Carbon Adsorption Isotherms for Toxic Organics

RESEARCH REPORTING SERIES

Research reports of the Office of Research and Development, U.S. Environmental Protection Agency, have been grouped into nine series. These nine broad categories were established to facilitate further development and application of environmental technology. Elimination of traditional grouping was consciously planned to foster technology transfer and a maximum interface in related fields. The nine series are.

1. Environmental Health Effects Research
2. Environmental Protection Technology
3. Ecological Research
4. Environmental Monitoring
5. Socioeconomic Environmental Studies
6. Scientific and Technical Assessment Reports (STAR)
7. Interagency Energy-Environment Research and Development
8. "Special" Reports
9. Miscellaneous Reports

This report has been assigned to the "SPECIAL" REPORTS series. This series is reserved for reports targeted to meet the technical information needs of specific user groups. The series includes problem-oriented reports, research application reports, and executive summary documents. Examples include state-of-the-art analyses, technology assessments, design manuals, user manuals, and reports on the results of major research and development efforts.

This document is available to the public through the National Technical Information Service, Springfield, Virginia 22161.

DISCLAIMER

This report has been reviewed by the Municipal Environmental Research Laboratory, U.S. Environmental Protection Agency, and approved for publication. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

FOREWORD

The Environmental Protection Agency was created because of increasing public and government concern about the dangers of pollution to the health and and welfare of the American people. Noxious air, foul water, and spoiled land are tragic testimony to the deterioration of our natural environment. The complexity of that environment and the interplay between its components require a concentrated and integrated attack on the problem.

Research and development is that necessary first step in problem solution, and it involves defining the problem, measuring its impact, and searching for solutions. The Municipal Environmental Research Laboratory develops new and improved technology and systems for the prevention, treatment, and management of wastewater and solid and hazardous waste pollutant discharges from municipal and community sources, for the preservation and treatment of public drinking water supplies, and to minimize the adverse economic, social, health and aesthetic effects of pollution. This publication is one of the products of that research; a most vital communications link between the researcher and the user community.

This laboratory has had a continuing interest in the adsorption of organic compounds on activated carbon. During the past several years adsorption data have been determined for compounds for which little or no data are available in the literature.

The recent interest in toxic substances and their treatability by carbon has created a need for this kind of information. To meet this demand data from this laboratory have been collected under one cover. A second purpose of this report is to encourage some uniformity in the testing protocol and handling of data so that adsorbability data can be compared among compounds.

Francis T. Mayo
Director
Municipal Environmental Research
Laboratory

ABSTRACT

This research program was initiated with the overall objective of determining the capability of activated carbon to sorb priority pollutants and other hazardous organic compounds from aqueous solution.

An experimental protocol for measuring the activated carbon adsorption isotherm was developed and applied to a wide range of organic compounds. Methods for treatment of the isotherm data and a standard format for presentation of results are presented. In the early phase of the study selection of compounds for testing in the experimental program presented a formidable task. Initial selections were based on the following criteria: (1) annual quantity produced, (2) critical concentration required to produce an adverse environmental effect, (3) probability of occurrence in water or wastewater, (4) persistence in the water environment, and (5) solubility. During the course of the study the Occupational Safety and Health Admintration's (OSHA) list of regulated carcinogens and the U.S. Environmental Protection Agency's Consent Decree list of priority pollutants were developed. These compounds were added to those previously selected for the experimental phase of the study.

This report covers a period from August 8, 1972, to March 31, 1980.

ACKNOWLEDGEMENTS

The authors gratefully acknowledge the laboratory and editorial assistance of Michael Jelus. Others who assisted in the laboratory phase include Richard J. Middendorf, Mary Anne Leugers, Richard A. Fiutem, Elmer D. Lipp, and Amy Knipschild.

Carcinogenic compounds specified in the text were investigated by Illinois Institute of Technology Research Institute under Contract No. CI-68-03-2559 and 68-03-2834. Edward G. Fochtman served as Principal Investigator for both contracts.

SECTION 1

INTRODUCTION

A vast number of synthetic organic chemicals are being produced by industry, some of which are introduced into the environment. A measure of the immensity of the problem can be obtained from the American Chemical Society's Chemical Abstract Service whose registry of chemicals lists 4,039,907 distinct entities as of November, 1977. New compounds are being added to the registry at an average rate of about 6,000 per week (1). Of these, Chemical Abstract Service lists some 33,000 chemicals that are thought to be in common use, excluding pesticides, pharmaceuticals, and food additives. Thus, a large number of synthetic organic chemicals are being introduced into the environment. By 1976 some 1,260 organic chemicals were reported found or suspected in fresh water (2) and the list is expanding rapidly as analytical techniques are refined and surveys are conducted on streams, industrial, and municipal wastewaters and potable waters.

The presence of synthetic organic compounds in the environment can have severe adverse effects. These effects include toxicity, carcinogenicity, mutagenicity, or teratogenicity in man and animals, toxicity to aquatic life, and degradation of the quality of water for human consumption. Hence, there is a need to develop control technology capable of removing hazardous organics from water to prevent further dispersion into the environment. Adsorption on powdered or granular activated carbon is being increasingly considered as a method for removal of organic compounds.

While studies on the adsorption of specific organic compounds on activated carbon are extremely limited when the vast number of chemical entities are considered, a substantial number of investigations have been reported. A summary of some of the literature is described below. Linner and Gortner (3) studied a series of 31 organic acids. More recent studies have investigated the adsorption of organic compounds of environmental concern. Morris and Weber (4,5) reported data on the adsorption of phenol, sodium salts of sulfonated organics and pesticides. Adsorption of aromatic acids has been reported by Ward and Getzen (6). Carbon loading values of 300 mg/g of carbon at a residual concentration of 1 mg/l have been reported for the herbicide 2,4-dichlorophenoxyacetic acid (7). Dedrick and Beckman (8) found approximately 20% less adsorption capacity for the same compound. Weber and Gould (9) and DiGiano and Weber (10) investigated the adsorption of organic pesticides including related phenols. Freundlich parameters have been reported for the carbamate insecticides Sevin (1-naphthyl-N- methylcarbamate) and Baygon (2-isopropoxy-N-methylcarbamate) (11). Bernardin and Froelich (12) measured the adsorption of aldrin, dieldrin, endrin, DDT, DDD, DDE, Toxaphene and PCB on activated carbon and were able to achieve residuals of less than

1 ug/l for each compound in the treated water. Lawrence and Tosine (13) studied the adsorption of polychlorinated biphenyls from aqueous solution and sewage. The effect of molecular structure on the adsorption of substituted benzene compounds was determined by Al-Bahrani and Martin (14). Argaman (15) compared the adsorption of dichloroethane on three different activated carbons. Singer and Yen (16) studied the adsorption of phenol, methylphenol, ethylphenol, dimethylphenol and isopropylphenol on a petroleum-base carbon. Murin and Snoeyink (17) studied the adsorption of 2,4-dichlorophenol and 2,4,6-trichlorophenol at different pH values and determined the effect of humic substances on the adsorption capacity. Removal of methoxychlor from potable water was investigated by Steiner and Singley (18). Adsorption of benzene, toluene, o-xylene and ethylbenzene was investigated by El-Dib and Badawy (19). Peel and Benedek (20) emphasized the kinetic factors in a study on the adsorption of phenol and o-chlorophenol. Fochtman and Dobbs (21) measured the adsorption isotherms for naphthalene, 1,1'--diphenylhydrazine, beta-naphthylamine, 4,4'- methylene bis(2-chloroaniline), benzidine, dimethylnitrosamine, and 3,3'- dichlorobenzidine and described general procedures for handling chemical carcinogens in the research laboratory.

Although the literature contains data on adsorption of specific compounds, the experimental techniques and methods of reporting the data are so varied, that it is difficult to compare adsorbability among compounds. As a result, a major objective of the present study was to standardize the experimental procedure as well as the method of reporting results. Under these conditions, information on adsorption can be compared on a common basis. A second objective was to provide carbon adsorption data for selected compounds of environmental concern. The approach chosen to describe adsorption was batch equilibrium carbon adsorption isotherms with the results plotted according to the Freundlich adsorption equation.

SECTION 2

CONCLUSIONS

The results of experimental studies on the adsorption of priority pollutants and other hazardous organic compounds have shown that activated carbon treatment can effectively remove many of these substances from aqueous solution. Pesticides, polynuclear aromatic hydrocarbons, phthalates, phenolics, and substituted benzenes are readily adsorbed by activated carbon. Certain low molecular weight compounds with high polarity are not amenable to activated carbon treatment. Compounds in this category include low molecular weight amines, nitrosamines, glycols, and certain ethers.

The experimental protocol developed for the isotherm testing provides a simple reproducible procedure for estimating the capacity of activated carbon for adsorption of specific compounds from aqueous solution. The data summary containing the Freundlich parameters and the calculated carbon requirements for granular and powdered carbon treatment simplifies the evaluation of treatability by carbon adsorption.

SECTION 3

RECOMMENDATIONS

Activated carbon adsorption isotherm testing of specific organic compounds should be continued in order to develop a broader base of information for assessing the potential of the process for control of toxic or hazardous compounds. Studies should be directed toward correlation of laboratory isotherm capacity with column loading in treatment operations. Kinetic factors for both granular and powdered carbon treatment need to be investigated. Correlation of adsorption capacities with fundamental molecular properties should be attempted in order to develop the capability to estimate treatability of compounds for which isotherm data are lacking.

Isotherm data for a variety of different activated carbons should be developed using a standard protocol for selected compounds in order to compare adsorption capacities with carbon properties.

SECTION 4

MATERIALS AND METHODS

SELECTION AND SOURCE OF COMPOUNDS

Compounds selected for the present investigation were taken from the following: (1) U.S. Environmental Protection Agency Effluent Guidelines Division list of priority pollutants, (2) Occupational Safety and Health Administration's list of regulated carcinogens, and (3) a list of special interest compounds chosen by the authors.

The organic compounds were used as received from the suppliers: Aldrich Chemical Company, Eastman Organic Chemicals, Chem Service, Inc., and the U.S. Environmental Protection Agency's Health Effects Research Laboratory. Carcinogenic compounds were obtained from National Cancer Institute's Chemical Repository at IIT Research Institute. In general, the compounds assayed greater than 95% and were used without correction for purity.

ADSORBENT

Filtrasorb 300 granular activated carbon, a product of Calgon Corporation, was used as the adsorbent. The granular carbon was pulverized in a ball mill and then screened for classification. Only that portion which passed a 200 mesh (0.0736 mm) screen but was retained by a 400 mesh (0.0381 mm) screen was used for isotherm tests. The carbon was repeatedly milled and screened so that practically all of the original carbon was retained as a powdered sample. After classification the powdered carbon was oven-dried overnight at 105^{o}C, cooled in a desiccator and stored there until needed for experimental purposes. A slurry of the pulverized and screened carbon was prepared in distilled water at an appropriate concentration and the thoroughly wetted carbon suspension was used in the isotherm tests.

ANALYTICAL METHODS

A variety of analytical procedures were used to analyze samples for initial and residual concentration of test compound.

Chlorinated volatile compounds were analyzed by purge and trap gas chromatography as described by Bellar and Lichtenberg (22). A Tenax GC trap was used in conjunction with a 0.2% Carbowax 1500 on 60/80 mesh Carbopack C column. Samples were analyzed using a Tracor Model 222 Gas Chromatograph equipped with a Tracor 310 Hall Electrolytic Detector.

Aromatic and substituted aromatic compounds were generally determined by U-V spectroscopy. A Beckman Model 25 Spectrophotometer equipped with automatic sampler was used to obtain a scan of each test compound in aqueous solution and for the fixed wavelength quantitative measurements.

Solvent extraction - gas chromatography was used for compounds with limited solubility which were not measurable by U-V spectroscopy or purge and trap gas chromatography. The method involved solvent extraction of the aqueous sample with Freon, methylene chloride, or hexane followed by sodium sulfate drying, concentration of the extract in a Kuderna-Danish apparatus, and gas chromatography as reported by Austern, et al., (23). Extracts were analyzed using a Varian Model 3700 gas chromatograph equipped with flame ionization and electron capture detectors.

Polynuclear aromatic hydrocarbons with limited solubility were analyzed by fluorescence spectroscopy. An American Instrument Company Aminco-Bowman Spectrophotofluorometer Model J48960 equipped with Xenon lamp was used for fluorescence measurements. Excitation and emission wavelengths used for analytical purposes are presented on the appropriate data forms.

Several low molecular weight compounds were analyzed with a Beckman Total Organic Carbon Analyzer Model 915B. Samples were acidified and purged for total organic carbon analysis or injected directly for a total carbon measurement. The latter was the method of choice for volatile organics which could not be purged without significant loss of compound.

A more complete description of recommended test procedures for the analysis of priority pollutants has recently been published by the Environmental Monitoring and Support Laboratory of the U.S. Environmental Protection Agency (24).

SECTION 5

EXPERIMENTAL PROCEDURES

A general description of the carbon adsorption isotherm procedure used in the present study is presented in Appendix A. Slight modifications were required for certain compounds. These will be described at the appropriate place in the text.

PREPARATION OF CARBON SLURRY

All isotherm tests were conducted using a thoroughly wetted carbon slurry. The initial slurry was prepared by weighing 50.00 grams of pulverized and screened carbon and diluting to 1.0 liter with distilled water. Other working standard slurries were prepared by serial dilution of the original stock. Desired carbon doses were achieved by using dispensing pipettes of differing volumes. The initial slurry and all serial dilutions were stored in the dark until needed for isotherm testing.

PREPARATION OF TEST SOLUTIONS

Standard solutions of the compounds were prepared in distilled water or mineralized distilled water by several methods. Aqueous solutions of the volatile compounds were prepared by injecting an ethanolic standard solution into the bottle containing distilled water. The bottle was completely filled and capped to minimize loss of compound.

Polynuclear aromatic hydrocarbon stock standard solutions were prepared by injecting a methylene chloride solution of the compound into distilled water and stirring for one to three days to ensure dissolution. Analysis of the resulting solution for methylene chloride at the end of the mixing period indicated complete loss of the solvent. Dissolution of the polynuclear aromatic hydrocarbons was carried out in the dark to avoid photochemical decomposition. Some of the more insoluble polynuclear aromatic compounds were treated by a modified protocol. Standard solutions were prepared using coated-glass beads as described by May and Wasik (25). Each isotherm point corresponding to a single carbon dose required a separate standard solution often at a different initial concentration. Since the initial concentration varied for the series of carbon doses, a modified data reporting form was developed for these cases.

All pesticides and polychlorinated biphenyls were added to the distilled water as an acetone standard solution. Use of an organic solvent facilitates the dissolution of the organic compound in aqueous solution. Minimum quantities of acetone were used and no effect on the isotherm was

expected from the small concentrations of solvent because of the very low adsorbability of acetone and the concurrently high adsorption of the pesticides.

Several compounds were weighed and added directly to the distilled water to prepare aqueous solutions. These were mostly solids which were readily soluble in water. Simple aromatic compounds were added as alcoholic solutions.

VALIDATION OF EXPERIMENTAL PROTOCOL

Several aspects of the general isotherm protocol needed to be evaluated in order to validate the proposed procedures. These included: (1) the effect of ethanol on the measured adsorption capacity of a compound, (2) rate of adsorption of compounds to determine whether or not the proposed two-hour contact time was adequate and, (3) reproducibility of the total procedure.

The maximum concentration of ethanol used in the preparation of the aqueous test solutions was 0.008 % w/w (78.9 mg/l). In most cases ethanol concentrations were 0.002 % w/w (15.6 mg/l) or less. Two tests were performed to determine the effect of added ethanol. In the first test an isotherm was obtained using ethanol in aqueous solution as the test compound. The second test determined the effect of the presence of ethanol on the adsorption capacity of 2-chlorophenol. Results are summarized in Table 1.

TABLE 1. EFFECT OF ETHANOL ON ADSORPTION CAPACITY OF 2-CHLOROPHENOL

0	61	0.38
0.001	56	0.38
0.010	57	0.39
0.100	58	0.33

*Sp. gr. 0.789

(a) Adsorption capacities are calculated at a residual concentration of 1 mg/l in equilibrium with activated carbon at neutral pH.

The rate of adsorption was investigated using three compounds selected to represent acidic, basic, and neutral compounds with weak, moderate, and strong adsorption capacities. The compounds selected were 2-chlorophenol, diphenylamine and 2-chloronaphthalene. Each compound was tested at a concentration of 2.0 mg/l at one carbon dosage. Carbon dosages were selected to remove most of the compound but still leave sufficient residual concentration for analysis by U-V spectroscopy. The resulting data on the

approach to equilibrium are presented in Figure 1.

Reproducibility of the experimental isotherm protocol was determined by repetitive measurement of the adsorption capacity for 2-chlorophenol at neutral pH. The results of seven independent isotherm measurements are given in Table 2.

TABLE 2. REPRODUCIBILITY OF EXPERIMENTAL PROTOCOL

Isotherm No.		Adsorption Capacity*, mg/g
1		62.0
2		63.3
3		52.1
4		52.1
5		53.9
6		56.9
7		60.1
	Average	57.1
	Standard deviation	4.7

*Calculated for an equilibrium concentration of 1.0 mg/l of 2-chlorophenol.

Successful demonstration of the basic protocol was followed by an extensive program to obtain isotherms for the compounds selected. Isotherms were obtained on all of the desired compounds, with some exceptions. Those excluded were (a) compounds which were gases at room temperature, (b) substances not readily available or not available at reasonable cost, (c) compounds which exhibited some form of instability in aqueous solution. In cases where a series of similar or related compounds were listed, enough members of that class were included in the isotherm study to provide a basis for estimating the adsorbability of members not actually tested. For example, not all PCBs and polynuclear aromatic compounds were tested. However, those that were measured indicate that all of the class are adsorbable. The results are presented on standardized data forms developed to facilitate comparison of adsorption data.

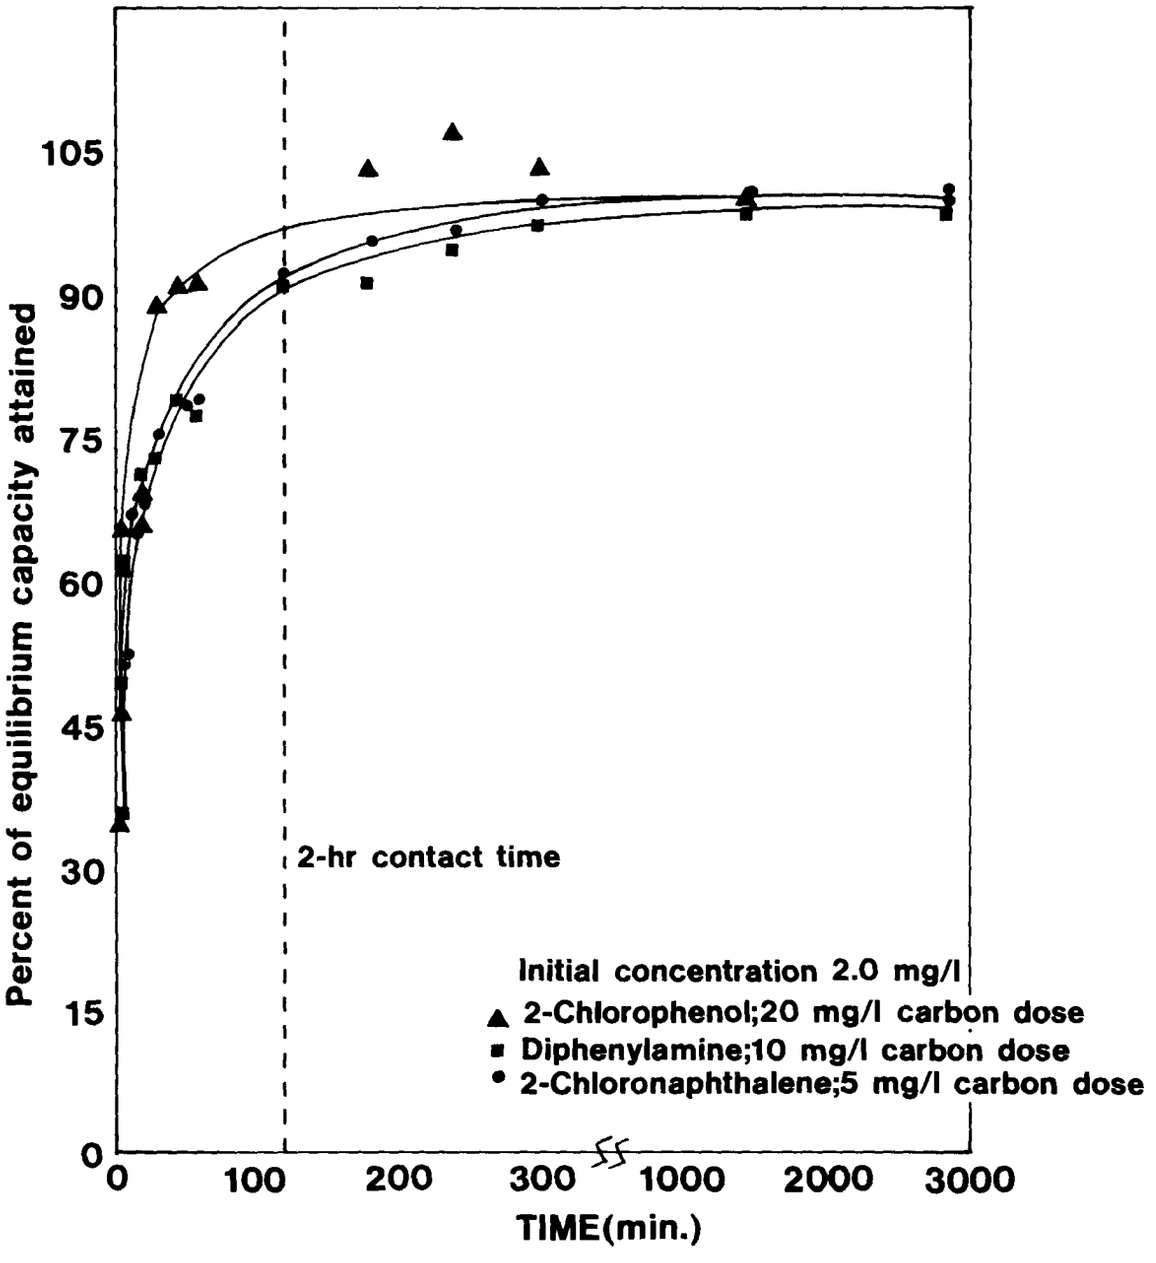

Figure 1. Percent of equilibrium capacity attained as a function of time.

SECTION 6

RESULTS AND DISCUSSION

An attempt to measure an isotherm for ethanol at an initial concentration of 67 mg/l showed less than a 10% reduction in residual concentration for a carbon dose of almost 10 g/l. Therefore, it was concluded that ethanol was not adsorbed and would not compete for adsorption capacity with the test compounds.

Although adsorption from an organic solvent has been reported to be much lower than that obtained from aqueous solution (26) the concentrations of ethanol used in the present study did not alter the adsorption capacity of 2-chlorophenol even when ten times the maximum concentration used in the experimental study was tested as shown in Table 1.

The two-hour contact time specified in the adsorption protocol appears to be adequate for purposes of comparing adsorption characteristics of different compounds. Percent of equilibrium values for the two-hour contact time for 2-chlorophenol, diphenylamine and 2-chloronaphthalene were 92%, 91% and 92%, respectively, as illustrated in Figure 1. In these calculations, equilibrium was considered to be attained after 3,000 minutes, since no further adsorption occurred between 2,000 minutes and 3,000 minutes of contact time. A four-hour contact time would result in slightly greater capacities and may be preferred for some applications. However, other factors, such as purity of the reagents, photochemical effects, variations in different lots of carbon, and method of chemical analysis may all contribute to the measured adsorption capacity in a more significant manner than the additional contact time.

The reproducibility of the total isotherm protocol has been demonstrated to be $\pm$ 8.2%. The adsorption capacity for 2-chlorophenol (57.1 $\pm$ 4.7 mg/g) at an equilibrium concentration of 1.0 mg/l illustrates the reproducibility that can be expected. Results from another laboratory have been reported on several compounds included in the present study using the protocol presented in Appendix A (27). Results between laboratories were reproducible with deviations less than $\pm$ 10%.

TREATMENT OF ISOTHERM DATA

The carbon adsorption data were plotted according to the Freundlich equation. While the equation is empirical it is nonetheless widely used and has been found to describe adequately the adsorption process in dilute solution. The Freundlich equation has the form:

$$X/M = KC_f^{1/n}$$

where:

X = C_o-C_f is the amount of compound adsorbed from a given volume of solution,

M = the weight of activated carbon

C_o = the amount of compound in the untreated solution,

C_f = the amount of compound remaining in the treated water,

K and 1/n are empirical constants characteristic of the compound and carbon used in the test. Graphically, K is the X/M intercept of the isotherm plot at C_f = 1 and 1/n is the slope of the line when the equation is plotted on logarithmic paper. The intercept is an indicator of adsorption capacity and the slope of adsorption intensity. The concentration of adsorbate on the adsorbent in equilibrium with a concentration C_f is expressed by X/M. In this study X/M was expressed as mg compound adsorbed per gram of carbon.

Data were fitted to the logarithmic form of the above equation, which has the form:

$$\log X/M = \log K + 1/n \log C_f \qquad (2)$$

PRESENTATION OF DATA

The experimental data for each of the compounds tested are summarized on standardized data forms. Carbon dosages used in the isotherm procedure are shown on the left hand column along with the initial C_o, and residual concentrations after treatment with pulverized activated carbon. Data are expressed in mg/l. These values were then used to calculate the amount of compound removed (C_o-C_f) and the carbon loading, X/M expressed as mg/g. The data were plotted according to equation(2) on logarithmic paper. Linear least squares regression analysis was used to locate the isotherm line. Some of the compounds were tested at differing pH's. When pH affected adsorption, individual lines were drawn to show the effect of pH. If pH had no observable effect on adsorption, all of the data points were plotted and represented by a single line.

On the first page of the data form for each compound, the molecular structure, formula and molecular weight are given. The equation of the regression line was used to calculate the values for the intercept, K, and the slope 1/n. The K value represents the carbon loading, X/M, in mg compound/gram of carbon at an equilibrium concentration of 1.0 mg/l of compound. K values were summarized at this concentration for comparison purposes even though 1.0 mg/l exceeded the solubility of several of the compounds tested. Thus, some K values for the extremely insoluble compounds represent a substantial extrapolation of the data by as much as two or three orders of

magnitude. Available information on the solubility of test compounds is presented in Appendix B. Also shown on the data form is the correlation coefficient, r, for the linear regression analysis.

As the Freundlich equation indicates, the loading on the carbon, X/M, is a function of the equilibrium concentration of organic compound after carbon treatment. This effect is shown in the next table on the data sheet. The adsorption capacity in mg/gram for varying equilibrium concentrations of organic compound ranging from 0.001 to 1.0 mg/l, were calculated from the equation of the regression line.

The Freundlich equation can be rearranged to calculate the carbon dose required to reduce any initial concentration of compound to some predetermined residual concentration. If, for the term X, use is made of its equivalent, C_o-C_f, in which C_o equals the initial concentration of organic compound and C_f the residual concentration, the equation can now be written as follows:

$$\frac{C_o - C_f}{M} = KC_f^{1/n} \qquad (3)$$

Equation 3 can be solved directly for the carbon dose required or the equation can be rearranged to the logarithmic form:

$$\log (C_o - C_f) - \log M = \log K + 1/n \log C_f \qquad (4)$$

Equation 3 is linear when M (carbon dose) is plotted against C_o initial concentration on ordinary coordinate paper. These calculations were made for a range of initial and final concentrations. The resulting carbon doses are tabulated in mg/l for neutral pH in the bottom table of the data sheet (solution of equations 3 and 4 gives M = grams/liter if C_o and C_f are in mg/l and K is in mg/g). For compounds which were essentially non-adsorbable, the calculated carbon dosages were considered too high to be practical and are shown in the table as greater than 100,000 mg/l carbon.

The tabulated carbon doses represent removals obtainable in a single-stage contactor. More efficient use of carbon can be realized by multiple stages of contacting. The carbon dose values are, however, useful for comparative purposes and to ascertain whether use of carbon is feasible for removal of a compound.

Data are provided to calculate the carbon dose to reduce any initial concentration of a compound to any desired final concentration. For example, consider the following for benzidine. To calculate the carbon required to reduce a benzidine concentration from 10 mg/l to 0.1 mg/l in neutral solution, equation 4 is used. Values for the constants are taken from the first page of the data sheets for benzidine. Thus,

$$\log (10 - 0.1) - \log M = \log 220 + 0.37 \log 0.1$$

$$M = 0.100 \text{ g/l or } 100 \text{ mg/l}$$

The tabulated carbon doses are also useful to illustrate the benefit of more than one stage of treatment. Consider again the case of benzidine. To reduce an initial concentration of 10 mg/l to 0.1 mg/l in a single stage requires 100 mg/l of activated carbon. If removal is accomplished in two stages; i.e., 10 mg/l to 1.0 mg/l in the first stage followed by 1.0 mg/l to 0.1 mg/l in a second stage, the carbon dose is 40 mg/l + 9.4 mg/l = 49.4 mg/l of carbon or about one-half the dose required in a single stage process.

The ultimate number of stages in a carbon adsorption system is achieved in column operation. Carbon requirements for column adsorption systems can be estimated from the Freundlich equation. To estimate the granular carbon requirements for column operation obtain the adsorption capacity from the isotherm plot for the concentration of compound to be treated. This capacity designated $(X/M)_{C_o}$ is the ultimate capacity of the carbon for the adsorbate at that concentration (C_o). This capacity represents the ultimate loading for a single component solution that can be attained during granular carbon column treatment, if the column is operated until the adsorbate concentration in the effluent is equal to the influent. Granular carbon requirement (G_C) can be calculated from the following equation:

$$G_C = \frac{C_o}{(X/M)_{C_o}} \qquad (5)$$

If C_o is in mg/l and X/M is in mg/g carbon requirements will be in g/l. Multiplication by 1,000 gives mg/l and multiplication of that product by 8.337 gives pounds per million gallons to be treated. For example, consider the case of granular carbon treatment of a solution containing 1 mg/l of benzidine (C_o = 1.0 mg/l; X/M = 220 mg/g). Solution of equation 5 yields:

$$G_C = \frac{1}{220} = 0.0045 \text{ g/l or } 4.5 \text{ mg/l}$$

SUMMARY OF DATA

A summary of the adsorption capacities for all of the compounds tested (at neutral pH) are shown in Table 3. The values are arranged in descending order. The constant, K, expressed as mg compound/gram of carbon, corresponds to the capacity, X/M, when the equilibrium concentration of compound is 1.0 mg/l.

Activated carbon exhibits a broad range of effectiveness in adsorbing organic compounds. Low molecular weight compounds with polar characteristics are not well adsorbed, if at all. Pesticides, polychlorinated biphenyls, polynuclear aromatic hydrocarbons, phthalates, aromatic, and substituted aromatic compounds were strongly adsorbed on activated carbon. Treatability of water and wastewater for removal of organics can be evaluated using the isotherm procedure.

TABLE 3. SUMMARY OF CARBON ADSORPTION CAPACITIES (cont.)

NOT ADSORBED

Acetone cyanohydrin	Adipic acid
Butylamine	Choline chloride
Cyclohexylamine	Diethylene glycol
Ethanol	Hexamethylenediamine
Hydroquinone	Morpholine

Triethanolamine

*Compounds prepared in "mineralized" distilled water containing the following composition:

Ion	Conc., mg/l	Ion	Conc., mg/l
Na^+	92	$PO_4^{\equiv}$	10
K^+	12.6	$SO_4^{=}$	100
Ca^{++}	100	Cl^-	177
Mg^{++}	25.3	Alkalinity	200

(a) Adsorption capacities are calculated for an equilibrium concentration of 1.0 mg/l at neutral pH.

SECTION 7

APPENDIX A

ACTIVATED CARBON ADSORPTION ISOTHERM PROTOCOL

1. General Discussion

1.1 Purpose of Test

Application of activated carbon for removal of solutes from aqueous solution is based on a property known as the adsorption capacity. The adsorption isotherm procedure is a method for the determination of the adsorptive capacity of activated carbons. The test can be used to compare adsorption capacities of different carbons for a given solute or to measure the adsorbability of different solutes on a given carbon.

2. Apparatus

2.1 Jar mill, jar and cylindrical grinding medium

2.2 Standard 200 mesh and 400 mesh sieves with 0.0029 inch (73.6μ) and 0.0015 inch (38.1μ) openings and mechanical sieve shakers.

2.3 Coordinated magnetic stirrers and stirring bars or jar test apparatus.

2.4 Ground-glass stoppered reagent bottles (1000 ml or appropriate volume).

2.5 Volumetric dispensing pipettes.

2.6 Filtration equipment; select from the following: 0:45μ membrane filter, sintered silver filter disc, glass fiber filter paper, syringe equipped with a Swinney filter holder, or pressure filter apparatus.

2.7 Analytical balance

2.8 Drying oven

2.9 Desiccator

2.10 pH meter

3. Reagents

All reagents must be prepared with "organic-free " distilled water. Treatment of conventional distilled water with large amounts of activated carbon in a column or batch process is suitable for this purpose. If isotherm tests are to be conducted on volatile compounds the carbon-treated distilled water should be boiled for 15 - 20 minutes or purged over night with inert gas in order to remove volatile compounds which may contaminate distilled water during distillation or storage.

3.1 Preparation of adsorbent:

Although granular carbons can be compared or evaluated in their original form by means of a batch test, the general procedure is to pulverize the adsorbent. Use of pulverized carbon assures more rapid attainment of equilibrium. If the adsorbent is in granular form, place in jar with grinding medium. Jar should not be more than half full to insure efficient grinding of the carbon. Place on a jar mill until sample is pulverized. Sieve the pulverized material through a 200-mesh (0.0736 mm) sieve and retain on a 400-mesh (0.038/mm) sieve. Return carbon which did not pass through the 200-mesh sieve to the jar for additional grinding. Repeat procedure until approximately 90% of the sample passes the 200-mesh sieve. Powdered carbons are classified as described above without the grinding operation. Use the 200/400 mesh fraction for isotherm testing. Dry the classified carbon overnight in a drying over ast 105^{o} C. Cool in a desiccator and store until needed for experimental purposes.

3.2 Preparation of activated carbon stock slurry: weigh out 50.00 grams of oven-dried and cooled pulverized carbon and transfer to a one-liter volumetric flask. Dilute to mark with "organic-free" distilled water. One ml of stock suspension contains 50 mg carbon. Prepare other working standard slurries by serial dilution of the stock slurry. Transfer slurries to appropriate flasks containing dispensing pipettes to provide a wide range of carbon concentrations. Table I lists the carbon dosages obtained with various volumes of stock slurry for one-liter sample volumes.

Table 1. Carbon Dosages for Given Pipette Volumes

Volume of Dispensing Pipette, (ml)	Carbon Dosage,* (mg/l)
5	250
10	500
15	750
20	1000
25	1250

* Not corrected for dilution of the one-liter sample volume

Dilution of the stock slurry by 1:10 and 1:100 would result in carbon doses 1/10 and 1/100 of those shown in Table 1.

3.3 Hydrochloric acid 6N. Dilute concentrated HCl 1:1 with "organic-free" distilled water.

3.4 Sodium hydroxide 6N. Add 240 grams of NaOH pellets to one liter of "organic-free" distilled water.

4. Procedure

4.1 If the test solution contains volatile or semivolatile components, place one-liter samples in a series of ground-glass stoppered reagent bottles. Add increasing carbon dosages to each successive sample. Add no carbon to one sample and use as a control. An initial concentration of 10 mg/l of test compound might require carbon dosages of 5, 10, 25, 50, 100, 250, 500, and 1000 mg/l. A preliminary isotherm may be required to bracket the desired range of dosages. Immediately after addition of the carbon dose, fill the reagent bottle to the bottom of the ground-glass stopper with additional test solution so that no air space remains. This will minimize loss of volatile solutes. Reagent bottle volumes should be recorded on the bottle and closely matched bottles used as a set. One-liter reagent bottles typically have a total volume of 1070-1090 ml. Carbon doses and test solution concentrations can be corrected for dilution associated with completely filling the ground-glass stoppered reagent bottles. In general, this correction is small and can be ignored.

4.2 Place the carbon-dosed samples on a coordinated magnetic stirrer apparatus and stir the control and samples for two hours. At the conclusion of the contact period separate the pulverized carbon from the test solution by an appropriate filtration procedure and analyze for the component of interest. Choice of filtration process will depend upon the characteristics of the test solution and the method of chemical analysis. Analysis of the control or a standard solution before and after filtration will determine whether or not a proper filtration method has been selected. Filtration of the sample should not result in a significant change in concentration of components.

In the case of volatile compounds, a syringe equipped with a Swinney filter holder can be used if the volume of filtrate required for analysis is small (i.e., analytical methods such as purge and trap gas chromatography, total organic carbon, or ultraviolet spectroscopy). Pressure filters can be used if larger volumes are required for analysis. Vacuum filtration with pre-washed membrane filters is suitable for solution containing nonvolatile components, provided adsorption losses are not encountered on the membrane. If adsorption losses are evident, sintered silver membranes or glass fiber paper can be used for separation of the pulverized carbon. Carbon can also be separated by centrifugation.

4.3 Analysis of the filtrate: The concentration of solute in equilibrium with each carbon dose is measured by an appropriate quantitative method such as spectrophotometry, colorimetry, total organic carbon, gas chromatography, evaporation to residue or other analytical technique.

5. Treatment of Data

5.1 Calculation of adsorption capacity: Activated carbon adsorption isotherm data are usually plotted according to the Freundlich equation. Detailed discussion of the equation and its uses can be found in the literature. Although the equation is empirical, it is nonetheless widely used and has been found to adequately describe the adsorption process in dilute solution. The Freundlich equation has the form:

$$X/M = K\, C_f^{1/n}$$

where $X = C_o - C_f$ which is the amount of solute adsorbed from a given volume of solution

C_o = initial concentration of solute in the untreated solution

C_f = final concentration in the treated solution at equilibrium

M = weight of activated carbon added to the solution

K & 1/n = empirical constants

Data are fitted to the logarithmic form of the above equation which can be written as follows:

$$\log X/M = \log K + 1/n \log C_f \qquad (2)$$

For dilute solutions this equation yields a straight line with a slope of 1/n and an intercept equal to the value of K (when Cf = 1) when X/M is plotted as a function of Cf on logarithmic paper. The intercept is an indicator of adsorption capacity and the slope of adsorption intensity.

A convenient form for tabulation of adsorption isotherm data is shown on the standard data form. Carbon dosages are shown in the left-hand column. The next column for each set of data contains the residual concentrations remaining in solution after carbon treatment. The C_f value for the control sample corresponding to the zero carbon dose is the C_o value. The amount of solute adsorbed (X) is calculated by subtracting each C_f value from C_o and is summarized in the appropriate column. Dividing "X" in mg of solute by the carbon dose in grams gives the adsorption capacity (X/M) per gram of carbon shown in the final column for each set of data. X/M values are plotted as a function of C_f according to equation (2) on logarithmic paper.

5.2 Least squares regression analysis may be used to locate the best-fit line for the plotted data points. A small programmable calculator is convenient for this purpose.

5.3 Extrapolation of the plotted isotherm to C_o (C_f value with zero carbon dose) gives the adsorption capacity at the initial concentration by noting the corresponding value from the X/M axis. Adsorption capacities at other concentrations can be read in the same manner. As the Freundlich equation states the adsorption capacity of carbon, X/M, is a function of the equilibrium concentration, C_f, of the solute.

5.4 Freundlich parameters: The plotted isotherm can be used to obtain the Freundlich parameters K and 1/n. K can be read from the X/M axis at $C_f = 1$. The slope (1/n) can be measured graphically using a ruler (i.e., mm rise/mm span) or taken from the programmable calculator. These parameters are useful in comparing the adsorbability of solutes and in rating the efficiency of different activated carbons.

6. Alternative Procedures

6.1 The pH of the test solution can affect the equilibrium adsorption capacity. For acidic solutes adsorption is favored at low pH while basic compounds are more strongly adsorbed at higher pH values. Solution pH can be adjusted with hydrochloric acid or sodium hydroxide prior to addition of the carbon if these effects are to be measured. Values of 3.0, 7.0, and 9.0 are recommended as a suitable range to determine pH effects. Use of buffers may be desirable in certain cases where a change in pH during adsorption is to be avoided.

6.2 In cases where nonvolatile solutes are to be measured it is not necessary to fill the reagent bottle to the bottom of the ground-glass stopper. If any doubt exists as to the volatility of the solute(s) completely filled reagent bottles should be used.

6.3 Isotherm testing is usually conducted at room temperature (22 ± 2^{o} C) although conditions can be varied experimentally if desired.

16. ABSTRACT

An experimental protocol for measuring the activated carbon adsorption isotherm was developed and applied to a wide range of organic compounds. Methods for treatment of the isotherm data and a standard format for presentation of results are shown. In the early phase of the study selection of compounds for testing in the experimental program presented a formidable task. Initial selections were based on the following criteria: (1) annual quantity produced, (2) critical concentration required to produce an adverse environmental effect, (3) probability of occurrence in water or wastewater, (4) persistence in the water environment, and (5) solubility. During the course of the study the Occupational Safety and Health Administration's (OSHA) list of regulated carcinogens and the U.S.Environmental Protection Agency's Consent Decree list of priority pollutants were developed. These compounds were added to those previously selected for the experimental phase of the study.
