group of artworks using heart rate as interactive action, with a peculiar characteristic: action is usually involuntary. Rafael Lozano Hemmer explores the scope of this approach in a series of works entitled «*Pulse Room*» (2006), «*Pulse Park*» (2008), «*Pulse Spiral*» (2008), and «*Pulse Tank*» (2008). All versions share a common operation: the user pulse rate is translated into light impulses or water movements, in closed or even open spaces.

B) Lungs
Works that use breathing or blowing as interactive action connect to lung activity as a contact point with the installation. Scott Snibbe developed his work «*Blow Up*» (2005), where whistling supports the whole experience. An interface composed of a matrix of small coolers waits for the user to activate it. Through blowing, the user makes the micro cooler blades turn. The air pattern is memorized and then replicated in an analogous, larger structure with big coolers. That small gesture is reproduced by strong drafts in the installation space. Other people present in the room can stand before the larger cooler matrix and feel the wind designed by the user, in the analogous interface, on their skin. In this case, the work combines partial modes of interaction/reception.

C) Brain
In some works, the measurable phenomenon that drives the evolution of the artwork tangible form is brain activity. In «*Eunoia*» (2013), by Lisa Park, brain waves are read in order to manipulate water movement in containers surrounding the body of the performer, who interacts while

remaining utterly still. Surfaces vibrate, and water forms varying patterns driven by an intangible inner process.

The work «*Neuroknitting*» (2013) by Varvara Guljajeva, Mar Canet, and Sebastián Mealla, provides the user an interface to measure brain activity. The visual representation of waves makes up the knitting pattern of a machine that reproduces the design. When the experience concludes, the user gets a physical weave that reflects inner, mental activity.

In such cases, we find a paradox: bodies interact while seemingly at rest. When looked at from the outside, they do not differ greatly from spectatorial bodies. In fact, considering their eyes remain closed, they seem to be closer to sleep than to wakeful activity. However, there is an ongoing interactive process connecting the inside with the outside.

Conclusion

Body engineering has come to Art, not always in the form of physical reconfiguration, as expressed boldly in prostheses and foreign body implants. There is a subtler way, though equally impactful on the artistic experience: body design in the artwork, the conception of a body which will be *perceived* by another body (the machine's) and which will be allowed to act under certain circumstances and in particular contexts. *Represented* bodies overlap or run in parallel, and are elevated from the physical level to the symbolic level.

Behind the optical illusion of *whole* bodies in interaction, we may discern the presence of a *symbolic* body, different from the *physical* body within the space of the work, holding metaphors as well as sensations. The body is contained in a double sense: contained by the design limits, and contained as an inherent part of the expressive proposition put forward by the artistic event in which it is inscribed. It is usually assumed that content is beyond the interface, that the interface represents the border between the subject and the content. The changes we are witnessing may be signaling that the time has come to rethink these notions, and realize that the body, in Interactive Art, is incorporated as an expressive resource in the artist's palette, through new media.

Post-Humanism in Post-Modern Dance

Julie Akerly

Julie Akerly Movement
Phoenix, AZ United States
Julie@nuebox.org

Abstract

Post-modern art has adapted to post-humanism, and has begun to use technological advances as an extension of the human body. This paper will address the technological transformation occurring in the post-modern post-human dance era. The primary focus will be on pixelated representations of the moving body, mechanically generated art, and extensions of the physical body through technological sensing systems. The use of technology as an extension of the physical body in post-modern dance is a model of human computer interaction in the post-human era. This model can be utilized to maintain a connection between the physical body and an environment that is shifting faster than the evolution of the biological body.

Keywords

Post-Humanism
Post-Modern Dance
Mechanically Generated Art
Sensed Body

Introduction

Post-humanism is usually associated with futuristic science fiction, where the human becomes the machine. However, in Cybernetics and Post-Humanist Theory, the human has already become post-human. 1 In her book *How We Became Post Human,* author atherine Hayles warns of two possible routes that can be taken in a post-human era. One path is lead by Descartes ideology where the mind can exist without the body. If this path dominates the post-human evolution, human beings will be perceived as individual parts that can be recreated and replaced. 2 The second, more favorable path will be that the post-human consists of extensions that integrate with the biological body. 3

Post-modern art and dance have adapted to post-humanism, and have begun to use technological advances as an extension of the organic body. This paper will address the technological transformation occurring in the post-modern post-human dance era. The primary focus will be on pixelated representations of the moving body, mechanically generated art, and extensions of the physical body through technological sensing systems.

The Edited Body

Representing the movement of the body in a pixelated form separates the original occurrence from time and space. In order to document movement, the original event is cataloged in encoded text, and when replicated undergoes a process of decoding. Through post-production editing and broadcasting, the original movement becomes a pixelated, post-human extension of the original event.

Philosophers such as Hayles warn against the segmentation of the human body. 4 The pixelated body dissects the body into non-organic parts, but it also enhances the body's abilities. The pixelated body breaches the limitations of time and perspective, and can defy the laws of physics. Re-coding a live event changes the way we view the human body and frees the body from its physical constraints. 5

Movement Abstraction

Online databases of choreographic scores have re-contextualized movement. MotionBank is a video database that has created text to describe the events of the body, and digital representations of movement. 6 William Forsythe's *Synchronous Objects* was a primary leader in this type of visual adaptation. Figure 1 is an example of a still from a visual manipulation of the original film. The image shows movement patterns co-existing in a shared space. However, these events did not originally occur simultaneously. The post-production of Forsythe's work becomes an extension of the original work by manipulating time and space. 7

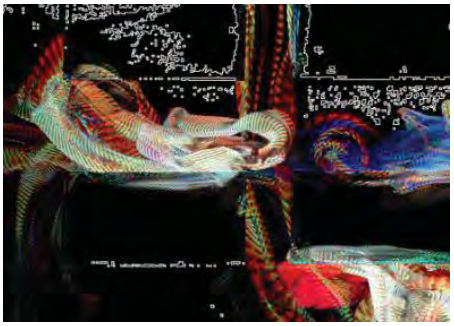

Fig. 1 Synchronous Objects: One Flat Thing

Post-Production Video Editing

Post-production editing gave choreography the ability to detach movement from time and space. In 1946, Maya Deren created *A Study for Choreography and the Camera*. 8 The film explored post-production editing tactics in dance such as tempo, space and repetition. Deren's film served as a guide to editing movement. In post-production video editing, movement can be repeated, reversed, slowed down or speed up. Editing also allows the movement to modify space by flipping the image across horizontal and vertical planes, changing the point of view of the camera, or taking the body to a new location all together.

The Camera as a Bodily Extension

In the late 1960s, the camera decreased in size and cost, and the time required for post-production editing was reduced. The camera turned into an extension of the post-human body as it became more accessible and portable. 9 Other artists began to further explore choreographic editing concepts manipulating time and space. Members of the Judson Church Project frequently used video and projection as an extension of their body's limits during live interdisciplinary events such as "9 Evenings." 10, 11 Film allowed their faces to become larger, the viewer's attention to be localized, and their bodies to simultaneously exist in more that one place at a time.

The Viewer as a Bodily Extension

With the increase in broadcasting networks and household television sets, the viewer gained the ability to become the editor. From our iPhones, we can manipulate another's body by turning a video on and off, rewinding and repeating, and observing the movement from any location at any time.

Broadcasting generated yet another way to increase the body's capabilities. A performer's body can now be viewed anywhere on film, and their physical body does not need to be present. 12

Through broadcasting, the viewer gains the ability to experience events they cannot physically attend. The viewer also gains the ability to replay and re-experience an event. 13 Some theorists such as feminist film theorist Annek Smelik and cybernetic theorists Roy Ascott would argue that being places without your body would eliminate self-identity and control over oneself, leaving the performer at the mercy of the editor, broadcaster and viewer. 14, 15

Post-human extensions of choreography on film raise multiple ethical questions. Once the dancer and choreography are captured and logged, who becomes the artist? Is it the dancer and choreographer, editor or viewer who ultimately chooses the location, length and frequency of an event? To what extent does a viewer have the right to manipulate an artist's work? To what extent does an editor or viewer have the right to manipulate another person's body?

The Mechanically Generated Body

In the case of post-humanism in post-modern dance, the artist is the one who generates the idea, and their post-human extension is the crafters or tools who help them manifest a final product. Artists began to use computers as a tool to manifest their ideas or to provide them with ideas. This is visible in work by visual artist, Vera Molnar, who developed a computer program that evolved shapes into a visual work (fig 2). Once she approved of the machines adaptation of the original image, she would paint the end result by hand. 16 If the computer generated algorithms design the patterns, who is the artist, the programmer, computer algorithm or painter?

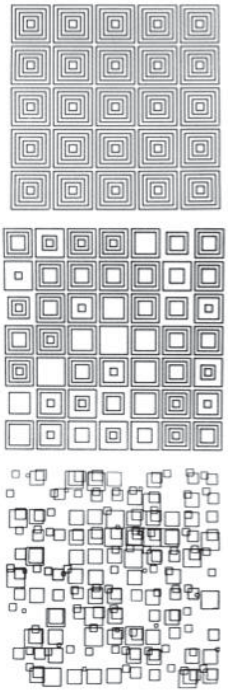

Fig. 2 Computer Drawings

Dance performances such as *Choreobot 2.0* by Julie Cruse raise similar questions of authorship between the program designer, artist and tool of expression. *Choreobot 2.0* programs chance procedure algorithms into a computer that determines the choreography of the dancer in real-time. Choreography determined by computers turns the computer into a technological post-human extension of their creator. Both in Molnar and Cruse's work, the computer assisted in the process of generating a product, and the body was used as a tool to create the program's decisions.

The Sensed Body

The next stage of post-humanism in post-modern dance involves utilizing data from the moving body and sending it to a computer to produce a final product. The final product achieves a result that the body could not create with only their body's movements, but instead require a post-human integration.

Artists began to expand the limitations of the human body through motion-tracking systems and sensors. Prior to cybernetics, computational technologies and interactions with technology had been based on the idea that the brain can exist without a body, and that the human does not need a body to use the technology. In this scenario, the human would become more like a machine.

Cybernetics shifted the way human computer interactions are designed by attempting to make the machines more human. There is continuous investigation on redesigning technological interaction based on the somatic use of the embodied mind. This occurrence is visible in the

adaptability of technology as it molds in size, shape and weight to become an extension of the physical body. Hayles points out that humans are not evolving as quickly as their environment. To compensate, humans are generating tools that can allow their bodies to execute tasks in the evolving world, be it an axe to chop wood, or a portable camera in the palm of a hand. 17

In dance performance, the human body gains a post-human extension by sensing and tracking devices. The devices react to the movement's tempo, axis, size and frequency, and produce visuals and sounds that accentuate the physical movement. In the dance work, *Mortal Engine*, a team including computer programmer Frieder Weiss, generated a system that tracked the movements of the dancer from above, and produced visual images and audio. 18 In this instance, the human-computer integration served as an audiovisual extension that affected the space around the movement.

In addition to video tracking, data from the body's movement has also been captured through sensing devices such as muscle sensors, accelerometers, gyroscopes, and pressure sensors. In *Re-Mapping the Body* from the dance company Linga, muscle sensors on the dancers send data to computer systems, and is then utilized to produce audio. The audio is responsive to the muscular activity of the performer. The company describes the sound system as a place where "dancers explore a new relationship with their bodies, **augmented** by the possibility of making sound." 19

In these two examples, the technology systems respond and expand the physical actions of the body, and generate a post-human bodily experience for the performers. Sensing technologies bridge the gap between the human and the computer, and allow the dancer and technology system to communicate simultaneously.

Conclusion

Post-modern dance has been evolving parallel to the path of post-humanism. The mechanically generated body and the edited body have the potential to drive post-modern dance towards a post-human body that is a combination of individual parts. When edited, the body can be separated and replicated through broadcasting, film or other pixelated representations.

The mechanically generated body drives post-modern dance towards a post-human state where the body becomes a machine, free from thought. As the machine controls the actions of the body, the mind of the dancer and/or artist is no longer necessary.

Body sensing systems require the mind-body-system to co-exist in order for the system to work. As post-modern dance continues to expand into their post-human bodies, body sensing models should be used to maintain a connection between the changing physical environment and the physical body.

Abstract

Parallax is a contemporary dance work that integrates live performance and stereoscopic illusions. This performance work was designed to demonstrate the transformative potential of stereoscopic technology for contemporary dance.
Parallax explores how the technology can change the traditional theatrical idea of space. We propose that the theatrical space is overlaid by a stereoscopic space that is best defined as a square pyramid. The stereoscopic image within the theatre environment creates a new area for the, choreographer, dancer and audience to experience dance and opens new creative possibilities. First, the choreographer needs to negotiate a different form of perceived space, and to work with both live and animated bodies. Second, the dancer may become less central and more part of a technical system, and s/he is required to negotiate digital environments and objects that are invisible to them.
Finally, the audience experience of the stereoscopic dance performance is significantly different from, and potentially more immersive than, other forms of dance that use technology. This paper proposes that the inclusion of three-dimensional (3D) scenography requires a reorganizing of the conception of space in the creation and performance of contemporary dance and theatre.

Keywords

3D, stereoscopic, dance technology, choreography, multi-media dance, trans-media dance.

Introduction

This paper focuses on the use of stereoscopic imagery in live contemporary dance performance. In particular, we examine how the stereoscopic illusion changes the perception of space in the theatrical stage setting. We will argue that through the use of the stereoscopic illusion the perception of space is altered and the experience of space is transformed for the participants of dance, the choreographer, dancer and the audience. We will do this by focusing on a contemporary dance stereoscopic contemporary dance work, *Parallax*, created by the first author. [1] Through *Parallax* we will highlight how 3D changes the traditional role of participants of dance performance, the choreographer, the dancer and the audience. The choreographer needs to negotiate how the stereoscopic imagery exists within the live performance and stereoscopic space and how the 3D imagery can be placed with the live performer in space.

Through the use of stereoscopic imagery the performer is required to dance with images that are mostly invisible to them but which provide powerful contextualizations through virtual stage settings and performance partners. The dancer also needs to perform 'with' these images, which have a different form of gravity and space. Audience perception of a 3D enhanced performance space is very different from that of a traditional theatrical space since the audience becomes part of the technical process, in the sense that the audience must 'complete' the technical process of 3D projection by fusing the images in their minds. The 3D imagery opens up the theatrical stage space with panoramic views and environments that can rapidly change and which are inhabited by stereoscopic objects that appear to move into the audience space. We aim to show how conceiving of the theatrical theatre space as having a pyramid shaped overlay that embeds the stereoscopic content is a helpful concept in understanding how this is altered environment functions artistically and aesthetically.

Approach

Parallax was developed using a multi-modal practice-based research approach, intertwining artistic and theoretical perspectives. The practice-based method is described by Australian and English writer and academic, Linda Candy as; 'original investigation undertaken in order to gain knowledge partly by means of practice and the outcomes of that practice' Candy's explanation of a practice-based methodology encapsulates the processes undertaken within this work. [2] The performance *Parallax* was created to explore the issues involved in using 3D in live performance as part of a dual process where the creative domain of art creation and the investigative domain of 3D informed each other. Australian choreographer and academic Cheryl Stock describes the dual process:

'These artist/researchers play dual roles reflecting on, contextualizing and theorizing their own practice whilst drawing on dance and cultural studies and a range of methodologies to inform their practice.' [3]

In this process, the first author/choreographer particularly drew on technical work by Robert Neuman a stereoscop-

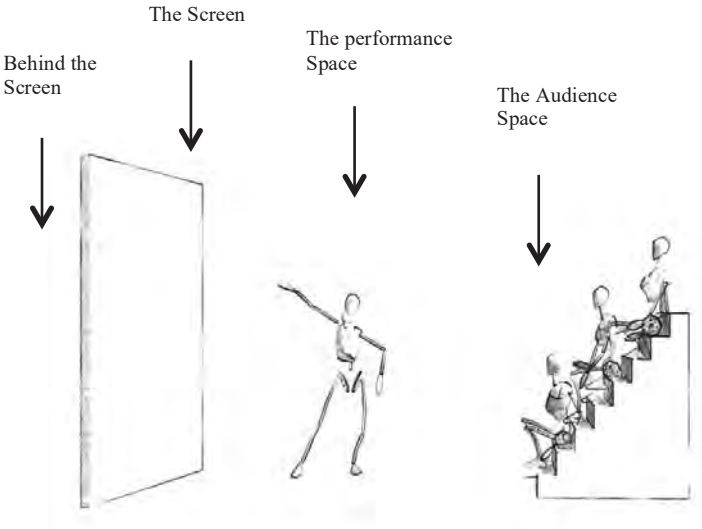

Figure 2. Live Dance Performance Depth Budget. ©Megan Beckwith

ic supervisor at Walt Disney Animation Studios. His work provided a rich source of technical artistic provocation in relation to space, during the development of the performance *Parallax.* She also drew on her triple roles as choreographer, performer and animator in the development of *Parallax*, using a hybrid process to create the different elements of the performance. These multiple roles gave the choreographer/animator a unique insight to the development and creation of performance work that utilizes stereoscopic illusions for performance and the construction of the performance and stereoscopic space as one entity. The stereoscopic dance practice was developed in an intertwined and reciprocal process where the animation and choreography informed each other.

Parallax was created as a 40-minute contemporary dance and stereoscopic work. The dramaturgy serves to help drive the journey of the live character, explain and contextualize the constantly changing environments and give the audience a hook in which to situate the performance. The work explores the human body in an induced illusionary and virtual environment. Through the use of 3D stereoscopic animations *Parallax* explores how a person might physically and emotionally interact with illusionary or hallucinated worlds. This work explores two key questions; how does the body react within a distorted reality and how does hallucination affect emotions? This performance takes the dancer and the audience through a seemingly infinite set of virtual spaces, which are animated abstract environments, hyper-real landscapes and rooms. These spaces are inhabited by stereoscopic props that function as agents of change that seemingly 'interact' with both the dancer and audience.

The work explores the boundaries between the real, virtual and illusionary states. The performance opens as a woman drinks a green drink and appears to enter an induced illusionary world in which she is transported through a series of iconic spaces and times. The hallway she is standing in becomes a portal to new digital worlds. Each world she enters is different, sometimes dangerous, though sometimes not. The environments she enters contain fragments of the past that are 3D objects such as, Leonardo da Vinci's spheres from his *Treatise on Painting* and Charles Wheatstone's stereoscopic cubes from his paper *Contributions to the Physiology of Vision. Part the First. On Some Remarkable, and Hitherto Unobserved, Phenomena of Binocular Vision*. Each object she encounters creates different physical and emotional problems the woman needs to negotiate. In each world she sees herself from different perspectives, creating an effect of parallax.

Background to Stereoscopic Imagery in Performance

The stereoscopic image changes the perception of space. The stereoscopic image is a visual illusion that manipulates binocular vision, transforming the appearance of space and the animated objects within it. Imagine the letters on this page floating towards you and the page falling through your hands and away from you into infinity. It is this type of illusion of visual depth and relief that the stereoscopic image can achieve. Objects appear to hang impossibly in space directly in front of the audience's eyes and scenographic views fall away from the audience infinitely. Two-dimensional (2D) projected surfaces appear three-dimensional and panoramic scenes and animated objects seemingly become part of the viewer's world. It is these apparently magical possibilities that have an impact on the live theatrical performance space and require new conceptual ideas around space and relationship with the choreographer, dancer and audience.

The use of the stereoscopic image in live theatre and in particularly with dance is not a new phenomenon. The stereoscopic image has been in the domain of film since its

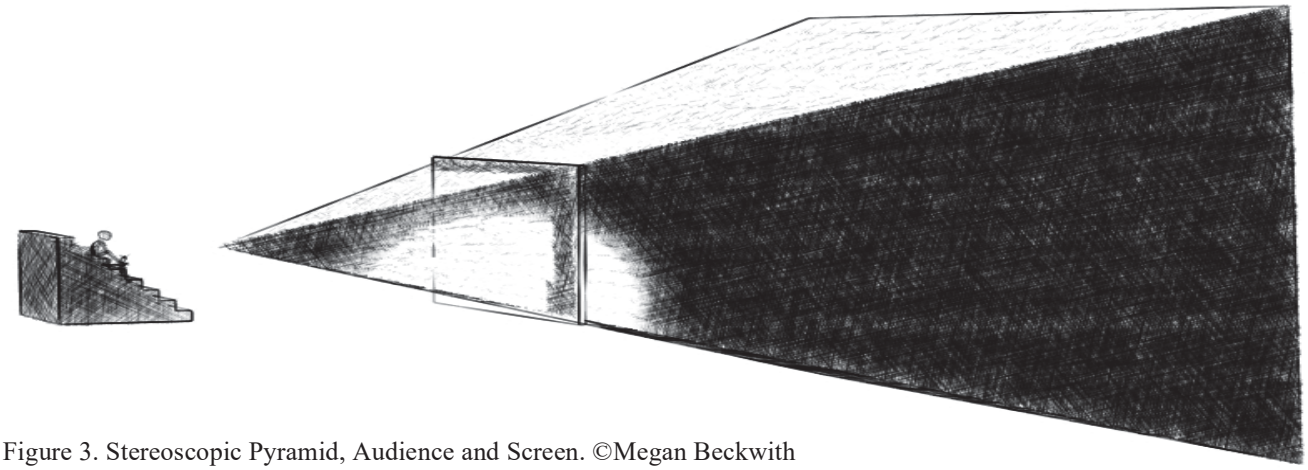

Figure 3. Stereoscopic Pyramid, Audience and Screen. ©Megan Beckwith

inception in the peepshow boxes of the 1900s. There was one early attempt by Laurens Hammond, the inventor of the Hammond organ, to popularize the stereoscopic illusion for live performance. [4] Hammond's patented *Shadow Graph* an anaglyph lighting technique was used within the 1927 Florenz Ziegfeld's review called *Padlocks*. [5] From Ziegfeld's seminal 3D dance performance it was not until the 1990s that the stereoscopic image was more successfully used in dance performances in dance works by artists such as; Billy Cowie; Klaus Obermaier; Robert Lepage; Heather Raikes; John McCormack; Wayne McGregor and Garry Stewart. The dance and animated shows that these artists create represent an emerging style of performance that includes stereoscopic 3D within the theatrical staging conventions and is a small but growing phenomenon.

Stereoscopic Space and the Live Theatrical Space

The use of the stereoscopic element in performance creates a digital aesthetic that is different, both from other dance forms and from dance that has historically used technology. One of the changes that the stereoscopic illusion affords dance is how the space is perceived and potential use of this space within live theatrical performance setting. This research is born from a desire to explore the potential of the 3D environment for contemporary dance performance and live theatre to create a greater understanding of the stereoscopic illusion in my own practice. The key point is to examine specifically the impact of stereoscopic image on live dance, which introduces a different kind of perceptual experience to performance. Part of this experience is how the live theatrical performance space is changed with the use of stereoscopic imagery and how can it be potentially be utilized.

The stereoscopic image offers an alternative layer of artistic possibilities for the creator of dance or live theatrical performance. The stereoscopic animated image appears other than just background or an interesting lighting device. This image is constructed by a technical system that presents two different but very similar images to the right and left eye. The images themselves are slightly off center, one for each perspective of the right and left eye. The two images are fused together in the brain where the illusion of relief and depth is created. The brain processes the stereoscopic illusion as a three-dimensional landscape or object. The visual (and neurological) impact can be seen when the audience reacts to the 3D imagery by jumping, flinching or reaching out to grab the projected image. [6] Even though the audience knows it is an illusion, it is almost impossible to fight the urge to react. Some audience members enjoy and indulge this instinctive effect.

In tandem with the physical reaction the audience may also experience an emotional reaction to stereoscopic illusion. Robert Neuman describes this emotional response:

'the emotional distance we feel from what we see transpiring on the screen is proportional to our separation from it in 3D space. Of particular significance the emotional distances is the relationship of the subject to the point of zero parallax, the screen'. [7]

Neuman is describing how when the 3D images move past the screen and closer to the audience there is potential to elicit a more emotional response from the animated content. This artistic technique is potentially a powerful tool for the choreographer or theatre creator as audience reactions can be increased or decreased by the placement of the animation in space in relation to the audience.

In film, the detailed placement of 3D imagery is described as a depth budget. The depth budget is 'analogous to a musical score in how it is orchestrated to reflect the emotional content over time'. [8] This technique is also relevant to live theatrical performance that uses 3D imagery. However, the depth budget for live performance is different from a depth budget for film. In film, the stereoscopic image moves through the screen and, as Neuman

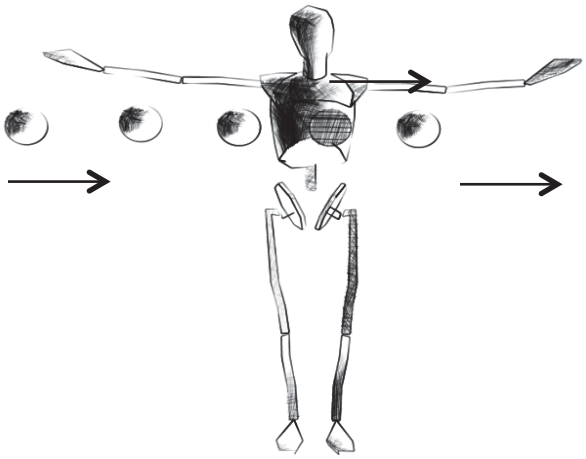

Figure 4. Front Projected Choreographic Violation, as the 3D image moves across the un-polarized body the 3D affect is lost ©Megan Beckwith

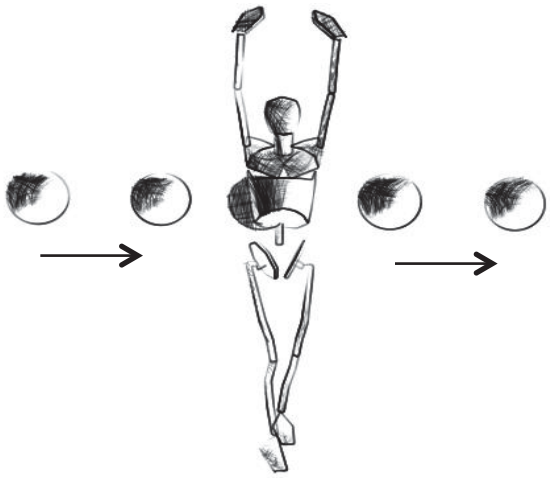

Figure 5. Back Projected Choreographic Violation, as the 3D projected image moves behind the body the 3D image it is hidden from view or occluded by the performer's body and the illusion is lost ©Megan Beckwith.

describes, into the 'audiences space' (See Fig.1). [9] Yet, stereoscopic live performance has another layer, the performance space (See Fig.2).

We propose that using stereoscopic projection in live performance creates a space that we refer to as the performance stereoscopic space. This space is created by the elongation of the animation due to the larger animation throw created by the need for the dance performance space. This space stretches from the screen to the audience space. We also think of this space as a pyramid as this is more accurate and precise term as it indicates the height, depth and width of the shape rather than indicating the floor space or a general area. The pyramid of animation space is situated lying on its side, with the tapered end facing the audience (See Fig. 3).

If the animation moves out side of this pyramid space a window violation will occur and a visual conflict will be created for the audience, also known as a 'paradoxical stereo window effec. [10] Neuman describes the window violation as 'the conflict of depth cues that occurs when an element that in terms of stereopsis lies in front of the screen, nevertheless is being occluded by the vertical surrounds of the frame line, which lies behind it as screen depth.'[11] In short, when a stereoscopic image appears that in front of the screen moves off the screen without appearing to move behind the screen, a visual conflict happens.

There are two common ways to project the stereoscopic imagery in the theatrical stage setting. The first method involves the projectors placed in front of the performance space, usually hung from the lighting rig, with the stereoscopic image being projected onto a polarized screen. Alternatively, the projectors are situated behind the performance space and the projection is shone through a shear polarized scrim. Even though the stereoscopic image is being projected from different directions, the pyramid scape is the same as the illusion is created through the separation of the imagery and not the direction of the projection.

The dancer appears in the stereoscopic space as they are bathed in the projection light and placed within the same visual scape as the animation. Due to the live performer appearing in the stereoscopic pyramid 'choreographic violation' can occur. Not unlike window violations, 'choreographic violations' become apparent with front projection when the stereoscopic image appears over or occludes the performer. The stereoscopic image appears to squash flat on the performers body (See Fig. 4). This flattening of the animation happens due to the stereoscopic image needing a polarized surface to be projected from. Unlike the stereoscopic screen surface the performer is not a polarized surface and therefore the illusion is unable to be maintained, since two identically shaped but horizontally separated images are no longer presented to each eye.

With the back projection, the image does not appear on the body as the image is occluded by the live body. The audience perceives this as the 3D imagery disappearing behind the performer. The visual conflict can occur if the illusion is perceived further forward than the live performer in space. As the image disappears behind the live body it appears to impossibly disappear only to re appear on the other side of the performer. (See Fig. 5) This visual conflict created is very similar to a window violation. This visual conflict appears to be more forgiving than front projection and is a way of reducing the appearance of occlusion of the imagery of the body. However, in the theatrical stage setting the use of back projection can be problematic as the space required at the backstage of the scrim is often only available in very large theatres even with the use of short throw projection lenses.

The construction of the stereoscopic space in the theatre environment is very different from the traditional use of theatre space where the wings, cyclorama, backdrop, floor

and proscenium arch mark out the viewing and performance space. While the space itself is not structurally changed by the use of the stereoscopic image the audiences' perception of space is altered. For the audience the back wall is opened up with panoramic views that have texture, depth and ambiance and the screen appears, as Neuman describes in the case of 3D movies, as 'proscenium arch to this stereoscopic content'. [12] The space above and around the stage can be potentially filled with 3D objects. The theatrical imagined fourth wall can be breached by animated imagery and the space directly in front of the audience can be apparently filled with 3D objects.

In *Parallax* the construction of this performance design can be understood from the layering of the different components within the performance scene. There are three elements that make each of the individual components work in conjunction with each other and builds the work in three ways, through: 1) an animated background that can include 2D and 3D animations and video content; 2) a dance work that is situated within the traditional performance space and; 3) stereoscopic imagery that exists behind the screen, in the performance and audience space (See Fig. 6). The use of this volume and indeed the perception of space changes for each participant of dance; the choreographer, dancer and audience members.

The Choreographer's Space

The negotiation of space is different for the choreographer in a performance work that uses 3D imagery due to the different layers of real and illusionary content. The stereoscopic image creates alternative choreographic opportunities within a carefully constructed virtual world that appears spatially infinite containing endless possibilities, but also has specific limitations. The opportunities are found in the animation process where the director or choreographer could create any image and is only limited by imagination, time and financial budget. Limitations can be found in the pyramidal nature of the stereoscopic animation space and the need to confine imagery to within the cone defined by this space and particularly, to the available space in front of the screen. The pyramid space narrows as objects move closer to the audience and in the use of the live body within that space is limited by the need to avoid choreographic violations by avoiding obscuring key stereoscopic imagery.

In *Parallax* the ability to place animated objects within the choreographic and stereoscopic space was an interesting element. The animated objects could be choreographed, not unlike live performers, and could appear as a soloist, duo partner or virtual corps de ballet.

In *Parallax* this dance between the 3D objects and performer was a careful negotiation between choreographic and animation processes. The choreographer/animator started with the animation process creating the stereoscopic landscapes, environment and props for the performer to work with and contextualize themself. The linking to the animation and the movement was conducted throughout the choreographic development. She often re-worked ani-

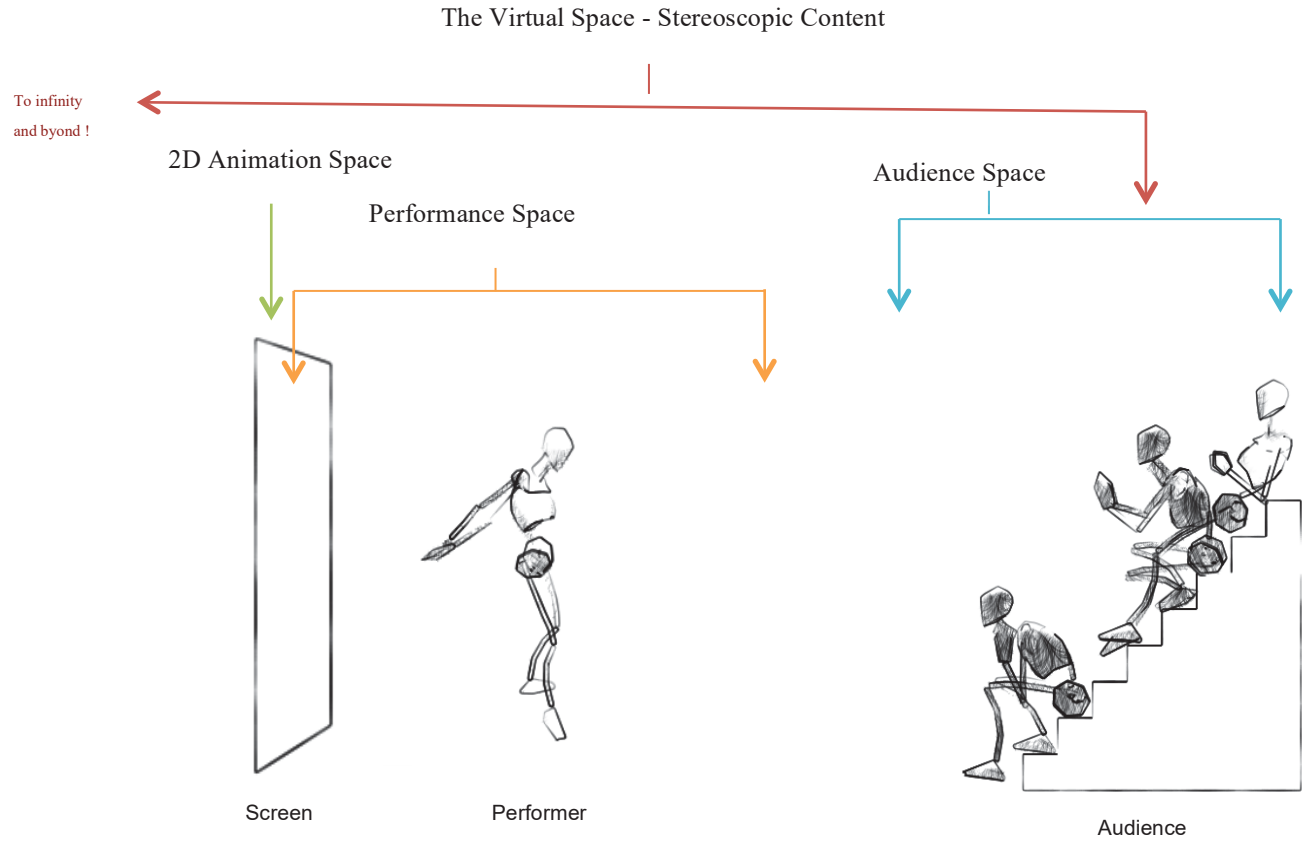

Figure 6. The Layered Design of the Space. ©Megan Beckwith

mation during the choreographic process drawing the two different elements into one performance. In this way the different elements work in conjunction with each other and appear as one performance.

One reoccurring problem within the space of *Parallax* was the creation of choreographic and window violations. One technique that proved useful was the use of animated small particles as this seems to confuse the eye and appeared to be a more forgiving affect. Yet, simply dropping the performer to the floor or moving the dancer out of the way of the animation was also very useful. Furthermore, using the choreographic violation proved a powerful effect when employed to deliberately disturb the audience. When animation moved forward in the space towards the audience, due to the visual perspective the animation appears larger, however the stereoscopic pyramid space tapers in, creating possibilities for window and choreographic violations. This visual conflict is usually avoided by keeping the images within the stereoscopic pyramid. However, in *Parallax* where relativity of size was not paramount, reducing the size of the animated objects as they moved forward in space was a successful way of avoiding violations. In the future, the use of back projection would possibly also help minimize the affect of choreographic violations in my work.

reflection, not dissimilar to visualization and ideokinesis

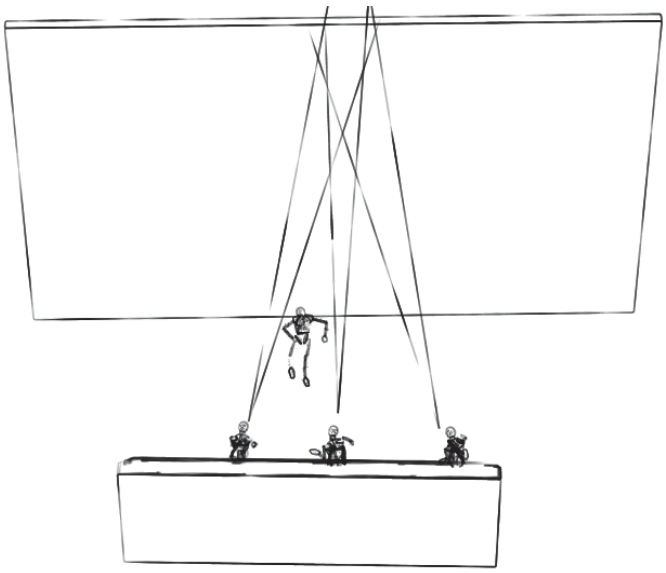

Figure 7. Example of the different view points of the stereoscopic image fro the audiences point of view. In relation to the performer the image changes perspective. ©Megan Beckwith.

The Dancers Space

In stereoscopic performance the dancer must negotiate both physical and virtual 3D space. The stereoscopic image appears to co-exist with the dancer and becomes part of the dance performance, appearing as both content and performance partner. The stereoscopic animation transforms the environment and situates the dancer differently within the performance space.

The dancer experiences the stereoscopic space much differently from the choreographer and audience members. The dancer does not wear glasses and is facing away from the screen and therefore cannot see the 3D illusion. The performer can only see the video content on the screen as a blurred 2D image. In *Parallax* this issue was addressed in several ways. The choreography and movement was carefully blocked with an eye on where the animation would appear, and marking of the floor with tape was also helpful for dancer orientation. The performance was rehearsed with the animation footage from the early development phase and the animation in turn was animated directly over the rehearsal video footage. The use of a video fold back during performance was also extremely helpful in enabling the dancer situate herself within the space and in relation to the animation.

While the animation is palpable for the audience but invisible to the dancer, in *Parallax* the performer needed to appear to interact with the animation. This interaction was difficult, and for the performer, the stereoscopic space had to become like an imagined space. In a way that seems, on techniques used in contemporary dance development, the dancer needed to create a 'virtual map' of the space rather than simply respond to the visible, physical, limits of the performance volume.

In *Parallax* the performer is sometimes not the most important thing in the space. Often, the audience was presented with imagery that are not visible or apparent to the performer. This can be unusual for a dance performer as the focus of most contemporary dance performance tends to centre on the performer, and specifically the performer's embodied presence. Furthermore, the audience wearing glasses can be a distancing effect for the performer, who cannot see the audience's eyes or gaze, and this presents a different environment in which the dancer relates or responds to the audience. Finally, in *Parallax* the video element does not change as the video projection is pre-rendered. Performing with an animated partner that does not alter or react to the dancer is unforgiving and the dancer needs to employ a spatial accuracy throughout the choreography and movement that is defined by the image, not the performer or the physical space.

The Audience Space

The audience perceives the theatre space differently when stereoscopic imagery is used. In a stereoscopic performance the audience completes the performance and the stereoscopic animation. This could be said of all live performance, yet within stereoscopic theatrical performance the animation is fused within the audience's perception. If

the audience is not present, no one can see the animated objects as three dimensional. In this way the audience is, in a sense, part of the technical set up as they must perceptually fuse the animation. By wearing 3D glasses, the audience completes the animation and the stereoscopic element and stereoscopic performance space emerges.

It is the fusing of the imagery that tricks the brain's perception of the stereoscopic imagery as if it was a real object, prop, scene or room. In *Parallax,* by using animated imagery as a choreographic element the choreographer was able to create emotional audience reaction. This was achieved by bringing the 3D imagery forward (downstage) and backward (upstage) in the space. This positioning of the 3D imagery in relation to the audience became an interesting choreographic tool.

In *Parallax* it also became apparent that established and traditional theatrical placement cues and choreographic blocking of the space had changed through the use of the stereoscopic image. The dancer is bound by the normal conventions of time, space and motion in the stage space. However, powerful and compelling 3D imagery and theatrical information can be included in space not available to the live performer, such as behind the screen, above the performer and directly in front of the audience within the stereoscopic pyramid. It also appears that the ability to fill the space directly in front of the audience can draw the audience into the performance making them feel like they are almost part the show.

Each audience member has a different viewpoint of the performance, which happens in live theatre and film, however the issue is amplified by 3D projection. The perspective or angle of the stereoscopic animation in space can change dramatically in relation to the placement of the live performer, and objects appear to move horizontally depending on how far from centre the viewer is located. This can create visual conflicts depending on where the audience member is sitting (See Fig. 7). This shifting of perspective for audience members has the potential to create a new premium-seating plan for stereoscopic performance audiences, where the middle centre of the performance seating becomes the prime space rather than the traditional stall seating plan.

The potential placement and perception of stereoscopic imagery in live performance is outlined in Beckwith and Vincs (2013) [14].

Conclusion

Parallax, the performance, demonstrates some of the ways in which stereoscopic imagery in live contemporary dance performance changes the perception space in the theatrical stage setting. The perception of the theatrical space in contemporary dance is altered and the experience of space is transformed for the participants of dance, the choreographer, dancer and audience. In particular, *Parallax* reveals how the traditional roles of the choreographer, dancer and audience can be changed. The choreographer's role has shifted as s/he is required to negotiate stereoscopic imagery and live performance within a performance space that is embedded within a pyramid shaped stereoscopic space. The performer is required to dance with images are mostly invisible to them but are a powerful contextualization, stage setting and performance partner. The audience perception of the performance space is also altered as they become a part of the technical process by fusing the imagery and space in their own minds and experiencing animation that appears from infinity to directly within their space. New possibilities became apparent that include alternative choreographic strategies, such as the use of animated imagery and depth control to heighten the audience's perceptual experience through the use of the stereoscopic space in tandem with the live space.

The use of stereoscopic imagery in live dance performance may not be for everyone. Just as not all movie audiences seek out 3D experiences, stereoscopic work in dance has sometimes been described as 'more of a distraction than enhancement', and may be interpreted as confusing, disconcerting and an annoyance for some theatrical theatre audiences' [13]. Our contention is that the spatial ambivalence between physical and 3D projected space can be constructed as either troubling and confusing, or as choreographically generative and productive, by virtue of the potential for disruption of traditional stage space and choreographic process described here.

Future explorations would see a development of the *Parallax* performance or other new performances with specialized theatrical lighting for the optimizing of the 3D effect. Powerful stage lighting can enhance or reduce the stereoscopic illusion and animation texture. The use of active projection techniques for live performance would also be an interesting possibility.

Authors’ Biographies

Megan Beckwith is a Melbourne based choreographer who works across the fields of dance and animation. Megan is currently studying for her PhD at the Motion.lab at Deakin University and is researching the application of the 3D stereoscopic illusion within the live theatre environment. Megan creates live animated dance works by combining contemporary dance and animation in a choreographic process that layers one over the other. Megan is a research assistant within the Building Innovative Capacity in Australian Dance through New Visualization Technology Building Creative development project for Kim Vincs, she also teaches at Deakin University and is a founding member of the hybrid live arts organisation Punctum Inc.

Professor Kim Vincs is the Director of the Deakin Motion.Lab, Deakin University’s motion capture studeio and performance technology research centre, which she established in 2006. She has been a choreographer for over twenty years, and has focused on interactive dance technology for the last ten. Kim has five Australian Research Council projects in dance, technology and science, and has established numerous industry collaborations in motion capture, movement analysis and digital art.

Abstract

The use of media in interactive performance is continually developing. Performers are exploring increasingly complex relationships with media agents including robots. One common approach to developing performer-media relationships is to base the interaction on pre-set patterns and direct control of the media. However, performance theory shows that performer-performer interactions incorporate elements of improvisation. Two key elements are trust and the perception of intention, which provide the basis for reciprocal communication. Recent research has developed models for performer-media interaction that incorporate reciprocal communication in the context of performer improvisation with ephemeral (audio/ light based) media agents. This project explores whether these same principles of embodiment apply to physical (robotic) media in performance. One might expect that a performer senses (sees or hears) the movement of media object and responds to it regardless of the form of the media (ephemeral or physical). However, research in performers' cognitive process suggests that their intersubjective and cross-sensory perception produces subtle differences in the perception of ephemeral and physical media. We suggest these differences could have a great impact on their experience. We present our findings from two pilot studies exploring robots as interactive dance partners that use principles of embodiment as cues for interaction.

Introduction

Practice and research in interactive performance has largely focused on the use of auditory and light based media (ephemeral) [8] while the use of responsive physical objects (robotics) has remained under researched. Though the use of robotics in performance is not new, explorations with robotic agents on stage has recently gain momentum [1][17][20] [22]. This trend is supported, in part, by developments in electronic prototyping platforms such as Arduino and tools such as quad-helicopters. These developments have made the design and implementation of robotic systems by performance practitioners more financially and technically accessible. These systems also allow for new models of interaction to be designed and implemented.

The traditional approach to designing interactive systems, for both ephemeral and physical media, has focused on the *system's* ability to sense the actions of the performers. Earlier research by the authors in performer/system interaction with sound and light based media has shown that it's possible to heighten trust and understanding of the system's gestures by leveraging the *performer's* perception of the system's intention to act [6][7]. Researchers in the field of human-computer interaction have also shown that designing for anticipation can affect the effectiveness, efficiency and quality of robot-human interaction [11]. However, a performer's perception of an improvising robot in the context of performance remains under researched.

One might expect that a performer senses (sees or hears) the movement of media object and responds to it regardless of the form of the media (ephemeral or physical). However, research in the cognitive process of performers interacting with media suggests that cross-sensory perception provides subtle differences in *how* the ephemeral and physical media are perceived [5]. The impact of these subtle differences on the performer's experience holds many opportunities for new research. A better understanding of the principles for embodied interaction in the context of responsive physical *objects* requires a unique understanding of the performer's perception. Building this understanding could help in the development of new models of performer-system interaction.

We are interested in finding parallels and differences between the performer's experiences of working with ephemeral media (auditory and light based) and their experiences with responsive physical objects (robots). We use the term ephemeral based on the changeable quality of the media. This paper presents our work-in-progress research focused on developing approaches to Performer-Robot interaction that leverage the body knowledge of the performer. At this stage in the project we are investigating if the principles of embodied interaction that have been explored in the context of ephemeral media remain the same in the context of physical media. We have conducted two studies with participants improvising with robots. The interaction design for these sessions has been informed by earlier work on performer-system interaction and research in human perception of interaction. We have implemented a model of performer-system interaction for physical media that moves towards supporting more embodied modes of interaction, based on research from performance theory

and pedagogy, cognitive science on human perception of intention and performer-system interaction. Our studio sessions serve to test this model.

Background

Ephemeral and Physical Media in Performance

Digital media and computation have had a long and varied position in performance practice [8]. Developments in interactive media have influenced both the way performers work with media and the role the media takes in the performance. The increasing accessibility of interactive tools such as the Kinect, programming environments such as Max and Processing, and devices such as Roomba, Lego Mindstorms and Quad-copters have provided a new push to the continually growing use (history) of media in performance. These different types of interactive tools and media are being used to extend and heighten the artistic expression of the performers. It is reasonable to expect that as interactive technology develops, performance practitioners will be developing increasingly complex approaches to performer-system interaction with an increasing variety of media. The current range of performer-system relationships continues to expand and now includes: responsive tools such as MIDI instruments, triggered lighting systems [3][4][19], semi-autonomous media agents such as projected lighting and interactive scores [19], and autonomous agents such as AI systems and robots for dance and theater performance [7][15][19][22]. As performers offer more autonomy to media agents, including robots, the process of exploring a *collaborative* relationship in place of a *control* relationship requires new models for interaction to be developed.

Performance Improvisation and Intention

One standard approach to incorporating ephemeral or physical media into a performance is to base the interaction on an *Instrument* paradigm [19]. This approach includes programming the system's behaviour with a set of patterns (similar to choreography or blocking) that are directly controlled or triggered in response to the performer's actions (similar to "knowing one's lines). This paradigm can be viewed as deriving from an extreme or highly rehearsed style of performance. What is missed in this approach to designing the system-performer interaction is an understanding that in every interaction between human performers there is an element of improvisation [9][18]. Cognitive science and performance theory suggests that the interaction between human/ performers is always a reciprocal communication happening often in anticipation of the subject's actions.

Bogart and Landau, in their teaching of 'Viewpoints', coach students of improvisation to "*trust* in letting something occur onstage, rather then making it occur" [2]. To trust in the 'something that will happen' is to coordinate the actions and enable the development of events as a group. Yet this development of events cannot be done in response, such as trying to re-contextualize or direct a partner's actions. The improviser must move beyond the cognitive actions and trust in the intuitive actions to foster a balanced or reciprocal communication for negotiation [15].

For a performer to be open to negotiation with others on the stage, they must trust the environment. A sense of support is established when their actions both affect and support other agents. This support comes from trust in the inter-subjective understanding of the moment. This understanding keeps the ensemble synchronized, but requires that all the performer-agents are able to track the intention of the others. Therefore, it becomes imperative that all agents be able to project their own intentions.

Human Intuition of Intention

The understanding that performers negotiate their interaction using a sense of intuition runs parallel to developments in the understanding of performer-performer interaction and general human social interaction [2][10][11][15].

Research in the field of neuroscience has recently suggested links between *intuition* and *intention*. Neurons found in pre-motor areas of the brain have been shown to fire not only when producing a sound or action, but when the subject hears the sound or observes others doing the action as well [10][13][12]. The firing of these neurons allows the subject to predict the outcome of their own actions as well as the actions of others. "This implicit, automatic, and unconscious process of motor simulation enables the observer to use his/her own resources to penetrate the world of the other without the need of theorizing about it" [9]. What is crucial to this phenomenon is that the action observed must be goal oriented, that is it must have intention [10][13][12].

However, there is some question as to the usefulness of mirror neurons in human-computer interaction. The findings to date concerning a person's ability to perceive intention in others suggest that this ability is linked to the physical similarity with the other. This means that a human subject is able to perceive the intention of other humans well, but less so apes, only slightly with other animals and not at all with machines [9][10]. The prevalent reason given for this distinction is a perceived similarity of motion [10]. For this reason it is then unclear whether a system's response actions, if accurately modeled on human movement, would affect a performer's per-cognitive process of perceiving intention.

Still, the presence of this pre-cognitive function implies that the human cognitive system as a whole works in connection with this mechanism, and that even at a cognitive level, interaction is governed by the prediction of events as much or more then reaction to events, an interpretation supported by the presented theories on improvisational performance. These findings suggest that as social being we have developed the ability to intuitively predict the actions and sounds of those around us.

The idea that human action and intention happens before the act has been shown in other experiments as well. Wegner in his book "The Illusion of Conscious Will" presents the work of Kornhuber and Deecke (1965) as well as Libet (1983). These researchers measured a rise in brain activity up to 800ms before an action took place. In the case of Libet's experiments, brain activity was recorded over 300ms before the subject was even aware they wanted to act [21].

These findings further indicate that humans do not live in a static present moment but rather in a moment becoming the next. Our social engagements are informed by an embodied empathy that allows minor predictions of those around us. We react not in the moment but in the next moment over half a second late.

Research in Interactive Performance

Referencing this research in human perception of intention, research in the interaction between ephemeral media agents and performers has shown that the performer's ability to sense the media's preparation to act, its *intention*, is important in how the performer perceives and interacts with the media system [7][11][17][18][22]. In the context of audio agents, it has been show that the sound of a breath leading into the audio gesture improves the performer's ability to understand and interact with the audio gesture [6]. In the context of visual media, it was found that a light agent that indicates its intention to move was experienced by dancers as more engaging to work with [7]. Underlying both these findings is a contingency that the preparation cue is felt by the performer as connected to the system's mechanism for acting. In the case of the audio agent, performers commented that the *breath sound* seemed to be the system breathing in order to play the instrument. In the context of the light agent the graphic simulating the agent, a circle of light, shifting its center of gravity in order to move. It has been suggested that it is this connection to the perceived mechanism for acting that leveraged the performer's embodied knowledge [5][6][7][10][13]. We are interested in how these findings apply with a physical object that has a physical mechanism for acting.

Research has show that the construction of an embodied understanding in the context of media in performance relies on cross-sensory perception and the iterative process involving their *contextual awareness*, *physical awareness*, and *interpersonal awareness* [5]. This constructed understanding also involves assigning a trust of agency: exploring if the performer trusts the agent to provide usable information, guidance, and support for the continued structuring of the performance [7].

Yet the research also shows that the cognitive process is iterative and complex [5][7]. The interaction between the system and the performer's perception of the environment has three aspects: Environment – Object – Agent [7]. The decisions made by the performer and the trust they have with the system in the moment of performing are all affected by subtle aspects of their perception of the media agent [5]. Research into some of the prominent parameters of perception for visual and auditory media in performance has suggested connections to general interaction design theory and theories in cognitive science [1][20]. However, in the context of robotic media, the parameters for projecting a media agent's intention remains under researched.

System Design

The Sphero Robot

We have used two robot platforms to help us explore the parameters of physical media that may engage or facilitate the performer's embodied understanding of the robot's upcoming gesture or intention. In the first part of the study we used a Sphero 2.0 [www.gosphero.com/]. The Sphero 2.0 is a robotic ball, 2.9 inches in diameter and 5.9 ounces, controllable by an app on a smart device. We control the Sphero's movement and colors using an iPad app called "Drive". The Sphero 2.0 provided a commercially accessible robot with the maneuverability that we required for this study. The ball shape robot is somewhat familiar as an object to engage with and its movement is very natural and smooth making it a suitable test robot for first part of this study.

Figure 1. Sphero Robot

Custom Robot

The second part of our study required that the robot be able to indicate its intended change in direction. Indicating the intended direction before moving was not possible with Sphero. We designed a custom two-wheeled robot approximately the same size of the Sphero. The two-wheel design enabled this robot to turn in place as well as make smooth turns. The robot was programmed to randomly change its direction and speed. LEDs placed in a semi-circle around the font of the robot could be light up to indicate a intended change in the robot's direction.

The robot was programmed with two basic modes, 1) using the LEDs to indicate a change of direction and 2) not using the LEDs (so the intended change of direction would not be indicated). When using the lights, a delay was programmed between when the LED turned on and when the

robot moved in that direction. This delay was varied throughout the study from 100 – 800 ms.

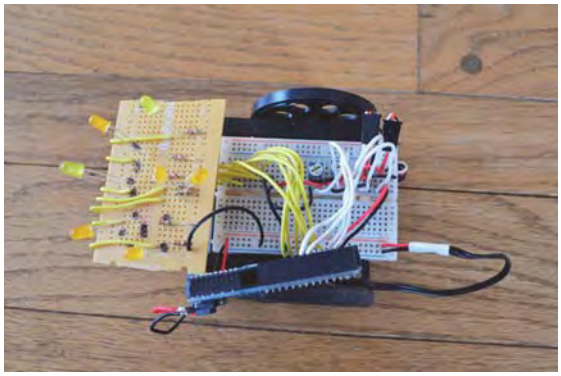

Figure 2. Top View of Custom Two-Wheeled Robot

Studio Research Method

We use a combination of Case Study and First Person methodologies to explore the experience of the performer to the two robots. The study was separated into two parts. In Part 1 we explored the experience of student performers working with the Sphero. Part 2 focused on the first person experience of the researchers working with the custom robot. The sessions in both parts of the study were done using structured improvisation between a single performer and a single robot. Each system was tested separately to keep the focus on the experience of the system itself, rather than on a process of comparison.

Structure of Case Studies with the Sphero

Each participant worked with the Sphero for one session consisting of three stages. During the session, the researchers noted observations and collected comments from the participants. The structure for the session was based around simple 'Tag" game progressing in intensity. Over the course of the session, the participant played several rounds of tag with the Sphero. This basic structure provided consistency between the participants while still leaving room for them to experience improvising with the robot. The stages that made up each session were:

- Familiarization session: the participant was introduced by a researcher to a Sphero on the studio floor and was asked to physically move around with it. Any initial impression of his/her experience was captured.
- 'Tag' game session in a slow speed: the participant played the tag game twice with the Sphero at its a slowest speed setting. The participant started as 'Not It' and becomes "it" when tagged by the Sphero.
- 'Tag' game session in a fast speed: the participant played tag twice with the Sphero at its fastest speed setting. The game proceeded in the same way as the previous session.

The Sphero was controlled by a human. Rules were added to constrain the participant's movements. These constraints provided more challenge for the participant, heightening their awareness of their interaction with the robot. For example, the participants had to walk normally on white lines intersecting the play space (see Figure 3) and tag the robot with their hand.

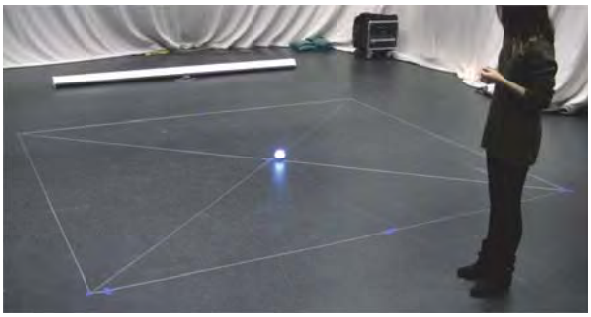

Figure 3. Stage Setup for the Sphero Study

Structure of Sessions with the Custom Robot

The sessions with the two-wheeled robot were based on a single task derived from Viewpoints "kinetic response" and Contact Improvisation. Viewpoints and Contact Improv are established forms of movement improvisation. Combining Viewpoint's concept of Kinesthetic Response with the general practice of Contact Improv outlined a basic task for the performer to stay as close as possible and respond to movement gestures such as spins while not touching/ interfering with the robot.

Each First-Person session consisted of multiple improvisations with the robot. The researchers journaled throughout each session and between sessions about their experience improvising with the robot. The behavior of the robot was varied for each improvisation to test different conditions. These conditions were: no LEDs to indicate the robot's intended direction, and LEDs lighting up 100 ms/ 300 ms/ 600ms/ 800 ms before the robot's movement. For all these conditions, the same task was applied. The robot's style of movement was adjusted during the tests to explore if the approach to an embodied interaction was affected by the style of movement.

Working with the Sphero

It was not surprising that for some performers, working with robots had a novel appeal. In general, participants reported being engaged with the robots and had a tendency to anthropomorphize the robots when describing their interactions. Participants often commented on the Sphero seeming like an animal or small child and evoking feelings of caring and protection. These perceptions or feelings seemed to lay a foundation for the performer-robot interaction.

Relationship Shifts with Sphero

During the study, participants discovered and built different relationships with the robot. These relationships did not necessarily appeared in a linear order.

a. Initial relationship making

At the beginning of the studies, most of the participants did not move much and just paid attention to Sphero's movement. They were observed taking time to investigate its characteristics and figure out how they would respond. Since the robot is very small and rolls on the floor, the gaze was grounded all the time.

"I just look at its movement and what I do is to break it down. So I look at the characteristics, how's it moving and what it does."

b. Caring Relationship

Even though most of participants knew there was a robot controller, they often reported feeling that they were playing with the robot not with the human controller. Because of the size and the simple behaviors of Sphero, participants felt that they should take care of it and reported their personal memories related to this. This phenomenon was also observed, mostly during familiarization sessions but participants kept the caring attitude to the robot through out all sessions. For example, when Sphero was closer to participants, participants became more careful not to stepping on it and let it move around them.

'I feel like I am a cat when I am following the robot…when I am being chased by the robot, I feel like I am a cat."

"…Makes me feel like I am playing with my 2 year old niece. I do exactly the same thing, like I lift my legs. She runs after me. Very playful.'

"This reminds me looking at a hamster's play"

"I don't want to step on it."

"When I was young, my sister had a pet hamster. This reminds me that."

c. Collaborative Partnership

Over the study sessions, participants often reported feeling they were collaborating with the robot. The information obtained from the initial familiarization session helped them to define the relationship with the robot. They tried to move around the robot and to do something with it. In the slow sessions, the participants were moving much slower to balance the quality of movement with the robot. They were waiting for the robot when it was off track. Participants were often observed trying to talk to the ball by expressing their emotion or cheering the ball on.

"The robot is much simpler but I feel like I improvise with my dance partner… First time, you get to know the person observing how the person moves… You kind of need to see the partner and analyze the partner's movement (like they typically do?) I am starting to guess what would be good with this…This is kind of the same principle but the human is more complex."

Competitive relationship

During the 'tag' game sessions, participants often reported feeling competitive with the robot. When Sphero was moving fast, participants felt more anxious about the game and tried to move fast to win the game.

"Oh my gosh, it's coming to me what do I do next."

Movement Cues from Sessions with Sphero

The quality of the participant's movements was affected by the quality of the ball's movement. There were multiple elements that affected the participants in terms of how they moved and made choices.

Speed cue

In the 'tag' game sessions, the Sphero was rolling at two speeds: slow and fast, which were set by the app. Speed elements definitely affected the participant's movements. In the slow speed, they reportedly enjoyed the aesthetics of the ball movement and spent more time on how and where they move at the end of lines. When the robot moved faster the participant moved faster and changed their directions in the middle of the lines more often. It seemed people enjoyed the faster speed with Sphero. They reported that it was more fun, engaging and focused.

"When it is slower I have more time to think but when it was faster it was intimidating."

Trajectory cue

The ball moved very much like a real ball, which was smooth and natural. When it rolled, it moved in curves. However the participants' movements were constrained by the rule to walk on the lines in the game setting. So the participant needed to balance their attention between observing the robot's trajectory and his own movement. Participants mostly found it was difficult. From the initial familiarization session, participants learned that the ball moved widely and couldn't make quick turns. So they could predict the ball's movement and move in response to it.

"The robot is coming after me, I had to wait for a second to see the robot's path and turn to the opposite direction."

"I needed to predict which way it travels. I needed to think one step ahead."

"I was just watching. It was going like an arc or circle. I noticed the pattern. It's gonna cross over right here. So I tried to guess it."

"I tried to dodge. It looks like the ball has to turn wider. So if I made a sharp corner, it would be tricky."

Color cues

Observations suggest that the colors of Sphero were appealing, and participants consider colors as aesthetic ele-

ments rather than informational elements. Sphero had two color modes: solid blue mode and gradual changing mode. When the ball was chasing the person, the color of the ball was blue and when the ball was being chased, the color was gradually changing in hues. The blue color mode helped participants to focus on the path of the robot on the stage. The gradual changing mode helped participants to see the ball all the time without staring at it even when it is in the periphery vision.

Distance cue
When participants were playing with the robot, the distance to the robot seemed to affect what they felt and how they moved. When the ball was rolling close to the participants, they ignored their peripheral vision and just focused directly on the ball. This encouraged participants to connect to the robot and immerse into the immediate situation. However, they weren't able to move freely and this forced them to decide on their movement right away. In contrast, when the ball was far away, participants were able to take time to observe the robot's movement. In these situations it was easier for the participants to predict where the ball was going and to move freely in the environment.

> *"When its close, it's hard to move with it because I had to make sure that I'm not stepping on it or it's not on my way. So it makes me slow. I had to think more, but when it's far away, I don't think too much."*

> *"When the ball is too close to me, it was hard to predict. When it's far away, I was able to see how and where it is going"*

Sound cue
The sound that the ball made when it was rolling on the hard floor helped participants to be engaged in the situation by supporting the perception of its quality of motion (speed, acceleration, direction etc.). The data is unclear whether it helped participants assess the Sphero's intention.

Working with the Custom Robot

Relationship Shifts

Over the course of the sessions, the relationship with the custom robot approached the level of collaboration and then diminished. The journal entries suggest that as the movement pattern of the robot became more aesthetically interesting it was easier to engage with the robot on an embodied level. Such comments suggest that is was the quality of the movement that encouraged the engagement with the robot. However, when the LEDs that indicated the robot's intention were turned off, the relationship was lost. The speed and style of movement were adjusted to try and compensate but the relationship could not be reestablished until the LEDs were engaged again.

Movement Cues moving with the Custom Robot

Quality of speed.
The speed of the robot at first made the robot unattractive as a partner. But the speed was also the main inspiration for working in close proximity, and for using techniques of contact improvisation in the sessions.

Sound cues
The sound of the custom robot's motors was reported to be very consistent and quickly ignored, as not providing any information to the movement intention of the custom robot.

Trajectory cues
It was found that noting the current path of the robot help interact with where it was going. This was especially noted when working with the robot without the LEDs. However, it was also noted that in sessions where the robot's movement gestures where short, the gesture was over by the time the trajectory was perceived which caused problems with the interaction at close proximity.

LED cues
The most common comment concerning the LEDs was that they seemed to indicate the intention of the robot but were not connected to it. When describing the experience with the robot with the LEDs engaged, phrases such as *"I consider…."*, *"I see …"*, *"I think…"* suggest a rational rather then embodied understanding of the LEDs. However, some comments refer to the LEDs as lying, which could indicate a social or embodied relationship to the information being presented.

LED timing
Throughout the sessions, the timing of the delay time between the direction LED lighting up and the robot's change of direction was adjusted. It is significant to point out that the strongest comments of being engaged with the robot occurred when the delay time was 800 ms.

LED mis-triggers
During the sessions, the robot's LEDs would light up but the robot would not move in that direction. These mis-triggers in the LEDs were commented on as confusing and as reducing the performer's trust in the LEDs in general as useful information. It was also commented that some LEDs were more likely to mis-fire then others. Along with these journal entries were comments that sequences of LEDs were responded to. This is of interest because there was no significance to the sequence of LEDs programmed in to the system.

Discussion

In this paper we have outlined theories concerning a performer's perception of objects and agents in a performative environment. Theories from cognitive science and performance theory suggest that performers interact in anticipa-

tion to each other. Research on performer-system interaction in the context of ephemeral media (light and sound) has show that systems can be built that leverage the performer's ability to anticipate an agent, by modeling embodied cues connected to the action of the media agent. For example a system generating sound is interacted with in a more natural manner when a model of breathing is incorporated into the behaviour of the media agent [7]. It has also been shown that performers build their understanding of a performance environment through a cross-sensory experience iteratively with knowledge based on their training and expectations [5]. This project has explored whether this same principle of embodiment applies to physical media in performance such as robots.

Comments collected from participants suggest that performers make dynamic relationships to the physical media they are interacting with. This means that the performer is constantly observing, learning and reassessing the robot's movements and adjusting their own behavior to best suit what they feel the performance required. This finding is not surprising and is very much inline with the iterative process observed in other research projects on interactive performance media.

It is also not surprising that the quality of the robot's motion was found to have a large effect on the relationship and resulting interaction that the performer felt they *could* have. Again this finding is in line with earlier research in interactive performance.

A discrepancy in the experiential data seems to be uncovered when we look at the comments on anticipating the intention of the robots. First, the participants working with the Sphero mentioned anticipating the actions of the robot based on its motion. These comments mention tracking the robots trajectory, showing how skilled humans are at using the information they are provided with to try and anticipate their environment. It also suggests that the physical nature of the robot is enough to engage this human skill. Yet, the researcher found that they were not able to effectively anticipate the movement of the custom robot when the LEDs were turned off (providing no indication of the intention of the robot). If the physical nature of the robot was enough, then the physical presence would make it possible to anticipate both robots equally.

Other comments made by participants working with the Sphero suggested that the speed and proximity of the robot to the performer effects where the how the performer relies on anticipation. The researcher working with the custom robot tended to be in close proximity so depended on the robot's projection of its intention 800ms in advance of the action based on the research discussed earlier done by Libet. This finding suggests that we can design mechanisms for projecting the robot's intention through their physical structures, making them more natural to collaborate with.

However, the 800 ms used in this study is at the long side of the window suggested by Libet. In earlier research with a light based media agent it was found that 200 ms was sufficient for the performer to intuitively feel the intention of the media agent. If we are to say that the LEDs on the robot are engaging the embodied intuition of the performer, we should explain this discrepancy. Research with ephemeral media has found that the performer will often not even notice that they are responding to the media agent's projected intention to move, but they comment on intuitively feeling the intention. The researcher working with the custom robot described their experience as considering and seeing, suggesting rational perceptions of the robot's intention rather than intuitive perceptions. We contend that the extra cognitive process of rationally perceiving the LEDs accounts for the additional 600ms of time. This explanation suggests that the LEDs are not as much an embodied projection of the robot's intention, but more a pre-signal to the performer that they learn as part of the specific performance environment.

The last piece of this puzzle may lie in the perception of cause and effect. Participants experienced the rolling of the Sphero as a natural and smooth motion. The arching turns obeyed the participant's expectations of how a ball can – and therefore would- move, allowing them to anticipate the movement. The custom robot was designed around a two-wheel design allowing it to turn on the spot. This allowed it to engage in performer's movement patterns that were unusual for a wheeled object, therefore making it harder to anticipate. This analysis suggests that the robot's mechanism for moving may affect how it needs to indicate its intention to move. The LEDs on the custom two-wheeled robot were not perceived as part of its movement mechanism and therefore perceived as signals rather then embodied cues. In the earlier research with the light-based agent, the graphic modeling of a shift in center of gravity was perceived by the performer as a *cause* to the resulting motion.

Conclusion and Future Work

Through this study we have found that the principles for embodied interaction that were previously developed for ephemeral media do generally translate to physical media. However, we found that the *quality of motion* and the performer's perception of how the physical object to move (enacting its intention) needs to be considered when modeling an embodied interaction. While physical objects have inertia and are subject to the same laws of physics as the human performer, the mechanical mechanism does not always show its preparation to move in the same way that a human does, making an embodied perception of the system's intention weak. While adding this preparation to move is relatively easy with ephemeral media, physical media is still constrained by the actual physics of its motion, so designing a preparation can de a large design challenge. We will explore this challenge further in future work.

We also found that size of the robot had an impact on the type of relationship the performer felt they could engage in. The smallness of both robots made them seem fragile and not able to withstand true contact. In future

studies we plan to explore the performers experience with larger robots.

This study has also illustrated that proximity between the performer and the media agent is a key factor in determining what information the performer requires in order to feel engaged with the robot. We found that performers looked for an embodied based interaction with the robot most strongly when working in close proximity. We will be conducting future studies focused on close proximity interactions between robots and performers.

Robots and other physical media will continue to be used in performances. As the tools, programs, and devices become more accessible, performers will be extending the relationships they have with interactive physical objects on stage. By understanding how these design challenges relate to research already done with ephemeral media, the path to robots as engaging partners on stage will be made easier.

Puzzling Gestures: Prototyping a Teleoperated Interactive Artwork Using Techniques from Glass and Electronic Art

Mark Hursty and Victoria Bradbury

Abstract

This paper presents the initial stages of prototyping a digital-sculptural project that mines conventionally undesirable artifacts of mass production and material residue for their expressive worth. These artifacts are used as both inspiration and raw material to transform touch and movement into reflexive structures. This is done in the form of a remote controlled 'teleoperated' interactive artwork. This artwork, called *Gesture Puzzles*, is inspired by antique glass and wood-framed dexterity puzzles that use a player's hand movements to maneuver a marble through a maze. The piece describes practical collaborative methods that use creative electronic process to exploit both desired and undesired material residues from molten pressed glass, waterjet cutting and touch screen interfaces.

Keywords

Glass, waterjet, electronics, gesture, puzzle, digital sculpture, prototype, Rapid tooling, interactivity. Teleoperation, touch screen

Introduction

Fingerprints, smudges and smears remain on touch screens as biological residue of daily use. While often unnoticeable, these marks compose a tangible reminder of physical actions that have initiated digital results.

This paper will describe the creative process behind making a sculpture in which disused processes and materials, including screen swipes, serve as a medium to prototype a teleoperated artwork. This work combines material residue in the form of wasted wood, glass and evidence of user interaction. These create the physical structure of this work, and in the rationale for their use, as a basis for conceptual frameworks in future iterations.

These objectives are supported by the following three aims. The first is to creatively utilize the tactile experience of remote control/teleoperated machines in an artwork. This artwork is influenced by antique dexterity puzzles in which a player maneuvers a marble through a maze. The second aim is to creatively integrate latent materials and performed actions. This concerns the advantages of recycling, or making creative use of discarded or overlooked resources, including how to capture hand gestures and transform them into digitally fabricated objects through rapid manufacture. The third aim is to promote interdisciplinary collaboration between the fields of glass and electronic art. This is approached by reinterpreting, not only glass, but other analog craft processes in digital ways. This reciprocity is relevant to the field of electronic art because, with access to proper training and equipment, glass' nature as an inert, non-conductive material can be implemented expressively and structurally in digital artworks. After addressing these aims, this paper concludes by reviewing progress and suggesting future directions.

Project Description:
What is a Gesture Puzzle?

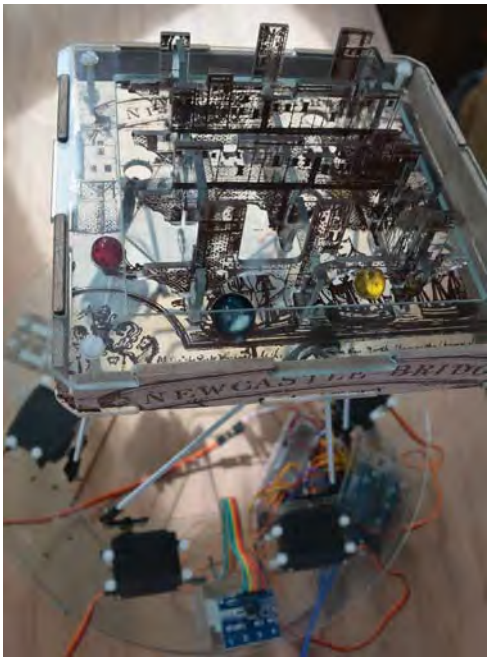

Figure 1. *Gesture Puzzle 1: Newcastle Bridge.* Glass, enamels, wood, capacitive touchpad, Arduino microcontroller, servomotors. Hursty, Bradbury. 2015.

The *Gesture Puzzles* will use a tablet or mobile phone to remotely tilt a glass and wood-framed box to maneuver a marble through a maze. The boxes are designed and cut

through CAD/CAM. When being manipulated, their pitch is controlled by servomotors, which adjust the rotation of the X and Y axes. These servos are controlled by an Arduino microcontroller and will be manipulated through a tablet touch screen interface.

To interact with this sculpture, the teleoperator will swipe a tablet to control the movement of the box. This movement is similar to the analog mechanism of Labyrynth, a popular sphere-in-maze, pitfall dexterity game developed by Brio, a Swedish company in 1946.

Figure 2. Brio Labyrinth game. [1]

In *Gesture Puzzles,* a program will record the direction and pressure of a participant's swipes. These recordings will be processed to display the gesture visually as 2D forms. Our current prototype (Figure 1) uses a capacitive touch pad, but we are pursuing a resistive touch screen interface as the most promising approach to registering the pressure of the screen swipes as 3D data.

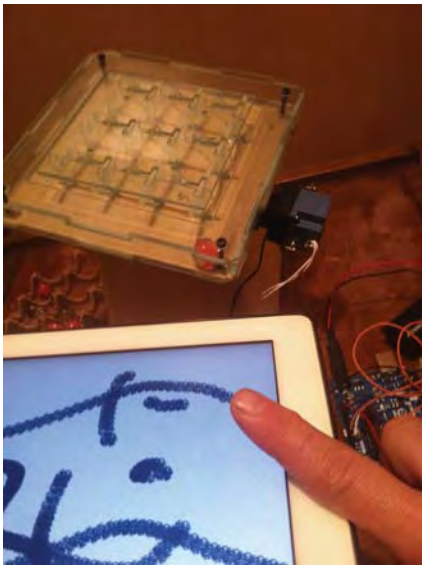

Figure 3. concept image of maneuvering a maze by swiping a tablet. Hursty, 2014

This data will be used to print 3D profiles as sculptural records of each time the puzzle is used. Depending upon the various pressures applied in each swipe, they will appear like the troughs and peaks of a sound wave. These will be incorporated into the subsequent sculpture as part of a grid structure that constitutes the navigable maze.

Background: Path to Puzzle Making

Gesture Puzzles resulted from a series of projects that used press-molded glass creatively. These projects used waterjet cutting and rapid manufacture to make bespoke molds for pressing molten glass. *Muqarnas*, 2014, were the first artworks in this series. *Puzzle Boxes*, 2014, followed. The residual materials generated by these presented an opportunity to make *Gesture Puzzles*.

The choice to make glass boxes arose from applying the rising prevalence of Rapid Tooling in Rapid Manufacture to the cutting of sheet glass molds into which molten glass could be pressed. [6] The *Puzzle Boxes*, 2014, were developed to demonstrate how molten pressed glass forming, an obscure method within glass art, could be used artistically. [5] The specific premise was that by creatively reinterpreting pressed glass, which is based on elaborate

mold-making, a method could evolve in which the mold permanently encompasses the finished artwork.

Developing this method resulted in a series of works entitled *Puzzle Boxes*. These are box-shaped mold artworks inspired by Chinese puzzle boxes. The Qing dynasty (1644 – 1911) boxes were carved from ivory, wood or jade. They opened in elaborate or hidden ways and were prized curiosities exported along maritime trade routes to the West. The term 'puzzle box' also refers to boxes containing sets of intricate carved ivory puzzles during this same period. [2]

Figure 5. Chinese export puzzle set, 19th century. Copyright 2014, Discovery Museum, Newcastle

Hursty's *Puzzle Boxes, 2014,* were made out of bespoke sheet glass produced for the field of artistic fusing. These could be heated to a high temperature and then poured into with ladles of hot glass. The project was conceived for two reasons. First, as transparent shells for witnessing the normally opaque process of pressing molten glass into a metal mold's crevices. Also to fuse designs of varied glass colors, including the mold itself, together, like glass marquetry.

Fusing glass molds like this is a new technique for mold-pressed and cast glass that can expand the creative possibilities for glass casting. This development also inspired performative work that focused on the spectacle of the flowing molten glass (Figure 6). Importantly, this technique substituted glass for making molds instead of metal, the most favored material used for press forming. Pouring into transparent molds in this way makes the opaque process of pressed glass visible.

Figure 6. Montage of pressing molten glass into a sheet glass *Puzzle Box*. Hursty, 2014.

The glass boxes that resulted, as well as the discarded wood that was sacrificed in the process of making them, evolved into the *Gesture Puzzles* described in this paper. This happened by recycling the disposable byproducts of the design and making process, the scrap glass and wood components, to make experimental boxes that could never be fused together. Instead, they are being developed as interactive dexterity puzzles inspired by the movement and flow of hot glass.

The ebb and flow of process that influenced the final *Gesture Puzzles* also involved electronic methods. First, it influenced the CAD/CAM that was required to make the components. Second, it became an inspiration to develop an interface to manipulate the boxes through touch-screen teleoperation.

Using Residue as a Creative Resource

The raw materials, the glass and wood used to make *Gesture Puzzles* emerge from the residue of rapid manufacture and digital process. The residual glass came from experiments with disposable window glass rather than expensive fusing glass. This provided an inexpensive way to test that the tolerances of the joining nodes could be fit by hand and that they could be cut reliably using the waterjet machine.

Waterjet cutting is a computerized numerical control (CNC) process that uses extremely high pressures to allow a .75 millimeter stream of water infused with garnet abrasive powder to cut glass (and most other materials). When cutting sheet glass with high water pressure, a backing board is required to avoid breaking delicate pieces. This underlayment is usually made of wood, though other materials are possible. This incidental support is cut as a twin, in the exact pattern as the overlain glass material. It is usually disposed of as it is considered scrap. In *Gesture Puzzles*, both the wood and inexpensive non-fusing glass are kept and assembled to make up the platform and boxes. Using these materials in this way allows for different assemblages and aesthetic permutations to result across the series.

Figure 7, *left.* Waterjet cutting glass with disposable wooden backing board underneath. Hursty, 2014
Figure 6, *right.* Discarded waterjet cut wood underlayment. Hursty, 2014

Another source of residue for the boxes comes from mark-making. The concept of *Gesture Puzzles* is for them to function like a drawing tool by making creative use of tactility. The movements of playing are simultaneously transformed into mark-making that is both immediate and mediated. The marks imply meaning as both a record of the teleoperator's intent to get a ball through a maze and as an artistic record. This represents the path taken through the maze and the biological residue in the form of fingerprints and smears that are left behind. These gestures reflect not only the daily performativity that occurs between tablet users and screens, but as an interface between manual touch and digital results.

Design Researcher Tavs Jorgensen explores the possibilities of digital products whose physical forms bear the traces of manual shaping. One such product was a set of tea towels on which motion capture imagery of a hand using a tea towel was printed. [6] In that application Jorgensen utilized a 3D motion capture glove for its 2D expressivity. The goal of the *Gesture Puzzles* is not only to register screen swipes as X and Y axes for 2D profiles but also to capture the pressure of the swipes as a Z axis in order to transform the movements of a user' movements of 3D profiles for digital manufacture.

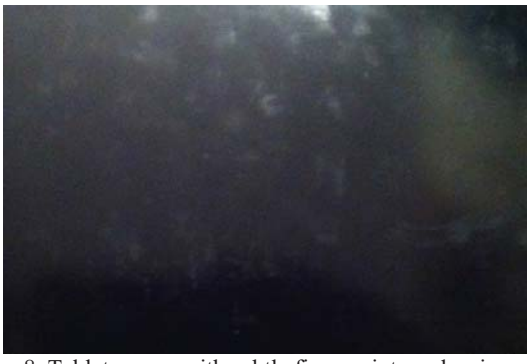

Figure 8. Tablet screen with subtle fingerprints and swipe marks visible.

Screen swipes have been used by artist Evan Roth in his *Multitouch Paintings*, which were "created by performing routine tasks on multi-touch hand held computing devices." [7] In this series, the fingerprinted gestures of playing a game, using an app, or engaging with social media are displayed in a grid (Figure 9). This flattens, concretizes, and equalizes the time and effort that has gone into these otherwise fleeting acts. Whereas Roth employs the 2D nature of multi-touch through painting, *Gesture Puzzles* seeks to capture the depth of such mark making to make them into tangible objects.

Figure 9. *Angry Birds All Levels*. Ink on tracing paper. Evan Roth, 2012. [7]

Judith Donath expresses the signifigance of mediated touch in communication channels that depend upon screen-based devices.

> *"As human beings, we interact with one another through many modalities: gaze, touch, gesture, and speech. In our daily experience with laptops and desktops—e-mail checking, Web surfing, and game playing—touch and text are our main communication channels."* [4]

As we use mobile devices to access information online, play games, and to interact socially, our physical gestures disappear with only the slight residue of fingerprints remaining. *Gesture Puzzles* would freeze these gestures in time, reinterpreting and reconstituting them as components for new boxes. They would then serve as physical reminders, ghosts of movements that would otherwise disappear.

Technique: Making the boxes

When the boxes were first assembled, they drew comparisons to mass produced antique puzzles. Belying this simplicity was an iterative and complex process, which is described here.

The sides of the boxes are cut in uniform patterns from 3mm thick sheets of wood and glass. These create flat interlocking sections that are possible because the patterns contain complementary dovetail joints, allowing the various segments to fit together. The profiles are drawn using CAD in multiple versions. After being cut, in order to be fit together, they are heated to 575 degrees centigrade, and then poured into by molten glass at 1260 degrees centigrade. Once experimentation with fusing glass began, further versions had to be made to improve annealing of the boxes (slowly cooling them to relieve destructive tensions within the glass) and to accommodate new designs. This experimentation generated the substantial amount of disposable wood and glass components mentioned earlier.

The original *Puzzle Boxes* had annealing problems. These arose because the height of the protruding glass tabs was too extreme; the overlapping tabs would not anneal properly or would crack. To minimize this problem, dovetail joints, common in woodworking, were applied to glass cutting. By doing this, overlapping joints became practically flush with each other. This improved their annealing prospects.

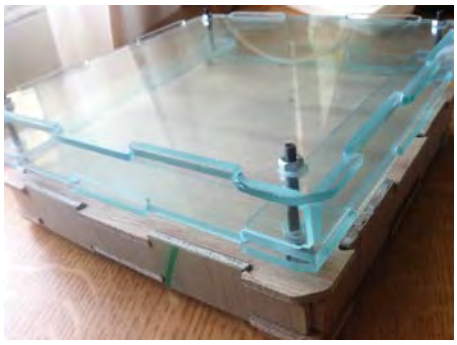

Figure 10. Waterjet cut dovetail joints in glass and wood. Hursty, 2014.

From a tooling perspective, cutting dovetails at the perimeter of the glass was a quicker and less fragile technique than poking holes, which had been done in previous versions. The reason these design decisions led to the *Gesture Puzzles* was that with so much material being cut to develop an ideal shape, their underlying sheets of backing plywood and scrap glass result in an equal amount of matching components. Because the sheets of wood and glass are the same size, they are interchangable and can be swapped to make hybrid glass and wood boxes. These boxes resembled sphere and maze games such as *Labrynth* and *The Busy Bee*.

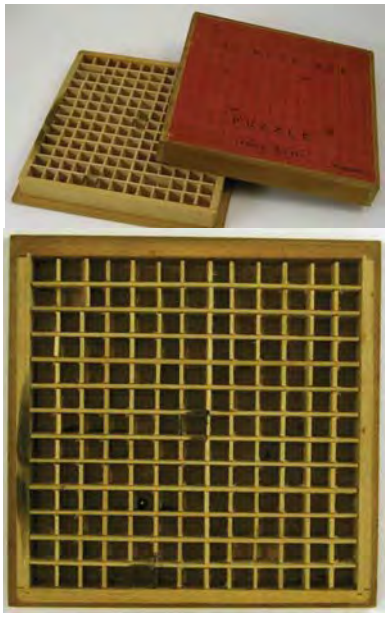

Figure 11. *The Busy Bee*, sphere in maze route finding puzzle, late 19th century. The Puzzle Museum. [2]

Wooden games traditionally would have been cut by hand, band saw, or router. Due to the fact that glass can only be cut in certain ways without shattering, the glass and wood shapes used in *Gesture Puzzles* are cut with high-pressure waterjet. This type of cutting, in terms of detail, provides results similar to laser cutting. This level of detail, from an ancient technological perspective was achieved by Chinese jade carvers who used abrasive powder on thin bronze wire bow saws to carve intricate patterns.

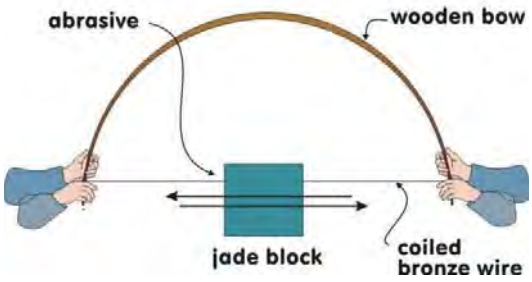

Figure 12. Chinese bow saw used for ornamental jade cutting.

Though the glass boxes were originally intended as one-time use molds for pressing molten glass, they have been used in different ways throughout the series.

A Duel in the Air: teleoperation

Maneuvering the puzzle boxes as a gestural fluid motion game also took inspiration from glass's molten properties. Hot glass practitioners must constantly maneuver glass to balance it "on-center" like a gyroscope. This maneuvering can be compared to dexterity puzzles like *Sky Pirates*,

where a biplane pilot, or his marble proxy, must avoid falling into holes fired by a piratic dirigible.

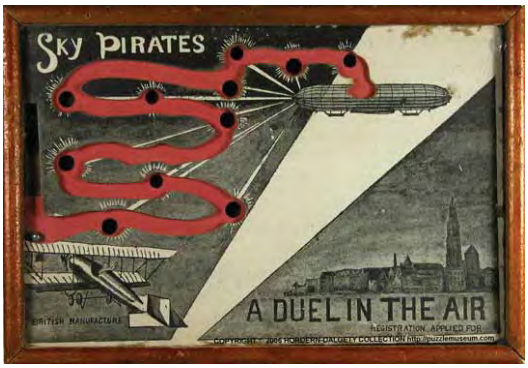

Figure 13. *Sky Pirates*, sphere in pitfall maze dexterity puzzle, 1910-1918. The Puzzle Museum. [2]

Hot glass has a time limit and can only be worked for short periods. In the course of playing *Sky Pirates*, a mistake can be reset. With one-time use glass molds, however, once a mistake is made and the glass fuses together, the process is irreversible. To reflect the reality that hot glass cannot be directly manipulated by hand, but rather through intermediate tools, it was decided that the boxes should be toggled remotely through electronics. The *Sky Pirates* slogan, *A DUEL IN THE AIR*, resonates with teleoperation, which uses invisible communication to maneuver something from across a room or removed to a different location entirely.

The feedback loop between human and machine sought by *Gesture Puzzles* points to a cyclical conversation of touch and materiality. This is reflected in an analog sense in dexterity puzzles such as *The Busy Bee* game (Figure 13), in which a player was tasked to move a ball around a maze, the route and pathways of which they could not clearly see. This draws a comparison to the underlying, hidden nature of programming code that directs and manages our interactions with electronic devices. Sitting beneath the surface of our gestures and communications sits a labyrinth, an obfuscated language that controls us in ways of which we are only superficially aware.

Conclusion

This paper describes the creative development of the first *Gesture Puzzles* prototype. Process and content have been linked from the original objective of making an artwork from press-molded glass to incorporating that project's residue into the *Gesture Puzzles*. This ethos of reuse inspired the current work's content without losing the series' original pressed glass focus.

Though the assembled boxes were no longer used for pressing glass, a metaphor for molten glass evolved that used the trope of antique maze games. This was intended to elicit a comparison to the formal theme of the work; abstracting touch and movement into reflexive structures.

This research brings little-known glassworking processes in line with electronic art. Waterjet cutting and rapid manufacturing techniques resonate with electronic arts practice, which is versed in rapid prototyping and laser cutting, but less so with cutting and melting glass. One benefit of an exchange between glass and electronic art is that the same CAD files can be used in both laser cutting and in the comparatively obscure practice of waterjet cut glass.

While it is understood that analog materials have physical limitations, digital formats are expected to have unlimited potential to do what we ask of them. Analog limitations of glass include specific ways of how, and at what temperatures it can be fit together. Limits of digital interfaces include the requirements of programming code to perform pre-determined actions in precise ways. Comparing analog and digital materiality through this interdisciplinary artwork problematizes the expectation of ultimate efficiency in digital formats with questions of interface and intuition.

This crossover was seen in *Gesture Puzzles* in the following examples. Teleoperation parallels the enforced distance and intermediate tools that must be used when working with glass. It also removes the hand of a player from obscuring the glass box, allowing light to be projected through the object. *Gesture Puzzles* offers an open-ended maze, with numerous exit doors, that are not intended to restrain, but to open a framework for digitally transforming physical gestures into tangible glass objects. While glassworking is an ancient technique, its use here demonstrates to the field of electronic art that new, potentially relevant glass techniques are still being discovered for creative use. This relevance also applies to how glass, with its properties of clarity, light and many other qualities, can be employed as a source of content by electronic artists.

For future *Gesture Puzzles* iterations, further comparison will be forged between teleoperating a machine and mediated social relationships. Transforming actions between digital and physical, sometimes over long distances, could be compared to interacting with other people, both on and offline. These different social modes can be evaluated as they are communicated through touch and iterative object.

The shape of the box forms could also evolve to a point in which the functionality of the maze breaks down completely as visual and physical complexity grows. Instead of composing a maze, the components can be used to build other sculptural forms. Whatever new forms result with this platform, the focus on remote control and the absence of tactile and vestibular (balance) feedback remain relevant for continued development. As teleoperation allows more tasks to be performed remotely, an emphasis on preserving a sense of tactility and sculptural resonance will remain.

Abstract

The **Laboratory for Audience Interactive Technologies (LAIT)**, has been established at the University of Illinois Urbana-Champaign to investigate possibilities for mobile devices to enhance the dramatic and informational experience of audiences at theatrical events, including dance, theater, music concerts, sports events, and installation. LAIT has a two-fold mission to 1) create a new type of theatrical experience for the 21st century, 2) provide an experimental platform for industries to develop applications for entertainment and informational use. This paper describes a mobile development platform that will enable theatrical producers to rapidly prototype and produce deployable applications that run on services provided either by LAIT or by the end user, without the need to write a custom application for each production. This will provide a cost-effective application solution for individual theater, dance, music, and installation producers. LAIT also intends to provide guidance for aesthetic use of applications within the context of live performance, so that it can enhance or augment that experience, rather than distract or detract from it.

Keywords

Mobile applications, theater, dance, music, installation, augmented reality, LAIT, smartphone, tablet computer, DSL, Unity

Introduction

Growing out of a successful experiment with designing and deploying a custom mobile application for an audience to use during a dance production at the University of Illinois Urbana-Champaign (UIUC), the Laboratory for Audience Interactive Technologies (LAIT) was established at UIUC to investigate possibilities for using mobile devices to enhance the dramatic and informational experience of audiences at theatrical events, including dance, theater, music concerts, sports events, and installation art. LAIT's mission is two-fold: 1) create a new type of theatrical experience for the 21st century, 2) provide an experimental platform for industries to develop cutting edge content for entertainment and informational use. Rather than providing application development services, LAIT is developing a *platform* that will enable theatrical producers to rapidly develop and deploy solutions that run on services provided either by LAIT or the end user. This obviates the need to create a custom application for each production, and provides a cost-effective, rapid development solution for theater, dance, music, and installation producers. LAIT also intends to provide guidance for aesthetic use of mobile technology within the context of live performance, helping users to produce content that can enhance or augment that experience, rather than distract or detract from it.

Background

Kama Begata Nihilum, [1] a dance that premiered at UIUC's Krannert Center for the Performing Arts in February 2014, featured a cast of seven dancers moving onstage with networked iPads that displayed synchronized graphics and texts, controlled by custom software written specifically for this performance. A mobile application made available to the audience provided for the display of additional graphical content including augmented reality, that provided meaningful content to users who pointed their smartphones and tablets at a projection on the stage, that was not available otherwise.

The proximity of the iPads to the bodies of the performers, along with the connection the audience felt to the performance through their personal digital devices, resonated in a tangible way throughout the theater. At a Q&A session after the performance, one audience member said that, because of the smartphone application, he had never felt connected to a performance as he had that evening – he claimed that the experience was highly "interactive." Even after being challenged on his use of that word (in this case, the mobile application afforded no user input capability), he insisted that his experience was "really and truly interactive." Others attending the performance not only echoed these sentiments, but also provided several suggestions for expanded uses of this technology.

The enthusiasm felt by this audience might be explained by Camille Baker's findings that mobile devices can help bring "liveness" and "presence" to performance in the 21st century [2], particularly in the connection among participants in a shared event. Owen, Dobbins, and Rebenitsch also describe similar audience involvement and engagement to what we experienced with *Kama Begata Nihilum*. Their "Theater Engine" performances explore the use of mobile devices for live dance, and the technical and design

considerations necessary for these types of productions. [3] Like *Kama Begata Nihilum,* their highly complex work faced challenges coordinating multiple specialists working many hours on each production as well as challenges with respect to infrastructure and deployment.

To address some of these difficulties and to continue to build on audience enthusiasm for mobile devices as part of performance events, an effort was begun to leverage the research and design resources available through the National Center for Supercomputing Applications at the University of Illinois (NCSA) to develop the expressive, informational, and integrative possibilities afforded by personal digital devices in the context of live performance. The result of this effort is the Laboratory for Audience Interactive Technologies, or LAIT. Taking advantage of the phones, tablets, watches, or other devices an audience member may use to connect to the world around them, LAIT intends to extend that connectivity to the domain of live performance to assist artists in engaging their audience and in conceiving new works with mobile devices at their core.

Artists generally don't have access to the resources necessary to develop and deploy a mobile application. Since the idea of using this technology to enhance or augment live performance is new, they also may not have the ability to readily imagine what might be possible.

LAIT's strategy to counter these deficits is two-fold:

- Develop a platform, or toolkit, to assist artists in creating content for mobile devices and provide a ready delivery method immediately useful in live performance and flexible enough to accommodate last minute changes;
- Consult with individual artists and host group brainstorming sessions to assist creators in conceptualizing how content for mobile devices might be used in live performance.

Defining the problem space

One of the challenges facing a builder of a generalized platform aimed at using audience member's mobile devices in the context of live performance lies in the paucity of previous discussion on the topic. While it bears a resemblance to the design disciplines commonly found in the performing arts, like lighting design or scenic design, its role in the context of performance is not as clearly or easily defined as those disciplines.

Much of our work has been driven by discussing the potential of the platform with prospective users and collaborators. On May 1, 2015, we held a "LAIT Day" general discussion about the capabilities and possibilities that our platform can bring to live events. Participants were asked what role the content provided by the LAIT platform should, or can, play in a performance. Their answers generally make reference to three broad, yet distinct, modes in which a LAIT designer ought to be able to create.

The first of these is the *display*, or exhibition, of content in support of the overall aesthetic of a performance. In *Kama Begata Nihilum*, this was the only functionality afforded. However, we discovered that even simple actions such as the ability to remotely change the color of a phone's screen, display an image, or vibrate the device, can have a profound expressive effect.

Another mode that interviewees felt would be important is leveraging the use of *input* afforded by mobile devices. From allowing a user to click on a button to signal recognition of a specific dance gesture [4] to using the aggregate accelerometer data of an entire audience to drive a particle system projected on a screen behind the performers, the potential of using this kind of data in performance is exciting, even though the technical challenges are complex – particularly on a scale of massively attended events.

The final mode appearing in preliminary discussions about this platform's role is *annotative*. A broad array of performances could benefit from the addition of content to help audience members understand complex art forms. Operas often require supertitles, which now could be provided in many different languages. Novice orchestra concertgoers could learn from the identification of an instrument currently playing a solo. Or, an actor's true motivation could be hinted at via audience's devices.

These three broad modes of content creation, then, function as guidelines for developing the LAIT platform.

LAIT Platform Architecture

LAIT is an extension of the application we built for *Kama Begata Nihilum.* It is being built for speed and reliability, because in live performance, precise cueing times and reliability are absolutely necessary. A performance will suffer, or even fail, if a cue comes too late or doesn't show up at all. Therefore, LAIT is being developed using the Unity 3D game engine, a proven commercial platform used by game developers worldwide. Unity 3D offers a robust scripting layer that allows for extensive customization, along with reliable networking functionality.

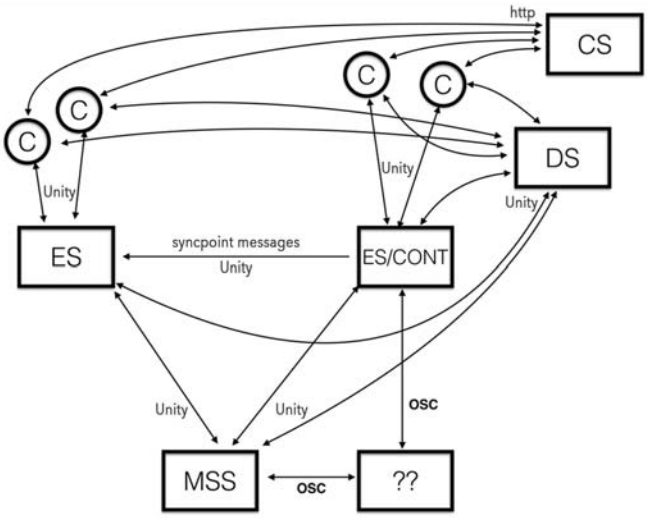

Figure 1. LAIT System Architecture

The LAIT architecture consists of several components whose interconnection is illustrated in Figure 1:

- Client (C) – the mobile device carried by the audience member
- Directory Server (DS) – helps to direct Cs to a server associated with a specific live performance event
- Event Server (ES) – relays cue messages (Qs) to the Cs during a live performance
- Event Controller (ES/CONT) – as above, with additional functionality allowing for the triggering of Qs
- Content Server (CS) – delivers any content needed for the performance
- Message Stream Server (MSS) – accepts and parses input from the audience members' devices
- Other Services (??) – output to other services, computers, and processes

Prior to a performance:

- An audience member downloads the Client (C). Upon launch, C connects to the DS.
- DS sends a list of events that are currently active.
- Audience member chooses the event he/she is attending from the list provided by the DS. This connects C to the event's ES.
- C is directed to download the Q-List and other necessary assets from the CS.
- C parses the Q-List and constructs the content specified within it.

During a performance:

- Q triggers are sent rom the ES/CONT to C's.
- C's response to the Q trigger is described in the specifications of the Q-List (e.g., display a graphic or text, flash a color, vibrate phone, etc.).
- Any input from C (accelerometer data, screen touches, etc.) is passed through ES directly to the MSS.
- MSS collects input from all the ES's. It may choose to process the data itself or pass this data on to an external process. The input data may ultimately be used in or out of the system.

Scalability is achieved by the ability to deploy multiple ESs for any given live performance. If an event were expecting one hundred audience members, one ES would suffice. For five hundred seats, two or three ESs might be necessary, and so forth. Theoretically, LAIT could be scaled to thousands of users. Extensibility is achieved through modular design and by communicating with components outside the LAIT architecture using the Open Sound Control protocol (OSC). [5] OSC is used for data communication among interactive applications, and implementations exist on a wide variety of platforms.

The Domain Specific Language

In order to promote speed, flexibility and ease of use in our networked platform, we have implemented a modular domain specific language (DSL). A "Q-list" Document (QLD) written in the DSL is loaded by the C upon connecting with the Event Server. The QLD tells the C what content or function will be needed during the performance, and associates that content with an integer index, or "Q". Then, during the performance, concise messages containing a Q's index are used to trigger relatively complex sequences on the C, such as displaying a graphic, changing the color of something, playing animations, etc. The capability to execute these Qs is handled by *modules*, components that function similarly to plug-ins, each of which provides a specific capability to the LAIT system. Thus, the architecture has been structured to easily add capabilities as desired, such as dynamic location detection, biometrics, etc.

For example, in order to display a background color on the C, a plane must be created and a color applied to the plane. Specifying the color of the plane requires at least 256 bits of data for four floating-point numbers describing its red, green, blue, and alpha values. This number grows when adding consideration for the position, size, and orientation of the plane on which the color is to be displayed, and greatly increases if animating it on the fly. It is easy to see that sending messages of this size to hundreds of phones at the same time is inefficient, leading to latency and lost information on even robust wireless networks. However, since the C has pre-loaded the QLD, a single integer is all that is required to perform actions on a C.

While loading the event-specific QLD in advance of the performance allows for efficient use of network bandwidth, it also necessitates an abstraction of the content to be delivered to the device. This abstraction is further being used in the development of a simple WYSIWYG tool for content creation that automatically generates the QLD for use in the LAIT infrastructure. This tool will allow non-specialists to create their own content for mobile-device enabled events, significantly lowering the overhead and development time when compared with building a custom application.

Initial Experiments

LAIT exists at the intersection of performance and HCI as posited by Spence, Frohlich, and Andrews, in their Performative Experience Design (PED) framework. [6] An interesting use of the LAIT system in this context occurred during the American College Dance Festival at Iowa State University in March 2015. Dancers holding mobile devices were guided through an improvisation with LAIT. Just prior to the event, several dancers who volunteered to be leaders had their photos taken and uploaded to the CS (Fig. 1). Then the dancers loaded the LAIT application. At a certain point during the dance, the leaders' photos were displayed randomly on random phones. Dancers then gathered around and followed the movements of the dance leader who appeared on their screen. At another point, the display of random colors was used to form and re-form groups within the mass of dancers. Later, random evocative words were displayed on random devices, inspiring a

collage of movement and sound qualities that redistributed the dancers around the space. In these ways, LAIT melded spectator, performer, and group dynamics into a set of new and complex interactions that would have been otherwise unavailable. This experiment served as a proving ground not only for basic infrastructure and functionality of the system, but also demonstrated the ability to change content dynamically.

An example of LAIT's capabilities as an annotative tool occurred at a concert by the band Cody and the Gateway Drugs at the Krannert Center for the Performing Arts in April 2015. The LAIT system successfully delivered lyrics to patron's devices in synchronization with the live performance. Photos of the band members and promotional materials were also displayed. By offering more information about the band and its repertoire, LAIT was able to extend and enhance the audience's enjoyment and appreciation of the performance.

Conclusion

With LAIT we are hoping to help usher in a new era in live performance, where mobile devices are integrated into events instead of being banned from the performance venue. The usual dictate to turn your phone off at a performance is based on the notion that checking social media or playing games makes it impossible to pay attention to what is happening at the performance, and is distracting to your neighbors. However, if within valid aesthetic parameters, the phone is used to enhance lighting effects, display augmented reality content not otherwise visible, communicate hints regarding a character's motives, or to encourage audience participation by eliciting synchronized movement, then the device can be elegantly integrated into an artist's work, and add value for the event's producers.

Anecdotal experience has shown that people are unwilling to shut down their devices when attending a dance, music concert, drama, or movie. So, why not make use of their tremendous capabilities to push the boundaries of art by augmenting live performance? As we announced to the audience who attended *Kama Begata Nihilum*: "Don't turn your cell phones off, turn them on!"

Authors Biographies

John Toenjes has a BA from Stanford University, and an MA in Music Composition from the University of Missouri-Columbia. He is Associate Professor and Music Director of the UIUC Department of Dance. His numerous interactive dances and movement-based installations include *Inventions Suite* (Cleveland Ingenuity Festival 2008), and *e's of water* (UW-Milwaukee 2007). He wrote the music and designed the wireless sensor networks for Trisha Brown's *Astral Convertible Reimagined* (UIUC 2010), and for *FraMESHift* (Teatro Astra, Turin, Italy 2011-12). He was Technical Director for IJPAN, the Illinois-Japan Performing Arts Network (2010-13), which produced his *Timings: An Internet Dance*, with dancers co-located internationally and connected to live avatars via Kinect. John is now Director of the Laboratory for Audience Interactive Technologies. http://lait.ncsa.illinois.edu

M. Anthony "Tony" Reimer's passion is designing sound effects and writing music for theater, film, video games and interactive experiences; his compositions and sound designs have been heard in venues across the US and internationally. He has a BGS from Ball State University, an MM in Computer Music and New Media from Northern Illinois University and is pursuing a DMA in Music Composition at UIUC. Tony has been audio director/composer for Mutiny Games. He has designed and implemented interactive installations and data sonification projects at UIUC's Krannert Art Museum and Krannert Center for the Performing Arts. Tony teaches sound design in the UIUC Department of Theater, and is a researcher at NCSA, working on projects involving the use of technology in art.

Abstract

This paper explores user experience specifically in the context of telematic dance and networked spaces. New electronic sensor technologies that capture the movement of bodies provide opportunities to redesign the body in space. While much research in this area is informed by technology directly, in this research a 'user-centered' point of view is used to explore new design criteria for movement-based interaction. I discuss a series of performance-based projects titled *Mashup Realities*, an online platform for interaction, collaboration and creativity. The starting point for these projects is the exploration of people's performance experiences of communication and interaction through bodily movement, to make this experience a source of inspiration for the resulting designs. In this paper I will describe the process and technology behind *Mashup Realities*. By working with a range of dancers, choreographers, musicians, designers and programmers through adopting a participatory approach, this paper will outline how performers can be supported in developing a more meaningful and richer interactive experience to extend non-verbal communication and collaboration through the internet.

Keywords

User Experience, User Experience Design, Networked Interactive Environments, Dance and Technology, Non-verbal Communication

Introduction

In 1977, Kit Galloway and Sherrie Rabinowitz created *Satellite Arts Project,* the world's first interactive composite image satellite dance, between performers on the Atlantic and Pacific Coasts of the United States [1]. Existing research on the subject generally takes the viewpoint of the technologists or the performer. This research focuses instead on user experience design, speaking to the needs of the choreographer and dancers as they develop their art within the technological environments. This approach will outline design criteria to contribute to the development of a framework for technologists and non-technologists alike to utilise these tools and create interactive networked performances of their own. To achieve this, I am looking into the best possible way for available technologies, both hardware and software, to be redesigned, rebuilt and reengineered for an optimal performance space and spontaneous, real-time reaction and interaction in dance performance.

Mashup Realities is a platform for interaction, collaboration and creativity between dancers separated by distance, and will drive the practice-led research. Through observation and experimentation, we aim to develop a cross-cultural and cross-disciplinary platform to facilitate a cross-pollination of dance and new media arts. This paper discusses three dance projects: *Experiment.spaces no.1*, *Metakimosphere no.1* (MetaSeminar Digital Technologies Lab project, Brunel University) and *Experiment.spaces no.2 [Spheres]* that make use of a interdisciplinary approach, enabling collaboration between dancers, choreographers, musicians, designers and programmers. Given its key role in the practice-led research, *Mashup Realities* has two ultimate objectives: (1) supporting creativity in performance by investigating the potential for user experience design and (2) increasing non-verbal online communication and collaboration in remote Australia.

The internet is a key tool for the performing arts, especially in geographically remote locations. Online, networked communication offers artists working in these areas opportunities to network, research and create international collaborative relationships, when they would otherwise experience professional and social isolation relative to their city counterparts [2]. It expands the realm of their collaborative opportunities and vastly increases their interaction with other artists.

In this study, interactive environments are defined as spaces with technology-based interfaces that react to user input creating responsive physical and virtual spaces. Users are able to form embodied experiences by seeing, hearing, and feeling realistic perceptual cues linked to those experiences. Embodied experiences are defined as the state of being 'surrounded by simulated sensorimotor information in mediated environments that create the sensation of personally undergoing the experience at that moment' [3].

The term user experience (UX) is used by web designers and developers to describe the human–computer interaction between the application and user. The user in this context is not the audience but the dancers using the environments. UX encompasses all aspects of the dancer's interaction with the environment covering whether the system is easy to learn, efficient to use, pleasant, satisfying and meaningful.

According to Jodi Forlizzi, a rich experience is an interaction 'with a product which is satisfying, an experience that has a positive and pleasing value for the user, allowing the user to perceive beauty in the product and its use' and which 'has a sense of immersive continuity and interaction, which may be made up of a series of satisfying experiences' [4]. This term 'rich' is useful as it helps to describe the forms of interactive models and UX design methodologies used to create complex digitally mediated interactive environments.

The term networks in the present context means the distribution of content (visuals, audio and movement) over telecommunication and information technology systems. Research into telematic performance, dance and technology has described the application of information technology in dance as 'digital or virtual extensions of the body' [5] and 'the intersections of technology, body and code' [6]. Space, time and body are components of movement for contemporary dance, and space in particular is a key factor contributing to the shape of movement. This research aims to investigate distributing space – extending the physical parameters in which artists can perform – through the creation of hybrid connected environments, both physical and virtual.

These interactive environments offer rich layers of perceptual information encompassing lighting, costumes, choreography, sound, visuals and movement. Furthermore, digital scenography, as defined by Birringer [7], is the live performance architecture incorporating analogue, digital and network dimensions, where performers are inside and outside the digital worlds simultaneously. Meaningful interaction between the performer and space is crucial for the performance, and designing UX for these hybrid spaces will be an exploration of the 'convergences between performance, telematics, textile/fashion design and movement, clothing and choreography, visual expression, film/photography, and interactive design' [8].

In this paper I describe the process and technology behind the ongoing dance projects, *Mashup Realities*. These projects investigate user experience in networked interactive environments for dance, and methods that can be used to design for 'rich' experience. I aim to identify design criteria which support the creative process for dancers in interactive environments. To this end, flow theory and quantifying tools will be used, as well as industry UX testing methods. A user-centered approach is being adopted in order to create meaningful embodied experiences in interactive environments. A key question the research addresses is: what makes a meaningful 'rich' experience for the people choreographing, rehearsing, performing or collaborating within a networked interactive system?

Exploring user experience

Within the scope of this research, 'the performer is always the user, player and participant in an operating system' [8]. The dancer, understood in the context of interaction design as a user, has a unique set of requirements and aspirations. Through researching existing UX models and methods I aim to not just clarify the immediate needs, but also to get behind the driving motivations and values of the user: the dancer.

The initial approach will be to examine Birringer's research into telematic performance by applying the ideas from Csikszentmihalyi's flow experience, and its possible role in measuring and supporting engagement. Johannes Birringer is the Chair of Drama & Performance Technologies Research for Theatre at Brunel University London's School of Arts. He is focused on the exploration of networked performance and 'the intersections of technology, body and code; the aesthetics and politics of programming, the poetics of online communication or online contact improvisation, and the relays between architectural structures, institutional structures and distributed networks' [6]. Mihaly Csikszentmihalyi, who first developed the 'flow' concept in 1975, is a leading researcher in positive psychology and currently teaches psychology and management at Claremont Graduate University. With the aim of understanding experience and mental states in order to improve the design of the interaction, an user-centred approach will be used, or in other words a 'direct and active participation of all stakeholders in the design development process' [9].

Body (wetware)

Human bodily movement, non-verbal communication and interaction may be subtle or expressive, and occur at different scales of gesture or expression. In the context of software and hardware, the thought processes of users which lie behind the operation of computer systems are referred to as "wetware". Of relevance in the exploration of embodied experience are the thought processes behind bodily movement within interactive environments. Flow theory can help us to better understand these processes.

Csikszentmihalyi's flow theory has been used extensively in the study of human computer interaction (HCI) as an important means of understanding the efficacy of interactive environments, and in dance research for gaining insight into the possible facilitating and inhibiting factors that would support flow for dancers.

Flow experience is defined as a state of concentration so focused that it amounts to absolute absorption in an activity [10]. With relation to dance, 'flow is believed to be a psychological state in which the mind and body 'just clicks', creating optimal performance' [11].

The dancer has a unique set of skills, needs, emotions and experiences. *Mashup Realities* will study and evaluate how to support dancers own flow experience and how they feel about performing in an interactive environment. The aspirations of dancers will be factored into the system's design in order to understand how good UX design 'allows for personal and useful interaction, and arouses an emotion which unifies a satisfying experience' [4].

According to Jaime del Val (2013): '93% of our expression are in the form of non-verbal communication, yet current media reduce non-verbal interaction to a highly

reduced set of standardised and traceable gestures of interaction through interfaces' [12]. This research addresses the importance that non-verbal communication and embodied expression has for dancers and their collaborative processes. Throughout development, the aim is to utilise UX design to support non-verbal communication in networked interactive environments.

Code (software)

Movement-based and gesture-controlled interfaces will be designed and built to detect, measure and interpret physical movement. This creates a HCI system for dancers in interlinked physical and virtual spaces, including real-time digital mixing of audio, light, video and computer-generated imagery controlled by the user. The architecture consists of responsive behaviours that can be modified by the user through visual and audio parameters triggered by certain expressive movement and gestures. Also, at a later stage, the interactive environment will be developed to record and playback performances as a tool for collaboration and sharing.

An intriguing further consideration will involve system behaviours which are proactive and anticipatory. Research into intelligent movement-based interfaces investigates 'environments that can observe their human inhabitants, can interpret what they know, want and do, and reactively and proactively support them in their activities' [13]. This form of artificial intelligence could provide real-time feedback as to what the user is experiencing or feeling, including pain, fatigue, frustration and irritation, by collecting and analysing data about the user's regular patterns of bodily activities.

Technology (hardware)

The interactive environment is a sensory space for sound, vision and movement. The technology employed will sense and capture movement within the space and output visual and audio back into the space.

Digital scenography, as defined by Birringer [7], is live performance architecture that incorporates analogue, digital and network dimensions, where performers are inside and outside the digital world simultaneously. Meaningful interaction between the performer and space, therefore, is crucial for the performance. The exploration of latest sensory technologies for movement will inform the design of these hybrid spaces.

The intersection of body (skill, emotion, need and experience), code (interface, interaction and environment), and technology (sensing, capture and output) is where I believe we will find the 'rich experience' that Forlizzi describes.

Related work

Artists, performers and designers have experimented with the use of networks, telecommunications and information technology as a means of broadening their creative experience for decades. *Metabody, Zero Point, Danceroom Spectroscopy* are three current projects with goals closely related to that of the present research.

Metabody is a project financed by the European Commission which commenced in July 2013 and will run until July 2018 [12]. *Metabody* investigates cultural diversity, non-verbal communication and embodied expression by examining networks that connect institutions, organisations and people. The research aims to achieve an interactive mobile architectural structure for outdoor spaces (performances, interactive installations and immersive durational experiences). The resulting structure will include both analogue and digitally mediated environments consisting of space modules, objects modules and wearable modules, working both locally and telematically, with the possibility of connecting protagonists in different cities and countries. *Metabody* seeks to generate a new methodology for interdisciplinary research and artistic creation between this area of the arts, information and communication technologies, human science and philosophy.

Darren Johnston is a UK director, choreographer and video and sound artist with a contemporary dance background. Johnston undertook a week-long residency at the Barbican Theatre in London in March 2014 to experimentally use his own software in an interactive performance titled *Zero Point*. Using motion-sensing technology, video projections and light, he designed a performance in which shapes of light moved over a backdrop of darkness – 'it bathed the bodies of dancers with graphic texture and light.' The sensors and programming mapped and selected the dancer's body in the three-dimensional space and created a shape based on that of the detected dancer, which was then projected back onto their bodies in real time.

UK based *Danceroom Spectroscopy* is a science/art collaboration exploring languages and crossovers between physics, interactive art, performance and technology. It interprets people as energy fields, allowing them to influence both graphics and sound within the interactive environment using their movement. The technologies *Danceroom Spectroscopy* utilises in many of their installations are Max/MSP, Ableton Live and Microsoft's Kinect sensors.

Studio work

Three project (to date) form the foundational basis of my practice-led research. I will discuss in detail *Experiment.spaces no.1* and then briefly outline *Metakimosphere no.1* and *Experiment.spaces no.2 [Spheres]*. The performance installation *Metakimosphere no.1* was created from a workshop at Brunel University, London. *Experiment.spaces no.2 [Spheres]'s* application is in its very early stages of prototyping and testing.

Experiment.spaces no.1 - Choreography

This initial project laid the foundation for collaboration between choreographer (Seeta Indrani) and designer (myself), and by extension how we will collaborate with

the performers. Indrani and I started by discussing how to better understand and explore the possibilities that technology holds for the performance.

As a creative device, we employed 'Chance Operation' as a methodology for the performance and design of the interactive environment. From the Dadaists (Jean Erp), Cornelius Cardew, John Cage to Merce Cunningham, this technique has been used to employ non-predetermined and unpredictable elements that cause an event to have a certain result. Merce Cunningham introduced Chance Operations into contemporary dance and it quickly evolved to become an important compositional device. Cunningham was a leading American dancer and choreographer and is considered one of the most important choreographers of our time. He describes Chance Operation as a device, 'when I choreograph a piece by tossing pennies - by chance, that is - I am finding my resources in that play, which is not the product of my will, but which is an energy and a law which I too obey' [14].

Seeta Indrani graduated as a dancer from the London Contemporary Dance School. She made her stage debut as Cassandra in the original London production of Andrew Lloyd-Webber's *CATS*. Indrani describes the choreography concept: 'Relinquishing control to the randomness of the software is almost an existential approach. Unlike many works I'd created in the past this was not to be an organic journey of the emotions, characters, stories or instinct. We felt chance or randomness was a good fit. We knew we wanted elements of the computer or the software taking control and vice versa – the dancers triggering the computer software in real time.'

The choreographer's starting point was very simple 4 x 32 count phrases to be performed in a random order, with the computer determining the structure. These phrases would form the basis of all of the choreographic content. To fulfil these requires it was evident a gesture-controlled user interface would be needed.

Experiment.spaces no.1 - Technology

A great deal of research has gone into investigating the available software and hardware that best suit the project's requirements. We needed hardware to sense and capture movement, software to translate motion into data and additional software with a programming language to utilise the data to control or manipulate the environment via gestures, both visual and audio. The criteria was to find hardware which was cost effective, accessible and easy to set up.

After two months of researching and testing various applications, and investigating similar projects in London, we decided on the Microsoft Kinect motion sensor and a combination of applications and programming framework; Synapse, Syphon, Particle Warfare, Max 6 and Quartz Composer [Figure 1].

The Microsoft Kinect is a reasonably accurate motion sensor with a range of about 5 metres. Synapse is a piece of open source software designed by Ryan Challinor for the Kinect to send joint positions and hit events via Open Sound Control (OSC), a protocol for communication among computers. The software captured the user's movement via the sensor, which is then represented as a red skeleton or wireframe. Each point of the wireframe (10 of them; Head, Torso, Elbow (L), Elbow (R), Hand (L), Hand (R), Knee (L), Knee (R), Feet (L), Foot (L)) is measured and mapped as constant streaming X, Y, Z positions. This data is then fed into other applications that can receive OSC events. Both Max 6 and Quartz Composer can receive OSC events.

Max 6 by Cycling 74 is a visual programming language used by a variety of new media artists, musicians and programmers for interaction, moving image and sound. In this project it will be used to receive data from Synapse/Kinect and create a series of small applications called Patches, which will create the audiovisual contents of the responsive environment. Max 6 primarily handles the X, Y, Z position data from the Kinect sensor. Using these coordinates, hotspots in the environment (3D space) were created via a Patch based on a hand gesture. This triggered the random Patch, which selects a video at random from the database to be displayed in the background of the projection via Syphon (application-to-application communication) to Quartz Composer. Quartz Composer by Apple is also a visual programming language, but its strengths are processing and rendering graphical data. Therefore, all the visual elements of the environment are controlled by Quartz composer.

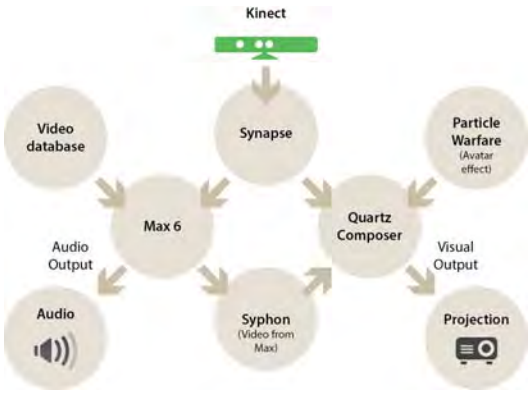

Figure 1. Applications and their relationship: Synapse, Syphon, Particle Warfare, Max 6 and Quartz Composer

Experiment.spaces no.1 - Practical work

In February 2014 we trialled this model in a London studio with a contemporary dancer and a martial artist. The aim was to test the responsiveness and range of the Kinect and software, and also to flag any potential issues the applications might have. The hardware setup included the Kinect sensor, a laptop computer and a projector. We created an environment where specific gestures triggered sounds and audio changes. The studio was 5mx7m and the sensor was placed at the front, with the user's wireframe or skeleton projected onto the main white wall. The visualisation was smooth and immediate, but the audio was

hit and miss. Three issues became evident. First, when the user moved too fast the wireframe was lost and the data, X, Y, Z positions, stopped feeding the OSC events. The second, range was less than 5 meters. At times we lost the wireframe and needed to recalibrate. The third, the sensor seemed to be confused when one performer crossed in front of another.

In August 2014 we started to conceptualise a performance, seeking to simulate two spaces networked together within the one performance area. The choreographed performance structure would be informed by the application randomly selecting the order of 4 x 32 count phrases in real time. The random patch would be triggered by the dancers via a particular gesture. The interactive environment was designed and developed over a two month period.

In October 2014, in my role as designer and developer, I entered the studio with two dance graduates from the Victorian College Of The Arts, Rachel Heller-Wagner and Louis Matthews, and the choreographer, Seeta Indrani. In this stage of the project I wanted to work closely with the users and the choreographer, utilising a participatory design approach to develop the interactive environment application and performance to a point ready for a public rehearsal. The choreography would play an important role in designing the interactive environment and the development of the programming.

For this initial studio work, I divided an image capture studio space located at MADA (Monash Art design and Architecture) into two sections [Figure 2]. The two halves would not be technically networked environments, but I wanted to use a technically simple division to allow communication between the dancers and the applications without too many IT issues. This helped me observe the non-verbal communication between the dancers and choreographer and better understand what will be required when we proceed to the next stage, linking two spaces separated by distance. Although the dancers were physically in the space together, the choreographer, Seeta Indrani, was collaborating via Skype. This provided an interesting insight as Indrani highlights, 'I was aware I was missing nuance, moments which might organically grow, take us off in other directions. Unspoken vibes.'

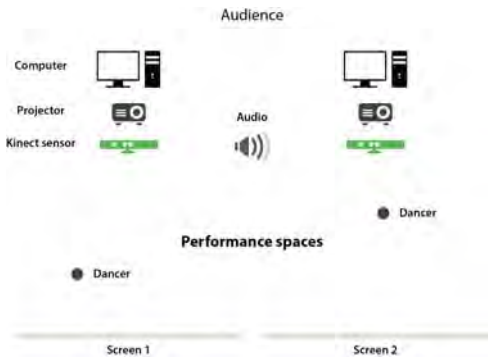

Figure 2. *Experiment.spaces no.1* performance spaces and the technology layout.

Working directly with the dancers and choreographer at this early stage in the development of the interactive environment's programming, I discovered new opportunities to refine the process that I would not have contemplated alone. From my professional experience as a web designer, understanding the user is key to building successful online systems. As Elizabeth B.-N. Sanders, PhD Experimental Psychology from Ohio State University's design department, notes, 'the roles of the designer and researcher blur and the user becomes a critical part of the process', and she continues, 'if we can access people's experiences (past, current and potential), then we can make user experience the source of inspiration and ideation for design' [9].

The public rehearsal was performed to a small audience and lasted eight minutes. The structure was divided into three parts; choreographed introduction with small solo performances, then followed by the Chance Operation approach where the order of the 32 count phrases were determined by the computer, and then final part had the dancers perform the phrases in unison in a predetermined order to finish the piece. A video sample of the public rehearsal can be view on Vimeo (vimeo.com/mashuprealities) [Figure 3].

Figure 3. Screen grabs from *Experiment.spaces no.1's* public rehearsal video documentation.

Experiment.spaces no.1 - Feedback

I asked for feedback from the choreographer, a dancer and an audience member regarding their experience of the project and the public rehearsal. This feedback was not

designed to measure experience, but simply to improve future studio work collaboration. Feedback questionnaires alone are not sufficient to evaluate experience. A combination of documentation (video), observation, experimentation, interviews, questionnaires and research, will provide valuable ways to measure these experiences.

Seeta Indrani, choreographer, was not physically present during the studio performance in Melbourne. She is a London based choreographer, actress and director. We linked up with her via Skype. The setup had the camera pointing towards the performance space and the audio running through the speaker system, so Indrani could view the dancers and communicate directly with them.

> "There is no substitute for being in the space together. I was aware I was missing nuance, moments which might organically grow, take us off in other directions. Unspoken vibes. All the reasons why we congregate in a rehearsal space in the first place. However, Chris and I have a strong working language and the dancers were very open with their suggestions and feedback which allowed the collaboration to move forward," Indrani.

Indrani's comments highlight the importance of how movement, both subtle and expressive, is communicated over the internet. In this case, 'unspoken vibes', or small movements which were significant to the collaboration and choreography, were lost during the Skype linkup.

Despite this, the collaboration in the studio between the dancers, choreographer and myself presented new ideas and opportunities to better design the interactive environment for the performance.

> "I enjoyed discovering what the technology could offer the movement. The dancers were very free in playing in the studios throwing out ideas, which usually then set Chris quite impossible tasks – but this was part of the experiment. How can it best serve the performance," Indrani.

Rachel Heller-Wagner and Louis Matthews, graduates from the Victorian College Of The Arts, are very skilled contemporary dancers and brought a lot of their own ideas to the collaboration.

> "Alongside new challenges and learning to work in alternative ways, I felt that the structure of the project facilitated creativity and thus allowed positive outcomes to occur... i.e. having a programmer able to explain and change things as you go, another dancer to bounce info and movement off etc," Matthews.

For the dancers this was the first time they collaborated on a project where the technology played a large part in the choreography. This highlighted how important instant feedback and communication was to the process. Specifically, how quickly the environment responded to movement, real-time feedback, during the rehearsals was crucial.

> "I found the motion sensors / projection component the most impressive and responsive part of this collaboration. Being able to see the visual programming of the project alongside a realised image behind was great to work with," Matthews.

Most importantly, as a designer, collaborating directly with users meant I could start to observe and interpret the project from other viewpoints. Their insight into performance and how the technology could facilitate and extend it meant I had a new scope of ideas to take on board in refining and optimising design.

> "I would really like to see some alternative objects/technology used i.e. rear projection screen, projection screens in non-conventional locations i.e. movement tunnel, suspended at angle from ceiling. I think that this could really aid to the interactivity of the project and start to separate it from the traditional 'action - viewer' experience. I expect all of these can be explored in future arenas where time and resources permit," Matthews.

Tony Gillan, is a fellow designer and developer, attended the performance as an audience member. The observation Gillan made was about the gesture which randomly changed the video backgrounds wasn't evident.

> "The wide sweeping movements of the dancers seemed to mesh well with the backgrounds and the feedback light effects produced by the application. Combined with the music, the effect was quite hypnotic. The two dancers and various sequences were harmonious, but I believe there could have been more interaction or cross-over between the 2 dancers and backgrounds, if the technology allowed. Also I didn't realise that the dancers themselves were changing the backgrounds until it was explained after the performance," Gillan.

Metakimosphere no.1, MetaSeminar Digital Technologies Lab project, Brunel University

The performance installation *Metakimosphere no.1*, by Azzie McCutcheon, Martina Reynolds, Helenna Ren, Seeta Indrani, Cameron McKirdy, Yoko Ishiguro, Johannes Birringer and myself was born of an eight week long *MetaSeminar Digital Technologies* workshop at Brunel University, London, facilitated by Johannes Birringer. The workshop was constituted of technologists, designers, dancers, musicians and artists, who all contributed to the installation.

Figure 4. *Metakimosphere no.1*'s dancers inside the gauze structure with particles projected onto their bodies.

The installation was created with hung and draped gauze in a circular formation with projections of particle effects from four sides, angled into and through the structure. The dancers were located in the centre with gauze draped over their bodies to form a single body within the structure. A Kinect sensor was placed inside the structure, so that each of the dancers' movements directly influenced the behaviour of the particles. As the dancers increased the frequency and speed of movement, so the movement of the particles would intensify and multiply. The audience was able to walk around and into the structure [Figure 4 and 5].

Figure 5. *Metakimosphere no.1,* a dancer moves in front of the Kinect sensor.

McCutcheon, Ren and Ishiguro have danced on a number of interactive digital performances, while for Heller-Wagner and Matthews from *Experiment.spaces no.1*, it was their first time. This performance installation gave some insight into how these experienced dancers interacted with the environment. They are much more aware of their surroundings and how their movement translates to the projections and images. The sense that the environment was an extension of their bodies was very evident in this project.

Experiment.spaces no.2 [Spheres]

This project is currently in the prototype stage, but was successfully tested during the *MetaSeminar Digital Technologies Lab* workshop. *Experiment.spaces no.2 [Spheres]* is an application which allows dancers to interact and guide virtual forms, in the shape of spheres, inside an online virtual space. Another dancer in a different location can also access this same virtual space over the internet and interact with the spheres [Figure 6].

Experiment.spaces no.2 [Spheres] is created from Max 6, which connects two computers directly using their IP addresses. Similar to *Experiment.spaces no.1,* the coordinates of the hands are tracked via the Kinect sensor and fed into Max 6. The coordinates are used to position and guide the spheres. In addition, the spheres and the virtual space have their own behaviours; the spheres respond in a similar fashion to a rubber ball and the environment simulates gravity. We are investigating how this application can be incorporated into a networked performance. From a UX design viewpoint, the aim here is to address slow internet speeds, delays, tolerance of error and loss of quality of movement over the internet and how these impact on user experience.

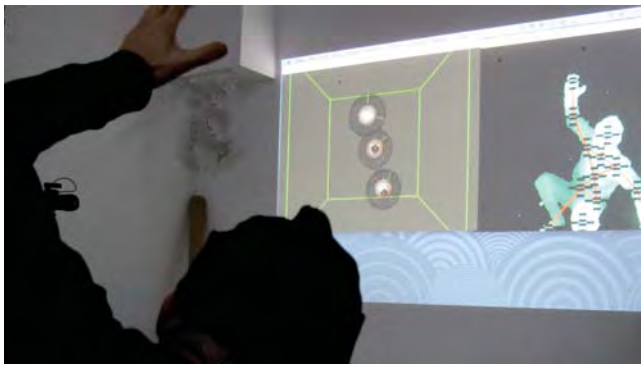

Figure 6. *Experiment.spaces no.2 [Spheres]* prototype testing.

Conclusion

My research is motivated towards providing artists in remote Australia with a set of tools to enhance their ability to collaborate online, assist the creation of interactive works and promote further development of performance in regional Australia. As expressed by Trinidad and Broadley: 'By connecting to the outside world it allows the outside world to view the value of the community. By bring the outside world into these communities allows the people to feel a sense of pride and importance in their cultural context' [15].

From the course of studio research investigated to date, we identified several aspects that were relevant to the user experience supporting non-verbal online communication. Based on these aspects we deduced the beginning of design criteria for the movement-based interaction. As the research continues to develop, criteria for effective system design will undoubtedly grow and these identified aspects will be refined:

- Three dimensional interactive space, both physical and virtual
- Cost effective, accessible and easy to setup technologies
- Low bandwidth streaming technologies
- Gesture interface controlling visual and audio outputs
- Communicate subtle and expressive movement
- Real-time immediate feedback

Formative studio work has revealed that a participatory design approach was beneficial for the development of the application, identifying processes that support and guide users, and towards a 'rich experience' for the user. While we are still at a very early stage in the development of the project, preliminary findings have indicated that subsequent design will benefit from building upon existing UX design principles and adopting flow theory to better understand users' embodied experiences.

The series of prototyping projects, outlined in this paper, informs the direction of *Mashup Realities*. It forms a critical and valuable stage in the research as we work towards the final project in which an Australian and a European dance school will participate in an online live dance networked performance. It is the ambition of the *Mashup Realities* project for geographically remote participants to dance, choreograph and rehearse together without leaving their home countries. The end result will be two simultaneous live performances, which will be combined online to create a single dance piece in a shared virtual space.

Abstract

We describe our approach to collecting, analyzing and visualizing expressive movement data to support the creation of an interdisciplinary performance and installation work, *3 Movements in Translation*. We seek to understand how three perspectives (the performer, the audience, and the machine) can inform one another to create a cross-cultural performance that allows a broad audience to kinesthetically engage and empathize with expressive features of taiko performance. Taiko is a Japanese artistic practice that combines stylized movement with drumming technique. We share initial results in machine-learning analysis of taiko sound and movement. These results are used, in combination with a performer's perspective, to inform artistic visualizations of important expressive features within taiko. Through this process, we explore how multiple perspectives of taiko can inform the translation process between the performer, the audience and the machine.

Introduction

3 Movements in Translation is an interactive performance work that explores three perspectives of taiko performance: the performer, the audience and the machine. We seek to understand how these varying interpretations of taiko can inform one another in order to create a cross-cultural performance that allows a broad audience to kinesthetically empathize, appreciate, and understand taiko performance.

To support the creation of *3 Movements in Translation*, we formed an interdisciplinary team of researchers from Simon Fraser University, University of Illinois and an independent taiko artist. Each author focused on a different aspect of the project including machine learning, data capture, data visualization, movement analysis, choreography, and taiko drum technique. This work is still in progress, but is envisioned to be an interactive installation and performance. The installation will help expand the audience's kinesthetic awareness of taiko, while also influencing the outcome and perception of the performance.

In order to create this type of work we need to identify expressive components of taiko performance, find a method to extract these components from the data, and explore ways to create new representations of these expressive features so that they can be communicated in performance settings. According to Camurri et al (2004), "Expressive content concerns aspects related to feelings, moods, affect, intensity of emotional experience" and is not necessarily tied to a denotative meaning. This definition implies that expressive qualities can be found in any movement that contains information about the state of the mover—from everyday actions, such as walking, to actions executed in performance settings (Camurri et al. 2004).

While digital motion capture technology has helped generate an expanding corpus of visual movement features to analyze, insight into what these features mean in the context of expression has been challenging to isolate and recognize. In our research we examine how the artfortm of taiko is taught. Through examining taiko instruction, we can identify perceptually evident features within the technique that are important to its artistic expression and integrity.

The Japanese practice of taiko also provides an ideal form to analyze expressive components of performance because expressive movement and sound are explicitly integrated in taiko technique. This multi-modal coupling allows us to study expressive components through both sound and movement simultaneously, which can help inform the recognition process.

Overview of Taiko

Taiko, meaning "fat drum," most commonly refers to a Japanese form of ensemble drumming that became popularized as a performing art in the mid-20th century (Varian 2005). Taiko is a unique form because stylized, choreographed movement is highlighted and integrated with drumming technique. Stylistically correct sounds in taiko can only be produced with stylistically correct movement forms. Therefore, the accuracy of movement qualities can not only be *felt* and *seen*, but also *heard*.

Taiko is traditionally communicated through *kuchi-showa*, a phonetic vocal notation system that represents the timbre qualities of taiko sounds. There are six main sounds in taiko technique: *Don*, *Doro*, *Tsu*, *Tsuku*, *Ka* and *Kara*. Don is a loud sound, Tsu is a soft sound, and Ka is a rim sound. Doro, Tsuku and Kara refer to either 2 Don, Tsu, or Ka

(a) Front View (b) Side View (c) Back View

Figure 1: Kinect Sensor raw depth map data modulus 256

beats (respectively) played in succession. Jason Overy of Uzume Taiko in Vancouver British Columbia (Overy 2014) created a syllabus defining aspects of taiko that are traditionally demonstrated, but not verbally articulated in traditional taiko technique. In Overy's syllabus all taiko sounds can be performed within five gears that refer to the body part or action initiating the sound, such as fingers, wrist, elbow, full-arm, and jumping (labeled Gear 1-5 respectively). Traditionally Don is is played in high gears (e.g. Gear 4/full-arm and Gear 5/jumping) and Tsu is played in low gears (e.g. Gear 1/fingers and Gear 2/wrist). Within each gear Overy defines five levels that refer to the angle of the drumstick in relation to the drum. Level 1 is 0 degrees and level 5 is 90 degrees. This level system is inspired by techniques used in drum corps training.

Data Collection Process

Taiko Informed Data Collection

We used Overy's syllabus to inform our data collection process. Using the gears and levels as a guide, we gathered a wide range of Don and Tsu strokes performed in similar gears and levels. We discuss initial results for distinguishing between Don and Tsu strokes performed in Gear 2 Level 4, Gear 3 Level 4, and Gear 4 Level 5. We chose to start with these particular combinations because they felt "natural" to the performer when playing both Don and Tsu sounds.

Motion Capture

In order to digitally capture movement, we used the Microsoft Kinect sensor to allow the taiko artist to perform as expressively as possible by providing an environment that limited technical intrusions into the performance. The Kinect captures movement through the generation of depth maps, utilizing a camera and an infrared sensor. From the depth maps, a variety of informative data can be extrapolated, such as a skeleton frame representing positional data of the subject. This provides subjects with a minimally invasive situation where they are not required to wear any additional devices that may inhibit their ability to replicate the physical qualities of performance. This is especially important in the case of taiko, where expressive performance demands high levels of control over a diverse range of nuanced percussion techniques. This control can be dramatically affected by extra weight (e.g. an attached accelerometer) or atypical performance attire (e.g. a motion capture suit). The Kinect sensor is also more practical for the artwork and will allow us to present the work in a large variety of venues.

We arranged five Kinect version 2.0 sensors in a circle around the performer with one sensor directly in front of the performer, providing a panoramic view of the drummer (see Figure 1). All sensors were set at waist level except the front sensor, which was elevated to head level in order for the drumhead to be seen clearly.

Audio Capture

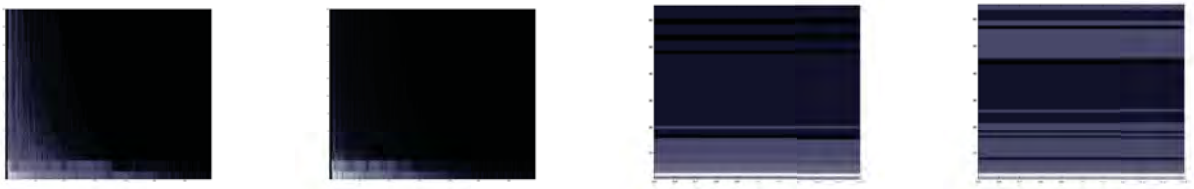
We captured audio from multiple perspectives in order to fully realize the expressive sounds produced by the taiko drum and performer. To accomplish this, we used an array of cardioid condenser microphones: one below the drum that captured the more resonant sounds of the drum; one above the drum that captured higher frequency attack sounds; and one off-drum to the right of the performer that captured vocalizations and the ambient room sound. The audio data captured by the array was sent thorough a multi-channel mixer where only minimal processing was done in the interest of maintaining sonic integrity.

Machine-Learning Analysis

To identify expressive qualities of Don and Tsu strokes in taiko, we performed analysis on the data using two different machine-learning techniques: a Naïve Bayes (NB) classifier (John and Langley 1995) and the Hidden Markov Model (HMM) (Rabiner 1989). HMM is a method for analysis of temporally sequential data and performed better than the NB classifier in distinguishing the visual data of taiko gestures. The HMM and NB classifiers performed similarly for the audio analysis. We report a summary of our results in Table 1.

Audio Analysis of Taiko Sounds

In our analysis of taiko drumming audio classes, we generated two separate sample types for NB testing: the full audio sample without normalization (Audio1) and a shorter, attack-focused sample that was normalized with a 'room noise' spectrogram (Audio2). For the Audio 1 test we used a window size of 512, with 256 overlap. For the Audio 2 test we



(a) Audio 1 Don (b) Audio 1 Tsu (c) Audio 2 Don (d) Audio 2 Tsu

Figure 2: Plots of the square root of the magnitude of the spectrogram. Audio 1 depicts the entire duration of the sound (truncated to a range of 20hz). Audio 2 depicts a single window (only the attack).

Tests	Gear/Level	Audio1 (NB)	Audio2 (NB)	Visual (HMM)
Don/ Tsu	2/4	1.00	1.00	0.97
	3/4	1.00	1.00	0.97
	4/5	1.00	1.00	1.00

Table 1: Initial results of audio and visual analysis of Don and Tsu strokes: a total of 242 samples for Audio (81 samples for 2/4, 82 samples for 3/4, and 79 samples for 4/5), and 20 samples for each gear/level combination of the visual data. Audio1 = 2s length, not normalized, Audio2 = 0.045s length, spectrally normalized, and visual samples are manually segmented (starting from raising the drumstick and ending up to 10 frames after the stroke).

used a window size of 2048 with no overlap (See Figure 2). Both audio tests used leave-one-out cross validation.

Both of our tests achieved 100 percent classification accuracy in distinguishing between Don and Tsu sounds played in different gears and levels. Furthermore, we found that even with amplitude measures minimized through normalization (Audio2), classification accuracy was not lost. This suggests that Don and Tsu sounds vary in both timbre and amplitude.

Visual Analysis of Taiko Movements

In order to analyze the style of movement when performing Don and Tsu strokes, we analyzed the average velocity of wrist movement during both the attack and recovery of the drum-strokes. Since there are only two major axes involved in performing the basic taiko drum-strokes, we analyzed the velocity in the Y-axis (vertical) and the Z-axis (camera). In the Kinect coordinate system the device is positioned at the origin, and the Z-axis represents the distance of the body from the Z-plane of the camera.

We found that the velocity of movement was the key feature in distinguishing between Don and Tsu drum-strokes. We used HMM to model and classify the wrist movement in Don and Tsu strokes. Each sample of the motion data is manually segmented, starting from raising the drumstick and ending up to 10 frames after the drum-stroke. For each gear/level combination we used 20 samples, with 70% of them for training and 30% for testing the model. We computed the accuracy through 10-fold cross validation (see Table 1) and used various features of the motion data to train the HMMs such as velocity, acceleration, and speed. Our experiments showed excellent classification of Don and Tsu gestures.

Figure 3 compares the average velocity of the Don and Tsu strokes in Y and Z directions. On the Z-axis we observe positive average velocity when attacking the drum, and negative velocity after the drum-stroke. This suggests that both actions are performed by moving the arm towards the body. We can also observe that in comparison with the Tsu strokes, the Don strokes have lower velocity in the Y-axis and higher velocity in the Z-axis. We can interpret this as the drumstick in Don strokes tends to hit the drum tangent to the surface, while the Tsu strokes use more force in the vertical direction. These findings align with the taiko performer's description, describing Don as having more "bounce" than Tsu and Tsu being more "controlled." These findings also closely relate to previous work by Dahl and Altenmüller that found correlations between stroke velocity, rebound, and the perceived timbre quality of the sound produced (Dahl and Altenmüller 2008).

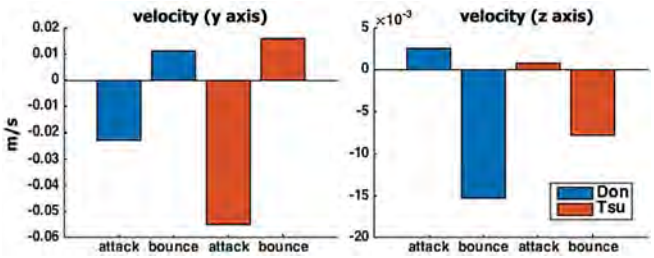


Figure 3: Comparison of the average velocity of performing the Don and Tsu sounds

Visualizing Expressive Features of Taiko

Through artistic visualizations we can mitigate the gaps between literature and artistic practices. In order to understand the expressive components of taiko from another perspective we created **visaphors**, meaning "visual metaphor" (Cox 2006).

The visaphors described below allow us to re-contextualize expressive components of taiko technique and will facilitate interactions between the audience and performer in *3 Movements in Translation*. Below we show a prototype of each visualization and describe how it was informed by var-

ious perspectives. A video of these visaphors is available at https://vimeo.com/130595155.

Visualizing Expressive Arm-Movements

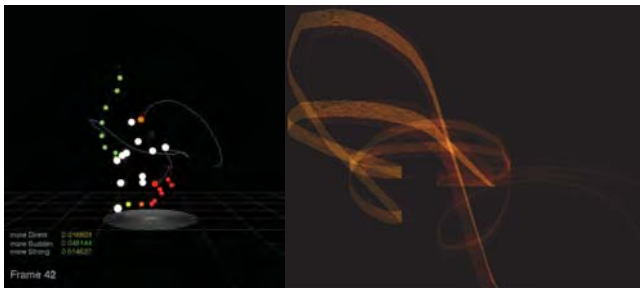

Figure 4: Visaphor 1: The trajectory of two wrists draw flaming ribbon strokes over time. ©Kyungho Lee 2015

The first *visaphor* was inspired by Kimberly Powell's phenomenological account of practicing taiko depicted in her published work, "The Apprenticeship of Embodied Knowledge in a Taiko Drumming Ensemble." Powell states, "I imagined colorful long ribbons trailing from my bachi [drumstick], as I snap my wrist upward and then extend my arm diagonally across my body down to an imaginary drum" (Powell 2004).

To depict this vibrant energy of taiko we used the trajectory of the performer's right-wrist and the velocity to change the form of a flaming ribbon (See Figure 4). The flames expand the space of the arm's trajectory, alluding to Powell's sensation,"I felt a sensory shift in the way I perceive the boundaries of my body in relation to space. I am aware of a different sense of my body, the way it occupies positive space against negative space" (Powell 2004).

Visualizing Don and Tsu

The second *visaphor* depicts differences between Don and Tsu. As mentioned previously, Don and Tsu sounds are distinguished in taiko as loud and soft sounds respectively. However, the difference between Don and Tsu goes beyond amplitude as shown both in our machine-learning audio results and as implied by the phonetic vocalizations of taiko sounds. As indicated by the machine-learning HMM analysis, velocity also played an important role in distinguishing between Don and Tsu gestures.

We chose to visualize the difference between Don and Tsu through a spherical representation. The sphere's surface is distorted by the momentum of each stroke. The more powerful the stroke is, the larger the displacement of the sphere and the darker the color. Figure 5 shows the Tsu stroke has less distortion than the Don stroke and is lighter in color.

Conclusion

We describe research undertaken to support the creation of our interactive performance and installation work *3 Movements in Translation*. In this work we seek to create a cross-cultural performance that translates expressive components of taiko performance into multiple forms that a broad audience can kinesthetically engage with and understand. We

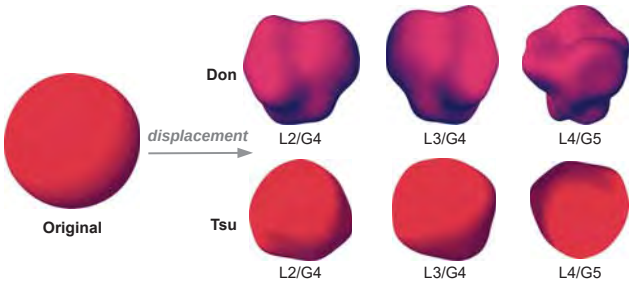

Figure 5: Visaphor 2: The original sphere's surface is transformed by the parameters extrapolated from drumming strokes: Don and Tsu ©Kyungho Lee 2015

shared initial findings in machine-learning analysis and combined these findings with the performer's perspective to create visaphors of important expressive features in taiko. We will use these visaphors in our interactive installation as a way to motivate audience members to partake in expressive movements that are important in taiko performance and to inform the translation process between the performer, audience and machine.

'Splitting Centre': directing attention in trans-media dance performance

Jordan Beth Vincent, Kim Vincs, John McCormick

Deakin Motion.Lab
Deakin University, Burwood, Australia
jordan.vincent@deakin.edu.au, kim.vincs@deakin.edu.au, john.mccormick@deakin.edu.au

Abstract

In theatrical vernacular, the term 'splitting centre' refers to two performers staged at an equal distance from a centre point and sharing the focus of the audience. This term encapsulates the notion that two people (or, in the case of trans-media dance, two or more performance entities) are dividing the attention of the audience, operating as equal collaborators in a performance context. The augmentation of live performance with 3D projected scenography and mobile devices offers a starting point for discussions on the potential for dramaturgy, choreographic process, and changing expectations for audience behaviour in the theatre. In 2014, Deakin Motion.Lab premiered *The Crack Up*, a trans-media dance work that incorporated live performance, 3D digital scenography, and *The Crack Up App*, an app for mobile devices that audience members were invited to interact with during the performance. This investigation into the potential of trans-media dance performance, (defined here as a live performance in which both the digital and biological elements are choreographed as artistic equals within the theatrical context) with the addition of a mobile device raises questions about how the makers of trans-media dance might direct the attention of their audiences when the work is performed simultaneously across multiple platforms.

Keywords

Dance, trans-media performance, digital and virtual environments, mobile devices, interactive apps, tweet seats

The integration of digital imagery with live performance is becoming increasingly common in Australia and overseas with artists such as Wayne McGregor, William Forsythe, Robert Lepage, Klaus Obermaier, Garry Stewart and Gideon Obarzanek among others creating work that enmeshes digital and biological performance entities within a theatrical context.[1] The works by these artists draw on a range of technologies, from interactive and motion tracking systems to registered projected video, motion capture, 3D scenographic landscapes and more, exploiting the possibilities of emergent technologies. As Dils & Naugle suggest, "the scope of dance is not narrowing towards digital, rather, it is expanding."[2] In 2014, artists at the Deakin Motion.Lab premiered *The Crack Up*, a new full-length trans-media dance work, (trans-media dance is defined here as a live performance in which both the digital and biological elements perform simultaneously as artistic equals within the theatrical context), directed and choreographed by Professor Kim Vincs.[3] Inspired by F. Scott Fitzgerald's 1936 short story of the same name, *The Crack Up* integrates performances by five dancers immersed and superimposed in 3D projected scenographic landscapes.[4] The creation of imagery rich environments augments Fitzgerald's first-person story about a man losing his grip on reality. 'Cracking' landscapes and crumbling digital characters provide a visual reflection of the ambivalence and despair of the text, reflecting on the notion of fragmentation.[5] *The Crack Up* also exploits the sense of 'cracking' (or dividing) the attention of the audience by introducing *The Crack Up App*, a universal app for mobile devices that audience members were invited to download prior to attending the show.[6] In theatrical vernacular, the cue 'to split centre' refers to two performers at an equal distance from the centre point of the stage. With lighting and set design, as well as within the frame of choreographic practice and dance training, to 'split centre' carries a meaning beyond a staging one. It is the notion that two people (or, in this case, two or more performance entities) are splitting the attention of the audience, operating as equal collaborators in a performance context. In essence, *The Crack Up* 'splits centre' across its multiple platforms, with the direction of focus shared between the screen on stage, the dancers on stage, and the mobile devices. This paper investigates the potential for augmenting live performance with 3D projected scenography and mobile devices, and offers a starting point for discussion on the potential for dramaturgy, choreographic process, and the directing of audience attention within trans-media dance performances.

Figure 1. Screenshot of *The Crack Up App*.

Activated within the theatre and with high-resolution imagery running parallel to the action on the stage, the content on *The Crack Up App* follows its own unique narrative trajectory, while contributing to the larger

visual story of the work as a whole. Drawing on the common usage of mobile devices for tweeting and texting, *The Crack Up App* quotes Fitzgerald's *The Crack-Up* (as well as other writing by and about Fitzgerald) and places these texts within visual contexts that reference and comment on the action on the stage and 3D projection screen. Although the content of the scenography and the imagery on *The Crack Up App* was largely pre-determined and fixed (aside from some audience interaction capability), the movement from scene to scene across the platforms was live. In this way, the performance of *The Crack Up App* happens in concert with the action onstage, with the work taking place simultaneously across multiple platforms and with multiple points for audience access. This offers a kind of 'choose-your-own-adventure' experience of trans-media performance, with the audience's decisions about where to look divided between three distinct options: 1) the larger-than-life imagery projected onto the stage screen; 2) the dancers standing within, in front of, and beneath the imagery, or 3) The content on *The Crack Up App*. As Vincs has argued, there is no 'right' place to look at any one time during *The Crack Up*; rather the work simply exists in multiple forms, simultaneously, with a multiplicity of experiences. By consciously drawing the attention of the audience away from the stage and actively encouraging some freedom of experience (i.e. only parts of *The Crack Up App* are interactive) *The Crack Up* utilizes a mode of dramaturgy akin to site-specific or gallery-based work, or perhaps work in which audience members are free to roam around the performers or where the parameters for performance are set, but are left relatively open and uncontrolled.

The challenges with dividing the attention of the audience across multiple platforms are fundamentally dramaturgical and technical ones, with the creation of a "performance that is no longer designed for a 'normal' three-dimensional space, but which must speak within an artificially constructed volume."[7] In other words, the traditional performance area for live performance (the stage) is challenged by the "altered, augmented and perceptually distorted spatiality" inherent in trans-media dance, offering many new directorial and perceptual possibilities.[8] For directors of live dance performances, the decision about where to draw the focus is integral to the shaping of the performance. As Johannes Birringer suggests, this is fundamental to the nature of the integration of digital bodies with live bodies in a performance context because "digital performance with real-time media always involves projectional activities at the same time, i.e., simultaneous and deferred image, sound and light movements and 'micro-tonalities' which happen in continuous contingent (causal and non-causal) interrelationship with each other in total architecture."[9] With lighting designed to direct the eye of the audience to the most important, the brightest, and the most lit form, the body at centrestage becomes, literally, the most visible object on the stage. However, *The Crack Up* takes place across multiple platforms simultaneously, with the moments of performance not solely beginning and ending within the geographical space of a proscenium theatre, but offering a performative example of convergence culture.[10] The 'stage' for *The Crack Up* is both the space beneath and within the proscenium, but also on the individual screens held and activated by each individual audience member.

Within trans-media dance productions, the 3D projections are literally made of light and, in the case of *The Crack Up,* are projected six meter tall screen. This offers an enormous visual draw for the audience, and, even without the presence of *The Crack Up App*, challenges some of the conventions that might govern choreographic practice. How the different performative elements are integrated provides a dramaturgical challenge, particularly when the components are not seen in terms of a theatrical hierarchy in which either live performance, or projection might be privileged. As Beckwith & Vincs have argued, the use of 3D scenography within a digital performance environment, while offering untapped potential for the telling of physical stories, also poses a number of challenges in terms of cognitive synthesis for the audience, including reconciling the "inherent disjuncture between the spatial objects" such as live bodies and digital entities within the same geographical space.[11] Beckwith & Vincs propose the use of Kurt Koffka's Gestalt theories as a means of "creating perceptual wholeness" for the endless stereoscopic possibilities.[12] The addition of a mobile app, which intrinsically draws the attention of the audience away from the stage and down to their devices, further challenges the cognitive synthesis of watching trans-media performance. However, it is perhaps less important how the components of the work are integrated as individual elements than it is how they cohesively translate a theatrical meaning to the audience.[13] This demonstrates that the entire notion of 'direction' with performance art that enmeshes digital and biological content/bodies questions the accepted norms of theatrical dramaturgy. This collision of traditional stagecraft with new technology fundamentally shifts the dramaturgical requirements of creating trans-media dance. In this way, *The Crack Up* perhaps draws on American choreographer Merce Cunningham's work in de-centralising the notion of the stage centre in dance, but rather than abolishing the idea of the centre, *The Crack Up* instead divides it, quite precisely and consciously, between different perceptual, temporal and technological modalities.

The augmentation of live performance with mobile devices has been hotly contested in recent years, with the spectre of 'tweet seats' already challenging the sanctity, or rather the *perceived* sanctity, of the theatrical,

Western, concert space.[14] An audience member in a 'tweet seat' is 'allowed' to access and utilise their mobile device, tweeting or publishing immediate responses from within the theatre. The presence of 'tweet seats' undermines the traditional theatrical adage to 'turn off your phone,' while simultaneously raising concerns about preserving the 'mysteries' of a performance or what it means to have only a partial, or third-person experience of a performance. For avid tweeters, or for those audience members unable to be physically present in the theatre, live tweeting during a performance adds an interactive and responsive dimension to the experience, colouring the social act of attending the theatre with the faceted and multi-layered experience of social media. Opponents to the inclusion of social media within the performance space, such as Alex Roe, Director of New York's Metropolitan Playhouse, have suggested "outside interaction, even of virtual kind, might keep people from getting lost in a good play."[15] According to Roe, "'Part of the whole theatrical experience is the thought of being present in the company of the rest of the audience and the actors… [and] the thought of encouraging people to tweet during a performance is necessarily a violation of that agreement.'"[16] In other words, live tweeting during a performance where it is not part of a dramaturgical design, would cause an unwanted 'splitting of centre' for the audience.

The difference with 'tweet seats' and *The Crack Up App* is not just a matter of content, nor is it a matter of a dramaturgical effect. Although *The Crack Up App* takes place on interactive devices, it limits the amount of control and interactivity the audience has over the content. However much freedom is offered to the audience, it's inclusion begs the question of how focus and attention may be diverted or controlled for theatrical purposes. In the triad of live performers, stereoscopic imagery and mobile devices, the process of 'splitting centre' in *The Crack Up* is not a battle between two performative entities, but three of them. *The Crack Up* addresses this issue by creating a three-way split between perceptual modalities that remains consistent throughout the work rather than introducing digital elements in discrete sections, and by tying the digital content more directly to the conceptual development of the work. However, there remains a fundamental disjuncture between views such as Roe's, that see any engagement outside the on-stage performative world as a detraction from the performance experience, and works such as *The Crack Up* which view divergent sources of engagement as a means of enhancing and extending the conceptual scope and sensory experience of the work. Perhaps the broader philosophical issue this debate raises relates to how one approached the idea of divergence itself, whether of attention, or materiality, of biology versus technology. We argue that 'splitting centre' could be considered in relation to how one responds to the changing nature of attention itself in a digitized culture—to resist the multifocal and multiplicitious, or to specially embrace and cultivate it in a performance context. With the increasing development and availability of new technologies, as well as their increased incorporation into dance and live performance, there is room for further research into how the notion of 'splitting centre' could be exploited to create new and exciting performative possibilities.

Author Biographies

Dr. Jordan Beth Vincent is an Associate Research Fellow at the Deakin Motion.Lab researching dance and digital technology, a position she has held since 2013. Jordan's background is in dance history and criticism, and she holds a PhD early 20th century Australian dance history from the University of Melbourne. Since 2008, she has been a critic for The Age newspaper, and has contributed to a range of online and print publications in the areas of dance, physical theatre and circus.

Professor Kim Vincs is the Director of the Deakin Motion.Lab, Deakin University's motion capture studio and performance technology research centre, which she established in 2006. She has been a choreographer for over twenty years, and has focused on interactive dance technology for the last ten. Kim has five Australian Research Council projects in dance, technology and science, and has established numerous industry collaborations in motion capture, movement analysis and digital art.

Dr. John McCormick is one of the pioneers of new media dance, motion capture and telematics performance. John has worked with Motion.Lab for the last five years, researching movement visualisation and analysis, and with the Centre for Intelligent Systems Research for the past three years investigating machine learning of movement and its application in the performing arts.

From scripts to scores – movement as an embodied material for digital interaction

liseamy.hansen@aho.no

Abstract

Today our environments are increasingly digitized and interactive. We generate data by the very way we move, from locative signals to accumulated traces outlining direction and intensity as well as computational and comparative information. These digital environments are currently being built, and ask us to decide which movements matter and which do not. In the design of movement-based digital interaction, movement becomes a material with which we may shape new expressions, functions and interactions. The borders and boundaries of decisions on movement that are set in binary code become a complex, meaning-making communication. I suggest that we need to visualize movement data together with movement expertise in order to harness an agency in movement itself, namely the kinesthetic, embodied sensation of movement as well as the relational ways we may move with data. I discuss several projects whereby code and the conceptualization of movement are explored jointly. The aim of discussing such processes is to find ways to tease out the rich communicative potential of full-body movement for digital interactions by enabling an explorative, creative engagement with movement data and, in turn, movement.

Keywords

Full-body Movement, Materialization, Digital Interaction, Design, Communication, Boundaries, Scripts, Scores.

Introduction

Today our everyday physical movements are increasingly tracked and traced by a variety of sensors, from simple signals registering time and location to accumulative records which in turn may feed back information. Software activates and instigates the dynamics between these: movement and sensors. This dynamic led Thrift to argue that today "software quite literally conditions existence" [22]. In particular, software requires a critical view on digital media in relation to physical movement. Pre-calibrated sensors can now track movement qualities such as direction and dynamics, posture and pace. Consequently, the scope of movement data is extending from registering the location of a person to tracking and analysing movements of the full human figure in real time [11].

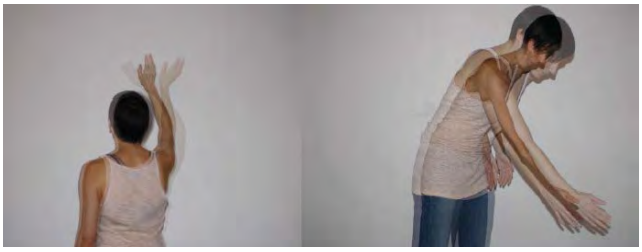

Figure 1. Performing our everyday life entails navigating invisible or immaterial structures and digital environments, where we physically have to explore what is 'seen' © Lise Amy Hansen

The main concern for this paper is the materialization processes where there are choices made as to which movements are made to matter. In other words, how physical movement is conceptualised in order to be processed by a digital medium. I am interested in the decisions made when writing such inscriptions, as this is about the laying down, in written form, a human and machine readable signal or representation of human movement. As Wood observes:

> A facet of digital technology, and of technology more generally, is not that they separate us from the world, but rather that they create within it distinct kinds of engagements [24].

We now live increasingly influenced by digital media. It is critical to understand the nature of movement data and the ways in which the data is set as code and how this code runs as software. As Kitchin observes, software actively shape "people's daily interactions and transactions, and mediate all manner of practices in entertainment, communication, and mobilities" [17]. These issues are of particular importance now, as the role of software is not settled:

> We are still laying down the infrastructure, structures and conventions, the uses, functions and ways of expression and communication [4].

Today programmers may alter the code and procedures for how we communicate; they can rewrite and implement a software's functions and effects. New code can be written in ways that affect the actions and behaviors of many. New movement may also impact on the code devised.

Movement material

Full-body movement is embodied in the sense that it requires a body. Thus it is cultural and conditioned, relational and gendered, lived and performed. It is also expertly perceived by others, acted upon and referred to. As a visual phenomena, full-body movement can be registered by digital media, typically to pre-set criteria. In effect, movement can be made digital in the sense that movement information is registered, calculated and stored disconnected from a specific body and thereby disconnected from a specific time and specific place.

Additionally, if we are to pick up such abstracted digital content referring to movement data, it must again be materialized. Following Blanchette, it must in some way or other be re-substantiated:

> However immaterial [digital information] might appear, information cannot exist outside of given instantiations in material forms [4].

So how may we get to grips with digital movement material? Creative projects that explore movement and digital media are predominantly collaborative and rely on the collaborators' ability to see material, expressive and functional possibilities in the fields of others. In order for movement-based interaction to explore kinesthetic agency and physical developments in movement, one needs to understand not only the way we currently move, but also the potential for change and repetition as well as subversion.

Berry has argued that in order to understand computation, we do not need to understand the writing of code alone but to analyze the different layers that make the code become software [3]. This distinction is relevant because of the way we generate data is by way of software. The moving body as a communicative source scripted via code provides a rich and complex communication potential. Movement material has been abstracted and then re-presented digitally. We need to be aware of the many pivotal decision we take when we choose which data to pull up, which sections of the body to foreground, and which speeds of which limbs to trace etc.

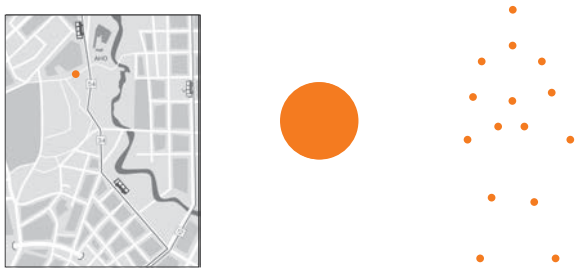

Figure 2. Granulation of movement data from the location of a singular dot marking presence in the world, to movement of a dot to several dots representing the body as a complex system © Lise Amy Hansen

These full-body movement centred perspectives are central considerations because data has no *necessary* form [9]. So for instance, the notion of age may be visually present in the way we move, or gender or culture and therefore may also be presented in the data. But if we do not look for ways of representing this as we work with the data, then we simply side step the issue of say, age and gender. Yet, we may write code based on assumptions on the intensity, the variety or the ability we have to move that in turn do hinge on notions such as age or gender or culture. Thus, a critical understating of how movement is formed is central for writing code that is based on or activated by movement.

Materializing movement

Motivated by the richness of interpersonal non-verbal communication, I am interested in exploring the way we move with, for and through movement data. My interest extends to finding ways to identify the switches and glitches in what is often envisaged as a seamless digital realm, whereby averages become the guiding measurement. The abstract borders and boundaries in binary communication quickly become physical and personal as we navigate, appropriate and communicate based on algorithms (see Figure 1). An everyday example of this is the automatic voice recorder: we change our voice according to how we think we might be understood by the identifying script running the automatic voice and we usually adopt a tone of voice that we would rarely use to address a person. Another example is the technology behind an automatic door. Here a person is recognized by a system that renders the movement (a person walking into a given area) into code, which then instructs machinery to open the door. This simplicity however is at odds with the sophisticated ways we leverage our movements to communicate intent and ability, such as whether we intend to enter the building or just pass by, or whether we're in a hurry or would need more time to enter. Thus intent and ability may partly be accounted for by considering the two movement qualities direction and speed.

A body typically has 240 moveable joints, each with six degrees of freedom, yielding 1380 in total. Thus we may quickly generate a wealth of information and the selection or granularity of this data is central (see Figure 2). Yet, higher precision and more detail may not give the kind of information that communicates nor provide the tools with which to work with or understand movement. New media is being developed towards an increased resolution, precision and capacity, yet there is a need to critically discuss how today's available technology is applied and the possibilities that come from how these new media already are applied or could be developed. When we find new ways to construe movement, I argue that we need to be aware of how we categorize and apply it, in the sense that when we alter this digital media, we may move *through* and not just *for* the media.

Switches & glitches

The 'on-off' character of digital information can take any form in the sense that digital files are indistinguishable whether they containing data from a movement phrase, a text document or an image. The digital properties of such media content come from the software used to create, edit, present and access this content [18]. In other words, we create the material simultaneously as we are figuring out how to create with it.

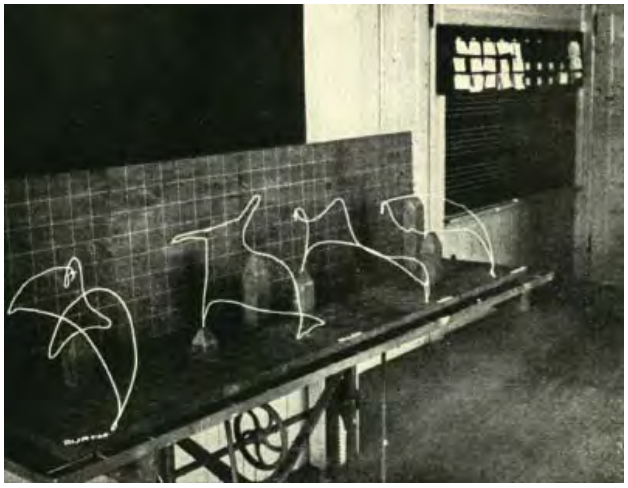

Figure 3. Gilbreths' movement studies of factory workers' routines in order to find unnecessary movements (Frank and Lillian Gilbreth, untitled motion models, c. 1913–14) Gilbreth Collection, National Museum of American History, Smithsonian Institution, Washington D.C.

Temporal data: new traces

When the Gilbreths used light photography inventively they were able to show a trace of actual movement abstracted from the body and traced over time. These traces were reduced to a still (see Figure 3). Now computation enables us to devise an added layer of information, whereby registered movement may also be calculated, compared or connected and again be made visible in near real-time.

Computational tools tend to focus on a detailed mapping, however, as Sheets-Johnstone writes, a description of an object's positions is not a description of movement [21]. Similarly, a music score does not contain information about the mechanisms or processes of performing beyond the 'formal characteristics' specifying the music to be realised [20]. A key question arises: What characteristics then do we need to find ways to represent in movement data?

Farnell points to a similar critique of representing a body when she asks Anthropology to consider the moving body, because 'the way human agency works is in terms of the signifying enactments of moving persons' [8]. In other words, the communicative qualities reflecting human agency occur temporally. This provides an impetus for the abstraction and conceptualization of these qualities also to be considered and represented temporally.

Dynamic visuals present time-based data the opportunity to be represented temporally and as there are aspects that otherwise would be lost in representing movement. We can now create expressions and functions around or for the way we *actually* move, rather than the way we *think* we would move.

Elusive data: WYSIWYG

We cannot perceive digital content as data is stored beyond our direct perception "below the 'threshold' of representation itself" [12]. This emphasizes the importance of choosing the relevant data or appropriate parameters for computers to compute or sensors to sense.

Exploring the concept of WYSIWYG (what you see is what you get), the *Synchronous Objects*[1] project addressed the notion of communicating potential of a choreographic idea, specifically away from the body. The sheer variety of representation developed showed the complexity of representing potential of movement. The resulting dynamic visuals of movement data are sketches and as such can be seen as a material anchor [14]. Arvola suggests that for complex creative concepts and their implications, such sketches can hold the design in place and make it 'stable enough to reason about' [1]. Following this logic, I argue that a material approach to movement data shifts the focus in a design process from objects to the communicative agency of our bodies. This is a meaning-making activity that has seen limited research to date.

By focusing on the dynamics of movement as it is expressed over time, shifts the focus, from comparing it or building a general systems of signification, to exploring how we may generate an understanding of movement through movement data [e.g. 2].

[1] http://synchronousobjects.osu.edu/

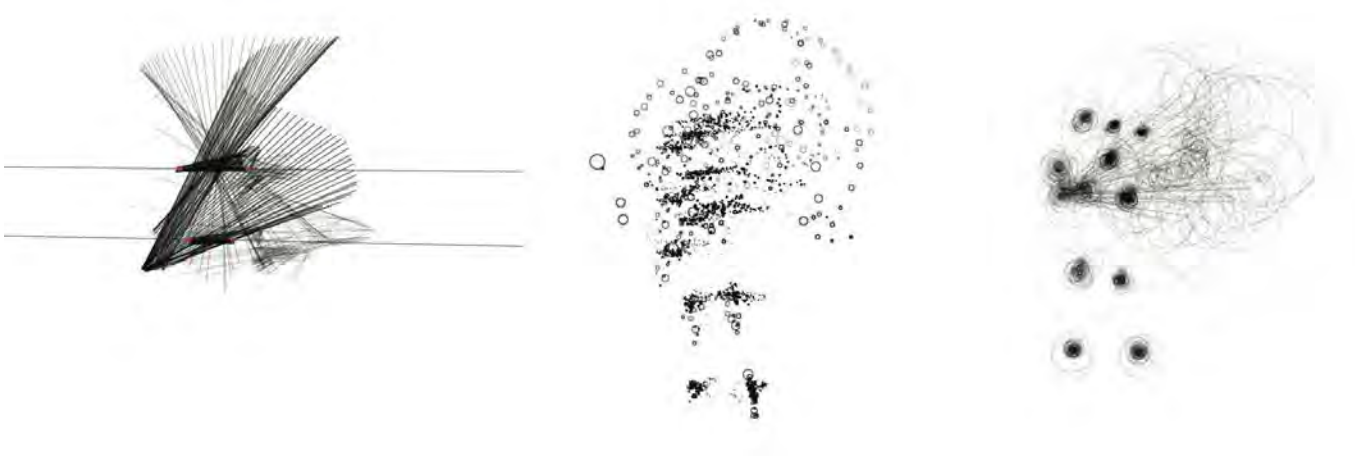

Figure 4. The *Sync* tool allows for movement data to be visualised live or repeatedly through recorded data. In this collage, a hand wave is visualised in three different ways. © Lise Amy Hansen

Corporeal data: *Sync*

I have investigated this potential through the co-design of *Sync*, a digital application, a tool that allows designers to visualize movement data [10]. *Sync* was developed with Hellicar&Lewis[2] to explore how corporeal qualities and dynamics in movement data could be presented in dynamic visualizations. (see Figure 4). *Sync* gives near real-time visualizations of movement, with a comparative video feed of the movement. In this way, one may see which data was captured in comparison to the performed movement. We get access to the ways in which movement data is different from physical movement. 'We always see less than is there […] We also always see more than is there' [5].

Sync currently draws on the data from Microsoft's *Kinect* and makes no distinction between whether the movement or the rate of change occurs on the x, y or z plane. Equally, it identifies where there is less or little movement. It has an option to show history, which is a visual trace of a point. Thus with little movement, one gets a build up of visuals, creating a denser mark the longer there is stillness.

The *Kinect* software uses depth data, i.e. a body outline to calculate, identify and track the various points to make up a human skeleton. However, as has been pointed out by several in performance studies [e.g. 25], the representation is not a skeleton in the sense that it is calculated based on information about how a body's outline changes – it does not act the way a skeleton acts.

There are further implications for creative practice here in that *Sync's* dynamic visuals can be seen as a mapping of variety and variation, whereby they inform design briefs for future designs. Drawing on Cosgrove, 'The map has a powerful recursive quality; it acts as a memory device that is also the basis for projective action' [7]. I mention these concerns because the implications of movement data being different to movement means there are advantages to articulating the agency of each, rather than optimizing one to the other [e.g. 22].

[2] http://www.hellicarandlewis.com/

From scripts to scores

Approaching digital movement as described above shifts the role of movement in creative processes of writing code from testing to co-designing. Or rather, the approach shifts movement from an 'end-user' role to a creative materials centred one, manifested in emerging material in and of itself.

Relational applications

Discussing software and materiality, Thrift points to the normative effect whereby software guides and guiles:

> "human embodied experience – that experience which is still so often considered to be a constant even as surfaces like screens and software have questioned its reach and meaning – is being decisively changed. Key human affordances are now being altered" [23].

In these challenges lie individual agency and freedom,. When they are anchored in code running our interactive environments, we need to understand how to build on the way we move.

ReacTickles[3] is a suite of applications that uses touch, gesture and audio input to encourage interactive communication (see Figure 5). These applications were developed in an inclusive design lab, with the overarching goal to generate ideas for technology interfaces that could engage and motivate people with poor verbal communication abilities, such as children on the autistic spectrum. Co-creating these various tools meant that important parameters, such as access and consistency, were identified as vital parameters in the design for engagement (as opposed to spectacle or immersiveness): "The simplicity and predictability of the application give the guests confidence that every action, however tentative, could be rewarded" [15].

Figure 5. The Body Paint tool initiated an expansive variety of imaginative performances by the guests using their whole body movements and also clearly enjoying the calming sensory experience of the smoothing the projection wall © by kind permission Hellicar & Lewis

The project highlights that perception is not only about vision, but that it is also informed through our other senses as well as from the kinesthetic sensation derived from movement itself.

Relational code

The Reactor for Awareness in Motion (RAM) Dance Toolkit[4] challenges the expertise of dancers as it extends their movement skills and the formalised practice of these through customisable visualisations. The toolkit provides visual information of how movement may be traced and the ways in which the scripted data can in turn generate new movements and new movement expressions. This is a creative coding toolkit which allows for the creation of a set of different environments called "scenes" for dancers, where movement data is visualised and is made available in real-time by a digital interpretant known as the "actor".

The tool generates environments for enhancing ideas for dance and the variety of scenes provides comparison of how movement data can be played out, by way of scalable visuals or choice of couplings in the data, for instance. By teasing out ways to address variation in movement, by way of dynamic visualisations such as these mentioned, we may reconsider the role of movement in interactions and the body not only as a given and mapped object but as a sensate origin of action [8].

By exploring materialising processes - conceptually and practically - we may gain an understanding of what underlying motives are at play, As I have argued, this is important because with computational material, meaning is not a given – both the material itself and its meaning is continuously made.

[4] http://interlab.ycam.jp/en/projects/ram/ram_dance_toolkit

In a sense, then software is continuously re-scripted. Thrift writes of software as 'a means of sustaining presence which we cannot access but which clearly has effects' [24]. In order to understand how we shape and influence software, despite its inaccessibility in everyday life, we need language to address aspects, elements or qualities of software as well as tools to explore what is yet to be named or what may be addressed. This is particularly pertinent when it comes to movement, another phenomena resisting traditional descriptive modes such as the written word or through photography or film.

Relational variables

With few conventions to rely on, there is a need to attend to what can change or what can be changed in regards to movement data and how it is applied through code. Exciting developments take the form of *Choreographic Coding Lab*[5] *(CCL)* focused on 'translating aspects of choreography and dance into digital form and applying choreographic thinking by working with patterns, structures and movement through finding, generating and applying them. The results range from 'prototypes for artworks to new plug-ins for working with dance related datasets'. The CCL format originates from *Motionbank*[6], a research project of the Forsythe Company[7].

The *CCL*, together with the examples above, *Sync, ReacTickles* and the *RAM Dance Toolkit*, provide an argument for a movement-sensitive approach to computer expertise. If new media is to truly draw on movement as a source of information and communication, then we need to find ways to communicate movement expertise. This is important, following Kirsh, as

> we can interact with digital elements by gesturing and body movement, by manipulating everyday objects, and even by training brain activity to control interfaces. To understand the design principles of such a world requires that we become familiar with the ongoing developments in embodied, distributed, and situated cognition, and build closer relations to their research agenda [16].

Everyday performance

In this paper I have outlined concerns and considerations of handling movement data a creative act. I argue, as Noland says, that

> gestural routines of inscription yield a kinesthetic experience that is a resource in its own right, a resource of sensation capable of subverting institutions of inscriptions by promising new, unmarked material to record [18].

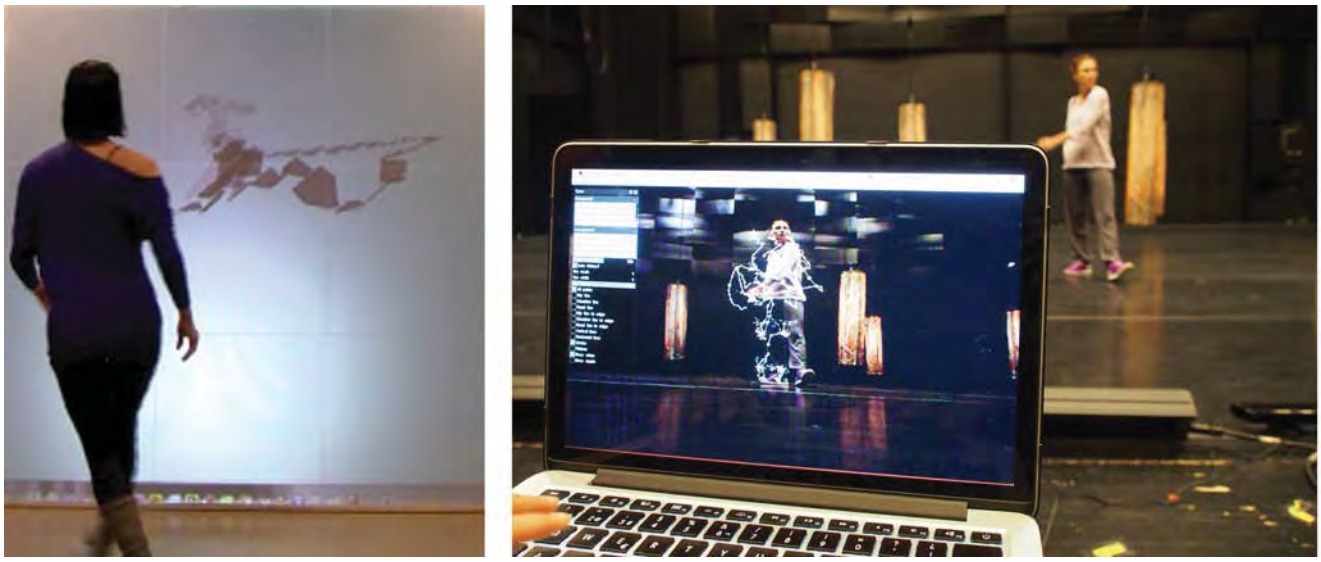

Figure 6. By moving with the data and toying with the possible effect in the generated visuals whilst simultaneously being influenced by them, movement scripts can be acted out in real-time © Lise Amy Hansen

With real-time visualizing tools, temporal qualities may be viewed, identified and named as well as felt and experienced (see Figure 6). Today, we are being badly choreographed by digital media as we perform our everyday lives. If we are to understand what is at stake we need to not only look at the effect of current digital media, but to explore the material possibilities brought about by new digital media as this media is still pliable, and it is clearly still in the making. Through such a material approach, I suggest that it is possible to explore movement as a digital material and thus leverage our complex movement knowledge.

This relates to both perception and performance, rather than allowing media alone to dictate or automate our movements. This development needs a critical approach, as Wood points out:

> The numbers of technological interfaces that frame how we see the world are rapidly expanding their influence, and there are questions to be asked about who controls and creates those interfaces and for what reasons [23].

By exploring what is particular to full-body movement and what is particular to movement data, by way of digital tools, we may leverage the high resolution with which we perform and perceive movement and enable digital media to go from 'replacing reality to shaping reality' [6]. As Haraway proposes, by reflecting on where our seeing is located 'we might become answerable for what we learn how to see' [13].

Author Biography

Lise Amy Hansen is a Senior Researcher at The Oslo School of Architecture and Design (AHO) and a designer. She has a PhD in Interaction Design, an MA in Communication Art & Design, Royal College of Art, London and a BA (Hons) from Central Saint Martins (CSM), and has been a lecturer at CSM and AHO. Her research evolves around the role of movement as a material in digital interactions and how we may explore movement and an understanding of movement through design research.

Technologies of Self-Fashioning: Virtual Ethnicities in New Media Art

Alice Ming Wai Jim

Concordia University
Montreal, Canada
alice.jim@concordia.ca

Abstract

This paper proposes a theoretical framework with which to discuss the critical engagement of media art projects in Second Life with racialized self-representation, fashion and ethnic dress. Examining Montreal-based Mohawk artist Skawennati's machinima series, T*imeTraveller*^{TM} (2008-13), a project of self-determination, survivance and Indigenous futurity, it argues the critically-aware act of 'virtually self-fashioning' racialized born-digital identities, or virtual ethnicities, disrupts ways in which today's vast proliferation of self-technologies enabling the creation, recreation and management of multiple selves, would otherwise remain complicit with neoliberal colour-blind racism.

Keywords

Self-fashioning, fashion, ethnic apparel, race, gender, coloublind racism, Second Life, virtual worlds, SLart, Skawennati, *Time Traveller*

Introduction

This paper discusses the possibilities of born-digital identities in Second Life created by artists of colour and Indigenous artists, to address the politics of racialized representation related to fashion and its Other—ethnic dress in-world and offline. Specifically I argue the critically-aware act of what I describe as 'virtually self-fashioning' racialized born-digital identities, or virtual ethnicities, disrupts ways in which today's vast proliferation of self-technologies enabling the creation, recreation and management of multiple selves, would otherwise remain complicit with neoliberal colour-blind racism, or neoliberal racism, as social critic Henry Giroux calls it. The paper is divided into three sections. The first section introduces the context from which this discussion emerges, namely scholarship concerning depictions of the racialized and sexualized body in Second Life and mixed reality performances that dispel the illusion of colourlessness in not only the fashion world but virtual worlds. Bringing together feminist interpretations of Foucault's theorizing on technologies of the self, critical race studies, fashion theory and postcolonial digital visual culture critique, the second section elaborates on how acts of virtually self-fashioning, allied to critique, help make critical distinctions between the ways in which selves are made and remade within and by the technologies of fashion and self-care, and the ways new media is used in artistic practice as potentially disruptive technologies that critique and redress the former. Why? Because the bodies engaged are themselves potentially disruptive, particularly when it is up against hegemonic social norms and conduct, of which dress is a significant marker. One of the artistic strategies is to facilitate the online critically-aware remediation of ethnic apparel (the entire outfit from makeup and hairstyles to clothing and accessories—even behaviours). Elsewhere I have argued that 'ethnic dress' (and its variants—'national dress' or 'world fashion') exist only because of the persistent Eurocentric perception of fashion as a purely Euro-American invention. 'Ethnic apparel" is thus used as a critical term whenever possible to underscore sartorial interventions cognizant of prevailing racist ideologies and discourses. The paper concludes with an exploration of Montreal-based Mohawk artist Skawennati's machinima series, *TimeTraveller*^{TM} (2008-13), as an example of the complex processes of cultural negotiation involved in the virtual construction of "Indian Country" in Second Life. A central aspect of the project is the artist's resourceful endeavours to create original Indigenous avatar skins and clothing, in addition to culturally-appropriate objects and environments, not readily available in the user-created online environment. It is safe to say that today, as art historian Martha Buskirk discusses in her book, *Creative Enterprise: Contemporary Art Between Museum and Marketplace* (2012), "contemporary art has become deeply embedded not only in an expanding art industry, but also the larger cultures of fashion and entertainment," referring to the art and handbags of Sylvie Fleury, Takashi Murakami and Fred Wilson. 1 With the Internet, this expansion has led to new relationships between new media art, new technologies of self-making and the virtual fashion and entertainment designed specifically for end use in virtual worlds.

Second Life Fashion and Ethnicity

> If in Real Life, you re Asian American, Asian Pacific American, fill-in Asian or Pacific Islander ethnicity American, please join this group Whether your passport says you re American or not does not matter. ou do not have to be Asian (or even human in SL) to join. 2

At the end of last decade (i.e. late 2010s) when the phenomenon of Second Life (SL) was still somewhat awesome and just days before the US would inaugurate its first

Black president in Barack Obama (January 20, 2009), SL scholar James Au Wagner asked: "Why s It Still Hard to Find a Good Ethnic Avatar Skin?" Fruitless searches in top SL fashion emporiums will only turn up "skins that are just darkened versions of light ones, or come without hair selections popular in black/Latino communities." 3 In fact, *Second Life Newser* reported that: "One kind of item that some residents complain they can't seem to find are ethnic avatars" which is why Tellaq Guardian created his SL store: "I couldn't find any good black skins for myself. As you can see in the store, there are many Afro skins"—there are also "some white, and one Asian." 4

In 2015, things haven't changed that much in terms of virtual diversity. The times in fact reflect more acutely the ascendancy in dominant public discourse of neoliberal ideology as well as its discontents. In a recent controversial 2014 study at Ohio State University on how racial diversity among virtual avatars in Second Life affected the experience of both white and Black users, Communications Studies scholar Jong-Eun Roselyn Lee "found that low-diversity representations of 'Second Life' dominated by white avatars led black players to create virtual avatars that also appeared whiter," and that "such circumstances even made black players less willing to reveal their real racial identity through their avatars"—the study did not "encompass other racial or ethnic groups such as Hispanics and Asians." 5 (It's just as bad for Asians, there are a lot of Harajuku and other favourite anime characters but not many human avatars expressing offline Asian identities.) 6 Lee's study is remarkable in what it says about "how strongly racial minority individuals identify with their particular race or ethnicity"; the appeal of SL's capacity, its openness for self-customizations for users to create avatars reflecting their true selves, is, as in video games, trumped by the fact that skin colour "still matters for the player's experience," enough that they will downplay, if not outright suppress the expression of their offline racial identity. 7 In contrast to gameworlds, user-created communities in Second Life have neither goal objectives nor pre-established game narratives, "relying instead mostly on the social interaction of users as well as an economy of user-generated content." [8] Despite how Lisa Nakamura has argued that "the adoption of the Internet by many more women and users of color since the nineties has occasioned innumerable acts of technological appropriation" 9 (and it has to a degree), this study and other recent scholarship on virtual diversity and cyberethnography in Second Life indicate there are still significant intersections of offline and online materializations of raced and gendered identities that underscore how experiences of racism, sexism and other forms of xenophobia in real-life, or worse, internalized forms of such ideologies of oppression, often impinge on the decision of SL users to self-represent their ethnicity, gender or nationality online, contributing to the ongoing lack of virtual diversity in the digital visual culture of Second Life.

Equally telling of the neoliberal tenor of the debates was the outcry against Lee's article, from arguments based on "design challenges" (that the lack of ethnic skins mainly has to do with "darker skins being far harder to give life to in a world like Second Life the textures don't stand out as much and therefore fewer content creators want to make them and fewer customers find them appealing" 10) to arguments based on market (there are few ethnic skins because there is no market for them, i.e. people who join online communities want to be someone or something else, certainly not identify with "races" marginalized in Real Life). The contention that scarcity of ethnic avatar skins is because they are simply not "appealing" to either ethnic or non-ethnic SL users, never mind SL residents, resorts to "race-neutral" discourses of neoliberalism that reduce racial problems to privatized concerns and issues of individual character and cultural depravity, and "human agency as simply a matter of individualized choices, the only obstacle to effective citizenship being the lack of principled self-help and moral responsibility." 11 Counter-arguments inevitably are rebuked with, as Giroux puts it, "power-evasive strategies such as blaming minorities of class and color for not working hard enough" (or too incompetent or unskilled to do so) and "refusing to exercise individual initiative." 12 (For Skawennati s *TimeTraveller™*, as we shall see shortly, this is simply not the case.)

And then there is the prevalence of "fashion anti-intellectualism" (anti-intellectual discourses about fashion), which, according to Minh-Ha T. Pham, is witnessed "any time a fashion designer, editor or retailer offers a non-apology about a racist, sexist or classist runway show or fashion shoot that begins with 'I m sorry if anyone was offended' and ends with 'but it s just fashion, don t take it so seriously.'" [13 One of the intellectual projects that fashion anti-intellectualism diminishes, notes Pham, is the understanding of "the social, cultural and socio-psychological relations between the body and clothing," or "enclothed cognition," an emergent field of study under embodied cognition studies spearheaded by cognitive psychologists Hajo Adam and Adam Galinksy: what you wear affects how you think of yourself. 14 It may seem this scientific conclusion was already figured out a long time ago, but even more surprising is how little discussion there has been about how affect pertains to the relationship between ethnic identity and dress, as well as the preconceived ideas associated with them.

Fashion (avatar apparel), specifically ethnic fashion as it is understood by the majority of SL residents, in contrast to ethnic 'skins', is much more easily obtainable in Second Life in any number of virtual outlets near you. While ethnic avatar skins are available in a limited fashion, it is the practice of "dressing up" or "going native" that is the more lucrative as sartorial commodities. In Second Life, users can dress up their avatars in the latest 'virtual world' fashions as well as in the latest 'world fashions' but one obvious observation is common, the majority of avatars, those that are human, whether dressed in "ethnic fashion" or not, are white and non-ethnic (there is more gender-bending than racial bending in Second Life). If one were to follow Adam and Galinsky's enclosed cognitive formulation, the

wearing of ethnic fashion does something to the psychology of the wearer that has no connection to the fact that the clothing isn't being worn by those whose ethnicity they are associated with.

This racial disparity in the phenomenon of ethnic chic isn't much different than what has been happening in Real Life where international fashion shows, and the models who walk the runways in them, are overwhelmingly white. While there was a spurt in the fashion industry in the 1980s and 90s when designers like Calvin lein, Gianni Versace and ves Saint Laurent routinely cast Black models without question, by the end of the supermodel era, fashion shows are as dominated by white models as they have been since the late 1990s. In the last decade that number has dropped and been replaced by obvious tokenism 15 (of a few size zero high end ethnic models) and the increased appearance of Asian models (in actuality, between 2008 and 2013, they "never comprised more than ten percent of turns on the runway. In five of the nine seasons, Asian models have *less* representation than Black models" 16) which is explained "specifically in terms of appealing to luxury customers in China. […] What is happening on the runways is the result of a very Eurocentric aesthetic that has taken over for the last 10 years and that has excluded other races." 17 What of Indigenous models? I could ask the same thing.

To change things, "the times need a real hard line drawn"; in the sixties, you would boycott," but today, says the iconic Iman, former supermodel and ves Saint Laurent muse: "If you engage the social media, trust me, it will hurt them in their pockets. If you take it out there, they will feel the uproar." 18 Twitter, other forms of social media, and an array of new fashion media communication technologies (blogs, vlogs, and mobile device apps) can revive the debate about race and fashion, but the fact remains: "There have been no obvious repercussions for those who still see colorless runways as an acceptable form of artistic expression. […] there are still many designers and casting agents who remain […] unmoved by the perception that fashion has a race problem in the first place." 19 Despite how luxury fashion has become a global business with an unfathomable number of consumers watching runway shows online, even virtual fashion shows are overwhelmingly white, as Pham's case study of the "Burberry Prorsum Autumn/Winter 2011 Hologram Runway Show" in China which marked the opening of Burberry's flagship store in Beijing, demonstrates: "Rather than spotlight Chinese supermodels or at least use them as prototypes for the digital models, white models overwhelmingly outnumber non-white models on this virtual fashion runway – just as they do on real runways." 20 Once again, the reproduction and (re)configurations of race, ethnicity, and gender in real life carry over in digital spaces, and in the case above acutely exemplified at the intersections of fashion and virtual identity play.

In this regard, the ongoing scholarship on race, ethnicity and diaspora in new media by Lisa Nakamura, Wendy Chun, and increasingly more other academics, are fundamental to understanding what is happening in new media art when it comes to talking about virtually self-fashioning racialized subjectivity online. "Racial formation theory has not often been used in reference to new media, partly because the frame of reference is so different and because the early utopian bent to Internet criticism meant that discussions of difference, especially if viewed as 'divisive,' were avoided." 21 While earlier racial formation theory assumed that racial projects "were ongoing and differential but nonetheless worked in a more or less one-way fashion," today, Nakamura writes, "new media can look to an increasingly vital digital cultural margin or counterculture for resistance." 22 Morever, vital to moving forward digital visual culture critique are intersectional critical methods that "read both race and gender as part of mutually constitutive formations." 23

Technologies of Self-Fashioning

> The self is not clothing, tools, or possessions. It is to be found in the principle which uses these tools, a principle not of the body but of the soul.
>
> – Michel Foucault 24

For the purposes of this study, "technologies" is understood in terms of what French philosopher Michel Foucault posited as "technologies of the self" and "care of the self" wherein the self is the *object* of both the technology and of the concern. Foucault defines technologies of the self as practices and strategies "which permit individuals to effect by their own means or with the help of others a certain number of operations on their own bodies and souls, thoughts, conduct, and way of being, so as to transform themselves in order to attain a certain state of happiness, purity, wisdom, perfection, or immortality." 25 Foucault did not write about fashion or dress but his ideas are useful to discuss how discourses about what we wear are internalized to the point that the relevance of lived experiences and alternative, non-hegemonic practices are often dismissed. His later writings are a reminder that "one has to take into account not only technologies of domination but also technologies of self." [26] Importantly, his method of inquiry into self care is "thinking with attitude": "thinking with attitude . . . generates the conditions of possibility necessary for subjects to cha[lle]nge their identities." 27

Only *critically-aware* acts of *virtually self-fashioning*, however, can intentionally and purposefully subjectivize the self who then becomes the one that is constructing the technologies *and* the self, and doing the concerning of itself as Moya Lloyd suggests, "self-fashioning, *when allied to critique*, can produce sites of contestation over the meanings and contours of identity, and over the ways in which certain practices are mobilized." [28 When self-fashioning involves race, itself a powerful technology, avatar identities run into what new media studies scholar Wendy Hui Kyong Chun posits as "race *as* technology," "a strange, and hopefully estranging formulation" that crucially "shifts the focus from the *what* of race to the *how* of

race, from *knowing* race to *doing* race by emphasizing the similarities between race and technology." 29 Of concern when it comes to talking about ethnic dress (and fashion in general), are two technologies of the self in particular: the technologies of self-esteem and of the market in which the technologies of desire and identity are intertwined through consumption. The former, self-esteem is closely linked to the technology of norms which produces certain kinds of selves. In order to be empowered, it is necessary to think of self-esteem as having more to do with self-assessment or self-worth than self-respect as can be surmised by the huge variety of self-help books, tapes, videos and other paraphernalia available for purchase. Nearly all the psychological technologies borrow from technologies of the market, namely consumption, which in turn borrows from technologies of the self because it uses the power of goods to shape identities. For our purposes here, falling under the illusion of having only the choice between off-the-rack/pre-fab brand avatar apparel and virtually-designed haute couture, as opposed to self-designed apparel, reflects upon the Second Life user's buy-in, or, if they are fortunate enough, buying power to show (off) who they are or want to be, communicating to others ultimately how they want to be perceived as the market would have it so. As certain traits are associated with certain clothes, deciding to don and wearing certain pieces make individuals feel good (enclothed cognition), changing personalities to incorporate those traits into one's behaviour—the question is: in whose hands is (given) the power to shape the identities in Second Life that users desire?

TimeTraveller™

> The Montreal-based Mohawk artist Skawennati offers the tremendous "TimeTraveller™" (2008-13)—nine machinimas (films made by using computer graphics engines) featuring two smart, sexy and utterly cool Mohawks who use magical glasses and computers to visit often harrowing past events (including an Aztec sacrificial ceremony and the violent 1862 conflict between Dakota Sioux and white Minnesota settlers). Ultimately, they relocate to a spectacular future in 2121.[1] 30

Exhibited as a projection-based work in the 2014 Biennale de Montreal (BNLMTL 2014), Skawennati's *TimeTraveller™* (http://www.timetravellertm.com/) is a multi-platform work featuring a website in which the main component is a nine-part sci-fi/cyberpunk machinima series (movies shot in virtual environments, in this case, in Second Life on AbTeC Island). As with her earlier 2005 web-based paper doll/time-travel journal *Imagining Indians in the 25th Century*), *TimeTraveller™* depicts Indigenous people living in the future as a vibrant, integral part of it, rather than in an idealized past. 31 The machinima tells the story of Hunter, an angry, disillusioned young Mohawk man, fashionably punk and jet-packed, living in the twenty-second century—a Montreal in 2121 of soaring skyscrapers and hyper-commercialized surroundings—"a dystopian exaggeration of contemporary Western neo-liberal society." [32] Hunter is able to time travel thanks to the special ultra-light *TimeTraveller™* 3D virtual reality device (available for purchase soon, according to the *TimeTraveller™* website) that allows him to visit (as well as engage in gameplay with) famous people, places and conflicts in Indigenous history (such as the riveting Episode 03 of the Mohawk Oka Crisis in 1990 in uebec) and embark on a vision quest without ever leaving his futuristic, technologized world. (The "look" of Hunter's world, and Hunter himself was inspired by Neal Stephenson s widely read 1992 novel *Snow Crash* and its Indigenous antagonist, the hacker Raven.) Strong female characters appear throughout the machinima, including key historical figures. As the story unfolds, the female protagonist, arahkwenhawi (who first appears as a baby in Episdoe 03), meets Hunter and they fall in love, debunking all real-world theories of space-time continuum. As Mohawk activist Ellen Gabriel once said to Skawennati: "Our people have always used time travel to figure out the problems of today." 33

The story of the making of *TimeTraveller™* and inhabiting of AbTeC Island is self-admittedly inundated with multiple layers of irony and parody. Already early on in 2008, Skawennati's project team virtually confronted how "on top of the existing irony of Indians buying virtual land and then colonizing it, there was now an additional irony of having to enclose that land to protect it from counter-colonization by a … somewhat belligerent group of technological adepts"—virtual squatter-pirates stealing their prims (primitives) which are needed to build 3D objects in Second Life. 34 I would suggest however that given the teleology of the Internet as the last but most permanent thus far of the Wild West frontiers, it might be more accurate to see the efforts around *TimeTraveller™* as ironically part of the larger project to decolonize cyberspace or take advantage of the critical purchase of a territory already colonized by a neoliberal techno-meritocracy, with varying degrees of successes and failures—one has to, after all, pay for virtual land to occupy it. Fundamentally the project exemplifies one of AbTeC's core arguments, "that the era of networked digital media presents a unique opportunity for Aboriginal people to present a self-determined image to the world," both in Real Life and in-world—"even on the Internet, Native people need a self-determined place to call home." 35

[1] Born in anahw :ke Mohawk Territory of mixed Italian and Mohawk heritage, Skawennati (Tricia Fragnito) (1969-) holds a BFA and graduate certificate from Concordia University and is Co-Director with Jason E. Lewis of *Aboriginal Territories in Cyberspace* (AbTeC). She co-founded the collective *Nation to Nation* in 1994 and co-created and curated *CyberPowWow*, an Aboriginally-determined online gallery conceived in 1996 which eventually culminated in the establishment of AbTeC in 2008. Developed with the support of the AbTeC research network, and winning the *imagineNative Film and Media Arts Festival*'s 2009 Best New Media Award, *TimeTraveller™* has been shown in numerous configurations. http://www.skawennati.com/

"Call It a Vision Quest"

> Interfaces inform all media—videos, television, literature—and as this happens we are witnessing the creation of new power differentials in visual capital. 35
>
> We can be the storytellers, not just have stories told about us. 36
>
> I mix history, Indigenous knowledge, pop culture and science fiction to create alternative realities and possible futures that provide touchstones to discuss our resistance, survivance and success.
>
> – Skawennati

In their essay, "Call It a Vision Quest," Elizabeth LaPens e and Jason Edward Lewis argue that *TimeTraveller*™ is an example of culturally-critical machinima as First Nations survivance—survival by resistance—a concept popularized by Anishnaabe writer and poet Gerald Vizenor who emphasizes the continuation of "Native survivance stories" and "reinforcing the existence of living indigenous culture in contemporary society." 38 One particularly strong dimension of this in effect in *TimeTraveller*™ is how the artist and her team have had to make their own customized First Nations skin tones and hair styles, hence developing a "rich set of First Nations characters in Second Life, an act which constitutes a powerful contribution to self-determination in cyberspace" (if ethnic avatar skintones are rare today with very few Indigenous characters around, they were even more limited when Skawennati first joined Second Life in 2007). 39 "Customization in machinima may involve making assets such as animations, textures, objects, and sounds" – hairstyle assets were purchased and modified to complement the ones the artistic team made themselves. 40 Among the many customized objects in *TimeTraveller*™, from sacred objects such as wampum belts and beads to accessories, props and the virtual sets and even customized moves (drumming, jingle dancing), was clothing. As is the case for ethnic avatar apparel, "finding culturally appropriate clothing for characters provided to be a challenge, since most of the depictions of First Nations culture in Second Life stem from romanticized pan-Indian stereotypes. […] As a result, the team created much of the clothing for the characters, such as ribbon shirts, fancy dresses, and jingle dresses." 41

As LaPens e and Lewis suggest, the lack of a predefined narrative in the making of machinima in Second Life facilitated the objective to create *TimeTraveller*™'s original narrative context "that looked to First Nations culture and science fiction as its main reference points" 41 —the outcome of which I suggest can be described as a conscious act of virtually sef-fashioning Indigenous presence in Second Life. "The first episode took two years, as we had to learn everything —how Second Life worked, how to move in it, how to dress people, how to make them look Indian." 42

Ethnic Ribbons and Regalia

> In the future, what will we wear as regalia? What kind of agreement would we honour with a wampum belt? 43
>
> The continuance of both ceremony and creativity is at the heart of cultural and political survival. 44

In Episode 04, we meet arahkwenhawi, a young university student from our present visiting the Saint Francis Xavier Mission Church in anahw :ke, uebec, to do research on the "Lily of the Mohawks," Blessed Kateri Tekakwitha, the first indigenous Canadian saint (posthumously in 2012), for her art history paper on representations of Indigenous people. She finds a pair of the TimeTraveller™ glasses and visits a spectacular futuristic powwow extravaganza in 2112 at the packed Winnipeg Olympic Stadium where the long-haired MC is like a rock star and jingle dancers take centre stage (fig. 1). 45 Not only is the head female dancer, Miss Universe 2111 and featured on the cover of Italian Vogue, later in the program, beautiful Indigenous female models take the catwalk in haute couture "Ovoid" gowns. Importantly, Karahkwenhawi gets to meet and interact with ateri Tekakwitha through to Episode 05, finishing her essay. She finally hooks up with Hunter at Alcatrez in Episode 06 and continue together to find out more about the history of Turtle Island and in the process themselves.

Figure 1: Jingle Dancers Assembled, TimeTraveller™ Production Still, 2011. Courtesy of the artist.

Three items struck me about fashion, ethnic apparel and self-fashioning self-determined representations watching these particular episodes in which not only Hunter, but arahkwenhawi (who later goes on her own vision quest), technically-speaking, avatars of avatars, become subjects of history surrounded by, if not interpellated through apparel. The first is, not to state the obvious, that the very ability to literally *move* the narrative temporally and spatially (with a click of a button) and metaphorically (to bear *witness* to historical moments of Indigenous resistance and *take part*) is, in fact, a engineered piece of fashion apparel—a pair of stylized (and stylish) designer eyewear, created by an *artiste*, branded and comes in limited editions. A

similar device is the cell phone whose ring reminds us arahkwenhawi is in our present even as she travels back to 1680 to meet the tragically small pox-stricken Saint a-teri in the "flesh." Phones are fashion these days. On the market today are cellphone accessories and apparel as well as cellphone clothing (to conceal your cell so you can pay attention to other things) in the 'coolness factor' wars. In *TimeTraveller*™, these objects of many prims, however, are more than just chic fashion accessories they are emitters of hip, tech-savvy identities as well as conduits to Indigenous lives past and present. In this in-world, they are specially-designed, transformative, disruptive technologies.

The second is how the powwow event is a particular moment in the series in which mainstream conceptions of pan-Indian dress is remediated and re-appropriated from pop culture, mainstream mass media and historical accounts. In reference to *Urban Indian Series* (2006) by Terrance Houle in collaboration with Jarusha Brown, which capture the artist going about his daily life but in full powwow regalia, curator and art historian Richard William Hill writes that: "It is when we ask ourselves 'why?' that the work does its real damage. Do we really assume that the visible signs of 'Indianness' are antithetical to ordinary contemporary experience, even when worn by an indigenous person?" [46 The careful attention and effort to fashion a rich set of First Nations characters in *TimeTraveller*™ ostensibly carves out and place-holds a critically-aware transhistorical space where self-determined Indigenous fashion, with its diversity in varying scales of production, indeed exists. This favourable condition of possibility, I argue is what acts of virtually self-fashioning born-digital identities are aligned with and aspire to.

Finally, although not discussed in this paper, at least a brief mention should be made about how virtually self-fashioning gendered identities is also realized in *TimeTraveller*™ not just in these episodes but through to the end. In Episode 09 arahkwenhawi visits at art gallery in 2121 (Hunter's present in which he is rich and famous having won the Extreme Time Traveller contest). In this future, arahkwenhawi would be an award-winning, successful art historian of the twenty-first century Indigenous art that are displayed on the walls of the futuristic gallery (fig. 2). She is as comfortable in her own skin as she is in the jingle dress that magically adorns her at the stadium powwow, a pair of jeans and t-shirt or a professional business suit and slick hairdo, and apparently very, very youthful still in 2121. arahkwenhawi decides to move to the year 2121 permanently, for love and the prospects of what an empowered decolonial future can bring despite the familiar spectre of neoliberal capitalism at every turn. As Sasha Sobrina suggests, the hyper-commercialized surroundings are how Skawennati connects 2121 to present-day reality in 2015, inviting viewers to imagine with her how the attainment of such a future is not entirely fantastical. 47 Notwithstanding, survivance needs to remain an ongoing project.

Conclusion

The born-digital fashioned body is always already embodied and always already performed. Self-depictions of born-digital identities are always mitigated by and remediated through the experiences and aspirations of their real-life creators. For people of colour and Indigenous people, the decision to create or choose avatars that self-represent their ethnicities however come with challenges of which not the least is how virtual worlds are hardly the utopian, democratic, race-neutral, post-racial spaces they are sold to be, beginning with the default choices of skin colour. This paper has argued that critically-aware acts of virtually self-fashioning racialized born-digital identities through ethnic avatar apparel—skins, ethnic dress, accessories—evident in Second Life art projects such as Skawennati's *TimeTraveller*™, constitute acts of resistance against persistent colourblind injustices online and off. In visualizing, affirming and ultimately empowering the vitality of self-determined histories, identities and the fashioned body, they call attention to how selves are made and remade within and by the visual and conceptual technologies of fashion, new media and self care always for a purpose.

Capturing and Recognizing Expressive Performance Gesture

Michael J Junokas, Kyungho Lee, Mohammad Amanzadeh, Guy E Garnett
Illinois Informatics Institute at the University of Illinois, Urbana-Champaign
junokas@illinois.edu, klee141@illinois.edu, amanzad2@illinois.edu, garnett@illinois.edu

Abstract

A better understanding and control of expressive performance gesture potentially could have a large and disruptive impact on electronic media and movement performance practice. We use digitally captured positional data, features extracted from this positional data, and a variety of machine-learning algorithms, to improve the accuracy of recognizing expressive qualities of performance gestures, using concepts derived from Laban Movement Analysis (LMA). Through these methods, we seek to develop better human-computer interfaces, to expand expressive movement vocabularies, and to shift movement aesthetics, by empowering users to exploit their full performance capabilities.

Keywords

Machine Learning, Expressive Performance Gesture, Expressive Movement Recognition

Introduction

Human-computer interfaces rely on merging user abilities and technological tools to form an enhanced performance environment. While advances in technology have allowed users to perform more complex tasks with greater ease, the added technological challenges can hinder the movement and expressive capabilities of the user. This interference limits functionality and compromises the diverse pallet of expressive movement qualities. We aim to create a more cognitively transparent computer interaction system that maximizes embodied knowledge based on movement, quantifiably capturing and recognizing expressiveness present in performance gesture.

Gesture in performance couples the functionality of achieving a task with the expression of aesthetic qualities, creating a dynamic and complex dual role. Our belief is that the expressiveness in performance gesture comes from subtleties of movement, extending beyond its practical function (i.e., "how a gesture is performed"(Caramiaux, Donnarumma, and Tanaka 2015). Musical conducting provides an excellent example of a gesture system that gleans expression from nuanced gesture, expanding the range of a conductor's performance from micro cues to a grandiose breadth. The work done in (Kolesnik and Wanderley 2004), (Maes et al. 2013), and (Morita, Hashimoto, and Ohteru 1991) all point toward taking advantage of this broad vocabulary, driving different technologies through movement. Our work similarly attempts to dissect a performer's gestural range, discovering the subtleties and range of their movement through feature extraction, statistical measures, and machine learning. Through this analysis, gestural nuance can be applied to technological interactions with greater control and more expressive means.

We describe the current state of our research in capturing, analyzing, and applying expression in performance gesture. To apply machine-learning algorithms to performance gesture, we needed to develop a vocabulary to clarify the movement qualities we wished to quantify. For this purpose, we chose Laban Movement Analysis (LMA)(Laban and Ullmann 1966) and used it to inform and guide the creation of our dataset and our methods of feature extraction. We describe these features and our use of several machine-learning algorithms (specifically k-means clustering, Hidden-Markov Models (HMM), and autoencoders), followed by a discussion of the results and implications of these approaches. Finally, we will offer conclusions and future directions we wish to pursue based on this research.

Classifying Movement through Laban Movement Analysis

Laban Movement Analysis is a method and language created by Rudolf Laban (1879-1958) analyzing, describing, and explaining movement in terms of functionality, tendencies, intention, and expression. The method is principally used by dancers and choreographers as a way to gain insight into movement from an expressive and intentional realm, but has expanded as a descriptive vocabulary for movement itself (Maletic 1987). We are centrally concerned with the goal that Laban states:

> Basically one has to start with the description of movement .... Our aim is thus the mastery of movement through explanation. (Laban and Ullmann 1966)

The 'mastery of movement through explanation is executed in our work by utilizing LMA as a framework from which we can build a classifiable dataset of labels that encompasses our movement capabilities. From this data set, we can perform digital analysis using machine-learning techniques. Using concepts from LMA, we develop a structure to represent

movement, intention, and expression.

LMA has five principal components that collectively create a comprehensive symbolism for movement: Body, Space, Effort, Shape, and Relationship. In our work, we focus on Effort, which relates most directly to expressive characteristics we are seeking.

There are four distinct components of Effort: Space, Weight, Time, and Flow. In our work, we focus on the first three components, omitting Flow, which tends to be based on the interconnection of other movement qualities. Each Laban Effort Component represents a continuum between an *indulging* and a *fighting* Basic Effort Factor (BEF). Space can be represented on an axis from direct (fighting: focused, channeled) to indirect (indulging: multi-focused, all around awareness). Weight can be represented on an axis from strong (fighting: forceful, firm) or light (indulging: fine touch, buoyant). Time can be represented on an axis from sudden (fighting: urgent, instantaneous) or sustained (indulging: lingering, gradual).

Through the combinations of these limits, eight Basic Effort Actions (BEA) can be created: Float (sustained, indirect, light), Flick (sudden, indirect, light), Wring (sustained, indirect, strong), Slash (sudden, indirect, strong), Glide (sustained, direct, light), Dab (sudden, direct, light), Punch (sudden, direct, strong), and Press (sustained, direct, strong) (Hackney 2003)(Laban and Lawrence 1947). These BEAs are the vocabulary upon which our model is built and establish a framework from which we can build a quantifiable, labeled dataset of expressive movement.

Data Capture System and Feature Extraction

In order to analyze BEAs, we turned to digital movement analysis. For our corpus, we asked 8 performers (6 non-experts and 2 with LMA training) to perform each of BEAs in isolation and used the Microsoft Kinect to capture the gesture data. From the captured data, we derived a skeleton using the x, y, and z position of 21 distinct joints of the performer, of which we focused on the right wrist.

The positional data was transformed into higher-level features such as velocity and acceleration. We also extracted comparative features to measure movement curvature, such as the dot product between successive positional or successive velocity vectors. Additionally, we applied Fourier transform to each of these features. All of these features were used singularly or in combination to create different views of the dataset through the features. These computations allowed us to view performance gestures as a series of feature segments, giving us a means to explore the expressiveness of each performance gesture.

In addition to using these features in their raw form, we turned to dimensionality reduction using Principle Component Analysis (PCA) (Wold, Esbensen, and Geladi 1987) and Independent Component Analysis (ICA) (Hyvärinen and Oja 2000) in tandem to isolate the features that contained the most representative aspects of the gesture. We also used unsupervised learning, specifically autoencoding (Ng 2011), to find machine-derived feature combinations that could optimally represent our dataset.

Recognition of Gestures

We applied a variety of machine learning algorithms to our extracted features in an attempt to best classify and recognize performance gestures. We experimented with k-means clustering, hidden Markov Models, and using autoencoding features with logistic regression models and support vector machines . Within each of these models, we attempted classification at varying time windows and with varying feature sets

K-Means Clustering

The k-means clustering algorithm allows us to categorize data with similar characteristics into discrete clusters. After generating a number of cluster centroids using the algorithm, we are able to characterize the data by its nearest centroid (Arthur and Vassilvitskii 2007). For a given BEF, a normalized motion profile histogram is created by tallying the nearest centroids of all the training BEFs data points, creating an average histogram over the number of samples. These motion profiles are then compared to input data histograms and classified as whichever BEF motion profile it is closest.

Through empirical evaluation, we found the best classification generating 32 distinct clusters using the combination of the velocity and normalized dot product of changes in positional data.

	Weight	Space	Time
Indulging	0.60	0.80	0.83
Fighting	0.72	0.45	0.55

Table 1: F1 scores of BEF classification with K-means clustering with 32 clusters using 8 frame feature windows of velocity and normalized dot product data

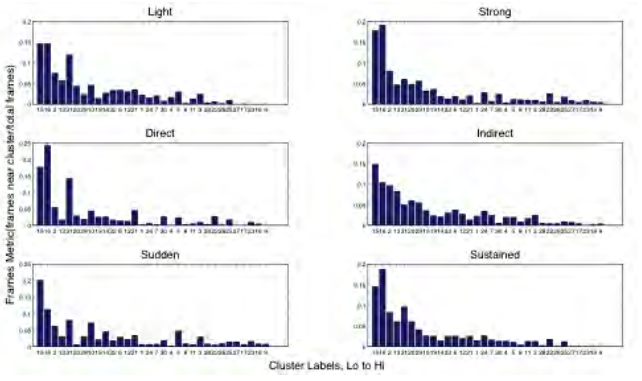

Figure 1: Motion profile histograms generated from k-means algorithm and velocity data

While using k-means clustering did not produce the highest F1 scores, it was an important step towards real-time movement analysis and provided direction for using more sophisticated algorithms.

Hidden Markov Models

Hidden Markov Models (HMM) have been widely used in modeling sequential data such as movement, and particularly, speech (Rabiner 1989). The model assumes that a hidden process with a finite number of states controls the observed data and assumes that the probability of being in a state at each time only depends on the state of the model at the previous time. Using these stipulations, the algorithm models a latent distribution of the data in each state of the model. Given a trained HMM, we can identify the likelihood of observing the input data within that model.

Like the template-matching model used with the k-means clustering, Laban Effort Component classifiers were made with two HMMs, each modeling the indulging or fighting BEF of the Laban Effort Component. We compared the likelihood of the input gesture to both HMMs and chose the model that resulted in the higher likelihood. Through empirical evaluation, we determined that using a moving average filter (Smith and others 1997) with 12 frames width on velocity resulted in the most representative feature of the data. We sliced the sequences into non-overlapping segments of 16 frames and trained HMMs with 8 hidden states. In order to predict the BEF of each frame of the test data, we sliced them into segments of 16 frames with 15 frames overlap.

	Weight	Space	Time
Indulging	0.71	0.81	0.87
Fighting	0.70	0.79	0.67

Table 2: F1 scores of BEF classification with HMM using 15 frame feature windows of velocity data

When testing HMM classification with different features, we noticed that the Fourier transform of features performed worse than non-transformed features. We decided to investigate how the Kinect was smoothing or filtering out information from our gestures.

To test this, we performed a hand movement moving periodically up and down at a rate of one beat per second (1 Hz) and gradually increased the rate to our maximum capability. We simultaneously recorded the movement with the Kinect and the accelerometer within a Nintendo Wiimote and compared the two. The Wiimote's accelerometer recorded the increased frequency throughout the recording. However, the Kinect stopped showing the increased frequency around 6 Hz and began to filter out a majority of the information (see Figure 2), potentially removing several important features of our data. The smoothing of the joint data can be altered within the Kinect Software Development Kit (Jana 2012) and will have to be further investigated if we wish to use FFT analysis to its fullest capabilities.

Autoencoder Features

In addition to utilizing algorithms for classifying, we were also able to obtain a machine-based representation of the data through unsupervised learning, specifically autoencoder

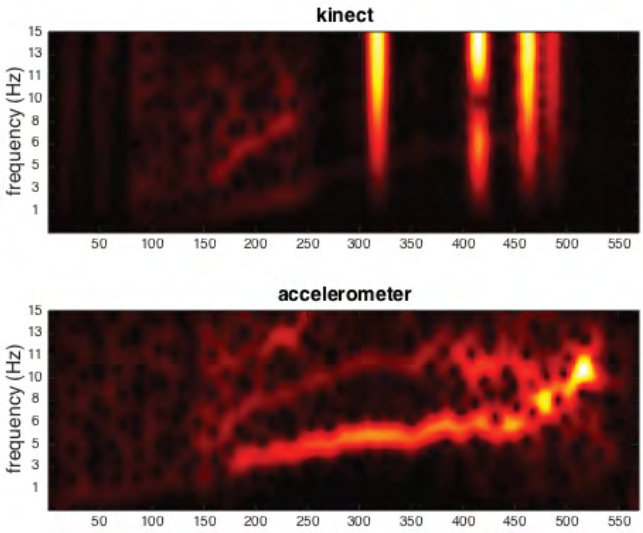

Figure 2: Comparing the Fourier spectrogram of kinect and Wiimote accelerometer as we increase the frequency of hand movement

	SVM	SVM w/AE	LR	LR w/AE
Sudden	0.78	0.81	0.49	0.57
Sustained	0.72	0.71	0.61	0.75
Strong	0.51	0.57	0.54	0.58
Light	0.68	0.69	0.46	0.55
Direct	0.52	0.56	0.52	0.60
Indirect	0.67	0.67	0.49	0.51

Table 3: F1 scores of BEF classification with support vector machine (SVM) and logistic regression (LR) classifiers using 16 frame feature windows of velocity data and activations from autoencoder (w/AE)

activations. Similar to principal component analysis, autoencoders generalize datasets to a representative collection of features, allowing us to reduce dimensionality and present a non-linear representation of our dataset (Hinton and Salakhutdinov 2006) (Ng 2011).

Using windows of 16 frames on velocity data as source data, we generalized our movement using 48 activation states. Using these activation states, we created training and testing feature sets from our LMA recordings. These feature sets were then fed to logistic regression and support vector machine classifiers. (see Table 3).

Discussion of Results

While the overall accuracy of our tests did show some level distinction between LMA gestures, the levels were not as high as we anticipated. This could be due to several reasons.

The windowed segments of the data could be less distinc-

tive than the labels imply. In preliminary tests, classification was attempted on the entirety of gestures rather than windowed segments. This resulted in much higher accuracies, but was not done in real-time, our ideal system setting. This suggests that there are distinctive elements within the gestures, but our windowing was unable to isolate those elements from the rest of the data. Steps must be taken to consider the balance between considering the whole gesture versus a real-time computing system. Using infinite impulse response filters or segmenting by specific points of interest in the gesture may provide a more ideal compromise between optimizing our data usage and working in real-time.

The features from a singular joint may not contain enough information to provide clear distinction between gestures. In our tests, we used only a fraction of the total features and only derived those from the right wrist. Testing with more features from additional joints in combination could lead to higher classification scores.

Autoencoding activations were used in replacement of velocity features for our tests. Alternatively, these activations could be concatenated with the original features, creating combinatorial feature representation of both sets, potentially improving accuracy.

Conclusions and Future Work

Our research in recognizing nuanced expression in gestures is beginning to show promising results and has directed our plans for future investigation. The combinatorial nature of feature representation still needs to be further explored in order to find the best representation of the data. A more generalized movement vocabulary that is simpler and more basic than LMA could allow for a more fundamental approach to movement, reducing intentional context. Locating and focusing on the most essential data segments rather than all segments could direct our research to the most representative gesture elements. While autoencoding has generated better feature representations of our data, that representation has only been used with select algorithms and should be used with others including HMMs or deep-belief networks. Kinect filtering will lead us into exploring the internal configuration of the latest release of Microsofts sensor in hope of manipulating the filtering that affects Fourier transforms of the data.

While there is still much work to be done, we have found promise in our current research. Through understanding the basic building blocks of performance gesture through machine learning, we can begin to more effectively understand and generalize that gesture. Through this understanding, we can start taking full advantage of our full physical capacities in human-computer interactions.

A deeper understanding of the expressiveness within performance gesture could lead to more efficient, liberated, and expressive human-computer interactions, which would foster user-driven innovation, providing more refined and robust methods of information control and exploration. This expansion of expression could redefine the very fundamentals of movement performance practice, disrupting the current paradigm and forcing a new approach to technology and movement aesthetics. Using digital feature capture, data analysis, and machine-learning algorithms, we seek definable expression and intention in performance gesture to realize this paradigm disruption.

Abstract

This paper examines the aesthetics of immersive experience in *Light Strings,* an interactive immersive environment. One of prominent aspects of Interactive Art is the notion of immersion. The concept of immersion is generally defined as a viewer "forgetting" the real world outside of the virtual environment and by a sense of being in a make-believe world generated by computational hardware and software. As an interactive artist and researcher, I conceive of immersion as any experience where integrated bodily, conscious, and pre-conscious states thoroughly intertwine with the world. Moreover immersion is where mind, body and environment interweave and communicate with each other inside of technically-mediated, spatially enclosed, and sensuously-interactive computational environments. *Light Strings* was created based on my previous art practice and research into immersion as a way to study participants' experiences with the artwork. In the participant study of *Light Strings*, participants were encouraged to describe the felt experiences of the installation through phenomenologically oriented research methods. As a result, an experiential model of the participants' experiences was developed by exploring bodily, spatial, and contextual consciousness with temporal considerations.

Keywords

Immersive installation, aesthetics of immersion, immersive Consciousness, audio-visual, case study

Introduction

One prominent aspect of Interactive Art is a notion of immersion. Immersion has been historically explored mostly by literary and film theorists and more recently, by Virtual Reality (VR) scientists and artists. It is generally defined as a viewer "forgetting" the real world outside of the virtual environment and by a sense of being in a simulated world generated by computational hardware and software. Most research into immersive experience has been conducted from a scientific perspective. The scientific research tradition typically standardizes or objectifies results and doesn't focus on the meanings and qualities of experience. Similar to other scientific studies, immersion researchers have largely used quantitative/empirical methods, such as measuring physiological data and conducting surveys after the participants' experience. [1-3]

In a movement parallel to Computer Science research, many Interactive Artists have also explored immersion within VR environments in collaboration with computer scientists in many times. Their general approach to immersion is somewhat different from those of scientists. Artists have explored full-body, sensory immersion through their artistic creations. [4-6] Their approaches countered the disembodying tendency of virtual reality discourses and their artistic pursuit was centred on creating immersive experiences using new technology (new hardware or complex systems). Rather than quantifying the participants' immersive experience, their focus was on creating new immersive experiences.

As an artist, I create interactive immersive installations exploring the idea of embodiment and materiality. My artist skills and interests have led me to experimenting with soft materials and light to create immersive environments. From over 15 years of experience with digital technology in Interactive Art, I believe that technology can help us to experience nostalgia and relive our memories, reawaken habituated senses and provide opportunities to perceive new things in a creative way. In this study, I created an interactive immersive installation, *Light Strings* and conducted participant study to examine how participants experience immersion, how immersion is constructed in my installation and what the main qualities are of the environment. This paper analyzes aesthetics of immersive experience collected from a case study. Participants were encouraged to describe their felt experiences through phenomenologically-oriented research methods. This allowed me to gather various data on participant experience.

Background

Understanding Immersion

The sense of immersion has been explored for a long time but there is no set or universally agreed upon definition for this term because all approaches converge on the word immersion from different knowledge areas. The term is widely used for describing immersive virtual reality, installation art and video games, but no one meaning dominates. Its meaning remains vague, but common to each meaning is the connotation of being absorbed, engaged and embraced. Different disciplines use these differ-

ent definitions. This means that immersion has multiple, flexible qualities that can be applied in different situations.

Contemporary Views

Immersion in New Media

Since the 1990s, more in-depth research on immersion has been conducted in the Arts and Humanities. The result is two streams of scholars and artists. One stream explores various immersive experiences in different realms: videogames, narrative, and human experience. The other stream focuses on building immersive experience within immersive VR spaces.

Salen & Zimmerman call immersion "double consciousness," that the game player is fully aware of the character as an artificial construct. They argue that this makes character-based game play a rich and multi-layered experience. [7] For Bolter and Gromala, a participant's awareness oscillates between feeling immersed and being aware of an immersive environment. However participants most of the time are still aware of the real environment and get immersed from the interplay between real media and virtual contents. [8]

Many other researchers have focused on the desire to use technology as the defining factors in immersion; they describe the term "immersion" as immersion into presence, a state of being engaged; in this way presence is a psychologically emergent property of an immersive system. Immersion describes a condition; presence describes an associated state of consciousness. [9] Carol Manetta and Richard Blade defined immersion as an observer's emotional reaction to being part of a virtual world. [10] They consider immersion as mental process created during the use of immersive VR systems that include HMDs and other equipment. Immersion can be stimulating process, but in most cases immersion "absorbs and provokes a process, a change, and a passage from one mental state to another". [11]

Immersion in Interactive Art

Immersion is in part a spatial experience, in the sense of enveloping the participant in a discrete and panoramic space. Moreover, it is also a temporal experience when combined with computational components. It creates an intimate connection as "a constitutive element of reflection, self-discovery, and the experience of art and nature". [11] Immersion is considered paradoxically as distance, as absorption, and as space and time blur in the immersive environment. The pioneering immersive artist Davies explored the concept of immersion using the metaphor of scuba diving (submersing in water) and using a concept of cognitive absorption in her projects [4]. Around the 1960s, early new media artists conducted experiments related to immersion. Artists and designers have new possibilities for interactive immersive works become more accessible and more powerful with programming tools. In relation to VR art, the sense of immersion is being explored in art projects that encourage the active involvement of the participant and evoke senses and/or fully engage with attention. Interactive artists often try to use limited, inexpensive technology but in creative ways to examine the sense of immersion because it is hard for them to use very expensive equipment and because the sense of immersion does not require photo-realistic or technologically complex multi-sensory environments. Immersion can be created from perceptual cues. [12]

Immersion in Physical Environment

Immersive spaces create subliminal awe [13], helping the viewer/participant become aware of inherent or internal body senses. Physically immersive environments expand the boundary of our vision and create imagination evoking immersive feelings from materials that affect with perceptions of dimension. Physical installations do not include normal architectural rooms or spaces where we live in the everyday life. Even though we are physically surrounded by a room or nature and may be engaged to something in the space, it is hard to call the phenomenon immersion. When we are habituated to the space, we are rarely aware of our connections to the environment and the reciprocal relationships within the space. In my study of immersion, it is critical to recognize that immersive consciousness is constructed through embodied experience in the relationships among body, mind and the world.

Methodology

Methodological Background

Art has been acknowledged as research among practitioners, theorists, and educators. [14] In contrast to academic and scientific research emphasizing the generalizability and repeatability of knowledge, art research expresses a form of experience-based knowledge [15] and explores subjective qualities of experience. Artists identify researchable problems discovered in practice, and respond or solve them through professional practice. Therefore, artists know their works and the questions around the works better than any other researchers. An artist is a researcher who has multifaceted roles: material experimenter, space designer, fabricator, critic, documenter and audience. [16] In other words, it is ideal that artists take a lead role in the research of their works, rather than being separated from the research process. In that respect, artists' research activities seem to be appropriate for Baumgarten's classical definition of the aesthetic domain.

Phenomenological Approach

In the realm of art research, there has not been much work dealing with research methods because artists' interests often lean more towards creating new works than investigating the aesthetic qualities and meanings of participant experience. However recent movements in interactive art indicate that some interactive artists put value on the quali-

ties and meanings of participant's experience with their works as well as the process of artistic creation. Phenomenology, especially as contained in Merleau-Ponty's work, has been acknowledged as an appropriate research method by contemporary new media artists. Phenomenology is not a single method. Phenomenological methods have been adopted and developed in many disciplines and are being actively explored in Cognitive Science and Human Science including Nursing. Because of the nature of phenomenology, there are multiple interpretations and modifications of phenomenological philosophy and phenomenological research methodology. However the focus is always to get descriptions about subjective experience from the first-person perspective "in their fullest breadth and depth". [17]

Phenomenological Case Study

Concept of *Light Strings*

Bodily Experience

The idea of considering the body as a main felt medium inspired by phenomenologists, Merleau-Ponty [18], Varela [19], and Johnson [20] has been a strong motivation for me to create interactive environmental works. Treating "Body" as not separated from the being who experiences an interactive work was critical while I developed my ideas of immersion. In *Light Strings*, bodily and sensorial aspects of the immersive experience were emphasized as one of the key properties of immersion. The participant's body connects to the physical and virtual world through movement. Movement that occurs within an environment makes intimate connections and interactions with aspects of that environment. I built an immersive environment that makes an immediate connection to the body. There is no direct sensory mapping for interaction. Any kind of bodily movement affects the environment and computational system, creating unique but varied qualities. To pursue this concept, I focused on the creation of a physically immersive installation.

Physically Immersive Space

In *Light Strings*, I tried to create a physically embracing space that is flexible and open, and provides participants with free movement in the space. Participants and multimedia agents co-exist and meet in *Light Strings* through touching and using their whole bodies. Full freedom of physical body movement, creating relations to the physical installation and a virtual world is a critical condition of *Light Strings.*

Since I create physically immersive environments that engage bodily experience, materials are very important for me as an artistic media. Physical materials are simple, direct, and apparent in and of themselves. Once they are combined with digital technology, materials are no longer simple. They become complex, integrated and interconnected and these new relationships create their own beauty. When they move, responding to the participant's motion in varying scales from wearables to environments, they can provoke a strong visceral feeling. The branching and joining of physical material and technology in my work echoes the symbiotic relationship between human and technology, exploring the idea of "hylozoism" [21] or life from material. In the process of art creation, fiber optics are not simply cold plastic strands to me. They live in the space the same as other computer generated interactive elements and participants as well as myself. This encourages active, self determined relationships within a work of art.

Implementation of *Light Strings*

The physical space of *Light Strings* (Figure 2) consists of over 2500 strands of fiber optics hung from the ceiling. I used custom produced, straightened fiber optics. Each end of the fiber optic strand was directly mapped to a point in the projection grid.

Figure 1. Audience Interaction with *Light Strings*

The interactive system design began with observations of participant experience. First of all, I tried the environment by myself with my collaborators. This exploration provided an ability to understand the range of movement possible in the space. Then, I invited a participant and observed their movement in the space without any interactive elements. I was able to classify their movements into four categories: ambient, exploration, play, and meditation.

- Ambient mode: no audience in the space.
- Exploration mode: slow walking
- Play mode: very active, fast movement
- Meditation mode: very slow or static movement

Based on this categorization, my sound collaborator and I started design behaviours for virtual agents (visual and sound) responding to participant behaviour by referencing the modes of movements. In addition, the agents' own behaviours were also designed. Similar to other living beings' behaviours, they come together, fight, and ignore each other sometimes.

Interactive System Design

The setup of *Light Strings* is a combination of three groups of equipment: a motion tracking system, a visual system, a

sound system as well as a fiber optic structure. The motion tracking system consists of a computer (Macintosh), two video converters and two infrared (IR) cameras hung on the ceiling grid. The computer continuously tracks participant's movement in the space, and analyzes the movement and sends the movement data to the visual and sound systems. The visual system consists of a computer (PC) and a projector that projects visual data on the grid of fiber optics bundles. The sound system has a computer, the audio interface and four speakers. M-Audio, an audio interface, spatializes the sound processed through the four speakers.

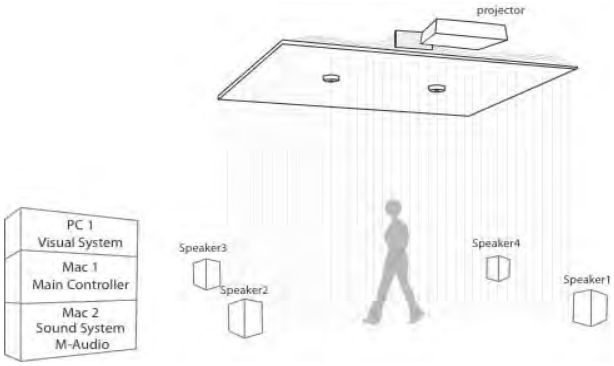

Figure 2. Technical Setup for *Light Strings*

Motion Tracking System
Two IR cameras detect the participants' motion in the installation. The light emitted by the fiber optics has a low level of infrared spectrum. This allows the use of IR cameras for tracking the movements of visitors in the space. Video images from two IR cameras were stitched together and the custom created application provided variables to produce interactive virtual agents. The visual and sound system received these values over the network and generated the interactive multimedia.

Visual System
The visual system consisted of a PC and a projector. The graphical aspect of visual agents was implemented using Processing. In the graphic environment, 8 to 10 visual agents are created and they move around depending on their characteristics and behaviours assigned to them initially. There are two kinds of visual agents: active and inactive. Two different colors (pink and blue) represent their characteristics. The pink ones behave actively and the blue ones are inactive. Their initial characteristics (color, size, movement, speed) may be changed in response to the participant's behaviour. All visual agents have circular shapes. Their sizes are randomly assigned between 80 to 100 pixels in diameter. The initial active agents (pink) are floating around in the space. They move faster than inactive agents (blue). They are curious and friendly beings and they explore the environment very dynamically. When they hit each other, they bounce off each other. The inactive agents are slow and less friendly beings. They tend to gather in one area. They are not interested in other beings in the same space. They don't care about the pink ones or the participant.

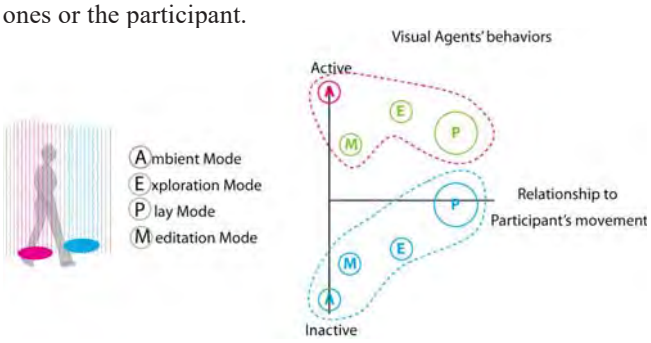

Figure 3. Diagram of the visual agents' behaviors

The images of the agents rendered by the system are projected on to the ends of a bundle of fiber optics. The fiber optic strands that fill up the installation space create a tactile light space allowing the light animation to move in the fiber optics hanging around the space. The behavioral movements of the agents create the illusion that they are alive.

Sound System
The sound system works along with the visual system to create an immersive environment. Our goal was to create natural but elemental sounds that respond to the participant's movement. They work as environmental sound agents similar to air in that they move around regardless of human existence and people can feel them through the movement of their bodies. The environment contains initial sound elements from white noise in Max, a visual programming language for music and multimedia. They are activated when the participant's movement is detected in the space and come and go while interacting with the participant.

Study Design

In the study, I focused on getting participants' experience from their first-person perspectives. To support the subjective first-person data, other data collection methods such as interviewing (second-person) and video recording (third-person) were also used. I used *Light Strings* as a case study to look at participants' qualities of aesthetics of immersive experience. The overall process can be summarized as 1) gathering a full set of naïve descriptions from participants who had experienced *Light Strings*; 2) analyzing the descriptions in order to grasp common elements that make the experience what it is; and 3) describing or giving a clear, accurate and articulate account of the phenomenon so that it can be understood by others.

Participants and Study Condition
16 participants were recruited through an open email call that was available to the general public. They were given ample opportunity to accept or decline. They were asked to

pay attention to their sensory experience and felt experience. The participants had a chance to experience *Light Strings* three times with different conditions (*Both*, *Visual*, and *Sound*). The physical environment was the same for all three conditions. In the *Both* session *Light Strings* had visual elements and sound elements. In the Visual session, the sound elements were taken away and the participants only experienced responsive light patterns in the environment. In the Sound session, there were no visual images, only a soundscape filled with fiber optic strings. Early test runs showed that the participants' experiences were affected by the order they experienced the three sessions. Therefore I used four different orders of the three sessions to structure the study (Table 1).

Table 1. Four different orders of participants studies

	Session 1	**Session 2**	**Session 3**	**Duration**
4people	*Both*	*Visual*	*Sound*	1:30-2h
4people	*Both*	*Sound*	*Visual*	1:30-2h
4people	*Visual*	*Sound*	*Both*	1:30-2h
4people	*Sound*	*Visual*	*Both*	1:30-2h

Procedure

Participants in the study were asked to experience *Light Strings*, three times for as long as they want to stay. They were free to do anything and there were no time limitations on how long they stayed in the installation. Participants experienced *Light Strings* aesthetically via the artworks' kinaesthetic tactile quality as well as visual and auditory qualities. While the participants were experiencing *Light Strings,* their movement inside of the installation was video captured. *Light Strings* was already capturing the participant's movement from above using two IR cameras to analyze movement in the space in order to create responsive virtual agents that the participants can interact with. Therefore, I was able to record the camera capture screen using another video camera. This video data was digitized and processed to investigate how the participants moved and behaved in the installation. I did not extract the video images from the motion analysis process because recording a video at the same time as analyzing it uses too much of computer's processing ability and made the entire system unstable.

After each session of experience, the light level of the room was adjusted for the next activity and the participant was guided to a writing station. Participants were provided a single card with three open-ended questions: "What did you experience?", " How did you experience?" and "How did you feel?" They were asked to write down their experiences quickly and fearlessly when answering the questions. The quick writing process without analytical thinking helps to extract their subjective experience effectively. The participants were instructed: "think back and describe your subjective experience of the artwork as much detail as possible." They were assured of the confidentiality of the information. They could write, note or draw their experiences in a hand written "journaling" form. This would give the participants the opportunity to take their time and to reflect on their experiences and to reconstruct the event in more detail on their own, without interference.

As soon as the writing session ended, participants were involved in an interview procedure. The participants were told that the interviews would be treated confidentially. The research instruments for the interview was an open-ended method. This protocol focuses on the researcher facilitating the participant in articulating a description of their experience, creating a phenomenological description. Each interview was digitally video-recorded. Video files were marked only with the session number and the participant number. Transcriptions of the interview were used for the analysis of the data. The participants experienced three sessions of the installation experience and wrote three times and interviewed three times.

Data Collection and Analysis

16 participants provided written descriptions of their experience by responding to three questions: "What did you experience?", "How did you experience?", "How did you feel?" (first-person data). Second-person data (of the participants experience) was collected using an interview technique adopted from Petitmengin [22] and Varela [23]. All the participants' bodily movements in the environment were video recorded and digitized (third-person data).

After the collected data were transcribed and coded, I focused on "themes" arising from the data. In the end, all the different themes were grouped for each participant and used to construct a model of qualities of the participant's immersive experience. This allowed the individual models and general model to be developed concurrently while being compared for validity. Based on the analysis, I constructed a combined model of immersive experience which can be used to develop a further understanding of the aesthetics of immersive experience.

Aesthetics of Immersive Experience

The focus of the research was to investigate the qualities of participants' immersive experience in physically immersive and interactive environments and explore to find meanings created by the experience. During the case study, it became apparent that the participants' experiences in *Light Strings* were immersive. Unlike other researchers' understanding of immersion, I focus on bodily experience engaged with culture, society, environment, and history. My analysis concentrates on building an experiential structure based on immersive consciousness considering temporal aspects.

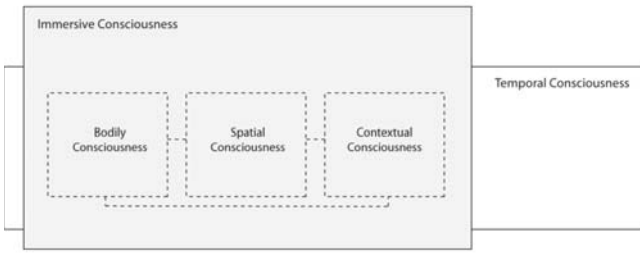

Figure 4. Experience structure of Immersive Experience

Immersive Consciousness

The notion of Immersive Consciousness that is built through my analysis is framed by Bodily Consciousness, Spatial Consciousness and Contextual Consciousness (Figure 4). I describe each of these elements in detail below. I have found that by using this model I am able to recognize similarities in sensorial and felt experience and processes across participants. In this paper, I define consciousness as embodied akin to the way it is defined by contemporary cognitive scientists [24-26]. Our consciousness can be affected by the existence of body or somatic or enactive processes. Therefore, Immersive Consciousness illustrates embodied consciousness as experienced through the body and explains how participants perceive an immersive space and make meanings out of it.

Bodily Consciousness

Body Consciousness focuses on the sensory experience of the participants in *Light Strings*. We learn and understand the world through our bodies. This is not just about a body rather a body in the space and in relationship to the installation. It is always connected to the world we live. Therefore investigating participants' sensory experiences allows me to examine the origin of immersive experience and frame immersive consciousness in terms of embodiment. Since *Light Strings* is a physically immersive installation, the participants experienced and described various sensory experiences including exteroceptive senses (sight, hearing, and touch) and interoceptive senses (proprioception, kinesthetics, and vestibular sense). The bodily consciousness includes mostly sensory experience focusing on what is seen, heard, touched, felt and some emotional valence from the sensory experience. Due to the aesthetic characteristics of *Light Strings*, multiple senses were stimulated and helped to create sense of immersion. Sensual richness helped create a deeper sense of immersion. It is also important to acknowledge that bodily consciousness is closely connected to spatial and contextual consciousness

New Sensations: Awe and Disrupted sensory habituation

Many participants described the experience in *Light Strings* as extremely new and said they never had a similar experience before. This was connected a feeling of being overwhelmed in the sense that their experience was sensorially very stimulating (awe).

> *"It was really hard to think of other things during that. I was sensorially overwhelmed by how cool that was."*

In *Light Strings*, the habituated perception of not being aware of any tactile feeling when we walk normally became disrupted. *Light Strings* is filled with fiber optic strings at a distance of three inches from each other. Therefore, any movement in the environment causes the fiber optic strands to touch the body. Descriptions from participants revealed feelings about new sensations that they did not experience in a daily life.

> *"It was like experiencing air"*

From this reawakened sensory experience, many sensory descriptions were collected. The descriptions focused on heightened individual senses. Sometimes senses were associated together and the participants experienced what might be described as a form of synesthesia, that is a recombination of their senses.

Associated Senses

Many of the participants said that they noticed two sensations at the same time. Senses worked together. In particular, the *Both* session showed a combination of sensory elements that really came together effectively. The associated sensations helped the participants to get engaged and immersed in the environment and created emotional and imaginative experiences. When the participants noticed two or more sensations at the same time, they often constructed associations and found meanings.

The tactile modality functioned primarily to integrate with the other senses. When other senses (visual or sonic) are prominent, the tactile sense intensifies those senses. In addition, the physicality and materiality of the fiber optics extended and enhanced the perceived quality of dynamicism.

> *"As I was moving through the fiber optics I just felt again that tactility but also the visual beauty of the lights combining together and moving away. And so that really had my focus for a really long time."*

Spatial Consciousness

Many participants described *Light Strings* as a space not an object. This is important that they perceived it not just by seeing with their eyes but via embodied seeing through the whole body. *Light Strings* provided an opportunity to expand their conscious experience through the space. Participants' spatial consciousness can be characterized by an emphasis on the sensation of a different world, metaphoric space, embodied space, and vast or proximal scales.

Different Space/World

In the installation, many participants experienced a different space/world, very different from outside. Moreover the participants' experiences in each session

were very different depending on the computer generated visuals and sound. At a basic level, the space was physically always the same, only the media changed. In general, where it was visual-centric, the space was perceived as warm, enclosed, meditative space. Many participants described these different worlds using metaphors from their memory, movies, and books.

> *"I feel like I'm in a different space; some kind of entering into another dimension or something – a space that you can explore, but at the same time, you feel like you're floating. You feel the curve and things like that."*

Metaphoric Spaces

After experiencing *Light Strings*, many participants reported that it is difficult to describe their experience in words. In the process of perceiving the space, the participants attempted to relate their bodily feeling to their previous knowledge or experience using metaphors (all 16 participants). Qualities of physical sensation evoked metaphors. The prevalence of metaphors means that as the participants were paying attention to their physical sensations, their imagination generated metaphors for the experience. The richness of poetic description really came from the interplay of their experience with the media of the system. This shows the success of the piece in terms of immersion.

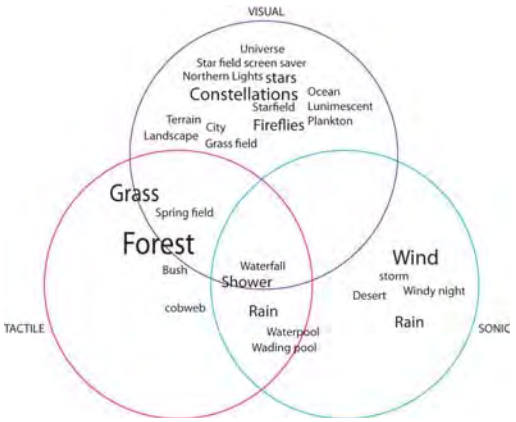

Figure 5. Metaphoric Spaces

Error! Reference source not found. is a visualization of word frequency in the descriptions of the participants' experience drawn from the written responses and interview data. All the metaphoric words for the space were collected and categorized by sensory modality. Some metaphors directly represent visual, sonic and tactile space such as fireflies and northern lights for visual space, wind and storm for sonic space, and bushes for tactile space. However, there were metaphors representing associated sensory spaces such as grass field for visual and tactile association. Different aspects of the sensory experience helped to build imaginative metaphoric spaces.

Embodied Space

Space is often defined by constituent and their behaviours: how inhabitants make a connection to environmental behaviors and how they frame it constitutes their space. If we look at *Light Strings* in terms of experiential qualities, it can be interpreted as a playful and meditative space. The most obvious qualities that the participants felt from the space were playfulness and meditativeness. These were characterized by the participants as extremely embodied. In the descriptions of the participants' experience, two different spaces (playful and meditative spaces) were being appeared depending on interaction with the environment.

> *"It felt very playful, kind of organic experience. It was very flexible and fluid and promoted my curiosity and sort of seemed to engage back because it was responsive and I really liked that. I just felt very open to it and sort of calm and curious at the same time."*

> *"Very small like um..at one point I just started collecting one string with another string and looking at it and then another string..it's like watching insects. As opposed to running around in a forest trying to climb trees. That's kind of the experience, it's more quiet, more gentle, more detail.*

Different Spatial Scale

The most interesting phenomenon of the immersive experience observed was that the participants perceived the space at widely different scales. *Light Strings* was perceived as two environments (vast and proximal) at the same time. The idea of multiple worlds means that the participants were able to connect to the physical sensation of vastness at the same time as noticing intimate poetic extrapolations. The specific amount of space in the installation was really contained. The participants were contained within the space but their subjective responses expanded beyond it. However, the space was often sensed and perceived as differently sized in a positive sense, evoking a feeling of wonder.

Discussion and Conclusion

Light Strings is a minimalistic but physically surrounded environment: it operates as part of a phenomenological case study. In the project, the physically immersive environment was created using fiber optic strings, with interactive components projected through the fiber optics and a surround-sound system. Due to the artistic use of fiber optics, kinesthetic tactility was found to be the main sense used in experiencing *Light Strings*, in association with other senses. The study reveals the primary qualities of *Light Strings*: connection, engagement, and attention. *Light Strings* became a medium for creating the participants' narratives by provoking metaphors. The participants brought various narratives and images related to nature and natural experience from the memories, books, and movies. Immersive environments like *Light Strings*

provoke the participants into being creators instead of passive receptors.

The whole experience in *Light Strings* can be interpreted as a meaning making experience with an immersive property that is co-constructed by the environment and participant. In the model I elucidate in this paper, immersion consists of bodily, spatial, and contextual consciousness. This model suggests how to explore immersion as a meaningful experience. My research journey through this model shows that immersion is not only present in virtual reality environments but also in physical but interactive realities that strengthen body, space, and contextual consciousness. This is very critical. I believe that awareness of our immersive experience will provide a highly promising path for transforming all fields of human experience, including the artistic, medical, pedagogical, and entertainment fields.

Abstract

Utilizing the tactile sensory channel as a key sensory modality in a full body, cross media artistic installation presents unique challenges. In this paper we describe our experiences with the design and utilization of garments containing embedded sensors and vibrotactile actuators. We follow the garments from their conception through their use in a artistic installation experienced by over 300 visitors. In particular, we focus on the relationship between touch, hearing, and sight – both in the technological implementation as well as the artistic conception.

Keywords

Multimodal display, haptics, wearable electronics, responsive environment, first person data, sensory participation

Introduction

This paper presents the dual outcomes of a research-creation project whose focus was developing a system for generating tactile signals in an artistic experience. The first outcome we will describe is the design and construction of garments containing embedded sensors and vibrotactile actuators as well as a wireless connection to a central server which transmits performance instructions. The second outcome we will describe is the artistic work which utilized these garments, a performative environment incorporating visual, aural, and tactile elements.

Participants

The team involved in this project consisted of artists, clothing designers, electronics designers, and haptic researchers. As in any collaborative interdisciplinary project the outcome depended upon a careful balancing of the multiple interests and priorities of the participants as well as the practical constraints of the project structure. Throughout this paper we will touch upon the disciplines of the different collaborators and the ways in which their contribution affected the creation of the garments. While much of our discussion will be focused on the characteristics of the tactile actuators which are embedded in the garments, we will also touch upon general issues raised by the inclusion of a garment of this kind worn by the general public (rather than a trained model or performer) within the context of an artistic installation.

Figure 1: Promotional Image for Ilinx. ©Chris Salter

Ilinx

'Ilinx' is a performative environment for the general public provoking an intense bodily experience that blurs the senses of sight, sound and touch. A promotional image for the work appears in figure 1. In the environment, a group of four visitors at a time wear specially designed garments. These wearables are outfitted with various sensing and actuating devices that enable visitors to interface with the performance space. During the event, a ritualistic progression which lasts approximately twenty minutes, the natural continuum between sound and vibration, vision and feeling becomes increasingly blurred, extending and stretching the body boundaries beyond the realm of everyday experience.

The project is partially inspired by work in the area of what is called sensory substitution – the replacement of one sensory input (vision, hearing, touch, taste or smell) by another, while preserving some of the key functions of the original sense. The term "ilinx" (Greek for whirlpool), however, comes from the French sociologist Roger Caillois and describes play that creates a temporary but profound disruption of perception as is common in experiences of vertigo, dizziness, or disorienting changes of speed, direction or the body's sense in space – "an attempt to momentarily destroy the stability of perception and inflict a kind of voluptuous panic upon an otherwise lucid mind." [2]

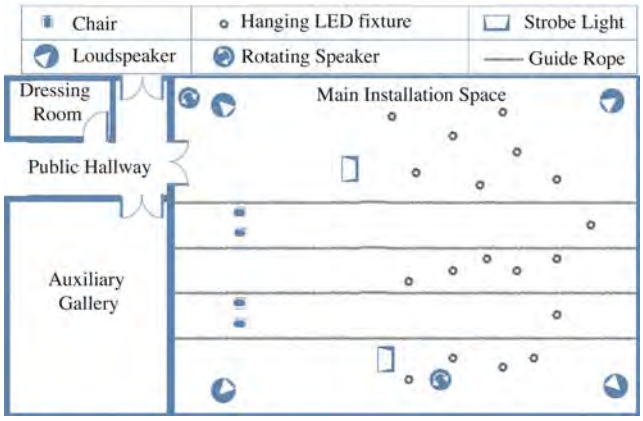

Figure 2: Diagram of the Ilinx installation space.

Figure 3: Participants in the Ilinx installation. ©Chris Salter

The garments worn by the visitors consist of a jacket, a pair of leggings, and a helmet with a semi-opaque full-face mask. The helmet serves to limit the visitors' vision to the perception of areas of light. Once garbed, participants are led into the main installation space and seated in chairs, as shown in figure 3.

The work is structured into two sections. The first section begins with a simple vibration pulse and corresponding sound. The sound is generated by a combination of a quadraphonic full-range speaker system as well as a pair of directional speakers each mounted on a rotating gimble. Throughout the first section new sonic material is introduced. A loud bell and the appearance of faint lights in the distance signal the beginning of the second section. In this section, visitors are able to stand and take hold of guide-ropes which allow them to safely explore the space. As they walk into the space they pass through a field of suspended LEDs as seen in figure 2. Towards the end of the second section bright flashes from a pair of strobe lights contrast with the faint illumination of the suspended LEDs, and build towards a gradual climax. After a final combination of a loud sound, flash of light, and set of vibrations the piece comes to an end. At that point the visitors wait where they are for a guide to come and lead them out of the space.

Background

Although there are numerous examples of multi-sensorial artworks which incorporate tactile stimuli (normally in the realm of "tactile audio"), the implementation and conceptualization of a system for generating these stimuli remains a challenge. [15, 6, 17] Conceptually the tactile sensory channel is very different from the aural and visual channels. Not only are tactile sensory receptors located throughout the human body but there are also multiple types of tactile receptors optimized for different kinds of stimuli.

The Haptic Channel

Haptics is an umbrella term which encompasses both tactile and kinesthetic perception. The former is issued from a complex network of mechanoreceptors which are located with varying densities all over our skin. In the most sensitive areas, such as the hands, we can count up to 10000 mechanoreceptors per limb, while in other areas (mainly hairy parts of our body) the density of tactile receptors is much lower. [23]

Four types of mechanoreceptors have been identified, each of which contributes to sensing specific features of a vibrating stimulus applied to the skin. Much research has been devoted in the last decades to identify what these features are, specifically in terms of frequency and amplitude range of perception. For glabrous skin, it is commonly stated that the skin is sensitive to stimuli from 40 to 1000 Hz (with a peak at around 200 Hz), and that amplitude perception can be as low as 1micrometer displacement. [4] These values have been mostly gathered from perceptual studies involving simple, sinusoid-like vibrating stimuli; more recent research though seem to indicate that for more complex signals (i.e. signals with richer spectral content) the upper limit might be higher than 1000 Hz. [3]

Tactile Perception in Art Installations

There are certain types of tactile stimuli which can be conceptualized as similar to visual and aural stimuli. Perhaps the most common experience of this are the vibrations created by high-amplitude low-frequency soundwaves. These sensations tend to be experienced as emanating from the environment, and not as being localized on a specific body part.

Previous projects developed by Salter, including *Just Noticeable Difference* and *Displace 2.0*, present a different approach to this kind of single-signal whole-body stimuli. [18, 19] In these project audio transducers designed for low-frequency signals are attached to platforms. When participants lie or sit on these platforms the vibrations are transferred to their body.

Conceptually, we can create an analog between the difficulty we have determining the directionality of low-frequency audio signals with the difficulty in determining the location of high-amplitude low-frequency vibrations. However, there are key differences. For example, in the platforms described above, the participant's ability to consciously change their seated position causes different parts of their body to come in

contact with the platform. The change of sensation generated by this kind of movement enable them to locate the vibration as coming from the platform rather than from the environment. This creates a different kind of immersion from that of an immersive sound- or colour-field. One consequence of this is a limitation to the creative possibilities presented to the artistic creators, in that any sequenced tactile stimuli will be filtered through the unpredictable coupling of the participant to the vibrating platform.

Another way in which tactile sensations can be viewed as analogous to visual and aural sensations is through the concept of sensory translation or sensory substitution. A classic example in this sense is the early work of neuroscientist Paul Bach-y-Rita, who theorized that it could be possible with sufficient training to re-map the visual cortex in the brain of a blind individual to another sensory organ such as the skin. [1] This led to the development in the late 1960s of a prototype of a tactile augmented chair: an array of solenoids attached to the back of the chair would be connected to a videocamera, and display on the back of the subject seated on the chair a *tactile translation* of the image. Scientists involved in the project reported that after some training participants would be capable of recognizing basic shapes through the display.

Of course many artworks incorporate tactile elements which are chosen for their own unique qualities. In Louis-Philippe Demer's "The Blind Robot," for example, a visitor sits in front of a (pseudo-)robotic arm. [5] The arm then reaches out and explores the face of the visitor. While exploring the sense of presence and engaging in a non-verbal dialogue, the main tactile elements of the piece remain the surfaces of the robotic arm as it touches the visitor's skin. Artworks such as this have the benefit of creating systems which can provide specific and highly-detailed tactile stimuli. However, they are limited to only creating the specific stimuli for which they are designed. Conceptually one can imagine them as similar to creating a bell carillon, or any robotic musical instrument whose material properties are fixed.

A different approach to creating a system for tactile stimuli is to have the system itself correspond to the primary characteristic of systems for visual and aural stimuli production. We have the expectation that a stereo speaker system, for example, will be able to create sounds that utilize the full-range of our hearing. This means not only reproducing the perceptible frequency spectrum but also reproducing appropriate amplitude levels as well as spatial location.

A tactile-stimuli system, therefore, should be also able to engage the full range of our tactile senses. In theory this would mean being able to recreate any form of tactile sensation which we might encounter in the real-world. This would require an equal engagement with all of the locations of tactile receptors on our body, with appropriate frequency and amplitude capabilities for each location on the body. In addition, the tactile stimuli created should be able to engage with the different kinds of mechanoreceptors described above.

It should be clear that the creation of such a full-range tactile stimuli generator presents a formidable challenge. The system we designed in no way comes close to fulfilling all of the requirements for such a system. Nonetheless, the design approach we describes one way to attempt to reconcile the requirements of such a full-range tactile stimuli reproduction system with the practical implementation necessary for artistic use.

Immersive Sensory Installations

Ilinx's focus on the combination of vision, sound and touch seeks to go beyond the A/V emphasis of most "immersive" media environments where "surround" is usually defined as an image encircling the visitors. [8] In this sense, with Ilinx's emphasis on exploring perceptual disorientation through cross-modal effects among different sensory modalities beyond vision, the installation participates in a larger critique of visuality that has been introduced by researchers in both new media and in the area of sensory anthropology. [10, 11] Simultaneously, Ilinx builds on and extends several previous projects from Salter and Martinucci that focus on cross-modal sensation, including the above mentioned *JND* (Just Noticeable Difference), and the multi-sensory environment *Displace*. The installation JND, for example, explored how the distinctive modalities of the acoustic and the haptic could be combined within a singular technological and perceptual framework, in particular leading to design choices that emphasized both the separation and combination of both modalities. For example, in designing sound structures that were interesting from both a sonic as well as tactile perspective, the creative team set out to work with material that was not easily representational (i.e., presenting a likeness or reference) and, at the same time, created a strong visual as well as aural sense of space. Tantamount to this was using sound to give the impression of different spaces that would shift from one moment to the next; something particularly important given that any common visual experience of space would essentially be thwarted due to the extreme darkness encountered in the installation environment. This "sense of space" carried over into the creation of specific tactile sensations, particularly the manner in which visitors could feel different tactile patterns on the body and how such spatial patterns could be modulated from clearly perceivable to essentially noise. The focus on immersion not as surround but as something which has tangible embodied presence, that operates on different bodies to produce potential affects is one of Ilinx's major points of departure from both "tangible audio" - based sound as well as immersive media installations emphasizing vision and audition over other sensory modalities.

Tactile Augmented Garments

In terms of the garments developed for Ilinx, several tactile-augmented garments have been produced in the past decades both for research and industrial purposes. We can identify two main categories of devices: performance/entertainment displays and navigational displays.

The first category covers tactile-augmented body suits conceived to be used in performances and art installations, or for enhancing user experience while consuming media such as cinema or tv. Gunther et al. developed a tactile suit intended to be used to compose music for the sense of touch. [9] This *tactile music* would be composed to accompany a regular musical piece and would take advantage of the suit designed for

the project. Eleven actuators of different size and power embedded in the suit would be attached to the body of the audience by means of velcro bands. Participants would experience vibration directly correlated to the musical piece composed for the installation. In another implementation, Lemmens et al. design a tactile augmented jacket featuring 64 vibrating actuators to be used for entertainment. [14] The actuators are arranged in 16 independent modules of 4 actuators each and are controlled by a custom software allowing an intuitive design of tactile effects.

In the second category, much industrial research in the field has been driven by potential military applications. Van Erp et al., for example, developed a tactile augmented belt designed to indicate waypoints to impaired users. [21] In this system, a vibrating signal would indicate the direction in which the user has to move.

Piateski and Jones developed a tactile display to be installed on the torso of the user and composed of a 3 by 3 matrix of vibrating actuators. [16] Several patterns of activation of the nine actuators have been tested to convey movement instructions to users. This type of device could be extremely beneficial to visually impaired users, and could take advantage of the haptic channel to receive information about the surrounding environment.

Development of the Ilinx garment

The primary objective at the beginning of the Ilinx project was to more fully engage the haptic channel in an immersive, multi-sensory artistic installation. From the earliest stages our goal was thus to create a garment which would allow for tactile stimuli over the whole of the participants' bodies. In order to create the most immersive and versatile system given the constraints of this project we leveraged contemporary research in haptic perception as well as a modular approach to electronics design.

Leveraging Contemporary Research in Haptic Perception

As previously stated, tactile receptors in the skin are not evenly distributed across the body. This, together with other perceptual effects, limits the number of both spatially and temporally close tactile stimuli that can be perceived as being individual events. For instance, after a prolongated exposure to a tactile stimulus at the same amplitude and frequency, mechanoreceptors eventually stop responding to the stimulation, producing an *adaptation* effect which makes subsequent stimuli go unnoticed. *Masking* effects can also happen when the second stimulus presented too temporally close to the preceding one is not perceived correctly.

The literature on tactile perception states that the average interval between two stimuli is 18ms in order for them to be perceived as separate events, and that the spatial resolution largely depends on the body part being stimulated. [3] Hands and feet remain the most sensitive parts, while torso and forearm for example are much less sensitive. [21]

Other important perceptual effects are so-called *tactile illusions*: for instance, by calibrating the delay between subsequent stimuli one can simulate a motion on the skin of the interested body part. This effect is generally known as *the cutaneous rabbit illusion*. [7]

All these considerations played an important role in our design of the tactile garment and control signals. The number of actuators was limited to 6 per limb, so not to overload the haptic sensory channel with too closely spaced stimuli. The distribution of the actuators was conceived to foster the emergence of tactile illusions such as the cutaneous rabbit: the actuators were disposed on straight lines on the limbs and across the torso to produce illusions of vertical and circular motion on the body of the participants. In our pilot user studies we demonstrated that by varying the temporal delay between actuations and the overlap between each motor actuation, we could progressively move from stimuli perceived as separate events to more continuous ones. This worked particularly well in the vertical direction, while the illusion of a circular motion across the torso could not be consistently produced.

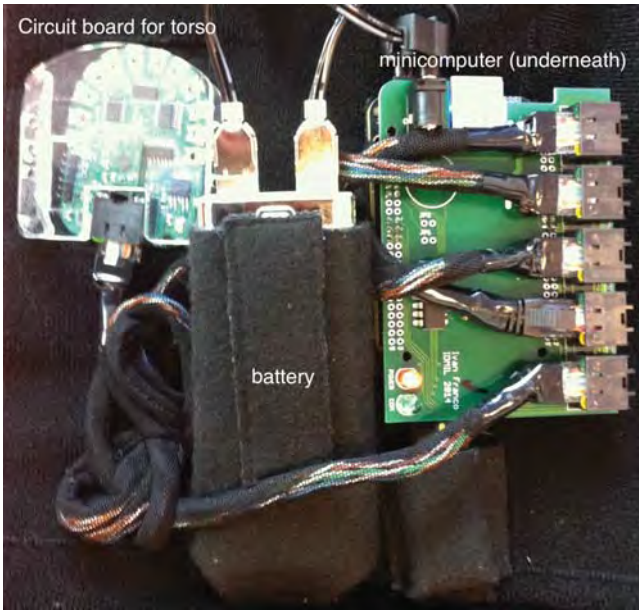

Figure 4: Electronics in the garment. ©Ian Hattwick

Visual Aesthetic

Visual aesthetics also played a strong role in the experience of the wearer and hence, the design of the Ilinx garments. An important consideration from the start was that the garments work as aesthetically pleasing and desirable objects, which could be read, understood, and accepted as a garment as opposed to a technological apparatus. Another consideration was that the garment be unisex so that it could appeal to and be worn by both men and women. The design was inspired by minimalist japanese fashion, such as the clothes of Comme des Garons and Yohji Yamamoto, and executed in muted tones of black grey and dark blue to adhere to the overall installation colour palette. The final design was a deconstructed suit jacket and two separate leg coverings that recall chaps.

Practical considerations

The use of the garment within a public artwork to be presented less than one year after the origination of the project, lead to a formidable set of practical considerations that needed to be taken into account by both designers and engineers within the project. Foremost among these considerations was the durability and stability of the system, concerns with battery life and maintenance, and manufacturing time. A detailed discussion of these issues is contained in forthcoming publications, which address issues including battery management, manufacturing scaling, and useability design.

Wearable Considerations

As demonstrated by previous works employing garments worn by audience members, numerous practical considerations come into play when designing for the body, performance, and multiple-users. [13] As the garments were to be worn by both women and men, sizing had to be adjustable to both sexes and accommodate a wide variability in form and size, including variations in the size of torso and the length and circumference of the arms and legs. As it was important that the garment rest comfortably on the body to maximize the contact points with the vibrotactile actuators, the final design was inspired by athletic and injury braces utilizing velcro or elastics to wrap around the body tightly. The garment parts were reduced to the smallest textile surface needed to house and contain the electronic circuits, which was combined with adjustable velcro straps. A second and equally important consideration was the efficiency and ease of putting on the garment over existing clothes, thus permitting the participants to remain in their clothing, as well as to minimize the need to launder the costumes after each performance or use. Furthermore, it was important that the guides would be able to, with a minimum of assistance from Ilinx staff, quickly put on and remove the garments without damage to the wearables.

Final Implementation

Here we provide a brief description of the construction of the Ilinx garments.

Technical Description

Each garment is embedded with a total of 30 motors divided into 5 groups, located on the four limbs and the torso. Each motor group has its own custom circuit board to generate the signals used to drive the motors. This board also includes a 9 DoF inertial measurement unit which can be used to derive orientation. The five driver boards are then connected via cat6 cable to a central processing-unit, implemented using the BeagleBone Black single-board computer. The BeagleBone Black, battery pack, and driver board for the torso are all contained in a pocket of the front of the garments jacket as seen in figure 4.

As depicted in figure 5, each garment communicates via Wi-Fi to a central computer. This central computer receives sensor data and sends control information for driving the motors.

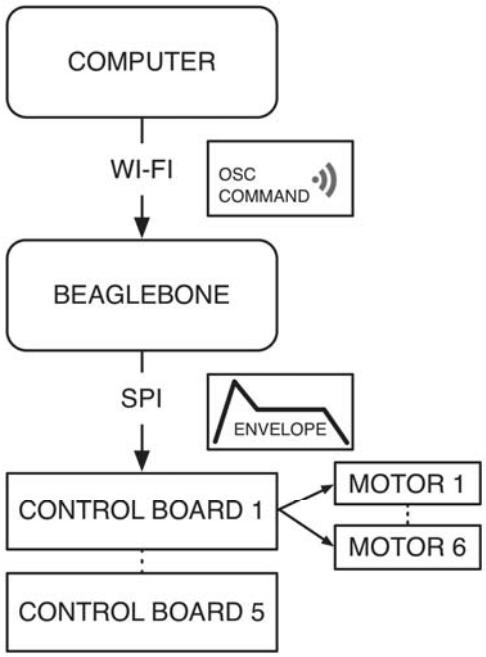

Figure 5: Signal flow showing the central computer communicating with a single garment.

Control Signals

Each motor is driven by a varying PWM signal whose parameters are determined by an amplitude envelope. The job of each motor driver board is simply to translate incoming amplitude envelopes into the appropriate control signals for the motors.

While it is possible for the sequencer on the central computer to generate individual amplitude envelopes it is more efficient as well as conceptually appropriate to produce tactile signals in groupings. These groupings might be intended to create a single perceptual effect, for example controlling sequentially controlling motors laid out along the length of a limb to create a sensation of a vibration moving linearly. When composing an effect in this way it is useful to think in terms of beginning point, end point, overall amplitude, and duration. A sub-algorithm can then be used to generate the individual motors amplitude envelope in real-time.

Wearable construction

In developing the circuitry for Ilinx a number of parameters shaped the final design outcome. The overall weight and flexibility of the garment dictated that we create soft e-textile circuits that could be sewn directly onto the garments, as opposed to relying on rigid and bulky wires. A very low resistance thread was chosen and sewn with a conventional machine to create the circuits. In general, the principal weak spot in e-textiles is often the junction between hard to soft circuit components. These connections can easily come undone and cause electrical or communication drops and breaks. With this weakness in mind a 3D printed casing was designed to

contain the actuators so that they could create a robust hub between the hard motors and soft conductive thread. The wires from the actuators were soldered to metal ring terminals which fit on top of circular cutouts in the housing. Conductive thread was then embroidered around the ring terminal which made the electrical connection as well as secured the housing to the garment. This proved to be a very efficient solution as we were able to sew the motors and e-textile circuits together onto the inside surface of the garments, providing a close touch contact between the motors and wearer without the bulk of wires or any issues of lost connection. Finally, after a series of tests, it was determined that a light lining fabric was needed to protect the e-textiles circuits and actuators from getting caught on and pulled by the wearers' garments or accessories while they were dressing.

Initial Presentation of Ilinx

The initial presentation of Ilinx was from September 25-28 at the TodaysArt 2014 festival in The Hague. Over four days more than 300 visitors experienced the installation while wearing the garments. To help meet the challenge of helping that many people don and remove the garments TodaysArt organized shifts of four volunteer guides. Not surprisingly, the interaction of visitor and guide played a key role in the participant's experience.

Figure 6: Visitors being dressed by the volunteer guides. ©Ian Hattwick

Visitor / Guide Interactions

Clearly, the visitors' experiences were highly mediated due to the use of the garments. The most obvious factor was the limited number of visitors able to experience the installation at one time. Six garments were constructed, with the intention that four visitors at a time would visit the installation. In order to create an orderly and planned dressing/undressing period, visitors were asked to make an appointment via on online appointment calendar.

On the first day few appointments were made, as many visitors had yet to find out about the installation and the online appointment system. On subsequent days, however, most of the appointments were quickly filled. Approximately 80% of appointments were kept which allowed for a limited number of stand-by visitors. By the last day the dressing room was a very social environment due to the number of people waiting for their appointment or hoping to fill-in for a missed slot.

The first experience visitors had once they arrived was usually a period of waiting for the previous round of visitors to return from the installation and be undressed. While the volunteer guides were asked not to volunteer information regarding the experience, the visitors still were curious to discuss the reactions of the previous group as well as see the garments being worn before they themselves were dressed.

This injunction for the guides to not volunteer information contrasted with the highly intimate acts of dressing the participants as seen in figure 6. Since the garments contained embedded electronics and consisted of three parts with associated wiring, visitors were asked to not dress or undress themselves. Typical guide/visitor interactions during the dressing phase consisted of visitors asking for information regarding the installation and not receiving any answer, while the guides were adjusting straps and fastening jackets and leggings while asking the visitors how they felt. The final step of the dressing process was the placement of a helmet with a semi-opaque full-face mask which served to limit the visitors vision to detecting areas of light. Once the helmet was in place the guide would take the visitor by the hand and guide them to a spot along a wall, where the visitor would wait until the installation was ready to begin. A picture of participants dressed, positioned along a wall, and ready to enter the installation is shown in figure 7.

When all four visitors were dressed the guides would take their hand and lead them out of the dressing room and a short way along a public hallway to reach the door to the installation space. The installation space itself was pitch-black at the beginning, so once entering the space the visitors were entirely blind. The guides would then lead the participants to chairs located on one end of the installation space, where the visitors would be seated. Each guides would then quietly issue a short set of instructions to the visitor they led in. The instructions indicated where the guide ropes were located and what signal to listen for in order to indicate that it was okay to stand and traverse the installation space.

At the conclusion of the 18 minute event, the visitors would wait for the guides to come and take them by the hand and lead them back to the dressing room. At this point the helmet would be removed and the undressing procedure began.

By requiring this intensive set of dressing/undressing rituals the use of the garments created a specific and highly social environment which bookended the visitors' experiences. In several key ways this augmented the nature of the time spent in the installation proper. The first is that, having seen the previous participants wearing the garments, a visitor would be able to identify themselves as wearing a kind of uniform or costume – a set of clothing which indicates they would

be either playing a particular role or would be stepping out of everyday life. The visual combination of the helmet and garment drew many associations from visitors, ranging from martial arts and riot police to science fiction references. This sensation was augmented by the facts that the suits were strapped tightly to their body (in order to facilitate transduction of the vibrations to their body) and that the garments had a certain weight and feel to them due to the embedded electronics and wiring.

A second key element to the visitor's preparations was the level of trust engendered by the guide/visitor relationship. Elements which contributed to this trust were the intimacy of the dressing procedure, the uneven flow of information between guide and visitor, the lack of vision of the participant, the guides leading the visitors by the hand, and the quiet instructions given once the visitors are seated.

Figure 7: Three of the volunteer guides suited up and ready to enter the installation ©Ian Hattwick

Participant Feedback

In order to evaluate the Ilinx experience from a user-centered design perspective, a series of over 100 collective "exit" interviews/conversations were conducted by one of the authors during the installation's premiere in September 2014 in the Hague. Seeking to reflect on how the visitors' sense perception might have been reconfigured during the installation, we utilized techniques arising from the domain of sensory anthropology and sensory ethnography; what anthropologist David Howes has termed "participant sensation." [12] The methodology of participant sensation involves a collective conversation comprised of discussions and recollections and even reflexive analysis of specific sensations and impressions as the visitors are guided through the process of making sense of the novel sensory interrelationships they have just undergone. In this way, many profoundly eloquent testimonies are elicited. Participant sensation (in contrast to the more distanced "participant observation" found in anthropological or sociological ethnographic work) also aligns with Varela and Shear's argument for the necessity of first person methods or what they label 'phenomenal data' to complement third person methods in understanding the workings of consciousness. We engaged in informal yet recorded conversations with the participants in order to capture in language the kinds of almost indescribable bodily affects that might have occurred during the installation experience. [22] As Varela and Shear have argued, "[b]y first person events we mean the lived experience associated with cognitive and mental events". While third-person accounts "concern the descriptive experiences associated with the study of other natural phenomena," first person methods deal with subjective experience that "refers to the level of the user of one's own cognitions, of intentions and doings, in everyday practices."

The interviews with Ilinx participants revealed a number of similar patterns in experience. More than half of the participants interviewed used the word "floating" to depict their experience during the period in which they walked through the space. Moreover, when describing the transition from sitting and experiencing the purely haptic-driven sensations to walking, the majority of the participants indicated a shift in modalities from touch to vision. Although Welch and Warren's notion of modality appropriateness (a hypothesis that claims that when confronted with an intersensory discrepancy, a conflict between different sense modalities, one sense may "bias" another based on the strength of its particular modality) has been recently challenged in the neuroscience literature on cross modal integration, the fact that many participants forgot they were experiencing haptic sensations when in locomotion and instead concentrated on the position and intensity of the light around them, suggests that there may indeed be something specific to the structure of the stimulus in the modality over the modality (vision or touch) itself. [20] More curiously, a number of participants described intense feelings of disorientation, confusion, and, in some cases, vertigo as the result of both having vision blurred and having to walk into the space itself with little sense of spatial visual or acoustic cues. While not statistically rigorous, these exit interviews reveal a strong set of cross modal correlations between modalities that are normally thought to be separate.

Future Work

It was always the intention that the garments designed for Ilinx would form the basis of further work. As always in projects involving the creation of custom technology it is impossible to fully explore their capabilities, subtleties, and implications within the context of a single project. We are therefore fortunate to have several new projects which will utilize the Ilinx garments or build upon them and which will allow us to explore these aspects more fully.

Haptic Fields A direct followup to the current project, "Haptic Fields" focuses on the creation of shared tactile experiences. How can the sense of touch be shared by participants within a space? Additionally, how can we draw upon cultural and anthropological understanding of touch to help develop technology and artwork to further haptics research? In order

to scale up from Ilinx's limited number of visitors, we are currently exploring game-based scenarios for both small and large groups which involve the social sharing of and transmission of touch-like sensations among different groups.

Sensory Entanglements The idea of the senses as being cultural constructs leads to the question of how members of different cultural groups can share their sensory experiences. "Sensory Entanglements" brings together First Nations/Indigenous and non-Indigenous artists, scholars, and researchers in a unique research-creation project which seeks to elicit, interpret and experimentally model Indigenous ways of sensing as expressed through art and analyzes the distinctive forms of sociality they support. Among the different sensory contexts to be explored, touch and vibration will feature prominently.

Conclusions

While the incorporation of tactile stimuli in artistic work is increasing, the design of a system able to provide a general-purpose set of tactile stimuli remains a challenge in terms of scalability, somatic considerations and cultural contexts which tend to lend focus to visual aesthetics. The work presented here demonstrates one approach to the design of such a system. We recognize that the garment described herein is capable of only a limited set of tactile signals, partly due to combination of the complexity of the haptic channel as well as the practical demands of the context of Ilinx itself. However, for use in the context of a multi-sensorial art installation we found that the capability of the suit is sufficient to allow for the creation of a wide variety of visual/audible/tactile correlations and hence, a powerful affective experience for the participants.

Acknowledgments

The authors wish to thank the former Canada Council for the Arts and GRAND Art and Science funding scheme for the financial support that enabled the project to take place. Additional thanks to Olof von Winden and Remco Schuurbiers from Todays Art.

Abstract

In the last two decades, emerging fields alternately termed Synthetic Biology, Artificial-Life Art, Bio-inspired Design and Smart Materials, to name a few, have acted as loci that spawned new methods for creating novel artworks based on phenomena that is generally described as *"natural"*. At the same time, there has been increasing interest and research in creating differing kinds of immersive environments, responsive architectures and inhabitable worlds. *Grene Epiphytes* is an artwork that grew from an exploration of bio-inspired theories and a rethinking of engaging and immersive inhabitable aesthetics. It offers a perspective grounded in the lineages of immersive artworks and aesthetics that engage participants (not with representations of other life-forms, but) with non-human life-forms, and question the distinctions of human and nature. In this paper, we articulate assumptions and theoretical constructs that inspire our approaches for creating and *"engineering"* this artwork, and address some of the challenges. Rather than creating nature-like experience where humans are assumed to be at a remove, rather than part of nature, the inhabitable environment presented here is focused on a context enlivened by human and non-human entities, their varied responses to each other and to aspects of their intertwined worlds, as well as a questioning of materials.

Keywords

Biomimetic- Performative Materials- Synthetic Aesthetic- Immersive Artwork- Algae- Bio Inspired- living and non-living

Introduction

As interests in interactive immersive environments re-emerge and grow, so too do the ways in which the aesthetic aspects of their design and conception are considered. This move toward interactive, immersive and affective aesthetics is partly generated by a desire to create more engaging and complex levels of nature-like beauty and conceptual interaction.

A set of approaches, each representing slightly different terminologies such as Synthetic Biology, Bio-inspired Design and Smart Materials carry with them certain assumptions about the role of the user, artists and ideas of interaction [20]. Broader processes of interaction that grants a participant's full-body interaction and sensory immersion with emphasis on design and style seem to be reappearing [13].

Nature -assumed to be somehow distinct from the human- has inspired artists and designers for centuries; but recent developments in technology and in our understanding of biological systems have expanded the range of possibilities for combining design and biology. At the same time, questioning the centrality of humans above all other life forms, and its purported distinction from *"nature"* is evident. The so called posthumanism, as well as an increased interest in materiality, sustainability of a planet threatened by humans and renewed interests in *"the nody"* embodiment and the plastic aspects of senses and capabilities that were thought to be static and separate. Taken together, this combination of new and renewed ideas and practices challenge the status quo on fundamental levels, which, in turn, also offer opportunities to reimagine what art and human-made inhabitation may mean and may be.

The postnatural [19] approach between humans, nature and technology becomes more and more apparent within art and design discourses surrounding so-called performative materials and Synthetic Biology. Postnaturalism and posthumanism argue not only new methods, but also fundamentally different ways of being where living and non–living, human and non-human boundaries are breached through cybernetic, biological substrates, systems and contexts. These become, in a sense, palettes, subjects and experiences for artists who are creating novel artworks [13].

The setting for creating such artworks has never been more auspicious. The revelations of systems theories and computation combined with biology (e.g. in the field of Synthetic-Life), has changed our understanding of life. Notions of life and computation has been deeply invested in art and has greatly inspired artists, addressing new approaches to creating art based on the synthesis of life-like phenomena.

Goals and Motivation

Experiences from our childhood persist, almost as specters that overlay our daily experiences: playing with the flow of water in the river, disturbing the marching path of ants, following the attractive and colorful butterflies – beauties to us, but horrific and monstrous bodies for our colleagues.

Some of us leapt off fences; convinced we could, if only we tried hard enough, to fly. These memories became our first motivations for an interdisciplinary research and development of an interactive and immersive art installations.

Our two key areas of interest are Biomimetic and Inhabitation. We draw from biology as a material and inspiration for designing artworks by exploring its unique properties and exploring processes of *"nature"* and radically different ways of being, such as imagining how bees see, how bats taste, how vines might sense the fence they wind around.

What motivate our artistic practice are interests in the synthesis of life-forms and materials that posses life-like properties and affordances. The challenge is how to create an aesthetic openness in which art, life, play, and computation momentarily cohere, akin to fascinating, sublime experiences of nature. In fact this is not a new goal, John Dewey in his book Art as Experience called for *"recovering the aesthetic experience with normal processes of living"* [4].

Background, Concept and Theory

What is Life?

In order to create evocations of nature-like experiences, and aesthetic experiences that involve human and non-human life-forms, ones needs to not only understand and study *"natural phenomena"*, in traditional ways, but one also needs to study in other ways; that is, *to be* and *to be with* non-human life-forms. This implies the expansion of the artists' task — from representing the way nature looks, to expressing and evoking in the manners of how nature works. "*Nature"* has been one of the most powerful sources of inspiration; however, our contemporary notions of nature reinforces our habits of assuming that we are outside of it, more distant from what humans paradoxically see as the original creative force. Therefore, in studying and observing non-human life-forms, we believe it is necessary to be with them in ways that may open our experiences from observing and "*interacting"* with them as still-separate, other beings, — and to nurture alternative ways of being with non-human life-forms.

The question of what life is has been a primary preoccupations for scientists and artists since ancient times, yet no single clear answer is agreed upon as satisfactory by all [9]. Contemporary accounts of life usually include such characteristic features as growth and development, reproduction, evolution and adaptation, responsiveness and autonomy, metabolism, self-organization and emergence [19].

For any explanation of life to be useful for the artists who engage in creating with inhabitable life-forms, that explanation must, in some way, be capable of coping with ways of thinking and being that are also required by an aspect of their medium; in this case, for example, that aspect is a model made by computer-generated prototyping. Computational language may indeed seem antithetical to our enterprise, but at the same time, it makes evident that even computational prototypes must allow levels of sensitivity, adaptation and responsiveness; accompanied by design methods where complex relationships can be analyzed and refined as part of exploratory processes [14].

Bio-Art

Bio-Art is art composed partly or entirely of living, non-human organisms, and/or art created in association with nonhuman organisms, remains in common use as stated by Capucci, Torrani and Gessert [10]. It crosses the line between the scientific domain and the domain of art and it may touch the border between the living and the nonliving therefore it has transcendence boundaries.

Bio-Art is a new direction in contemporary art that explores the processes of life. Thus, it is frequently deployed as one approach to generate and express Synthetic Life. Invariably, Bio-Art employs one or more of the following methods to address how life is brought into real world contexts and how to seek the meaning of life through such interactions with the world [5]: *"(1) the coaching of bio materials into specific inert shapes or behaviors; (2) the unusual or subversive use of biotech tools and process; (3) the invention or transformation of a living organism with or without social or environmental integration."* Bio-Art emphasizes the dialogical and relational (such as cell interaction, interspecies communication, and so on) as much as the material and formal qualities of art (such as shapes, colors and patterns,) [5]. Contrary to traditional art, which generates and produces objects, crafts, or environments, Bio-Art focuses more on its "core materials", which means the organism's development and species' evolution.

Boundaries of living and nonliving

Are there categories of life? Biologists would answer yes, presenting the whole discipline of taxonomy. However, as regards ethical issues such as the moral status of natural or artificial life, the boundaries must be drawn somewhere other than simply between species.

As Christian Martin [2] points out "life" is not a merely descriptive phenomenon but also includes a normative component. He suggests a differentiation of the term life [1] into three steps: (1) *"mere life"* (2) *"prereflexively self-conscious life"* and (3) *"reflexively self-conscious life."*

Even in biology, there is no satisfactory definition of life. Most attempts to describe what life is are limited to a list of functional features of life [17]. Therefore it is hard to define a boundary between the living and the nonliving, even from a scientific point of view.

Disciplinary Boundaries

Bio-Art is a new direction in contemporary art that explores the processes of life. Thus, it is frequently deployed as one approach to synthetic biology, which challenges

[1] The prototype for mere life is that of single-cell organisms, whereas self-conscious life encompasses the experience of a *"self "* in the form of pain. Reflexive self-conscious life entails understanding, judgment and the ability to conclude [2].

biotechnology by applying engineering principles in biology. Synthetic biologists intend not only to understand life better but also to utilize it in applications to minimize and optimize, to variegate and transcend life, to design and to standardize it.

A fundamental trait of synthetic biology is its interdisciplinary character. To be able to deal with the complexity of biological systems, synthetic biology crosses disciplinary boundaries. So does bio-art which, crosses not only disciplinary borders within science but also the line between science and art.

Related works

Invariably, Bio-Art employs one or more of the following methods to address how life is brought into real world contexts and how to seek the meaning of life through such interactions with the world [5]: *"(1) the coaching of bio materials into specific inert shapes or behaviors; (2) the unusual or subversive use of biotech tools and process; (3) the invention or transformation of a living organism with or without social or environmental integration."* Bio-Art emphasizes the dialogical and relational (such as cell interaction, interspecies communication, and so on) as much as the material and formal qualities of art (such as shapes, colors and patterns,) [5]. Contrary to traditional art, which generates and produces objects, crafts, or environments, Bio-Art focuses more on its *"core materials",* which means the organism's development and species' evolution.

In exploring the journey of life and synthesis of life, while certain artists experiment with plants (e.g *Streptocarpus hybrid* by Gessert, 2002), other groups look into *"tissue culture"* (e.g *Digital montage* by Catts and Zurr, 1998), some might also follow the coupling of the organic and inorganic, or the living and the machine (e.g *Victimless Leather* by Oron Catts and Ionat Zurr 2004). Some might look into biological systems of self-organization and collective decision-making, and the process of achieving dramatically varied results with very small alterations in an initial settings. (e.g *Objectivity* by Bar-Shai, 2007) and some might use the living organism as new material for design of inhabitable aesthetics (e.g Alive: New Design Frontiers by ecoLogicStudio) [5].

In our work, we adopted the third approach (*the invention or transformation of a living organism)* during the process of designing algae and its behaviors, precisely because it works in the living, from a single cell to a mammal. Such synthesis uses the properties of life and its materials, changes organisms within specific species, or invents life with new characteristics.

We believe that Bio-Art is not simply about creating metaphorical representations of scientific concepts — it is about using actual scientific techniques, creating hybrids and manipulating live organisms. As Eduardo Kac stated: *"After the age of robotics and digital technology, the new media is biotechnology"* [4].

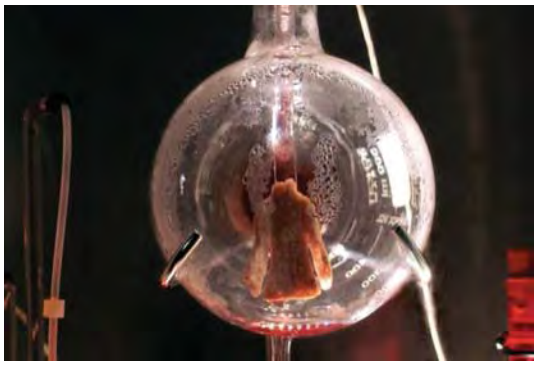

Figure 1. The Tissue Culture and Art project (Victimless Leather), led by Oron Catts and Ionat Zurr, have used tissue culturing in art. Their work features the semi-living: animal cells (which have included frog, human, pig, and mouse cells) that live and grow within bioreactors. The series is an ironic commentary on the positivist promises of growing leather and meat in a vat, without the ethical murkiness of having to kill an animal [5].

Figure 2. Nurit Bar-Shai's Objectivity [tentative]. The work explores the network and communication systems of Paenibacillus vortex bacteria. It explores the intersection of Art, Science and Technology. Using various settings to visualize the "chemical tweets" of microorganisms as beautiful and rare image patterns [5].

Figure 3. Alive: New Design Frontiers is an interactive / living environment installed at the EDF Foundation in Paris. Its morphology emerges from the reinvention of one of the archetypes of architecture, the column; imagined as a living and responsive organism, a photobioreactor of microalgae, ecoLogicStudio [24].

Creation of the artwork

Art as it could Be

To create the aesthetic relationship between living and nonliving, we gather interdisciplinary knowledge that supports the development of an analog computation to study biological behaviors within digital computational systems, including such processes as growth and evolution. This strategy of making possible complex phenomena by simulating simple components is known as a *"bottom-up"* approach [1].

A consequence of a *"bottom-up"* approach may be uncertainty regarding the outcome, but proponents of Artificial-Life are interested in the multiple phenomena that emerges from biologically-inspired artificial processes, even if the results have no direct counterparts in the natural world: an ecology of possible life made or orchestrated by humans rather than by nature. Langton characterized it as *"life as it could be",* in contrast to *"life as we know it"* [7].

The study of *"life as it could be"* has cultural importance; it implies a movement from an anthropocentric view toward regaining a balance with a cosmocentric point of view. This means that humans become one of many possible intelligent beings in the universe, rather than the only one [7]. The suffix *"as it could be,"* indicates a shift in thought and experience beyond the immediately apparent to the imaginable and possible: this lies at the heart of exploratory aspects of our artwork [8].

Our tendency is to find consummation in our experiences, to integrate or crystallize the loose ends of expectations and anticipations into an aesthetic experience. However, we believe that art capable of stirring our usual conceptions in ways that do not fully resolve into an easy experience and understanding has its own merits, ones that may persist beyond the initial experience with an artwork. One may be disturbed, delighted or struck with awe or disgust by participating with an artwork. Such an experience may reflect intensified emotions, and may be remembered as significant. An aesthetic experience is made of the same *"material"* as experience in general, but is intensified, without being arrested, diverted or distracted; *"Then and only then is it integrated within and demarcated in the general stream of experience from other experiences"* [4]. Life is not an uninterrupted flow, but has a distinct rhythm; Art also follows this principle (regardless of the medium), and those rhythms may be dissonant or sublime.

By deepening our knowledge of how nature works, and by questioning uneasiness by redefining ourselves *as* nature, we can integrate life and art in the creation of speculative new worlds capable of engendering more powerful aesthetic experiences.

The installation

Grene Epiphytes is an interactive-living installation emphasizing the sense of aliveness and implying continual changes in living things/organisms.

The morphology of *Grene Epiphytes* emerges from a lattice system housing arrays of clusters filled with algae; a living and dynamic network that arc above and around our attention and senses.

The system employs a series of transparent tubings, which are knotted into networks of a mesh-like structure; these in turn form the bio-matrix, connecting floor to ceiling in an arch-like shape. Living algae is pumped through the textile-like mesh, soaking up the daytime sun. Through photosynthesis, the algae forms a continuum of growth, change and interaction from processes of photosynthesis to harvesting by humans. The tubes, arranged in a textile-like mesh become an inhabitable form not only for the algae, but for human participants as well. The transparency of the tubes, help in directing participant's attention to the living forms and processes of the algae that temporarily *"house"* human participants. In this manner, the Spirulina algae are multiplied food for humans and other animals, co-producers of the very air we breathe, and in a way, keepers of time and transformers of light.

The overall shape of the installation offers an immersive experience for participants: an otherworldly space made of living biological substances and entities. Somewhat unexpected behaviors emerge in continuous motion and exchange in across differing time-scales.

Figure 4. Growing an algae culture and production of different colors with medium and nutrient changes in a lab setting (to test the changing color behavior in exhibition).

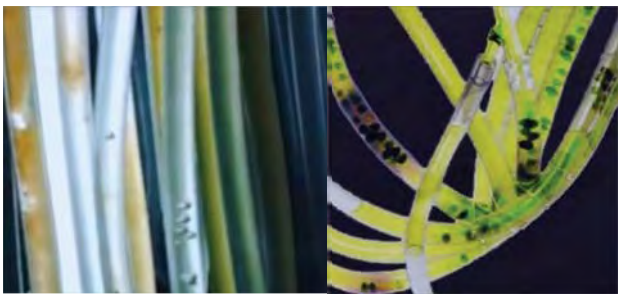

Figure 5. Fidelity prototype of the *Grene Epiphytes* concept using tubings filled with blue-green algae.

The Algae

Microalgae, like any other plant, when grown using sunlight, consumes (or absorbs) carbon dioxide (CO_2) and as they grow, releasing oxygen (O_2) and Biomass (lipids-natural oils).

The flows of energy and growth pattern in *Grene Epiphytes* responding and adjusting to weather patterns and participants movements during the exhibition. With more direct sun, for instance, the algae photosynthesize and grow more intensively; thus transparency, variant colors and the growth are some of the *"products"* of this complex set of relationships among climate, micro-algae, participants and the synthetic control system.

The bio-matrix hosts blue-green microalgae organisms (Spirulina) embedded with ambient light, sensors, actuators and a programmable virtual interface. Flows of energy (natural glowing light in dark), matter (biomass, carbon dioxide) and information (participants behaviors and movement) induce multiple mechanisms of self-regulation and evolution of novel forms of self-organizing algae during the exhibition.

The life of this hybrid organic system tries to marginalize Wilhelm Reich's idea that *"all plasmatic matter perceives, with or without sensory nerves. The amoeba has no sensory or motor nerves, and still it perceives... The terror of the total convulsion, of involuntary movement and spontaneous excitation is joined to the splitting up of organs and organ sensations. This terror is the real stumbling block..."* [18].

Why Algae?

It is now time to overcome the separation between technology and natural phenomena, to embrace its fuller potentials and genius across the multi-levels of design and everyday life. In this artwork, the boundaries between the materials, spatial and technological dimensions have been carefully articulated. The goal is to experiment the notion of hybrid space and the boundaries of living and non-living and to introduce and illustrate one of the natural sources of energy on earth and its efficiency, flexibility and beauty.

Algae are the fastest-growing organic material on the planet (ten times faster than trees). Some species double their volume every 6 hours. Compared to some of the plants that humans grow, microscopic Algae's yield per hectare is considerably higher than that of sunflower or rapeseed. Moreover, microscopic algae are a group of relatively simple organisms that capture the energy of light through photosynthesis, using it to convert inorganic substances into organic matter. Perhaps most surprising is that while humans in industrial mindsets see algae's potential as a form of energy which may replace petroleum (oil), it is also a food, but a food not commonly consumed as other animals do (whales, shrimps, flamingos). Rather, it is packaged and sold as tablets (e.g boosting the immune system, improving memory, increasing energy and metabolism). That algae, then, is not used as a form of common, widely available food, full of anti-cancer properties and so high in nutrients that it would outstrip the so-called *"superfoods"* is curious.

Conclusion

This artwork is intended to reveal the evolving beauty and complexities of a life-form we regularly take for granted and dismiss on the one hand, or to a much lesser extent, revered as a new raw *"superfood"* (in encapsulated form) on the other hand. *Grene Epiphytes* creates ways in which algae transform in our imagination from an annoyance that clouds our ponds and pools to an immersive environment that reveals its own responsiveness to our changing climate and movement of participants. Also the artwork enables complex understandings of its responsiveness and of mechanisms that transform light into the invisible ether we breathe. It emphasizes the many ways in which easy definitions of 'the virtual' and 'the physical' are problematic categories that cannot be maintained, and provokes speculation more on direct experience rather than on abstract concepts of creativity and beauty, and of nature and design. In these and other ways, *Grene Epiphytes* expands recognizable art-forms into more specular experiences of *"art as it could be" [8]*.

Contribution

This research contributes to emerging interests in Bio-Art, nurturing ways that humans and non-human life-forms may explore the inhabitable moments when their perspectives, needs and relations collide and collude. Implicitly, participants are asked to 'a-volve' their imagination and notions of life and evolution as they immerse themselves in physical, intellectual and emotional dialogues with the work. Artwork such as this may also facilitate diverse forms of interaction and alternative understandings among the art, computer science, life sciences and scientific communities. Ultimately, *Grene Epiphytes* may encourage artists and their public participants to further seek out informative resources and multiple engagements with this fascinating form of art.

Author(s) Biography(ies)

Mahsoo Salimi:
Mahsoo Salimi is a PhD student under supervision of Dr. Diane Gromala at School of Interactive Arts and Technology (SIAT), Simon Fraser University. Her doctoral project is about Bio Robotic Architecture and Immersive environments.
Before joining SIAT she was a research fellow at Terreform ONE, working under supervision of Dr. Mitchel Joachim and Maria Aiolova. During almost 6 month residency at Terreform ONE she was part of a collaborative team for BioWall exhibition series: Venice Biennale International Architecture Exhibition 2014, Biodesign exhibition (NAI) in Rotterdam and OCAD gallery University of Toronto. During Spring 2013 she was a Visiting Scholar and Research Assistant at Professor Nikolaus Correll Lab at the Department of Computer Science at the University of Colorado with focus on swarm robotics and smart materials.
She received her Master of Architecture from University of Colorado, where she has started the research on Biomimetic as inspiration for architectural design.

Diane Gromala:
Prof. Diane Gromala is the Canada Research Chair at Simon Fraser University in Canada. Her research works at the confluence of computer science, media art and design, and focuses on the cultural, visceral, and embodied implications of technology, particularly in the realm of pain. Gromala's insistence that her theoretical work is tested in fleshy, messy, meaty milieu results in work that tends to raise and wrinkle brows. She misspent her youth in the 1980s working in the Silicon Valley, mostly at Apple Computer.

Xin Tong:
Xin Tong is a MSc student under supervision of Dr. Diane Gromala at School of Interactive Arts and Technology, Simon Fraser University. She holds a Bachelor of Engineering degree from Beijing University of Posts and Telecommunications. Her graduate research concentrates on how to alleviate chronic-pain patients' pain on the basis of developing Immersive Virtual Environments. Her work focuses on Virtual Environments body interface and wearable technology, and interaction design.

Living media: Transgressing bios, transgressing techne and paving the way to further transgressions

Marta Heberle

Adam Mickiewicz University, IRSA – Institute for Research in Science and Art
Poznan, Poland
heberle@amu.edu.pl

Abstract

It was only a while ago that a clear opposition could be traced between *bios* and *techne*. However, together with the emergence of new branches of science, such as biotechnology, stemming from discovery of the code of life and an assumption, that there exists a certain relevancy, a pattern of relationships between genetic and computer codes were established and developed vastly at the intersection of the two, once distant domains. The silicone versus carbon division ceases to exist. Rather it's silicone and carbon, a come back of the material, of the carbon remediated by data, by codes and algorithms. An immense transgression this type of media elicited is that they are literally alive: living synthetic cells, living tissues, living organisms. Moreover, they transgress classical media theories, philosophical concepts and, when employed into artistic practice, common art theories. They may also pave way for further transgressions such as disruption of the boundaries of species as a consequence of deliberate scientific experiments or laboratory aberrations. In my presentation I would like to address these issues and make an attempt of tracing foundations and goals for the theory of living media

Keywords

Living media, transgression, bios, techne, media theories, art theories, bio art.

The rise of a unique type of media, comprising not only of silicone but also of carbon components mingled together, or to be precise, of organic, often living materials significantly transformed or empowered by the domain of technology, has been long predicted. Suffice to look back at a manifesto by Roy Ascott, first presented as an installation in 2000 in Graz. The piece is a prediction of a moist future, where a convergence of computational systems and wet biological processes will occur: ”Moist media comprises bits, atoms, neurons and genes.” [1] The consequence of the emergence of moist media would be the spread of intelligence to every part of technology as well as tremendous extension of our sensorium: “Between the dry world of virtuality and the wet world of biology lies a moist domain, a new interspace of potentiality and promise.” [2] Several years later, with the rise of molecular biology and biotechnology, this prediction becomes a fact. Biomedia, a seemingly congruent term coined by Eugene Thacker addresses the problem of “technological configurations in which biology can surpass itself.” [3] These processes are never destined to erase the body, the biological through digitization. On the contrary: in the concept of biomedia the bodies are informatic, the information corporeal and the technology disappears altogether. As Thacker explains, biomedia is a constant inquiry into a question of „what a body can do.” [4] It is a perpetual optimization of biology, allowing the body to be elaborated and reformulated. However, Thacker seems to understand the remediation, in which flesh is made data and subsequently data is made flesh in a rather Marxist manner, as a necessary translation of the body into products that serve the body: “The investment in bioinformatics is not purely digital or computational, but a dual investment in the ways in which the informatic essence of DNA affords new techniques for optimizing DNA through novel software, which in turn makes possible the development of techniques for enhancing the biological body via new compounds (pharmacogenomics), new therapies (stem cell therapy), or new diagnostics (patient-specific disease profiling).” [5]

Regardless of the name, when we look closely at physical examples of these media it turns out that often times they are alive: living synthetic cells, living tissues, living organisms. For this reason, I would like to propose a term living media. This designation is far from being easily defined; rather, it indicates an unsolved dispute surrounding the problem of life, and points to endless attempts of distinguishing dead matter from the living in scientifically rigorous definition. Almost every domain of human knowledge, from philosophy, humanities, to natural sciences has been preoccupied with the problem of life, however a consensus was never reached: a single coherent definition comprising all aspects has not yet been developed, the concepts proliferate forming thermodynamic, reductionist or cybernetic definition to name just a few. Edward Trifonov, a researcher at the Genome Diversity Center in Haifa has counted “123 uncertain definitions of this uncertain phenomenon,” [6] all of them equally vague and unsatisfying. This multiplicity at the same time suggests a disturbing potentiality, that life is a phenomenon of relative rather than absolute character. In The Magic Mountain by Thomas Mann we find an enigmatic statement: “What was life? No one knew. It was undoubtedly aware of itself, so soon as it was life; but it did not know what it was.” [7] We tend to say that we know life when we see it. But how is it possible that there is no absolute, universal definition for an apparently obvious problem? Today we are facing an even greater challenge. Not only we have to define what life is, but we are also compelled to reflect upon life cre-

ated by means of technology, upon life that often differs from one we have thus far known and that disrupts our notions of species. These definitions, which in the first place are based on the existing definitions of life, are multiple and leave us with even more uncertainties. Therefore the only way to comprehend living media is to understand them as technological mediations of a phenomenon that according to a chosen acknowledged definition could be described as life.

Before we move on to examining further features and qualities of living media and how they transgress *bios* and *techne* as suggested in the title of this paper, it is necessary to provide a definition of transgression in the first place. In natural language, transgression is understood as a "violation of a law or a principle and the exceeding of due bounds or limits." [8] According to this understanding, the transgression elicited by living media can be perceived as a violation of the agreed borders of knowledge domains; a disruption that destroys their assumptions. Transgression produced by living media results in cognitive doubts because it is a phenomenon so vague and liminal, that it cannot be fully described by designations and models elaborated by either of the domains

It is precisely the aspect of strange, peculiar liveliness that constitutes the greatest transgression to standards adopted by biology and media theory alike. The latter has been focused mainly on conceptualizing means of communication and their impact on various aspects of human life, yet a reflection concerning the medium itself was equally important. The so-called old media, such as radio, telephone or telegraph, by reason of their analogue signal, were still embedded in the material. Then, together with the emergence of the digital and the binary coding system, the media, despite the great mass of servers and storing hardware, became seemingly immaterial and ephemeral. Today, as the bio increasingly merges with the digital, we are experiencing a come back of the material, of the carbon remediated by data. The new media are real, material and factual and, moreover they are often times alive. This leaves media theories confused and limits their competence to speaking only about the process of remediation, which involves computational machines with their codes and algorithms, not of the very results of this process.

For majority of biological concepts, technologically mediated life is seemingly similar to the one that emerged in a 'natural' way, provided that it constitutes a sincere copy, which fits in an established category of species. However when the outcomes of laboratory experiences and aberrations greatly differ from these assumptions, and disrupt the boundaries of species, they are too much of a transgression to be accepted within the scope of this domain. Biological typology proves to be anachronistic and insufficient to grasp effects of artificial, rapidly occurring evolution and the new living entities are only referred to in terms of mythological and science fiction designations that migrated to popular jargon: the monster, the hybrid, the chimera.

An especially interesting case is the problem of organisms conceived via technological means in one of the trends of contemporary art. Bio art is, briefly speaking, the appropriation and exploitation of techniques of synthetic life creation developed within the field of molecular biology for artistic purposes. The answer to the question of why life could become both the subject and the object of art should be traced back to conceptual art, probably the greatest transgression that art has ever experienced. The main concern of artists associated with this trend was a perpetual revisioning and self-questioning of art. One of the most significant questions they posed was why something can become a piece of art, and how this affects our understanding of this phenomenon. They promoted art understood not as a domain devoted to producing objects of aesthetic value, but rather as a place for discussing, defining, evaluating and teaching art, whereas the role of the artist was supposed to comprise of both the craft and the theory. In the realm of bio art, contemporary artists continue this tradition by dealing with a fundamental problem of philosophical nature. The question of what is life and whether it can become an object of art is posed via various material realizations of this ambiguous phenomenon. William Burroughs expressed a conviction that "all artists are **trying** to literally create life." [9] An immense transgression elicited by bio art is that they **are** literally **creating** life. The creationist aspirations and simple curiosity are however infinite and apart from identical organisms, new, thus far unknown living creatures are being created. Admittedly, they remain in a certain relation with the prototypical organisms for they are created mainly with known genes and proteins. They therefore sustain a certain link with the 'natural'. However, they are at the same time unfamiliar and uncanny and constitute a transgression to the 'natural', as we know it. These beings urge us to reflect upon the problem of life again, and to rethink and expand our assumptions concerning its possible incarnations. If we are to trust Joseph Kosuth, who expressed a conviction that the essence of art should be the questioning and undermining of its nature and tradition, then not only conceptual art, but also bio art with its challenge of introducing increasingly strange cases of life as both subject and object of art is a pure transgression.

Let us briefly examine few artistic manifestations of these transgressions. A good example is provided by Eduardo Kac in his work Edunia. During a museum encounter Edunia appears to be an ordinary plant. However the artist's explication reveals that it is a hybrid object, a 'plantimal', which encompasses biological features of both a plant and a human. Kac had a gene isolated from his blood and introduced into the DNA of petunia plant. The resulting hybrid expresses his gene within red veins running across the petals. Edunia is a unique and individual organism, it is not an organism that can be found in nature.

Figure 1. Natural History of Enigma: Edunia, Eduardo Kac, 2008.

Being a hybrid it also disrupts biological taxonomies as well as species and kingdom boundaries. It cannot be classified neither as a plant nor as a human: it is a completely different, liminal, borderline form of life. Were it not for molecular biology and translations between human, plant and machine codes, the project would have been impossible. Yet media theories, when confronted with the end product of these operations also have very little to say. A completely new, interdisciplinary approach is needed in order to be able to conceptualize this new organism created through genetic manipulations. Another good example of *bios* and *techne* transgression is Spectrum by Robert B. Lisek. Lisek has prepared a new strand of luciferase-mediated *E.coli* bacterium, which self-replicates in the water at an extremely fast rate. He carefully analyzed the communication networks of Warsaw in order to check their ability for spreading the bacteria-induced disease. Thus, the project became a simulation of a bioterrorist attack on the capital of Poland. The strain of genetically engineered luciferase bacteria, which rapidly multiplies in the water is not originally found in nature. It mimics the mechanism of *E. coli* bacteria, but at the same time is a different, genetically engineered entity. It exceeds the abilities of biological agents and incorporates a feature of bioluminescence, which occurs mainly among marine vertebrates and terrestrial invertebrates. It provides a disquieting potentiality of alien life that could, according to the conceptual assumptions behind the project, literally enter into our reality. Just like Edunia, Spectrum leaves both biological and media theories concepts puzzled and confused.

With today's technological capacity growing exponentially, with the mutations and transformations that could be introduced on selected genes or whole fragments of genetic setup, it seems that we have infinitely many possibilities and combinations of creating new lives that will forever evade norms, definitions, classifications and theories. For now, the approach to living media should be interdisciplinary and methodologically open in order to draw upon numerous, apparently distant branches such as ontology, molecular biology and technology studies to name just a few.

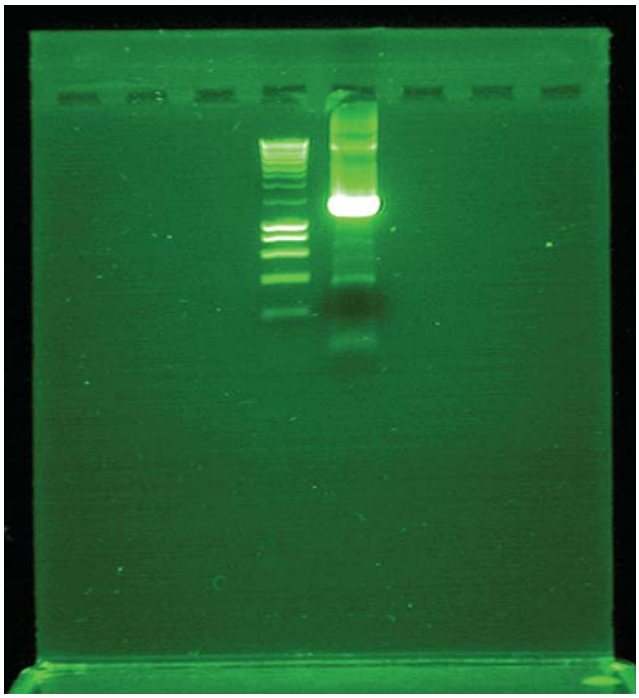

Figure 2. Spectrum, Robert B. Lisek, 2008.

An adequate approach to the problem of transgression is equally important. It should be thought of as an essential factor of change and infringement without which no progress would ever be possible. Hermeticism, conservatism and isolation cause domains and theories to become obsolete and dead, and eventually unable to speak of reality. The situation biology and media theory are experiencing with regard to living media deserves not empty conclusions about disciplinary crisis, but an effort of creating new approaches and methodologies, new useful transgressions. To recall the words of Ludwig Wittgenstein, used as a closing of his Tractatus Logico-Philosophicus that simultaneously call for its rejection, anyone who recognizes anachronism and inadequacy of a discipline "must transcend these propositions and then he will see the world aright" [10].

Author Biography

Marta Heberle is a theorist and critic of culture. She specializes in issues related to bio art and bio media. Heberle is an author of numerous articles concerning contemporary art and aesthetics with a focus on transhumanist perspectives. Currently she is preparing her PhD at the University of Poznan. Her main focus is the problem of life, which, according to acknowledged definitions seems to be a phenomenon of relative rather than absolute character. She employs a non-humanistic approach to push the boundaries of biological systems. Heberle's work balances theoretical and applied research: she is also an artist concentrated on transgressive sensory experiments located at the intersection of sound and performance.

Radical Reordering: *Bit*-size Chunks in the Al Grano Project

Pat Badani

Editor in Chief, New Media Caucus
United States of America
pat.badani@gmail.com

Abstract

The paper unpacks my working methodology in the creation of large, multi-year projects based on the segmentation and grouping of ideas, materials, and objects into *chunks*. As case study I use my current project *Al GRANO: Framing Worlds*, a composite gallery installation with individually installable pieces that can be connected in various combinations. Exhibited together, the *chunks* compose a large project that addresses conflicting historical, cultural, technological, and political positions related to maize, a contested grain considered both food and cultural symbol in Mexico, and source of macro profits for multinational agribusiness. I discuss the process of recodification embedded in the artwork itself and the influence of a Latin American literary 'tour de force' in my practice of dismantling languages and codes. I furthermore examine how the structure of material, changed through bioengineering, can be used to stress that the hybridization between natural and biotechnological genes is a source of division that spawns - in countries such as Mexico - the need to establish geopolitical immunological structures for the protection of ecological and cultural infection from external forces. I conclude by articulating that an interdisciplinary approach in the use of art and technology tools and systems can serve to critically inspect temporally and spatially continuous permeation of infamous incidents throughout social and political worlds.

Keywords

Maize, biodiversity, contamination, Mesomaerica, histories, languages, chunking, composition, decomposition, recodification.

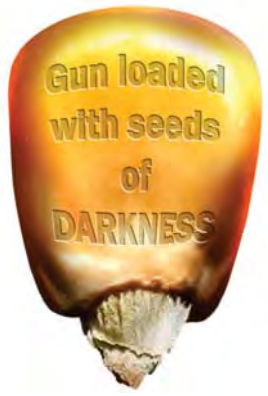

Figure 01. Digital image of transgenic corn seed, etched with a text from the novel *Men of Maize* (2013). ©Pat Badani, 2015.

Introduction

Al GRANO is a hybrid, multi-year project in which I use art tools and methodologies to inspect the debates between Mexico and the USA about maize and its genetic avatars; [1] controversies that involve monumental issues about cultural validation, language, identity, ecological balance and heterogeneity in Mexico, center of domestication and biodiversity of maize. [2] I view the defense of maize from a Latin American perspective influenced by my own cultural journey: I was born in Argentina, and I lived in Mexico and in the U.S.A. Corn Belt. The fundamental arguments involve a reaction to capitalist interests that instigate the protection of Mesoamerican cultural integrity, specifically by indigenous populations who defend native seeds, their lands and their livelihoods. With this in mind my work *Al GRANO: Framing Worlds* evaluates the idealized vision of scientific and technological progress and questions the rush by agribusiness to produce genetically modified corn to supply the needs of an expanding industry of processed foods and bio-products. This brings about a chain of imbalances in environmental and human ecologies affecting maize's biodiversity, causing impoverished soils and water depletion, and furthermore instigating the demise of small-scale farmers and the loss of ancestral agro-ecological knowledge systems (Fig. 1).

Approach

AL GRANO: Framing Worlds deploys a staging of fact and fiction where various registers of images, objects, texts and time-based pieces overlap; a strategy that I also applied in previous multi-year projects such as *Tower Tour* (1994-1997), *Home Transfer* (2000-2002), and *Where are you from?_Stories* (2002-2009). [3] As with these precedents the *AL GRANO* enterprise (begun in 2010) develops in *chunks* with the creation of aggregate projects that are hosted under the *Al GRANO* umbrella. Developing a project via *chunks* is part of my research and creation method, which consists of an inquiry on inhabitation, transculturality, human migration, and sustainable living. 'Chunking,' a term coined by one of the founders of cognitive psychology, George A. Miller, [4] is used to describe the splitting and grouping of concepts into small

meaningful units. It is considered an information measure for cognitive systems, from computer science to linguistics, with applications into broad cognitive skills (from pianists' finger tapping, to chess players' memory retrieval.) Studies claim that ideas are represented in the cerebral cortex by overlapping sets of neuronal assemblies and their synaptic interconnections. In chunking new ideas, a new neuronal assembly is recruited to represent a thought. The meaning of the new *chunk* idea is established via 'chunk-constituent overlap' and/or 'chunk-constituent association.' [5] Chunking, seen as both a triggering device and as a code building device, provides me with a useful theoretical framework to describe my operational model when researching and exhibiting layered, multi-year projects – a system that requires me to identify *chunks* from a sequence, and to then organize and classify these into categories that relate to the whole (Fig. 02), much in the same spirit of what Nelson Goodman referred to as "composition and decomposition" in the process of "worldmaking;" a practice that consists of:

> "…*taking apart and putting together, often conjointly: on the one hand, of dividing wholes into parts and partitioning kinds into sub-species, analyzing complexes into component features, drawing distinctions; on the other hand, of composing wholes and kinds out of parts and members and subclasses, combining features into complexes, and making connections. Such composition or decomposition is normally affected or assisted or consolidated by the application of labels: names, predicates, gestures, pictures, etc*." [6]

The method of chunking (taking apart, reordering, and putting together) helps me inspect a complex subject by focusing on a particular *chunk,* with all *chunks* allied to the project's nodal concept (such as sustainable living in Al GRANO). In combining *chunks* into *chunks* one can gain greater information, and by breaking them down one can examine their constituent parts. Any *chunk* is always connected to another and can potentially impact or reshape other *chunks*. The process is analogous to putting together Lego pieces in that interlocking *chunks* can conjoin in any direction to create a larger form. When I assemble *chunks* of research as a group in public exhibitions, different subjectivities are produced as viewers/participants experience spatio-temporal orderings of *chunks* that provide new experiences and sensations of known and fresh information, allowing the brain to create new connections – to 'rewire' itself and construct new insight and meaning. In my view, this process favors the emergence of new knowledge.

Languages / Histories / Codes / Glitches

Al GRANO: Framing Worlds is a gallery installation composed of three *chunks* having as common element the

Figure 2. *Al GRANO Project Mind Map* (2010). Sketch from Pat Badani's notebook. ©Pat Badani, 2015.

manipulation of languages, histories and codes – the latter pointing to the underlying structure of genetic systems. The individual yet connected *chunks* are titled: *Al GRANO: Hack*, *Al GRANO: Crop-Cropping* and *Al GRANO: Injection-Infection*.

Al GRANO: Hack is composed of 13 digital images printed on adhesive vinyl – silhouettes cut out in the shape of Maya glyphs adhered directly onto a gallery wall. *Al GRANO: Crop-Cropping* is an interactive work designed for portable, touch-sensitive devices. These two pieces illustrate how even when I focus on one particular *chunk*, this one is always part of another *chunk,* connected in a way that might change the content but not the concept of the *chunk*. As I discuss further on, the connection between these two is the notion of 'glitch.'

Additionally, both *chunks* integrate Mesoamerican Maya glyphs as well as texts from a seminal novel that I discovered over the course of my research: *Men of Maize,* written by Miguel Angel Asturias, Nobel Prize winner of Latin American Literature. Published in 1949, [7] it intermingles social commentary, myth and legend to address the sustained struggles by indigenous populations who defend their right to grow maize as daily sustenance and not as commodity to be commercialized for profit – a profanity in the eyes of Mayan people whose sacred belief

system sustains that men are made of maize. Although the novel *Men of Maize* was inspired by corporate exploitation of maize and the demise of Mayan peasants in Guatemala in the 1930s, the country is never named with the intent to represent Latin America as a whole, embracing the continent's whole history of conquest. *Men of Maize* is deeply influenced by early Mesoamerican Maya Quiché [8] narrative culture, and though it was misunderstood when it was first published due to its style and structure, it is now considered to be one of the "vertebral literary texts of twentieth-century Latin America." [9] It was the first great experiment in what critics now call "magical realism" and today it is also considered "a green conservationist document." [10]

After reading Asturias' novel in Spanish and in Gerald Martin's English translation, I became fascinated by its relevance in the present. What Asturias described as a phenomenon of exploitation occurring in the first half of the twentieth century, can be easily transposed and applied to what is happening in Mexico today in the twenty first century, namely, the exploitation of indigenous peoples, of the land, and of maize, by national and international corporations. The menace was – and still is – not only the potential erasure of domesticated maize seeds and of ecosystems, but also of indigenous Mesoamerican cultures and their ancestral knowledge systems.

Miguel Angel Asturias' biography was in itself revealing to me. I learnt that he had studied ethnography in Paris where he became involved in translating the famous Mayan bible the *Popol Vuh* or Book of Counsel, considered to be the Maya book of origin. Asturias was deeply influenced by the *Popol Vuh* when writing *Men of Maize*. Not only was he impressed by the narrative structure of the mythical text, most importantly, the very act of translation helped him discover the weight that words carry for indigenous peoples for whom naming is a sacred act with magical characteristics that furthermore empower what is named. [11]

Taking into account that I was a language translator myself in my youth, this biographical note revealed during my research on Asturias was of great interest to me. I was equally drawn by the complexities involved in the translation of culture through language. This accounts for my fascination with the three-step process involved in the translation of the *Popol Vuh*. The process entailed a conversion from the phonetic Mayan hieroglyphic system, to the Western alphabetic system, and then to the Spanish language; a translation detour that actually began in the 16th Century during the Spanish conquest with bishop Diego de Landa who imposed the Western alphabetic system onto the Maya writing system (Fig. 03) by teaching and forcing Maya scribes to write their language in Latin letters. [12]

The denaturing imposition of one writing system onto another has resulted in many transcription errors [13] – or what I'd like to call 'glitches.' Seen in this light, the processes of recodification begun by De Landa and sustained through time, adds up to compounded dislocations that Asturias takes on in his novel, and that I address in *AL GRANO*. They are disjunctions about empirical attitudes towards reality, notions of space and temporality, and the displacement of languages and writing systems – what Gerald Martin describes as the division of the eye and ear via the juxtaposition of the syllabic over the phonetic writing method. [14]

I found this account intriguing due to my works' focus on the social sphere and the means by which people have a voice in society. Additionally, my long-standing interest in language form, language in context, and the associated processes of social and cultural translation that convey and assign meaning, compelled me to delve deeper into Mayan hieroglyphs – an investigation that guided my decision to adopt certain glyphs as icons for two *chunks*; *Al GRANO: Hack* and *Al GRANO*: *Crop-Cropping*. I created new juxtapositions of languages and codes to generate purposeful glitches where hidden transcripts reside, hence representing the incessant efforts by elite groups to penetrate, disrupt and erase sites of knowledge and the corresponding efforts by subordinate groups to defend them. [15] To such a degree, these glitches embody a creative activity of resistance and the option to cultivate, and to even mobilize new modes of thinking and of doing.

I began work by researching and consulting existing Maya dictionaries – looking into basic glyph signs that have been deciphered – and I created a discrete inventory of glyphs that represent nouns, adjectives and verbs, or verbal phrases, all of them related to the area under discussion, for example: maize god, earth, tortilla; to scatter, to harvest, to demolish; in addition to representations of time, such as: it happened (past), it happens (present), it will happen (future). [16]

Once done with the lexical inventory, I probed into my archive of digital images of corn that I have photographed in the past four years, and opened them - not in an image editor - but rather in a 'hex' editor that revealed the images' coded hexadecimal and ASCII languages. [17] Then, with the intention of putting into practice my own recodification process, I proceeded to crop and erase sections of digital code, introducing citations from the novel *Men of Maize*; excerpts that speak of the devastating effects produced by capitalism and international companies on the lives of indigenous maize growers, having a profound effect on their customs, ancestral beliefs and cultural identity.

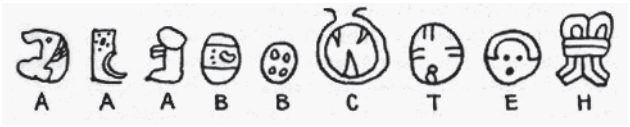

Figure 03. Detail of Diego de Landa's "alphabetic" interpretation of Maya hieroglyphs in *Relacion de las cosas de Yucatan*, 1566.

Figure 04. *Al GRANO: Hack* (2014). Two glitch images silhouetted as Maya glyphs included in the solo exhibition at the Centro de Museos, Universidad de Caldas, Festival de la Imagen 2014, Manizales, Colombia. ©Pat Badani, 2015.

My relentless process of code erasure and substitution – via the injection of content in a different language – created ineludible disruptions in the digital corn images resulting in digital glitches. These glitches play an idiosyncratic role in the *chunks*: *Al GRANO: Hack* and *Al GRANO: Crop-Cropping* and they draw attention to the notion of 'denaturing' [18] that animates the whole *Al GRANO* thesis. In a match of front and back, the glitches embody the tensions between surface appeal and the exposed background clamor. *Al GRANO: Hack* shows the front end of code that drives the artwork and *Al GRANO: Crop-Cropping* the back end.

The *chunk* titled *Al GRANO: Hack* (Fig. 04) is composed of 13 curvilinear silhouettes in the shape of Maya glyphs that bear individual language representations: maize god, earth, tortilla; to scatter, to harvest, to demolish, etc. They appear under the guise of deceptively bright graphic symbols that upon closer inspection reveal their 'denatured' character as corrupted digital images. Indeed, these silhouettes showcase the 'front end' of photos of corn whose 'back end' codes have been hacked, modified by a steady nervous tension infusion of disquieting texts from the novel *Men of Maize*. The resulting glitch images have an attractive and lush surface appearance dominated by striated bright colors such as pink, red, turquoise, and blue; colors quite unlike those of the objects photographed. In truth, the prints are as eye-catching in their surface appeal as packaging designs of processed foodstuffs sweetened with fructose corn syrup derived from genetically modified corn, and as deceptive as the shallow promise of a better world anticipated by bioproducts such as corn ethanol and corn plastics (PLA). (Fig. 5)

Figure 05. *Al GRANO: HFCS + PLA* (2011). Digital composites representing foodstuffs containing High Fructose Corn Syrup (top) and products made of PLA bioplastic (bottom). ©Pat Badani, 2015.

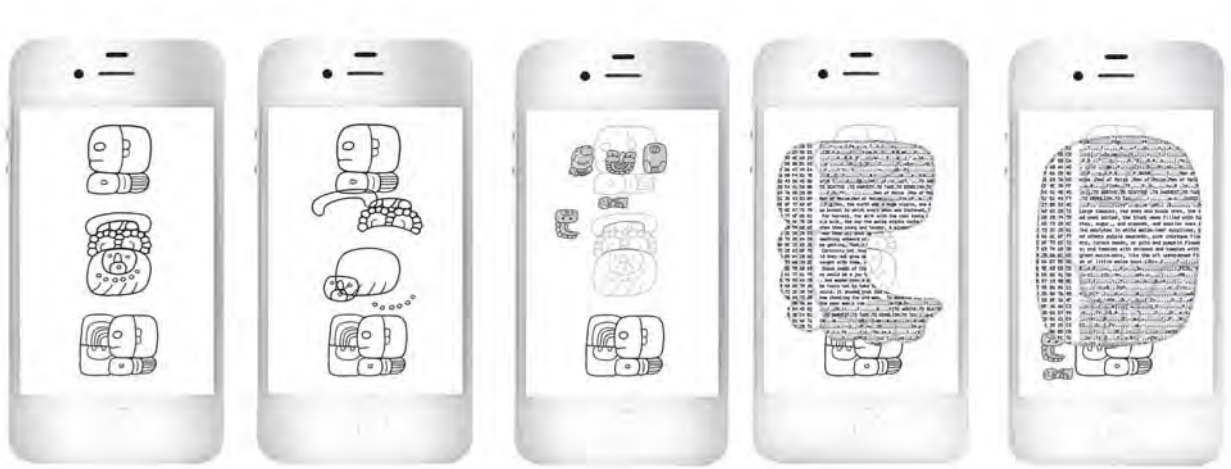

Figure 06. *Al GRANO: Crop-Cropping* (2013). Composite image with screenshots captured on an iPhone from the interactive App. ©Pat Badani, 2015.

The *chunk* titled *Al GRANO: Crop-Cropping* (Fig. 06) is a free App designed for mobile devices and it has a pictographic interface bearing the same 13 Maya glyphs used in the piece I just discussed – but devoid of all color in this instance. The work can be seen as the previous *chunk*'s shadow due to its austere black and white presentation showcasing the 'back end' hacked code that drives the 'front end' of the lip smacking GM corn glitch images. In addition, the piece's interactive design invites the user to engage with the past, the present and the future of maize by using their fingers in small gestures. By tapping, swiping, pinching and zooming, they engage in a game of deciphering meaning through ASCII and hexadecimal languages mixed with texts in the western syllabic language. These texts, extracted from the novel *Men of Maize*, highlight the plight of indigenous Mayan people in defense of maize culture (Fig. 07).

Yet another *chunk* titled *Al GRANO: Injection-Infection* (Fig. 08) is comprised of three sculptures. With the intention of exposing how the structure of material is changed through bioengineering, I used a 3D printer and PLA bioplastic to produce the sculptures. These three dimensional renderings show the structural formula of fructose, amylase, and polylactic acid; laboratory-processed components sourced mostly from transgenic corn, and used in the production of foodstuffs, biofuels and bioplastics. The work points to the effects of large-scale agro-industrial production of transgenic corn in order to optimize crop yield intended for the production of bioproducts. High fructose corn syrup (HFCS), corn plastics (PLA), and corn based ethanol – sourced from GM corn – cause a genetic and physiological imbalance in native maize varieties, disrupt local ecosystems, damage agricultural fields and also take away from local populations – specifically indigenous populations in Mexico – land that could be used for subsistence food crops. Indeed, the spread of USA-led agribusiness supported by the colossal NAFTA trade accords [19] required neither seed segregation nor labeling and in 2001 Mexican researchers discovered contamination of native maize landraces by GM corn genes that threatened maize's viability and the ancestral diversity developed there through traditional breeding. Truly, maize agriculture – whether native, hybrid or transgenic – does not only touch upon cultural and identity issues, it also touches on economic and civil realms. The contamination of

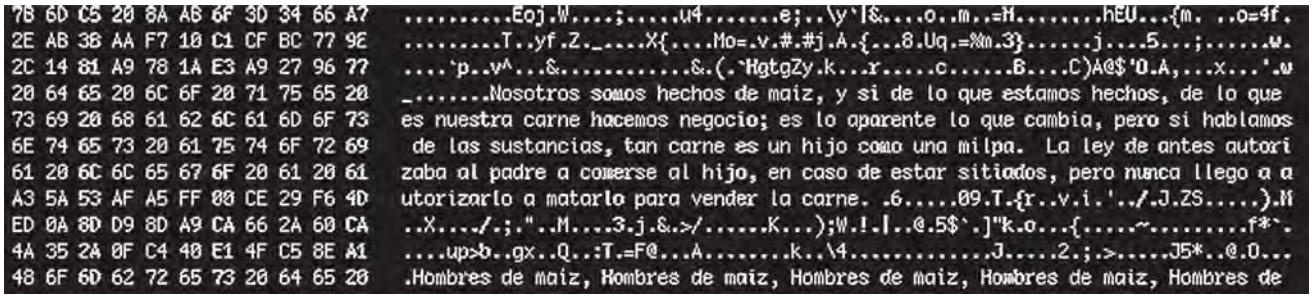

Figure 07. Recodification process. Detail captured from the hex editor in one of several digital prints on transparent acetate included in AL GRANO's solo exhibition. Centro de Museos, Universidad de Caldas, Festival de la Imagen 2014, Manizales, Colombia. ©Pat Badani, 2015.

Figure 08. *Al GRANO: Injection-Infection* (2014). Installation detail. 3D digital prints (designed in collaboration with Chris Wille) encased in glass domes. Centro de Museos, Universidad de Caldas, Festival de la Imagen 2014, Manizales, Colombia. ©Pat Badani, 2015.

landraces created the need to establish geopolitical immunological structures for the protection of cultural, ecological, and commercial infection from external forces [20] such as government-required moratoriums and requests that the USA undertake mandatory seed segregation so that it could guarantee Mexico the importation of only nonGM-corn. Further – to this day – citizen-led groups of resistance continue to lobby in defense of maize. Noted examples formed by indigenous, mestizo and rural communities are *Red de Defensa del Maiz* [21], and *Pro-Oax* [22] an organization in Oaxaca spearheaded by artist Francisco Toledo.

Conclusion

Al GRANO: Framing Worlds embodies internal disciplinary means that relate to its external relational context. Shaped by conflict situations instigated by a small grain with monumental impact and informed by interdisciplinary research in geopolitics, literature, science and technology related to maize and to GM corn, the *Al GRANO* enterprise exemplifies how creative practice in electronic arts can shape material complexes in a critique that is essential, incisive and also disruptive in its analysis of knowledge systems, processes and ideologies. The project's artistic means – tools, artifacts and systems – brings into play transnational communities and their practices over time, sites of memory and displacement, languages, codes and glitches.

With the intention of constructing a comprehensive image about a very complex topic, I use a "radical reordering" [23] research and creation method involving chunking and restructuring of temporally and spatially heterogeneous material and information. Gallery visitors encounter spatio-temporal orderings of installation pieces that articulate contrasting positions (Fig. 09). They engage in a process of "elaborative encoding," [24] associating and connecting new and known information, and encoding

Figure 09. Viewers encounter spatio-temporal orderings of installation pieces. Festival de la Imagen 2014, Manizales, Colombia. ©Pat Badani, 2015.

unfamiliar features or attributes to the representation of events. This process of reframing knowledge favors the emergence of fresh perspectives needed to challenge the idealized vision of scientific and technological progress, fomenting the possibility of cultivating alternative modes of being and making.

Aware of differing narratives that tenaciously emerge out of government officials; out of policy makers; out of research scientists and biotechnology experts; out of media and journalism; out of lobbying groups; out of farmers, artists, writers and the general public, my aim with this highly faceted multiyear project is to reveal a new pattern of value and enquiry in a troubling phenomenon that has persisted for decades. I speak to the gaps and glitches that exist in processes of codification, and recodification of national and continental narratives related to maize as food, and equally as cultural symbol. [25]

Endnotes

1. The term 'genetic avatars' refers to new genetic organisms created by scientists working for biotechnology corporations who are able to rewrite and alter the genetic codes of different species, and by so doing, create a new incarnation or manifestation. The term is used by Maryse Carretero in the title of her book *Histoires de maïs: d'une divinité amérindienne a ses avatars transgéniques* (Paris, Editions du CTHS, 2005).

Author Biography

Born in Argentina and having lived in Uruguay, Peru, Mexico, Canada and France, Pat Badani currently lives and works out of Chicago, U.S.A. She is an arts practitioner, critical thinker, educator, editor, and curator. Badani's praxis is concept and context driven and involves artistic research and creation around such topics as inhabitation, transculturality, human migration, and sustainable living. Her works have been shown extensively in international venues – museums, festivals, art centers and galleries. Essays examining her practice have been published in several languages in solo and group exhibition catalogues, in art-magazines, academic journals, and in thematic anthologies. Her own scholarly essays have been published in English and Spanish in symposium proceedings, journals, and in book chapters. As art educator in several institutions in Canada, France and the U.S.A., she has been instrumental in curriculum creation related to interdisciplinary practices. Since 2011, she is Editor in Chief of *Media*-N, Journal of the New Media Caucus, an international scholarly online and print journal.

Owner of a Lonely Heart: Zebrafish Embryonic Heartbeats

Dr. Clarissa Ribeiro, Dr. Huanqi Zhu

UCLA Department of Chemistry and Biochemistry
Los Angeles, California, USA
almeida.clarissa@gmail.com
hqzhu11@gmail.com

Abstract

The work presented here was developed in collaboration between the media artist Clarissa Ribeiro and the scientist Huanqi Zhu, by the time they worked together as researchers at James Gimzewki lab, UCLA. The 8 (eight) screenshots and the derived (sonified) environmental sound that integrate the piece "Owner of a Lonely Heart"(2014), were traces of an observation – a scientist measuring the heartbeat of a zebrafish (Danio rerio) embryo's lonely heart. After recording the data, using a microelectrode precisely prepared for the experiment, the scientist generated a series of graphs using the software OriginPro 8.1 and started zooming in different regions, looking for specific points where the patterns fit his expectations according to the main purposes of the research. Despite the procedures were initially part of a bigger project involving several labs and researchers, the actual collaboration was developed as a parallel experiment were the scientist joined the artist in a poetic reflection about the scientific procedures that became part of the artwork itself. Integrating the artist solo show at the Art Sci Gallery, UCLA (June/July 2014), the work invites the audience to reflect critically about the importance of observation in the creation of 'truth' in science, what plays a crucial role in the creation of 'reality', having radical influence in the ways we behave, in our survival strategies, in who we are.

Keywords

Art and Science, Data Sonification, Problem of Measurement in uantum Mechanics, Observer-observation relations in uantum Mechanics, Heart Beating Patterns of Zebrafish Embryo.

Introduction

In the work 'Owner of a Lonely Heart', the authors invite the audience to think about the role of observation in the creation of reality – a basilar concept related to problems of measurement in uantum Mechanics. Observation, from this perspective, is the active agent that collapses quantum possibilities into actualities. Bell 1 reflects on the consequences of a misuse of the word 'measurement', what can make it easy to forget that the results of quantum experiments "[…] have to be regarded as the joint product of 'system' and 'apparatus,' the complete experimental set-up." He emphasize that, as we learned from names like Bohr, the instruments don't play a purely passive role.

Taken as a poetic reflection about these considerations, beyond the realm of uantum Mechanics, the 8 (eight) screenshots and the environmental sound that integrate the installation are memories of an experiment where a scientist was measuring the heartbeat of a zebrafish embryo. The microelectrode where the heart extracted from the embryo's body was placed and accommodated the electronic microscope the web cameras computer hardware and software human's hands; the eyes the human heartbeat… – all intertwined in a quantum level as parts of a system (the apparatus included) that creates the observation itself.

Extended-Altered-Entangled

Our computer-mediated world amplifies our natural perceptional abilities and we can be non-locally engaged in observer-observation relations which nature and implications goes far beyond the use of our so called 5 (five) senses. In this scenario, engineered systems and sensors integrated in apparatuses of all kinds, help in approaching levels of reality from cross-scalar perspectives, bringing to the horizon the emergence and potentiality of exploring innovative aesthetics, procedures, technologies, discourses. This is the context from which the work 'Owner of a Lonely Heart' emerges. A context in which, if we consider ourselves as active elements of Complex Affective Systems (CAFFS), it could be easy to think about the ways we can non-locally affect and be affected by universal forces, by each other, by ourselves, creating realities from a multi-level perspective. A Complex Affective System (CAFFS) is a term the author coined to describe and discuss certain Complex Adaptive Systems (CAS) focusing on affectiveness as the main bond between the systems' elements, relating this aspect of system's interconnectedness, and the ability its elements have of non-locally communicating, to the phenomena of quantum entanglement.

In an objective observation in science, considering the procedures involved in laboratorial experiments in the most diverse areas of investigation, the ideal observer is the one who causes no perturbations to the system under observation. Nevertheless, the physics of the 20th century faced the challenge of questioning the role of the observer. From the uantum Mechanics' perspective, the observer and the system observed become somehow intertwined that the results of any observation seemed to be determined, partially, by the actual choices of the observer. This problem concerning observer-observation relations is represented by the wave function. The main intention in this collaboration was 'to observe/integrate the scientific observation', building a 'meta-point of view' to poetically reflect on how, by means of observing having an hypotheses in mind, the scientist radically influences the results of the experiment. According to Edgar Morin,

> "The meta-point of view is only possible if the observer-conceiver integrates himself or herself into the observation and the conception. This is why complex thought requires the integration of the observer and the conceiver in its observation and conception." 2

In 'Owner of a Lonely Heart', together, collaborating, the scientist and the artist become part of the observation itself and the system (CAFFS) 'scientist-artist-apparatuses-observation' become the 'reality' encapsulated in an art piece. As part of the procedures, the heart of the zebrafish embryo was extracted from the fish's body in search for more precise measurements. The interval from life to death of the 'extracted heart' accommodated on the top of the microelectrode, varies – it can last around one minute or so.

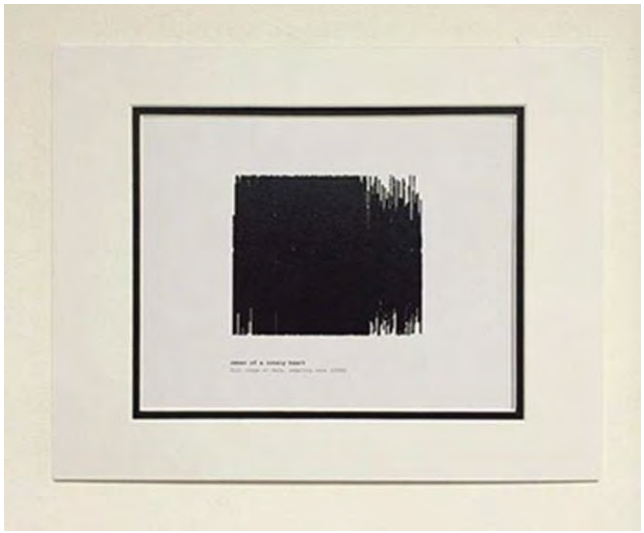

Figure 1. The entire dataset in OriginPro 8.1: the zebrafish embryo heartbeat caption's resultant graph from where the 'zooming procedures' start.

After collecting/recording the data, the scientist generated a main graph (figure 1) using the software OriginPro 8.1 and started zooming in different regions of the graph, looking for specific points where the patterns fit his expectations, according to the main research hypotheses. In this specific case, the purpose of the experiment was to study the beating pattern of zebrafish at different developing stages. The beating patterns can serve as markers to help identifying healthy and mutant hearts, being, in turn, used to test drugs that can improve specific functions of the organ. A control sample with healthy heart was studied. The detected electrical pulses were strong, regular and consistent. An experimental sample with a mutant heart showed the electrical pulses were very irregular and weak. After the administration of a specific drug, the heart function from the mutant sample was restored, and the detected electrical pulses became periodic and normal – an indication of the validity of the initial hypotheses referent to the functional reparatory qualities of the drug.

The Owner of a Lonely Heart

'Observing poetically an observation that could be decisive in a near future by making precise assertions about specific drugs that can effectively fix a damaged human heart' – this was the position of the collaborators in the conception and production of 'Owner of a Lonely Heart'. Together with the scientist, the artist was following and observing the procedures – from the measurements to the search for patterns in the resultant graphics and never-ending datasets.

Figure 2. Beating pattern selected from the entire dataset by the scientist, looking for equivalence with healthy human heart beating patterns.

Eight different screenshots from the entire dataset analyzed were selected to integrate the installation. Each screenshot represents a decisive selection made by the scientist in the search for patterns that matches his expectations – a regu-

lar pattern that is similar to a human's healthy heartbeat an irregular pattern that indicates a malfunction. These specific patterns can only be found in extremely short segments of the dataset, considering that the heart of the zebrafish was extracted from the embryo's body, placed on the top of a microelectrode, and was beating for no much more than one minute. From life to death – from the first screenshot to the last one, the audience could observe in the gallery the lifespan of the embryo's heart from the scientist-artist-apparatus meta-point of view.

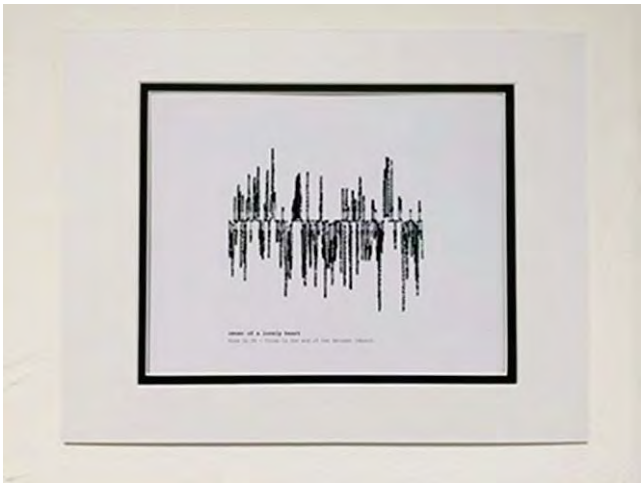

Figure 3. Graph showing the zebrafish's heart near death.

Gentler and deeper: mindful awareness

The sound was derived via data sonification from the entire dataset – full range of data, sampling rate 1000Hz. The artist manipulated the data using the software *Audacity* and *Adobe Audition*, altering the speed and adding effects to give it spatial qualities and explore specific nuances in the perception of the raw data patterns. Similar strategies for data sonification have becoming common during the last two decades, in works that emerge from collaborations involving artists and scientists. One work that was very influential to the artist in the development of the present project is the 'Blue Morph', collaboration between media artist Victoria Vesna and nanoscientist James Gimzewki – an interactive installation that uses nanoscale images and sounds derived from the metamorphosis of a caterpillar into a butterfly. According to Vesna and Gimzewski 3 , the sounds used in this piece were acquired and recorded by detecting nanoscale motions of the pupa surface using atomic force microscopy (AFM) and optical beam deflection during the developmental stages of metamorphosis.

According to Walker and Nees, from Georgia Tech 4 in sonification it matters which specific sound dimension is chosen to represent a given data dimension. Reducing the speed from the original (corresponding to 0,000) to -98,000, was a strategy to enable the audience to perceive subtle variations in the raw data (22,400 lines/ values Figure 1) directly sonified in Audacity 2.0.5. In a subsequent editionof the exported *.wav* file in Adobe Audition CS6, effects as echo were applied to give the sound qualities that could stimulate mindful awareness and relaxation.

The intention was to produce a sound that could allow for a perception of the data recorded via microelectrode array (MEA) from a poetic perspective that brings all the fragility and subtleness of a life in its early stages. In addition, another intention was to emphasize all the ephemeral qualities a heart extracted from a fish embryo could awake when the audience gets immersed in a rhythmic travel from the moment it was recently extracted and is pulsating in all its strength (Figure 2) to the very last moments when it is dying (Figure 3).

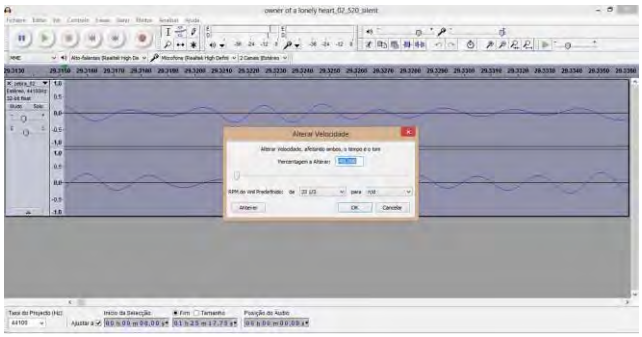

Figure 4. Direct Sonification using Audacity 2.0.5

Subtle Apparatuses for Extrasensory Affectiveness

The installation is a result of the artist's most recent project that is focused on the conception of a series she named 'Subtle Apparatuses for Extrasensory Affectiveness', some of those were in her solo exhibition at the Art Sci Gallery, CNSI – California NanoSystems Institute, UCLA, in Los Angeles, form June 5th to July 5th , 2014. The 'subtle-apparatuses' could be understood as semi-material systems conceived as exercises on experimental metaphysics – performing ventures in realms beyond the physical domain, bearing questions about the nature of reality and our bodies, our affective dimension, consciousness and the self. According to Professor Michael Punt,

> "The fact that technologies rapidly become associated with a class of objects that are fundamentally material should not deflect our attention from the semi-material: another class of objects that emanate in our fullest relationship with the world as necessary mnemonics to our affective dimension." 5

By means of the artist approach in the work 'Owner of a Lonely Heart', apparatuses are not taken as external forces that operate on bodies from the outside. Following the considerations of aren Barad, apparatuses could be considered as "[...] material-discursive practices that are inextricable from the bodies that are produced and through which power works its productive effects." 6 According to Roy Ascott, apparatuses as the "scanning tunneling microscope (STM), as an example, calls for touch rather than vision to navigate the nanofield and to manipulate individual atoms." 7 Professor Ascott emphasizes that "[...] the nanofield mediates between pure matter and pure consciousness and that its significance as an interface between two levels of reality can hardly be overestimated." 8 Travelling through touchable and untouchable, 'Owner of a Lonely Heart' is a call to explore the very power of observation in the creation of the realities we inhabit.

Acknowledgements

The author would like to thank the Fulbright Program that awarded her a Post-Doctoral grand in Arts (2013-2014) and to the Art Sci Center and Lab, including the researchers from Professor James Gimzewski's laboratories at the UCLA Department of Chemistry and Biochemistry and the CNSI – California NanoSystems Institute, and from Professor Victoria Vesna's studio at UCLA Department of Design Media Arts, within which she was working during the grant period. A special thanks to Professor James Gimzewski, that always stimulated the collaboration between the researchers working under his supervision.

Authors Biography

Clarissa Ribeiro, Ph.D., is a media artist and researcher. She is currently the main Associate Professor of Roy Ascott Studio in Shanghai, China. Recently, she was awarded a Fulbright grant in Arts, and was living in Los Angeles, California, as a Postdoctoral Research Scholar, connected to the UCLA Art Sci Center and Lab, collaborating with artists and scientists that are running cutting edge projects in their areas. During her Ph.D. in Visual Arts by the University of Sao Paulo, Brazil, by the time she was together with the Gilbertto Prado's group, she was a visiting research member of the CAiiA-Hub of the Planetary Collegium, U . As an independent artist, she has been producing and exhibiting a series of experimental interactive installations exploring complex affectiveness through macroscale metaphorical translations of the non-local phenomenon of quantum entanglement. At present, regardless of living in Shanghai, she is still 'non-locally' collaborating with the Art Sci Collective.

Huanqi Zhu, Ph.D., is a researcher at Nano and Pico Characterization Research Lab, UCLA, specialized in quantitative analyses and predictions in physical systems. He has hands-on experience and working knowledge in physical sciences, with extensive experience in noise isolation and noise cancelation with comprehensive training and skills in data processing.

Toxicity and the Equidistance of Biotechnology and Biopolitics

Dr. Melentie Pandilovski

Video Pool Media Arts Centre
Winnipeg, Manitoba
vpdirector@videopool.org

Abstract

The paper looks into how "Toxicity" entrenches itself into what Phenomenology sees as the co-constitution of society and technology. The cultural deciphering of the toxic societal terrain resonates with current socio-economic global transformations. The topic of toxicity reconstructs the current environmental situation and socio-political contexts by looking into modes of contemporary cultural and technological production. Biopolitics maintains an extended role today by shaping life and attaining central role in society. It adds a complexity of layers that allows radical reconstruction of relations between politics and nature, allowing for a reassessment of how we look at life today. The trajectory of development of Biopolitics is altered, for life appears not to be what we have originally assumed that it was, and therefore its regulation cannot continue under previously granted premises. The dualities of power and right, sovereignty and law, do not leave the contemporary Biopolitical discourses for a minute. The Bio-political characteristics of Toxicity are seen by some in line with eugenics, as the toxins will most certainly lead to sterility of the indigenous population, and are to be seen in correlation with the degenerative pathology of the prevailing illnesses such as alcoholism, STDs, obesity, diabetes, cancer, etc.

Keywords

Toxicity; biotechnology; biopolitics; Foucault; Heidegger; bio art; phenomenology; Enframing; bio-society; apparatus

The idea of *Toxicity*, in its theoretical and practical results, entrenches itself into the standard phenomenological understanding of the co-constitution of society and technology. The cultural deciphering of the toxic social terrain resonates with current socio-economic global transformations. The topic of toxicity reconstructs not only the current environmental situation, but also sociopolitical contexts by looking into modes of contemporary cultural and technological production, the extraction of minerals, toxic waste, local and international policies, community-based responses and processes of production, consumption and disposal.

We are continually subjected to processes whose full impact is hard to comprehend; the phenomenological approach allows us to reveal these processes. The Heideggerian *Dinge* (Thing) contains within itself the possibility of gathering together the contents of the universe, *toxins* included. Relations between Things become crucial, acquiring different features depending on the contexts of where and how they are situated. The discourses of biotechnology are evolving, showing us that their latest theoretical and practical developments have a potential to cause a tectonic shift in our society and culture, wherein we experience the world at the intersection of the engineered and the biological. *Toxicity* appears precisely at this intersection, and its biopolitical modes must be understood. Marshall McLuhan noted that the creation of the technological world has created a neural exoskeleton. I maintain that this skeleton has become tainted by Toxicity in numerous ways, from the bioenvironmental to the info-financial.

The extended role of biopolitics today focuses on the crucial question of how biotechnology shapes life and comes to assume a central role in society. Biotechnology, through its complexity, radically reconstructs the relations between politics and nature, allowing for a reassessment of how we look at life today. Under biotechnological pressures, the regulation of life cannot continue under the premises of what had been previously taken for granted. The dualities of power and right, sovereignty and law, do not leave biopolitics for a minute. Additionally, biotechnology generates its own internal conflicts (e.g., Monstanto vs. Dupont in regard to GMO seed patenting.) We become witnesses of a process in which the state control of the biological is increasingly being ceded to biotech companies. In Michel Foucault's words: *For capitalist society it is the biological that is important before everything else; the biological, the somatic, the corporeal. The body is a biopolitical reality, medicine is a biopolitical strategy.*

Life, politics and economics intersect at such speeds in the globally-connected society that a novel biopolitical model is emerging which alters this society's operational functions. I refer here to the social and political functions of the Biotech Revolution. The technological and psychosomatic constitute the two poles in this emerging biopolitical discourse. At the centre of this discourse is the notion that *life* can now be moulded as we see fit, enabled by biotechnology. Biopolitics is therefore able to control life by taking it out of the *natural domain*, reshuffling it at will and subsequently using it in a functional or structural form, thereby *freeing life* from nature. This intertwining of nature and technology makes the schematic of biopolitics increasingly complex. The question of articulating sovereignty no longer depends on the suppression of life; our understanding of life and death has altered. Biopower, embedded in biopolitics, now concerns itself with the mere reshuffling of biological units of data. We have moved a step closer to

the fulfillment of Foucault's prophesy about the extension of biopower: *the excess of biopower appears when it becomes technologically and politically possible for man not only to manage life but also to make it proliferate, to create living matter, to build the monster, and ultimately to build viruses that cannot be controlled and that are universally destructive. This formidable extension of biopower, unlike what I was saying about atomic power, will put it beyond human sovereignty*. Thus, we have effectively banned experiments with plutonium, but we continue to be quite liberal with the experimentation, research and use of biotechnology.

In order to contemplate fully the notions of life, flesh and the body, we must now surpass the Heideggerian dichotomy between existence and life. We are witnesses and participants in the creation of the Biopolitical Apparatus in all of its paraphernalia. And when we speak about this Apparatus, we should remind ourselves of Vilém Flusser's remark that apparatuses are based on technical and political programs which are highly ideological and always biased. There is no value-free technology. And indeed, we can see that biopolitical conflicts are accelerating in both the real and virtual worlds among governments, NGOs and corporations over genetic-technological practices, stem cell research, bioethics and bio-patenting. Public engagement in biotechnology can be seen in the increasing interest in DNA profiling, personal genomics, biodata gathering and, most recently, genetic social networking. One of the possible outcomes of this arrangement is the creation of a genetically based value system. Another outcome may be the development of appealing forms of neo-eugenics and the creation of new utopian communities. Biology has a long history of being politicized, but we must admit that the biotechnological changes in the past two decades are indeed profound. *Historically, all technological revolutions have resulted in an alteration of the political, social and economic spectrums of society. We find ourselves as a society facing radical changes in power relationships in the local and international domains*. This biopolitical shift registers at the economic (bio-capitalism) and cultural (bioculture, bioart) levels. This shift, generated by the Biotech Revolution, configures the biological as political and economic. *The biological as political* includes notions of human rights, the changing and increasingly toxified environment and bioterrorism. *The biological as economic* sees bio-capitalism as the latest stage of capital's development, but also discloses a certain negation of profit-oriented values and the necessity of growth, thereby holding an ambivalent ethical position regarding capitalist production values.

As contemporary biopolitical discourses intersect in the re-contextualization of the relations between state apparatuses, scientific protocols and cultural systems, the consequences of the Biotech Revolution become apparent in the political and economic spectrum. These relations coalesce in the construction of a global Biopolitical Apparatus, encompassing new vectors of power with regard to social, political, economic and administrative mechanisms, as well as knowledge structures which have the capacity to create, maintain or destroy contemporary society. Biotechnology thus enables a certain neo-politicization by putting into motion control mechanisms based on a coding system, altering the dynamics between state and individual and resulting in an increasingly programmable and disciplined society. This up and coming Biotech era has the potential of inaugurating a very different constellation of political visions and social visions just as the Industrial era did. The current debate over cloning human embryos and stem cell research marks the beginning of the new biopolitics.

Félix Guattari taxonomizes the apparatuses of subjectification in three ways: as *pathways of power, pathways of knowledge and pathways of self-transformation*. The relations between these three pathways determines how society is established and whether the Biotech Revolution will create the conditions for new *existential territories* for humanity, rather than replicate and continue present alienation systems. I am of the opinion that in order for the pathways of self-transformation to influence the pathways of knowledge and power, we will have to embrace collectively the idea of *biopolitical and biotechnological responsibility*, which will assist us in further developing the governmentality of *bio-society* according to the theoretical and practical pathways of self-transformation.

The overall implications of technology are exemplified in the everyday relations that technology establishes. The disclosure of the world through technology also is a disguise of these relations, relations that can, however, be unconcealed. In "The Question Concerning Technology," Heidegger noted that the essential unfolding of technology harbours within itself what is least expected, the possible rise of a saving power. Where does this saving power of technology reside? Will salvation be found in art and activism, that is, strategies of resistance? Perhaps the Biotech Age will allow us to witness what Heidegger called the second beginning of thinking, the meeting of the world in historical time-space, and perhaps this space can be built only in art.

At the same time, artistic and cultural research into biotechnology has questioned established philosophical systems, ethical beliefs and cultural practices by proposing new ways of looking at life and society, as artists, critics and theorists navigate the maze of the global Biopolitical Apparatus. How art and technology interrelate, how this interrelation changes in the cultural, sociopolitical and ecological landscape and how biotechnology infiltrates into everyday life are important research areas. Artistic responses have included examining biopolitical conflicts in the real and virtual worlds; pollution; corporeality and somatic biopolitics; energy control, fuel material and alternative energy sources; the inheritance and programmability of life; the causes and consequences of environmental changes; environmental sustainability; micro and macroecologies; life, empathy and questions of ownership; GM products; death and appearance; and the ethical implications of working with biological media in an art context.

Practical strategies of resistance such as these need to

address structures of knowledge in order to achieve broader ethical and philosophical concerns concerning biotechnology; they must also look into what Heidegger would have called the Biotechnological *Gestell* (Enframing) of everyday life and address the changes that Toxicity causes in the cultural, sociopolitical and ecological landscape. Of course, those concerned with Toxicity must be aware that this Enframing has infiltrated deeply into the system, aided by lobby groups mediating between the biotech cartels and various governments. Any potential resistance must engage in a robust imposition into mass media channels and make periodic feedback analysis to assess its progress. Phenomenology's meta-social function is necessary for this. In particular, an analysis of the *natural attitude* must be implemented. The phenomenological investigation of the biopolitical must look into element of reflexive interplay between biotech programmers' standards (content development) and the lifeworlds of actual people – the interplay in which new identities are forged. After all, Heidegger tells us that Enframing is *destining* from which the *essence of all history is determined*. Enframing is the essence of modern technology because, for Heidegger, technology is rooted in *tēchne*: it is a means for sourcing true forms and ideas that exist prior to their phenomenal appearance. Heidegger's concept of Enframing can be deciphered today using Eugene Thacker's triumverate of *encoding, recoding and decoding*, as today the dissemination of biological data through information networks either on demand or out of necessity creates a new situation in which the biological is seen as a digitally packaged commodity.

In conclusion, in order to track the changes brought about by the Biotech Revolution, we must utilize both phenomenology and biopolitics. Phenomenologically speaking, the social order and reality of interactions between institutions and individuals are constructions. Society is a fragile construction. It is consciousness that determines the actions of all entities. There is no alternative but creativity in this process, and therefore human beings must act as creative agents in the construction of their social worlds. It is necessary to assert meaning in a process which would otherwise seem chaotic.

As far as biopolitics is concerned, the biotechnological changes that our civilization is witnessing are profound, and as all technological revolutions throughout history have resulted in significant changes in the political, social and economic levels of society, so we find ourselves collectively facing radical alterations in local and international power relations. Thus, we are in a different situation than the one predicted by Foucault, as biopolitics today begins to realize that biotechnology potentially allows for a further emancipation of the human being in terms of its self-understanding, its own genetic make-up, all of its flaws and virtues. The constant advances in biotechnology, and we can note the Human Genome Project as a sign of this advancement, signify a shift in the balance of power in favour of a society that can select and design desirable life-forms in advance.

Thacker reminds us that biotechnology takes place on a global level, be it in terms of exchanging biological information, controlling epidemics, deterring biological attacks or standardizing intellectual property laws. Importantly, the Biopolitical Apparatus suggests novel blueprints of power allocation in the domain of the governance over life. Thus, any interpretation of biopolitics, in light of these new developments, must take into account how biopolitical discourses have changed in terms of *the biological as political* and *the biological as economic*. This necessitates the articulation of *Biotechnological Responsibility* and the development of *Modes of Governmentality for Bio-Society*. This future bio-society could take upon itself a variety of roles including the role of *hegemon*, and might develop new modes for *governance*, *economic domination* and the *repositioning of our relationship towards nature*. However, alongside the potentially negative consequences of the Biopolitical Apparatus, we must also consider a more humane role, indicated by Giorgio Agamben in his *What is an Apparatus?*, wherein we learn that at the heart of friendship, philosophy and politics lies the same experience: the shared sensation of being.

Abstract

Biomodd is a global series of art installations in which computer technology and ecology converge. Computer networks built from upcycled computer components are provided with living internal ecosystems. In a symbiotic exchange, plants and algae live alongside electronics and use the latter's waste heat to thrive. Sensors and robotics provide additional interaction possibilities with the organisms. The first version of the project was completed in the US, while the second version was built in the Philippines. Using a postcolonial stance, we reflect on the challenges involved in translating the project from one context to another. We focus on issues related to heat recycling in the tropics; authenticity and hybridity; obsolescence and the convertibility of capital; cultural sampling, remixing, and appropriation; and structures for social organization. We advance Biomodd as a significant contribution to art-science collaborative initiatives in the global South.

Keywords

Postcolonial computing, installation art, collaboration, ICT4D, HCI4D, digital games, e-waste, recycling, gaming, ecology, biological art

Introduction

Many practices of contemporary art have wandered into and set up shop in territories traditionally held by science, and vice versa. [1] This crossover between art and science seems particularly noticeable to those of us who live in what media theorist Rolando Tolentino has termed "advanced capitalist countries", in which intellectual practices and concerns in scientific and artistic disciplines have experienced particular shifts and turns. [2, p. 101] However, a review of the literature on why science matters in so-called 'global South' countries (like the Philippines, from where we are currently writing this paper) reveals that questions of existential philosophy or aesthetics hardly figure. Instead, issues that do appear to matter – and for which the study of pure and applied sciences is encouraged – include improving food security, achieving better maternal health outcomes, preventing the spread of communicable diseases, and addressing other challenges articulated in texts such as the United Nations Millennium Development Goals. [3] In response to these socio-economic challenges, perspectives on information and communication technologies for development (ICT4D) and human-computer interaction for development (HCI4D) have been advanced within computing science. [4] While such perspectives are interdisciplinary and do draw from the arts, much work could be done to advance the intersectionality of the arts and the sciences and their role in addressing the diverse range of issues particularly in the "imperialized formations" of the global South. [2, p. 101]

For instance, art-science collaborations matter in addressing the global challenge of fostering what might be thought of as a *critical awareness of connectedness*. By this we mean a shared understanding of how the flourishing of human societies relies on our interaction with the natural ecosystems on which we depend, and on a critical engagement with the artificial systems that we create. This includes an acknowledgement and understanding of the fact that social, natural and artificial systems are continuously impacting on and reshaping each other. These dependencies and interactions have underpinned a diverse and burgeoning corpus of artistic and design work that has emerged over the years, marked by an interest in imagining a new "ecology of relations" through interfaces and systems that link humans, organic materials, and machines. [5] For instance, *The Telegarden* features a robot arm that tends to a garden and which human participants can remotely control. [6] Mussels control lights and sounds in Natalie Jeremijenko's *MUSSELxCHOIR*. [7] *Biolesce* uses electric motors to agitate algae that luminesce in response to the heart rate of audience members. [8] *Legend of the Sea Lord* uses mobile technologies to deliver a "mythological spectacle" and parable on the impact of human activity on marine ecosystems. [9] In each of these cases, the artists have responded to the invitation to address critical awareness of connectedness through poetic and technology-led forms of interventions.

In this paper, we present our attempt to find a shared space for inquiry and practice between contemporary arts and sciences in a postcolonial, global South context. In particular, we reflect on how we navigated problematic engagements during a process of reimagining and reinterpreting an interactive, new media art work that was originally designed in US and led by a Belgian artist/scientist – titled *Biomodd [ATH[1]]* – in the context of the particular social, cultural, and economic conditions of the Philippines. The result of this translation we titled *Biomodd [LBA[2]]*. (For brevity, we abbreviate these two projects as *ATH[1]* and *LBA[2]*, respectively.)

ATH[1] and *LBA[2]* are both part of *Biomodd* (www.biomodd.net), a global, collaborative, cross-cultural platform that brings together these various threads of artistic praxis into an integrated artistic work through interdisciplinary collaborations between artists, scientists, and other social change-makers. While *Biomodd* has been discussed in relation to climate change adaption and to education, we have as yet not teased out what we feel are the most salient cultural themes that have figured in the process of carrying out the project. [10], [11] This paper aims to address that gap.

Postcolonial critique and new media art

To frame our reflections, we refer in part to Irani et al's discussion of "postcolonial computing", which they define not as a new way of doing things, but "an alternative sensibility to the process of design and analysis" of digital products. [12] The term was advanced in the context of the application of HCI and human-centred design to a growing range of complex global problems, including "technological cultures, digital divides, multiple stakeholders, [and] economic disparities":

> *We take as our starting point a move from "development" discourse to postcolonial discourse – that is, a discourse centered on the questions of power, authority, legitimacy, participation, and intelligibility in the contexts of cultural encounter, particularly in the context of contemporary globalization.* [12]

Postcolonial critique of digital media and the electronic arts first surfaced in the late 1990s but then disappeared from the technology and computing design discourse until its resurgence a decade later. [13] We aim to contribute to the thickening of *postcolonial discourse in interactive art and technology design* by using the lens of postcolonial computing to retrospect on *LBA[2]*.

Biomodd Themes and Approaches

Biomodd reimagines and integrates relationships between social, natural, and artificial systems. The project was initiated by the second author of this paper in 2007 and has been undertaken in collaboration with various groups and individuals in the USA, Philippines, Slovenia, Belgium, the Netherlands, New Zealand, Chile, and the UK. [14] Figure 1 shows some of the different *Biomodd* versions. While the project does not solely aim to create a singular art object, like many other process-oriented projects, *Biomodd* projects nevertheless coalesce into physical structures that have been shown in exhibition contexts, whereupon the installation stands as a material testament to the dialogues, negotiations, and other exchanges underpinning the work.

Biomodd is predicated on a range of concerns that, taken together, form a conceptual framework.

Case modding and hardware hacking: *Biomodd*'s name is derived from the practice of *case modding*, the practice of transforming computer cases into imaginative structures. [15] *Biomodd* is inspired by the codes and techniques in the case modding subculture.

E-waste and its creative reuse: Obsolete hardware is reused in *Biomodd* functionally and visually. As we discuss in the next section, the difference between obsolescence in the industrialized West and in the global South presented a number of challenges in *LBA[2]*.

Symbiosis between electronic and biological systems: *Biomodd* installations bring biological life in proximity with electronic hardware, and provide mechanisms for the two systems to communicate with each other through meaningful symbiotic relationships.

Open sourcing: *Biomodd* encourages the use of open source operating systems and software applications in order to extend the modification potential for the artwork as far as possible. In return, online guides have been produced that allow anyone interested to build their own version of the *Biomodd* installation.

Digital games and gaming culture: *Biomodd* installations can function as multi-player gaming environments. Games are either modified open source games or, as in the case of *LBA*^{2}, developed from the ground up by team members.

Recycling: After showcasing the project, the team that built the piece dismantles it and adopts the various components, or else recycles them in thrift stores, recycling centres, and institutions that might find use for the materials.

Juxtaposing the local and the global: Selected parts of previous versions are integrated into subsequent versions, which are built with different collaborators and new materials, but with the original concept reinterpreted according to local cultural and social conditions. In this way, *Biomodd* echoes Irani et al's observation that "technology travels … around the world in projects of design and development". [12] However, as we discuss in this paper, this goal of juxtaposition creates tensions due to conflicting histories, value systems, and narratives.

From Ohio to Los Baños: The Biomodd migration

As mentioned, the first *Biomodd* version, *Biomodd [ATH*^{1}*]*, was designed in Athens, Ohio in the US in 2007-2008. The second version, *Biomodd [LBA*^{2}*]*, was completed in Los Baños, Laguna in the Philippines in 2009. *LBA*^{2} was largely patterned after *ATH*^{1}. The social, cultural, and economic contexts of these two sites are widely different and resulted in outcomes that we feel reflect these differences. To discuss *LBA*^{2} sufficiently, we first describe *ATH*^{1}.

Figure 2. The *Biomodd [ATH*^{1}*]* installation

Led by this paper's second author, *ATH*^{1} was designed by a group of artists, scientists, and social change makers, and developed in the USA as part of an artist residency at The Aesthetic Technologies Lab at Ohio University in Athens, Ohio between September 2007 and January 2008. Around nineteen collaborators contributed to the project, which initially began without "a specific detailed design in mind"; and was instead left open as a an open-ended concept of translating "social heat" into "computer heat" and then finally into "life-sustaining heat":

> *Biomodd [ATH*^{1}*] reflects our attitude towards technology: never satisfied with the status quo, machines are endlessly evolved, systems are boosted and performance gets violently pushed. Overclocking of computer processors becomes a metaphor of contemporary society; a society fascinated by growth and productivity but at the same time generating massive amounts of excess heat.* [16]

The material outcome of the process was a living sculpture that functions as a social gaming station. Figure 2 shows the completed *ATH*^{1} installation, which featured the following components and subsystems:

- A metal frame covered with acrylic panels that contains exposed computer components and various plants;
- A networked system of five upcycled computers running a Linux distribution; the different computer parts are visible and mounted throughout the case;
- A multiplayer computer game that runs on the networked computers;
- A liquid cooling system that used a green algae culture as coolant liquid and stored in a large glass aquarium;
- A second aquarium – inhabited by goldfish – that was used to cool the algae coolant liquid; and
- Living plants housed within the case and whose growth was enhanced by the heat produced by the computer

Like *ATH*^{1}, *LBA*^{2} emerged out of a formal engagement between this paper's second author and with a university, namely the UP Open University in Los Baños. We co-led *LBA*^{2}, with the first author acting as the second author's local counterpart in the project. *LBA*^{2} heavily built further upon the design that was established during *ATH*^{1}. We initially aimed to use the same approach as in *ATH*^{1}, starting with a standardized conceptual framework without strict guidelines on how to formally interpret that framework. To facilitate the process, we offered the team the idea of interpreting the *ATH*^{1} system using local materials and aesthetic vernaculars, but only as a point of departure. However, a variety of contingencies forced the team to transform what was originally an exploratory design exercise into a blueprint for the final installation. These contin-

Figure 3. The Biomodd [LBA^2] installation

gencies relate to real complexities around funding, space, temporality, collaboration, collegiality, authority, and power. For reasons of space, we postpone further discussion on these contingencies, though we have previously covered some of the relevant issues in an examination of *LBA*^{2} as a platform for teaching and learning new media art. [11], [17] For now, we note that the team felt that they augmented the initial design to such an extent that they preferred to keep it in the final presentation. These augmentations cantered on the multiplayer game, an embedded aquaponic system, environmental sensing, and the use of traditional woodcarvings.

In this section we focus on five aspects of the *LBA*^{2} project that deserve analysis in the context of the postcolonial. We begin the discussion of each aspect with a discussion of material aspects of the installations. We believe that the political is embedded in the material. [18] Reflecting on the material differences between the two versions provides us a platform to unpack five issues: appropriate metaphors for heat in the tropics; colonization, authenticity, and hybridity; defining e-waste and leveraging the convertibility of capital; sampling, appropriating, and remixing; and the rhizome and the tree as metaphors for social organization.

Appropriate metaphors for heat in the tropics

One of the significant challenges we faced was reinterpreting in fact the central idea from *ATH*^{1} of the creative transforming and upcycling of waste heat. In temperate climates where excess heat generated by machines can be effectively used to keep spaces more liveable or productive (as with greenhouses), similarly generated excess heat in already hot tropical climates is extraneous and near useless. That technological solutions cannot simply be ported over from one context to another is well established, at least in other fields of science and technology such as agriculture and architecture. [19] Irani et al's observations on *appropriate technology* strikes close to the problem: "Many such well-intentioned efforts to 'migrate' technologies from industrialized contexts to other parts of the world have foundered … on social, cultural, political, or economic assumptions that do not hold." [12] In the case of the migration of Biomodd to Los Banos, the assumption was an environmental one.

The solution we settled on was brought forward by one of the team members who happened to specialize in aquaponics – the practice of recirculating water from aquaculture tanks to a hydroponic system. [20] The warm fertilized fish tank water in *LBA*^{2} was used to irrigate a vertical system of hydroponically grown plants inside the case. This elegantly closed the conceptual and thermodynamic loop: if people were using the game more intensively the computers would heat up more. As a consequence the algae culture would also heat up and dissipate more heat to the fish tank. The increased temperature of the fish tank consequently increased the fish's metabolism creating more nutrients for the plants in the vertical hydroponics system. Playing boosted growth.

Colonization, authenticity, and hybridity

In *ATH*^{1}, the processor of the server of the network was cooled using a water-cooling setup. But instead of commercial coolant liquid, we used a living culture of single-cell *Chlorella* algae. The warm algae culture was subsequently cooled using a simple heat exchanger. The warm algae were pumped through a submerged spiral in a fish tank. In this way the heat dissipated in the fish tank.

The algae's provenance is relevant. Originally sourced from Belgium, the algae was dried and revived in the US during *ATH*^{1}. *Chlorella* is known to exhibit a high tolerance to desiccation through the formation of spores. [21] Moreover, *Chlorella* algae are so-called bioaerosols and can be carried along through the air. [22] As a consequence, "American" algae "contaminated" the "Belgian" algae, which were cultured in a non-sterile, open environment during *ATH*^{1}. We repeated the process in *LBA*^{2} and cultured the *ATH*^{1} algae – an American/Belgian hybrid – with the expectation that the local Philippine variant would infect the *ATH*^{1} algae mix.

During a talk that we gave in the Philippines, the concept of mixing algae spurred some discussion with the audience. "Why not use a purely local species?" we were asked. There was a criticality to the question. It carried weight. After all, as a poetic act, the notion of one algae strain "infecting" or "contaminating" another is a powerful. But as a political act, it raises question about cultural integration. Was the audience member's question a veiled expression of xenophobia? Perhaps, but it is well worth stressing that the Philippines is a postcolonial state that has only relatively recently emerged out of over a combined

425 years of Spanish, then American, rule. It has been well documented, in fact, that the United States "sought to make over the Filipinos into little brown Americans". [23] Around the time *LBA*[2] was initiated in the Philippines, the nation was (and to this day still continues to be) engaged across multiple scales in dynamic processes of cultural and personal *identification* characterized by an inclination towards an "imagined community" that could be seen to transcend precolonial identities. [24], [25] As historian Fernando Zialcita has observed, "many Filipinos question the 'authenticity' of their identity… [They] are uneasy about the heavy Spanish influence that came in with colonialism… [and] wonder if their culture is a mixture of conflicting traditions." [25] Little wonder, then, that the provenance and metaphoric signification of the algae provoked questions.

But if there is uneasiness about hybridity and absence of authenticity in some quarters, an opposite sensibility – one that celebrates the mutability of identity and the possibility of a global cosmopolitanism – characterizes other areas of the Philippine experience. [26] Seen in this light, Biomodd's deliberate hybridization of *Chlorella* could be seen as desirable. It resonates with Irani et al's reminder of the instability of geographical or physical distinctions when demarcating the boundaries of culture. [12]

Defining e-waste and leveraging the convertibility of capital

Biomodd attempts to engage with the problems posed by electronic waste (e-waste). *ATH*[1] featured a networked system made of computer components – motherboards, hard drives, optical drives, CRT monitors – that had previously been discarded and regarded as obsolete. Team members assembled these components into fully functional computers by identifying usable or repairable components and maximizing their functionalities – for instance, by maximizing random access memory (RAM) use – and by installing lightweight operating systems. In addition to reusing computer components functionally, the team also used e-waste as architectural elements in the installation based on what Kim and Paulos have identified as the *material, shape,* and *operation* properties of e-waste. [27]

Functionally and visually, e-waste was used in similar ways in *LBA*[2] as in *ATH*[1]. However, the process by which we acquired the e-waste differed drastically between the two contexts. Technological obsolescence is different in the US than in the Philippines. This was highlighted in an extended search we conducted for discarded Pentium 4 motherboards – a difficult task since at the time we were working on *LBA*[2], most offices and homes in the Philippines were not willing to part even with Pentium 2 computers. (Our request for such powerful computers was met with visible amusement by the manager of a local recycling plant!) A discussion arose within the team about whether we should work with and hack what was readily available. In the end, we decided to stick with the original minimum specifications, as we believed that hacking older computers required technical skill, which would be harder to find than Pentium 4s.

Decisions such as these highlight the types of trade-offs and *conversions* that we had to make in sourcing material, labour, and other forms of capital. (Our use of the term 'capital' is based on Bourdieu's notion of forms and convertibility of capital and Talisayon's typologies of intangible assets. [28], [29]) Since we had little by way of *structural* capital (sufficiently powerful but somehow also obsolete computers) or *human* capital (skilled programmers who could hack the old computers that were readily available), we turned to our *social* capital. The team held a public event where we invited friends and family and colleagues (and their friends and family) to come and donate their old computers to the *Biomodd* team.

Indeed, our reliance on converting one form of capital into another extended to a bewildering array of activities, from barbecuing donated hotdogs, and selling cocktails created with cases of donated vodka at parties; to convincing people at social events to drop the equivalent of 50 US cents in a "*Biomodd* bowl" for the opportunity to have their photography posted on the *Biomodd* website. We crowdfunded in real crowds. After two failed grant applications (a failure to secure *financial* capital) and an initial level of disinterest from major art spaces in providing *infrastructural* support, we realized that building our social capital was the most viable way to keep the project growing. Over the course of about six months, we grew the *Biomodd* team to the point where we had about 10 core team members, about 40 occasional team members, and over 70 people on the team mailing list. The final roster of *Biomodd* was immense and featured supporters from academia, the nonprofit sector, industry, private individuals, the arts, and the sciences. The convertibility of tangible and intangible forms of capital is crucial to all projects that seek growth and is particularly powerful in the context of the global South. [29]

Sampling, appropriating, and remixing

A strategy for responding to the postcolonial condition can be retrieving, reinscribing, and (to an extent) reimagining what precolonial narratives, value systems, and histories have persisted. While *ATH*[1] featured a modified version of an existing open source game, in *LBA*[2], our team of game designers designed a persistent game based on the folk mythology of *Maria Makiling*. *LBA*[2] was built near the base of Mount Makiling, a forest reserve. Maria Makiling is the deity believed to protect the mountain. [30] During the initial conceptualization stage of the computer game, the *LBA*[2] team decided to use Maria Makiling's mythology as core inspiration specifically because its overtly ecological undertones. The entire team was invited to contribute concepts and narratives, both through on site discussions and through the mailing list.

It quickly became clear there were roughly two groups in the team: people that had little or no experience with computer games, and people that considered themselves literate in games with at least basic knowledge about game

mechanics and genres. The first group tended to focus on creating detailed narratives, more akin to scriptwriting in film. The second group was more concerned about creating a technically feasible gameplay that would emanate some of the mythology's core ideas. One particular discussion stood out during game development: how much of the mythology could be reinvented and rehashed? When someone suggested mixing characters (in the form of different mountains from the Philippines), this caused a backlash with some of the team members. One of the core team members gave a compelling argument: "Putting [the mountain] Banahaw as a character [in a game about the story of Mount Makiling] would be like placing a Marvel character into a DC comic. If this were all a parody, why not? But it's not."

Our colleague's concerns runs along a similar vein in the world of commercial video games where (up till recently at least) stories and perspectives of indigenous peoples around the world have been under- or misrepresented. [31] Here we find it relevant to highlight categories on the use of traditional themes that others – such as game company Upper One Games – have articulated. Upper One Games specializes in designing games on indigenous themes and narratives, and distinguishes between games that *appropriate*, *sample*, *depict,* and are *infused by* indigenous culture. [32] While our goal in *Biomodd* was to infuse, perhaps we ended up at best sampling. However, we strove to avoid unauthorized appropriation. We did not find any cultural proscriptions about how the narrative of Maria Makiling (or, for that matter, of Banahaw) could be shared – unlike, for example, a case that Irani et al have described concerning an Australian Aboriginal people and one of their sacred narratives whose telling was strictly regulated. [12] Still, the issue raised many questions around the extent to which we were at liberty to remix ideas, symbols, and mythologies.

In the end, we decided that the Maria Makiling mythology would be the overarching theme of the entire *LBA*[2] project, including the game. Two players on one keyboard can play the resulting multiplayer game. The game world is a single screen in which the character of Maria Makiling takes centre stage. The goal of the game is to help protect her forest ecosystem and assist with reforestation. Destructive projectiles from outside are attacking the forest. Players can either choose to be a protector, or a grower. Protectors can set up temporary barriers while growers can plant trees. In order for the forest to fully develop, players have to collaborate. When the game is left alone, the forest will disappear. The character of Maria Makiling also tweeted about the state of her forest and thanked players for helping out. In this way the *Biomodd* also continued beyond the walls of the spaces where it was exhibited. Figure 4 shows a screenshot from the game.

Figure 4. The *Biomodd [LBA*[2]*]* game. Video of a gameplay sample is available on http://youtu.be/7TtlKs4gq4Q.

The rhizome and the tree

One of *ATH*[1]'s main features is the metal frame that encases the electronics and the living ecosystems that have been brought into close contact with each other. It is a singular structure, erect and imposing. In subsequent versions of *Biomodd*, this central structure has grown increasingly monumental. In addition to commenting on the potentially phallocentric imagery that this evokes, there was discussion in the team about reimagining the structure instead as a redistributed system of smaller structures. It was suggested by at least one member of the Philippine team that this perhaps might be a more 'truthful' or 'progressive' vernacular aesthetic that resonates in the Philippine context because of many reasons, including the archipelagic geography of the country; the importance and pervasiveness of many small-scale economic structures (such as the pervasive *sari-sari* stores and countless sidewalk vendors); and the continued failure of large-scale governance. [33] There was even a material and practical basis for such a distributed structure: one of the workshops we had undertaken involved creating tiny *Biomodd* structures using inexpensive shower racks as scaffolding. It would not have been too much of a stretch to build on these tiny structures and link them together to form a dense network of small *Biomodd* structures.

We believe that this debate within was in fact rooted in the team's (perhaps implicit) understanding of two basic structures that Deleuze and Guattari have described: the tree and the rhizome. [34] The rhizome "resists structures of domination" and "ceaselessly establishes connections between semiotic chains, organizations of power, and circumstances relative to the arts, sciences, and social struggles". [34, p. 7], [35] Deleuze and Guattari contrast the rhizome against the tree, which is linear, and has "dominated Western reality and all of Western thought, from botany to biology and anatomy, but also gnosiology, theology, ontology, all of philosophy". [34, p. 18] Thus, the rhizome could be seen as a possible structure of postcolonial grassroots movements: decentralized, distributed, and resilient to rupture.

But the monolith prevailed, for reasons related to why *LBA*[2] as a whole emerged as a functional, rather than a conceptual, translation of *ATH*[1], as already mentioned. Perhaps the single, monumental case persisted also because of what Deleuze and Guattari have called the "arborescent schema" that pervades contemporary imperialized, postcolonial cultures. [34, p. 328] The debate, however, was

not forgotten. A later *Biomodd* workshop in St-Niklaas, Belgium, expanded on the shower rack prototyping exercise. Using found objects of all sorts, participants produced a diverse array of 'miniature' *Biomodd* systems whose sensibilities ranged from the grotesque to the delightful, recalling the heterotopia of the rhizome. All were networked and displayed in a horizontal layout. A recent Biomodd workshop in Santiago, Chile generated similar small systems distributed throughout the trees and scrubs of an art gallery garden.

Towards a heterotopia of design fictions

We deliberately concluded the previous discussion on postcolonial themes in *LBA*^{2} with the theme of the rhizome, as well as with a mention of subsequent *Biomodd* versions. Since *LBA*^{2}, we have facilitated other *Biomodd* projects in other countries. But several other versions of *Biomodd* were also built independently by other groups in the Philippines in response to *LBA*^{2}. [17] To what extent can the independent *Biomodd* projects be called *Biomodd* versions? Perhaps the most appropriate answer is a question: does it matter what the answer is? The heterotopia of the rhizome rests on the belief that diversity matters, that diversity is good. It is one we subscribe to, at least for now.

We had mentioned that one of the contingencies that the *LBA*^{2} team were forced to reckon with was temporality. Reflecting on our experiences in *LBA*^{2}, we wonder what would have happened if we had more time than the eight months that we had to work on the project. Would it have looked very different? Probably. Perhaps we could have better taken to heart Irani et al's abstracted framework for a postcolonial computing design collaboration, involving *engagement*, *articulation*, and *translation*. [12] This abstraction, it seems, allows people room to breathe, and think, and act, and then breathe again. We have found that creating ground-up movements of art-science collaboration in the Philippines requires time. An open call for scientists and artists to collaborate with us on *LBA*^{2} went unheeded for months. It was only after we had spent several months building networks, holding social events and fundraisers, did we finally manage to attract the kind of expertise that significantly contributed to the growth of the project.

Nevertheless, we take the fact that independent groups in the Philippines initiated their own *Biomodd* initiatives as a sign that there is indeed a space for projects that straddle the boundaries of art and science. We submit that like Irani et al's notion of postcolonial computing, *Biomodd* is a sensibility, not a methodology. It is an approach that seeks to nurture that awareness of critical connectedness, and affiliates itself with the countless of other projects around the world that hopes to do the same thing (or, rather, something similar enough). For instance, we also see *Biomodd* as an example of design fiction or speculative design. [36] Biomodd does not meet directly solve an immediate problem, but it does aim to suggest to the viewer a parallel reality that in which alternative ecological relations exist.

Conclusion

In this paper, we used a postcolonial lens to re-examine our experience of working on *Biomodd [LBA*^{2}*],* a large-scale, collaborative, art-science project in the Philippines that was based off a prior project completed in the USA. We used a comparative discussion of the components of the physical installations that were built in both contexts to examine how the different social, political, and economic contexts influenced the final outcomes. We revisited the appropriateness of the metaphor of heat recycling in the tropics; unpacked issues regarding authenticity, hybridity and colonization in the poetic use of multiple varieties of *Chlorella* algae; examined how conflicting definitions of obsolescence in e-waste led to the conversion of different forms of capital; reflected on whether our use of folk narratives constituted sampling, remixing, and appropriating; and elaborated on the rhizome and the tree as metaphors for collaboration and social organization. We hope to report in future publications on the outcomes of other *Biomodd* projects that have been initiated since *LBA*^{2}, and on our continuing effort to build alliances with individuals, organizations, and initiatives that seek to articulate the sensibilities that the *Biomodd* platform embodies.

Acknowledgements

We thank the *Biomodd* [*LBA*^{2}] team – particularly the core team – for their tremendous contributions. *Biomodd* [*LBA*^{2}] was created with the support of the Flemish authorities and the Faculty of Information and Communication Studies at the UP Open University. At sea with the past: reflections on an artwork

Jean Brundrit

University of Cape Town
Cape Town, South Africa
jean.brundrit@uct.ac.za

Abstract

This paper offers reflections on an artwork entitled, *At Sea*, (2012). *At Sea* is a picture derived from a 3d laser scan of a wave, presented as a two dimensional digital image, and printed at variable scales. My conceptual interests in this artwork were concerned with disrupting perceptions of the 'first world' as being perceived as 'the centre' and the 'third world' as being perceived as marginal.

I have written this paper from the position of both the artist and commentator. I discuss my background research, working process, innovative use of technology, thoughts about ways of looking, methodology and results. Particularly noteworthy is my use of 3d laser scanning within a fine art context.

Keywords

Colonisation, 3d laser scanning, mapping.

Introduction

I made the artwork *At Sea* in 2012. It depicts a wave, rendered in small, light dots on a black, panoramic format background. This two dimensional image was made from source information collected by a 3d laser scanner. The artwork has been exhibited in a variety of ways: as an image on a billboard (Figure 1.), as a print on vinyl adhered to a gallery wall and as a conventional inkjet print.

At Sea was commissioned by Radar, a contemporary arts programme that develops new work linked to academic research, located at Loughborough University. The commission was associated with a conference, *Home/Land: Women, citizenship and Photographies* (2012) which in turn was generated by an international research project led by Marion Arnold and Marsha Meskimmon, academics from the Visual Art Department at Loughborough University, in the United Kingdom.

The margins and the centre

The commission's brief was closely aligned to the concerns of the aforementioned research project but also

Figure 1. *At Sea* exhibited as a publically sited artwork in Loughborough, U.K. 12 – 25 November 2012

highlighted the following areas for consideration: land and identity, gendered, virtual and imagined landscapes, contested lands/spaces, national identity and nationalism, (post)colonial lands, the globalisation of land, borders, cartography and the politics of land.

With this in mind I began to consider current global socio-economic and political structures in relation to the 'west' being viewed as 'the centre' and my home, South Africa, as on the periphery. I also wanted to establish some kind of connection between Loughborough and Cape Town. I have lived in Cape Town for most of my life but prior to going there I knew little about Loughborough. During a two week residency in Loughborough, as part of the commission, I researched, followed up thoughts, photographed and worked towards a proposal for an artwork.

I looked to the past as a way forward. Loughborough is a medium sized market town, dominated by its university. It is situated in the east midlands of England, and surrounded by more well known towns such as Derby, Leicester and Nottingham. In 1780 the navigable waterway system was expanded to include Loughborough in its vast web of canals that linked towns, transporting coal thereby facilitating growth in industry and the town's role in the industrial revolution [1].

The principal form of global travel at this time was via water. Shipping and naval prowess were important channels of colonisation, with inland waterways and the sea linking Britain to the colonies, Loughborough to Cape Town. I had found a connection: Loughborough, with its industry and location on the canal system, was linked to Cape Town through colonisation, the industrial revolution and water transport. Coal-driven steam engines played a major role in shipping, effectively bringing the colonies closer in travel time.

An imaginative connection can be mapped through water: a drop of water could travel through the Grand Union Canal from Loughborough to London, out to sea with the River Thames, and there get caught up by the great ocean conveyor belt and find itself off Cape Town at the southern end of Africa.

My concept began to take shape around thinking about the Cape as a British colony and the connections between the sea, power and control. The final piece of supporting information for my artwork was making a link to mapping. During the creation and expansion of the British Empire land was 'discovered', named, surveyed and mapped, then 'claimed' and 'owned'. Using surveyor's tools the image I have made is a futile attempt to map the unmapable.

Disruption and resistance

Using a specialised land-surveying instrument, a 3d laser scanner, I surveyed and scanned the waves. To survey is an act of authority, control, ownership and order. To survey waves, from a mapping point of view, is a pointless exercise. At the time I made *At Sea* I wrote:

> I was particularly interested in the futility of this activity, of mapping moving water, a thing that cannot truly be owned, that will not be ordered, even if it can be measured. This artwork is a representation of chaos using measured, contained, scientific visual language. [2].

It is a disruption of the original purpose of surveying and of the concept of a map that demarcates place and by association, ownership. It is a non-map, it cannot be used to locate position and it cannot define areas of ownership in a conventional or meaningful way. In this it is a celebration of chaos, an act of defiance. It is my way of talking back to the centre from the periphery.

My intention here shares much with post-colonial texts that talk back to the centre to re-interpret and destabilize supposedly immutable positions and 'truths'. By 'talking back' I am referring to theorists Ashcroft, Griffiths and Tiffin's seminal book, *The empire writes back: theory and practice in post-colonial literatures,* that explores the complexities of post-colonial writings. Their book title quotes from the title of an article written by Salman Rushdie, *The Empire Writes Back with a Vengeance,* published in the London Times, 3 July 1982.

Scanning waves

I undertook a voyage in a small boat twenty-five nautical miles south of Cape Point. This expedition, while only a few hours and in moderate weather conditions, was long enough to make some observations about deep sea waves as they welled up and bulged, retracted and opened into cavities. Although there were generally defined swells and troughs these seemed to be an underlying form onto which endless surface variations occurred. Water collected, patterning the surface one moment, then falling away, insubstantial the next - a dynamic, heaving mass.

This far out to sea no land is visible. The seascape is all one can see and this contracts and expands as the boat rises and falls, changing one's point of view. As the boat descends to the bottom of a trough, the world contracts. The next instant a vast seascape opens up around one, as the boat rises to the crest of a wave. This constantly shifting view point is reminiscent of moving about in the 3d laser generated, virtual scanned sphere, but in the real world I have less agency and am bound by physical forces. The physicality of ocean waves and the structure of the sea surface inspired the formal qualities depicted in *At Sea*.

A detailed illustration (Figure 2.) shows some of the topography and variations in the scanned waves' surface - there are peaks, ridges, a cliff - like area in the top left hand corner, and along the upper edge the image fractures into blackness. In the final artwork the panoramic frame acts as a window, selecting part of a larger scene that extends into vastness beyond the picture. This is a sea to loose oneself in.

The coastline around Cape Town is sometimes referred to as the Cape of Storms and as its name suggests, it is notorious for heavy weather and a dangerous, unruly sea. The waves I chose to scan meet the coastline in front of Green Point Lighthouse in Cape Town, the oldest lighthouse in South Africa. I specifically selected this site as the lighthouse was first operational in 1824, when the Cape was a British colony. The lighthouse is situated on the eastern headland adjacent to Table Bay, assisting with navigation into the bay for those wishing to land.

While researching this site I learnt about the *SA Seafarer* that stranded directly in front of the lighthouse during the winter of 1966. This disaster was well documented and aerial photographs show the ship on the rocks with the Green Point Lighthouse clearly visible in the background. The wreck was so close that the lighthouse's rotating light was stopped and the beam pointed towards the ship so that the rescue operation could continue after dark. Other dramatic photographs document huge waves breaking over and engulfing the ship, eventually splitting the hull apart. Accounts of this event reinforced thoughts of the precariousness of coastal activity and the sea's ferocity,

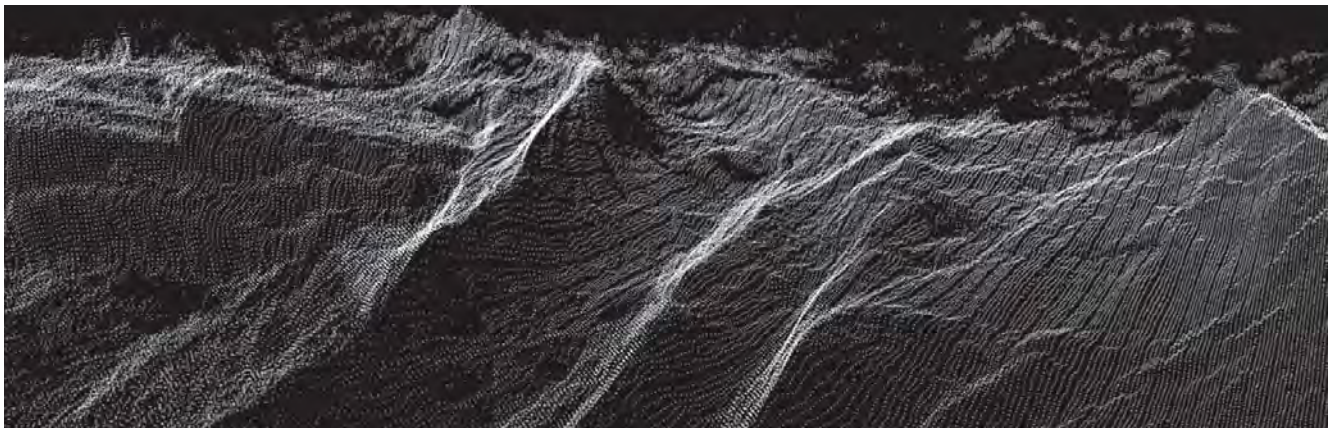

Figure 2. A detail from the digital source file for *At Sea*

and stressed the futility of any attempt to exert authority or control over it. This accentuated the pointlessness of scanning and mapping the waves.

I generally make art using a camera and this was the first time I had worked with a 3d laser scanner and its associated technology. The scanner is mounted on a leveled tripod. The scanner head rotates horizontally as the laser spins on a vertical axis while firing beams to record information in its spherical range. Each laser pulse records a point, a return distance reflected from an object's surface. Its application in surveying is to measure the distance between any of the recorded points, allowing complex environments to be surveyed in a short period of time. Depending on the model of scanner the distance that the laser travels varies. A scanner has a fixed reach, for instance eighty meters. Figure 3. shows an overview of the scan site with the elevated promenade above the sea wall providing a protected location for the scanner. Although this view looks from the edge of the scanned sphere back towards the land, the lighthouse was not recorded as it was beyond the scanner's range.

One of the limitations of laser scanning is that water diffracts the laser beam, so it does not record a return point distance and no image is captured. This was brought to my attention by Cape Town based land surveyors, Gavin Lloyd and Justin Hill, when I approached them to assist with this project. In discussion we decided to experiment, to see if a scan of a breaking wave with foam, a reflective surface, would record an image. This was successful.

My image making using the scanner, consisted of two activities. The first entailed gathering information on site with the scanner, the second interpreting that information on computer. With each scan a sphere or point cloud of information is recorded, a spherical mini sample of the world.

Using software this mini sphere can be interpreted in a 'photographic' way. By this I mean the same formal decision making processes that I go through when I take a photograph can be applied here, except I am not bound by gravity and the physical world. In the virtual information sphere I can float about and choose any position to 'photograph' from. I can 'photograph' from the position of the scanner, or position myself at the edge of the sphere and look towards anything that interests me, in any position I imagine. Like conventional photographic image making I can decide to take a wide shot, or zoom in close to my subject. I can include many formal elements in my composition or compose an image with a large negative space. In this way I can interpret and select information in the mini sphere to compose and 'take' my final image.

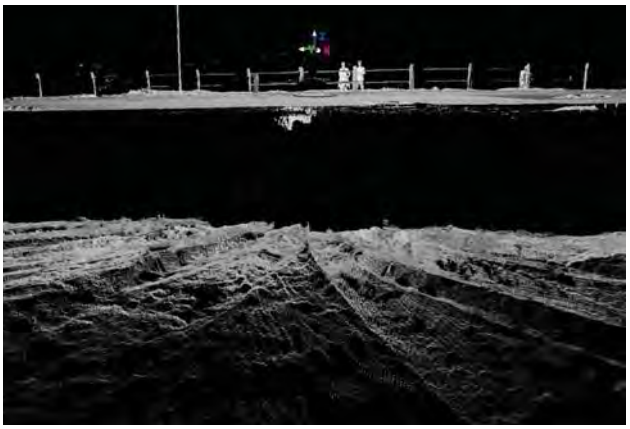

Figure 3. A laser scan detail showing the position of the scanner on the elevated walkway (below the XYZ), in relation to the waves scanned. On the immediate right of the scanner are two figures, inadvertently scanned, myself and land surveyor, Justin Hill.

Shifting perceptions

Unlike human visual perception, the 3d laser scanner has no discernment, no 'filters' and all information, in the on site scan, is gathered with equal attention and with the same 'neutrality'. This echoes sentiments about photography's supposed objectivity expressed in the 19th century, for example -

> But in its early years photography was celebrated for its putative ability to produce accurate images of what was

> in front of the lens; images which were seen as being mechanically produced and thus free of the selective discriminations of the human eye and hand. [3]

Today few people still believe in the 'neutrality' of the photograph. And any 'accuracy' is undermined when motion is present, either with the recording device or in the subject. In making *At Sea* both scanner and subject were moving.

A scan takes approximately a minute. This technology and its way of looking and recording, is disrupted when the subject moves while being scanned. 3d laser technology is also referred to as 'real scene copying'. This implies a facsimile of the original and this is possible only when the original subject remains static during scanning. Here however, the subject, the waves, are moving so the result recorded is not a facsimile of a wave, but an impression of a wave, a trace of movement.

The speed and direction of the wave relative to the scanner's position and rotation influence what is recorded. In this instance the wave moved and scanner rotated in the same general direction. As a wave meets the shore it speed varies, it slows as it builds up prior to breaking, then accelerates with gravity, slowing once again as it dissipates. The scanner moves at a constant speed. If the wave moves at the scanners rotational speed the points recorded will be recorded without distortion. However if the wave over takes the scanner the points will be spaced further apart, conversely if the wave is slower than the scanner, the points will be condensed. This made it difficult to predict results. Until we had done it I had no idea what was actually going to be recorded.

Here the recording device (the scanner) and subject relationship has shifted from a mimetic relationship (real scene copying) towards an interpretive relationship. This 'mechanical' interpretation coupled with my post scan, 'photographic' interpretation and selection of the final composition made *At Sea* an imaginative translation of a sea experience, rather than a naturalistic visual representation.

Conclusion

My initial interest was sparked by the historical and contemporary socio-political distribution of territories on the globe, and perceptions that map some areas as the 'centre' and mark others as the 'margins'. The title of the work, *At Sea* alludes to the subject of the artwork and to the idiomatic expression, *to be at sea*, meaning to be confused or at a loss. Through the process of making I have interrogated global power dynamics and in this regard I am less at sea. However I have been captivated by the sea as a rich area of investigation, and a project that began in a town in the English midlands has led me to discover the shifting quality of the ocean in relation to my own history and geography.

Author Biography

Jean Brundrit is a visual artist who works with photographic media. She has exhibited extensively in South Africa and contributed to a number of international exhibitions. She is a Senior Lecturer at the Michaelis School of Fine Art, University of Cape Town where she teaches photography. She is a NRF rated researcher. Her research interests are primarily concerned with exploring the environment and identity, specifically lesbian identity and strategies of representation within a South African context. Her work pertaining to the environment is focused on the impact of rapid climate change and how this is represented in art; as well as the interconnectedness of humans and their relationship to the natural world.

Abstract

We have developed water based electronic elements which we built into electric circuits to control different parameters of electronic sound and video tools. As a result of our research we have constructed a complex controller whose main component is water. This tool makes it possible to control analog and software synthesizers as well as video software and other electronic devices, especially microcontroller based platforms like Arduino or Raspberry.

Keywords

controller, computer interface, water, electronic music, video, mass inertia, fluid, potentiometer, switch, fader

Introduction

Many traditional music instruments such as violins, guitars, timpani, pianos, and trumpets can give the musicians an immediate tactile response to their play. A strike on the timpani makes the mallets bounce back in a very specific manner, depending on the velocity, intensity, point, and angle of the beat. Plucking a guitar string, bowing a violin, sounding a trumpet or pushing a key on the piano not only requires overcoming a resistance but it also produces a kickback. On a piano for example, this kickback consists of the hammer falling back, an effect which the musician, upon touching the keys, can feel directly in his fingers. The nature and strength of this kickback response depend on both, the type of the action (plugging, beating, blowing, striking), and the strength, the sound quality, the pitch.

In electronic music the tactile feeling of the generated sound is absent. We cannot grab into the electric power and influence the sound quality with our hands in a direct manner. We cannot feel the swinging of an oscillating electric circuit consisting of transistors, resistors, and capacitors. Musicians have to play electronic instruments always in an indirect manner via interfaces.

These days the development of many industrially produced interfaces tends to avoid mechanical components as much as possible or to use only a minimum of mechanical parts. This leads to the fact that the input devices themselves do not create any music adequate resistance against the musician´s acting. Moving a fader or potentiometer from point zero up to half (50%) requires the same force as moving it from half to the top (100%). If this tool is used to influence the volume or the amount of distortion of a sound, one would wish for a fader whose sanding resistance increases according to the distance. Certain attempts have been made at finding a solution but the results have not yet gone beyond the status of a dummy, i.e. they are not actually included in the work circle of the sound production.

The best known example of such a development are the weighted keys of a keyboard. They are supposed to imitate the feel of a traditional piano but are not actually linked to the sound production. However, these particularities of the electronic sound generation do not imply a lack because the listener is rewarded with an immense amount of sound possibilities, a wealth that hardly exists in music produced with traditional instruments. On the other hand we have to admit that these particularities clearly influence the aesthetic perception of the work. Especially in the beginning of electronic music people used to describe the sound as very mechanical.

Fluid Control

The artist group „wechselstrom“ has made an attempt to develop the potential: A first approach consisted of producing the movement of sounds in space with an interface that gives the musician a physically tangible reference to his actions. These movements are normally regulated with a pan knob or a joystick. We equipped the interior of a closable plastic box with metal wires that took over the function of inputs and outputs of a mixer. These wires were isolated from each other, i.e. they hung free-floating inside the plastic box (Fig. 1).

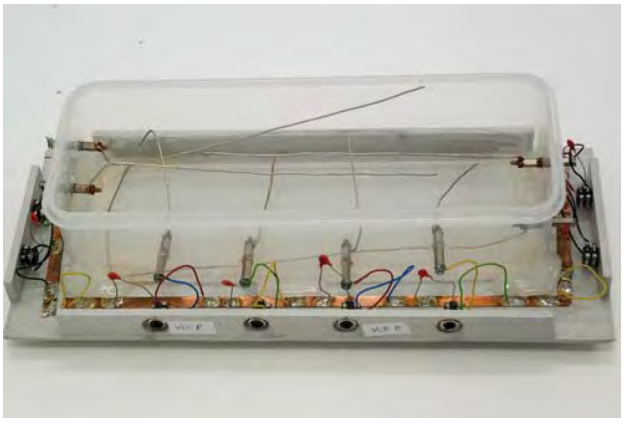

Fig. 1

The moment when the box was filled with (tap) water a complex structure of potentiometers was created mutually influencing each other. The wires took over the function of electrodes and the water served as a variable resistor. Measurements showed that the electrical resistance between two electrodes was between 15 - 50 kohms, depending on the immersion depth and the degree of wetting. These values are also used in normal potentiometers in electric circuits.

We have called this new instrument the „Fluid Control" box. It has been our goal to use Fluid Control as a matrix mixer which combines the functions of controllers, switches, faders, panning regulators, and joysticks in one hand. The movement of the water inside the box, the sloshing of the liquid reveals not just an audible image of the movement of sounds in space. Furthermore, the player / musician can bring his own body into a tactile relationship with the shifting weight of the water. The body and the instrument can now get into a resonant interaction. This process is similar to the rhythms of a sand- or rice-filled egg shaker which sound most lively when one succeeds to synchronize the movement of the grains with the swinging movements of the hand and arm.

In summer 2012 (during the festival Sound Barrier) we set up two Fluid Control boxes, two CD players, which resulted in a total of four mono tracks, and a 4-channel sound system. The four mono tracks coming from two CD players were launched into the input side of the first Fluid Control box mixed together with the appropriate proportion of water and sound levels on two tracks. This mixture was fed into the second Fluid Control box and distributed dynamically to the four channels of the sound system (Fig. 2).

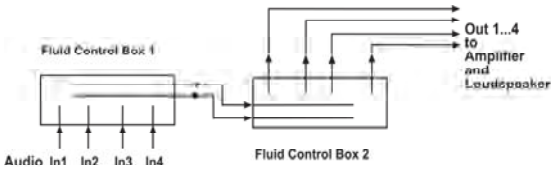

Fig. 2

Following the golden rule "current is current is current" the next step was to modulate not only audio signals but also to modulate control voltages generated in analog synthesizers. These electronic devices have the advantage of providing multiple physical inputs and outputs that can be plugged in directly. We showed this second setting for the first time on Sept 15th 2012 in the Jazzschmiede in Düsseldorf. We used the possibilities offered by Fluid Control for influencing the control current that was produced by an analog sequencer in order to drive an analog synthesizer (Fig. 3).

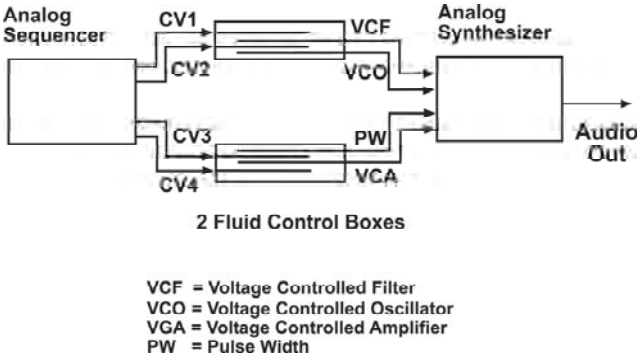

Fig. 3

As a result of our research we have created a tool which makes it possible to control electronic sounds within the dispositive of preselected sequencer and synthesizer setups in a very fast, dizzy, sophisticated, and sometimes chaotic way. Developing this tool we intended to make the change of the sound parameters in electronic music physically tangible. We also wanted to give the player a resistor / a weight into his hand which enables him to react in a more immediate and body conscious way to changes in sound beyond the scope of what controllers and interfaces like buttons, faders, rotary potentiometers, and touch screens can do.

As a the third we wanted to bring Fluid Control into the sphere of the digital world of computers, software synthesizers and, as a follow up, of video or any other multimedia software. All well-known software synthesizers like MAX, pd, Reaktor etc. and most video/graphic software (MAX/jitter, Resolume) use and understand MIDI specification to control various parameters. We used a MIDI box which provided MIDI inputs and outputs and was connected via USB or FireWire to the computer on the other side at the same time. For the creation of a reliable MIDI data stream we took the +5 volt CV (Control Voltage) specification as an equivalent for the midi data value 0…127. We generated the corresponding data stream via a CV-to-MIDI converter. We modified the control voltage, which is often constructed with a single potentiometer, by adding the Fluid Control Box and by building it pre-, and/or post-fader or as a side channel into the electric circuit
(Fig. 4).

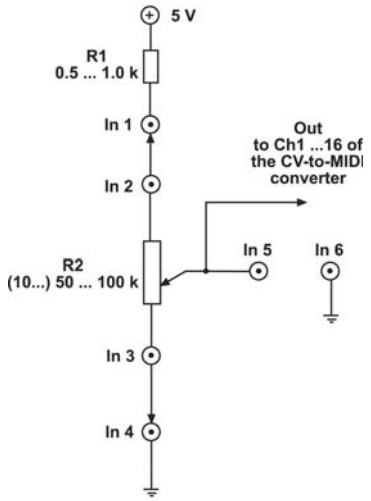

Fig. 4

"In1" and "In4" (socket symbol with arrow) are sockets with switching contacts, all other sockets are without switch. R1 is a resistor preventing a short circuit when sockets are connected in a wrong way (e.g. if you connect In1 to In6). The out goes to the input of one of the 16 channels provided by the CV-to-MIDI converter, which means that this circuit diagram was built 16 times (Fig. 5).

Fig. 5

Connections can be made between all sockets, even between sockets of different channels. However, only the following connections produce an effect: In1-In2, In1-In5, In2-In5, In3-In4, In3-In5, In4-In5 and In5-In6.

Fig.6, 7, and 8 show the basic connections. In Fig.6 two Fluid Control boxes are looped in. Together with R2 they build a voltage devider. When the slider of R2 is in the upper position the first Fluid Control box has more influence than box nr.2 and vice versa. When for instance the second box is plugged out the remaining box achieves the highest effect with the slider of R2 being in the upper position. When the slider is in the down position the box is inactive because the slider is connected to ground, therefore the output voltage is zero. In Fig.7 and Fig.8 the box achieves its highest efficiency when the slider is in the center position.

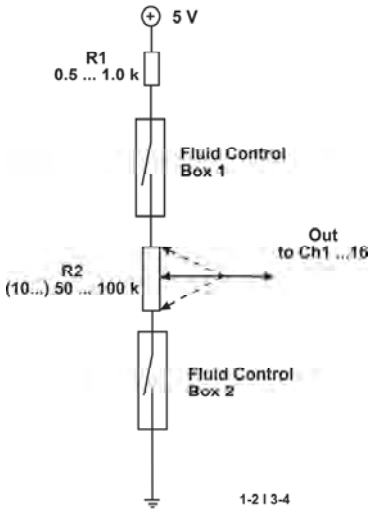

Fig. 6

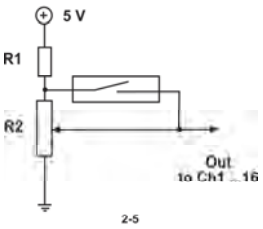

Fig. 7

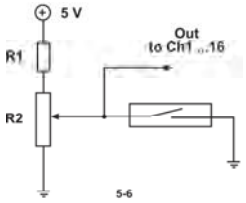

Fig. 8

Obviously, Fluid Control can be connected to any microcontroller or computer. In this case a MIDI-translation is not necessary, the circuits shown in Fig.4 - Fig.8 can be directly plugged into the analog inputs of the Arduino or Raspberry.

Film clips illustrating the operation of this instrument are available under the following Internet links:

wechselstrom

Christoph Theiler & Renate Pittroff

"wechselstrom" is a label owned by Renate Pittroff and Christoph Theiler. Based in Vienna, "wechselstrom" runs a so-called "offspace", which offers room for exhibitions, media activism and all art forms on the fringe of culture.

Selected works:

Piefkedenkmal – the construction of a monument for the musician Gottfried Piefke, who is also the namesake of the well-known Austrian derogatory name for Germans (2009 Gänserndorf)

Samenschleuder – a tool for environmentally conscious car driving (2009 Weinviertel, Lower Austria)

bm:dna – the government department for dna-analysis (2005 Vienna)

Tracker Dog - follow a (your) dog and track the route with a GPS, then print and distribute new walking maps (2008 Mostviertel, Lower Austria)

Community Game – a tool for distributing government grants using a mixed system of democratic vote and randomized control (2006 Vienna - distributing 125.000 Euro)

whispering bones – a theatre play asking for the whereabouts of A. Hitler´s bones (2004 Vienna, rta-wind-channel)

Reply - mailing action: resending Mozart´s begging letters under our own name to 270 people: to the 100 richest Germans and Austrians, to managers and artists of the classical music business, and all members of the Austrian government (2005/06 Vienna)

Abstract

Artists like Sachiko Kodama have demonstrated the aesthetic potential of ferrofluids in unique, visually spectacular installations like the *Morpho Towers* and *Breathing Chao* [2]. This paper presents a more systematic approach to ferrofluid manipulation: a vertical display, build under project-name: "Liquid Choreography", later released as "Ferrolic". [1]

This Digital FerroFluid Display's (DFFD) potential rests in visual references to movement of fluids but also living creatures. Specific dynamic and graphical properties that generate a narrative in the form of an animation are displayed in a video [1] that is central to this paper. In order to understand the written descriptions in this paper, it is strongly advised to review this video before reading this paper. Also see figure 1 and figure 2.

In the first part of the paper, the principles of operation of the DFFD are described. Creation of images, transitions between images and fundamental aspects of FF manipulation are presented.

In the second part of the paper, a first attempt to come to a vocabulary for the use of the DFFD as an expressive platform is presented. For this purpose seven different animations were generated and presented to in total five experts in the field of art and design. These experts were interviewed about their personal constructs for the animations. Based on a systematic (thematic) analysis of these interviews, the vocabulary was derived.

Keywords

FerroFluid, display, tangible, content, choreography, liquid, narrative, dynamics, nature, electromagnets, Ferrolic.

Introduction

Motivation

Intrigued by the aesthetics of Sachiko Kodama's work on ferrofluids [2], people who practice both art and science such as Louis-Philippe Demers [3] and Neri Oxman and work of many students, artists and designers like Marcin Ignac [4] who visualised data in very creative ways, motivated me to turn a long shelved idea on *how to shape and move a liquid body* into a physical reality.

The value of new and inconceivable embedded in a natural looking appearance - regardless it's true level of artificiality - is likely to have a natural attractiveness to people. Well known examples are Neri Oxman's life-size tangible sculptures that are based on microscopic biological physical structures [5] and Harvard's technology that grows flowers on a nano scale [6]. I believe these new unique technologies are not only carried widely because of their technological uniqueness, but also because their natural appeal; Meaning, their close visual relation to nature itself.

Purpose and Goals

There is a well established body of art-work on FerroFluid. Sachiko Kodama made it well known in the form of *liquid sculptures* [2]. The opportunities for manipulation of FerroFluid in these sculptures are however limited. In this work we aimed to create a technological platform that allowed for more freedom in manipulating FerroFluid and to develop a vocabulary for the creation of content.

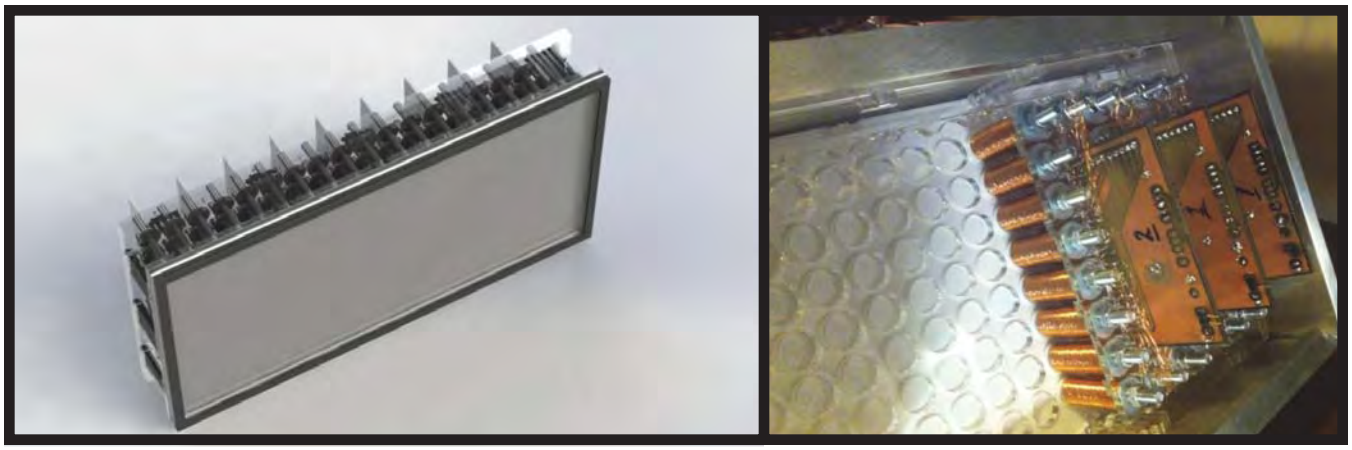

Figure 2. The DFFD: A quantity of FF is contained between two glass plates, sealed at the edges. Behind the FF container, a rectangular array of electromagnets is used to manipulate the fluid. At the right a detail showing the configuration of magnets. ©Zelf Koelman

An open research model was applied to get grip on the design process, yet, leave room for innovation. [7]

Background

We conceive the majority of digital information through two-dimensional arrays of light-sources, better known as LCD displays; A large number of small light-sources packed densely together because just a few, so called, *pixels* would have no meaning. Perceived information is generated by multiple formations of many pixels, each with different colours that can produce a (from a humans perspective) *infinite* amount of combinations.

To make matter understandable, the *infinite* is reduced to a useful set combinations that we recognise as visuals with meaning. Among clearly observable text, photo and video, this new unreal mini-world on a screen seems to be always in conflict with its own size. Software interfaces try to help us bridge the unnatural gap of *it all happening on this small screen* using functional methods like scaling, tabs, windows, scrolling, etc.. Eventually, displayed content that refers to *real world matter* will never be observed as natural as its tangible counterparts.

Tangible means perceptible by touch. It is one property an LCD display can not forward when it is displaying content. For displays, tangibility is a property that does not per se mean that the matter has to be touched to be observed. Examples of displays that use tangible matter are the flip-

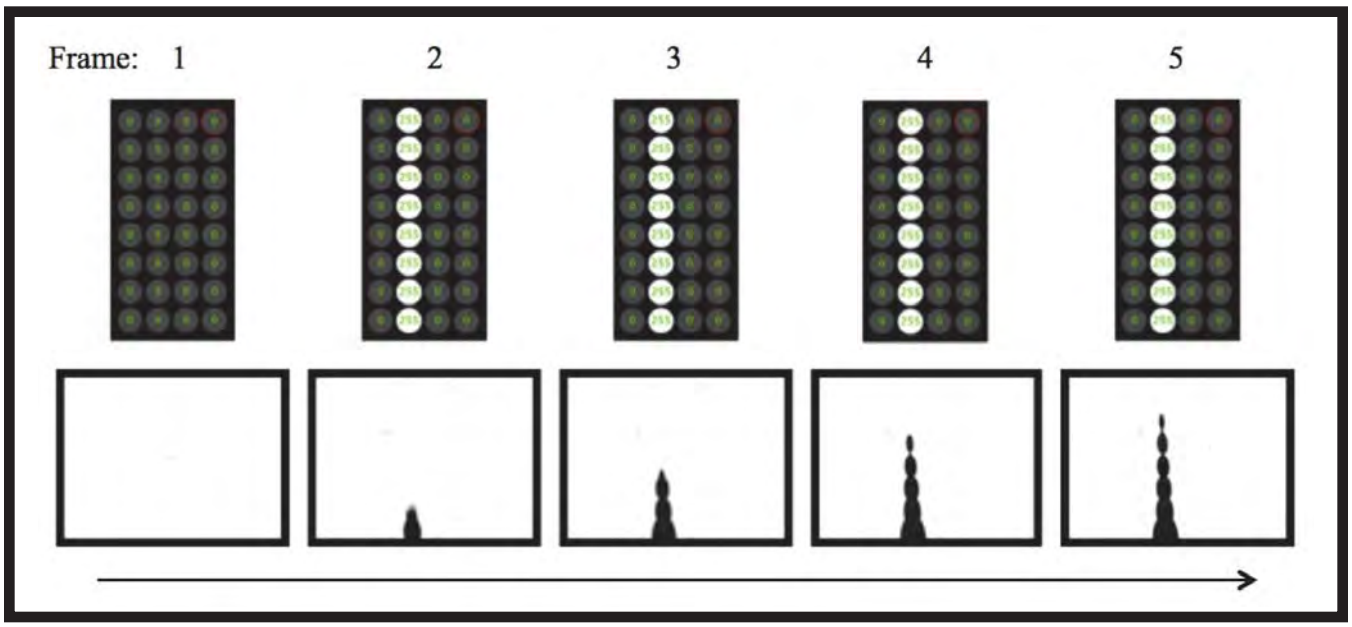

Figure 3. How a straight vertical line builds up in FF. Frame one is the initial state, in frame 2 a vertical line of magnets is switched on, frames 3, 4 and 5 depict how the FF moves up from the reservoir at the bottom of the display. ©Zelf Koelman

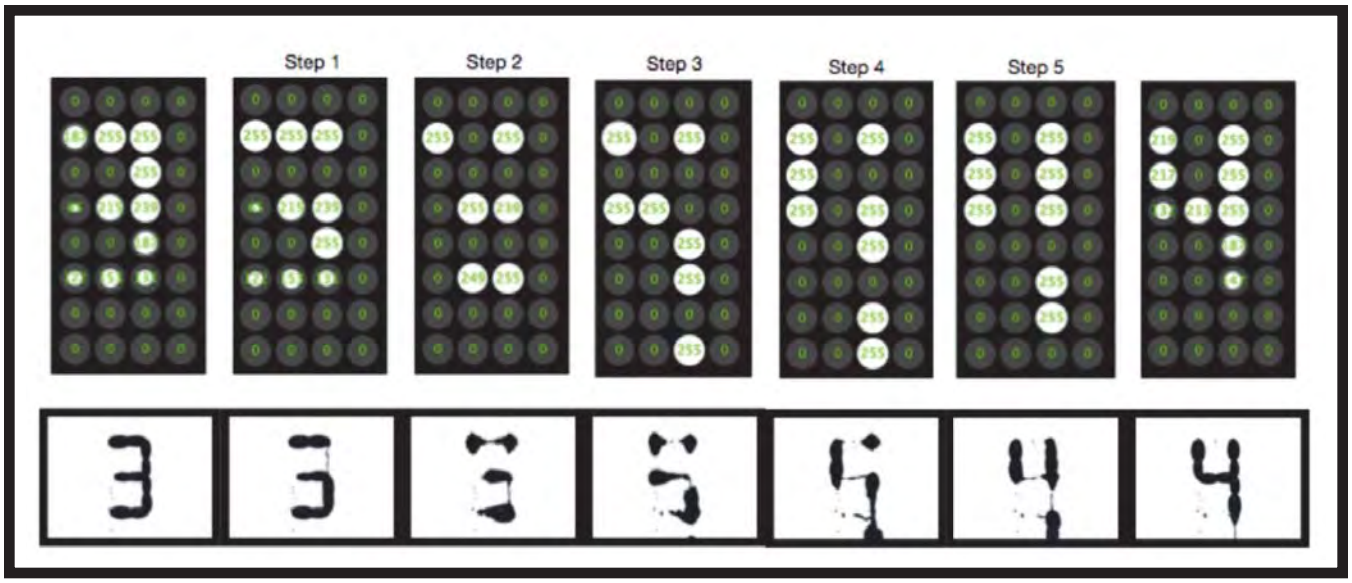

Figure 4. Making a transition from a number “3” to a number “4”. Note how first the “3” is broken down into separate dots of FF, extra FF is attracted from the reservoir, before the “4” is formed.

disk display [8] that we often see installed on city-busses and The Water logo by Hara Design Institute [9] that systematically displays text in the form of water-droplets floating on hydrophilic fabric. These tangible displays all have a specific characteristic because of their own physical properties. Properties that are visually been observed as true matter. This paper covers specific characteristics that belong to the digital FerroFluid display.

The Digital FerroFluid Display

The DFFD in essence consists of an array of electromagnets behind a container of FF. Every electromagnet can be controlled individually by setting the current through the coil.

With this array of magnets, images can be created and manipulated dynamically. Figure 3 shows how a straight vertical line builds up. In total 5 time frames are shown, one every 500 milliseconds. At the top half of the figure, the black/green screens represents the applied magnetic forces for every pixel. In this example only “on” and “off” is used. A white dot is “on”, at the bottom half of the figure, the actual observed FF (ferrofluid) distribution is shown.

The straight line builds up from the FF reservoir at the bottom of the DFDD. If the same force is applied to all pixels, the line will be thickest at the bottom and get narrower towards the top. The actual density distribution between two adjacent pixels is influenced by several factors: gravity, adjacent magnetic fields, locally available amount of FF and cohesive forces in the FF fluid. The combination of cohesion and gravity cause the broadening towards the bottom of the line.

For a controlled manipulation of FF it is necessary to incorporate these factors. Figure 4 shows an example of a transition between two shapes, the number “3” and the number “4”. In this case, the used algorithm calculates the needed quantity of FF, breaks up the “3” into 3 separate dots on strategic positions and creates an additional FF dot from the reservoir. From these dots the number “4” is created. Notice how the strengths of the magnetic field is not the same for all pixels. It is lower near the bottom and at the pixel at the lower left corner of the “4”. The latter is because this pixel is effectively helped by the neighbouring pixels. Though many ways are possible to achieve this shape transition, this one illustrates the considerations to be made in such a transition.

Towards a vocabulary for FF manipulation

After having the first animations reviewed in a set of exploratory user-tests, it became clear there was an evident difference in *appeal* for the different animations. It was also hard to communicate the specific values for viewers and maker alike. To further develop this medium it was (and is) necessary to be able to clearly communicate about its specific characteristics.

Expert evaluations

In order to map the specific characteristics, seven animations were made that all contained a mix of specific visual characteristics. The seven animations of the first test-set have been described and labeled in table 2.

These animations were evaluated by in total 5 professionals from the field of arts and design, all with a different background. Table 1 outlines the procedure for the inter-

view. Next we describe the parts in turn. The participants were individually interviewed. The experimental setup was as following: participants were invited into a closed room and sat next to the interviewer in front of the Digital FerroFluid Display. The interviewees were given a short introduction on the following steps.

Part	Average Duration	Summary
I	3 minutes	introduction to the study
II	21 minutes	reviewing 7 animations and answering the primary question
III	4 minutes	answering secondary question
IV	2 minutes	debriefing

Table 1. Procedure for interviews series 1.x

Participants were asked to review a sequence of 7 animations that were displayed on the DFFD in random order. In Table 2 these animations are described. The first question to the interviewee was *what do you see*? which had to be answered for every single animation. This question, as well as the physical setting, was borrowed from the *Rorschach test* [10]. Descriptions were vocally explained by the participants during their reviewing. There was no particular time constraint for every animation. The participants reaction was recorded during the interviews as written notes.

In the interviews series 1.x, two out of five participants mainly judged the animations on its specific visual characteristics (i.e. *leaking*, or *morphing*), two participants mainly judged the animations on its narrative (i.e. *A chase of two creatures* or *9 am*) and one participant judged the animation on both.

After all 7 animations where reviewed by the participant, the second question was to judge the animations again. This time, participants that focused on the visual characteristics were asked to focus on the narrative and vice versa. All participants were able to take both perspectives. Table 3 shows frequently used properties (at least more that twice by different participants) over the two methods of observing and explaining the content.

Name	Description
Pattern	A repeating cycle of: An array (horizontal line) of separate bodies arising from the bottom, moving up and dropping at the top.
Chase	One body following another, variations in speed and distance
Clock	Four digits displaying the actual time
Fountain	FF spraying upwards from a point in the reservoir
Pong	A game of Pong animated in FF
Smiley	Different Smileys morphing into each other
Rain	A continuous cycle of bodies moving upwards from the left and right of the reservoir into a large body at the top of the display and raining down again into the reservoir

Table 2. Seven different animations. The first test-set.

Observations on narratives

In the interviews, different type of narratives about the animations came forward:

- *body language*: A direct reference to animalistic or humanistic behaviour. Also called *anthropomorphism* which is closely related to *empathy* [11].
- *written figurative matter*: Translation of meaning through letters that form words and/or trough numbers that form values.
- *non-written figurative matter*: Direct translation from visual representations to meaning.

Combination of narratives also occurred.

Participants mainly had difficulties to translate animation 5 (pong) and 7 (rain) into its narrative. Further questions revealed that they did not recognise the narrative be-

Category / Level	Specific visual characteristics		The narrative
	Dynamics	**Graphics**	**Information**
Description	Actions	Figurative and abstract physical references	The narrative and/or emotional reference
Average physical scale	1 to 4 square actuation points	1 to ∞ square actuation points	1 to ∞ square actuation points
Vocabulary	Morphing, Leaking, Speeding, Accelerating, Dropping, Moving, Disintegrating	Pattern, Mass, Systematic, Repetitive, Randomness	Agression, Playfulness, Exchange, Cagey, Cyclus, Raincloud, Chase

Table 3. Mapping a vocabulary

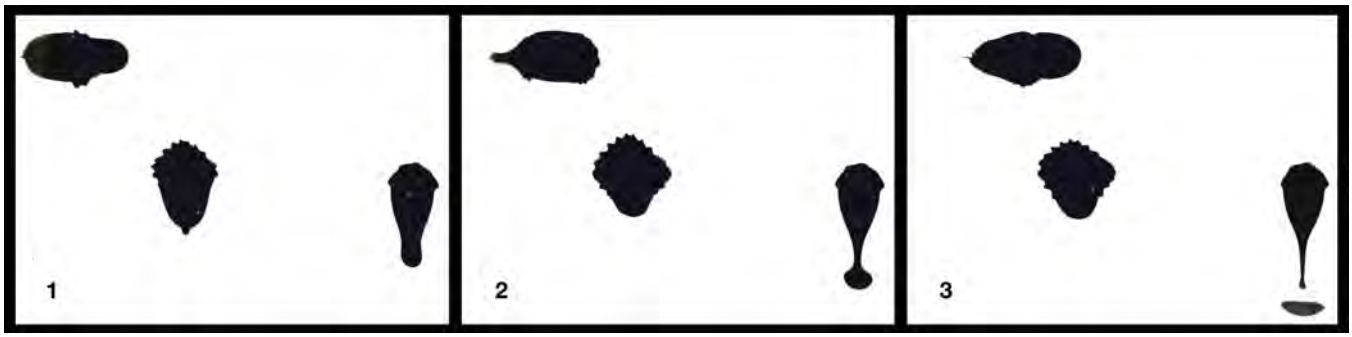

Figure 5. Example of moving, morphing and leaking bodies. ©Zelf Koelman

cause of *lack of detail*. The tests showed that, due to the low resolutions of actuation points, a simple combination of very basic distinguishable figurative matter - like *dots* and *lines* forming text and numbers - is likely to be successfully translated into meaning. If a *dot* itself shows specific dynamics, it is judged upon references to animalistic behaviour. A side-conclusion could be that the more physical detail the figurative matter is expected to have, the less likely it is that the narrative is readable.

A living entity Testing the first prototype (one vertical array of magnetic actuators) a thing reveal itself when a sinus wave was applied to the actuators. A FerroFluid drop that got separated from a mass that floated on the bottom, was perceived as a *body*. Not only a *body* in physical terms, but like interviews 1.x also turned out: *body* with a strong relation to a living organism. The current DFFD prototype allows this *body* to freely move vertical and horizontal over the full width and height of the display.

Participants associated the visual effect of this phenomena to the movement of biological organisms that move through water. They regularly recognised tadpoles, little fish and undefined little *creatures*. The participants explained to be intrigued by the unknown playful movements. The *creatures* seemed harmless and evoked the participants to discover them and it was mentioned to be perceived as a pleasant experience.

This visual reference might be the same reason why the artificial FerroFluid bodies, moving through water and forming a tail, are perceived as *living creatures*. Similarities put forward in several discussions are that the *creatures* perform a degree of random behaviour, have a third dimension (in contrast to LCD displays), are made of true matter, are explorable into fine detail and share different visual dynamic relations like *speeding stretched bodies*. Here is an interesting similarity to *Disney's Twelve Basic Principles of Animation*; A set of principles of animation introduced by the Disney animators Ollie Johnston and Frank Thomas in their 1981 book *The Illusion of Life: Disney Animation*.[12] Where it is their goal to produce more realistic animations adhering to the basic laws of physics. The most discussed principle *squash and stretch* [12], which gives a better sense of weight and flexibility to a virtual object, happens to be a core property of the digital FerroFluid display since this visual effect is caused by true natural physics itself. The success of theses principles and the relation to what is perceived on the DFFD may illuminate an important value of using true (liquid) matter in animating a narrative.

Positioning the DFFD

Though practically everybody that was invited to experience the DFFD was deeply intrigued by it, it is hard to pinpoint a potential natural habitat for it. To shed some light on this matter, at the 2014 International Robotics, Art and Science forum *Bal Robotov 2014* in Moscow, Russia, a second round of interviews was done with five experts from five different institutes. They represented the realms of indeed art and science. All had in common that their personal projects, like this one, somehow bridges science, art and technology. These interviews 2.x - inter alia, with Alexander Reben from MIT Media Lab and Louis Philippe Demers from NTU, Singapore - added perspective to these uncertainties. Below some relevant quotes from the interviews.

The experts visions Its basic function is *generating a very specific kind of aesthetics*. What it is and where it lives highly depends on the kind of content.

"You want to create an aesthetic threat for people. You want to give someone an experience. Show them something interesting and beautiful. And your medium is technology, your medium is digital but the actual piece is definitely an artwork..... It could also be practical; It could be a clock. But it will probably be expensive, heavy and consume a lot of power so... that's why it's still art." (Interview 2.4 - Jonathan Tippett)
