Intermittent Walking has Similar Effects on 24-Hour Glycemia as a Calorically Equivalent Continuous Walk in Older Adults

Kate Lyden¹, Tracy Swibas², Kerry Hildreth², Rachael Van Pelt², Catherine Jankowski, FACSM², Edward L. Melanson, FACSM².
¹University of Massachusetts, Amherst, MA. ²University of Colorado, Denver, CO. (Sponsor: Ed Melanson, FACSM)
Reported Relationships: K. Lyden: Consulting Fee; PAL Technologies.

Older adults spend more time engaged in sedentary behavior (SB) than any other segment of the population. Interrupting sedentary time with short bouts of walking improves 24-hour glycemic control compared to uninterrupted sitting. However, it is not known if short-walking bouts are as beneficial to 24-hour glycemia as a single bout of continuous exercise. **Purpose** To compare the effectiveness of multiple, short intermittent walking bouts and one, calorically equivalent continuous bout of walking on 24-hour glycemia in older adults. **Methods** Healthy, overweight/obese older adults (N=18, 67 ± 5 y, BMI = 32.2 ± 4.3 kg/m²) completed two, 24h conditions in a whole room indirect calorimeter; 1) Intermittent walking (IW): 1.5 min of moderate intensity treadmill walking (36 min total) every 30 minutes and 2) continuous walking (CW): 36 min continuous, moderate intensity treadmill walking performed in the morning (~8AM). Outside of the prescribed walking times, subjects remained in SB for the remainder of the waking day. Continuous glucose monitoring was used to measure interstitial glucose concentrations every 5 minutes. Energy and macronutrient intake was standardized between conditions. **Results** 24-hour energy expenditure (2257 ± 329 vs. 2165 ± 302 kcal, mean ± SD) and RQ (0.84 ± 0.03 vs. 0.84 ± 0.03) were similar during IW and CW, respectively. Peak postprandial glucose following dinner was lower (p<0.05) during IW (120.4 ± 10.7 mg/dl) compared to CW (135.3 ± 15.3 mg/dl). No differences were observed in any other 24 hour glycemia variables, including 24 hour area under the glucose curve (IW = 154862 ± 12724 mg/dl, CW = 158096 ± 15156 mg/dl), glycemic variability (standard deviation of 24 hour glucose concentrations) (IW = 12.2 ± 4.4 mg/dl, CW = 12.2 ± 4.2 mg/dl), and peak postprandial glucose concentrations following breakfast (IW = 144.0 ± 22.7 mg/dl, CW = 144.8 ± 27.2 mg/dl) and lunch (IW = 137.9 ± 17.1 mg/dl, CW = 139.2 ± 17.8 mg/dl). **Conclusion** These results suggest IW had similar effects as CW on 24-hour glycemia, although the postprandial glucose response to meals consumed later in the day may be lower with IW. IW may improve cardiometabolic health in older adults.

82 Board #2 May 31 9:30 AM - 11:30 AM
Mobility Improvement After an Exercise Program for Older Adults: Role of Initial Mobility

Wan-chin Kuo, Randall J. Gretebeck, FACSM, Katherine M. Mead, Kimberlee A. Gretebeck. *University of Wisconsin-Madison, Madison, WI.*
Email: wkuo4@wisc.edu
(No relationships reported)

Basic mobility tasks are often used to assess improvement in response to physical activity interventions for older adults. However, it can be argued that if strength and endurance capacities are adequate prior to engaging in a program of exercise, further increases in capacity are not expected to alter basic tasks. Usual Gait Speed (UGS), 6 Minute Walk (6MW), and Timed Up and Go (TUG) are often used in research evaluate the efficacy of an exercise training program for older adults. However, the change in these measures has not been evaluated in relation to initial mobility. **PURPOSE:** To evaluate the improvement in basic mobility tasks in response to a ten-week community based exercise program for older adults with high or low functional ability. **METHODS:** Sixty-one older adults (age= 72.7 yrs±7.9); BMI=32.3±7.2) completed the 10-week Physical Activity for Seniors for Life (PALS) group exercise and lifestyle behavior change program. TUG (time in seconds to rise from a chair, walk 3 meters, return to chair and sit), 6MW (distance covered in 6 minutes), and UGS (meters/second to walk 6 m distance) were measured before and after the exercise program. Participants were divided into upper and lower functional groups based on the median for each mobility task. Repeated measures ANOVA and Effect Size (Cohen's d) were used to examine mean differences within the two groups. **RESULTS:** After the exercise program, the lower functional group showed significant improvement in all basic mobility tasks (p<0.001). The upper functional group showed significant improvement

in 6MW (p<0.001) and TUG (p=0.006), with no significant change in UGS (p=0.816). Importantly, the lower functional group demonstrated much higher effect sizes in all three tests (6MW: 763 vs 1121 feet, d=0.936; TUG: 13.3 vs 11.2 seconds, d=0.858; UGS: 6.3 vs 5.4 seconds d=0.800), pre, post respectively, while the higher functional group showed only moderate or low effect sizes, 6MW (1414 vs 1522 feet, d=0.562), TUG (9.1 vs 8.3 seconds d=0.577), UGS (4.65 vs 4.62 seconds d=0.041) pre, post respectively. **CONCLUSION:** These results suggest that UGS may be better suited for use with a frail population, while TUG and 6MW may be useful across a wider range of functional ability in older adults.

83 Board #3 May 31 9:30 AM - 11:30 AM
Unemployed Older Adults' Social Participation was Associated with More Physical Activity and Less Sedentary Time

Hiroyuki Kikuchi¹, Shigeru Inoue¹, Noritoshi Fukushima¹, Tomoko Takamiya¹, Yuko Odagiri¹, Yumiko Ohya¹, Shiho Amagasa¹, Koichiro Oka², Neville Owen³. ¹Tokyo Medical University, Shinjuku-ku, Japan. ²Waseda University, Tokorozawa, Japan. ³Baker Heart and Diabetes Institute, Melbourne, Australia.
Email: kikuchih@tokyo-med.ac.jp
(No relationships reported)

PURPOSE: Social participation provides health benefits for older adults, but it is not known whether social participation is associated with their being more physically active or less sedentary. We examined these associations in a population-based sample of older Japanese adults.

METHODS: A mail survey conducted in 2010 and gathered data from 1146 community-dwelling, non-working older adults (mean age: 70.1 years, 43% men) on social participation, physical activity, sedentary time and socio-demographic characteristics. Median splits were used to categorize social participation, physical activity and sedentary behavior as either 'higher' or 'lower'. Multivariate logistic regression analyses were used to calculate odds ratios (ORs) for the associations of higher versus lower social participation with being physically active and having higher sedentary time. Similar analyses were conducted after classifying sedentary behaviors into two distinct types: passive sedentary behaviors (consisting of "television viewing", "sitting around", and "listening or talking while sitting") and mentally-active sedentary behaviors (consisting of "computer use" and "reading books or newspapers")

RESULTS: Those with higher social participation had a significantly greater odds of higher physically activity (OR=2.10, [95% confidence interval (CI): 1.44-3.06] among men; OR=1.93, [1.39-2.68] among women); and a significantly lower odds of higher sedentary time among men (OR=0.62, [0.42-0.90]), but not among women (OR=0.80, [0.58-1.11]). Those with higher social participation had significantly lower passive sedentary time (OR=0.55, [0.38-0.81] for men; OR=0.72 [0.51-0.99] for women), but this was not the case for mentally-active sedentary time (OR=1.36, [0.91-2.02] for men; OR=1.17 [0.83-1.63] for women).

CONCLUSIONS: Promoting social participation among older adults may be effective for increasing their physical activity and reducing sedentary time.

84 Board #4 May 31 9:30 AM - 11:30 AM
Effects of Stair Climbing on Leg Muscle Strength in Older Adults Attending Physical Activity Programs

Nobuko Hongu¹, Mieko Shimada², Rieko Miyake², Yusuke Nakajima³, Ichirou Nakajima⁴, Kevin G. Bowden⁵, Yutaka Yoshitake⁶. ¹The University of Arizona, Tucson, AZ. ²Chiba Prefectural University of Health Sciences, Chiba, Japan. ³Urawa University, Saitama-shi, Japan. ⁴International Budo University, Katsuura, Japan. ⁵The University of Arizona, Parker, AZ. ⁶National Institute of Fitness & Sports in Kanoya, Kanoya, Japan.

(No relationships reported)

Purpose: Stair climbing can be a strenuous task and stair accidents/injury are common among older adults. We evaluated the effectiveness of daily stair climbing on leg muscle strength in older adults participating in weekly community physical activity programs for 6 months. **Methods:** Seventy-four healthy older adults (50 women, 24 men, mean age, 73.5 ± 5 years) were recruited. Participants attended weekly physical activity programs at their community center and recorded their daily walking and stair climbing steps using a pedometer, Omron, HJA-403C, which detects both types of steps. Prior to and after the 6-month study period, height, weight, and leg strength (i.e., abductor muscle strength, adductor muscle strength, and knee extensor strength) were measured. During the study period, the instructors encouraged participants to engage in stair climbing by explaining the health benefits, providing information on locations of stairs nearby, and listening to participants' experiences on routine stair use. A paired t-test was used to determine the changes in steps and leg strength before and

after the 6-month study period, and Pearson correlation analysis was used to identify correlations between the stair climbing steps and leg strength. **Results:** Forty-nine participants (34 women, 15 men) completed the study. At the baseline, the participants recorded an average of 120 stair steps per day, which was approximately 2% of their daily total walking steps. After the 6-month study period, the mean walking steps ($6,607 \pm 3,235$ steps vs. $7,556 \pm 2,715$ steps) and stair steps (119 ± 90 steps vs. 166 ± 123 steps) increased significantly ($p \leq 0.01$). There were no significant changes in leg muscle strength (Pre-test vs. Post-test: Adductor, 0.35 ± 0.11 vs. 0.35 ± 0.10 kg/kg, Abductor 0.41 ± 0.11 vs. 0.44 ± 0.10 kg/kg). However, in men the correlation coefficient between the stair steps and abductor muscle strength was observed (Pre-test: $r=0.428$, $p=0.04$, Post-test: $r=0.556$, $p=0.03$). **Conclusions:** Stair-use campaigns increased routine daily stair use (about 50 steps) in older adults. This did not significantly change leg muscle strength, however in men the relationship between the stair steps and abductor muscle strength was observed. In a future study, cross-sectional evaluations of stair steps and leg muscle strength will be examined.

85 Board #5 May 31 9:30 AM - 11:30 AM
Effects of Tai Chi on Mobility in Older Adults with Multisite Pain

Tongjian You, FACSM¹, Elisa Ogawa¹, Saurja Thapa¹, Yurun Cai¹, Huan Zhang², Satoshi Nagae¹, Gloria Yeh³, Peter Wayne⁴, Suzanne Leveille¹. ¹University of Massachusetts Boston, Boston, MA. ²Huan's Tai Chi, Cambridge, MA. ³Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA. ⁴Brigham and Women's Hospital and Harvard Medical School, Boston, MA.
 Email: tongjian.you@umb.edu
 (No relationships reported)

Chronic pain is associated with impaired mobility and risk of falls in older adults. **PURPOSE:** To examine the effects of Tai Chi on mobility in older adults with multisite pain and risk of falls. **METHODS:** Fifty-four community-dwelling older adults (≥ 65 years) with multisite pain who reported falling in the previous year or using an assistive device were randomized to gentle body exercise or mind-body exercise (Tai Chi), each offered twice weekly for 12 weeks. Assessments were performed at baseline and within 2 weeks after completing the intervention. Mobility was measured in 2 conditions: single-task walking and dual-task walking with a cognitive attentional challenge, by using a 16-foot sensorized gait mat. Paired t-tests were used to assess changes within each group, and student t-tests were used to assess differences between groups. **RESULTS:** Twenty-three participants in the body exercise group and twenty-two participants in the Tai Chi group completed the study. The body exercise intervention did not change any gait measures. However, the Tai Chi intervention significantly improved single-task stride time (from 1.20 ± 0.11 s to 1.16 ± 0.10 s, $p < 0.05$) and swing time (from 31.77 ± 3.20 % to 32.23 ± 2.82 %, $p < 0.05$), and decreased dual-task gait asymmetry (from 5.40 ± 3.92 to 2.87 ± 3.07 , $p < 0.05$). Also, comparing the 2 interventions, participants in the Tai Chi group versus the body exercise group significantly decreased dual-task gait asymmetry from baseline to the post-intervention assessment (body exercise: 0.33 ± 3.54 vs. Tai Chi: -2.53 ± 4.41 , $p < 0.05$). **CONCLUSION:** Tai Chi improved several single-task and dual-task gait measures in older adults with multisite pain and risk for falls. A larger study is required to examine the effectiveness of Tai Chi on mobility and fall risk in older adults with multisite pain. (Supported by NIH Grant R21 AG043883)

A 3-Month Dalcroze Eurhythmics Intervention May Improve Gait Speed in Community Dwelling Elderly Participants

Lisa Ferguson-Stegall, Mandy Vang, Anthony S. Wolfe, Kathy Thomsen. Hamline University, Saint Paul, MN. (Sponsor: Donald Dengel, PhD, FACSM)
 Email: lstegall01@hamline.edu
 (No relationships reported)

Falls lead to lower quality of life, reduced independence, and increased mortality in the elderly. Many falls occur while walking, especially when performing other tasks simultaneously. Dalcroze eurhythmics (DE) is a music-based movement training program that emphasizes multitask coordinated movement. A previous 6-mo DE study in the elderly demonstrated significant improvements in gait and balance. However, the effects of a short-term DE intervention on fall risk-related outcomes is unknown. **PURPOSE:** To determine if a 3-mo DE intervention improves measures of gait and balance, self-perceptions of health, and fear of falling in a community-dwelling elderly cohort. We hypothesized that improvements would be detected in all outcome measures after the intervention. **METHODS:** 9 participants (8 females, 1 male; age 79.0 ± 12.3 y) completed the intervention. DE sessions, led by a certified DE instructor, were held 1x/wk at a community senior program. Pre and post-testing sessions occurred 1 wk before the program began, and 1 wk after the last session, respectively. Gait speed (m/sec) was determined by the 6-m walk test (6MWT). Dual-

task gait speed was determined from repeating the 6MWT, but while participants counted backward from 50. Balance and coordinated stability was assessed using a Swaymeter test. Participants' perceptions of overall, physical, and mental health was assessed by SF-12 questionnaires. Fear of falling was assessed with the Tinetti Falls Efficacy Scale. Paired t-tests were used to compare mean differences. **RESULTS:** Gait speed improved significantly post-intervention (0.92 ± 0.11 vs 1.04 ± 0.12 m/sec, $p=0.004$). Dual-task gait speed also improved (0.77 ± 0.09 vs 0.92 ± 0.11 m/sec, $p=0.0005$). Trends toward significance existed for improvements in SF-12 total score (91.5 ± 4.4 vs 100.6 ± 3.9 , $p=0.08$), and mental component score (52.8 ± 3.3 vs 58.0 ± 2.3 , $p=0.06$), and Swaymeter results (10.0 ± 1.5 vs 7.9 ± 1.7 deviations, $p=0.07$). No differences were found for SF-12 physical component scores or in fear of falling after the intervention. **CONCLUSION:** Participating in Dalcroze eurhythmics for 3 mo may improve gait speed under single and dual task conditions. This movement training approach could be considered for use by community senior programs as a possible fall risk reduction intervention for the elderly.

Yearlong Walking Exercise Improves Depression and Health-related Quality of Life in Older Adults

Takumi Aoki¹, Haruo Sakuma², Kojiro Ishii¹. ¹Doshisha University, Kyoto, Japan. ²Ritsumeikan University, Shiga, Japan. (Sponsor: Susumu S. Sawada, FACSM)
 (No relationships reported)

Previous studies suggest that moderate-intensity aerobic exercise and strength training are effective for improving depression and health-related quality of life (HRQL) in older adults. However, the effects of long-term walking exercise on depression and HRQL in older adults has not been determined. **PURPOSE:** The purpose of this study was to assess the effectiveness of 12 months of walking exercise in improving depression and HRQL in older adults. **METHODS:** We divided 180 apparently healthy older adults into 2 non-randomized groups: a 12-month walking exercise group ($n = 110$, 60 men and 50 women; mean age, 72.2 ± 6.4 years) and a non-walking exercise group ($n = 70$, 39 men and 31 women; mean age, 72.6 ± 3.8 years). The Center for Epidemiological Studies Depression Scale (CES-D) and the Medical Outcomes Study 36-Item Short-Form Health Survey version 2 (SF-36v2) were used to measure depressive symptoms and HRQL. In Japanese, SF-36v2 scores are summarized in physical HRQL scores (physical component summary [PCS]), mental HRQL scores (mental component summary [MCS]), and role / social HRQL scores (role / social component summary [RCS]) (Suzukamo et al. 2011). Therefore, in the analysis of SF-36v2 scores, we evaluated PCS, MCS, and RCS. **RESULTS:** Participants in the walking exercise group showed significant improvement in CES-D scores (11.0 ± 4.1 points vs. 9.7 ± 4.8 points, $p < 0.001$), MCS scores (54.5 ± 9.1 vs. 56.8 ± 8.6 , $p = 0.005$), and RCS scores (49.4 ± 9.4 vs. 52.8 ± 9.0 , $p < 0.001$) compared to the baseline values. Overall, the average step counts per day of the walking exercise group participants significantly increased, compared to the baseline values (7747 ± 1782 steps / day vs. 8736 ± 2701 steps / day, $p < 0.001$). **CONCLUSIONS:** Twelve months of walking exercise may be effective for improving CES-D, MCS, and RCS scores in older adults.

Physical Activity and Sedentary Behavior of Older Adults Related to Physiological Metrics of Walking Effort

Dain P. LaRoche, FACSM¹, Edward L. Melanson, FACSM², Morgan P. Baumgartner¹, Breanna M. Bozzuto¹, Victoria M. Libby¹, Brittany N. Marshall¹. ¹University of New Hampshire, Durham, NH. ²University of Colorado Anschutz Medical Campus, Denver, CO.
 Email: dain.laroche@unh.edu
 (No relationships reported)

Older adults spend nearly ten hours of the waking day in sedentary activities that increase risk for chronic disease progression and loss of physical function. It is important to understand how the physiological demands of ambulation contribute to ambulatory and sedentary behavior so effective interventions can be implemented in this at-risk population. **PURPOSE:** To determine whether neuromuscular, pulmonary, and cardiac demand during a fixed-paced walk explain variance in sedentary behavior and walking activity in community-dwelling older adults. **METHODS:** Twelve women and thirteen men, 77 ± 9 yr, 74.6 ± 15.5 kg, 26.0 ± 4.3 kgm², performed a four-minute, steady-state walk on a treadmill at 1.25 m s⁻¹ while activation of the vastus lateralis muscle, heart rate, and minute ventilation were recorded. ActivPAL accelerometers were used to record time spent walking and sedentary over 96 consecutive hours. Sleep logs were used to calculate time spent awake during the monitoring period. Walking time and sedentary time were then recorded as percent of the waking day. Stepwise regression determined whether peak muscle activation, minute ventilation, and heart rate predicted sedentary and walking time. **RESULTS:**

Participants spent $56 \pm 11\%$ (9.0 ± 1.9 hr) of the waking day sedentary and $12.5 \pm 3.0\%$ (2.0 ± 0.5 hr) walking. Partial correlations from stepwise regression showed that sedentary time was positively related to muscle activation during walking ($r = 0.56$, $p = 0.011$), but not to ventilation ($r = 0.23$, $p = 0.346$) or heart rate ($r = 0.03$, $p = 0.915$). In contrast, walking time was inversely related to minute ventilation ($r = -0.57$, $p = 0.008$), but was not related to muscle activation ($r = -0.04$, $p = 0.881$) or heart rate ($r = 0.14$, $p = 0.569$). **CONCLUSIONS:** Physical activity and sedentary behavior are independent disease risk factors and this study's results indicate that different aspects of physical function may contribute to their variability in older adults. Time spent sedentary was related to the degree of neuromuscular demand during walking suggesting that older adults who have high muscle activation during ambulation are more likely to engage in sedentary behavior. Time spent walking was inversely related to pulmonary demand suggesting that those who walk with a high ventilatory rate are less likely to engage in walking activity.

Fitness and Body Composition Outcomes in Adolescent Athletes Consuming Chocolate Milk or Gatorade Post-Exercise

Philip Cheshire, Katelyn Born, Erin Dooley, John Bartholomew, FACSM. *University of Texas at Austin, Austin, TX.* (Sponsor: John Bartholomew, FACSM)
Email: andyc6@utexas.edu
(No relationships reported)

Purpose. This study examined fitness and body composition outcomes for adolescents consuming chocolate milk (CM) or a carbohydrate/electrolyte (CHO) drink throughout a school-sponsored summer strength and conditioning program. **Methods.** Participants were 100 high school athletes (M age = 15.1, $SD = 1.3$; 78% male; 46% Afr. Amer.). Measures included a bench press (BP), squat, power clean, bodyweight, and hand-held BIA body fat assessment. BP and squat were combined for a composite strength score (CSS). Participants completed 4 days/week of strength and conditioning training for 6 weeks. The workouts consisted of a 1-hour free weight resistance training session followed by 1-hour of on-field agility drills and conditioning sprints. Participants were randomly-assigned to receive either CM (16 oz, 300 Cal, 5g fat, 360 mg Na, 44 g carbs, 16 g protein) or CHO (28 oz, 0 g fat, 320 mg Na, 42 g carbs, 0 g protein) immediately post-exercise. **Results.** A 2-way repeated measures ANOVA showed no bodyweight changes from pre- to post-test ($p = .071$, $d = .06$). Additionally, there was not a significant change in body fat percentage ($p = .89$, $d = .03$). No interactions presented by condition for weight ($p = .49$, $\eta_p^2 = .005$) or body fat ($p = .43$, $\eta_p^2 = .006$). Both groups showed an improvement in power clean ($p < .001$, $d = .22$) across time with no interactions. However, the CSS showed a significant condition by time interaction ($p = .044$, $\eta_p^2 = .08$) wherein the CHO group did not significantly increase over time ($p = .406$) while the CM group significantly improved in CSS from pre- to post-test ($t = -4.153$, $p < .001$). Paired samples t-tests of the separated BP and squat showed that the CHO group significantly decreased in mean BP (7.26 lbs, $p = .044$) but had no change in squat (17.7 lbs, $p = .154$). The CM group showed significant increases in both BP (9.06 lbs, $p = .039$) and squat (36 lbs, $p < .001$). **Discussion.** This is the first study comparing the impact of CM and CHO on athletic outcomes in an adolescent population in a field-based environment. The use of CM appears to have provided a moderate benefit for increases in strength. This study replicates the findings of laboratory studies, and extends them by showing a benefit in adolescent athletes in a naturalistic setting. Future research will benefit from longer study durations with larger numbers of participants.

A Novel Approach To Calculate Work Rate On A Treadmill (TM) In Early-and Late-pubertal Children

Ronen Bar-Yoseph¹, Janos Porszasz², Shlomit Radom-Aizik¹, Pearl Law¹, Dan M. Cooper¹. ¹UCI, Irvine, CA. ²Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA.
Email: rbaryose@uci.edu
(No relationships reported)

Childhood obesity and children who survive previously fatal diseases and conditions highlight the need for rigorous metrics of fitness in children and across the lifespan. Cardiopulmonary exercise testing (CPET) data in children must be scaled to the magnitude of the metabolic perturbation. In CPET using cycle ergometry (CE), the external work (WR) is readily determined. With TM testing WR is hard to estimate from its key elements of speed, incline, and body mass (S, I, M) given the complexity of the mechanics of energy cost as S and I change. **PURPOSE:** To estimate WR associated with TM exercise (S,I,M) in early and late pubertal boys. **METHODS:** Our strategy involved: 1) Using CE to establish the regression coefficient (a) and intercept (b) from the linear equation $\dot{V}O_2 = aWR + b$; 2) assuming the same relationship we estimated work rate (WR') from the $\dot{V}O_2$ measured on TM using S, I, M (Fig A) and S^2 , I, M (Fig B); 3) analyzed the regression parameters from the function $WR' = a(S^2, I, M) + b$ in 10 early pubertal (mean age 9.8 y/o, tanner stage 1-2) and 10 late pubertal boys (15.8 y/o, tanner stage 4-5), performed CPET on CE and TM. **RESULTS:** WR' was moderately and non-linearly correlated with S I M (mean $r = 0.61$, Fig A). However mean $r = 0.96$ and linear relationship was found with $WR' = a(S^2 I M) + b$, (Fig B). Further, the slope (a) was significantly higher in the younger (0.0395 ± 0.006) compared with the older boys (0.0316 ± 0.008 , $p = 0.017$). **CONCLUSION:** This approach enables CPET data interoperability between TM and CE. WR' seems to be a square function of S, making it a linear function of kinetic energy (MS^2). CPET slopes (e.g., $\Delta\dot{V}O_2/\Delta WR$ or $\Delta HR/\Delta WR$) can be calculated and provide useful insights into disease mechanisms and progression in children and adults, when maximal efforts are questionable. The maturational related differences between WR' and SIM suggest a biological difference in the efficiency of muscular work as children grow and develop. Effectiveness of the Scaling Method in Normalizing Strength Measurement of U.S. Children And Youth

Hai Yan, Weimo Zhu, FACSM. *University of Illinois at Urbana Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)
Email: haiyan2@illinois.edu
(No relationships reported)

PURPOSE: Studies have shown that body size may affect athletes' performance in fitness tests. Thus, individuals with larger body mass (BM) often exhibit a greater amount of muscle tissue and perform well on certain fitness tests when the load is "absolute" (i.e., the load, e.g., a 10 kg dumbbell, keeps the same across the test takers). To account for this effect, it is common practice to normalize athlete performance by simply dividing the outcome variable by BM. Yet, the effectiveness of this approach has not been well studied in children and youth. Using the data from the 2012 NHANES National Youth Fitness Survey (NNYFS), this study was to explore and evaluate possible scaling methods to eliminate the effect of body mass on children's performance in fitness tests, especially strength tests. **METHODS:** 1640 participants (50.2% male; aged 3-15 yr.) took part in the physical fitness tests. Lower body muscle strength (LBMS) was derived from knee extension tests and hand grip strength (HGS) was determined by the handgrip dynamometer. Five different scaling methods (dividing the outcome variable by BM, BM^2 , BM^3 , square root (SQRT) of BM, and natural logarithm (ln) of BM) were applied and the correlations between test results and BM (kg) before and after scaling were examined in each method. **RESULTS:** Results from the correlation analysis showed that BM is highly correlated with strength measures in both boys (LBMS: .702, HGS: .793) and girls (LBMS: .666,

HGS: .790). By dividing by BM, the overall correlation coefficients were significantly decreased (LBMS: .687 to -.102, HGS: .780 to -.258) and the body size effect was better adjusted in boys (LBMS: -.044, HGS: -.171) than in girls (LBMS: -.173, HGS: -.412) using the scaling method.

	Scaling Method	LBMS (pounds)	HGS (kg)
Boy	None	.702	.793
	/BM	-.044	-.171
	/BM ²	-.658	-.823
	/BM ³	-.673	-.776
	/SQRT(BM)	.444	.530
	/ln(BM)	.596	.695
Girl	None	.666	.790
	/BM	-.173	-.412
	/BM ²	-.698	-.834
	/BM ³	-.716	-.778
	/SQRT(BM)	.348	.417
	/ln(BM)	.529	.653
Overall	None	.687	.780
	/BM	-.102	-.258
	/BM ²	-.676	-.824
	/BM ³	-.693	-.774
	/SQRT(BM)	.406	.483
	/ln(BM)	.569	.669

CONCLUSION: The effect of body size on measurement of LBMS and HGS could be adjusted by simply dividing by BM and the effect was more significant in boys.

Interpopulation Variations in Height Growth: a Potential Explanation for Differences in Adolescent Swim Performance

Kosuke Kojima¹, Paul L. Jamison², Christopher L. Brammer¹, Joel M. Stager, FACSM¹. ¹Counselman Center for the Science of Swimming, Indiana University, Bloomington, IN. ²Indiana University, Bloomington, IN. (Sponsor: Joel Stager, FACSM)
 Email: kokojima@umail.iu.edu
 (No relationships reported)

Maturation-based superiority in adolescent sport performance has been well documented. Because the timing of maturational events differs among ethnic or geographically-disparate populations, we hypothesized that interpopulation variations in physical growth patterns may be related to differences in athletic performance. **PURPOSE:** To determine the relationship between height growth and swim performance progression for two geographically disparate populations (Japanese, JPN; and the U.S., US) and the extent to which interpopulation variations in height growth are related to respective swim performance progression. **METHODS:** Growth reference data were acquired for JPN (MEXT, 2000) and US (Kuczumski et al., 2002). All performance times (sec) in 50-meter long course freestyle (50Fr) for JPN (N = 46900) and US (N = 60739) in 2008 were compiled from each swimming federation's database. For each age within each sex, a t-test was performed to compare 50Fr between JPN and US. Pearson correlation coefficient was used to evaluate 1) the strength of the relationship between age-related median height and median 50Fr for each sex within each country and 2) the extent to which interpopulation variations in age-related height growth (expressed as JPN to US ratio) are related to those in age-related 50Fr progression for each sex. **RESULTS:** As compared with the respective US cohort, age-related peak height gains occur approximately two years earlier for JPN (10 vs 12 yr in girls; 12 vs. 14 yr in boys). The 50Fr was faster for JPN girls aged 7 to 11 yr and JPN boys aged 7 to 9 yr ($p < 0.001$), not different for girls at 12 yr and boys at 10 and 11 yr, and slower at 13 yr and older for JPN girls and 12 and older for JPN boys ($p < 0.001$). Median height was correlated with median 50Fr during adolescent ages for US girls and boys ($r(12) = -0.97, p < 0.001$), JPN girls and boys ($r(9) = -0.97, p < 0.001$). The JPN to US ratio in height growth was also correlated with that in 50Fr progression in girls ($r(9) = 0.71, p = 0.015$), but not in boys ($r(9) = 0.49, p = 0.12$). **CONCLUSIONS:** Maturation-related superiority in swim performance is not only observable within a population but also between populations. Interpopulation variations in the timing of maturational events (as measured by age-related peak height gain) partially explain differences in adolescent athletic performance.

Activity Profile of Pokemon GO in College Students
 Charles Fountaine, Emily Springer, Jasmine Sward. *University of Minnesota Duluth, Duluth, MN.* (Sponsor: John R. Keener, FACSM)
 Email: cfountai@d.umn.edu
 (No relationships reported)

Since its debut in July 2016, Pokemon GO has been a wildly popular mobile gaming app. In contrast to many previous exergames, Pokemon GO requires the user to be physically active. However, the extent to which Pokemon GO contributes to physical activity is unknown. **PURPOSE:** to investigate the activity profile of playing Pokemon GO for 60 minutes in college students.

METHODS: College students (n=24, n=15 female) were fitted with an accelerometer, pedometer, and heart rate monitor to assess the activity demands during a 60-min bout of playing Pokemon GO. Troiano accelerometer cut points were utilized to estimate time spent in sedentary, light, moderate, and vigorous physical activity.

RESULTS: Descriptive statistics for heart rate (average and peak), total steps, and time (min) spent in sedentary, light, moderate, and vigorous physical activity are displayed in the table below. On average, 82.7% \pm 10.1% of the play time was spent in moderate-intensity physical activity.

CONCLUSIONS: The results of this study suggest that playing one hour of Pokemon GO can be an effective means of accumulating recommended levels of physical activity.

Avg. HR (bpm)	Peak HR (bpm)	Steps	Sedentary (min)	Light (min)	Moderate (min)	Vigorous (min)
100.3 \pm 11.3	133.8 \pm 17.7	5992.1 \pm 578.8	4.9 \pm 3.0	6.1 \pm 3.9	50.1 \pm 5.3	0.15 \pm 0.4

95 Board #6 May 31 9:30 AM - 11:30 AM
Associations Among Perceived Motor Competence, Motor Competence, Physical Activity, And Health-related Physical Fitness Of Children Ages 10-15 Years Old.

Emily M. Post¹, Dawn P. Coe, FACSM², Eugene C. Fitzhugh², Jeffrey T. Fairbrother². ¹The Ohio State University, Columbus, OH. ²The University of Tennessee, Knoxville, TN. (Sponsor: Dr. William Kraemer, FACSM)
 (No relationships reported)

PURPOSE: To examine the associations among perceived motor competence (PMC), motor competence (MC), moderate to vigorous physical activity (MVPA), and health-related physical fitness during middle childhood and early adolescence. **METHODS:** Participants were 47, 10-15-year-old youth (12.2 \pm 1.64 yrs, 50.2 \pm 16.2 kg, 157 \pm 13.1 cm). Each participant made two visits, separated by at least 7 days, in East Tennessee or northwest Ohio, during which they completed the Bruininks-Oseretsky Test of Motor Proficiency, 2nd Edition, Harter's PMC questionnaire (Harter, 1978), and the FITNESSGRAM battery for health-related physical fitness. Actigraph GT3X+ accelerometers were worn for seven days to measure MVPA. **RESULTS:** There were significant ($p \leq 0.05$) positive correlations between physical fitness and both MC ($r_s = 0.44, p < 0.01$) and PMC ($r_s = 0.32, p < 0.05$). Additionally, a significant positive correlation was discovered between PMC and MC ($r_s = 0.47, p < 0.05$). There were no significant correlations between average daily MVPA and the other variables.

CONCLUSION: Results indicated that higher MC and PMC were associated with higher levels of health-related physical fitness. The interrelationship of these three variables was consistent with previous studies linking the development of fundamental motor skills to participation in complex movement behaviors, such as sports and other lifetime fitness activities, and the development and strengthening of PMC (Stodden & Robertson, 2009; Hands et al., 2008; Cliff et al., 2011; Zask et al., 2012; Barnett et al., 2010).

96 Board #7 May 31 9:30 AM - 11:30 AM
Tracking Physical Activity and Sedentary Behavior in Adolescents using a Mobile Application
 Todd Buckingham, Karin Pfeiffer, FACSM. *Michigan State University, East Lansing, MI.*
 Email: buckin21@msu.edu
 (No relationships reported)

During adolescence, sedentary time tends to increase while physical activity (PA) declines. Self-report measures of adolescents' activities are often prone to recall bias and are limited by their inability to detect simultaneous activities. Real-time measurements (Experienced Sampling Method, ESM) may address these limitations

by assessing activities when they take place. **PURPOSE:** To describe adolescents' after-school behaviors through use of a mobile application using ESM. The secondary purpose was to examine the feasibility and acceptability for adolescents to track their after-school PA and sedentary behaviors.

METHODS: Participants completed surveys on the behavior in which they were engaged at the time the survey was sent, using an app on their mobile device. The surveys occurred randomly, three times, from 3:30-9pm, for seven days. Participants also completed a 15-minute, telephone-based follow-up interview to assess ease and likeability of using the app on 5-pt scales (1=very easy, 5=very hard; 1=disliked a lot, 5=liked a lot). **RESULTS:** Thirty adolescents, 11-15 years old, submitted 560 surveys using the mobile device app (89% response rate). The adolescents most often reported engaging in "Other" activities (e.g., shopping, sitting) at 16.8% of total responses, followed by physical activity (14.3%). The least common activity was using their computer (1.6%). Two participants reported engaging in multiple activities at the same time (0.5%). Participants indicated the app was very easy to use (mean=1.5), and that they liked using the app (mean=3.9). On average, adolescents completed the survey in 0:08:06. However, from the time the survey was sent to the time they began the survey, it took the adolescents nearly 3 hours to begin.

CONCLUSIONS: To be considered ESM, participants must answer surveys immediately after they are sent. Although the mobile app appears to be appealing and easy to use, adolescents did not always answer the surveys in a manner that qualifies as ESM. Mostly, this was due to participants' lack of reliable access to their own mobile device. ESM may be an improvement over self-report recall surveys, but future investigators should note the limitations of using ESM with adolescents. Fitness, Adiposity, Sports Participation, and Arterial Stiffness in Youth With Chronic Diseases or Physical Disabilities.

Tim Takken¹, Kristel Lankhorst², Frank Backx¹, Anne Visser-Meily¹, Eero A. Haapala³. ¹UMC Utrecht, Utrecht, Netherlands. ²HU University of Applied Sciences, Utrecht, Utrecht, Netherlands. ³University of Jyväskylä, Jyväskylä, Finland. (Sponsor: Jos J de Koning, FACSM, FACSM)
Email: t.takken@umcutrecht.nl
(No relationships reported)

PURPOSE: To investigate the associations of cardiorespiratory fitness, body adiposity, and sports participation, with arterial stiffness in 140 children and adolescents with chronic diseases or physical disabilities.

METHODS: Cardiorespiratory fitness was assessed using maximal exercise test with respiratory gas analyses either using shuttle run, shuttle ride, or cycle ergometer test. Cardiorespiratory fitness was defined as peak oxygen uptake (VO_{2peak}) by body weight or fat free mass (FFM). Body adiposity was assessed using waist circumference, body mass index standard-deviation score (BMI-SDS), and body fat percentage. Sports participation was assessed by a questionnaire. Aortic pulse wave velocity (PWV) (PWVao), as a measure of arterial stiffness, and augmentation index (AIX%), as a measure of peripheral arterial tone, were assessed by a non-invasive oscillometric tonometry device.

RESULTS: VO_{2peak} / body weight (standardized regression coefficient $\beta=-0.222$, 95% CI=-0.386 to -0.059, $P=0.002$) and VO_{2peak} / FFM ($\beta=-0.173$, 95% CI=-0.329 to -0.017, $P=0.030$) were inversely and waist circumference directly ($\beta=0.245$, 95% confidence interval (CI)=0.093 to 0.414, $P=0.002$) associated with PWVao. However, the associations of the measures of cardiorespiratory fitness with PWVao were attenuated after further adjustment for waist circumference. A higher waist circumference ($\beta=-0.215$, 95% CI=-0.381 to -0.049, $P=0.012$) and a higher BMI-SDS ($\beta=0.218$, 95% CI=-0.382 to -0.054, $P=0.010$) were related to lower AIX%.

CONCLUSIONS: Poor cardiorespiratory fitness and higher waist circumference were associated with increased arterial stiffness in children and adolescents with chronic diseases and physical disabilities. The association between cardiorespiratory fitness and arterial stiffness was partly explained by waist circumference.

The Effects Of Creatine And Creatinine On Rates Of Apoptosis In Doxorubicin-treated Myoblasts

Eric C. Bredahl, Sarah A. Kottensette, Nathaniel R. Marshall, Meghan K. Wagner, Kristen Drescher, Joan M. Eckerson. *Creighton University, Omaha, NE.* (Sponsor: Joan Eckerson, FACSM)
Email: ericbredahl@creighton.edu
(No relationships reported)

Doxorubicin (DOX) is a powerful chemotherapy agent that is associated with a number of deleterious side effects, including skeletal muscle dysfunction and skeletal muscle wasting. Although the exact mechanisms behind the observed myotoxicity have yet to be fully understood, the direct effect of DOX can generally be attributed to the generation of reactive oxygen species (ROS) and interference with DNA replication. Conversely, creatine (Cr) supplementation has been shown to have a therapeutic role in several disease states characterized by muscle atrophy, which is a hallmark of DOX treatment. Yet, there has been no investigation into the effects of Cr or creatinine (CrN) on DOX-induced apoptosis. **PURPOSE:** To investigate the effects of Cr and CrN treatment on DOX-induced apoptosis. **METHODS:** Rat skeletal muscle cells (RKSMC) were cultured in skeletal muscle growth medium until they reached 90-95% confluency. Cells were then collected and seeded on to a 96-well plate at a density of 10,000 cells/ml containing fresh skeletal muscle growth media and allowed to recover for 24 hours. Cells were then exposed to fresh growth media containing either 1.5 μ M of DOX, 10 mM of Cr, 10 mM CrN, 1.5 μ M DOX + 10 mM Cr, or 1.5 μ M DOX + 10 mM CrN for an additional 24 hours. Rates of apoptosis were then assessed using an Annexin V apoptosis detection kit (BD Pharmagen) and high contrast staining. **RESULTS:** In the cells treated with DOX, 31 \pm 5.9% of imaged cells were undergoing apoptosis, which was significantly higher than the Cr (11.9 \pm 3.8%) and the CrN (10.1 \pm 4.9%) treated group ($P=0.04$ and $P=0.03$, respectively). No significant difference in rates of apoptosis was found between Cr+DOX, CrN+DOX, or the DOX treated groups. **CONCLUSION:** Initial evidence from this investigation does not support the use of Cr or CrN to protect against DOX-induced apoptosis.

(No relationships reported)

Cancer-cachexia (CC), loss of muscle mass in cancer, is directly responsible for 20-40% of cancer-related deaths depending on type of cancer. Currently no efficacious therapies exist to reverse CC leading to the conclusion that efforts need to be focused on prevention of CC. Unfortunately, few studies have been performed to fully examine the progression of CC across the timecourse of development. **PURPOSE:** To examine phenotypic alterations in skeletal muscle across the timecourse development of CC in a murine tumor implantation model. **METHODS:** 1×10^6 Lewis Lung Carcinoma cells (LLC) or Phosphate Buffered Saline (PBS, control) were injected into the hind-flank of C57Bl6/J mice at 8 wks age, and tumor allowed to develop for 1, 2, 3 or 4 wks. Muscle fiber size was assessed by cross sectional area (CSA) of individual myofibers following H&E staining and muscle oxidative phenotype by succinate dehydrogenase (SDH) staining in sections of tibialis anterior muscle. Stress kinase signaling through p38 MAPK relative phosphorylation was assessed by immunoblot. A One-Way ANOVA was utilized to detect statistical significance with a Student-Newman-Keuls post hoc analysis to delineate differences between groups, significance was set at $P=0.05$. **RESULTS:** Mean myofiber CSA was significantly reduced by 3 wk following tumor implantation compared to PBS control ($795 \pm 22 \mu m^2$ in 3 wk vs. $957 \pm 70 \mu m^2$ in PBS) and further reduced 4 wks post tumor implantation ($556 \pm 43 \mu m^2$). Percent of SDH positive (oxidative) myofibers was lower at 4 wks post implantation compared to all other groups ($44 \pm 0.04\%$ in 4 wk compared to $68 \pm 0.05\%$ in PBS). Relative p38

MAPK phosphorylation was significantly greater in 4 wk post implantation compared to PBS, 1 and 2 wk (~3.4-fold greater than PBS in 4 wk), with no other significant differences among groups. **CONCLUSION:** Small changes in myofiber CSA can be seen as soon as 3 wk following tumor implantation in the LLC model. Reductions in portion of oxidative myofibers and increases in p38 MAPK signaling are not seen until 4 wks following tumor implantation. p38 MAPK isoforms α and β have been implicated in promoting atrophic signals through Atrogin/MURF and autophagy genes, and may in part explain the greater drop in myofiber CSA seen 4 wks following tumor implantation.

Effects Of Creatine Supplementation On Doxorubicin-induced Myotoxicity

Zoltan A. Torok, Raquel B. Busekrus, David S. Hydock,
University of Northern Colorado, Greeley, CO.

(No relationships reported)

Doxorubicin (DOX) is an effective chemotherapy treatment associated with several deleterious side effects, including skeletal muscle dysfunction. Previous research from our lab has shown that ex vivo creatine (Cr) pretreatment, prior to DOX incubation, attenuated DOX-induced fatigue in the EDL, but not the SOL. The effects of in vivo supplementation on DOX myotoxicity, however, are currently unknown. **PURPOSE:** To investigate the effects of in vivo Cr supplementation on DOX myotoxicity. **METHODS:** Male Sprague-Dawley rats were randomly assigned to the control (CON), doxorubicin (DOX), or creatine + doxorubicin (CR+DOX) group. CR+DOX received rodent chow supplemented with 3% creatine monohydrate and the CON and DOX received standard rodent chow. After two weeks of feeding, CR+DOX and DOX groups received a bolus (15 mg/kg) intraperitoneal (i.p.) DOX injection and CON received an i.p. saline injection as a placebo. Dietary interventions then continued for 5 more days. Forelimb grip strength was then measured as an indicator of in vivo muscle function and muscle fatigue was analyzed ex vivo using a 100 second fatigue protocol. **RESULTS:** When compared to CON, a significantly lower grip strength was observed in DOX (-23%, $p < 0.05$), and creatine monohydrate feeding attenuated this decrement in grip strength (-15% CR+DOX vs. CON, $p > 0.05$). In isolated muscle experiments to explore fatigue, solei (primarily type I muscle) from CON produced significantly less force than baseline at 60 s ($p < 0.05$) and solei from DOX produced significantly less force than baseline at 30 s ($p < 0.05$); however, CR+DOX produced significantly less force than baseline at 60 s ($p < 0.05$) suggesting that Cr feeding attenuated DOX-induced fatigue in type I muscle. In the primarily type II EDL, a significant decline in force production from baseline was observed at 50 s in CON and CR+DOX ($p < 0.05$) and at 20 s in DOX ($p < 0.05$) suggesting that Cr attenuated DOX-induced fatigue in type II muscle. **CONCLUSIONS:** A diet supplemented with Cr attenuated the decrease in grip strength and increase in fatigue that accompanies DOX treatment. These findings suggest that Cr supplementation may have use in managing DOX myotoxicity in cancer patients.

The Effect Of Resistance Training During Chemotherapy On Grip Strength In Rats.

Mackenzie D. Twaddell, Alison Tigner, Meghan K. Wagner, Eric Bredahl, Joan Eckerson, FACSM. *Creighton University, Omaha, NE.* (Sponsor: Joan Eckerson, FACSM)

(No relationships reported)

Doxorubicin (DOX) is a powerful chemotherapy agent associated with a number of harmful side effects, including cardiovascular and skeletal muscle dysfunction. Although it has been shown that aerobic and anaerobic exercise can minimize the degree of DOX-induced muscle dysfunction, few studies have examined the effect of resistance training (RT) during chemotherapy treatment on DOX-induced muscle dysfunction. **PURPOSE:** To examine the effect of RT exercise during DOX treatment on grip strength in rats. **METHODS:** Male Sprague-Dawley rats were randomly assigned to a RT (n=10) or sedentary (SED) group (n=10) for 10 wk. Animals in the RT group were housed in specialized cages where the food and water height was progressively elevated so that they achieved an erect bipedal stance to access their food and water. After the initial 10 wk training period, animals were further sub-divided into a RT+DOX (n=5), RT+saline (SAL) (n=5), SED+DOX (n=5), and SED+SAL (n=5). Rats in the RT groups continued to train for an additional 5 wk and, during this same time period, animals receiving DOX were given a weekly intraperitoneal injection (3 mg/kg) for 4 wk. Grip strength was measured every 5 wk during the 15 wk study using a rat grip strength meter. **Results:** At 5 wk, grip strength in the RT (16.3±1.5) group was significantly higher than the SED (18.3±1.05) group ($P=0.018$), however, there were no differences at 10 wk. Following the 5 wk treatment period with DOX or SAL, animals in the SED+SAL (14.6±0.9), RT+SAL (22.2±1.3), and RT+DOX (19.8±0.9) groups demonstrated significantly higher grip strength than those in the SED+DOX (16.8±1.0) group ($P < 0.0001$). **CONCLUSION:** These findings suggest that RT regimen during chemotherapy treatment may be effective for minimizing DOX-induced muscle dysfunction.

(No relationships reported)

PURPOSE: Resveratrol, a polyphenol found in grapes and red wine, that has been previously reported to improve muscle function in a mouse model of Duchenne muscular dystrophy, mdx mice. In 5-week old mdx mice after 8 weeks of treatment, significant improvements in rotarod performance and in situ peak tension of the triceps were observed. In addition, the total immune cell inflammation was significantly reduced, while significantly increasing IL-6 gene expression after 8 weeks of treatment. The aim of this study is to evaluate muscle and cardiac function of Resveratrol after 12 weeks of treatment using a comprehensive phenotyping platform. **METHODS:** This study was performed on two groups (n=11-12); group 1: Normal diet and group 2: diet with Resveratrol) of mdx mice in a blinded manner. Mice were randomized based on body weight and evaluated using a series of functional (In vitro force contractions, Echocardiography), behavioral (Grip strength, open field digiscan and Rota-rod), and histological evaluations. To unmask the mild phenotype of the mdx mice we subjected all mice to treadmill running (12 m/min; 30 min) bi-weekly except during data collection timepoints.

RESULTS: Resveratrol treatment showed no changes in body weight, forelimb and hindlimb grip strength measurements, or latency to fall in comparison to the control group after 12 weeks of treatment. There was, however, a significant decrease in the vertical activity on the open field digiscan behavioral measurement. In vitro force measurements of the EDL showed no significant change in the maximal force or specific force after treatment in comparison to the control mdx mice. Further, evaluation of cardiac function (% ejection fraction or fraction shortening) using echocardiography showed no significant changes. Histological analysis showed no change in the number of degenerating, regenerating, of inflammatory cells after 12 weeks of treatment.

CONCLUSIONS: This study has showed that Resveratrol did not alter the disease phenotype of the mdx mice. The inconsistency between studies may have been brought about by various factors such as the testing facility, the chows, experimenters performing the experiments to name a few. Therefore, it is essential to have independent laboratories validate the pre-clinical data prior to proceeding onto human clinical trial.

(No relationships reported)

PURPOSE: Preclinical efficacy evaluation in mouse models of human diseases is an important component of drug development. It has been reported that phase II clinical trial success rates have fallen in recent years, with a lack of efficacy being the most frequent reason for failure. Since most of the selected candidate therapeutics have gone through preclinical efficacy testing, this failure could be due to 1) the poor predictive power of disease models, 2) questionable targets, 3) lack of rigor in preclinical trial design, 4) poor control for potential bias, or 5) variable reporting standards. The quality and reproducibility of preclinical trials depend on the thoroughness of the preclinical study, including the design, execution, analysis, and reporting of the preclinical data. Here we have developed a comprehensive phenotyping system to ensure success rate of preclinical candidate evaluations for DMD.

METHODS: We subjected mdx mice for following assessments at early (8 weeks) and late (12 months) stages of the disease to represent ambulatory and non-ambulatory stages of the human disease. We assessed **Non-Invasive Repeated measures** (Open field activity measurement, Grip strength measurement (GSM), Bodyweight, Inflammation assessed by cathepsin activity using optical imaging, and Echocardiography) and **Terminal Endpoint measures** (Muscle function test (in vitro force contractions), Histological evaluations, Fibrosis measurements, Serum enzymes analysis).

RESULTS: Sample size/power estimates showed that EDL muscle specific force, Grip strength and % SF by echocardiography require 5, 11 and 8 mice per group at early stages of the disease and 2 mice/group for all 3 parameters at 12 months' age. Fibrosis in the heart is less apparent at early stages and require more mice (136/group) in comparison to old age (2mice/group) Cardiac assessment showed that both

ejection fraction (EF) and fractional shortening (FS) significantly decreased by 11 months of age in the mdx mice. Evaluation of inflammation in live animals showed that inflammation is more at 2 months than at 12 months. **CONCLUSIONS:** Our data demonstrates that the quality and reproducibility of preclinical trials depend on not only on the parameter to be analyzed but also on the stage of the disease and sample size required to meaningfully interpret the data.

Exercise-Induced Leukocyte Infiltration in Skeletal Muscle under Chemotherapy
 Chia-Hua Kuo, FACSM. *University of Taipei, Taipei, Taiwan.*
(No relationships reported)

BACKGROUND: Weight training can cause muscle inflammation. However, inflammation mechanism is essential for increasing or maintaining muscle mass after challenge. **METHODS:** We examined leukocyte infiltration in rat muscle challenged by downhill running after adriamycin administration, which is used to systemically inhibit cell regeneration (2.5 mg/kg per body weight). **RESULTS:** Leukocyte infiltration in exercised muscle was completely eliminated in adriamycin-treated rats in exercised muscle. A significant proton leak was observed under adriamycin treatment. Results from long-term adriamycin treatment show a significant development of sarcopenia. **CONCLUSION:** Blocking cell proliferation eliminates muscle inflammation induced by exercise, which may account for development of sarcopenia and eventual death after prolonged chemotherapy.

The Effects of Impaired Arm Function on Quality of Life in Breast Cancer Survivors
 Sarah A. Sayyari¹, Bolette S. Rafn¹, Stanley H. Hung¹, Alison M. Hoens¹, Margaret L. McNeely², Chiara A. Singh³, Winkle Kwan⁴, Carol Dingee¹, Elaine C. McKeivitt¹, Urve Kuusk¹, Kristin L. Campbell¹. ¹*University of British Columbia, Vancouver, BC, Canada.* ²*University of Alberta, Edmonton, AB, Canada.* ³*Fraser Health Authority, Surrey, BC, Canada.* ⁴*BC Cancer Agency, Fraser Valley, BC, Canada.*
(No relationships reported)

PURPOSE: Treatment for breast cancer is associated with long-term impaired arm function typically characterized by pain, muscular weakness, poor range of motion or lymphedema, which can negatively impact quality of life (QoL). An appropriate definition for impaired arm function specific to women with breast cancer is needed to guide treatment decisions and evaluate efficacy of interventions. The purpose of this study is: 1) to explore the relationship between impaired arm function and QoL; and 2) to propose a definition for impaired arm function that may be utilized to identify women who could benefit from a targeted exercise intervention. **METHODS:** Women with breast cancer were assessed for self-reported arm function and QoL at pre-surgery and 12 months post-surgery. Arm function was measured by the QuickDASH (Score: 0-100) and QoL was measured by the Functional Assessment of Cancer Therapy Breast (FACT-B+4). The minimally clinically important difference (MCID) of 14 for QuickDASH was used as a cut-off point to categorize participants as having impaired arm function. Pearson's correlations were used to examine the association between arm function and QoL. Further, independent t-tests tested the difference in QoL between participants with and without impaired arm function. **RESULTS:** Thirty-seven women between ages 30-75 were enrolled. QuickDASH at 12-months post-surgery strongly correlated with the physical well-being subscale of the FACT-B+4 ($r=-0.58, p<0.01$). Moderate correlations were found between QuickDASH and the arm function subscale of the FACT-B+4 ($r=-0.49, p<0.01$) and the functional well-being subscale of the FACT-B+4 ($r=-0.33, p=0.05$). Applying the MCID of 14 points on QuickDASH displayed a difference in QoL between participants with and without impaired arm function in the same physical well-being ($p<0.01$) and arm function ($p<0.01$) subscales of the FACT-B+4. **CONCLUSIONS:** QoL and arm function strongly correlate at 12-months following surgery for breast cancer. Applying the MCID for QuickDASH is effective in identifying participants whose impaired arm function is associated with decreased QoL. Utilizing this cut-off point may help identify women whose arm function has not recovered after treatment for breast cancer and who could benefit from a targeted exercise intervention.

A-23 Exercise is Medicine®/Thematic Poster - EIM On Campus

Wednesday, May 31, 2017, 9:30 AM - 11:30 AM
 Room: 101

University Physical Activity Classes: Impact on Students' Body Weight and 1.5-Mile Run Performance
 Wenhao Liu, FACSM, Ethan E. Hull, Istvan Kovacs. *Slippery Rock University, Slippery Rock, PA.*
 Email: wenhao.liu@sru.edu
(No relationships reported)

PURPOSE: Weight gain among university students is observed widely, which may result in decline in cardiorespiratory fitness. On the other hand, regular physical activity (PA) participation is considered an effective means to maintain and improve body weight and cardiorespiratory fitness. This study investigated impact of PA classes on university students' body weight and 1.5-mile run performance. **METHODS:** Body weight and 1.5-mile run were assessed at the beginning (pretest) and end (posttest) of a semester for 126 students (mean age: 20.71±.99; 72 males and 54 females) who were enrolled in PA classes of a university in USA. Paired-samples t tests were used to examine differences in weight and 1.5-mile run performance between the two test points. In addition, based on the pretest performance in 1.5-mile run and ACSM's Fitness Categories for Maximal Aerobic Power (2014), students were categorized into three aerobic power groups by sex. Those with 1.5-mile run at top 20 percentiles were in Superior/Excellent Group (SEG), 40 to 79 percentiles in Good/Fair Group (GFG), and 1 to 39 percentiles in Poor/Very Poor Group (PVPG). Binomial tests were used to examine whether a significantly larger proportion of students in each group improved 1.5-mile run at the posttest. **RESULTS:** Performance in 1.5-mile run was improved significantly ($p < .01$) for males (11:47±2:07 vs. 11:29±1:47) and females (14:15±2:28 vs. 13:54±1:55) at the posttest. As for body weight, it remained unchanged ($p > .40$) for both sexes (males: 180.83±32.11 vs. 180.61±31.10; females: 140.75±18.20 vs. 140.58±17.74). In addition, for both sexes SEG had smaller portions of students improving their 1.5-mile run (male: 7 improved vs. 11 not; female: 5 vs. 6); GFG had non-significantly larger portions of students improving their 1.5 mile run (male: 17 improved vs. 8 not; female: 15 vs. 8); finally, significantly larger portions of students in PVPG improved their 1.5-mile run performance (male: 23 improved vs. 6 not, $p < .005$; female: 16 vs. 4, $p < .05$). **CONCLUSIONS:** PA classes are effective to control body weight among university students. In addition, PA classes can significantly improve students' 1.5-mile run performance, and it is especially true for students with relatively poor 1.5-mile run performance initially, especially those at the bottom 39 percentiles.

109 Board #2 May 31 9:30 AM - 11:30 AM
Pokemon Is Medicine: On (BYU) Campus
 Neil E. Peterson, Kielee L. Wiser, Hannah M. Schmidlein, Craig Nuttall, James D. LeCheminant. *Brigham Young University, Provo, UT.*
 Email: neil-peterson@byu.edu
(No relationships reported)

The Exercise is Medicine (EIM) global health initiative includes an "On Campus" component that encourages faculty, staff, and students to work together toward improving the health and well-being of the campus and surrounding community. **PURPOSE:** To describe the implementation of EIM On Campus at a large U.S. university in the mountain west. **METHODS:** A multidisciplinary EIM On Campus leadership team was assembled, comprised of faculty members from nursing (2) and exercise science (1), as well as university students (2). A physical activity event (Pokethon 3k Fun Walk) was planned using the currently popular Pokemon theme and promoted through flyers, posters, word of mouth, social media, and homecoming parade float. The event was guided by the following principles in order to attract participation from those who might otherwise not be active: 1) free of cost, 2) open to all, 3) use of a currently popular theme (Pokemon), 4) safe 3k route with plenty of nearby parking, 5) late morning start time, 6) free "lures" activated at all "Pokestops" within the Pokemon Go game along the 3k route, and 7) numerous prizes given at random to incentivize participation rather than speed. **RESULTS:** The Pokethon 3k Fun Walk event was held during Fall 2016. A total of 140 people were involved in the event: 5 (3.6%) were EIM On Campus leadership members and event organizers, 23 (16.4%) were volunteers, and the remaining 112 (80.0%) were event participants. Of the 112 participants, 72 (64.3%) were community members and the remainder

WEDNESDAY, MAY 31, 2017

were university students. Verbal feedback included high levels of satisfaction and interest in making it into an annual event. **CONCLUSION:** The EIM On Campus leadership team successfully implemented an event to promote physical activity based on principles that would encourage participation. The next steps are to: 1) add more members to the EIM On Campus leadership team from diverse areas, 2) hold educational opportunities, and 3) implement the physical activity vital sign within the student health center.

110 Board #3 May 31 9:30 AM - 11:30 AM
**Exercise Is Medicine On Campus Week 2016:
 Increasing Campus-wide Integration And Coordination**

Zack Papalia, Melissa Bopp, FACSM, Christopher Bopp, Michele Duffey, Lori Gravish-Hurtack, Nancy I. Williams, FACSM. *Pennsylvania State University, University Park, PA.* (Sponsor: Melissa Bopp, PhD, FACSM)
 Email: zvp5003@psu.edu
 (No relationships reported)

BACKGROUND: Exercise is Medicine on Campus (EIMOC) is an international initiative promoting physical activity (PA) participation on college campuses, targeting the decline in PA seen with the transition to college. Pennsylvania State University has been promoting EIMOC since 2010 and hosting annual EIMOC Week events since 2012. **PURPOSE:** To evaluate strategies for expanding EIMOC partnerships and collaborations across campus since 2015.

METHODS: EIMOC Week has been held each year since 2012. In an attempt to expand and enhance the impact of EIMOC, the EIMOC committee has worked to improve campus-wide integration and increase participation and support from other University entities. Following the 2016 EIMOC Week event, organizations that participated or provided support through the 2015-2016 campaign were interviewed regarding future goals, EIMOC impressions, barriers to collaboration, and general observations. Results were compiled, transcribed and coded for common themes. **RESULTS:** Organizations working with EIMOC (n=15) were divided into three categories: University entities, student organizations, and community outreach. University entities (n=7) included University divisions and departments (e.g. academic unit, colleges), student health services, and campus recreation. Student organizations (n=4) were primarily undergraduate and graduate students groups, such as clubs. Community outreach entities (n=4) included private businesses and other off-campus organizations. All of the organizations strongly supported the concept of EIMOC, and were interested (93%) in supporting EIMOC in a mutually-beneficial fashion (i.e. referrals, increasing membership). Future goals included expanded collaboration (53%) and a more defined partnership (40%). Common barriers to collaboration were time (80%), logistics (80%), available resources (40%) and departmental/university rules and regulations (47%).

CONCLUSIONS: The current study offered insight on the challenges and potential success in expanding EIMOC on a large campus. As this EIMOC initiative enters its 7th year, expanding its reach and improving University-wide collaborations are key for sustained impact. Identifying common strategic goals and pooling resources across multiple entities may prove essential to the future of EIMOC.

111 Board #4 May 31 9:30 AM - 11:30 AM
**To Use The Reach, Effectiveness, Adoption,
 Implementation, Maintenance (reach) Methodology To
 Evaluate Exercise Is Medicine- On Campus Program
 (eim-oc)**

Renee Jeffreys - Heil, Patricia Bauer, Eric Shamus, Mitchel L. Cordova, FACSM. *Florida Gulf Coast University, Fort Myers, FL.* (Sponsor: Mitchel L. Cordova, FACSM)
 Email: rjeffreysheil@fgcu.edu
 (No relationships reported)

PURPOSE: To use the Reach, Effectiveness, Adoption, Implementation, Maintenance (RE-AIM) methodology to evaluate Exercise is Medicine- On Campus Program (EIM-OC).

METHODS: In 2015, the EIM-OC program at Florida Gulf Coast University (EIM@FGCU) was launched. The program consists of monthly EIM@FGCU events, a referral network, faculty/student research, and service learning projects (SLP). EIM-OC programs can be more than just referral networks, and offer multiple opportunities for students and faculty to utilize the EIM framework. This project uses the RE-AIM methodology to evaluate the effectiveness of 1 EIM-OC program.

RESULTS: *Reach:* During the 2015-2016 academic year, over 500 students attended EIM@FGCU on campus events, and 85 students were referred to the EIM@FGCU program by Student Health Services. Seven (7) different poster presentations were delivered and on average 22 ± 11 hrs of SLP were performed by exercise science (ES) students. *Effectiveness:* ES students in EIM@FGCU events report “. . . makes me want to learn more about adaptive training and working with various populations, clinical or otherwise”. Of the 85 students referred, 16 participated in baseline assessment. There were 2 undergraduate student presentations at national meetings,

5 faculty presentations, and 3 in process faculty publications. *Adoption:* Starting in the 2016-2017 academic year, there was an increase in the number of EIM@FGCU Events (2015-2016- N = 5 to 2016-2017 - N= 10) with two additional referral sites were added (Center for Academic Achievement, and Counseling and Physiological Services). *Implementation:* Program implementation was designed to be low through the utilization of student SLPs. This project is currently funded through internal campus resources (\$10,500). The cost per referral is \$584 per person; however, when students impacted by monthly events is included the cost drops to \$20 per person. *Maintenance:* The amount of faculty/student scholarship is increasing. The change in physiological markers of participants in the program will not be known until the end of this academic year.

CONCLUSIONS: Because EIM-On Campus programs have broader implications than a simple referral networks, methodologies such as RE-AIM can be utilized to determine project effectiveness.

112 Board #5 May 31 9:30 AM - 11:30 AM
**Exercise Is Medicine On Campus: Case Study Of
 Resistance Training On Chronic Low Back Pain**

Michael D. Carnevale, Gregory Hannum, Bryan Rudd, Melissa W. Roti, FACSM. *Westfield State University, Westfield, MA.*
 (No relationships reported)

Low back pain (LBP) can be described as pain or discomfort in the lumbar spine. Due to the vast interconnected system of bones, muscles, nerves, discs, tendons and ligaments, this area of the body is susceptible to injury if not trained properly. “Sarah”, a 49 year old female with chronic LBP, volunteered to participate in an 8-week Community Fitness Partners program, a Westfield State University Exercise Is Medicine On Campus initiative. Sarah was given a whole body exercise prescription based on FITT recommendations by the American College of Sports Medicine for individuals with chronic LBP. **Purpose:** To determine the effectiveness of resistance training and stretching for the treatment of LBP. Improvements in cardiovascular endurance and lean muscle mass, as well as weight management, were desired goals from the program. **Methods:** The initial meeting included goal setting, a health and fitness screening and a Par-Q to determine the individual’s vital signs and whether she has a preexisting condition that would limit her participation in this exercise program. Subject characteristics included: Height= 1.65m Body Mass=57kg, BMI=21.9, and HRrest=56bpm. Sarah completed an 8-week full body concentric and eccentric resistance training program two times a week, along with at home physical activity and stretching. **Results:** Before participating in the program Sarah was not able to perform a single bilateral body weight squat through a full range of motion, without experiencing LBP. Sarah’s pre-test results were push-ups= 6 repetitions, curl ups(crunches)= 44 repetitions, body weight squat = 0 repetitions. Post-training, Sarah can now perform multiple bilateral body weight squats through full range of motion at the ankle, knee and hip joints without experiencing LBP. Her post measurements include: push-up = 10 repetitions, curl-up= 50 repetitions, body weight squat= 5 repetitions. **Conclusion:** Within an 8-week resistance training program, a combination of static, dynamic, and PNF stretching was used to treat LBP and increase strength as well as activities of daily living. Sarah is also more comfortable and confident with exercise and in particular resistance training. She has gone from never taking part in a resistance training workout regimen to completing a 8-week resistance training program.

 (No relationships reported)

The Exercise is Medicine-on Campus (EIM-OC) initiative is growing across the nation, requiring a need to share programming and implementation outcomes to grow the limited body of empirical evidence. **PURPOSE:** The purpose of this study was to provide descriptive data on the EIM-OC programming and associated promotional efforts at a Midwestern Masters Comprehensive University. **METHODS:** During October (official EIM-OC month), promotional efforts were achieved through campus-wide flyers, website banners, and a marketing Presidential video with associated photos. To further awareness a website and social media feeds were established (Facebook, Twitter and Instagram) and articles were published in University newspapers. **RESULTS:** Grand Valley State University has 22,081 undergraduates, 3,046 graduate students, and 2,500 faculty/staff. The total student participants for the EIM events included; Walk with the President (210 total; 127 females, 75 males, 1 non identified; 12 freshmen, 30 sophomores, 87 juniors, 69 seniors, and 4 graduate), Zumba Party (109 total; 106 females, 3 males), Discovery Scuba (8 total), Wheelchair Basketball (33 total), Faculty/Staff Pedometer Challenge (460 total; 115 teams, 133,454,370 total steps), and Celebrating EIM at GVSU (116 total). Compared to

the previous month, October increased EIM-OC website page views 144% (502) and increased return visits 192%. In addition, the Student Recreation Center increased usage by 23.2% from Aug-Oct when compared to the same months in the previous year. Facebook garnered 170 "Likes," reaching 1,115 people and engaged 357, while Twitter amassed 90 followers. **CONCLUSION:** A large, diverse sample of students and faculty were reached via various marketing outlets. Such descriptive data is warranted to share evidence of successful implementation and marketing of EIM-OC programming for other institutions to emulate in the larger goal of increasing participation from Colleges/Universities across the country.

114 Board #7 May 31 9:30 AM - 11:30 AM
Physical Activity Counseling in College Students
 Christopher M. Bopp, Melissa Bopp, FACSM, Zack Papalia.
Pennsylvania State University, University Park, PA. (Sponsor: Melissa Bopp, FACSM)
 Email: cmb56@psu.edu
(No relationships reported)

Exercise is Medicine (EIM) is a global health initiative focused on encouraging health care practitioners to include physical activity when designing treatment plans for patients. EIM on Campus (EIM-OC) calls on institutions of higher education to promote physical activity (PA) as a vital sign of health. **PURPOSE:** The purpose of this investigation was to determine where college students obtain physical activity information and rates of physical activity counseling from health care practitioners. **METHODS:** Participants were college student volunteers (n=537, 56.7% male, 75% Caucasian) that completed a fitness assessment and online survey. Aerobic fitness, muscular endurance, body composition (BMI and bioelectrical impedance) and blood lipids were assessed. The survey assessed participant demographics, current PA, PA counseling at on or off-campus clinics and typical sources of information about PA. Independent t-tests and chi squares examined differences in PA counseling by fitness outcomes. **RESULTS:** 62% of our participants reported some counseling for PA. There were no differences in rates of counseling by BMI nor VO₂max, however, individuals with higher percent body fat were more likely to report counseling from their healthcare provider (t=2.76, p=0.006). There were no differences in counseling by current moderate or vigorous PA. Females were more likely to be counseled than males (X² = 4.39, p=0.04). Reports of counseling were higher at off-campus clinics than on-campus clinics (X² = 42.2, p<.001). Among our population 5% of participants obtained PA information online, 16.5% from peers, 73% from magazines, 51% from apps, 91% from TV, 40% from family, 17.7% from fitness professionals and 45% from health care practitioners. **CONCLUSIONS:** The current study provides insight into healthcare provider counseling for PA among college students. Off-campus healthcare providers were more likely to provide counseling, indicating an area of possible focus for further study. College students are typically not looking to a health care practitioner for their PA information, indicating that further information is needed on the role of healthcare providers and on-campus health clinics in counseling for PA among this young adult, typically healthy population.

115 Board #8 May 31 9:30 AM - 11:30 AM
Exercise Self-efficacy And Social Support In Community Training: An Exercise Is Medicine On Campus Initiative
 Troy R. Doming, Nicole R. Lanoie, Frank A. Hoyle, Melissa W. Roti, FACSM. *Westfield State University, Westfield, MA.*
(No relationships reported)

Exercise self-efficacy, an individuals' perceived confidence as it relates to a specific behavior, is positively related to behavior change and long term exercise adherence. Social aspects of exercise can also contribute to exercise self-efficacy. This is especially important in regards to the adult population due to the difficulty of transitioning to the maintenance phase of behavior change. **Purpose:** To determine the benefits that an EIMOC initiated Community Fitness Partners program has upon self-efficacy and social support, as monitored and structured exercise programs have been shown to improve upon these aspects. Individual personal training was completed in a group setting to expose participants to additional sources of social support. This study aims to investigate the relationship between this community setting, social support and exercise self-efficacy. **Methods:** Subjects aged 44.0 ± 13.2y volunteered to participate in an 8 week structured group community fitness partner program. Subject characteristics include: body mass (74.0 ± 20.8 kg), height (1.65 ± 0.08 m), % BF (28.0 ± 8.2), HRrest (68 ± 10 bpm), and BPrest (124 ± 19 / 78 ± 9 mmHg). All subjects underwent pre and post participation screening to determine baseline and concluding health and fitness measures. Each individuals' perceived confidence levels related to exercise were determined by the Self-efficacy For Exercise (SEE) Scale (Resnick & Jenkins, 2000). Participants completed the Social Support and Exercise Survey to identify influences from friends and family regarding exercise participation (Sallis et al., 1987). Paired sample t-tests were used to determine differences pre to post program. **Results:** Pre and post measurements of SEE scores were 58.2 ± 18.8 and 63.7 ± 17.0 (p > 0.05). Pre and post measurements of family participation support

were 20.4 ± 11.4 and 24.0 ± 13.5 (p > 0.05), respectively while the friend participation support measured at 17.6 ± 7.5 and 19.2 ± 12.1 (p > 0.05). Although the social support and self-efficacy data did not reach statistical significance, there is still a notable positive trend. **Conclusion:** Overall most individuals experienced an increase in efficacy and social support values. Therefore, a group personal training protocol may be beneficial in the improvement of exercise self-efficacy and social support.

A-24 Thematic Poster - Energy Availability and Expenditure
 Wednesday, May 31, 2017, 9:30 AM - 11:30 AM

Dietary Carbohydrate Restriction Is Necessary For High-Fat Diet Induced Alterations In Substrate Oxidation During Exercise

Gareth Fletcher¹, Elisa I. Glover², Janice L. Thompson, FACSM¹, Gareth A. Wallis¹. ¹*University of Birmingham, Birmingham, United Kingdom.* ²*GlaxoSmithKline UK, Brentford, United Kingdom.*
 Email: gareth.x.fletcher@gsk.com
(No relationships reported)

BACKGROUND: Manipulating the dietary intake of carbohydrate and fat results in differences in the circulating hormonal and metabolic milieu alongside differences in the myocellular substrate storage profile. These divergent metabolic profiles can dramatically impact substrate utilisation during exercise, with high fat low carbohydrate diets substantially elevating rates of fat oxidation compared to a low fat high carbohydrate diet. A caveat to prior studies employing a high fat diet is they are also typically restricted in carbohydrate, and so metabolic changes could be attributed to the manipulation of either macronutrient.

PURPOSE: To determine if a high fat diet both with (HF) and without restricting carbohydrate intake (N+HF) impacts substrate oxidation during exercise in endurance-trained women compared to a control diet that reflects normal intake (N).

METHODS: Over three separate periods of 5 days, in a randomised counterbalanced order, endurance trained women (means ± SD: age 34 ± 8 yrs; VO₂max 55.1 ± 2.5 ml/kg/min) were provided with 3 diets designed with the following macronutrient composition (% of energy intake [carbohydrate/fat/protein]): N (50/35/15); HF (20/65/15), and a hypercaloric (130% energy intake) N+HF (50/65/15). Post-diet intervention, in the overnight fasted state, subjects completed a 90min treadmill run at 65% VO₂max with indirect calorimetry employed over the exercise bout to determine substrate oxidation. Data was assessed for differences using a repeated-measures one-way ANOVA.

RESULTS: The relative contribution of fat oxidation to energy expenditure over the 90min exercise bout was significantly (p<0.01) greater after the HF trial (76 ± 9%) than N (57 ± 11%) or N+HF (59 ± 11%) with no significant differences between diets not limited in carbohydrate (N and NHF).

CONCLUSIONS: In contrast to when carbohydrate is restricted (HF), adding a comparable amount of fat to a control diet (NHF) did not augment fat oxidation during exercise. Thus the restriction of carbohydrate intake appears to be an obligatory step in eliciting dietary induced alterations in whole body substrate oxidation not greater fat provision. This work was funded through a BBSRCi CASE studentship with GlaxoSmithKline the industrial partner.

118 Board #2 May 31 9:30 AM - 11:30 AM
Metabolic and Behavioral Correlates of Low Energy Availability in Exercising Men
 Jay Petersen. *University of Nebraska at Lincoln, Lincoln, NE.*
 Email: jpetersen22@huskers.unl.edu
(No relationships reported)

Low energy availability (EA) has been identified as a primary driver of metabolic and endocrine aberrations characterizing the female athlete triad. Although it has been established that men engaged in sports that favor leanness and/or low body weights are also at risk of low EA, little is known about the etiology and metabolic effects of low EA in habitually active men.

PURPOSE: To assess the relationship between EA and body composition, metabolism, eating behavior traits, and health-related outcomes in young, exercising men.

METHODS: Eighteen men (23.4±4.4 y; 81.8±10.2 kg; 9.8±3.5% body fat) participated in this cross-sectional study. EA was determined as the amount of energy remaining after subtracting the energy cost of exercise, both derived from 7-day diet and exercise logs, and was normalized for fat free mass (FFM) assessed by bioimpedance. Participants completed tests for resting metabolic rate (RMR) and aerobic fitness as well as questionnaires regarding exercise and diet habits, eating behaviors, and medical history. Based on their EA, participants were divided into tertiles: low EA (LEA): 19.9-31.5 kcal/kg FFM, moderate EA (MEA): 31.9-38.3 kcal/kg FFM, or high EA (HEA): 39.8-48.6 kcal/kg FFM.

RESULTS: BMI (LEA: 25.6±2.9 kg/m², MEA: 25.9±3.7 kg/m², HEA: 24.0±2.3 kg/m²) and body fat percentage (LEA: 11.0±4.6%, MEA: 10.5±2.8%, HEA: 8.3±2.8%) were similar among EA groups. The ratio of measured/predicted RMR was similar between LEA (0.96 ± 0.05) and HEA (0.93 ± 0.06) but lower in MEA (0.89 ± 0.06; p=0.03). Resting respiratory quotient was reduced in LEA (0.81 ± 0.09) when compared to MEA (0.90 ± 0.05; p=0.03) and HEA (0.93 ± 0.12; p=0.04). Compared to HEA, participants in LEA were more likely to report past weight fluctuations (p=0.05) and dieting (p=0.01). There were no differences among EA groups for eating behavior traits such as dietary restraint (p=0.29), emotional eating (p=0.36), and drive for thinness (p=0.40).

CONCLUSION: Despite being in an apparent energy deficit and showing evidence of increased fat oxidation, exercising men with LEA did not exhibit altered body composition or RMR suppression per se. Nevertheless, LEA seems to be connected to issues related to weight control and a history of dieting. Future research is needed to quantify the metabolic and endocrine consequences of LEA in exercising men.

119 Board #3 May 31 9:30 AM - 11:30 AM
Energy Availability Amongst Elite Rugby Union Players During Pre-Season Training

Katherine Black¹, Chloe Hindle¹, Claire Gibson¹, Joanne Slater¹, Dane Baker², Phil Healey², Rebecca McLay-Cooke¹, Rachel Brown¹, Brett Smith³. ¹University of Otago, Dunedin, New Zealand. ²Chiefs Super Rugby, Hamilton, New Zealand. ³University of Waikato, Hamilton, New Zealand.
 Email: katherine.black@otago.ac.nz

(No relationships reported)

In elite rugby union the pre-season training period is used to optimise players' strength, power, endurance and body composition. Given the increased training loads during this time, players could find themselves at risk of Low Energy Availability (LEA). A state of LEA can be caused by large energy expenditure in exercise (EEE) and/or low energy intake (EI), which reduces the amount of energy available for physiological functions. Despite the majority of the literature focusing on female athletes, it is possible that male athletes are also at risk of LEA, particularly during periods of increased training load such as pre-season.

PURPOSE: The purpose of this study was to examine the energy intake, energy expenditure and energy availability of elite male rugby union players during pre-season training.

METHODS: During this observational study, three-day diet records were collected for 23 Super Rugby players using video, photographs, checklists and recalls. Energy expenditure data was also collected via heart rate monitoring, GPS tracking and Activity Logs. Skinfold thicknesses (International Society for the Advancement of Kinanthropometry protocols) were used to assess body composition. Data was analysed based on groups established by training goals determined by the teams support staff: weight gain (n=8)/weight maintenance (n=8)/weight loss (n=7). One-way ANOVA was used to identify differences between groups, with post-hoc pairwise comparison of means, adjusted using Bonferroni.

RESULTS: For all participants exercise energy expenditure was 2,240 ± 1,140 kcal (mean ± SD). The average energy intake was 3799 ± 958 kcal.day⁻¹ for all participants. The weight loss group had significantly lower mean (± SD) energy availability (6.7 ± 6.4 kcal.kgFFM⁻¹.day⁻¹) than the weight maintenance (20.3 ± 7.6 kcal.kgFFM⁻¹.day⁻¹, p=0.003) and weight gain (28.6 ± 8.0 kcal.kgFFM⁻¹.day⁻¹, p<0.001) groups.

CONCLUSION: This research shows that NZ Super rugby players can, and do suffer from short-term LEA during the intense pre-season training period. However, as this study was observational, the results are only indicative of the three-day sampling period. Therefore, the duration of LEA cannot be determined from this study nor can any health or performance implications.

Supported by the University of Otago Research Grant

120 Board #4 May 31 9:30 AM - 11:30 AM

Energy Availability and Muscle Glycogen Levels in Division I Beach Volleyball Athletes

Marguerite B. Gilchrist¹, Toni M. Torres-McGehee¹, Meaghan Minori¹, Dawn M. Emerson², Kelly Pritchett³. ¹University of South Carolina, Columbia, SC. ²Kansas University, Lawrence, KS. ³Central Washington University, Ellensburg, WA.

(No relationships reported)

Beach volleyball is considered a lean body sport, which may increase the risk for low energy availability (LEA). There is currently limited research on beach volleyball athletes, particularly in terms of energy availability (EA) and muscle glycogen levels.

Purpose: To examine EA and muscle glycogen levels in beach volleyball athletes. A secondary purpose examined macronutrient intake. **Methods:** Local NCAA Division I female beach volleyball athletes (n=18; ages 19.9 ± 1.5 yrs; weight: 63.3 ± 5.1 kg; height: 174.5 ± 5.6 cm) participated in the study. EA and energy expenditure were measured via a 7-day food and activity log. Resting metabolic rate (RMR) was measured via indirect calorimetry. Muscle glycogen levels were evaluated for the gastrocnemius (GS), rectus femoris (RF) and biceps brachii (BB) pre and post-practice using the MuscleSound ultrasound device. **Results:** When examining RMR, 55.6% beach volleyball players did not meet the RMR caloric needs compared to their associated dietary intake. LEA was present in 94.4% of the participants. For proteins, 61.1% were under recommendations and 5.6% were over the recommendations. All beach volleyball players were under the recommendations for carbohydrates (CHO), and 33.3% were over the recommendations for fats while all others met the recommendations for fats. Repeated-measures analysis of variance indicated a main effect for GS and RF muscle glycogen pre-and post-practice across 5 days; however no specific interactions were found. No significant differences were found with BB measurements. Chi-square analysis revealed no significant differences for level of muscle glycogen vs. CHO intake. **Conclusion:** Beach volleyball athletes are at risk for LEA due to both the high energy expenditure demands of their sport and low nutritional intake. Health care professionals working with beach volleyball athletes should consider monitoring nutrition and implementing nutritional education sessions in order to prevent long term LEA and its negative health consequences. The MuscleSound device can be a good tool for determining if an athlete strays from their norm over time, but more research is needed in order to use this device as a tool for determining chronically low CHO intake.

PURPOSE: To describe a novel way of estimating dietary behavior using a wrist-worn accelerometer. **METHODS:** The eating behaviors of one subject were captured via video recording while motions were concurrently recorded using a wrist-worn ActiGraph GT3X, set at 100Hz sample rate on the dominant wrist. The video recording and ActiGraph were synchronized at the start of data collection through action of a transient event visible in both data sources. Behaviors and motions, which included both eating and non-eating behaviors we captured for 30 min. A taxonomy was developed to code the video recording (e.g., fork to mouth, spoon away from mouth) and three raters identified the exact times of actions, to the nearest millisecond. Categorical assignments of each rater were used to identify "true" start and stop times of each movement; while similar, each was used separately to train a classifier. These categorical markings were then used to select data from the accelerometer. A feature set of each sample in the categorical sets, surrounding each category of action, were used to train a supervised machine learning naïve bayes classifier. The feature set consisted of mean, standard deviation, and binned spectral analysis of raw, first derivative (ddt), and angular derived measures; this totaled 110 measures across the original x,y,z and other resultant measures. Given the relatively small data set (i.e., 180,000 samples for 30 min), the training dataset was also used for testing this proof of concept. **RESULTS:** Adjusting for the prior probability of each categorical selection (i.e., ten categories of eating behaviors), the agreement for specific food actions between the video and the classifier predicted action was found to be 63%. Simplifying to consider cases of eating and non-eating only, agreement improved to 67%. Agreement was 66% when prediction results were condensed to "not eating," "drinking," and "eating." **CONCLUSION:** These findings present a plausible new method of estimating dietary behavior. Further refinement is necessary to generalize to larger and more diverse populations, though the potential of providing real-time, objective, dietary behavior analyses is a promising area for research and practice.

Exercise usually results in less weight loss than expected. It is therefore postulated that changes in energy expenditure (EE) and/or compensatory increases in energy intake (EI) occur to counteract energy deficits induced by exercise.

PURPOSE: Compare changes in all components of daily energy expenditure (24hrEE) after 24 weeks of exercise training between varying doses of exercise recommended for weight loss.

METHODS: Forty-one (28 F, 13 M) obese (35.2±3.7 kg/m²) middle aged (47.8±12.5 y), sedentary individuals from the Examination of Mechanisms of Exercise-induced Weight Compensation (E-MECHANIC) study were randomized to either a healthy living control group (HL, n=13) or a supervised, controlled aerobic exercise intervention that achieved 8 kcal/kg of body weight/week (KKW, n=14) or 20 KKW (n=14). 24hrEE (metabolic chamber), total daily energy expenditure (TDEE, by doubly labeled water), energy intake (by Intake-Balance method), and VO_{2peak} (by graded exercise test) were measured before and after the intervention.

RESULTS: Compared to the HL group, VO_{2peak} increased in the 8 KKW (p=.004) and 20 KKW (p<.0001) groups. With 20 KKW, TDEE (and 24hrEE) increased (p=.04) and weight loss (-2.5±0.9 kg, p=.04) was significant but approximately half of what was expected based on the increase in energy expenditure from exercise. Fat mass (-2.1±0.8 kg, p=.02) but not fat-free mass (-0.4±0.3 kg, p=.79) was also significantly reduced. A 151 kcal/d energy deficit was detected at week 24. The increase in TDEE is attributed to the increased physical activity (p=.03) and not to changes in EE during sleep, arousal or the thermic effect of food. Besides physical activity, the largest change in EE was a reduction in spontaneous physical activity by ~15% (p=.04). With 8 KKW, there was no significant weight or body composition change and no significant increase in TDEE. An energy deficit of 23 kcal/d was detected at week 24. None of the components of EE were changed in the 8 KKW group.

CONCLUSIONS: Structured aerobic exercise that expends up to 1800 kcal/wk increased TDEE but produces less weight loss than expected possibly due to compensatory increases in EI and behavioral adaptations that could lead to reduced spontaneous physical activity.

 (No relationships reported)

Energy intake (EI) is frequently under-reported by study participants and can be biased for reasons such as memory, incorrect estimation of portion sizes, deliberate manipulation, etc. It is important that EI is reported as accurately as possible when used for dietary assessment for research studies. **PURPOSE:** To compare self-reported EI from a Block Food Frequency Questionnaire (FFQ) to resting metabolic rate (RMR) in Collegiate Athletes, Reserve Officer's Training Corps (ROTC) Cadets and Midshipmen, and Masters Athletes. **METHODS:** This cross-sectional study included 21 Collegiate Athletes (8 females, 13 males) and 15 ROTC Cadets and Midshipmen (7 females, 8 males), 18 to 25 years of age. It also included 18 Masters Athletes (6 females, 12 males), 26 years of age and older. Indirect calorimetry was used to determine RMR. Participants completed a self-administered Block FFQ to assess dietary patterns over the previous year. A ratio ≤1.35 for EI to RMR was considered under-reporting of dietary intake on the FFQ. **RESULTS:** The mean ratio of EI to RMR for all participants was 1.24 (±0.38) and the frequency of under-reporting was 67% (n=36). Percentage of under-reporting was significant (p<0.01). Seventy-three percent of males (n=24) and 57% of females (n=12) under-reported EI. Sixty-two percent of all Collegiate Athletes, 73% of ROTC Cadets and Midshipmen, and 67% of Masters Athletes under-reported EI. Sex significantly affected reporting status (p<0.01), with males more likely to under-report than females. **CONCLUSIONS:** Significant under-reporting of energy intake was found in these athletes. Further analyses is required to determine why males in these three athlete populations were more likely to under-report than females. These represent data from an unfunded research project

 (No relationships reported)

Purpose: To explore the acute serum metabolomic responses following single bouts of aerobic and anaerobic exercise in differentially-trained subjects. **Methods:**

Subjects (N = 40) were equally distributed into one of 4 groups (n = 10) based on a combination of sex [male (M) or female (F)] and training history [endurance (E) or resistance (R) trained] (M = 24 + 4 y, 160.5 + 17.2 kg, 12.8 + 5.7 %BF; F = 22 + 2 y 135.5 + 15.8 kg, 23.3 + 4.8 %BF). On separate days, 45 min aerobic (A) or weight-training (W) exercises were performed. Serum was collected pre, 0 & 60 min post exercise (T0, T1 & T2), and analyzed via UHPLC/MS for identification of 754 biochemicals. Principle components analysis (PCA) was used to define metabolite profiles. RMANOVA's for sex, training status, exercise type, and time were run with significance set at P < .05. **Results:** Both A and W increased glycolysis (A = 3.5 + .7 fold; W = 3.9 + 1.0 fold; P<.05), with a significantly greater activation for RW, P<.05. TCA activity (AVG = 1.5 + 0.3 & 1.9 + 0.3 fold; P<.05) also increased. Downstream TCA intermediates (succinate, fumarate, & malate) were increased at T1, particularly for succinate in E (P<.05), and returned to baseline by T2. During exercise, A increased fat metabolism as evidenced by elevation of multiple FFAs and acylcarnitines (i.e., palmitate increased 2.0 + 0.4 v 1.0 + 0.1 fold in A v W) and elevated ketone bodies at T1 in RA & EA. Across exercise conditions, E showed relatively lower FFA and BCAA catabolism than R at T2 (E v R changes from baseline: stearate = 1.4 + 0.3 v 1.4 + 0.2 fold; 3-hydroxyisobutyrate = 1.8 + 0.2 v 2.2 + 0.1, P<.05) and generally faster returns towards baseline for all metabolites. Sex-dependent differences in global metabolite profiles were more pronounced in E than R groups, including elevated FFA's and muted TCA intermediate levels and BCAA catabolism in FE during both A and W. **Conclusion:** The biological response to exercise is dictated by the metabolic demand of the exercise and the physiology of the exerciser, allowing exercise type and individual variation to alter the exercise metabolome. Data support greater TCA capacity in E and greater glycolytic power in R leading to differential fuel selection during exercise, particularly with matched mode. Females displayed lower TCA activity, yet higher FFA oxidation with sex differences most apparent in the E groups.

 (No relationships reported)

Markers of oxidative stress such as F₂-isoprostanes (a marker of lipid peroxidation) are elevated in the blood of patients with chronic obstructive pulmonary disease (COPD) compared to healthy individuals. Oxidative stress may reduce quality of life and contribute to morbidity and mortality in patients with COPD but unfortunately its origin is unclear and, therefore, it cannot be treated effectively. The inspiratory muscles may contribute significantly to systemic oxidative stress in COPD because the work of breathing increases to overcome airway resistance. **PURPOSE:** To investigate whether the inspiratory muscles contribute to systemic oxidative stress during inspiratory flow resistive loaded breathing. **METHODS:** Four young healthy adults (3 males and 1 female) who were free from respiratory disease undertook inspiratory flow resistive

loaded breathing for 30 minutes. Subjects maintained breathing frequency at 15 breaths·min⁻¹, duty cycle at 0.5 and transdiaphragmatic pressure at 70% of maximum which was provided by a variable sized aperture with a length of 2 mm. Inspiratory muscle work was estimated by the diaphragm pressure-time product (PTP_{di}), which was calculated by multiplying breathing frequency by transdiaphragmatic pressure integrated over the period of inspiratory flow. Plasma samples were collected at rest (0 min), 5 and 30 minutes during, and 30 minutes after (+30 min) inspiratory flow resistive loaded breathing and analyzed for F₂-isoprostanes using isotope dilution mass spectrometry. Time comparisons were made using a one-way ANOVA with repeated measures. **RESULTS:** PTP_{di} increased (P<0.005) from 663 ± 102 (mean ± SD) at 0 min to 1931 ± 501 and 1618 ± 258 cmH₂O·s·min⁻¹ at 5 and 30 min, respectively. Plasma F₂-isoprostanes increased (P<0.05) from 154 ± 22 at 0 min to 197 ± 35, 229 ± 83 and 206 ± 58 pg·mL⁻¹ at 5, 30 and +30 min, respectively. **CONCLUSIONS:** Lipid peroxidation increased during, and remained elevated following, inspiratory flow resistive loaded breathing. Our novel data are the first to indicate that the inspiratory muscles may directly contribute to systemic oxidative stress during periods of increased inspiratory muscle work, such as those encountered in COPD. Supported by University of Southern Queensland Centre for Health Sciences Research sponsored research grant scheme.

Competitive Runners Can Adapt To Nasal Breathing With Similar Peak Running Velocity And Lower Ventilation

Steve R. McClaran, George M. Dallam, Carol P. Foust. *Colorado State University Pueblo, Pueblo, CO.*

Email: steve.mcclaran@csupueblo.edu

(No relationships reported)

PURPOSE: This study investigated the effect of breathing restricting to the nasopharynx (NB) versus the oropharynx (OB) in 10 mixed gender (5 males, 5 females) recreationally competitive runners (VO₂max = 40.10 ± 2.65 ml/kg/min). **METHODS:** Each subject performed a maximal graded exercise test (GXT) and a subsequent six minute high intensity steady state run (SSR) during random order NB and OB days. All runners had previously adapted themselves to nasal only breathing at all levels of running intensity. **RESULTS:** In the GXT trials the subjects exhibited no significant mean difference in time to exhaustion (TE) (NB = 428 ± 24 vs. OB = 421 ± 18 secs), absolute maximal oxygen consumption (VO₂max) (NB = 2.55 ± 0.25 vs. OB = 2.75 ± 0.25 L/min) or peak lactate (NB = 7.0 ± 0.76 vs. OB = 7.2 ± 0.76 mmols/dl). In the nasally restricted breathing condition they demonstrated a significantly lower mean ventilatory equivalent for oxygen (VE/VO₂) (NB = 35.20 ± 1.34 vs. OB = 41.30 ± 1.59) and carbon dioxide (VE/VCO₂) (NB = 29.4 ± 1.33 vs. OB = 32.8 ± 1.13) and peak ventilation (VE) (NB = 92.8 ± 10.8 vs. OB = 112.6 ± 16.8) with a significantly higher breathing frequency (RR) (NB = 39.2 ± 2.1 vs. OB = 49.4 ± 2.5) at VO₂max. During the SSR trials the subjects exhibited no significant difference lactate (NB = 9.05 ± 0.88 vs. OB = 7.92 ± 0.98 mmols/dl) and again demonstrated a significantly lower mean VE/VO₂ (NB = 32.43 ± 0.77 vs. OB = 36.70 ± 1.03), VE/VCO₂ (NB = 28.47 ± 0.68 vs. OB = 32.92 ± 0.92) and VE (NB = 84.4 ± 8.5 vs. OB = 102.1 ± 8.2) with a significantly higher RR (NB = 36.4 ± 1.8 vs. OB = 43.2 ± 2.3). **CONCLUSION:** This study confirms the ability of competitive recreational runners to adapt to breathing restricted to the nasopharynx during running at both a maximal effort and a subsequent high intensity steady state effort, with a lower VE and RR and without a loss in TE or VO₂max.

Does Competitive Swimming During Puberty Affect Lung Development?

Joshua M. Bovard, Joseph F. Welch, Kristin M. Houghton, Donald C. McKenzie, James E. Potts, A. William Sheel, FACSM. *University of British Columbia, Vancouver, BC, Canada.* (Sponsor: A. William Sheel, FACSM)

(No relationships reported)

Whether or not competitive swimming (CS) accentuates lung development beyond genetically endowed growth has been widely debated. **PURPOSE:** Given that peak growth velocities for the lungs occur during puberty, this longitudinal study aimed to determine if one season of CS affected lung development in pubertal females. **METHODS:** Female swimmers (SWIM; n=11, 3.3±1.7 y of CS experience, 19±8 km swimming/week) and healthy active controls (CON; n=10) underwent pulmonary function testing before (PRE) and after (POST) one season of CS (7.3±0.5 months). The groups were matched for age (SWIM 12.4±0.8 vs CON 13.2±1.3; p=0.10), height (PRE 161±8 vs 158±7, POST 163±7 vs 161±7 cm; p=0.38) and weight (PRE 52±11 vs 46±5, POST 56±10 vs 49±6 kg; p=0.10). Sexual maturity rating was self-reported to be pubertal (Tanner stages 2-4) for all of the SWIM and 90% of CON. Changes in lung volumes, spirometry, diffusion capacity (DLCO), and maximal inspiratory (MIP) and expiratory (MEP) mouth pressures were compared using 2-way mixed model ANOVA. **RESULTS:** Despite having a similar body size as controls, swimmers had a larger

total lung capacity (TLC; PRE 4.73±0.73 vs 3.93±0.46, POST 5.08±0.68 vs 4.19±0.64 l; p<0.01). Forced vital capacity (PRE 3.92±0.71 vs 3.13±0.50, POST 4.15±0.61 vs 3.28±0.54 l; p<0.01) and peak expiratory flow (PRE 6.48±0.92 vs 5.70±0.86, POST 6.97±0.84 vs 6.00±0.77 l/s; p=0.03) were higher in SWIM. Although DLCO was greater in SWIM (PRE 23.4±2.6 vs 20.7±1.9, POST 24.1±1.9 vs 21.0±3.2 ml/min/mmHg; p=0.01), there was no difference when expressed relative to alveolar volume (PRE 5.1±0.6 vs 5.4±0.4, POST 4.9±0.6 vs 5.2±0.4 ml/min/mmHg/l; p=0.20). Both MIP (PRE 87±26 vs 71±24, POST 103±22 vs 79±26 cm H₂O, p=0.06) and MEP (PRE 112±17 vs 98±18, POST 114±13 vs 84±19 cm H₂O; p<0.001) were greater in SWIM. Changes from PRE to POST were similar between groups (interactions p>0.05). No association between CS training volume (km/week) and change in lung size (delta TLC) (r=-0.02, p=0.95) was found. **CONCLUSION:** This data shows that pubertal female swimmers already had larger lung capacities, higher flows, and greater indices of respiratory muscle strength compared to matched controls. One season of CS did not further accentuate this enhanced function, suggesting that CS during puberty did not affect lung development. Support: NSERC

Operational Lung Volumes While Seated, Supine, and During Exercise in Obese and Nonobese Children

Dharini M. Bhammar¹, Jonathon L. Stickford², Vipa Bernhardt³, Rubria Marines-Price⁴, J. Todd Bassett⁴, Maria C. Roman⁴, Tony G. Babb, FACSM⁴. ¹Valdosta State University, Valdosta, GA. ²Appalachian State University, Boone, NC. ³Texas A&M University-Commerce, Commerce, TX. ⁴Institute for Exercise and Environmental Medicine, Dallas, TX.

Email: dmbhammar@valdosta.edu

(No relationships reported)

PURPOSE: The effects of adult obesity on lung function at rest, such as reductions in functional residual capacity and expiratory reserve volume, are well recognized. However, the effects of obesity on operational lung volumes at rest, while lying supine, and during exercise in obese children are unknown but could create meaningful respiratory limitations. **METHODS:** 11 nonobese (Ht: 143.3 ± 5.2 cm; Wt: 35.8 ± 3.8 kg; BMI percentile: 50 ± 21; Body fat: 27 ± 6%) and 12 obese (Ht: 149.7 ± 6.7 cm; Wt: 65.8 ± 14.4 kg; BMI percentile: 97.5 ± 1.4; Body fat: 46 ± 3%) children underwent dual energy x-ray absorptiometry, pulmonary function testing, and measurement of operational lung volumes when seated upright, while supine, during constant load cycling at 40W, and during maximal exercise testing. **RESULTS:** Ratio of forced expiratory volume in the first second and forced vital capacity (FEV₁/FVC) was lower in obese compared with nonobese children (83.6 ± 4.1 vs. 88.6 ± 4.1%; P = 0.004). Functional residual capacity (FRC) was lower in obese compared with nonobese children when seated upright (38.5 ± 4.8 vs. 49.3 ± 4.0% TLC; P < 0.001) and while supine (35.0 ± 6.4 vs. 45.4 ± 6.5% TLC; P < 0.001). Three children (2 obese) experienced expiratory flow limitation (EFL) while supine. Both end expiratory lung volume (EELV) and end inspiratory lung volumes (EILV) were lower during exercise at 40W (P < 0.01) and EILV was lower at peak exercise (P = 0.048) in obese compared with nonobese children. EELV did not change from rest to exercise at 40W or peak exercise in nonobese children. In obese children, EELV was higher at peak exercise (44.4 ± 4.7% TLC) compared with rest and exercise at 40W (40.5 ± 4.1 and 38.7 ± 3.1% TLC, respectively; P < 0.05). None of the nonobese children experienced EFL during exercise. In obese children, one experienced EFL during exercise at 40W (44% tidal volume; V_T) and seven experienced EFL at peak exercise (37 ± 22% V_T). Higher levels of fat mass were associated with lower levels of FRC when seated (r = -0.88; P < 0.001) and while supine (r = -0.65; P = 0.003), and EELV during exercise at 40W (r = -0.68; P = 0.001). **CONCLUSIONS:** Obese children demonstrate low lung volume breathing when seated, while supine, and during exercise, which may contribute to an obstructive breathing pattern at rest as well as EFL and dynamic hyperinflation during peak exercise.

130 May 31 10:30 AM - 10:45 AM

The Effect Of Thoracic Gas Compression On Forced Expiratory Flows Is Increased At High-altitude

Troy J. Cross¹, Courtney Wheatley², Glenn M. Stewart¹, Kirsten Coffman¹, Alex Carlson¹, Jan Stepanek², Norman M. Morris³, Bruce D. Johnson¹. ¹Mayo Clinic, Rochester, MN. ²Mayo Clinic, Scottsdale, AZ. ³Griffith University, Southport, Australia.

Email: cross.troy@mayo.edu

(No relationships reported)

It is well-known that the maximal expiratory flow-volume (MEFV) curve may be underestimated due to the confounding effects of thoracic gas compression (TGC) at sea-level. This artefact, if not addressed, reduces the sensitivity/specificity of pulmonary function testing to detect expiratory flow-limitation and changes in bronchomotor tone. The magnitude of TGC artefact increases the more compressible is the gas inhaled. With this in mind, we reasoned that magnitude of TGC artefact would be greater at high-altitude (> 2,400 m) where the density of air is lower, and its

compressibility increased. **PURPOSE:** To determine whether high-altitude engenders a greater magnitude of TGC artefact on the MEFV curve. **METHODS:** Twenty-four adults (10 women; 44 ± 15 yrs) with normal baseline pulmonary function (>90% pred.) completed an 11-day sojourn at Mt. Kilimanjaro. Participants were assessed at Moshi (Day -1, 843 m) and at Barafu Camp (Days 8-9, 4,837 m). Typical MEFV curves with no TGC correction were obtained in accordance with ATS/ERS guidelines. MEFV curves were then corrected for TGC by performing 7-9 vital capacity manoeuvres at varying degrees of expiratory effort. Both MEFV curves were further corrected to account for differences in gas-density between altitudes. **RESULTS:** At both altitudes, peak expiratory flow rate (PEFR), and forced expiratory flows at 75, 50 and 25% of vital capacity (FEF_{75%}, FEF_{50%}, and FEF_{25%}, respectively) were higher after correction for TGC ($P < 0.05$). The magnitude of change in the MEFV envelope incurred by TGC-correction was relatively greater at Barafu Camp compared with data at Moshi for FEF_{50%} ($\Delta 16 \pm 19\%$ v $\Delta 3 \pm 5\%$, $P < 0.05$) and FEF_{25%} ($\Delta 34 \pm 40\%$ v $\Delta 15 \pm 16\%$, $P < 0.05$). Once corrected for TGC and gas-density, we observed that PEFR, FEF_{75%}, FEF_{50%}, and FEF_{25%} were lower at Barafu Camp compared with data at Moshi ($P < 0.05$). **CONCLUSIONS:** Our data further emphasize what is already well-known at sea-level: that is, the MEFV envelope is significantly underestimated if no attempt is made to correct for TGC. More importantly, however, we show that the underestimation of the MEFV curve due to TGC is worsened upon ascending to higher altitudes, particularly for those expiratory flows occurring over the effort-independent portion of the MEFV envelope.

Effect of Acute Expiratory Loading on Abdominal Muscle Function and Exercise Tolerance in Healthy Humans

Bryan J. Taylor¹, Isabelle O'Keefe², Jennifer L. Hammond².
¹University of Leeds, Leeds, United Kingdom. ²University of Exeter, Exeter, United Kingdom. (Sponsor: Lee Romer, FACSM)
Email: b.j.taylor@leeds.ac.uk

(No relationships reported)

Heavy-intensity whole body exercise sustained to the limit of tolerance elicits fatigue of the diaphragm and expiratory abdominal muscles. Such respiratory muscle fatigue is likely involved in exercise limitation in healthy humans. Acute submaximal inspiratory muscle loading causes a transient increase in diaphragm excitability and inspiratory muscle strength, and may enhance subsequent exercise performance. Whether loading of the expiratory muscles has a similar ergogenic effect is unknown. **PURPOSE:** To determine the effect of acute expiratory muscle loading on expiratory abdominal muscle function and exercise tolerance in healthy humans. **METHODS:** Using a single-blind, placebo-controlled design, nine male subjects [$\dot{V}O_{2peak} = 50.1 \pm 3.8$ (SD) ml·kg⁻¹·min⁻¹] cycled at ≥90% of $\dot{V}O_{2peak}$ to the limit of tolerance after 1) 2 × 30 expiratory efforts against a pressure-threshold load of 40% maximal expiratory pressure (MEP) (EML-EX), and 2) 2 × 30 expiratory efforts against a pressure-threshold load of 10% MEP (SHAM-EX). Abdominal muscle function was assessed before and after expiratory muscle loading and 5 min after exercise by measuring 1) the gastric pressure response to maximal voluntary expiratory efforts ($P_{ga_{max}}$), and 2) gastric twitch pressure ($P_{ga_{tw}}$) in response to magnetic stimulation of the thoracic nerve roots. **RESULTS:** From before to after expiratory muscle loading in EML-EX, there was no change in non-potentiated $P_{ga_{tw}}$ (30.3 ± 10.6 vs. 32.9 ± 10.3 cmH₂O, $P = 0.232$), potentiating $P_{ga_{tw}}$ (36.3 ± 8.0 vs. 38.9 ± 8.1 cmH₂O, $P = 0.079$), or $P_{ga_{max}}$ (190 ± 44 vs. 202 ± 45 cmH₂O, $P = 0.611$). Similarly, there was no change in expiratory abdominal muscle function from pre- to post-expiratory muscle loading in SHAM-EX. Exercise time to the limit of tolerance was not different in EML-EX vs. SHAM-EX (480 ± 132 vs. 489 ± 120 s, $P = 0.792$). The severity of exercise-induced abdominal muscle fatigue was not different in EML-EX vs. SHAM-EX (potentiating $P_{ga_{tw}} - 25 \pm 12$ vs. $-22 \pm 9\%$, $P = 0.376$). Perceptual ratings of dyspnoea and leg discomfort (Borg CR10) were not different at min 1, min 3, and at end-exercise during EML-EX and during SHAM-EX ($P > 0.05$). **CONCLUSION:** Acute expiratory muscle loading does not improve expiratory abdominal muscle function or subsequent exercise tolerance in healthy humans. **Supported by The Physiological Society.**

Diagnosing Exercise Induced Bronchoconstriction: A Comparison Of Eucapnic Voluntary Hyperpnoea And Exercise In Low Humidity

Anna R. Jackson¹, James H. Hull², James G. Hopker¹, John W. Dickinson¹. ¹University of Kent, Chatham, United Kingdom. ²Royal Brompton Hospital, London, United Kingdom.

(No relationships reported)

Eucapnic Voluntary Hyperpnoea (EVH) is a sensitive indirect airway challenge to assist in the diagnosis of Exercise Induced Bronchoconstriction (EIB). However, it has been previously reported that a positive EVH challenge may not necessarily predictive a positive exercise challenge (EX). EX have previously shown varying sensitivity due to differences in control over the inspired air water content, with studies being conducted in ambient lab conditions or using medical grade dry air.

PURPOSE: To compare the EVH challenge with an EX in a controlled dry air environment, to see if a standardised EX can be used in the diagnosis or EIB. **METHODS:** Thirty-one healthy participants (10 female; 21 males, age 36 ± 10 yrs, exercising 7.7 ± 3.0 hrs per week) gave informed consent. Eight had a history of asthma but were not taking preventative medication. Participants completed an EVH and an EX on a cycle ergometer in a randomised order. The EVH required participants to breathe a gas mixture (5% CO₂, 21% O₂ and 74% N₂, <2%RH) at a rate equivalent to 85% predicted MVV. The EX was conducted in an environmental chamber (16°C, 25%RH). Following a 4-min set warm up participants completed 6-mins of cycling at a work rate associated with 85% HRmax. Tests were deemed positive if there was a fall in FEV₁ of ≥ 10% following the challenge. Results were analysed using paired *t*-tests and Pearson's correlation and are presented as mean ± SD. **RESULTS:** Seven participants were positive to EVH. Of these, only two had a positive response to EX. No differences in baseline FEV₁ between EVH and EX were found (EVH: 4.06 ± 0.79, EX: 4.06 ± 0.77L, $p = 0.746$). There was a strong correlation between the % fall in FEV₁ post EVH and EX ($r = 0.520$, $p = 0.003$). However, the % fall in FEV₁ post EVH was significantly greater than post EX (EVH: -7.5 ± 5.4, EX: -2.0 ± 3.8 %, $p < 0.001$). The total amount of air expired was significantly higher in 6 mins EVH compared to 6 mins EX (EVH: 686.5 ± 141.7, EX: 617.9 ± 83.1 L, $p = 0.002$). **CONCLUSION:** A positive EVH challenge may not be predictive of a positive Exercise Challenge in a dry environment. EVH may have a greater sensitivity due to the lower water content of inspired air and a greater VE. This suggests that a mild positive EVH challenge (a fall in FEV₁ of 10-15%), may not be predictive of EIB.

Core Temperature Responses To Exercise Using A Simulated Burn Injury Model: Impact Of Body Size

Matthew N. Cramer, Ken Kouda, Gilbert Moralez, Paula Y.S. Poh, Daniel Gagnon, Craig G. Crandall, FACSM. Institute for Exercise and Environmental Medicine, Dallas, TX. (Sponsor: Craig Crandall, FACSM)
Email: matthewcramer2@texashealth.org

(No relationships reported)

BACKGROUND: The US Army's Standards of Medical Fitness indicate that a burn injury spanning ≥40% of total body surface area (BSA) "does not meet the standard." While whole-body sweat production and thus evaporation are diminished in burn survivors with extensive skin grafts, the impact of a 40% BSA burn injury on core temperature regulation during exercise is likely dependent on body size, as larger individuals will have a greater absolute skin area that can still participate in heat loss despite the same percentage BSA burn injury. **PURPOSE:** Using a simulated burn injury model, we tested the hypothesis that the detrimental effect of a 40% BSA "burn injury" would be exacerbated in individuals of smaller versus larger body size during exercise due to a lower absolute (i.e., in m²) skin area available for heat loss. **METHODS:** On separate occasions, healthy non-burned individuals of small (SM: n=8, 62.4 ± 5.8 kg, 1.69 ± 0.11 m²) or large (LG: n=8, 99.1 ± 8.4 kg, 2.25 ± 0.09 m²) body size cycled to elicit ~500 W of metabolic heat production for 1 h in a 39°C and 20% relative humidity environment with and without (0%) a simulated burn injury of 40% BSA. Burn injuries were simulated by affixing a highly absorbent, vapor-impermeable material to the torso (20% BSA), arms (10% BSA), and legs (10% BSA) to prevent sweat evaporation. Core temperature was measured in the gastrointestinal tract (T_{gi}). **RESULTS:** Greater increases in T_{gi} were observed in SM at 0% (SM: 1.09 ± 0.33°C; LG: 0.64 ± 0.22°C; $P=0.03$) and 40% (SM: 1.65 ± 0.32°C; LG: 1.14 ± 0.23°C; $P=0.01$). However, the exacerbated rise in T_{gi} from 0% to 40% was not different between groups (SM: 0.57 ± 0.28°C; LG: 0.49 ± 0.24°C; $P=0.60$). **CONCLUSIONS:** Preliminary data suggest that the exacerbated rise in core temperature with a simulated burn is not dependent on body size. Nevertheless, SM subjects with a simulated burn exercising at the same rate of metabolic heat production experienced the highest absolute T_{gi} and would therefore be at the greatest risk for a heat-related injury. Does the Exercise-Induced Heat Load Influence Whole-Body Heat Loss in Type 1 Diabetes?Sheila Dervis¹, Martin P. Poirier¹, Pierre Boulay², Ronald J. Sigal³, Janine Malcolm¹, Naoto Fujii¹, Glen P. Kenny¹.¹University of Ottawa, Ottawa, ON, Canada. ²University of Sherbrooke, Sherbrooke, QC, Canada. ³University of Calgary, Calgary, AB, Canada.

(No relationships reported)

To date, only two studies have examined the effects of Type 1 diabetes (T1D) on the body's ability to dissipate heat during exercise in the heat. The first study showed no effect of diabetes on local or whole-body heat loss during moderate intensity exercise. However, a recent study revealed that differences may be heat load dependent as evidenced by the fact that attenuations in sweating only were observed for select skin sites at moderate-to-high exercise intensities. It remains to be determined however if these regional attenuations in sweating may lead to reductions in whole-body heat loss thereby compromising body core temperature regulation. **PURPOSE:** To examine if T1D impairs whole-body heat loss as function of increasing exercise-induced heat loads. **METHODS:** Young (27 ± 6 years) adults with (n=6, hemoglobin A1c: 8.0 ± 1.7%, duration of diabetes: 15 ± 7 years) and without T1D (CON, n=6) were matched for age, physical characteristics and aerobic fitness (VO_{2peak}). Participants performed three 30-min bouts of cycling at fixed incremental rates of metabolic heat production of 200 (Ex1), 250 (Ex2) and 300 W·m⁻² (Ex3) in the heat (35°C), equivalent to 35, 52 and 65% of their VO_{2peak}. Each exercise bout was followed by a 30-min recovery. Whole-body evaporative and dry heat loss and metabolic heat production were measured by direct and indirect calorimetry respectively. The change in body heat storage was calculated from the temporal summation of the rate of heat production and heat loss. **RESULTS:** Evaporative heat loss tended to be lower in the T1D group at the end of the second (T1D: 401 ± 71 W; CON: 424 ± 60 W, p=0.15) and third (T1D: 462 ± 75 W; CON: 479 ± 62 W, p=0.12) bouts of exercise only when compared to their healthy counterparts. No differences in dry heat gain were measured between groups for all exercise bouts (all p>0.05). Accordingly, the individuals with T1D stored more heat relative to healthy counterparts during the second (T1D: 247 ± 48 kJ; CON: 167 ± 48 kJ, p=0.03) and third (T1D: 314 ± 70 kJ; CON: 250 ± 83 kJ, p=0.02) exercise bouts. **CONCLUSION:** Our preliminary findings demonstrate that T1D may impair whole-body heat loss during exercise in the heat. Further, we show that the influence of T1D on heat dissipation is dependent upon the exercise-induced heat load. Support provided by the Canadian Institutes of Health Research.

136 May 31 10:00 AM - 10:15 AM

Are Type 2 Diabetes-Related Impairments in Heat Dissipation Heat Load Dependent?Martin P. Poirier¹, Sheila Dervis¹, Pierre Boulay², Ronald J. Sigal³, Janine Malcolm¹, Glen P. Kenny¹. ¹University of Ottawa, Ottawa, ON, Canada. ²Université de Sherbrooke, Sherbrooke, QC, Canada. ³University of Calgary, Calgary, AB, Canada. Email: mpoir026@uottawa.ca

(No relationships reported)

Older adults with type 2 diabetes (T2D) have an attenuated physiological ability to dissipate heat during moderate intensity exercise in the heat. However, it is unclear if T2D-related impairments in heat dissipation only occur above a certain exercise-induced heat load and therefore level of heat stress. **PURPOSE:** To examine whether T2D-related impairments in whole-body heat loss, as assessed by direct calorimetry, occur above a certain heat load threshold. **METHODS:** Twelve older (60 ± 7 years) habitually active males with (n=6, hemoglobin A1c: 6.8 ± 0.6 %, duration of diabetes: 9 ± 5 years) and without (n=6) T2D (CON) matched for age, body surface area, and fitness (VO_{2peak}) completed three successive 30-min bouts of semi-recumbent cycling performed at fixed incremental rates of metabolic heat production of 300 (Ex1), 400 (Ex2) and 500 (Ex3) W in the heat (40°C). This was equivalent to 37, 50 and 62% of their pre-determined VO_{2peak}. A 15-min recovery period followed each exercise bout. Whole-body heat loss (evaporative and dry heat exchange) was measured using direct calorimetry. The simultaneous measurement of metabolic heat production via indirect calorimetry was used to calculate the change in body heat storage. **RESULTS:** Whole-body heat loss was reduced in the T2D group relative to CON at the end of Ex1 (T2D: 235 ± 23 W; CON: 261 ± 34 W, p=0.004), Ex2 (T2D: 294 ± 24 W; CON: 335 ± 44 W, p=0.030), and Ex3 (T2D: 330 ± 59 W; CON: 390 ± 39 W, p=0.02). Given that dry heat gain was similar between groups at the end of all exercise bouts (all p>0.05), differences in whole-body heat loss were only due to differences in evaporative heat loss. The relative difference in the maximal level of whole-body heat loss achieved between groups became greater with increasing exercise-induced heat loads (Differences: Ex1=10.5%, Ex2=14.0% and Ex3=20.5%). As such, the individuals with T2D stored more heat during all exercise bouts (Ex1: 197 ± 39 kJ; Ex2: 236 ± 67 kJ; Ex3: 334 ± 78 kJ, p<0.05) compared to the control group (Ex1: 150 ± 61 kJ; Ex2: 160 ± 74 kJ; Ex3: 248 ± 80 kJ). **CONCLUSION:** Our preliminary findings show that

type 2 diabetes impairs the body's ability to dissipate heat during exercise in the heat and that these differences are first evident at a moderate heat load of 300 W (equivalent to 37% of VO_{2peak}).

(No relationships reported)

PURPOSE: To establish the extent of thermoregulatory impairment in paraplegic and tetraplegic athletes compared to able-bodied controls during exercise and passive recovery in the heat using an experimental method that accounts for differences in biophysical factors. **METHODS:** Thirteen trained males were separated into three groups based on spinal cord injury (SCI) level: tetraplegia (TP; C5-C8, 26.8±5.4 y, 71.2±7.1 kg), paraplegia (PA; T4-T12, 25.6±4.6 y, 74.0±19.7 kg), and able-bodied (AB; 26.2±2.2 y, 78.8±3.9 kg). Participants exercised on an arm ergometer for 30 min at a heat production of 4.0 W/kg (AB vs. TP) or 6.0 W/kg (AB vs. PA) with 3 min rest every 10 min, followed by 45 min of passive recovery in 35°C, 50% RH. Esophageal (T_{es}) and gastrointestinal (T_{gi}) temperature and local sweat rate (LSR) on the forehead and upper back were measured throughout. **RESULTS:** After 30 min exercise, ΔT_{es} was greater in TP (1.13±0.25°C) compared to AB (0.34±0.10°C). Similarly, a greater ΔT_{es} was evident for TP (1.60±0.28°C) compared to AB (0.28±0.15°C). Core temperature peaked at 45 min post-exercise for TP, with ΔT_{es} and ΔT_{gi} reaching 1.94±0.18°C and 1.83±0.13°C, respectively. No sweating was evident in TP however in AB, end-exercise ΔLSR was 0.38±0.26 mg·min⁻¹·cm⁻² on the head and 0.36±0.15 mg·min⁻¹·cm⁻² on the upper back. Differences between PA and AB were evident after 30 min exercise for ΔT_{es} (0.56±0.32°C vs 0.38±0.08°C) and ΔT_{gi} (0.75±0.38°C vs 0.50±0.09°C), which is when core temperature peaked for both groups. At 45 min post-exercise, PA remained greater than AB for ΔT_{es} (0.45±0.16°C vs 0.38±0.15°C) and ΔT_{gi} (0.46±0.22°C vs 0.28±0.18°C). Furthermore, ΔLSR was greater in PA than in AB after 30 min exercise, both at the head (1.03±0.75 mg·min⁻¹·cm⁻² vs 0.87±0.20 mg·min⁻¹·cm⁻²) and the back (1.03±0.30 mg·min⁻¹·cm⁻² vs 0.49±0.18 mg·min⁻¹·cm⁻²). **CONCLUSION:** The increase in post-exercise body temperature in TP demonstrates the inability to dissipate heat in hot conditions, primarily due to the lack of sweating. A greater, but less pronounced increase in body temperature during exercise was also apparent in PA compared to AB, suggesting there is a graded effect of SCI level on thermoregulatory impairment.

Multiple Sclerosis Impairs Sweating but not Skin Blood Flow during a Passive Whole-Body Heat StressDustin R. Allen¹, Mu Huang¹, Iqra M. Parupia¹, Ariana R. Dubelko¹, Elliot M. Frohman², Scott L. Davis¹. ¹Southern Methodist University, Dallas, TX. ²University of Texas Southwestern Medical Center, Dallas, TX.

(No relationships reported)

Multiple sclerosis (MS) is an autoimmune disease that affects the central nervous system (CNS), disrupting autonomic function. **PURPOSE:** The aim of this study was to test the hypothesis that individuals with MS have blunted control of thermoregulatory reflex increases in sweat rate (SR), and cutaneous vasodilation compared to controls during a passive whole-body heat stress (WBH). **METHODS:** 18 individuals with relapsing-remitting MS and 18 healthy controls (CON) participated in the study. Core temperature (T_{core}), skin temperature, heart rate, arterial blood pressure, skin blood flow (laser-Doppler flowmetry: LDF), and SR were continuously measured during normothermic baseline (34 °C water perfusing a tube-lined suit) and WBH (increased core temperature 0.8 °C via 48 °C water perfusing the suit). Following WBH, local heaters were warmed to 42 °C, inducing maximal cutaneous vasodilation at the site of LDF collection. Cutaneous vascular conductance (CVC) was calculated as the ratio of LDF to mean arterial pressure and expressed as a percentage of maximum. **RESULTS:** Individuals with MS had an attenuated SR response to WBH (ASR from baseline: MS: 0.42±0.2 vs CON: 0.60±0.3 mg/cm²/min, p=0.005), while Δ% CVC_{max} was similar between the groups (CON: 41.7±16%; MS: 37.6±12 %, p=0.39). Additional analysis revealed SR responses were blunted as a function of T_{core} in MS (interaction: group*T_{core}, p=0.03), of which differences were evident at ΔT_{core} 0.7 °C and 0.8 °C (p<0.05). Similar analysis for Δ% CVC_{max} revealed no significant

interaction **CONCLUSION:** Taken together, the attenuated sweat responses in MS may be a result of altered neural control of sweat rate, while the control of the cutaneous vasculature is preserved in response to a WBH.

He's All Heart

Elana Bannerman¹, John H. Stevenson¹, Pierre Rouzier, FACSM², Greg Little². ¹*University of Massachusetts, Worcester, MA.* ²*University of Massachusetts, Amherst, MA.*
(No relationships reported)

HISTORY: An 18 year old male freshman diver at a division 1 university presented to the student health clinic for his pre-participation exam. On discussing his medical history, he reported that at age 8 he syncope while climbing a rope at gymnastics practice. He was taken to the ED for evaluation, and, after a normal glucose and CT scan of the head, the episode was attributed to dehydration. Over the coming weeks the patient syncope twice more at practice. He was then admitted to the hospital for further evaluation.

PHYSICAL EXAMINATION (at PPE): BP 112/76. HR 60. NAD. CV: NRRR, no murmurs, gallops, rubs. PMI is mid-clavicular with a normal impulse. Lungs: CTAB. The patient has a 5cm diagonal well-healed scar at the upper lateral corner of the L chest.

DIFFERENTIAL DIAGNOSIS: Dehydration, orthostasis, neurocardiogenic/vasovagal syncope, hypoglycemia, seizure, aortic stenosis, hypertrophic cardiomyopathy, cardiac ischemia, supraventricular tachycardia, ventricular tachycardia (Long QT, CPVT, Brugada), bradyarrhythmia.

TEST AND RESULTS (during hospital admission): CT head WNL. ECG WNL. EEG WNL. Exercise stress test revealed concomitant increase in PVCs with increase in HR. Genetic testing (+) for RYR2 gene.

FINAL WORKING DIAGNOSIS: Catecholaminergic Polymorphic Ventricular Tachycardia (CPVT)

TREATMENT AND OUTCOMES: Initially placed on nadolol 60mg daily. Significant athletic restrictions imposed. 3 years later restrictions loosened and he began competitive diving and started weightlifting and performing light cardio. 3 months prior to starting college, he sustained an episode of cardiac arrest while walking on the treadmill. Medications changed to nadolol 60mg daily and flecainide 100mg BID. Implantable loop monitor placed. Patient continued to dive and restrictions tightened to decrease the intensity of training. 3 months later the patient sustained a 3 minute episode of PVT while doing burpees at practice. He then underwent a PM/ICD placement and a left cardiac sympathetic denervation. Started diving again 2 months later. Chose not to reveal medical history during college recruitment process due to concern that he would not be recruited. Currently cleared to perform modified practices and compete in 1m and 3m springboard. Restricted from platform diving.

143 May 31 9:50 AM - 10:10 AM

Aortic Root Dilation in Professional SCUBA Diver

Email: f.morales.acuna@gmail.com
(No relationships reported)

HISTORY: A 34 years old asymptomatic male underwent a complete cardiovascular screening as part of his occupational health screening in the Special Police Force,

Diving Section. Physically active (e.g. running, martial arts, strength training, swimming, and diving). He reports no history of chest pain, syncope, dizziness, palpitations, or dyspnea. His past medical history is unremarkable. No family history of sudden death. He has no current or prior history of smoking or drug use.

PHYSICAL EXAMINATION: Anthropometrics: height 179 cm; weight 83 kg; BSA 2.02 m². Vitals: HR 60 bpm; BP 120/70 mmHg. The cardiac exam revealed a protodiastolic murmur that was heard in the inferior left sternal border, intensity 2/6 with no irradiation. Rest of the examination was normal.

DIFFERENTIAL DIAGNOSIS: Physiologic Murmur, Healthy.

TEST AND RESULTS: Electrocardiogram: Normal sinus rhythm, 60 bpm, axis 0°, PR 0.16 s, QTc 0.38 s, early repolarization, IRBBB, U waves V2-V6. Echocardiogram: Aortic root is severely dilated (aortic annulus 30.5 mm, z-score 1.6; sinuses of Valsalva 50.7 mm, z-score 5.5; sinotubular junction 43.5 mm, z score 5.2; proximal ascending aorta 42.0 mm, z-score 4.2). Aortic valve is tricuspid with mild aortic regurgitation. Distal ascending aorta, aortic arch and descending aorta are normal in size. Left ventricular dimensions show mild LV dilation. LV wall thickness is normal with normal contractility, EF 66%. Cardiac MRI: Aortic root aneurysm (48 mm diameter) and effacement of the sinotubular junction. Tricuspid aortic valve without significant stenosis or regurgitation. Rest of the thoracic aorta is normal.

FINAL WORKING DIAGNOSIS: Moderate to severe aortic root aneurysm with tricuspid aortic valve and annuloaortic ectasia.

TREATMENT AND OUTCOMES: Valve sparing aortic root replacement (macroscopic hyaline degeneration of the aneurysm). Acetylsalicylic acid 100 mg/day for 3 months. Progressive aerobic exercise training (low to moderate intensity) for 3 months. Strength training (40-50% of body weight) after first 3 months post-surgery. Referred to genetic testing. Control (3 months): Asymptomatic; ECHO: aortic annulus 27.4 mm, sinuses of Valsalva 35.4 mm, sinotubular junction 33.1 mm, proximal ascending aorta 33.1 mm. Is expected the return to diving activities after 1 year without complications.

144 May 31 10:10 AM - 10:30 AM

Transitory Cardiomyopathy In An Elite Swimmer: A Case Study

Demitri Constantinou. *Faculty of Health Sciences, University of the Witwatersrand, Wits, South Africa.* (Sponsor: Yoganathan (Yoga) Coopoo, FACSM)
Email: demitri.constantinou@wits.ac.za
(No relationships reported)

HISTORY: A 20-year-old swimmer presented with symptoms of chest pain, dyspnea and two episodes of syncope whilst training for Olympic trials. Symptoms started 4 months before and increasing. He had difficulty training. He reported palpitations at random and not related to syncope or chest pain. His heart rate would exceed 200bpm at times. He was referred to a cardiologist who applied a Holter monitor and inserted an implantable cardiac defibrillator. There was no previous history of any similar problem. History was suggestive of non-specific viremia several weeks prior. The swimmer had no medical or surgical history of note. He was not on any medication and had been using whey protein supplements and creatine, but denied using prohibited performance enhancing substances.

PHYSICAL EXAMINATION: Examination on several occasions did not reveal any abnormalities. Normal pulses and perfusion. Heart rate average 68 bpm, regular, good volume. Blood pressure equal in left and right arms, average 128/68 mmHg. The rest of cardiovascular examination normal.

DIFFERENTIAL DIAGNOSIS:

1. Viral myocarditis arrhythmia
2. Hypertrophic cardiomyopathy
3. Previously unidentified congenital cardiac pathology
4. Non-cardiac cause

TEST AND RESULTS:

Chest radiology normal. Electrocardiography investigations at time symptom onset, several times later on ambulatory readings did not reveal any pathology / arrhythmias. Cardiac enzyme markers initially showed marginal elevated Troponin T. Echocardiography showed dysfunction of left ventricle with wall hypomotility. Ejection fraction 45% using the Simpson method. Cardiac MRI scan reported no signs of severe left or right ventricle dilation or hypertrophy, but concentric hypomotility of whole left ventricle wall. Ejection fraction was 35% Valves were normal as was the rest of the assessment.

FINAL/WORKING DIAGNOSIS:

Transitory cardiomyopathy following possible viremia

TREATMENT AND OUTCOMES:

1. With detraining form not swimming, the athlete slowly recovered.
2. Follow up echocardiography after 6 months showed improvement with no regional wall motion abnormalities with uniform left ventricle contractility. Ejection fraction was 56%.
3. Chest pain symptoms persisted for at least 6 months, but other symptoms subsided.
4. He gradually returned to symptom-guided training

146 May 31 10:30 AM - 10:50 AM

Chest Pain- Volleyball

Samuel T. Dona, Jr.¹, Jeffrey M. Mjaanes, FACSM². ¹Rush University Medical Center, Chicago, IL. ²Northwestern University, Evanston, IL. (Sponsor: Jeffrey M Mjaanes, FACSM)
Email: Samuel_T_Dona@rush.edu
(No relationships reported)

HISTORY: A 20-year-old female collegiate volleyball player presented with a 3-month history of chest pain. Pain was non-exertional, localized to the mid-chest and described as constant with rating of 8/10. She initially sought consult 3 months prior in the emergency room with EKG and labs unremarkable. The patient was diagnosed with costochondritis and managed with a steroid dose pack that provided temporary relief. Her pain then progressively increased to inability to tolerate volleyball activity. Of note, she reported mild left hip and lower back pain that started one week prior to consult.

PHYSICAL EXAMINATION: Cardiac exam revealed regular rate and rhythm with no murmurs. Tenderness to palpation was significant over the sternomanubrial junction. Left hip exam revealed positive piriformis test and sacroiliac compression test. Range of motion was full throughout the bilateral upper and lower extremities. Strength, reflexes, sensation, and pulses normal throughout.

DIFFERENTIAL DIAGNOSIS:

1. Costochondritis
2. Osteomyelitis of sternum
3. Seronegative spondyloarthropathy

TEST AND RESULTS:

Anterior-posterior and lateral chest x-rays:

—Normal cardiac silhouette. No bony abnormalities.

Anterior-posterior and lateral pelvis x-rays:

— Normal joint space. No bony deformities.

Nuclear medicine total bone scan:

— Increased uptake at sternomanubrial interval concerning for inflammatory process.

Further evaluation with CT scan suggested.

CT scan of the sternum with IV contrast:

— Increased uptake at the manubriosternal joint demonstrating subchondral sclerosis.

CBC, RF, ESR, CRP, HLA-B27, ANA, Lupus panel and Lyme titers ordered.

— Lab results normal with the exception of slightly elevated ESR.

FINAL/WORKING DIAGNOSIS:

Seronegative spondyloarthropathy

TREATMENT AND OUTCOMES:

1. Patient referred to Rheumatology given concern for inflammatory arthritis.
2. Initiated NSAIDs and physical therapy for suspected piriformis syndrome.
3. MRI of bilateral SI joints performed and suggestive of sacroiliitis.
4. In preparation for TNF agent treatment, patient found to be Hep B core antibody positive and referred to Hepatology.
5. Started entecavir for Hepatitis B treatment and adalimumab.
6. After 2 months, the patient returned to full volleyball participation with complete resolution of her symptoms.

HISTORY

A 36 year old previously healthy male presented to the medical tent via wheelchair with acute onset of dizziness and nausea after finishing a marathon. He had met his goal of finishing just under 3 hours. He alternated water and sports drinks for fluid replacement. He described the dizziness as a spinning sensation that began shortly after crossing the finish line associated with emesis. This persisted while lying still with his eyes closed. Symptoms were exacerbated by tilting his head or attempting to look up. No lightheadedness, chest pain, shortness of breath, hearing changes, numbness or altered mental status. No history of vertigo episodes, recent illness or head trauma. In the medical tent, he vomited 3 times. He was laid supine with his legs elevated. Over 45 minutes, he had 5 cups of oral electrolyte replacement, 3 cups of water and a banana without improvement. He was eventually able to walk one lap around the medical tent while keeping his gaze focused downwards.

PHYSICAL EXAMINATION

T 0 min:

BP 120/58, HR 94, RR 19, O₂ 94%

T 45 min:

Supine BP 116/64, HR 63

Standing BP 105/60, HR 72

Rectal temp 97.9F

He was mildly ill-appearing with clear mental status, alert and oriented x 4. Cranial nerves II-XII were intact and he demonstrated 5/5 strength in b/l upper and lower extremities. Extraocular movements and smooth pursuit were normal. No signs of spontaneous nystagmus. Nystagmus was observed with change in posture from sitting to supine to side lie. Head impulse testing was positive for compensatory saccade response. Dix-Hallpike maneuver to the right was positive for nystagmus and reproduction of symptoms.

DIFFERENTIAL DIAGNOSIS

1. Exercise associated postural hypotension
2. Exertional Heat Stroke
3. Exercise Associated Hyponatremia
4. Vestibular system dysfunction
5. Central nervous system lesion

TESTS AND RESULTS

N/A

FINAL/WORKING DIAGNOSIS

Benign paroxysmal positional vertigo (BPPV)

TREATMENT AND OUTCOMES

1. The Epley maneuver was performed, inducing one episode of emesis followed by gradual improvement of symptoms over the following 10 minutes.
2. Instructed to avoid rapid or frequent head movements for the next few days.
3. Gradual return to running after complete resolution of symptoms.
4. Follow up with primary care for any worsening of symptoms.

151 May 31 9:50 AM - 10:10 AM

Head Injury - Soccer

Christina L. Master¹, Eileen P. Storey¹, Lei Wang², Hasan Ayaz², Olivia Podolak¹, Matthew F. Grady¹. ¹The Children's Hospital of Philadelphia, Philadelphia, PA. ²Drexel University School of Biomedical Engineering, Philadelphia, PA.

(No relationships reported)

HISTORY: A 16-year-old female soccer goalie sustained a head injury during a heading drill. The player reported a few awkward headers, including one that hit her in the back of the head. The player developed a headache and nausea, but had a normal evaluation by an athletic trainer on the sidelines. The trainer still removed the athlete from play due to the mechanism of injury and the player's report of low-grade symptoms.

PHYSICAL EXAMINATION: The player reported only a mild headache at rest the following day when she presented to clinic. On clinical examination, the player had no symptoms or abnormalities with smooth pursuits, saccades, vestibulo-ocular reflex, visual motion sensitivity, convergence and accommodation tests.

DIFFERENTIAL DIAGNOSIS:

1. Concussion
2. Sub-concussive head injury
3. No concussion

TEST AND RESULTS:

- The player performed the physical examination both 1-day and 1-week post-injury while wearing a functional near-infrared spectroscopy (fNIRS) headband that recorded anterior prefrontal cortex oxygenation changes. Compared to her baseline, the player showed significantly different levels of oxygenation changes at 1-day post-injury that approached pre-injury levels but had not fully returned to baseline at 1-week post-injury.

- At clinical evaluation a week after injury, the player reported no symptoms at rest or during the physical examination. The clinician detected no abnormal findings on physical examination.

FINAL WORKING DIAGNOSIS:

Concussion with subclinical deficits

TREATMENT AND OUTCOMES:

1. At 1-day post-injury, the player was permitted to begin a return-to-learn plan as well as a return-to-play protocol.
2. The player was cleared to return to soccer at 1-week post-injury with resolution of symptoms and normal physical examination.

152 May 31 10:10 AM - 10:30 AM

Headache After MVA in Physically Active, Healthcare Professional

Enayet Neak¹, Vanessa Lalley-Demong². ¹St. Joseph's Family Medicine Residency, Syracuse, NY. ²St. Joseph's Family Medicine Faculty, Syracuse, NY.

Email: eneakmd@gmail.com

(No relationships reported)

HPI: 35 y/o F NP with hx of migraines, presented to the ED 1 day s/p MVA, c/o right-sided headache, nausea, photophobia. The patient went off the road at 30 mph, hitting a snowbank. She had a mild headache after the accident, saying her head whiplashed but denied hitting her head, or LOC. She took an ibuprofen but woke up the following morning with the worst headache of her life, prompting ED visit. Pertinent negatives: No retrograde amnesia, phonophobia, blurred vision, eye pain, hearing loss, tinnitus, neck pain, extremity weakness, paresthesia, dizziness.

In the ED, patient was told her eye dilated funny, but otherwise normal exam. CT head was negative. GCS 15. Symptoms improved with prochlorperazine, diphenhydramine. She followed up in the office 2 days later, with continued symptoms. Office SCAT2 scored 52. She was diagnosed with post-concussion syndrome, and treated supportively. Over the next several months, patient developed diplopia, vertigo, neck pain, fatigue.

EXAM: Vital signs were stable and afebrile, well-developed, AxAxO3, anxious. NCAT. Pupils were equal, round, and L pupil was sluggishly reactive to light. EOMI Visual acuity: OU20/20, OD/OS20/25. AROM/PROM of head and neck were normal. No ptosis, proptosis. CN 2-12 intact. Romberg test negative. Motor strength 5/5 UE & LE. Sensation intact.

Subsequent office visits revealed R neck pain to palpation, asymmetry along R levator and R trapezius muscles, with reduced range of motion.

DDX: Post-concussive syndrome, BPPV, chronic migraine with aura, CN injury, malignancy/tumor

TESTS/RESULTS: CT head (ED) negative. X-ray cervical spine AP/lateral negative. Non-contrast brain MRI negative. She received OMT for neck pain with mild improvement. While working with OT, patient was noted to have horizontal saccades on lateral gaze along L eye, with lateral deviation of L eye. She was referred to neuro-ophthalmology. She was diagnosed with CN3 palsy.

DX: Partial oculomotor (CN3) nerve palsy secondary to whiplash from MVA

TX & OUTCOMES: Tx: Optometry rehab with vestibular exercises, prism therapy, OMT, TP injections, PT/OT; Sumatriptan, amitriptyline, melatonin. 17 mo s/p MVA, pt continued to have intermittent headaches, light/noise sensitivity, trouble focusing. Symptoms have improved and pt resumed training for local 5K, which she completed. She is not at baseline.

153 May 31 10:30 AM - 10:50 AM

Partial Abducens Palsy Following Concussion

Brian Vernau. Children's Hospital of Philadelphia, Philadelphia, PA.

Email: bvernau@gmail.com

(No relationships reported)

HISTORY: 11 year old male presents to the sports medicine office for evaluation of concussion two weeks after he fell off his bike, hitting his head on concrete. He had no loss of consciousness. He was evaluated in the ED for laceration repair. Initial symptoms included headache, vomiting, and sleeping more than usual. Approximately one week into his injury he developed diplopia at which time his parents noticed his eyes were "crossing" more. Headaches and vomiting resolved 10 days post-injury. He endorses a history of color-blindness. He denies history of concussion, mood disorders, strabismus, amblyopia, or eye surgery. There is a strong family history of strabismus and eye surgery.

PHYSICAL EXAM: Neurological exam notable for left CNVI palsy on EOM testing. Normal resting gaze. Testing of smooth pursuits, saccades, and gaze stability did not provoke symptoms. Diplopia and left eye lateral gaze deficit persisted throughout testing, but this was variable. He was able to cross midline intermittently. Near point of convergence was 4cm and accommodation was 7cm bilaterally. Finger to nose testing was fast but inaccurate. Balance testing revealed difficulty with tandem walk backwards with eyes open and closed.

DIFFERENTIAL DIAGNOSIS:

Traumatic abducens palsy

Lateral rectus entrapment

Intracranial mass

Ocular migraine

Malingering

TESTS AND RESULTS:

CT and MRI brain both normal

Ophthalmology: left abducens palsy, bilateral resolving papilledema, recommended patching to alleviate symptoms

Neurology: Traumatic abducens palsy. Resolved papilledema. No other neurological findings.

FINAL WORKING DIAGNOSIS:

Concussion with left abducens palsy

TREATMENT AND OUTCOMES:

4 weeks after his injury he still complained of diplopia, but more intermittently and no longer requiring eye patches. He remained headache free with full academics. He had normal extraocular movements with slow pursuits, but deficit would return with fast eye movements.

He was lost to follow up, but per mother's report, diplopia resolved approximately 7 weeks from injury.

154 May 31 10:50 AM - 11:10 AM

"Post-concussion" Syndrome In A 16-year-old Female Basketball Player

Ryan Woods, Eric Crowley, Edward Laskowski, FACS. Mayo Clinic, Rochester, MN. (Sponsor: Edward R. Laskowski M.D., FACS)

Email: woods.ryan@mayo.edu

(No relationships reported)

HISTORY: 16-year-old female presents for evaluation of a possible post-concussion syndrome after being struck in the head by a dodgeball in gym class. Patient was asymptomatic at the time of injury. Two weeks following the injury she awoke feeling "different". Symptoms predominately consisted of headache, head pressure, nausea and photophobia. Her symptoms progressed to the point where she was unable to attend school. She was seen in the sports medicine clinic for presumed post concussive symptoms. Upon presentation she denied upper extremity weakness, radicular pain or sensory symptoms. Her post-concussion symptom score was 56 at the time of her sports medicine visit, with significant headache, light and noise sensitivity, and a continued sensation of feeling "not right." She had a history of concussion sustained two years prior to presentation in which symptoms resolved after two days.

PHYSICAL EXAMINATION: Healthy-appearing individual, sensitive to light. No cognitive deficit. Flat affect. Normal gait. Cranial nerve exam was normal. Full joint range of motion. Normal neurologic exam. Spurling's test was negative for radicular pain. SAC score: 29/30.

DIFFERENTIAL DIAGNOSIS: Brain tumor, Post-concussion syndrome, Migraine headaches, Depression, Anxiety

TEST AND RESULTS: MRI without contrast: No definite evidence of traumatic brain injury. Large cystic-appearing mass in the right lateral ventricle. MRI with contrast: Re-demonstration of mass. Appearance concerning for a neoplasm such as choroid plexus carcinoma metastasis. No evidence of metastatic disease on MRI of cervical, thoracic and lumbar spine. **FINAL WORKING DIAGNOSIS:** Right lateral ventricle brain tumor

TREATMENT AND OUTCOMES: Referrals were made to pediatric neurooncology and pediatric neurosurgery. The patient underwent a right tempoparietal craniotomy with full tumor resection. Surgery was without complications. Biopsy results confirmed a choroid plexus xanthogranuloma. Seven days following surgery she experienced postoperative seizures, and was placed on Kepra. She did not experience recurrent seizures and was able to be titrated down on her Kepra. A six month postoperative MRI scan is pending, with neurology and neurosurgery appointments to follow. She was slowly reintegrated back into school and is currently asymptomatic.

155 May 31 11:10 AM - 11:30 AM

Head- Lacrosse

Amy Valasek. *Nationwide Childrens Hospital, Westerville, OH.*
(Sponsor: James MacDonald, FACSMM)
Email: amy.valasek@nationwidechildrens.org
(No relationships reported)

HISTORY: A 14-year-old male sustained a closed head injury while playing recreational lacrosse with a friend. During a face off, he tripped over his feet and hit frontal aspect of head on turf. There was no loss of consciousness, hematoma, or bleeding. He was disoriented and taken home due to headache and confusion. He slept for 45 minutes, then, awoke with emesis three times. The family took him to a local pediatric emergency room, a head CT was performed and diagnosed with a concussion. He followed up in concussion clinic 8 days later. He reported symptoms of fatigue, motor slowing, and no headaches. After intake and history, he began computer Cogstate Concussion Test. Within 5 minutes of start, his father called for help due to a first time seizure.

PHYSICAL EXAMINATION: Not alert, sitting in chair with left arm flexed and left leg extended actively having a generalized tonic clonic seizure. He was lifted to the table and head tilt jaw thrust performed due to dusky appearance with improvement, 100% non-rebreather face mask was placed, and seizure self-resolved in 4 minutes. He was slow to arouse and answered questions slowly and appropriately. On examination vital signs were normal for age and no focal deficits elicited with equal strength, sensation, and reflexes bilateral upper & lower extremities. He was transported from concussion clinic to the pediatric emergency room by EMS for further evaluation.

DIFFERENTIAL DIAGNOSIS:

1. Cerebrovascular degenerative disease inflammatory/autoimmune
2. Intracranial lesion
3. Subdural hematoma

TEST AND RESULTS:

Head CT day of injury: No acute intracranial abnormality. Extensive confluent hypodensity in the periventricular cerebral white matter with atrophy.

MRI of brain with contrast 8 days after injury: Extensive, symmetric areas of T2 prolongation within the deep white matter of both cerebral hemispheres, with small cystic changes adjacent to the frontal horns of the lateral ventricles.

EEG: Intermittent slowing on the left is suggestive of underlying cerebral dysfunction.

FINAL/WORKING DIAGNOSIS:

Vanishing White Matter Disease

TREATMENT AND OUTCOMES:

1. Whole Genome Sequencing completed and positive for Vanishing White Matter Disease.
2. Held from all further contact sport participation.
3. Physical therapy and occupational therapy to address progressive weakness.

A-29 Clinical Case Slide - Shoulder I

Wednesday, May 31, 2017, 9:30 AM - 11:30 AM

Biceps Pain- Rock Climber

Stephanie Kramer¹, Darius Greenbacher², Pierre Rouzier, FACSMM³. ¹*Baystate Medical Center, Springfield, MA.* ²*Baystate Medical Practices, Northampton, MA.* ³*University of Massachusetts, Amherst, MA.* (Sponsor: Pierre Rouzier, FACSMM)
Email: stephanie.kramerDO@baystatehealth.org
(No relationships reported)

HISTORY: 44 year old right hand dominant rock climber presented with right sided anterior-medial biceps pain without acute injury, although history significant for 500 push ups and 100 pull ups daily, as well as 3-4 hours of rock climbing 3-4 times/week. He does have a history of a 15 foot fall while climbing (in harness and about 7-8 feet from last anchor point) after losing grip with his right hand, but does not associate this with the onset of his pain. He complains of pain with any type of elbow flexion, more with abduction to 90 degrees such as when climbing.

PHYSICAL EXAMINATION: Elbow exam: Inspection: No obvious defects of the biceps/anterior musculature. No overlying ecchymosis. Palpation: Mild tenderness over mid to distal biceps and myotendinous junction, no bony tenderness. ROM: full Strength: 5/5 Special: No Popeye sign. Pain with resisted flexion of the elbow (greater with thumb up) and resisted forearm supination.

Shoulder exam: Inspection: No asymmetry, atrophy or ecchymosis. Palpation: no pain with palpation. ROM: full Strength: 5/5 and symmetric Special: Jobe's test neg. Some mild discomfort with Speed's and Yergason's test at the mid biceps muscle belly but no proximal shoulder/arm pain. No pain with impingement tests. Biceps pain with O'Briens. Neurovascularly intact.

DIFFERENTIAL DIAGNOSIS for biceps pain: 1. Biceps tendon strain vs partial tear- distal vs proximal 2. Overuse injury at biceps myotendinous junction 3. Brachialis strain 4. Acute myositis 5. Sarcoma of the muscle

TEST AND RESULTS: MRI (not arthrogram) showed minimal tendinosis of supraspinatus but no rotator cuff tear. Large type II SLAP tear extending from just posterior to biceps anchor to the upper aspect of posterior labrum. Biceps long head tendon intact and normal position. Normal musculature at marker site placed by pt (approx 16cm from shoulder joint). No evidence of biceps retraction.

FINAL WORKING DIAGNOSIS: Type II SLAP tear

TREATMENT AND OUTCOMES: Minimal relief with rest/PT. Corticosteroid injection provided some relief and pt able to resume activities, however not yet at full volume 1 month after treatment

160 May 31 9:50 AM - 10:10 AM

Shoulder Pain and Weakness in 11 y/o Male after Bike Accident

Everett Hayes. *Evergreen Sports Medicine, Augusta, ME.*
(Sponsor: Peter Sedgwick, FACSMM)
(No relationships reported)

History: 11 y/o RHD male with no PMH presented for evaluation of left shoulder injury. He fell off his bike 3 weeks prior while visiting his aunt, landing on his left shoulder onto a sidewalk. There were no other injuries other than an elbow abrasion. He did not complain of any pain, but his mother became concerned when she noticed he wasn't moving his left arm much. When asked, the patient did admit to some pain over the lateral aspect of the shoulder. He could not lift his arm over his head despite lack of significant pain with the motion. He denied neck pain, radicular pain, numbness, tingling or prior shoulder injury. The symptoms had not improved since the time of injury.

Physical Examination:

General: well appearing, no apparent distress
L shoulder:

Inspection: antalgic carriage of shoulder, no deformity, atrophy, swelling
Palpation: tender over humeral head, glenohumeral joint, posterior shoulder
ROM: significantly limited in AROM despite lack of significant pain
Strength: Weak diffusely (3-4/5) out of proportion to minimal level of pain
Neurovascular: distal pulses intact, negative Spurlings, decreased sensation over anterior biceps, otherwise intact

Skin: no breakdown, erythema, ecchymosis

Differential Diagnosis:

Brachial plexus injury
Nerve root avulsion
Suprascapular nerve palsy
Shoulder dislocation
Fracture: humeral head, humeral neck, glenoid, clavicle, cervical
AC separation
Contusion
Non-accidental trauma
Altered pain inhibition

Test and Results: 3-view X-ray of L shoulder: proximal humeral neck fracture, minimally displaced and mildly angulated. There was no apparent involvement of the growth plates.

Diagnosis: Left humeral neck fracture with possible associated neurologic injury
Treatment and Outcomes:

- Placed in a sling for 2 weeks and limited to gentle ROM
- 5 weeks post injury: Repeat x-rays demonstrated appropriate healing. He still demonstrated reduced strength and ROM despite almost no pain so MRI was ordered.
- 8 weeks: MRI obtained and unrevealing for secondary injury that would explain the weakness. He had begun to show improvement with strength and ROM. Started home therapy exercises.
- 11 weeks: No pain, ROM and strength were continuing to improve. Repeat x-ray demonstrated good bone healing. Strengthening exercises increased with plan for resumption of all activities in 2 more weeks.

161 May 31 10:10 AM - 10:30 AM
Right Shoulder Pain

Arie (Eric) Dadush¹, Vincent Morelli¹, James Johnson².
¹Meharry medical college, Nashville, TN. ²Elite Sports Medicine, Nashville, TN.
 Email: ericdadush@gmail.com
 (No relationships reported)

History: A 48 year-old right-handed AAF with no significant PMH presented with right shoulder weakness and pain for 2 weeks. There was no inciting event or recent changes in activity. Her symptoms began 2 weeks after a viral URI. She works as a network manager and started developing acute pain for a few days, which was followed with stiffness, weakness and numbness on the lateral side of her arm. The pain then become constant and the numbness and tingling were intermittent and radiating into her hand. Her symptoms had been worsening over the prior week specifically with overhead activity. She had been using NSAID's, ice/heat and massage with no relief

Physical examination: Winging of the right scapula was noticed as well as tenderness over the deltoid. Passive ROM was normal with decreased active ROM; forward flexion and abduction 0-120 degrees, abduction external rotation 0-60 degrees. Supraspinatus, infraspinatus and triceps strength 3/5 with normal deltoid and trapezius strength. Hawkin's, Neer's, Empty can, and Impingement tests are all positive. O'Brien's, Yergason's and Crossover tests negative. **Differential Diagnosis:** Parsonage-Turner syndrome, Cervical disk disease, Shoulder impingement syndrome, Neoplastic brachial plexopathy, Supraspinatus tendinopathy **Tests and results:** Xray were obtained; no fracture, arthritis or soft tissue abnormalities were seen. Patient was sent for cervical and plexus MRI as well as EMG and nerve conduction studies. MRI results were without infiltrating process or extrinsic compression on the brachial plexus. Cervical spine MRI revealed a small right central disc extrusion without impingement. Nerve conduction studies demonstrated significant differences between the right and left Median and Ulnar nerves. The right Median and Ulnar nerves F-wave latency showed no response compared to 20.3 msc on the left side, which is consistent with a proximal injury as at the level of the plexus. **Final working diagnosis:** Parsonage-Turner syndrome

Outcome: Patient was given Toradol and Depomedrol IM as well as Medrol dose pack and Amitriptyline. She was also referred to PT.

Return to activity and follow up: 7 weeks after the initiation of the treatment patient reported almost complete resolution of her symptoms. She was instructed to follow up as needed if not complete resolution within 8 weeks.

162 May 31 10:30 AM - 10:50 AM
Chronic Axillary Pain and Weakness in a Recreational Weight Lifter

Christopher Chong, 19064, Kevin Duprey. Crozer Keystone, Springfield, PA. (Sponsor: Thomas Kaminski, FACSM)
 (No relationships reported)

HISTORY: A 19 year old college student and recreational weight lifter presents with chronic right axillary pain and mass. His pain started 8 months earlier while doing a human flag pole pose (holding onto a pole and lifting his body parallel to the ground). He felt an acute onset of sharp pain over right axillary region. He self treated with ice and foam roller without any improvement. He saw his primary care doctor who prescribed physical therapy. He attended 10 sessions with no improvement. Pain is currently 5/10, aching, worse after lifting weights and with palpation of the mass.

PHYSICAL EXAMINATION: Exam reveals no ecchymosis on inspection. There is a 2x2 non-mobile soft tissue mass over posterior inferior axillary region that is tender to palpation. Shoulder abduction and flexion on right is limited to 160 degrees with full internal/external rotation. 4+/5 strength with shoulder adduction.

DIFFERENTIAL DIAGNOSIS: Infraspinatus tear, teres major tear, latissimus dorsi tear, lipoma, liposarcoma, neurofibroma, hematoma, asymmetric fat deposition, rhabdomyosarcoma

TEST AND RESULTS: US of right latissimus dorsi: Imaging shows a heterogenous hypo and hyperechoic circular array within the right latissimus dorsi muscle measuring 2cm x3cm.

FINAL WORKING DIAGNOSIS: chronic latissimus dorsi tear.

TREATMENT AND OUTCOMES: Due to chronicity of symptoms and failure of physical therapy, patient elected for dextrose tenotomy. At one month follow up, he reported improvement in his pain from 5/10 to a 2/10, and was advised to slowly increase his activity. Three months after initial treatment, returned for follow up and reported 80% improvement in symptoms and strength. He elected for repeat dextrose tenotomy, and after the procedure was referred to physical therapy. After one month of physical therapy, he was discharged with full strength and complete resolution of pain. He was able to successfully audition for America Ninja Warrior.

163 May 31 10:50 AM - 11:10 AM
Shoulder Injury in a College Football Player

Ward McCracken¹, Justin Byers², Dave Smith¹. ¹University of Minnesota, Minneapolis, MN. ²Bethel University, St Paul, MN.
 (Sponsor: Suzanne Hecht, MD, FACSM)
 (No relationships reported)

HISTORY:

A 21 y/o male, college football running back and basketball player felt his left shoulder pop and shift during a contact play in a football game. He removed himself immediately from play, and on the sideline, he was diagnosed with an anterior glenohumeral dislocation. He had no prior shoulder instability. His shoulder was successfully reduced using a Hennepin-Kocher maneuver on the sideline. Examination immediately following the reduction showed no deficits and he was allowed to return to play wearing a Sully brace. Later in the same game, he was carrying the ball and stiff armed an opponent with the left hand and dislocated his shoulder a second time. Reduction on the sideline was initially unsuccessful the second time and he was taken to the athletic training room and his shoulder was there successfully reduced using a traction/counter-traction technique.

PHYSICAL EXAMINATION:

Left shoulder exam after the second reduction was significantly limited due to continued apprehension but generally showed diffuse weakness without focal deficit, limited AROM in all planes, no bony TTP, and neurovascular exam was intact.

DIFFERENTIAL DIAGNOSIS:

1. Glenohumeral Dislocation
2. Bony Bankart Injury
3. Hill-Sachs Lesion
4. Labral Tear

TESTS AND RESULTS:

XR

- 4V's (AP, Grashey, Axillary, and Scapular Y) negative
 MRI without contrast

- 3x2x1cm Hill-Sachs lesion, soft tissue Bankart injury, no evidence of any rotator cuff muscle tear, residua of moderate medial anterior capsular stripping inferiorly and of medial stripping of the inferior capsular attachment along the undersurface of the glenoid

FINAL DIAGNOSES:

1. Anterior Glenohumeral Dislocation x2
2. Soft Tissue Bankart
3. Hill-Sachs Lesion
4. Capsular Stripping

TREATMENT AND OUTCOMES: He was seen in the college's athletic training room three days following the injury. The medical team presented treatment options to him and surgical consult was obtained. After consideration, he opted for a trial of non-operative treatment. Presently, he continues to make excellent progress with range of motion and strength and has experienced no further instability.

164 May 31 11:10 AM - 11:30 AM
Subacute Presentation of an Elbow Injury-Work Related Delayed by Insurance

Ali Ashraf¹, John Chappa², Melinda Schalow³, Mimi Zumwalt¹.
¹Texas Tech University Health Sciences Center, Lubbock, TX.
²John Chappa, Lubbock, TX. ³Melinda Schalow, Lubbock, TX.
 (Sponsor: Jacalyn J. Robert-McComb, FACSM)
 (No relationships reported)

HISTORY: A 30 year-old, right hand dominant male firefighter sustained a right arm/elbow injury by attempting to catch a heavy garage door from falling during installation at work. He felt a pop with immediate pain. He experienced swelling/bruising in the ensuing couple of days, also difficulty using the affected extremity. Patient was initially seen at an urgent care clinic, then later by his primary care physician. Due to worker's compensation insurance requirements, an MRI was eventually done nearly 3 weeks out from initial injury, before he was referred for orthopedic consultation.

PHYSICAL EXAMINATION: Right upper extremity exam revealed tenderness/ecchymosis in the arm/elbow, weakness with resisted supination and positive hook test. He was still able to flex, extend the elbow plus pronate and supinate his right forearm. He reported no paresthesias or radicular symptoms, with sensation intact to light touch distally. Palpation also showed mild "popeye" deformity proximally at mid anterior arm.

DIFFERENTIAL DIAGNOSIS:

Partial distal biceps tendon rupture
Complete distal biceps tendon rupture
Bony distal biceps avulsion

TEST AND RESULTS: Right elbow anterior-posterior and lateral radiographs: -No fractures or dislocations Right extremity MRI: -Shows complete tear of the distal biceps tendon with retraction

FINAL WORKING DIAGNOSIS: Complete distal biceps tendon rupture - subacute
TREATMENT AND OUTCOMES:

Immediate open reattachment of distal biceps tendon (2 incision technique) to prevent any further retraction.

Arm kept in posterior/U splint with elbow flexed at 90 degrees-NWB R UE.

Follow up visit 10-14 days post-op then right elbow placed in dynamic brace.

Physical therapy protocol two weeks after surgery starting with gravity assisted elbow extension.

Regained full elbow ROM in 3 months (out of brace) with grip strength 90%.

Resolving proximal lateral forearm paresthesias.

Functional test planned at 6 months before returning to previous work/job.

A-39 Basic Science World Congress/Poster - Motor Control and Movement Disorders

180 Board #1 May 31 9:30 AM - 11:00 AM

Rock Climbing as a Novel Intervention to Improve Function in Parkinson's Disease: A Case Series

Joshua G. Woolstenhulme, Natalia Agüero, Elizabeth Ruckert, Susan J. Leach. *The George Washington University, Washington, DC.*

Email: jgwool@gwu.edu

(No relationships reported)

PURPOSE: To preliminarily characterize the feasibility and safety of indoor rock climbing (IRC) as a therapeutic intervention for persons with Parkinson's Disease (PD) and to explore any potential IRC may have for improving physical function.

METHODS: Subjects participated in 8 weeks of thrice weekly IRC. Each climbing session was comprised of 3 climbing sets. Sets gradually progressed from 5 to 8 min as did the degree of technical difficulty (5.5 to 5.7, assessed by the Yosemite Decimal System) over the 8-week intervention. Self-reported difficulty of movement and movement self-confidence were assessed using the Outpatient Physical Therapy Improvement in Movement Assessment Log (OPTIMAL). Dynamic balance was assessed using the Mini Balance Evaluation Systems Test (miniBESTest). Functional leg strength/power was measured using the five times sit-to-stand test (5xSTS).

Aerobic capacity was assessed using the 6-min walk test (6MWT). Grip strength (GS) was assessed using a hand dynamometer. All data were collected at baseline (T0) and after the intervention period (T1). Data for each subject were obtained at the same time of day on T0 and T1.

RESULTS: Three men on stable medication regimes (in order of recruitment: ages 73, 70, 72 yrs; BMI: 24, 24, 25 kg/m²; disease duration: 7, 13, 4 yrs; subjects 1 and 2 had idiopathic PD, subject 3 had familial PD) participated. Most subjects reported improvements in difficulty of movement (change scores [T1-T0] for each subject: -5, +3, -7) and all reported improvements in movement self-confidence (-4, -9, -15) on the OPTIMAL. Minimal dynamic balance improvements (+1, +1, +2) were noted on the total score of the miniBESTest for all subjects. Minimal improvements in functional leg strength/power for 2 subjects (-0.54, +1.27, -0.71 sec) were observed as measured by the 5xSTS. No improvements were observed for 6MWT or GS. No adverse events occurred.

CONCLUSIONS: IRC appears to be a feasible therapeutic activity with minimal safety risks for persons with PD. IRC may play a unique role in decreasing the perceived difficulty of movement and in increasing movement self-confidence for persons with PD. IRC may potentially improve dynamic balance and functional leg strength. This case series provides preliminary evidence for larger studies to examine potential benefits of IRC for persons with PD.

181 Board #2 May 31 9:30 AM - 11:00 AM

Impact of Rock Climbing on Complex Tasks in Persons with Parkinson's Disease: A Case Series

Susan J. Leach, Elizabeth Ruckert, Natalia Agüero, Joshua G. Woolstenhulme. *George Washington University, Washington, DC.*

Email: leachs@gwu.edu

(No relationships reported)

PURPOSE: Indoor rock climbing (IRC) incorporates a physical component of climbing a wall with a cognitive component of selecting an appropriate climbing route. A climber is required to divide attention between the physical and cognitive demands of the task, a necessary skill in many daily activities. The purpose was to examine the impact of a novel and challenging IRC intervention on complex tasks such as those requiring divided attention in individuals with Parkinson's Disease (PD).

METHODS: A pretest, posttest pilot intervention study had participants perform IRC 3 x per week for 8 weeks while increasing climbing duration and technical difficulty. Outcome measures included the Trail Making Part B test, the dual task Timed Up & Go (TUG) manual and cognitive tests, the timed Supine to Stand test, and the Four Square Step Test.

RESULTS: Three novice rock climbers with PD took part in this study. Participant 1 (P1) was a 73-year-old male with a 7-year history of idiopathic PD with early stage clinical presentation. Participant 2 (P2) was a 70-year-old male with a 13-year history of idiopathic PD with middle stage clinical presentation. Participant 3 (P3) was a 72-year-old male with a 4-year history of familial PD with early stage clinical presentation and cognitive involvement. The following results represent the change from pretest to posttest in seconds. Climbers P1 and P3 had faster and improved Trail Making Part B times P1: -3.89; P2: +22; P3: -8.57. Climbers P2 and P3 had faster and improved TUG manual times: P1: +0.041; P2: -0.141; P3: -0.976. Climber P3 had faster and improved TUG cognitive times: P1: +0.209; P2: +0.633; P3: -3.791 seconds. All 3 climbers had faster and improved timed Supine to Stand times: P1: -0.442; P2: -0.209; P3: -3.791. Climber P3 had faster and improved 4 Square Step Test times: P1: +0.3; P2: +1.258; P3: -1.458.

CONCLUSIONS: Three novice rock climbers with PD demonstrated improvements in complex tasks following 8 weeks of IRC: P1 and P2 in 2/5 measures; P3 in 5/5 measures. The extent of improvement appeared greatest in P3 who presented with cognitive impairment at baseline. It is possible that IRC prepares learners for task complexities similar to those encountered in the community. This pilot study provides preliminary evidence for larger studies to investigate potential benefits of IRC for persons with PD.

Val66met Polymorphism's Influence On Depression Symptoms And Responses To Exercise In Individuals With Parkinson's Disease

Sara A. Harper, 44883¹, Angela L. Ridgell². ¹Tiffin University, Tiffin, OH. ²Kent State University, Kent, OH. (Sponsor: Dr. Ellen Glickman, FACSM)

Email: harpersa@tiffin.edu

(No relationships reported)

Individuals with Parkinson's disease (PD) show high inter-individual variability in response to exercise interventions and in the severity of depression symptoms. It may be influenced by a genetic variation called brain derived neurotrophic factor (BDNF) Val66Met polymorphism. **PURPOSE:** To determine if the prevalence of the Val66Met polymorphism influenced incidences of depression symptoms and if

Val66Met polymorphism influenced changes in depression symptoms after dynamic cycling. **METHODS:** Fourteen participants (N=10, 6M/4F Val-allele group, N=4, 2M/2F Met-allele group, 64±9 years old), diagnosed with idiopathic PD were assessed with the Beck Depression Inventory (BDI-II) and provided saliva samples for BDNF Val66Met genotyping. The exercise intervention was three 40 minute dynamic cycling sessions separated by 48 hours. **RESULTS:** There were no differences in the severity or prevalence of depression symptoms at pre-intervention for Val-allele group (N=10, 11.20±12.43) or Met-allele group (N=4, 6.25±5.97) on a 0-63 scale ($P=0.468$). Four of the fourteen participants experienced moderate to severe depression symptoms: one participant - mild depression symptoms (15/63), two participants - moderate depression symptoms (22/63 and 23/63), and one participant - severe depression symptoms (38/63). Participants with moderate or greater depression symptoms had an average BDI-II score that significantly improved ($P=0.017$) from pre-intervention (24.50±9.68) to post-intervention (5.75±6.24). **CONCLUSION:** Val66Met polymorphism did not influence the presence or severity of depression symptoms and did not influence improvements in depression symptoms after dynamic cycling in individuals with mild depression symptoms. However, there was a significant improvement in participants who had moderate to severe depression symptoms regardless of the polymorphism presence. Future research will recruit individuals with PD who have moderate/severe symptoms to determine if these trends hold true in a larger sample. Supported by Kent State University's School of Health Sciences, Midwest American College of Sports Medicine, and Ohio Parkinson Foundation Northeast Region Grant.

Dynamic Cycling Improves Motor Symptoms And Mobility In Individuals With PD

Angela L. Ridgel, Dana L. Ault. *Kent State University, Kent, OH.* (Sponsor: Ellen Glickman, FACSM)
 Email: aridgel@kent.edu
 (No relationships reported)

Parkinson's disease (PD) affects more than one million people in the US and this number is expected to double by 2040. PD is a progressive neurodegenerative disease that leads to difficulties in performing activities of daily living, such as balance and walking. Dynamic high cadence cycling is a unique rehabilitation modality that has been shown to improve motor function in individuals with idiopathic PD after three sessions. **PURPOSE:** To assess if six bouts of dynamic cycling, on a custom motorized recumbent cycle, improves motor function and mobility in individuals with PD. **METHODS:** Individuals were randomized to either a dynamic cycling or a stretching group. Dynamic cycling consisted of a 5 minute warm-up at 50 revolutions per minute (rpm), 30 minutes of dynamic high cadence cycling between 75-85 rpm, and a 5 minute cool down. Motor function, balance and gait were assessed after every cycling bout using the UPDRS Motor III scale, Kinesia One, and Timed up and Go (TUG). **RESULTS:** Six bouts of dynamic cycling significantly improved UPDRS III scores ($p=.001$), hand movement amplitude ($p=.002$) and TUG time ($p=.005$) from baseline testing to end of treatment. There was a 17% improvement in UPDRS scores and a 22% improvement in TUG time from baseline testing to end of treatment. **CONCLUSIONS:** Six bouts of dynamic cycling improves motor symptoms, overall motor function and mobility in individuals with PD. These findings suggest that dynamic cycling could be a valuable rehabilitation modality in this population.

Cerebellar Transcranial Direct Current Stimulation For Motor Function In Parkinson's Disease

Lidio Lima de Albuquerque, Katherine Fischer, Song Vo, Merrill Landers, Brach Poston. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: John C. Young, FACSM)
 Email: limadeal@unlv.nevada.edu
 (No relationships reported)

INTRODUCTION: Cerebellar transcranial direct current stimulation (c-tDCS) is a non-invasive brain stimulation technique that has been shown to acutely increase motor performance in healthy populations. Since altered cerebellum activity contributes to Parkinson's disease (PD) pathology, anodal c-tDCS may improve motor function in PD. **PURPOSE:** The purpose of this study was to determine the long-term influence of c-tDCS on motor learning and transfer of motor learning in PD. **METHODS:** The study was a sham-controlled, double-blind, between-subjects design. Twelve PD patients were allocated to either a c-tDCS group or a SHAM group. Practice consisted of 9 daily sessions involving performance of a complex, visuomotor precision grip task (PGT) with their most affected hand during either c-tDCS (25 minute duration, 2 mA current strength) or SHAM. The PGT involved matching a target sine wave (target force range: 5-35% of maximum) for 10 trials in each session. PGT performance was quantified as the average force error relative to the target force. Transfer tasks were performed in 2 testing sessions performed before and after the 9 practice days and included the Unified Parkinsons Disease Rating Scale Part III (UPDRS) and the Jebsen Taylor Hand Function Test (JTT).

RESULTS: For the PGT, there was no difference in the percentage decrease in force error between groups from the 1st to the 9th practice sessions ($P = 0.64$; c-tDCS 29 ± 13%, SHAM 28 ± 14%). For the JTT, the main effect for Group was not significant ($P = 0.37$; c-tDCS 37 ± 8 sec, SHAM 33 ± 5 sec). Furthermore, the main effect for Test was not significant ($P = 0.42$; Test 1 35 ± 6 sec, Test 2 35 ± 7 sec). Finally, the Group x Test interaction was not significant ($P = 0.58$). For the UPDRS, the main effect for Group was not significant ($P = 0.53$; c-tDCS 18 ± 4 pts vs SHAM 18 ± 9 pts). Furthermore, the main effect for Test was not significant ($P = 0.38$; Test 1 19 ± 7 pts, Test 2 17 ± 7 pts). Finally, the Group x Test interaction was not significant ($P = 0.07$). **CONCLUSION:** These findings indicate that long-term c-tDCS does not seem to elicit improvements in motor learning or transfer of motor learning in PD. Therefore, c-tDCS may not be as effective as tDCS applied to the motor cortex in PD. The first author is a CAPES PhD student grantee (BEX 13509/13-6) This research was supported by a CTR-IN Pilot grant to Brach Poston.

The Effects of Water Aerobics Exercise on Cerebral Perfusion in Multiple Sclerosis

Brandon S. Pollock¹, Jennifer Petersen¹, Hayden Gerhart², John McDaniel¹, Mary Beth Spitznagel¹, Angela Ridgel¹. ¹*Kent State University, Kent, OH.* ²*Indiana University of Pennsylvania, Indiana, PA.*
 Email: bpolloc5@kent.edu
 (No relationships reported)

PURPOSE: To determine the effects of a 7-day water aerobics exercise intervention on the cerebral hyperemic response to a cognitive task in individuals with MS. **METHODS:** Thirty-one individuals diagnosed with MS were assigned to either an exercise group (N = 17) or a non-exercise group (N = 14). The non-exercise group maintained normal activity for the 7 days, while the exercise group participated in 1 hour of water aerobic exercise on each of the 7 days. Oxygenated hemoglobin (O₂Hb), deoxygenated hemoglobin (HHb), and total hemoglobin (tHb) were measured using near-infrared spectroscopy at rest and during a cognitive task prior to and after the 7 day period. For both groups, paired samples t-tests were used to compare differences in O₂Hb, HHb, and tHb from rest to cognition before and after the 7 days. **RESULTS:** There was no significant difference between O₂Hb from rest to cognition at pre-testing ($t(16) = -1.91, p = 0.07$), however O₂Hb significantly increased from rest during cognition at post-testing ($t(16) = -2.30, p = 0.04$). For the control group, O₂Hb significantly increased from rest during cognition at pre-testing ($t(13) = -2.51, p = 0.03$), but there was no significant difference between O₂Hb from rest to cognition at post-testing ($t(13) = -1.6, p = 0.13$). **CONCLUSIONS:** Water aerobics exercise could be a useful therapy for improving the cerebral hyperemic response to cognition in individuals with MS, which may help offset the cerebral hypermetabolic effects of the disease.

Effect Of Aquatic-treadmill Training On Cerebrovascular Function In Community-dwelling Stroke Survivors: A Pilot Study

Samuel J.E. Lucas, Karen Thomas, Rachel L. Wright, Jill R.E. Ramsay, Alexandra L. Medwell, Claire V. Burley. *University of Birmingham, Birmingham, United Kingdom.* (Sponsor: Professor Damian Bailey, FACSM)
 Email: s.j.e.lucas@bham.ac.uk
 (No relationships reported)

Exercise-induced increases in brain blood flow are a key mechanistic pathway for improved brain function through regular exercise. Water-based exercise augments this response and therefore may represent an optimal exercise strategy to target this mediator of improved brain health, particularly for those with impaired cerebrovascular vascular function such as stroke survivors. While aquatic treadmill exercise has been reported to improve gait re-education in stroke rehabilitation, no research has assessed whether cerebrovascular function in stroke survivors is improved following water-based training. **PURPOSE:** To examine the effect of a 4-wk aquatic treadmill (ATM) training intervention on cerebrovascular responsiveness in community-dwelling stroke survivors. **METHODS:** Six community-dwelling stroke survivors (58 ± 11 yrs), with chronic stroke (>6 months), completed a 4-wk ATM training intervention of 30 min water-based walking, 3 times/wk. Before and following the intervention, resting cerebral blood flow velocity (Transcranial Doppler) of the stroke affected and unaffected cerebral hemispheres was assessed along with cerebrovascular responsiveness, as indexed from the percent change in middle cerebral artery blood velocity (MCAv) to a 4-min hypercapnic stimulus (5% CO₂ in air). ANOVA was used to compare pre and post intervention measures. **RESULTS:** Pre-training resting MCAv was similar between the affected and unaffected side (mean ± SD: 46 ± 12 vs 46 ± 19 cm/s, respectively; $p=0.96$), and the

WEDNESDAY, MAY 31, 2017

4-wk intervention did not change this relation ($p=0.42$) nor significantly change the resting MCAv value (post training: 47 ± 11 vs 52 ± 15 cm/s; $p=0.29$). MCAv- CO_2 responsiveness increased by 40% in the affected hemisphere (2.8 ± 1.9 to 4.2 ± 1.8 %MCAv / mm Hg $P_{\text{ET}}\text{CO}_2$) and 65% in the unaffected hemisphere (3.0 ± 1.1 to 4.9 ± 0.9 %MCAv / mm Hg $P_{\text{ET}}\text{CO}_2$) following the 4-wk intervention, although this main effect did not reach statistical significance ($p=0.08$) nor was there statistical support for a differential increase between hemispheres (interaction effect: $p=0.41$).

CONCLUSIONS: This pilot study supports ATM training as a feasible option in stroke rehabilitation, and shows promising potential of enhanced cerebrovascular function for stroke survivors in this chronic phase of the rehabilitation pathway.

Effect Of Multidirectional And Unidirectional Exercises On Brain Blood Flow Activation In Chronic Stroke Patients

Eunkyung Park¹, Kyungock Yi², Youngsoo Jin³, Chang-Hyun Park², Soojin Yoo⁴, Jaehyun Yoo⁵, Yoonjung Park¹. ¹University of Houston, Texas, TX. ²Ewha Womans University, Seoul, Korea, Republic of. ³Konkuk Medical College, Seoul, Korea, Republic of. ⁴University of Texas Rio Grande Valley, McAllen, TX. ⁵Sahmyook University, Seoul, Korea, Republic of.
 Email: jennyjjang1004@gmail.com
 (No relationships reported)

PURPOSE: Recent studies reported that repetitive unidirectional exercise therapy (UET) like treadmill-walking stimulates subcortical brain areas and the cerebellum. UET may stimulate plasticity of the central nervous system by increasing blood flow in this area and hence increasing neuronal activity. The aim of this study was to examine the effects of two different types of exercise on brain blood flow activation in chronic stroke patients: multi-directional training using a half-dome ball and an aero-step (MET) versus UET on a treadmill. **METHODS:** Twenty chronic stroke patients were randomly assigned to two 12-week exercise programs, MET ($n=10$, 50.9 ± 15.0 yrs) or UET ($n=10$, 58.3 ± 12.1 yrs). Activation of blood flow in the brain was measured during leg movement using functional magnetic resonance imaging (fMRI) at baseline and after 12 weeks of exercise. The MET consisted of using a half-dome ball and an aero-step at 85% of maximal heart rate for 1h/day, 3days/week. SPM5 (<http://www.fil.ion.ucl.ac.uk/spm/>) was used for preprocessing and statistical analysis of the fMRI data ($p < 0.001$). Paired T-tests were used to analyze differences between pre- and post-exercise results ($p < .001$). **RESULTS:** Both MET and UET groups showed a significant increase in activation of blood flow after exercise training. However, there was no significant difference between MET and UET in the total area of activation of blood flow in the brain. While it was not statistically significant, the fMRI analysis reveals different patterns of activation: in the MET group, the most highly activated areas were motor movement and posture control ($t=10.54$, $t=8.6$, $t=8.12$, $p < .001$), while in the UET group, the highly activated areas were somatosensory functions ($t=13.10$, $t=10.08$, $t=3.95$, $p < .001$). **CONCLUSION:** Our finding suggest that although both MET and UET exercise program enhanced blood flow to the brain in chronic stroke patients, MET exercise promotes more activation in submotor areas responsible for unilateral involuntary motor movement and posture control.

Influence of Aerobic Exercise Intensity on Acute Changes in Motor Activation Post-Stroke

Connor M. Jansen¹, Dustyn Whitesel¹, Colleen Meyrose¹, Jennifer Westover¹, Daniel Carl¹, Jane Khoury², Brett Kissela¹, Kari Dunning¹, Pierce Boyne¹. ¹University of Cincinnati, Cincinnati, OH. ²Cincinnati Children's Hospital Medical Center, Cincinnati, OH.
 (No relationships reported)

Based on evidence among healthy adults, it has been proposed that aerobic exercise (AEX) could acutely activate the brain in ways that facilitate motor learning post-stroke. However, the acute effects of AEX on cortical motor activation have not been well described, and no previous studies have assessed the influence of aerobic intensity on this response among persons with stroke.

PURPOSE: To investigate the effect of AEX intensity on acute cortical motor activation among persons with chronic hemiparetic stroke.

METHODS: Using a crossover design, 10 subjects (5 male; mean \pm SD age, 60.1 ± 8.1 years; 6.1 ± 4.3 years post stroke; comfortable walking speed, 0.69 m/s [$52 \pm 25\%$ normal]; VO_2peak , 16.6 ± 3.4 mL/kg/min [$67 \pm 14\%$ normal]) performed one 20 minute session of moderate-intensity treadmill AEX (peak speed, 0.69 ± 0.30 m/s; mean VO_2 , $55 \pm 14\%$ VO_2peak ; blood lactate at end of session, 1.5 ± 0.5 mmol/L) and one 20 minute session of high-intensity treadmill AEX (1.29 ± 0.41 m/s; $62 \pm 15\%$ VO_2peak ; 5.7 ± 3.2 mmol/L) in random order, at least one week apart. High-intensity AEX used an interval training strategy involving 30 second bursts at maximum safe treadmill speed alternated with 30-60 second rest periods. Cortical motor activation

threshold of the paretic quadriceps femoris was measured immediately before and after each AEX session using transcranial magnetic stimulation. A fixed effects model to incorporate the crossover design was used to examine between-protocol differences in change.

RESULTS: During moderate-intensity AEX, motor threshold increased from 78.2 ± 2.2 to $81.4 \pm 2.2\%$ maximum stimulator output (MSO), indicating decreased paretic motor activation. During high-intensity AEX, motor threshold decreased from 80.6 ± 2.2 to $77.3 \pm 2.2\%$ MSO, indicating increased paretic motor activation. The between protocol difference was statistically significant ($p=0.037$).

CONCLUSIONS: In chronic stroke, high-intensity AEX (above the lactate threshold) appears to acutely increase paretic motor activation significantly more than moderate-intensity AEX (below the lactate threshold), which may have the opposite effect. Further studies are needed to confirm this finding in a larger sample and to determine whether this acute motor activation from high-intensity AEX can be used to improve motor outcomes following stroke.

CN-NINM Intervention For The Neurorehabilitation Of Disordered Speech And Emotion

Dafna Paltin, Yuri Danilov, Mitchel Tyler. University of Wisconsin, Madison, WI.
 (No relationships reported)

BACKGROUND: CN-NINM intervention combines the use of targeted exercise and non-invasive neurostimulation—delivered transcutaneously to the tongue—to enhance natural recovery mechanisms. In a case of chronic stroke, CN-NINM intervention successfully recovered speech and reversed symptoms of depression. **PURPOSE:** To evaluate the efficiency of CN-NINM intervention, using translingual neurostimulation (TLNS), in stroke patient populations. **METHOD:** The patient completed a thirteen-month intervention that consists of three components: (1) TLNS, (2) physical exercises for balance, posture and gait, and (3) speech training. For the first 6 months of the intervention this individual practiced all three components for one hour, twice daily. After 6 months of intervention, there was a 30-day withdrawal period, followed by an additional 6 months resuming the exercises, training, and device use. Improvements in speech and emotion were measured using the Dysarthria Impact Profile (DIP), the Quick Inventory of Depressive Symptoms (QIDS), and the Stroke Impact Scale (SIS). **RESULTS:** All measures demonstrated substantial improvement from baseline to end of intervention. Speech recovered by 49 percent. Depression score decreased by 10 points—a clinically significant improvement—from moderate depression to complete remission of depression. SIS scores for communication and emotion also improved by 13 and 20 percent, respectively. **CONCLUSION:** CN-NINM intervention can be used to recover and improve disordered emotion and speech in individuals with chronic stroke. These findings present a new non-invasive brain stimulation technique with applications in rehabilitative neurosciences. Additional research is necessary to understand the potential mechanisms of this phenomenon and optimize efficiency of the intervention.

Lower Extremity Function in Different Cognition Older Adults

Ian-Ju Liang, Linda L Lin, Wei-Chi Tseng, Tai-You Lin, Yen-Ting Shen. Institute of Physical Education, Health & Leisure Studies, National Cheng Kung University, TAINAN, Taiwan.
 Email: susan40935@gmail.com
 (No relationships reported)

PURPOSE: Lower extremity function is closely related to cognitive and balance impairments. Evaluate the difference of lower extremity function with different levels of cognitive impairment to find out the cognitive effects of balance functioning in community-dwelling older adults.

METHODS: Fifty-five adults aged over 60 (age: 74.36 ± 7.11 yrs, BMI: 23.43 ± 3.29 kg/m²) were divided into normal cognitive (NC, $n=17$), mild cognitive impairment (MCI, $n=16$), and dementia groups (D, $n=22$), using the SLUMS scale and physician's diagnosis. Lower extremity muscle strength (30-second chair stand test), lower extremity flexibility (chair sit-and-reach), agility/dynamic balance (8-foot up-and-go), stability score and single-leg static balance capacity were evaluated.

RESULTS: In static balance, NC group had better performance in stability score (1.77 ± 0.58 vs. 4.22 ± 2.03 , $p < 0.001$) than D group, especially in anterior-posterior side (1.57 ± 0.77 vs. 1.41 ± 1.02 , $p < 0.001$). In ankle proprioception, NC and MCI groups improved the joint position sense more slightly ($1.46 \pm 0.45/1.48 \pm 0.50$ vs. 2.07 ± 0.45 , $p=0.004$) than D group. Moreover, NC and MCI groups had significantly better performance in lower extremity flexibility ($7.5 \pm 8.56\text{cm}/8.72 \pm 6.69\text{cm}$ vs. $-2.57 \pm 10.89\text{cm}$, $p=0.001$), agility/dynamic balance ($6.08 \pm 1.52\text{sec}/6.65 \pm 1.74\text{sec}$ vs. $9.42 \pm 2.6\text{sec}$, $p=0.007$) than D group.

CONCLUSIONS: The abilities of lower extremity functioning and agility/dynamic balance may be affected by the level of cognitive impairment. We suggest that should

give priority for providing strategies of exercise intervention for balance to improve lower extremity function, especially when agility/dynamic, anterior-posterior control and ankle proprioception are limited because of early cognitive impairment.

Key words: dementia, mild cognitive impairment, muscle strength, balance, ankle proprioception

Psychophysiological Responses To Dual-task Postural Control In Older Adults After 3-month Of Cognitive-motor Intervention

Uros Marusic¹, Armin Paravlic², Mitja Gerzevic¹, Bostjan Simunic¹, Rado Pisol¹. ¹University of Primorska, Koper, Slovenia. ²University of Primorska (Institute for kinesiology research), Koper, Slovenia.
Email: uros.marusic@upr.si
(No relationships reported)

In the aging process, there is a higher competition for attentional resources during challenging/dual-task postural conditions, which consequently increases risk of falls. Fall prevention programs should therefore seek proper interventions to improve dual-task performance of the elderly. **PURPOSE:** To assess psychophysiological responses to dual-task postural control in older adults and the effectiveness of 3-month cognitive-motor intervention. **METHODS:** Thirty healthy older adults (70±6y, 76% women) were randomly divided into either 3-month cognitive-motor or control group. Postural control was monitored using a force plate (AMTI HE600600-2k, MA, USA) during quiet stance and in tandem position, both in normal and in DT conditions (subtracting three). Psychophysiological responses (heart rate and variability, breathing frequency, skin temperature and galvanic skin responses) were assessed with NeXus-10 MKII (Mind Media B.V., The Netherlands). Finally, the subjective ratings of physical and cognitive workload were assessed by Borg scale. The results were addressed by interactions of RM ANOVA at p<0.05. **RESULTS:** Significant interactions in terms of better outcomes for cognitive-motor group were found for heart rate (p=0.044) and breathing frequency (p=0.048) whereas results for postural sway failed to reach statistical significance (non-significant trend p=0.097). Furthermore, subjective ratings were increased in both groups with increased postural difficulty (p<0.05). Finally, the cognitive-motor group revealed higher accuracy of secondary (cognitive) task while balancing at the end of the intervention (p=0.032). **CONCLUSION:** Aging process is associated with structural and functional alterations of autonomic nervous system functions that are responsible for an impaired ability to adapt to environmental challenging tasks. The present cognitive-motor intervention was identified as a potentially promising method to counteract these age-related negative adaptations. Supported by Norway Grants, Project No. 4300-472/2014

¹Appalachian State University, Boone, NC. ²Appalachian Regional Healthcare Systems, Boone, NC.
Email: zwetslootjj@appstate.edu
(No relationships reported)

Weight loss can reduce health risks associated with obesity. Team-approach interventions that involve exercise, diet, and behavioral modification have been shown to result in successful weight loss. **PURPOSE:** The purpose of this project was to evaluate the effectiveness of a hospital-based team-approach physician-referred program that enrolls community members without use of incentives. **METHODS:** Participants included obese (BMI≥30) members of the community (COM, N=48) compared to employees of the local hospital (EMP, N=88). COM were referred to the program by a Physician while EMP were provided with incentives to participate. All participants were evaluated both pre- and post- a 16-week intervention period which included regular supervised exercise sessions and monthly consults with a Registered Dietitian (RD) and a Behavioral Health Specialist (BHS). Background information collected included, sex, initial weight (kg), BMI (kg/m²), percent fat (%) using Bioelectrical Impedance, and readiness for change (RTC) evaluation (modified Brownell LEARN RTC Questionnaire). Attendance at all sessions (RD, BHS, exercise)

were recorded. If final weight was obtained, then the program was considered completed. Independent samples t-tests (p<0.05) were used to determine differences in physical characteristics between groups as well as in total weight loss. Association between consultation attendance (RD and BHS) and completion was determined by Chi-square test for independence with a Bonferroni adjustment. **RESULTS:** No significant differences were detected between participant initial characteristics. There was no significant difference in weight loss between groups (EMP=-12.29±12.56lbs vs COM=-15.58±8.08lbs, p=0.20). However, overall program completion was lower in the COM compared to EMP (58% vs. 85%, respectively). In the COM program a Chi-square test revealed a significant association only between attending BHS consultations and program completion (X²(1,n=48), X²=6.291, p=0.01, phi=0.41). **CONCLUSION:** A team-approach weight loss program may be an effective intervention if the participants successfully complete the program. However, additional research is warranted to determine if adhering to BHS consultation visits could improve completion rates when other incentives are not offered.

Use It And Lose It: Fitbit Use, Daily Steps, And Weight Change Among Overweight Adults

Chelsea A. Larsen, Courtney M. Monroe, Delia S. West.
University of South Carolina, Columbia, SC. (Sponsor: Sara Wilcox, FACSM)
(No relationships reported)

Despite the increasing proliferation of advanced wearable physical activity tracking devices (e.g., Fitbit Zip), their value as tools for physical activity promotion and weight loss remains unclear.

PURPOSE: As part of a pilot intervention trial that examined the efficacy of a novel social support approach for enhancing weight loss, participants were provided with a Fitbit Zip to monitor their physical activity. The current study examined the relationships between Fitbit use and change in weight and daily steps over 4 months. **METHODS:** Overweight adults (N=36) were randomized to either a standard or social support-enhanced, 16-week behavioral weight loss intervention. In addition to a Fitbit Zip, both groups received weekly, in-person group counseling sessions and digital body weight scales. Participants in the social-support enhanced group received two extra Fitbits and scales to share with up to two persons in their social circle. There were no significant differences between conditions, so analyses collapsed groups and examined the full sample. Paired t-tests were used to evaluate changes in weight and daily steps from baseline to post-treatment. Spearman rank correlation coefficients were calculated to test the associations between the total number of days the Fitbit was used (out of 112 days) and changes in daily steps and weight. Fitbit use was objectively established by weekly monitoring of synced data from the Fitbit website. **RESULTS:** At baseline, participants were obese (M BMI= 36.1 + 7.3 kg/m²) and low active (M=5546 + 2390 steps/d). Weight losses averaged -3.5±4.3 kg (p<.0001) and daily steps increased an average of 1101±2395 (p=.009) over baseline. Participants used the Fitbit an average of 5.9±2.5 days/wk. A significant correlation between total number of days the Fitbit was used and weight loss such that there was greater use of Fitbit was associated with greater weight loss (r_s = -.60, p<.0001). A significant, positive correlation was found between the change in daily steps and the number of days the Fitbit was used (r_s = .43, p=.008). **CONCLUSION:** These preliminary findings suggest that advanced wearable physical activity trackers hold promise as tools for assisting with physical activity promotion and weight loss in adults within the context of a multi-component behavioral weight loss program.

(No relationships reported)

PURPOSE: The purpose of this study was to evaluate the efficacy of the Lifestyle Enhancement Program, a two arm, parallel group, randomized clinical trial comparing community-based physical activity (PA) program to a wellness control program as adjunctive smoking cessation treatment.

METHODS: All participants (n=392) received cessation counseling and the nicotine patch and were randomized to PA (n=199; YMCA membership and personalized exercise programming from a health coach) or an equal contact wellness curriculum (n=193). Primary (CO-verified continuous smoking abstinence) and secondary (PA

levels) outcomes were assessed at baseline, 7-week, 6- and 12-months. Indices of treatment perception, adherence, abstinence rates, and PA levels were compared between groups using chi-square analyses and ANOVA.

RESULTS: Smoking abstinence in the PA and wellness groups were 18.6% and 23.8%, respectively at 7 weeks, 15.1% and 16.1% at 6 months, and 14.1% and 16.6% at 12 months. Between group differences did not significantly differ from each other (all *p*-values > 0.18). In the PA group, increases from baseline to 7 weeks were observed for total minutes of PA/week (97.8 min to 145.2 min; *p*<.01) and total minutes of strength training/week (12.8 to 29.7; *p* < 0.005). For the PA group, total PA and strength training were not different at 6 and 12 months compared to baseline, and no changes at any follow-up were observed in the wellness group. Intervention session attendance over the year averaged 63% for the PA intervention and 72% for the wellness (*p* < 0.001). Participants in both the PA and wellness conditions found the intervention to be “very helpful” in quitting smoking [85% and 83% respectively (*p* = 0.20)]. Time commitment to the program was considered to be “not at all a burden” [88% in both conditions (*p* = 0.84)]. Participants indicated they would “strongly agree” to recommend the program to a friend [95% and 92% respectively (*p* = 0.06)]. **CONCLUSIONS:** A combination of individual smoking cessation counseling, nicotine replacement therapy, and a community-based PA or wellness program was acceptable to smokers but did not appear to improve long-term abstinence rates above what has been seen with nicotine replacement therapy in previous studies. Grant funded: PHS Grant R01 HL068569

Gesture Analysis for Yoga Alignment in Young Adults
 Paula R. Pullen, 30566¹, Nataly Gonzalez¹, William Seffens².
¹University of North Georgia, Oakwood, GA. ²Moorehouse School of Medicine, Atlanta, GA. (Sponsor: Walter R. Thompson, FACSM)
 Email: paula.seffens@ung.edu
 (No relationships reported)

Introduction: Biomedical research aimed toward a deeper understanding of yoga’s benefits and physiological mechanisms has become an active area of study. To decrease disparity between populations who can readily access yoga classes and therapies, benefits of yoga could be implemented in an exergame format at clinical or home environments. This platform could be installed with low cost hardware using the Cloud for analytics and data collection. **Purpose:** Objective was to analyze yoga posture alignment using a 3D room sensor to produce a physical activity exergame for specific groups, such as young adults. This research utilizes gesture analysis software to provide skill improvement feedback to students in a yoga course setting. **Methods:** We measured yoga posture alignment over the course of a 10-week period using Kinect SDK 2.0. A convenience sample of 12 undergraduate students with minimal yoga experience were recruited under an IRB approved protocol. **Results:** Five yoga postures were captured from seven yoga teachers, as a gold standard for comparison and used for training supervised machine learning algorithms. Default settings in Kinect Visual Gesture Builder produced solutions with high True Positives (99.5%) and low False Positives (0.03%) for most yoga postures sampled. Depth stream and skeleton coordinates for the 12 participants were acquired and analyzed against this trained solution. Analysis showed sensitivity for True Positives was greatest for “Side Bend” (0.496) and “Upward Salute” (0.141) and most postures had specificities for True Negatives near 1.0. Based on these results the higher the gesture score, the closer the postures were to the “gold standard”. **Discussion:** Gesture analysis for yoga alignment training may be a useful tool for the development of home and clinical yoga therapy for hard to reach populations. The exergame developed here provides a tool that scores the performance of yoga postures and improvement. Prior research has shown that even short-term yoga based lifestyle interventions were efficacious in weight loss, inflammation and stress and positively influenced cardiovascular risk factors. **Conclusion:** Our plans are to target special populations, study the potential effects of body mass and age on posture alignment, and assess breathing, heart rate and limb stretch.

Effects of a Dog Walking Intervention on a University Campus: A Pilot Study
 Melanie Sartore-Baldwin¹, Jaclyn Baker¹, Lacey Schwab¹, John Crenshaw¹, Maria D’Amico¹, Bhibha Das¹, Matthew Mahar, FACSM². ¹East Carolina University, Greenville, NC. ²San Diego State University, San Diego, CA.
 (No relationships reported)

A great deal of research has focused on implementing walking interventions with the intent of increasing employee well-being and decreasing organizational healthcare costs. The inclusion of dogs within a walking intervention can not only facilitate walking adherence, but also increase health benefits. **PURPOSE:** To assess the benefits experienced by university staff members after walking local shelter dogs during their lunch breaks. **METHODS:** Staff members at a local university were

recruited through a campus listserv. Seven full-time staff members (100% female, 100% white, 27-66 years of age) completed the study. Shelter dogs were transported to campus weekly for four weeks in the Spring of 2016. One week was canceled due to rain. Participants were paired and instructed to walk their assigned dog for 30 minutes using the sample walking routes provided. Accelerometer data (hip-worn ActiGraph GT3X) were collected during each walk to document intensity levels and post-intervention interviews were conducted upon completion of the study to assess participant’s perceived benefits from the intervention. **RESULTS:** Eighty-six percent of participants completed all walking sessions. Participants averaged 24.9 ± 7.4 minutes of moderate-to-vigorous physical activity (range 12-37 min) during the walk. Interview data revealed that participants sat anywhere from 3-7.5 hours out of their 8-hour workday. Participants self-reported being somewhat physically active outside of the workplace setting, but all wanted to find ways to be more physically active throughout the workday. Thematically, qualitative analysis suggested that participants signed up for the study because of their love of dogs, looked forward to their Friday walks, had fun during the walks, returned to work happy, and wanted the program to continue. **CONCLUSION:** Incorporation of dogs into a university-based walking program can encourage program adherence and promote moderate intensity walking among women staff members.

Effects Of Elastic Resistance Band Exercise On Older Women With Nonspecific Chronic Low Back Pain
 Nicole L. Rogers¹, Nicole B. Fritz², Phil Page, FACSM³, Andres Bello², Pia Altamirano², Jorge Flandez², Juan C. Colado⁴, Michael E. Rogers, FACSM¹. ¹Wichita State University, Wichita, KS. ²Universidad Austral, Valdivia, Chile. ³Louisiana State University, Baton Rouge, LA. ⁴University of Valencia, Valencia, Spain. (Sponsor: Michael E. Rogers, FACSM)
 (No relationships reported)

Nonspecific chronic low back pain (NCLBP) is a common ailment in older adults. It is possible that simple and inexpensive exercise programs could reduce pain and improve physical function, fitness and body composition in older women with NCLBP. **PURPOSE:** To analyze the effects of a short-term elastic band resistance program (EBRP) on pain, spine function, fitness and body composition in older adults with NCLBP. **METHODS:** 20 sedentary older women (70.9±5.9 yr) with NCLBP for at least of 6 months were randomly divided into two groups: control group (CG) (n=9) that continued normal activities without exercise; and EBRP group (EBRPG) (n=11) that performed an 8-wk EBRP on 2 d/wk with 6 multi-articular standing exercises for upper and lower extremities for 4 sets of 10 repetitions (8-9 perceived effort) with 60 s of recovery between sets. Participants did not consume any nutritional supplements and none had any pathology that was currently being treated. Measures assessed pre- and post-training were: visual analogue scale of pain (VAS); Oswestry disability index (ODI); categorized sciatica pain (CSP); back performance tests: pick and lift repetitions tests (PT and LRT, respectively); Schober flexion’s test (SFT); timed up and go test (TUGT); six-minute walk test (6MWT); isometric strength tests: vertical row (VRT), squat (SQT) and trunk curl (TCT); body fat percentage (BF) and fat-free mass (FFM) (via bioelectric impedance). **RESULTS:** CG did not change from pre- to post-testing while EBRPG significantly (*p*<0.05) improved all variables analyzed. Percentage differences are provided for CG and EBRPG, respectively: VAS +9.4 vs. -70.3; ODI +6.0 vs. -49.1; CSP +4.2 vs. -100; PT +66.7 vs. -85.7; LRT -4.2 vs. +26.4; SFT -2.6 vs. +4.6; TUGT -2.74 vs. -25.4; 6MWT -1.5 vs. +16.6; VRT -7.2 vs. +14.1; SQT -5.2 vs. +23.5; TCT -14.8 vs. +33.2; BF +1.6 vs. -2.4; FFM -1.1 vs. +2.44. Intergroup post-training significant differences were found on VAS, ODI, CSP, PT, LRT, and TUGT. **CONCLUSION:** An intense EBRP applied in a short time period appears to help reduce pain and improve spine function, physical fitness and body composition in older women with NCLBP. Further research is needed regarding the long-term impact of this program on NCLBP.

198 Board #19 May 31 11:00 AM - 12:30 PM
Effects of Combined Aerobic and Resistance Training: A Randomized Controlled Trial
 Susumu S. Sawada, FACSM¹, Michiya Tanimoto², Yuko Gando¹, Haruka Murakami¹, Ryoko Kawakami³, Hitomi Tsuda⁴, Hikaru Saito⁴, Steven N. Blair, FACSM⁵, Motohiko Miyachi¹. ¹National Institutes of Biomedical Innovation, health and Nutrition, Tokyo, Japan. ²Kindai University, Osaka, Japan. ³Waseda University, Saitama, Japan. ⁴Curves Japan Co., Ltd., Tokyo, Japan. ⁵University of South Carolina, Columbia, SC.
 Email: yusumi@gmail.com
Reported Relationships: S.S. Sawada: Contracted Research - Including Principle Investigator; Curves Japan Co., Ltd.

Limited data are available on the effect of combined aerobic and resistance training (combined training) in Asian populations.

PURPOSE: To determine the effect of combined training on fatness and fitness outcomes, including body fat mass, waist circumference, muscle strength, and flexibility; and also clinical outcomes, including blood pressure, brachial-ankle pulse wave velocity and fasting blood glucose in Japanese women.

METHODS: Forty-one women were randomized to a training group, n = 23 (age 47.3 ± 6.5 years) or control group, n = 18 (age 46.7 ± 6.5 years). The intervention included participation in a 24-minute circuit training session (combining aerobic and resistance training, each of which lasted 30 seconds) and 6-minute stretching 3 times per week for 16 weeks. The aerobic exercise was stepping on a step board while executing resistance training, using 12 different hydraulic devices developed for females to increase their muscle strength. During this training, the participants measured their heart rates once every 8 minutes based on the instructor's guidance to maintain them at 60 to 80% of their maximal heart rates throughout training by adjusting training intensity levels. All outcomes were measured at baseline and after the intervention.

RESULTS: Although there was no statistically significant change in the control group, there were significant reductions in waist circumference (91.0 ± 6.3 to 89.8 ± 6.5 cm) (p = 0.045), systolic blood pressure (127.5 ± 18.9 to 123.3 ± 19.5 mmHg) (p = 0.038), fasting blood glucose (101.0 ± 19.4 to 95.3 ± 13.2 mg/dL) (p = 0.015), and brachial-ankle pulse wave velocity (1315 ± 181 to 1271 ± 173 cm/s) (p = 0.009) in the combined training group. Also, significant increases in the knee extension strength (858 ± 184 to 1140 ± 216 watts) (p < 0.001) and flexibility (33.7 ± 6.4 to 35.9 ± 6.4 cm) (p < 0.001) only in the training group.

CONCLUSIONS: The results of this randomized controlled trial showed that a 16-week combined training significantly improved the fatness and fitness outcomes and the clinical outcomes in Japanese women.

199 Board #20 May 31 11:00 AM - 12:30 PM
Combination Of Sling Exercise Training And Nutritive Administration Of Carbohydrates And Protein By Food As A Strategy To Increase Strength In Older Men And Women

Patrick Diel, Gina Kiewardt. *Geman Sports University Cologne, Cologne, Germany.*
 Email: diel@dshs-koeln.de
 (No relationships reported)

PURPOSE: After the age of 60, muscle strength is reduced by 1-1.5% per year increasing to 3% per year. However, strength training can counteract age related loss of strength. Sling training, a specific type of strength training, has positive effects on balance and functional mobility. However, knowledge about its effects on force and strength is limited. Malnutrition may be part of aging; especially the uptake of proteins can be below nutrition recommendations which may result in reduced muscle mass. Therefore we investigated in this study combined effects of protein and carbohydrate intake by food immediately after sling training on the training response in older people.

METHODS: 31 subjects (25 female and 6 males, age: 65.9 ± 4.9) conducted a sling training (three times 30 minutes per week for 12 weeks). Immediately after training the intervention group received a meal consisting of 110 g sour milk cheese with two slices of whole meal toast and 250 ml of buttermilk. The nutritional values of these meal consisting of 38.95 g protein, 23.2 g carbohydrates and 2.9 grams of fat (= 1190 kJ / 278.5 kcal). Prior and after the intervention, maximum strength of trunk and leg muscles was tested.

RESULTS: Sling training resulted in a significant increase of strength in the control group as well as the intervention group. Average strength increased between 20 to 30% for leg and chest strength up to 40% to 130% for trunk strength (ventral, dorsal and lateral). For all kinds of trunk strength nutritive protein carbohydrate uptake resulted in an additive training effect which was significant for the left lateral trunk strength. Interestingly all volunteers like to have a common meal after training.

CONCLUSIONS: Our results indicate that a combination of sling training and nutritive protein and carbohydrate uptake by food may be a suitable strategy to counteract age related loss of strength and muscle mass and improve the quality of life in the elderly.

200 Board #21 May 31 11:00 AM - 12:30 PM
Effect of a Group Exercise Program in Symptoms of Depression and Physical Activity: Pilot Study

Wilfredo Feliciano-Hernández, Lucía R. Martínez-Colon, Mercedes Rivera-Morales, Farah A. Ramírez-Marrero, FACSM. *University of Puerto Rico-Río Piedras Campus, San Juan, Puerto Rico.*
 (No relationships reported)

Depression has the highest incidence among mental illnesses. Physical activity (PA) and exercise has been associated with lower symptoms of depression (SD). However evidence of the effectiveness of a group exercise program combining aerobic and resistance exercise in this population is scarce. **PURPOSE:** To evaluate the effect of a 6-weeks group exercise program combining aerobic and resistance exercise in SD and moderate to vigorous physical activity (MVPA). **METHODS:** Seven college students

(5 females and 2 males, 21 (21-23) years of age) with a score ≥ to 17 in the Beck's Depression Inventory-II (BDI-II) volunteered for the study. Participants underwent a 3 day per week combined aerobic and circuit resistance 6 week group exercise program. Before and after the exercise program participants completed the BDI-II and wore an accelerometer for 7 days. Tests to assess health related physical fitness (HRF) were also performed (% body fat, VO₂ max, leg and chest 1RM/lb body weight, isometric relative strength, push-ups and curl-ups) and results converted into a score. Wilcoxon Signed Rank were conducted to determine differences between pre- and post-tests, and Spearman's correlations to determine associations between SD, PA and HRF.

RESULTS: Differences were found between pre- and post BDI scores (pre=26 (23 - 27) vs. post=7 (5 - 9), p = 0.02), MVPA (pre= 275.5 (255.63 - 296.27) min/week vs. post= 250.55 (150.27 - 243.43) min/day, p = 0.04), and HRF scores (pre= 4 (4 - 6) vs. post= 7 (6 - 9), p = 0.02). Differences were also found between pre- and post HRF results: % body fat (pre= 34.4 (25.2 - 48.5) vs. post=28.8 (24.4 - 48.4)%, p = 0.02), VO₂ max (pre=23.5 (21.1 - 27.6) ml/kg*min⁻¹ vs. post= 27.2 (21.2 - 29.9) ml/kg*min⁻¹, p = .03), 1RM bench press (pre=.43 (.41 - .83) lb/bw vs. post=.50 (.48 - .97) lb/bw, p = 0.02), 1RM leg press (pre=1.51 (1.36 - 2.44) lb/bw vs. post= 1.99 (1.84 - 2.68) lb/bw, p = 0.02), and push-ups (pre=5 (3 - 13) vs. post=11 (4-20), p = 0.02). No significant correlations were found between SD, PA and HRF. **CONCLUSION:** A 6-week group exercise program can help achieve a reduction of SD and can improve the HRF components in young adults with SD. Exercise training plays an important role in the reduction of SD in physically active young adults.

201 Board #22 May 31 11:00 AM - 12:30 PM

A 12-week Modified Tabata Exercise Program On Functional Fitness For The Elderly: A Pilot Study

Lee-hwa Chen, Jhih-Syuan Liou. *National Taiwan Sport University, Taoyuan, Taiwan.*
 Email: lhchen@ntsuo.edu.tw
 (No relationships reported)

PURPOSE: This preliminary study sought to examine the impact of a 12-week modified TABATA circulative exercise program on functional fitness in an elderly population. **METHODS:** Subjects were community-dwelling older adults over the age of 60. They were recruited using flyers or telephone calls from a local community facility in New Taipei City. Subjects were consented and evaluated by a set of functional fitness tests at baseline and post intervention. The modified TABATA exercises incorporating squatting, forward lunge, heel raise, and table plank were conducted in a circular fashion with a 110 bpm music in the background. The exercise-to-rest ratio were 30:30, 30:20, and 40:20 seconds during the 1st -6th, 7th -10th, and 11th -12th week respectively using the high-knee stepping and side stepping in the rest sessions alternatively. This modified TABATA was implemented weekly for 12 weeks for an average duration of 50 minutes each time. The non-parametric Wilcoxon signed rank test was conducted to detect the pre-and-post differences in all functional fitness tests. Significant level was at α = .05. **RESULTS:** A total of 14 subjects were recruited. Ten (2 male and 8 female) of the participants aged 69.2 ± 5.7 years old completed both pre and post tests with an average attendance rate of 87.8%. After the once-a-week modified TABATA exercise program for 12 weeks, significant differences were found in % body fat (p=0.03), hand grips (left) (p=0.015), 30-seconds chair rise (p=0.007), chair sit-and-reach (left: p=0.033; right: p=0.028) and 2-minute stepping (p=0.012). **CONCLUSIONS:** With some little modification, TABATA exercise can be safe and feasible for older population. Specifically, it might be even more beneficial in prevention of the general deterioration in lower limb flexibility and muscular strength, and also the cardiorespiratory fitness normally occurred with age.

Keep Up The Good Work: Does Enrolling In An Exercise Program Influence Other Behaviors?

Vincenzo Lauriola¹, Kathleen McIntyre¹, Tse-Hwei J. Choo¹, Martina Pavlicova¹, Richard P. Sloan¹, Carol E. Garber, FACSM². ¹Columbia University, New York, NY. ²Teachers College, Columbia University, New York, NY.
 Email: lauriol@nyspi.columbia.edu
 (No relationships reported)

Many agencies promote a healthy "lifestyle" but this comprehensive vision of wellness contrasts with interventions targeting specific health behaviors. However, initiation of a new health behavior could promote, consciously or unconsciously, the modification of a second health behavior.

PURPOSE: To investigate if participation in an exercise program promotes spontaneous dietary modification. **METHODS:** Ninety-eight healthy, sedentary adults (53% female, aged 31.4±6.1 years; baseline BMI 25.0±3.9) were randomized to either 12 weeks of aerobic exercise training (n=44) - 4 days/week for 45 min at an intensity of 80-85% of maximal heart rate followed by 4 week deconditioning - or wait list control (n=54). A Food Frequency Questionnaire was administered at baseline and weeks 12 and 16, to derive caloric intake (Kcal), Alternate Mediterranean Diet Index (aMed), and Macronutrients

(Protein, Fat, Carbohydrate) intake. Repeated measures tested treatment, session, and their interaction as predictors with diet measure (Kcal, aMed, Protein, Fat, or Carbohydrate) at Wk12 and Wk16 as the response variables. All models were adjusted for the baseline value of the response variable and were repeated adjusting for gender. **RESULTS:** Both the exercise (Ex) and the waitlist (WL) groups significantly decreased, from baseline to week 16, mean caloric intake (Ex: $\Delta=-232.43\text{cal}$, $p<.01$; WL: $\Delta=-219.89\text{kCal}$, $p<.01$), mean protein intake (Ex: $\Delta=-11.26\text{g}$, $p<.01$; WL: $\Delta-9.42\text{g}$, $p<.01$), mean fat intake (Ex: $\Delta=-7.42\text{g}$, $p=.04$; WL: $\Delta=-8.29\text{g}$, $p<.01$), and mean carb intake (Ex: $\Delta=-24.00\text{g}$, $p<.01$; WL: $\Delta=-24.28\text{g}$, $p<.01$). No significant change in aMed over time was found for either group (Ex: $\Delta=-.31$, $p=.24$; WL: $\Delta=-.35$, $p=.05$). There were no significant difference between the groups in any of the 5 diet measures ($p>.65$).

CONCLUSIONS: Despite this intervention's singular focus on aerobic training, both groups showed a marked reduction in KCal and Macronutrients. Sedentary participants willing to enroll in an exercise study may already be in the action stage of behavior change and may independently elect to change dietary behavior to improve overall wellness. Future studies should investigate what psychological triggers lead to a behavioral "spillover" and if the degree of engagement in the primary behavior could predict the magnitude of the "spillover".

Effects Of Participating In Sports Events Through Exercise Class On The Establishment Of Exercise Habits
Kenta Kitamura¹, Yasutomi Katayama¹, Kiyoji Tanaka, FACSM².
¹Kogakkan University, Ise, Japan. ²University of Tsukuba, Tsukuba, Japan. (Sponsor: Kiyoji Tanaka, FACSM)
Email: kitamurakenta0312@gmail.com
(No relationships reported)

Participating in sports events through exercise class may be able to help goal setting, which may contribute to establishing exercise habits. **PURPOSE:** To examine the effects of participating in sports events through exercise class on the establishment of new exercise habits.

METHODS: The requirement of participants were 20- to 64-yr-old women who have not been having exercise habits and confidence to play sports for a long period of time without orthopedic and cardiovascular disease. Fifteen women participated in an exercise (EX) class (6 months, 90 min/session, twice a week) and 16 women who were recommended to participate in a weight-loss (WL) class (the first 3 months were only dietary guidance and the last 3 months were only exercise. Guidance and exercise were 90 min/session, and once a week). Two months after the EX class started, we set a goal to participate in a sports event (5 km running race or 6 km fun walking). The EX class started from low-intensity exercise (stretching and muscle strength training to load own body weight), and gradually transitioned to moderate- or vigorous-intensity exercise (walking, Nordic-pole walking, jogging or running) depending on the level of physical fitness. Ten participants finished the running race and the remaining 5 participants finished the fun walking. The WL class did not set any exercise goals. The participants' exercise habits were investigated and 3 METs or more physical activity was measured using an accelerometer after 1 year from the end of the classes.

RESULTS: The stability rate of the exercise habits was significantly higher in the EX class than in the WL class (EX, 12 participants, 80.0%; WL, 8 participants, 50.0%; χ^2 test, $p = .038$). However, 4 of the 8 participants in the WL class already had had the exercise habits before the class. In addition, 10 participants from the EX class who finished the running race last year have applied for the next year's race. However, physical activity did not differ significantly between the two classes after 1 year (EX, 4.3 ± 1.9 METs-h/day; WL, 3.8 ± 1.9 METs-h/day; t-test, $p = .466$).

CONCLUSIONS: It is concluded that when establishing exercise habits goals should be sets and making use of sports events through exercise class contribute to set definite goals easily and establish new exercise habits.

Quantitative And Qualitative Analysis Of An Individualized Consultation To Change Sedentary Behavior In The Workplace.

Alison Kirk, Ann Marie Gibson, Adrienne Hughes, David Muggeridge. *University of Strathclyde, Glasgow, United Kingdom.* (Sponsor: Dr David Rowe, FACSM)
Email: Alison.kirk@strath.ac.uk
(No relationships reported)

Independent of an individual's physical activity levels, prolonged periods of sedentary behavior are detrimental to health. Office-based workers engage in prolonged periods of sitting and are a target group for intervention. Individualized consultations have

potential to change sedentary behavior and offer a low cost alternative to interventions such as sit-to-stand desks. **PURPOSE:** To report quantitative and qualitative outcomes from a randomized controlled trial exploring the use of an individualized consultation intervention to change sedentary behavior in the workplace. **METHODS:** 48 participants (42F, 6M, mean age 42.9 ± 12.0 yrs, BMI 25.2 ± 3.8 kg/m²) were recruited from a university by workplace email and poster distribution. Participants were > 18yrs with full time desk based occupations. Participants were randomized to a control group (n=23) or an intervention (n=25) group who received a 30-45 minute individual consultation incorporating behavior change strategies to support reducing sedentary behavior. Before and after the intervention participants wore an activPAL monitor for 7 days. A sub-sample of 16 intervention participants took part in semi-structured interviews exploring intervention perceptions. **RESULTS:** No changes were reported in overall, weekday or weekend mean sitting, standing or stepping time; step count; sit-to-stand transitions or % of waking day spent sitting, standing or stepping ($p>.05$). Semi-structured interviews provided insight into participant intervention perceptions. Many participants mentioned increased knowledge and awareness of sedentary behavior and the associated physical and psychological benefits. However, several barriers to behavior change were reported including: social norms within a workplace; perceived negative opinion of colleagues; excessive workloads and deadlines and loss of concentration and productivity. **CONCLUSIONS:** The individualized consultation intervention was not effective in changing sedentary behavior. Multi-level barriers impede sedentary behavior change in the workplace. Further work is required to fully understand these complex influences on this behavior in a workplace setting to allow the development and implementation of effective interventions.

206 Board #27 May 31 11:00 AM - 12:30 PM
The Rehabilitation Effect Of Plank For Patients With Chronic Low Back Pain
wang qiang. *The Chengdu Sport's University, chengdu, China.*
Email: 657374975@qq.com
(No relationships reported)

Objective: contrast research plank on the rehabilitation effect of patients with chronic low back pain. **Methods:** choose in college affiliated hospital outpatient clinic hospital diagnosed with non-specific and income of 60 patients with chronic low back pain, single blind, randomized, controlled experiment method to are divided into conventional treatment group (zheng massage, cupping, infrared), additional McCann stomach stretch group (routine treatment added McCann base treatment of stomach stretch training) and the additional plank support training group. Three groups of subjects baseline data and evaluation index of no statistical difference before treatment, before treatment, 4 weeks, 8 weeks after treatment has been accepted Oswestry disability index (ODI) questionnaire scores and core strength tests. Data obtained by the SPSS T test and variance analysis. **Results:** 1. ODI is: before the trial, ODI scores of three groups of subjects had no significant difference, after the trial, ODI scores of three groups of participants is less than before the trial, group A $P < 0.05$, B and C group $P < 0.01$. After the trial, the ODI score of group C compared with group A score decreased, $P < 0.01$; Compared with group B score decreased, $P < 0.05$. 2. Core strength comparison: before the trial, all direction core muscle strength compared in three groups were no significant differences, after the intervention, the core strength of the C groups were all directions are also increase before experiment, $P < 0.01$; After the group B were at the core of the strength increase from before the trial, $P < 0.05$. Group C after the intervention, the direction of the core strength of group A were increased, $P < 0.01$; Is in the direction of B group were increased, among them, in the former flexion, left lateral flexion, left and right rotation strength increased significantly, $P < 0.01$. **Conclusion:** 1. Conventional treatment group, the additional plate support group, additional McCann base stomach stretch group, all three methods to different degrees of ease the pain of patients with chronic low back pain, and the latter two effect is better; 2. Plank and McCann stomach stretch training can both improve and increase the role of the core strength of patients with chronic low back pain, and tablet supported training the McCann, prone to stretch more comprehensive.

High Intensity Interval Training Improves Blood Lipid Profiles And Fatigue Resistance
Cory Bennett, Taylor Tolleson, William Beasley, Kendra Buer, Ludmila Cosio-Lima, Youngil Lee. *University of West Florida, Pensacola, FL.*
(No relationships reported)

High intensity interval training (HIIT) has merged as a novel metabolic modulator, mitigating metabolic syndrome (i.e., high blood glucose and LDL) and improving cardiovascular fitness. However, little research has been conducted, and importantly, mode, duration, and frequency of exercise remain unclear. **PURPOSE:** To investigate if HIIT improves health fitness-related biomarkers including: fasting blood glucose (FBG), resting heart rate (RHR), blood lipids, resting blood pressure (BP), and post exercise blood lactate production. **METHODS:** 13 healthy male subjects (age: 18-28 years old) were recruited in this study. Subjects were informed about the project

and allowed to familiarize with laboratory bicycle riding for two days, during which pre-test dependent variables (FBG, RHR, BP, blood lipids, maximal anaerobic power by Wingate Test, and post Wingate blood lactate) were measured. On the third day, the subject performed modified Wingate Tests with 2.5% of their body weight as the resistance (3 sets of 30 seconds with 2 minutes of active resting between sets, 3 times a week for 2 weeks). 24 hours after the last session of HIIT, the same dependent variables were assessed for post-test data collection. Results were expressed as mean ± SEM and analyzed with paired, one tail student t-test. **RESULTS:** The HIIT exercise reduced post-exercise BLA (pre-test: 11 ± 2.68; post-test: 9 ± 3.19, p<0.05), LDL cholesterol (17 ± 4.5% drop, compared to pre-test levels, p<0.05) and total cholesterol levels (9 ± 3% drop compared to pre-test levels, p<0.05), with no significant differences found in FBG, RHR or BP, and HDL cholesterol. **CONCLUSIONS:** HIIT was effective in lowering LDL and TC levels, and BLA during maximal anaerobic power exercise. Our results suggest that as reflected in long-term endurance exercise, short-term HIIT may also be a sufficient means of ameliorating cardiovascular risk factors, specifically bad cholesterol. Our results also suggest that HIIT would be effective to improve fatigue resistance evidenced by reduced lactate levels during maximal anaerobic power, which typically resulted from long-term endurance exercise. Taken together, our study supports emerging evidence that HIIT may be a potent mode of exercise contributing to preventing cardiovascular diseases.

ACSM Recommended Exercise of 30 minutes Per Day Improves Aerobic Capacity Similar to 60 minutes Per Day in Individuals with NAFLD

Erik P. Kirk, FACSM¹, Shelby Sullivan², Samuel Klein².
¹*Southern Illinois University Edwardsville, Edwardsville, IL.*
²*Washington University School of Medicine, Saint Louis, MO.*
 Email: ekirk@siue.edu
 (No relationships reported)

The effects of two different exercise doses on improving aerobic capacity (VO_{2peak}) in obese individuals with nonalcoholic fatty liver disease (NAFLD) is unknown. **PURPOSE:** The aim of this study was to evaluate the effect of the American College of Sports Medicine physical activity guidelines for adults (30min/d) on aerobic capacity compared to a high dose (60 min/d) in obese persons with NAFLD. **METHODS:** Eighteen obese people (mean ± SD, Age 46.8±5.2 years, BMI=37.3±4.9 kg/m²) with NAFLD were randomized to 16 weeks of verified exercise training (45-55% VO_{2peak} , 5 days/week) to either a low dose (LD, 30 min; n=9) or high dose (HD, 60min/day, n=9). Aerobic capacity (VO_{2peak}) was measured on a motor-driven treadmill. Participants walked to volitional exhaustion using the Balke treadmill protocol. Dual Energy X-ray Absorptiometry (DXA) was used to measure body weight (BW) and percent body fat. Magnetic resonance spectroscopy was used to evaluate (intrahepatic triglyceride) IHTG content. All measures were performed at baseline and 16 weeks. **RESULTS:** Aerobic capacity significantly (p<0.05) improved in both the LD (9.8 ± 2.8%) and HD (8.6 ± 3.0%) from baseline to 16 weeks with no significant (p>0.05) difference between groups. There were no between group differences for IHTG, BW, or percent body fat so data was combined. Exercise training resulted in a 10.5±4.7% decrease in IHTG content (p<0.05), but did not change total body weight (103.5±4.0 kg and 102.7±3.0 kg) or percent body fat (39.0 ±2.0% and 38.5±2.1%) from baseline to 16 weeks. **CONCLUSION:** Performing verified physical activity as recommended by the ACSM improves aerobic capacity, IHTG, and body composition similarly to a higher exercise dose of 60min/day in obese persons with NAFLD.

Types of Social Support and Weight Change among Overweight Adults

Courtney M. Monroe, Chelsea Larsen, Delia West. *University of South Carolina, Columbia, SC.* (Sponsor: Sara Wilcox, FACSM)
 Email: cmmonroe@mailbox.sc.edu
 (No relationships reported)

Engaging social support has been found to be an effective strategy to promote weight loss. Yet, little is known about the specific types of social support that may be the most influential. **PURPOSE:** The aim of this study was to examine the association between weight change and the types of social support adults participating in a behavioral weight loss intervention identified as the most helpful for their weight loss efforts. **METHODS:** Overweight adults (N=36) were randomized to one of two, 16-week behavioral weight loss interventions. Both treatments consisted of weekly, in-person group counseling sessions, Fitbit Zips for monitoring physical activity, and scales for monitoring body weight. One group also received two extra Fitbit Zips and scales to share with up to two persons in their social circle. There were no significant differences between conditions, so analyses collapsed groups and examined those who started the intervention (N=35). Participants completed an online survey at the end of each intervention week, which asked them to select the most helpful type of social support they received (informational; tangible; network; emotional; esteem). The support type

identified the most frequently as the most helpful type over time was determined for each participant and used in Fisher's exact tests to measure the frequencies with which each type of support was reported between those who lost > 5% of their initial body weight and those who did not. **RESULTS:** Participants were obese at baseline (M BMI = 36.1 + 7.3 kg/m²), and 43% lost > 5% of their initial weight by 16 weeks. Only emotional, esteem, and tangible support emerged as the most frequently reported most helpful types of support among all participants across the intervention period. A greater proportion of those who lost > 5% of their baseline weight identified esteem support as the most helpful type of support versus those who lost < 5% of their initial weight (47% vs 10%, p = .02). No significant differences between weight change groups were found for other support types (ps > .05). **CONCLUSION:** These findings suggest that esteem support may be especially influential for fostering weight loss. However, future studies should employ designs that allow for the direct comparison and more robust evaluation of the effectiveness of different types of support on weight loss in adults.

The Effect Of A Hiit And Resistance Exercise Program On Body Composition In Obese Females

Ashley Peart, Mynor Rodriguez-Hernandez, Shelby Foote, James McDonald, David Pascoe, FACSM, Danielle Wadsworth. *Auburn University, Auburn, AL.* (Sponsor: Dr. David Pascoe, FACSM)
 Email: azh0078@auburn.edu
 (No relationships reported)

PURPOSE: High intensity interval training (HIIT) has shown reductions in fat mass in normal weight populations¹ equal to or superior than continuous training. However, limited literature exists on the benefits and feasibility of HIIT training with obese participants. Furthermore, it is not known the additional benefits of incorporating resistance training with HIIT training on body composition for obese participants. The purpose of this study was to examine the effect of a 10-week HIIT and resistance training intervention on body composition in obese females. **METHODS:** 20 women (M Age = 37.1 ± 7.4) participated in a 10-week exercise intervention consisting of a high intensity interval treadmill protocol and resistance training three times a week for a total of 30 sessions. Body composition was assessed with the iDexa. **RESULTS:** Participants significantly (p=.007) increased lean mass from pre (107.5±16.4) to post (110.2±18.2) and significantly decreased fat mass from pre (101.93±33.5) to post (96.7±32.7). Greatest fat loss occurred in android (p=.007) and visceral (p=.006) area. **CONCLUSIONS:** Based on the results of this study, HIIT training is a feasible intervention to reduce fat in obese individuals. Combining HIIT training with a resistance training program resulted in favorable body composition changes in obese females.

Beat The Street - Harnessing Gamification For Population Level Changes In Physical Activity
 Marc A. Harris¹, William Bird². ¹*Cardiff Metropolitan University, Cardiff, United Kingdom.* ²*Intelligent Health, Reading, United Kingdom.*
 Email: marc.harris@intelligenthealth.co.uk
 (No relationships reported)

Purpose
 Intelligent Health delivers 'Beat the Street' with the aim to get a whole community more physically active. Beat the Street turns the town into a real-life game where players register their walking and cycling journeys by tapping a smartcard on RFID readers called 'Beat Boxes' placed on lampposts around the town. Players monitor their progress via a website where they can see their own and their team's progress, and the overall target
Methods
 During registration, participants complete a questionnaire which includes a single item physical activity question¹. follow up surveys take place at the end of the game and up to 8 months later. Pre-intervention/post-intervention comparisons are completed based on survey responses and in-depth analysis is completed based on data from each player's activity by tapping their card on beat boxes.
Summary of Results:
 In 2015, Intelligent Health delivered 11 Beat the Street projects, engaging 170,000 participants and collected baseline survey data from 45,136 adults. In 2016 prior to September, Intelligent Health delivered 15 Beat the Street projects, and reached the milestone of 500,000 people engaged and collected baseline survey data from 53,234 players. In 2015, across all Beat the Street projects the proportion of people reporting 0 or 1 days of physical activity decreased from 14% before Beat the Street to 8% after. The proportion meeting WHO guidelines increased from 43% to 48%, and the proportion of people walking for 15+ minutes on 5-7 days per week increased from 54% to 63%. In 2016, across all Beat the Street projects the proportion of people reporting 0 or 1 days of physical activity decreased from 8% before Beat the Street to

1% after. The proportion meeting WHO guidelines increased from 46% to 57%, and the proportion of people walking for 15+ minutes on 5-7 days per week increased from 47% to 61%.

Conclusion

Intelligent Health's analysis from the 26 completed Beat the Street projects to-date suggests that the concept of turning a whole community into a game leads to immediate changes in population levels of physical activity.

A Randomized Trial of Chinese Traditional Health-Promoting Exercises for Ankylosing Spondylitis

Huiru Wang¹, Liye Zou², Ting Li³, Minhua Lu⁴, Zhe Liu⁴.
¹Shanghai JiaoTong University, Shanghai, China. ²Springfield College, West Springfield, MA. ³Renji Hospital, Shanghai, China. ⁴Shanghai JiaoTong University, Renji Hospital, Shanghai, China.
Email: wanghrsju@163.com
(No relationships reported)

PURPOSE: The purpose of this study was to evaluate the influence of a 12-week traditional Chinese Qigong exercise (TCQG) on physiological and physical functions in patients with Ankylosing Spondylitis (AS).

METHODS: Sixty patients diagnosed with AS according to the modified criteria of New York were randomly assigned into either experimental (n = 30) or control groups (n = 30) using a computer-based random generator. AS patients in the experimental group experienced 60-minute Daoyinshu Qigong session twice per week for 12 weeks, whereas AS patients in the control group stayed with their original lifestyle during the 12-week intervention period. The TCQG exercise consisted of 15 basic movements associated with deep breathing, chest expansion, trunk rotation and bending, hip extension and flexion, flying bird movements, opening and closing the hands, and waving hands in the clouds. Health-related outcome measures included Modified Schober Flexion Test (MSF), Finger-to-floor test (FF), and Chest Expansion Test (CE), administered by two certificated physicians. The intragroup data within both groups were compared with the paired t test. The intergroup comparison of changes between baseline and week 12 was investigated with the unpaired t test.

RESULTS: AS patients in the experimental group showed an improvement from baseline to week 12 in all three outcome measures (p = .000), whereas the control group only showed an improvement in Finger-to-floor test (p = .012). For the intergroup comparison, significant differences were only observed in MSF (p = .001) and CE (p = .041), but FF (p = .483). More specifically, the experimental group showed greater improvement in the two tests than the control group.

CONCLUSIONS: Traditional Chinese Qigong exercise is effective in improving spinal mobility, chest expansion, and flexibility. Clinicians could incorporate the TCQG routine into rehabilitation program for patients suffering from AS.

Email: robin640@hotmail.com
(No relationships reported)

PURPOSE: Metabolic syndrome (MetSyn) increases the risk for morbidity and mortality from cardiovascular disease and exercise training is a fundamental factor in the treatment and prevention the clinical components of MetSyn. We conducted this study to investigate how an exercise program affects the risk components of MetSyn and exercise capacity in physically inactive adults. **METHODS:** Twenty inactive adults were randomly allocated to receive either moderate intensity training (MCT group) or high intensity interval training (HIT group). The MCT group performed aerobic training at an intensity of 55-75% of the walking on a treadmill at 60-80% heart rate max (HRmax) until expenditure of 300 kcal until the end of training. The HIT group performed running on a treadmill during 4 minutes at 85-95% peak HRmax and had a recovery of 4 minutes at 65% peak HRmax until expenditure of 300 kcal until the end of training. A MetSyn z-score was calculated for each subject from triglycerides, HDL-c, fasting glucose, waist circumference, and arterial blood pressure (MAP). Blood lipids and glucose, waist circumference, MAP and exercise capacity were measured at baseline and 12-weeks thereafter.

RESULTS: Z-score MetSyn changes were 1.546 (1.575) in the MCT group, -1.249 (1.629) in the HIT group (difference between groups -2.795 [95% CI, 1.276 to 4.311 (P=0.001)]. Average cardiometabolic risk factors changed -0.133 in the MCT group (p=0.040) and 0.018 (p=0.294) in the HIT group. There was a significant decrease in glucose fasting from 0 to 12 weeks in MCT group (P=0.039) compared to 12 weeks for the HIT group (P=0.001). Waist circumference was significantly reduced at 12 weeks compared to 0 weeks in HIT (P=0.010). Percentage body fat did not change in the MCT group 0.0 (0.8) and decreased in HIT group -1.1 (difference between groups 1.2 [95% CI, 0.1 to 2.4 P=0.04]). Muscle mass significantly increased throughout the 12 weeks of training in high intensity with significant differences between groups 0.8 kg [95% CI, 0.3 to 1.3 P=0.027]. MAP was significantly reduced from 0 weeks at 12 weeks in HIT group (P=0.019).

CONCLUSIONS: In inactive adults, this study showed that a 12-week HIT program can improve the clinical risk factor profile for MetSyn.

Self-care Posters Serve As A Low-cost Option For PA Promotion Of Hospital Nurses

Marcella Raney. Occidental College, Los Angeles, CA.
Email: raney@oxy.edu
(No relationships reported)

Overweight and obesity prevalence is higher in nursing than other healthcare and non-healthcare occupations in part due to minimal participation in physical activity (PA) not required for work. Nurses cite long shifts as a barrier to PA participation. Additionally, PA promotion efforts rarely target staff in the hospital setting.

PURPOSE: To examine the impact of PA monitoring and a poster campaign on the PA behaviors of hospital nurses. **METHODS:** A total of 26 nurses (control: n=13; experimental: n=13) participated in this study. Instructional exercise posters and lifestyle modification posters specific to the nursing profession were hung in the breakroom of two experimental hospital units. Posters were replaced every two weeks for a total of eight weeks. All subjects completed a PA behavior survey pre (week 1) and post (week 10) intervention. Subject PA was objectively monitored with an Actigraph wGT3X-BT accelerometer for 24 hours on three workdays during weeks 1, 5, and 10. All subjects were provided a pedometer in week 2 and received an activity time and intensity breakdown after each accelerometer wear period. PA changes were analyzed with a repeated measures ANOVA. **RESULTS:** Subjects spent more time sedentary (15.3±0.02 vs. 7.0±0.01%), took fewer steps (522.8±47.1 vs. 659.9±38.8 steps/hr), and engaged in less moderate intensity activity (9.8±0.6 vs. 8.0±0.6%) at home than at work independent of condition and study phase, p<0.05. Both groups increased activity-specific caloric expenditure (36.2±3.7 vs. 42.1±3.8 kcal/hr) and step count at home (472.9 vs. 610.9 steps/hr) from week 1 to week 5 (p<0.05). By week 10, activity levels were no longer statistically different than week 1 for either group (p>0.05). In contrast, subjects who incorporated PA into work breaks continued to increase caloric expenditure (+24.9±15.4%) and MVPA (+30.9±18.2%) from week 5 to week 10, p<0.05. At post-test, six experimental subjects were regularly performing exercises depicted in wall posters at work and/or at home compared to two control subjects who participated in PA breaks throughout the study duration.

CONCLUSION: Instructional and motivational posters promoting self-care are more likely to induce lasting changes on the daily PA behavior of hospital nurses than information provided through PA monitoring devices.

Zumba Fitness To Improve Body Composition & Physical Fitness In Inactive Employed Females

Yaira Barranco-Ruiz¹, Susana Paz-Viteri¹, Vinicio Sandoval¹, Marcela Guerendiain², Emilio Villa-González¹. ¹School of Physical Culture, Faculty of Health Sciences, National University Chimborazo, Riobamba, Ecuador. ²School of Medicine, Faculty of Health Sciences, National University Chimborazo, Riobamba, Ecuador.
Email: ybarranco@unach.edu.ec
(No relationships reported)

PURPOSE: to investigate the effect of two exercise interventions based on Zumba Fitness and Bodyweight training on body composition and physical fitness in inactive employed females. **METHODS:** A total of 56 inactive employed female participated in this study (38.7±1.00-yr). The sample was randomly divided into two groups: Zumba Fitness (Z, n=28, 1hour/per session) and Zumba Fitness + 20 minutes of Bodyweight training (ZB, n=28, 1.33 hours/per week), including both 3 days per week. Body composition (BMI, Fat mass, muscle mass and 6-skinfold) and Physical Fitness through Alpha Fitness Battery for adults: Motor fitness (one leg stand test), Musculoskeletal fitness (shoulder and neck mobility test, jump and reach test, hand-

grip test and sit up test), and cardiorespiratory fitness (2-km test) was analyzed at baseline and 16-weeks post-interventions. A Factorial Anova was used to analyze the effects and interactions of the type of intervention and the measure moments on body composition and physical fitness variables. **RESULTS:** The type of intervention showed a significant effect only in the case of rest heart rate after 2-km test, which was lower in ZB group compared with Z group ($MD=9.53.45$ bpm, $p=0.011$). However, both interventions showed a significant effects ($p<0.05$) on the majority of the studied variables compared baseline with post-intervention. BMI, fat mass, muscle mass, 6-skinfold, one leg stand test, hand grip test, and 2-km test, enhanced for both group after interventions, however, Z group reached the higher improvements. Shoulder and neck mobility test, sit up test and the Heart Rate post- 2km test, only improved after ZB intervention. **CONCLUSIONS:** Zumba Fitness intervention could improve the body composition and physical fitness in inactive employed females. Twenty minutes plus of bodyweight training seem not to generate changes in the variables studied.

217 Board #38 May 31 11:00 AM - 12:30 PM

Effects of Momentum-based Dumbbell Training on Quality of Life in Subjects with Mild Cognitive Impairments

Jiaojiao Lü, Yu Liu. *Shanghai University of Sport, Shanghai, China.*
Email: ljj27@163.com
(No relationships reported)

Mild cognitive impairment (MCI) is a transitional state between healthy aging and dementia. Individuals with MCI have been reported to reduce their cognitive and physical function and consequently worsen their quality of life and sleep quality. Given that no effective pharmacological treatment exists for MCI patents to alter the progress of cognitive decline exists, there is much interest in lifestyle approaches, such as exercise. Momentum-based dumbbell training is a self-initiated dumbbell-spinning exercise aimed at challenging, concurrently, physical and cognitive abilities. The health effects of this exercise on quality of life and sleep quality were unclear.

PURPOSE: The purpose of this study was to determine the effect of 12-week momentum-based dumbbell training on quality of life and sleep quality among older adults with MCI.

METHODS: We conducted a 12-week randomized controlled trial of 45 community-dwelling older adults with MCI. Participants were randomly assigned to either a dumbbell training group (DTG; $n=22$) or control group (CG; $n=23$). Participants in the DTG participated in a 3-time weekly exercise session for 12 weeks. The primary outcomes were changes in physical component summary (PCS) and mental component summary (MCS) of Short Form 36 health (SF-36) survey with secondary outcomes being eight subscales of SF-36 survey and the Pittsburgh Sleep Quality of Index (PSQI).

RESULTS: At post intervention, participants in the DTG, compared to those in the CG, had significantly improved SF-36 physical functioning (9.55 points; $F=4.14$, $P=0.048$) and vitality (16.51 points; $F=4.27$, $P=0.04$), PSQI total score (1.43 points; $F=4.08$, $P=0.05$) and sleep efficiency score (0.12 points; $F=7.13$, $P=0.01$). Compared to baseline, there was a significant within-group changes (improvement) in DTG group, including SF-36 MCS ($t=2.16$, $P=0.04$), the subscale of SF-36 ($t_{\text{bodily pain}}=3.56$, $P<0.01$; $t_{\text{vitality}}=4.84$, $P<0.01$; $t_{\text{mental health}}=3.96$, $P<0.01$) and PSQI total score ($t=-2.36$, $P=0.03$).

CONCLUSION: There is preliminary evidence showing the potential benefit of momentum-based dumbbell training to improve quality of life and sleep quality in older adults with mild cognitive impairment.

Momentum-based Dumbbell Training Improved Cognitive Function in Older Adults with Mild Cognitive Impairment

Yu Liu, Jiaojiao Lü, Lingyan Huang. *Shanghai University of Sport, Shanghai, China.*
Email: yuliu@sus.edu.cn
(No relationships reported)

Mild cognitive impairment (MCI) is a transitional state between healthy aging and dementia, which has higher risk for developing Alzheimer's disease. Older adults with MCI also experience decline of motor control, affecting their health and independence. Studies have demonstrated that combined cognitive and exercise training may well provide greater cognitive and physical benefits. Momentum-based dumbbell training is a self-initiated spinning exercise that uses dumbbells to generate momentum while performing exercise movements with varying configurations aimed at concurrently challenging physical and cognitive abilities.

PURPOSE: The main purpose of our study was to explore the effects of momentum-based dumbbell training on cognitive function in older adults with MCI. A secondary purpose was to examine its effects on physical function.

METHODS: Forty-five community-dwelling older adults with MCI were randomly assigned to either a dumbbell training group (DTG; $n=22$) or control group (CG; $n=23$). Participants in the DTG participated in a 3-time weekly exercise session for 12 weeks. All outcome measures were taken at baseline and post-intervention, including Alzheimer's Disease Assessment Scale-Cognitive subscale (ADAS-Cog), Mini-Mental State Examination (MMSE), Montreal Cognitive Assessment (MoCA), Trail Making Test-A/B (TMT-A/B), Digit Span Test-Forward/Backward (DST-F), Timed Up & Go (TUG), Timed 10m walking, Functional Reach (FR) and Berg Balance Scale (BBS).

RESULTS: Compared to those in the CG participants in the DTG had significantly improved ADAS-Cog (5.02 points, $F=6.95$, $P=0.012$ and MMSE score (1.23 points; $F=4.84$, $P=0.03$) with moderate and high effect size ($ES=1.28-0.51$). There were significant within-group changes (improvement) in ADAS-Cog ($t=-2.34$, $P=0.03$), MMSE ($t=2.00$, $P=0.06$), MoCA ($t=3.85$, $P<0.01$), TMT-A/B ($t=-2.80$, $P=0.01$; $t=-3.09$, $P=0.01$) and DST-B ($t=2.41$, $P=0.03$). Participants in the DTG improved their functional mobility (TUG=0.81s, $F=4.34$, $P=0.043$). There was no between-group difference in other outcomes.

CONCLUSION: A 12-week momentum-based dumbbell training can improve cognition and physical function in older adults with MCI, especially global cognitive function and mobility.

Departmental Variations in Wellness And Fitness Characteristics Of Firefighters

Charity Lane, 33612, John Mayer, 33612. *University of South Florida, Tampa, FL.*
Email: charitylane@health.usf.edu
(No relationships reported)

PURPOSE: Firefighters have a very physically demanding and dangerous occupation, resulting in high rates of cardiovascular and musculoskeletal disorders. Specific guidance on implementing wellness and fitness programs to promote adherence and long-term health improvements in firefighters is largely unavailable. The purpose of this study was to assess departmental variations in key wellness and fitness characteristics of firefighters.

METHODS: A cross-sectional study was conducted in career firefighters ($n = 264$; 32 F, 232 M) from 4 fire departments in the Tampa Bay region of Florida. Baseline data were assessed in participants enrolled in a worksite injury prevention trial, including anthropometric and health variables (e.g. BMI, blood pressure, heart rate), physical fitness (back and core muscular endurance, Functional Movement Screen), and health history (e.g. musculoskeletal injury history, Mediterranean Diet Questionnaire, International Physical Activity Questionnaire). Data were compared across the 4 departments.

RESULTS: Significant differences were noted across the departments in systolic blood pressure ($p = 0.0002$), heart rate ($p = 0.003$), physical activity ($p = 0.04$), and low back pain history ($p < 0.0001$). No significant differences were observed in other assessed variables. Of the total sample, 35.6% had high systolic blood pressure, 83.0% were overweight or obese, 60.6% reported a low or moderate physical activity level, and 66.3% reported a history of low back pain.

CONCLUSIONS: This study indicates departmental variations exist in some wellness and fitness characteristics among firefighters within the same region. These results are consistent with subjective observations from our group and others. For optimizing the implementation of wellness and fitness programming in firefighters, efforts should consider departmental variations by emphasizing standardization of approaches across fire departments, particularly when regional initiatives are implemented.

VO₂max and HbA_{1c} 3 Months After Participating In High-intensity Aerobic Interval Training Among Persons With Type 2 Diabetes.

Eva M. Støa¹, Sondre Meling², Lill-Katrin Nyhus¹, Jan Helgerud³, Solfrid Bratland-Sanda¹, Øyvind Støren¹. ¹University College of Southeast Norway, Telemark, Norway. ²Stavanger University Hospital, Stavanger, Norway. ³Norwegian University of Science and Technology, Trondheim, Norway.
Email: eva.m.stoa@hit.no

(No relationships reported)

PURPOSE: It remains to be established how participating in exercise interventions affect long-term effects on VO_{2max} and HbA_{1c} among individuals with type 2 diabetes (T2D). The present study investigated VO_{2max} and HbA_{1c} 3 months after participating in a 12 weeks training intervention consisting of high-intensity aerobic interval training (HAIT) (baseline HbA_{1c} of 7.7%). The results were compared with a moderate-intensity continuous training (MICT) group with HbA_{1c} levels below the recommended HbA_{1c} treatment goal of <7.0% (baseline HbA_{1c} of 6.9%).

METHODS: HAIT consisted of 4x4 minutes of walking or running uphill at 85 - 95% of maximal heart rate, and MICT consisted of continuous walking at 70-75% of maximal heart rate. After the training intervention, the participants chose themselves how to exercise during the next three months, and all training sessions were registered.

RESULTS: 19 individuals in each training group completed 12 weeks of supervised training, while 16 in HAIT and 10 in MICT completed the 6 months follow up. 3 months after intervention. HbA1c in HAIT was reduced by 0.7% points to 7.0% (p<0.01), and was thus close to recommended HbA1c treatment goal of <7.0%. The change in HbA1c was found after the intervention (from 7.7 to 7.1%) and was thus unchanged in the last 3 months (7.0%). VO_{2max} increased by 19% during the intervention (from 24.1 to 28.8 ml⁻¹·kg⁻¹·min⁻¹, p<0.01) and was also unchanged in the last 3 months after intervention (28.0 ml⁻¹·kg⁻¹·min⁻¹). No change was found in either VO_{2max} or HbA1c in MICT between the three measurement time points (25.9, 25.4, 26.4 ml⁻¹·kg⁻¹·min⁻¹ and 6.9, 6.8, 6.9%, respectively). The difference between HAIT and MICT after the 12 week intervention was statistical significant for both HbA1c and VO_{2max} (p<0.01).

CONCLUSIONS: HAIT is an effective exercise strategy to improve aerobic fitness and reduce HbA1c in T2D. The results from HAIT were still kept after 6 months.

PURPOSE: Excess gestational weight gain (GWG) increases the risk for adverse maternal and fetal outcomes. Recent reports link sleep deficiency to excess GWG; however, evidence in non-pregnant women suggests that physical activity improves sleep duration and sleep efficiency. Our objective is to report preliminary findings from a randomized aerobic exercise intervention throughout pregnancy, on the association between sleep quality, GWG, and the modifying effects of physical activity. **METHODS:** Thirteen mothers provided objective physical activity duration, total sleep time, and sleep efficiency via the SenseWear Armband (BodyMedia Inc.) for 5 consecutive days during the 1st, 2nd, and 3rd trimester. Physical activity level (PAL) was expressed as total energy expenditure divided by resting energy expenditure. GWG was calculated as pre-pregnancy weight (measured at 8-13wks) subtracted from weight at delivery. Appropriate versus excess GWG were categorized using 2009 IOM guidelines. **RESULTS:** Sleep duration significantly decreased from the 1st trimester to the 2nd trimester (Mean ± SEM = 436.1 ± 34.7 vs. 381.1 ± 30.0min, p=0.03) and plateaued in the 3rd trimester (381.1 ± 30.0 vs. 306.6 ± 29.0min, p>0.05). There was no difference in sleep efficiency throughout pregnancy. Compared with mothers with appropriate GWG, mothers with excess GWG acquired less sleep (389.6 ± 21.7 vs. 292.1 ± 36.1min, p=0.035) and slept less efficient (81.0 ± 3.8 vs. 61.6 ± 6.4%, p=0.029). Mothers randomized into the exercise intervention had higher sleep duration (412.8 ± 19.7 vs. 301.8 ± 23.8min, p=0.002) and better sleep efficiency (82.5 ± vs. 64.4 ± 4.7%, p=0.007) compared with controls. Multiple linear regression models assessing the independent effects of GWG and exercise intervention on sleep quality demonstrate that aerobic physical activity explains 39% of the variance in sleep duration and 31% of the variance in sleep quality, with no significant effects from GWG. **CONCLUSION:** Our findings suggest that physical activity may be a potentially effective way of improving sleep quality in pregnant women with or without excess gestational weight gain.

Effect of Moderate Versus High Intensity Interval Exercise Training on Vascular Function in Inactive Latin-American Adults: A Randomized Clinical Trial

Paula Andrea Hernández-Quiñonez¹, Alejandra Tordecilla-Sanders¹, Esteban Saboga², Jorge E. Correa-Bautista¹, Antonio Garcia-Hermoso³, Robinson Ramírez-Vélez¹. ¹Centro de Estudios para la Medicin de la Actividad Fisica «CEMA». Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá D.C., Co, Bogota, Colombia. ²Grupo GICAEDS, Facultad de Cultura Física, Deporte y Recreación, Universidad Santo Tomás, Bogotá, Colombia. ³Laboratorio de Ciencias de la Actividad Física, el Deporte y la Salud, Universidad de Santiago de Chile, Santiago, Chile.
 Email: robin640@hotmail.com
 (No relationships reported)

PURPOSE: Exercise training is effective for improving cardiometabolic health and physical fitness in inactive adults. However, limited research has been conducted on the optimal exercise training intensity for this population. We investigate the effect

of moderate versus high intensity interval exercise training on vascular function and physical fitness in physically inactive adults. **METHODS:** Twenty inactive adults were randomly allocated to receive either moderate intensity training (MCT group) or high intensity interval training (HIT group). The MCT group performed aerobic training at an intensity of 55-75% of the walking on a treadmill at 60-80% heart rate max (HRmax) until expenditure of 300 kcal until the end of training. The HIT group performed running on a treadmill during 4 minutes at 85-95% peak HRmax and had a recovery of 4 minutes at 65% peak HRmax until expenditure of 300 kcal until the end of training. Vascular function (flow-mediated vasodilation, FMD [%], aortic pulse wave velocity, PWV [m·s⁻¹]), blood lipids [fasting glucose, triacylglycerol, total cholesterol, LDL-cholesterol, HDL-cholesterol], blood pressure, and physical fitness (Muscle strength [handgrip [kg]], exercise capacity (VO_{2peak} and graded exercise test duration [minutes]), were measured at baseline and 12-weeks thereafter.

RESULTS: FMD changes were 2.2 (4.9) % in the MCT group, 7.7 (5.3) % in the HIT group (difference between groups -5.4 [95% CI, -10.3 to -0.6 (P<0.001)]. PWV changed 0.1 in the MCT group but decreased -0.3 in the HIT group, (not significantly different from the MCT or HIT group, P between groups = 0.91). Percentage body fat did not change in the MCT group 0.0 (0.8) but decreased in HIT group, -1.1 (difference between groups 1.2 [95% CI, 0.1 to 2.4 P between groups = 0.04]). No significant group differences were observed in physical fitness, blood lipids or blood pressure. **CONCLUSIONS:** HIT is more effective in improving endothelial function and reducing body fat than MCT in inactive Latin-American adults. **Trial registration.** ClinicalTrials.gov NCT02738385, registered on 23 March 2016.

223 Board #44 May 31 11:00 AM - 12:30 PM
Changes in Endothelial Function Following Fat Sugar Snacking With and Without Exercise Training

Catherine L. Jarrett¹, Wesley J. Tucker², Andrew C. D'Lugos¹, Jared M. Dickinson¹, Siddhartha S. Angadi¹, Glenn A. Gaesser, FACSM¹. ¹Arizona State University, Phoenix, AZ. ²University of Texas at Arlington, Arlington, TX. (Sponsor: Glenn Gaesser, FACSM)
 (No relationships reported)

PURPOSE: Caloric excess induces endothelial dysfunction. Exercise can improve endothelial function or mitigate the negative effects of excess caloric intake. We hypothesized that exercise training would prevent deterioration in endothelial function associated with 4 weeks of fat-sugar snacking. **METHODS:** 27 overweight/obese (BMI = 30.0±3.7 kg/m²) males (age = 29±7 yr) underwent 4 weeks of added fat-sugar snacking (+14,579 ±413kcal), in the form of donuts (6 days/week) added to their regular diet. Participants were randomized to one of three conditions: 1,000 kcal/week supervised moderate-intensity (MICT; n=8) exercise (50% peak VO₂), 1,000 kcal/week supervised high-intensity interval (HIIT; n=10) exercise (90-95% peak heart rate), or no-exercise control (CON; n=9). All participants were tested in the morning following a >10 h overnight fast at baseline and 4 weeks. Endothelial function was assessed by brachial artery flow-mediated dilation (FMD) and was further normalized for shear rate (FMD/shear rate). Two-way repeated measures ANOVA was used to detect time, condition, or time x condition interaction effects. **RESULTS:** FMD was unchanged in all groups (Control: Pre FMD = 4.6 ± 1.2 %, Post FMD = 3.7 ± 2.1 %, p=0.28; HIIT Pre FMD = 6.0 ± 2.7%, Post FMD = 5.5 ± 2.3%, p=0.56; MICT Pre FMD = 6.2 ± 2.4%, Post FMD = 5.5 ± 2.4%, p=0.43). With all groups combined there was a trend towards a reduction in FMD (p=0.16) and FMD/shear rate (p=0.09). Baseline diameter, peak diameter, blood flow velocity and shear rate were unchanged within all groups (p > 0.05). **CONCLUSIONS:** The addition of ~14,500 kcal of fat-sugar snacks in the form of donuts to the regular diets of overweight/obese men over a 4-week period was insufficient to induce deleterious changes in endothelial function. The consumption of additional energy predominantly as fat and sugar may have prevented improvements in FMD expected with HIIT and MICT.

A Feasibility RCT: Understanding Impact of Community Gardening on Physical Activity and Sedentary Behavior

Elizabeth Thomson¹, Kaigang Li¹, Ricky Pimentel², Alyssa Beavers³, Kelsey Burr⁴, Jill Litt⁴. ¹Colorado State University, Fort Collins, CO. ²Children's Hospital Colorado, Aurora, CO. ³Michigan State University, East Lansing, MI. ⁴University of Colorado Denver, Denver, CO.
 Email: Elizabeth.Thomson@colostate.edu
 (No relationships reported)

PURPOSE: To investigate the feasibility of using accelerometers to objectively measure physical activity (PA) during gardening to provide preliminary evidence for a large scale gardening intervention. **METHODS:** This randomized control trial was conducted in 2016 in a Denver low-income community. Repeated measures of PA and sedentary behavior (SB) were compared at two time points (T1: June and T2: October) between two groups (TG = gardeners and NG = non-gardeners). At both T1 and T2,

12 participants (mean age, 44.09 ± 16.26 years) wore the activPAL accelerometers for a 6-day period (including 2 weekend days). Each day, time spent in sedentary time, standing, walking at cadences above and below 120 steps/min, and number of steps were measured, and energy expenditure (EE) in metabolic equivalent-hour was estimated. The data were analyzed using MatLab and SAS. **RESULTS:** At T1, no significant differences ($p > .05$) for overall (weekday and weekend) sedentary, standing, walking times, and EE were detected between TG and NG. Unexpectedly, the TG had lower step counts (1.25 ± 0.35 vs. 2.05 ± 0.47 hrs, $P < .05$) compared to the NG at the <120 steps/min cadence at T1. From T1 to T2 data, the NG significantly increased time spent sedentary (1.09 ± 0.65 hrs, $p < .05$), significantly decreased time spent standing on weekdays (-0.98 ± 0.33 hrs, $p < .01$), and marginally significantly decreased overall time spent standing (-0.56 ± 0.45 hrs, $p = .09$). No significant changes were found between T1 and T2 in TG, nor did any other variables in either TG or NG change. The increased sedentary time and the decreased standing time in the NG but not TG indicated that gardening may protect against sedentary time and maintain PA. One gardener dropped out at T1 and two NGers started late at T2 (we have to submit the abstract before getting their data). All other participants wore the accelerometers for all six days (24 hrs/day), which indicates a good compliance. **CONCLUSIONS:** The accelerometers successfully tracked subjects' PA and SB for sedentary, standing and walking indicating that activPAL accelerometry is a feasible approach for assessing PA and SB. Although the results should be interpreted cautiously due to the small sample size, which precluded adequate statistical power, the study demonstrated feasibility of testing methods for a large scale gardening study.

Compensatory Mechanisms to Exercise Induced Energy Deficit
 Jacquelin Koehne, Bryan Smith. *Southern Illinois University Edwardsville, Edwardsville, IL.*
 (No relationships reported)

In recent years, more emphasis has been put on the importance of the role of exercise and proper diet in successful weight management. Weight loss due to an exercise induced energy deficit without changes in dietary intake is generally less than expected.

PURPOSE: The purpose of this study was to compare 24 hour changes in appetite/satiety and daily physical activity following bouts of either 200 or 400 kcal of aerobic exercise (walking) in sedentary overweight/obese ($BMI \geq 25$) college age females. **METHODS:** Overweight/obese college age girls (n=19) were recruited and scheduled for 3 trials. The exercise trials consisted of walking at 70% of their heart rate reserve on a treadmill until they expended either 200 or 400 kcal. Energy expenditure was verified by indirect calorimetry. The third trial was a non-exercise control. The order of the trials was randomized. Changes in physical activity (sit/lie time, sleep time, and standing time) were measured using the ActivPal² accelerometer during the 24 hours post exercise. Changes in appetite/satiety were measured via Visual Analog Scales immediately before and after the exercise session and at 60, 120, and 180 minutes following each trial.

RESULTS: There were no significant changes in sit/lie time between the 200K (575.7 ± 144.6 minutes), 400K (613.7 ± 90.1 minutes), and control trials (554.0 ± 113.3 minutes). There were no significant changes in sleep time between the 200K (532.6 ± 105.6 minutes), 400K (529.7 ± 91.9 minutes), and control trials (570.9 ± 91.8 minutes). There were no significant changes in stand time between the 200K (223.1 ± 110.1 minutes), 400K (187.5 ± 85.0 minutes), and control trials (216.6 ± 95.0 minutes). There was no difference in the appetite between the 200K (27.4 ± 12.2 cm), 400K (25.4 ± 12.9 cm), and control trials (30.4 ± 12.9 cm). There were no significant changes in satiety between the 200K (30.5 ± 17.5 cm), 400K (33.1 ± 15.0 cm), and the control trials (33.3 ± 14.6 cm).

CONCLUSION: In overweight/obese, college age females an exercise bout of either 200 or 400 kcal does not result in changes in daily physical activity or appetite/satiety in the 24-hour period immediately following the exercise session.

Examination Of Cardiovascular Risk Factors Among University Employees Participating In A Workplace Walking Program
 Lisa A. Leininger, Lydia Selzer, Joshua Olmeda, Veronica Jones, Kent Adams, FACSM. *California State University, Monterey Bay, Seaside, CA.* (Sponsor: Kent Adams, FACSM)
 Email: lleininger@csUMB.edu
 (No relationships reported)

PURPOSE: Worksite sponsored physical activity programs are prevalent at universities in an effort to improve health indicators, including risk factors for cardiovascular disease. The purpose of this project was to compare cardiovascular risk factors of university employees participating in a worksite sponsored walking program versus those who did not participate. **METHODS:** The research was a matched pairs design, with two groups. The study group (n=31) participated in the "Workplace

Walkoff Challenge" for six weeks, while the control group (n=11) did not participate. All cardiovascular risk factors, as defined by ACSM Guidelines, were assessed two weeks prior to the start of the walking program and then repeated during the last week. Risk factors assessed included family history, age, smoking status, physical activity amount, blood pressure, body composition (waist circumference and BMI), dyslipidemia (total cholesterol, HDL, LDL), and fasting glucose. To assess differences in these variables, dependent t-tests were performed.

RESULTS: Walking program participants significantly improved their physical activity amount ($p=.05$), body mass index ($p=.003$), waist circumference ($p=.03$), diastolic blood pressure ($p=.005$) and fasting glucose ($p<.001$) from baseline to end of program. There were no significant improvements for participants in systolic blood pressure or cholesterol (total and HDL). Despite a trend, there was no significant decrease in total number of risk factors following the walking program. The control group had no significant changes in physical activity, BMI, waist circumference, blood pressure or fasting glucose from baseline to follow up. However, the control group had a significant reduction in total cholesterol ($p=.05$). **CONCLUSIONS:** The participants in the walking program had many health indicators improve following the six week walking program. Therefore, short-term worksite walking programs may be effective in improving cardiovascular risk factors. Future research should focus on programming's effect on long-term adherence to physical activity and improvement of health indicators.

Occupational Sitting and Physical Activity among College Employees
 Sarah E. Wooley¹, Kristen Dempsey¹, Tracey D. Matthews¹, Raldy Laguilles¹, Jasmin Hutchinson¹, David A. Rowe, FACSM², Samuel A. Headley, FACSM¹. ¹Springfield College, Springfield, MA. ²University of Strathclyde, Glasgow, United Kingdom.
 (Sponsor: Samuel A. Headley, FACSM)
 (No relationships reported)

Time spent in sedentary behavior (i.e., < 1.5 METs while reclining), is linked to poor health outcomes. Persons who spend considerable periods of time daily in unbroken sitting are at higher risk of cardiometabolic disease. As sedentary time emerges as an independent health risk factor, the workplace has come under greater scrutiny due to its high percentage of computer-based, sedentary jobs. University employees were recently shown to spend 75% of their workday seated (Fountaine et al. 2014). However, apart from this study, little is known about sedentary behavior among employees at academic institutions.

PURPOSE: We subjectively assessed occupational sitting and physical activity of employees at a 4-year, private college. **METHODS:** At the start of the 2016 fall semester, all members ($N = 697$) of the college community received an online version of the Occupational Sitting and Physical Activity Questionnaire (OSPAQ; Chau et al., 2012). The OSPAQ measures perceived time spent in sitting and physical activity. 343 employees (49%) provided complete responses to the survey. Employees reported working 8.3 ± 1.8 hours per day. **RESULTS:** Data were expressed as raw and percent time spent sitting, standing, walking and heavy lifting. Administrators reported spending more hours (46.2 ± 10.0 hr/wk) and days (5.5 ± 0.8 d/wk) at work than faculty (45.0 ± 13.1 hr/wk and 5.1 ± 0.9 d/wk) and staff (40.4 ± 8.6 hr/wk and 5.2 ± 0.8 d/wk). One-way ANOVAs were computed to examine differences among employee categories (staff, administrator, faculty). For time spent walking (68.4 ± 53.4 min/day; $13.9 \pm 10.3\%$ time) or heavy lifting (11.3 ± 28.3 min/day; $2.3 \pm 5.6\%$ time) no significant differences existed among employment categories. Administrators sat (372.2 ± 112.8 mins/day; $73.2 \pm 17.7\%$) significantly more than faculty (314.5 ± 138.8 mins/day; $58.5 \pm 19.6\%$) and staff (315.1 ± 115.8 mins/day; $68.5 \pm 24.2\%$). Faculty stood (136.4 ± 89.2 mins/day; $25.8 \pm 14.8\%$) significantly more than administrators (62.1 ± 49.6 mins/day; $12.4 \pm 9.7\%$) and staff (67.8 ± 80.9 mins/day; $14.1 \pm 16.5\%$). **CONCLUSIONS:** Based upon our findings, targeted behavioral interventions are needed to help reduce the time that administrators spend sitting during their working day.

228 Board #49 May 31 11:00 AM - 12:30 PM
The Influence Of Physical Activities At The Workplace On Private Medical Center Employees
 Daniel S. Moran, FACSM¹, Achmed Naser², Karen Bronner³. ¹Ariel University, Washington College of Education, Ariel, Israel. ²Ariel University, Ariel, Israel. ³Assuta Medical Center, Tel Aviv, Israel.
 (No relationships reported)

Being aware of the increase in obesity and sedentary lifestyle, many organizations develop intervention programs to improve the health of their employees by offering them various physical activities at work. **PURPOSE:** To assess the barriers of engaging in physical activity among medical center employees, and the mental and physical impact of participation in physical activity lessons at work. **METHODS:** 231 private medical center employees including physicians, paramedical and administrative staff participated in this study. 135 participants were not active

in the lessons and 96 (70%) who were active, practiced twice weekly in various activities: Pilates, yoga, running, cycling, and Zumba. **RESULTS:** The physical activity group was found to have a higher workplace satisfaction level ($p < .001$), a decrease in burnout ($p < .01$), better health perceptions ($p < .01$), lower weight ($p < .05$), a reduction in chronic morbidity and drug consumption ($p < .05$), less smoking and liquor consumption ($p < .01$), healthier eating and sleeping habits ($p < .001$) and more physical activity outside of working hours ($p < .01$). Among the main barriers to participate in the activity lessons at work for the non-active group were: unsuitable lesson schedule (62%) lack of desire for sport (61%), lack of time (53%), fatigue (44%), prior family commitments (39%), non-payment of activity time (35%), and unawareness of the physical activity programs (27%). **CONCLUSIONS:** Physical activity programs at medical centers promote employees health thereby neutralizing negative aspects such as worker burnout, mental and physical fatigue and increases employee satisfaction at the workplace. Therefore, more promotion of physical activity at the workplace should be encouraged in order to increase employee participation. However, further research is needed in public medical center to verify these research findings among healthcare employees.

229 Board #50 May 31 11:00 AM - 12:30 PM

Everyday Pedelec Use and its Effect on Meeting Physical Activity Guidelines

Markus Hein, Johanna Boyen, Hedwig Theda Stenner, Armin Finkel, Gudrun Protte, Momme Küick, Uwe Tegtbur. *Hannover Medical School, Hannover, Germany.*
Email: hein.markus@mh-hannover.de
(No relationships reported)

While pedelecs became an important element of active transportation, little is known about the physiological responses during their everyday use so far. **PURPOSE:** To compare the heart rate (HR) response during everyday pedelec use and cycling and to determine if pedelecs are a suitable tool to meet American College of Sports Medicine (ACSM) physical activity guidelines for health benefits of 150 min moderate activity (64-76% of maximum HR (HRmax)) per week. **METHODS:** In a crossover design 101 employees recorded HR, duration and intensity of their rides via smart phone app during two periods, lasting two weeks each: one with a provided pedelec (P) and one with their own bicycle (B), in a randomized order. HRmax was determined in graded exercise tests on a cycle ergometer prior to the observation periods. **RESULTS:** The amount of trips per week was significantly higher during P compared to B (5.3 ± 4.3 vs. 3.2 ± 4.0 trips, $p < 0.001$). The average duration of trips did not differ significantly between P and B (37.5 ± 23.5 vs. 40.3 ± 27.8 min, $p = 0.45$). Perceived exertion during the trips was significant lower with P (11.7 ± 1.8 vs. 12.8 ± 2.1 , $p < 0.001$). Total ride time per week was significantly longer during P (174 ± 146 vs. 99 ± 109 min, $p < 0.001$). Average HR during P was significantly lower than during B (109 ± 14 vs. 118 ± 17 , $p < 0.001$) averaging 64 ± 8 vs. $67 \pm 9\%$ HRmax, respectively. There was no difference in the percentage of subjects meeting ACSM recommendations for physical activity between P and B (25 vs. 24% of subjects, $p = 0.86$). **CONCLUSIONS:** In everyday use, average HR during pedelec trips is only three percent lower than during cycling and sufficient to classify the intensity as moderate. Higher usage rates make pedelecs an equal active transportation alternative for fulfilling ACSM guidelines, especially for people who normally would not use a bicycle.
Supported by BMBF Grant 16SNI012D.

The Investigation On Health Status And Exercise Habit Of Chengdu Civil Servant

Xiaorui Zhang¹, Yushi hu¹, Xihui Liu², Hua Shen¹, quansheng su¹. ¹Chengdu Sport Institute, Chengdu, China. ²Sichuan Orthopedic Hospital, Chengdu, China.
Email: 814595664@qq.com
(No relationships reported)

Health is not only without disease or weakness, but also a good condition in physics, psychology and society. Civil servant is a special group, its health status has been aroused serious concern. **PURPOSE:** To understand the health status and exercise habits of civil servants in Chengdu, and helping to make formulation of the intervention to health status. **METHODS:** Using stratified cluster facilitation sampling method, 500 civil servants were randomly selected from Wuhou, Jinjiang, Qingyang, Jinniu and Chenghua District in Chengdu, conducted questionnaires of Health Rating Scale (SHMS V1.0, 40 questions about physical, psychological and social condition, reliability and validity have been verified) and exercise habit. Statistical analysis, T-test, one-way ANOVA and Pearson correlation analysis were conducted by SPSS19.0, $P < 0.05$ was considered statistically significant. **RESULTS:** ① 500 were sent out, 459 recycled, missing up to 2% were delete, 418 were valid. The healthy is only 6.70% (28/418), psychological unhealthy was the most, accounting for

76.08% (318/418). ② Male civil servants of non-health accounts 77.32%, higher than 68.75% of female ($P < 0.05$). ③ 50 to 59 year-old group was the highest 84.75% ($P < 0.05$), 20-29 was the second. ④ About exercise habits, 70.33% (294/418) are for keep fit. 3/week and 30-60min are the most, 61.72% (258/418) and 53.59% (224/418). Sitting 5-8 h/d and more than 8 h/d are the most, 38.28% (160/418) and 34.45% (144/418). ⑤ Duration time and unhealthy score are significant correlation ($P < 0.05$), while frequency and sitting time are not ($P > 0.05$). ⑥ Less than 30min and 30-60min have great difference in unhealthy score, physical and psychological. Less than 30min and more than 60min shows significant difference in unhealthy score, physical and social ($P < 0.05$). ⑦ 3-5/week and more than 5/week shows significant difference in psychological unhealthy ($P < 0.05$). Less than 3/week shows no significant difference with other group ($P > 0.05$).

CONCLUSIONS: ① The health status of civil servants in Chengdu is not prospective, and their sitting time is a little long. ② Exercising more than 30min can make great difference of health status in physics, psychology and society. Combining with frequency, 3-5/week and more than 30min/time are the best intervention.

231 Board #52 May 31 11:00 AM - 12:30 PM

Feasibility Of A Student-led University Wellness Initiative

Nathan W. Saunders¹, Laura M. Marioneaux², Christina A. Gonzalez². ¹University of Mount Union, Alliance, OH. ²Longwood University, Farmville, VA. (Sponsor: Steven T. Devor, FACS M)
Email: saundenw@mountunion.edu
(No relationships reported)

Exercise Science students have a unique opportunity to contribute to the wellness of their university community while also improving their own practical experience. **PURPOSE:** The aim of this study was to assess the feasibility and effectiveness of a low-budget wellness initiative at a small liberal arts university. **METHODS:** Deliberate choices were made throughout the planning phase to reduce cost and improve feasibility, even when it necessitated a less valid approach. Thirty-eight Exercise Science students with varying levels of education volunteered to be research assistants. An entirely online enrollment process was developed using Google Forms that included informed consent, PAR-Q, demographic information, activity history, and wellness. A baseline assessment of physical fitness included height and weight (digital scale with stadiometer), waist and hip circumference, 1-mile walk or 1.5-mile run, and resting and exercise heart rate (assessed via radial pulse). Participants were asked to log their self-reported total minutes of weekly physical activity and average rating of perceived exertion (6-20 scale). The product of activity duration and perceived exertion served as a numerical activity score. The student research assistants then contacted their assigned participants weekly for 10 weeks to record activity and create accountability. **RESULTS:** The feasibility of this study and \$2,000 budget allowed for a maximum of 450 participants. Of the 180 participants who completed the online enrollment process and scheduled their baseline fitness assessment, 117 actually showed up and were tested. While the initiative targeted the entire campus community, our study population included 57 employees (6.3% of all employees) and only 60 students (1.1% of all students). Attrition was greater than expected with 94% of tested participants reporting their activity in week 1, and progressively decreasing to a point where only 47% reported their activity in week 5. **CONCLUSION:** This study was extremely feasible and cost-effective. However, greater care must be taken in marketing the program to students and weekly incentives may need to be offered to improve activity reporting throughout.

232 Board #53 May 31 11:00 AM - 12:30 PM

Testing Intentions: Evaluating The Effectiveness Of Implementation Intentions In A Pedometer-Based Worksite Intervention

Anna I. Rinaldi-Miles¹, Bhishha Das², Rumit Singh³. ¹Illinois State University, Normal, IL. ²East Carolina University, Greenville, NC. ³Ithaca College, Ithaca, NY. (Sponsor: David Q. Thomas, FACS M)
Email: aimiles@ilstu.edu
(No relationships reported)

Pedometer-based interventions have been found to be successful in increasing physical activity (PA) during the intervention but adherence is challenging. Implementation intentions (II) are specific plans of action concerning when, how, and where an intended behavior will be enacted. The use of this self-regulatory skill with self-monitoring of the pedometer has the potential to initiate behavior change as well as adherence. **PURPOSE:** To test differences between participants that used both II and a pedometer and those that just used a pedometer. **METHODS:** Employees ($N = 51$) at a mid-sized public university were recruited via employee email to participate in an 8-week pedometer-based intervention. Only employees currently not meeting minimum PA recommendations (< 150 minutes of moderate to vigorous PA/week) could enroll. A 2-arm randomized trial was used to compare the effectiveness of: 1)

only pedometers (PED) (n = 25) and 2) pedometers and II (PED + II) (n = 26) on PA. All participants were asked to track steps daily. Participants in the PED + II group were asked to write three II for each perceived barrier to meeting their step goals in Weeks 1 and 4. Pedometers were reissued for a delayed post assessment 4 weeks after the intervention ended (n = 36). Paired t-tests were used to compare differences between baseline to Week 8 and 12 separately for the 2 groups. **RESULTS:** Significant increase in steps ($p = .004$) were observed from baseline (7100 ± 2452.5) to Week 8 (8542 ± 4244.1) for the both groups combined and for the PED+II group ($p = .004$; mean difference: 1458 ± 1009.2). No difference was observed for the PED group ($p = .112$; mean difference: 1427 ± 2511.1). Average steps significantly decreased ($p < .0005$) from Week 8 (9019.2 ± 4684.3) to Week 12 (6689.3 ± 1983.2) for the both groups combined. There was no between group differences in any comparison ($p = .159 - .854$). **CONCLUSION:** The PED+II group significantly increased steps during the intervention indicating that the behavioral strategy was effective. However, participants in both groups had a significant decrease in steps from the end of the intervention to the delayed-post assessment highlighting the struggle to maintain behavioral changes after the intervention ends. Future interventions should continue to combine behavioral modification strategies to increase adherence.

Lifestyle and Health Habits Among Canadian University Community

Alexandre Busque, Pierre-Luc Yao, Paule Miquelon, Marie-Claude Rivard, Émilie Lachance. *Université du Québec à Trois-Rivières, Trois-Rivières, QC, Canada.*
 Email: alexandre.busque@uqtr.ca
 (No relationships reported)

PURPOSE: It is estimated that by 2019, 55.4% of the Canadian adult population will be categorized as overweight (34.2%) or obese (21.2%) (Twells et al., 2014). Increase of obesity prevalence, calls for continuous search of effective obesity-prevention and health promotion strategies. Following the work of Perusse-Lachance and colleagues (2010), the present study aimed to further examine the prevalence of obesity and lifestyle habits through environmental factors in a different Canadian university community.

METHODS: A web based-survey assessing lifestyle habits such as physical activity and nutrition was sent by email to all university's students (n=14 500) and employees (n=2000). Students or employees had to be registered as part or full time during the 2016 fall semester to participate in the study. Response rate was 13.3% for students (n=1 989) and 24.3% for employees (n=485). All data were analyzed using SPSS.

PRELIMINARY RESULTS: Results showed that 18.7% of students and 28.5% of staff members were overweight (BMI = 25.0-29.9), 10% of students and 10.7% of staff members were obese (BMI \geq 30.0) while 40% of students and 37% of the employees were currently trying to lose weight. Results also revealed that 50% of staff members and 57% of students were considered sedentary (<150 minutes of physical activity/week).

Regarding fruits and vegetables intake, only 14% of students consumed four or more servings of fruits per day compared to 15% for staff members. In addition, only 15% of students consumed four or more vegetables servings per day as opposed to 26% for staff members. Finally, 91% of employees, compared to 81% of the students, were having breakfast every day.

CONCLUSION: Healthy environments are crucial in the adoption of healthy behaviors (Booth et al., 2001). In this regard, the herein results suggest that overweight and obesity can be an important concern in a well-educated sample and that this issue is associated with various health-related behaviors. These conclusions highlight the need to develop specific health promotion strategies in this Canadian University community.

Fitness Perceptions And Practices Of Medical Students From A Patient-Based Learning Curriculum (PBL)

Stephen H. Luebbert, Chrissa L. McClellan, Fred Murdock. *University of Missouri-Columbia School of Medicine, Columbia, MO.*
 Email: shlww4@health.missouri.edu
 (No relationships reported)

Purpose: To determine the knowledge of fitness and the fitness habits of medical students at the University of Missouri School of Medicine (UMSOM). There is currently limited research on the association of a Patient-Based Learning (PBL) curriculum with students' fitness as well as their implementation of patient exercise prescription.

Methods: Anonymous surveys were distributed to 394 medical students. Data were entered into the REDCap electronic survey tool and tabulated with REDCap and Microsoft Excel. In the survey, respondents were asked to state the Centers for Disease Control (CDC) recommendations for physical activity in adults. The survey

also included Likert scale questions concerning exercise, and the Godin leisure time exercise questionnaire. Godin scores were calculated and converted to CDC recommended activity levels.

Results: A total of 145 students responded for a response rate of 37%, with 97% agreeing that it is important for physicians to have and exemplify an active lifestyle. However, only 23% met the aerobic physical activity guidelines set by the CDC for adults. Based on the Fisher Exact Test ($P=1.1 \times 10^{-4}$) respondents who met CDC recommendations for exercise also indicated stronger agreement with the statement "I make physical fitness a priority in my life." Although 41% of respondents agree that the medical school curriculum has educated them on appropriate use of exercise, only 2.8% (4/145) were able to correctly state the CDC recommendations for physical activity in adults.

Conclusion: Most medical students in the UMSOM agree that it is important for physicians to maintain an active lifestyle but most do not achieve the CDC recommended level of exercise. Less than half of respondents agreed that the PBL curriculum educated them on appropriate use of exercise, and most could not state the CDC recommendations for physical activity in adults. Healthcare is evolving towards preventative care, including patient exercise counseling and prescription, which may be a current weakness of PBL. Further research is needed to compare PBL curricula to traditional curricula, as well as seeing the ultimate effect on the students' future medical practices.

Incorporating Spirituality and Role Models into Physical Activity Programs for Black Women: A Qualitative Inquiry

Rodney P. Joseph, Colleen Keller, Steven P. Hooker, FACSM, Barbara E. Ainsworth, FACSM. *Arizona State University, Phoenix, AZ.* (Sponsor: Barbara Ainsworth, FACSM)
 Email: rodney.joseph@asu.edu
 (No relationships reported)

Previous research has shown favorable outcomes for incorporating religion and spirituality into (physical activity) PA programs delivered through faith-based or faith-placed settings. Limited research has examined how these concepts can be incorporated into PA programs delivered outside of religious institutions. Likewise, few studies have explored the individuals that Black women consider to be physically active role models and how these role models can be leveraged in a PA program.

PURPOSE. To qualitatively examine how spirituality, religion, and roles models can be incorporated into a PA program for Black women.

METHODS. Twenty-five Black women (M age = 38.5 years, M BMI = 39.4 kg-m²) were enrolled in the study. Focus group guides were designed to gain information on how religion, spirituality, and roles models can be incorporated into a culturally relevant PA program for Black women. Focus groups were audio recorded and transcribed verbatim. Content analysis was used to analyze focus group data.

RESULTS. Participants reached consensus that incorporating aspects of spirituality (i.e., words of affirmation, meditation, mind-body activities) into a PA program was universally acceptable, regardless of religious affiliation. On the other hand, including concepts of religion (i.e., bible verses and/or quotes from religious leaders) was controversial and not recommended among women who did not identify with a religious faith. In reference to the topic of physically active role models, women identified various individuals they considered as role models, including relatives (i.e., their mother, siblings, and children), friends, community leaders, and celebrities (i.e., Michelle Obama, Oprah Winfrey). Participants endorsed the use of these role models in a PA program designed for Black women.

CONCLUSIONS. Findings suggest that including spirituality, as opposed to religion, is an acceptable and motivational concept to include in a PA program for Black women. Similarly, women reported a diverse group of individuals that could be included as physically active Black role models. Designing PA promotion programs to include aspects of spirituality and roles models can enhance the acceptability and salience of the program, which may ultimately lead to increased PA behaviors.

Pilates Exercise Improves Balance in Middle-Aged Chinese Women

Yi Dai¹, Hengjing Zou², Guangyi Lai². ¹Chengdu Sport University, Chengdu, China. ²Chengdu First People's Hospital, Chengdu, China. (Sponsor: Tongjian You, FACSM)
 Email: 763335348@qq.com
 (No relationships reported)

PURPOSE: To investigate if an 8-week Pilates exercise program could improve static balance, dynamic balance and core myodynamia strength in middle-aged Chinese women.

METHODS: Sixty middle-aged Chinese women (52-65 years old) were randomly assigned to experimental group (n=30) and control group (n=30). The Pilates exercise

was performed 90 minutes per time, 3 times per week, for 8 weeks, including core myodynamia training, static standing, muscle strength and endurance training of lower extremities. Static balance and dynamic balance tests were performed, and the strength of core myodynamia was measured using a BIODEX balance test system. The SPSS19.0 statistical software was used for data analysis. Paired tests were used for comparison before and after intervention within each group. Group comparisons in changes over time were performed by independent t-tests.

RESULTS: When comparing with themselves before the 8-week Pilates exercise, the women after the exercise had longer time of standing with one foot and eyes' closed (14.68±5.54s vs. 27.68±4.21s), the Romberg experiment with eyes' closed (40.23±6.47s vs. 66.58±7.43s), marching on the spot with eyes' closed (9.35±3.26s vs. 20.74±10.62s) and 8 degree abdominal bridge test (24.57 ± 8.71s vs. 82.78±21.53s) and shorter time of standing and walking (16.36±2.15s vs. 7.93±1.59s), vestibular step test (8.75±1.78s vs. 3.58±2.37s) and the risk of tumbling test (2.42±1.03s vs. 2.11±0.95s), and the difference was statistically significant (P all <0.05). Compared to control group who did not have the 8-week Pilates exercise, the time of standing with one foot and eyes' closed (15.06±4.98s vs. 27.68±4.21s), the Romberg experiment with eyes' closed (39.87±9.01s vs. 66.58±7.43s), marching on the spot with eyes' closed (9.47±4.03s vs. 20.74±10.62s) and 8 degree abdominal bridge test (25.41 ± 6.22s vs. 82.78±21.53s) were prolonged in the experimental group (P all <0.01), and the time of standing and walking (16.86±1.97s vs. 7.93±1.59s), vestibular step test (9.02±2.51s vs. 3.58±2.37s) and the risk of tumbling test (2.39±1.07s vs. 2.11±0.95s) were shorten (P all <0.01).

CONCLUSIONS: After 8 weeks of Pilates exercise, the experimental group' static balance and dynamic balance, and the strength of core myodynamia were improved; and this may reduce the risk for falls.

The Effect of University Worksite Walking Program on Physical Activity and Sedentary Behavior Among Employees

Joshua J. Olmeda, Lisa J. Leininger, Kent Adams, FACSM.
California State University of Monterey Bay, Seaside, CA.
 Email: jolmeda@csumb.edu
 (No relationships reported)

The Centers for Disease Control report that 79% of Americans are not meeting weekly physical activity requirements, increasing the risk of many lifestyle related disease. Due to the many benefits of regular physical activity, university worksites are increasingly offering physical activity programming to encourage employees to be more active throughout the workday. **Purpose:** The purpose of this study was to evaluate the effects of a university sponsored walking program on physical activity amount and sedentary behavior in employees who participated versus those who did not participate. **Methods:** The research was a matched pair design. The study group (n=33) participated in the Workplace Walkoff Challenge (WWC), a six week walking competition held at a small, California university. The control group (n=17) did not participate in the WWC. The International Physical Activity Questionnaire (IPAQ) was utilized to collect vigorous, moderate, and walking MET-Mins⁻¹ per week, and sitting hours during weekdays. Participants also wore an Omron® brand pedometer and reported weekly steps. To assess these variables, dependent t-tests were performed. **Results:** For the participant group, there were significant increases in vigorous (p=.05), moderate (p=.05), and walking (p=.02) MET-Mins⁻¹ per week. There were significant increases in steps from baseline to the last week of the competition (p.01). There were no significant changes in sitting hours per day (p=.39) for WWC participants. For the control group, There were no significant differences in vigorous (p=.18), moderate (p=.35), walking (p=.46) MET-Mins⁻¹ per week for non-participants. There were also no significant increases in steps from baseline to end of competition (p=.24). There were no significant changes in sitting hours per week day (p=.50) for non-participants. **Conclusion:** A six week worksite walking program may be effective in increasing physical activity amount among employees, despite no change in sit time while at the worksite.

 (No relationships reported)

The existence of public parks for the practice of physical exercise is common in several places of the world and the explanation could be linked to a health promotion strategy, which seeks to make free leisure activities accessible to citizens. Since this

is a public policy to promote health in the population, it is important to evaluate strategies that provide feedback on investments already carried out, on which we can base the best application of resources. This effectiveness evaluation is necessary as a form of accountability for citizens, allowing re-planning actions, if necessary.

PURPOSE: The objective of this study was to identify the reasons to join an exercise program offered by an outdoor gym located in the university campus, in the city of Rio de Janeiro, Brazil. **METHODS:** This survey relied on the participation of all users of the program "Rio Ar Livre" (RAL) ("Rio Outdoor"), UERJ unit, totaling 44 individuals (8 men and 36 women), with an average age of 64 years, varying from 23 to 87 years. The data were collected through a questionnaire with both closed and semi-open questions, developed exclusively for this investigation. This study was carried out between August and September 2015.

RESULTS: The main reason users frequented this physical activity program was "Due to the decision to improve fitness/to stay fit (women [W]: 57%; men [M]: 37.5%). The most cited positive points were: the "Participation of the teacher and trainee" (W: 88.6%; M: 75%), "Location of UERJ in relation to the participant's residence" (W: 60%; M: 62.5%) and the "attendance" (W: 62.8%; M: 75%). On the question of negative points: "Cleanliness" received the most votes (W: 57%; M: 37.5%).

CONCLUSION: It was concluded that the gym's structure is one of its negative points. However, aspects such as location, gym access and, especially, the competence of personnel working in the gym (RAL-UERJ) are probably the factors leading the user to join the program and remain enrolled in it. Supported by FAPERJ (E-26/210.231/2014).

Effect of an Educational Program Promoting Regular Physical Exercises in Subjects With Knee Osteoarthritis

José M. Rodrigues da Silva¹, Marcia U. de Resende², Tânia C. Spada³, Júlia M. D' Andréa Greve⁴, Lucila S. Francisco⁵, Emmanuel G. Ciolac¹. ¹*São Paulo State University (UNESP), School of Sciences, Exercise and Chronic Disease Research Laboratory., Bauru, Brazil.* ²*University of São Paulo (USP), School of Medicine, Institute of Orthopedics and Traumatology., São Paulo, Brazil.* ³*University of São Paulo (USP), School of Medicine, Institute of Orthopedics and Traumatology., São Paulo, Brazil.* ⁴*University of São Paulo (USP), School of Medicine, Institute of Orthopedics and Traumatology, São Paulo, Brazil.* ⁵*Universidade Guarulhos (UNG), Guarulhos, Brazil.*
 Email: capoeiragafa@hotmail.com
 (No relationships reported)

PURPOSE: The purpose of this study was to investigate the effects of an educational program emphasizing the regular practice of physical exercise on physical fitness, functional capacity and daily- living physical activity levels in patients with knee osteoarthritis (OA). **METHODS:** Two hundred and thirty-nine (239) patients in the public health system (male and female), with primary or secondary knee OA (degree I to IV in the Kelgreen and Lawrence scale), and with referral for OA clinical treatment were randomly allocated to intervention (IG; n = 112) and control groups (CG; n = 127). All subjects of both groups underwent assessment for physical fitness (six-minute-walking- tests), functional capacity (seat-to-stand, Up-and-Down-stairs and Timed-Up-and-Go tests) and daily-living physical activity (IPAQ short-version), before (pre), during (6-months) and after (12- months) the follow-up. Statistical analysis was performed with ANOVA two-way (group x time) with repeated measurements, Chi-square test and the Bonferroni's t test. **RESULTS:** During six months of follow-up, the IG showed significant improvements ($P < 0,05$) in Up-and-Down-stairs (19%), seat-to-stand (30%) and Timed-Up-and-Go (32.5%) tests, as well as a reduction of Body Mass Index (BMI) ($P < 0,05$), which were maintained during the 12 months. There was also an increase in the percentage of self identified "actives" and "very actives" subjects and reduction in the percentage of sedentary subjects in the IG during follow-up ($P < 0,05$). The CG improved only the Up-and-Down-stairs tests during the 6-months follow-up. There was also an increase in the percentage of very actives subjects in GC, however, this increase was lower than that was observed in the IG. There were no significant improvements on muscular capacity, aerobic capacity and flexibility during the 12-months follow-up in both groups. **CONCLUSIONS:** These results suggest that an educational program promoting the regular practice of physical exercise may be an effective tool for improving functional capacity in patients with knee OA.

Using Accelerometers to Quantify Exercise Intensity of Exercise Classes in Older Adults**

Harry Papadopoulos, Beau Lockmer, Audrey Ewing, Stephen Henry, Serine Phillips. *Pacific Lutheran University, Tacoma, WA.* (Sponsor: L. Jerome Brandon, FACSM)
Email: papadoha@plu.edu
(No relationships reported)

Accelerometers offer detailed minute-by-minute information over extended periods pertaining to physical activity behavior. Furthermore, accelerometers are typically placed on the right hip. However, accelerometers placed on the hip may not determine exercise intensity during an entire workout in older adults.

PURPOSE: The first purpose of this study was to use accelerometers to determine the duration of time spent in certain intensities during exercise classes for older adults. The second purpose of the study was to examine the intensity level during those exercise classes as determined by accelerometers placed on the hip and wrist.

METHODS: A total of sixty seven older adults (age: 73.8 ± 14.5 yrs, weight: 71.0 ± 19.0 kg) were recruited. Twenty-five of them wore an accelerometer placed on the right hip (H) and an accelerometer placed on the right wrist (W). All individuals participated in exercise classes that included periods of cardiovascular, strength, and balance exercises. In order to quantify exercise intensity, cut points (cpm) of sedentary (≤ 100 cpm), light (101-799 cpm), and moderate (800-5722) intensity were used. A two-tailed independent t test was used to examine differences between H and W in the amount of time spent in sedentary, light, and moderate exercise intensity. Statistical significance was set at $p < 0.05$.

RESULTS: Overall, the participants engaged in 17.1 ± 5.8 minutes of light and 12.3 ± 8.8 minutes of moderate intensity activities. Furthermore, the majority of the participants (91%) perceived the intensity as moderate. The average time spent in light exercise intensity was 19.1 ± 4.5 and 7.4 ± 2.1 minutes for the H and W accelerometers, respectively. The average time spent in moderate intensity activity was 11.4 ± 6.1 and 35.0 ± 4.2 minutes for the H and W accelerometers, respectively. There was a significant ($p < 0.01$) difference between the accelerometers for light and moderate exercise intensity.

CONCLUSIONS: The data showed that very little of the activity met the moderate intensity threshold by accelerometer data, but this was dependent on the placement of the accelerometer. Furthermore, the data suggests that in order to fully comprehend the intensity of an exercise class for older adults, accelerometers must be worn on both the hip and the wrist.

(No relationships reported)

An increased lifespan and body adiposity as people age are considered risks factors for all-cause mortality. Handgrip strength is a considered a powerful predictor of cause-specific and total mortality in older disabled women and to cardiometabolic risk in aging populations. Ethnic-specific heterogeneity of risk factors calls for comparative studies to better understand competent prevention and management, which might be one of the essential steps toward elimination of ethnic disparities for several diseases.

PURPOSE: To compare the upper body strength and body composition in elderly from Costa Rica (CR) and Kansas (KS). **METHODS:** Older adults from CR (men = 26, women = 52, mean age = 68.91 ± 4.79 yr.) and KS (men = 35, women = 65, mean age = 72.84 ± 5.59 yr.), underwent handgrip strength and body composition measurements (dual-energy X-ray absorptiometry). **RESULTS:** Men (31.24 ± 7.02 %) had lower %BF than women (41.28 ± 5.87 %; $p \leq 0.001$). Women (15.0 ± 1.7 kg/m²) had lower lean tissue mass index than men (18.0 ± 1.7 kg/m²; $p \leq 0.001$). Women (6.2 ± 0.8 kg/m²) had lower appendicular lean soft tissue index than men (8.1 ± 1.0 kg/m²; $p \leq 0.001$). KS participants (1.16 ± 0.11 g/cm²) had higher total bone mineral density than CR participants (1.08 ± 0.11 g/cm²; $p \leq 0.001$), and men (1.21 ± 0.11 g/cm²) had higher total bone mineral density than women (1.08 ± 0.09 g/cm²; $p \leq 0.001$). Significant correlations ($p \leq 0.003$ for all) were obtained between handgrip strength

and body height ($r = 0.72$), body weight ($r = 0.56$), arms bone mineral density ($r = 0.67$), total bone mineral density ($r = 0.56$), lean arms mass ($r = 0.78$), total lean mass ($r = 0.81$), body fat% ($r = -0.48$), body fat mass index ($r = -0.22$), lean tissue mass index ($r = 0.59$), and appendicular lean soft tissue index ($r = 0.69$). **CONCLUSIONS:** Differences in body composition and handgrip strength were found in older adults from CR and KS. Ethnic-specific heterogeneity on biologic factors and physical-related performance allows for culturally diverse prevention programs for the elderly.

Association Of Agility With Muscle Strength, Balance, Mobility And Physical Activity Status Of Older Women**

Akiyo Higashionna¹, Takahide Matsumoto², Hiroshi Nagayama³, Goichiro Yoshida², Yutaka Yoshitake². ¹Meio University, Okinawa, Japan. ²National Institute of Fitness and Sports in Kanoya, Kagoshima, Japan. ³Kyushu Otani Junior College, Fukuoka, Japan.
Email: a.higashionna@meio-u.ac.jp
(No relationships reported)

It has been reported that body-weight supported stepping training increases the walking speed of healthy older women. This suggests that stepping with body weight unloading improves the walking ability. We hypothesized that stepping in a sitting position is associated with the physical fitness, walking ability and the physical activity status of older people.

PURPOSE: The purpose of this study was to examine the association between the stepping rate (agility) and the muscle strength, balance, mobility and the physical activity status of older women.

METHODS: The participants included 108 healthy older women (age: 74 ± 5 years; range: 65-89). The stepping rate, muscle strength (handgrip strength, knee extension strength), balance (one-leg standing time with eyes open), mobility (timed up-and-go test [TUG], maximum walking speed) and physical activity of the participants were measured. The maximal stepping rate in 10 seconds, as measured using an industrial stepping rate counter (Stepping Counter; Yagami), was used as an index of agility. The participants were instructed to perform alternating steps with each leg as quickly as possible for 10 seconds, while in a sitting position. The total number of step for both legs was used as the participant's score. The physical activity status was measured for two weeks using a uniaxial accelerometer. A multiple regression analysis was used to evaluate the association between the stepping rate and each of the other variables.

RESULTS: The stepping rate was 74.8 ± 14.2 (range 34-108) times/10s and was not correlated with age. A multiple regression analysis adjusted for age revealed that the, stepping rate was associated with handgrip strength ($\beta = 0.345$, $p < 0.00$), knee extension strength ($\beta = 0.218$, $p < 0.05$), one-leg standing time ($\beta = 0.312$, $p < 0.01$), TUG ($\beta = -0.239$, $p < 0.05$), maximum walking speed ($\beta = -0.446$, $p < 0.001$) and the percentage of time engaged in low intensity PA ($\beta = -0.245$, $p < 0.05$).

CONCLUSION: The present study showed the association between agility and muscle strength, balance, walking ability and physical activity of physically independent older women.

Inter-rater And Test-retest Reliability Of The Y-balance Test In Healthy Women 50-80 Years Old**

Jacob Shepherd, Autumn Oostindie, Jared Locke, Srikant Vallabhajosula, Deborah Stettis, Jane Freund. *Elon University, Elon, NC.* (Sponsor: Dr. Stephen Bailey, FACSM)
Email: jshepherd3@elon.edu
(No relationships reported)

The assessment of dynamic balance through the use of standardized objective measures is important to identify impairments which may increase fall risk in older adults. Many of the current clinical balance tests are not challenging enough to assess balance and identify fall risk in healthy older adults. A test which may be appropriate for healthy older adults is the Lower Quarter-Y Balance Test (LQ-YBT). The LQ-YBT is a test of dynamic motor control at the limits of stability in single-leg stance which has typically been researched in younger athletic populations to evaluate dynamic balance and risk for injury. **PURPOSE:** To determine the inter-rater and test-retest reliability of the LQ-YBT in healthy women from 50-80 years old. **METHODS:** Eighty-six potential participants were screened and data collection included 60 healthy women 50-80 years old, with mean age $64.3 (\pm 7.9)$ years. Each participant completed the LQ-YBT in a standardized manner as described in the LQ-YBT manual. The scores for each participant were independently determined and recorded to the nearest centimeter by two examiners. After a 5-minute rest, a subset of eight participants performed the LQ-YBT a second time in the same session for the purpose of test-retest reliability. The maximum distance reached in each direction, normalized for leg length, was used for data analysis. Intraclass Correlation Coefficients [ICC (2,1)] were used to determine the test-retest and interrater reliability of the normalized reaches in each direction and the composite scores. **RESULTS:** The LQ-YBT demonstrated excellent

inter-rater reliability with ICC values of 0.98 to 1.0 for the various directions, and 1.0 for the composite scores, bilaterally. The test-retest ICC values were also excellent ranging from 0.75 to 0.93 for the various reaches and 0.96 and 0.95 for the right and left lower extremity composite scores, respectively. **CONCLUSION:** The LQ-YBT demonstrated excellent inter-rater and test-retest reliability in healthy women 50-80 years old and may be considered for use as a measure of dynamic balance in this population.

Purine Metabolites and HGPRT Activity in Male Speed-Power vs Endurance Masters Athletes Aged 20-90 Years

Jacek Zielinski¹, Ewa Slominska², Magdalena Krol-Zielinska¹, Zbigniew Krasinski³, Krzysztof Kusy¹. ¹Poznan University of Physical Education, Poznan, Poland. ²Medical University of Gdansk, Gdansk, Poland. ³Poznan University of Medical Sciences, Poznan, Poland.
 Email: jacekzielinski@wp.pl
 (No relationships reported)

PURPOSE: According to recent studies, purine metabolism better reflects exercise response and muscle adaptation than widely used indicators. Consequently, we proposed using purine derivatives, especially plasma hypoxanthine (Hx) concentration and erythrocyte HGPRT activity as indicators of training status in highly trained young athletes. The aim of this study was to compare the effects of many years' sprint and endurance training on levels of purine derivatives and HGPRT activity. **METHODS:** Master sprinters (SP, n=52), master endurance runners (ER, n=86) and healthy control participants (CO, n=60), age range 20-90 years, were compared. They underwent a treadmill test until exhaustion. Venous blood samples were drawn at rest and post exercise. Hx, xanthine (X), uric acid (UA) and erythrocyte HGPRT activity were assayed by means of HPLC method. Regression analyses were performed to show the relationships between purine derivatives and HGPRT activity and age. **RESULTS:** Resting and post-exercise Hx were similar in both athletic groups and different from the CO group, in which highest Hx values were observed. Resting and post-exercise X were only different between SP and CO groups. Resting HGPRT and post-exercise UA were different between all three groups. Age explained 87-96%, 69-94%, 17-55% and 41-54% of variance in Hx, X, UA and HGPRT, respectively, except for UA in the CO group (1-5%). The relationships between age and Hx and resting X were nonlinear (polynomial function of degree 2). The age-related changes in UA were only minimal in athletes and virtually nonexistent in the CO group. **CONCLUSION:** The age-related elevation in resting and post-exercise Hx suggests that the exercise-induced energetic stress considerably progresses with ageing. Increased Hx levels, despite increasing HGPRT activity that supports ATP resynthesis through the purine salvage pathway, bring about a delayed restoration of the adenine nucleotide (AdN) pool through the energy-consuming *de novo* synthesis. One can expect that in older subjects, subsequent high-intensity exercise bouts will require longer recovery to restore the AdN pool. In practical terms, older athletes should plan their high-intensity workout having regard to these implication of ageing. Supported by National Science Center Poland Grant 2013/09/B/NZ7/02556

Improving Power Output in Older Adults Utilizing Plyometrics in an AlterG Treadmill

Tyler J. Dobbs, Shawn R. Simonson, Scott A. Conger. *Boise State University, Boise, ID.* (Sponsor: Dawn P. Coe, FACSM)
 Email: tylerdobbs@u.boisestate.edu
 (No relationships reported)

In older adults, muscular strength has been shown to decline by up to 1-2% per year, and muscular power declines at an even higher rate. Plyometric training has shown benefits for increasing muscle force, power, and agility in adolescents and recreational adults; however, data on older adults is lacking. The AlterG treadmill allows for improved mobility, strength, and safety while improving functional capacity related to endurance, strength, and power. **PURPOSE:** To determine the effects of performing plyometrics in an AlterG treadmill on power output and functional strength in older adults when compared to traditional strength training. **METHODS:** Twenty-three subjects were randomized to a strength (SG) (n = 8), plyometric (PG) (n = 8), or control (CG) (n = 7). SG and PG exercised 3x/week for 8 weeks and CG performed no exercise. SG performed sets of 3x10 at 65-80% of one-repetition maximum (1RM) (estimated from 3-5RM) on the leg press (LP), leg extension (LE), and single leg lunge (LL). PG performed 3x10 in the squat jump, single leg bound, and power skipping at an intensity range of 65-80% body mass. Timed sit-to-stand and stair climb, estimated maximal muscular strength, and isokinetic power during leg flexion and extension were compared pre and post intervention. A 2 x 3 repeated measures ANOVA was used to determine differences between groups. Data was reported as percent change from baseline. **RESULTS:** Significant improvements occurred in the PG in the timed sit-to-stand (22.11 ± 8.48%, p = 0.013), timed stair climb (14.68 ± 6.28%, p = 0.002),

and stair climb power (16.59 ± 9.07%, p < 0.001). PG and SG significantly increased their estimated 1RM in the LE and LL (p < 0.05). PG was significantly more powerful at all 3 velocities in both flexion and extension except at 60°/sec extension, ranging from 24.54 ± 19.94% to 85.74 ± 62.23% (p < 0.001). PG increased muscular strength similarly or better than SG without performing resistance training. **CONCLUSIONS:** Eight weeks of plyometrics in an AlterG treadmill improved functional strength and power in older adults, accomplished through performing exercise requiring less total work per exercise session. Results suggest that plyometrics, if modified and performed in a safe environment, can increase muscular strength and power and improve functional abilities in older adults.

The muscle decline and your functional capacity have age association, strength capacity also be relation with life style. For health men, this factor still suffer the effects somatopause, but the data for sedentary men still need scientific attention. **PURPOSE:** The purpose of this study was to compare the muscle strength of sedentary adult men with different age group. **METHODS:** The sample was 331 sedentary men divided in tree groups of according with age 21-29 years (G1), 30-39 years (G2) and 40-49 years (G3). All sample non physically active <150 minutes for week. The subjects were anthropometric measurements, 1 minute of abdominal test (IAT), flexion strength of the elbow (FSE). It was made a descriptive statistic, and ANOVA one way with Tukey's post hoc (p<0.05). **RESULTS:** For men was verify a decline in the IAT of 26.8% (p=0,001) comparing G1 with G3 and 23,1% (p=0,001) when compared G2 with G3. But for FSE non significant results was verify in the different age group. **CONCLUSIONS:** We can conclude for the IAT and body mass was verify a significant reduction as advancing age in sedentary men. however that in the flexion strength elbow not detected a strength decline as advancing age in sedentary men.

Comparisons of Fat Free Mass and Fat Mass between Active and Inactive Older Women

Maressa P. Krause, Rodrigo Baumann Velho, Sergio Gregorio da Silva. *Universidade Tecnológica Federal do Parana, Curitiba-PR, Brazil.*
 Email: maressakrause@hotmail.com
 (No relationships reported)

Purpose: To compare the fat free mass and fat mass between active and inactive older women. **Methods:** Participated in this investigation 44 older women, mean aged of 66.0 (±4.5years-old). Sample was classified as inactive (Inactive group - IG, n=18), who was not enrolled in an exercise program in the previous six months, and active (Active group - AG, n=26), who have been participating regularly in the last six months in an exercise program (bench stepping group exercise - BSGE) promoted by the physical education department in the Technological Federal University of Parana. Body composition was analyzed by the Dual Energy X-Ray Absorptiometry (DXA) equipment. Data were described by mean and standard deviation and analyzed by the independent T-test using the SPSS software (p<0.05). **Results:** Comparisons between groups showed that IG had a significantly lower fat free mass for all measurements - right and left upper limb (1665.5±467.4 and 1506.8±443.4grams VS 2066.9±328.3 and 1866.9±282.2 gram, respectively), trunk (1996.1±3629.4 VS 22380.8±3695.9 gram), and right (5108.4±600.3 VS 6083.7±616.5 gram) and left (5112.8±738.6 VS 5979±542.0 gram) lower limb (all p<0.05). Also, the IG had a higher %fat mass for right (47.0±6.0) and left (47.4±7.0) lower limb than active group (42.2±4.8 and 42.5±4.8, respectively) (all p<0.05). **Conclusion:** Older women who participated in a bench stepping group exercise program had a better body composition than their inactive peers. This results were more evident for fat free mass which has been positively associated with functional-physical fitness and successful aging. Also, it is consensus that the accumulation of fat mass increases the risk for several metabolic and cardiovascular diseases, then the maintenance of %fat mass is crucial for a preventive health perspective.

Dynamic Postural Control by Body Mass Index and Walking Speed in Korean Elderly
 Eun Jin Hwang, Somi Yun, Dahye Lim, Dae Taek Lee. *Kookmin University, Seoul, Korea, Republic of.*
(No relationships reported)

PURPOSE: To investigate the influence of body mass index (BMI) and walking speed on postural control in Korean elderly

METHODS: A total of 127 elderly (76.4±7.0 yrs, 155.5±8.1 cm, 60.8±10.2 kg, 25.2±3.5 kg/m²) walked on a force platform for 4.5 meter distance on their pace and parameters of postural control such as Envelope Area (ENV), Rectangle Area (REC), total length from center of pressure (TLC), and Sway Velocity (SV) were measured. Based on their walking speed, they were divided into three groups; slow (S, n=41, 6.5<sec), average (A, n=47, ≤6.5 sec), and fast (F, n=44, ≤5 sec). In addition, based on their BMI, they were grouped as; normal weight (NW, n=35, 21.3±1.3, range 18.5-22.9), overweight (OW, n=38, 24.2±0.5, range 23.0-24.9), and obese (OB, n=54, 28.5±2.5 kg/m², 25≤). Their physical fitness was also measured by 2-min Step Test, 30-second Chair Stand, 8-Ft Up and Go, and One-leg Standing.

RESULTS: No differences in age and height were noticed when compared by groups of BMI. Body weight, fat content, and waist circumference were greater as BMI was higher (p<0.05). ENV (299±285, 316±286, and 252±253 mm²), REC (699±720, 985±2137, and 619±683 mm²), TLC (333±175, 331±175, and 289±117 mm), and SV (17±9, 17±9, and 14±6 mm/sec in NW, OW, and OB, respectively) were not different between groups of BMI. When compared by walking speed, all postural parameters such as ENV, REC, TLC, and SV were not different among S, A, and F. When physical fitness variables were analyzed, no group differences by walking speed and BMI were noticed.

CONCLUSION: The degree of sway of center of pressure during walking in elderly was not different when it was compared by groups of BMI and walking speed. Capability of maintaining body balance in elderly population during locomotion may not be predicted by their BMI or walking speed.

Maximal Velocity Adaptions During Unilateral Resistance Training In Older Adults
 Alex A. Olmos¹, Garrett G. Hester¹, Zachary K. Pope², Ryan J. Colquhoun², Mitchel A. Magrini², Alejandra Barrera-Curiel², Carlos A. Estrada², Jason M. DeFreitas². ¹*Kennesaw State University, Kennesaw, GA.* ²*Oklahoma State University, Stillwater, OK.*
 Email: olmosalex73@gmail.com
(No relationships reported)

Maximal velocity parameters are negatively affected by aging; however, little is known regarding the short-term effects of resistance training (RT) on maximal velocity variables in older adults. Furthermore, whether or not unilateral RT induces maximal velocity adaptations in the untrained limb has not been determined. **PURPOSE:** To examine the effects of unilateral RT on maximal velocity parameters of the ipsilateral and contralateral leg in older males. **METHODS:** Twenty-one untrained older males were randomly assigned to a training (TG; n = 10, age = 64.70 ± 6.91 yrs.) or control (CG; n = 11, age = 65.56 ± 11.56 yrs.) group. The TG performed 3 sessions per week of unilateral isokinetic RT for 4 weeks. RT sessions consisted of maximal concentric knee extensions at 45°·s⁻¹ for 4 sets of 10 repetitions. Subjects were instructed to "kick out as hard and fast as possible" during each RT session. Maximal concentric isokinetic testing of the knee extensors for the trained (TL) and untrained (UL) leg at 500°·s⁻¹ (ISOK₅₀₀) was performed before (PRE), at week 2 (MID), and after week 4 (POST) of RT. There was no resistance during ISOK₅₀₀, with the exception of the lever arm mass, as the velocity was above all subjects' maximum velocity. The highest velocity attained (PV; deg·s⁻¹) and the linear slope of the velocity-time curve (RVD; deg·s⁻²) were recorded for analysis. For the TL and UL, one-way repeated measures analyses of variance were used for the TG and CG separately. **RESULTS:** PV and RVD remained unchanged in both legs for the CG (p > 0.05). PV did not change in the TL (p = 0.084), while RVD increased from PRE to POST (+5.8%; p = 0.029) and MID to POST (+4.1%; p = 0.038). PV (p = 0.644) and RVD (p = 0.523) were unaltered in the UL. **CONCLUSION:** RVD appears to be more sensitive to change during the early-phase of RT compared to PV in older males. However, neither PV nor RVD in the UL appear to be affected by short-term unilateral RT. Since many neural adaptations are expressed bilaterally, the improvement in RVD for only the training leg suggests the adaptation is more likely mechanical in origin.

The Self-Reported Exercise Habits of Older Adult Women and the Associated Effects on Physical Fitness
 Robert C. Mason¹, Michael A. Horvat², Joe Nocera³. ¹*Delaware State University, Dover, DE.* ²*University of Georgia, Athens, GA.* ³*Atlanta VA Medical Center, Atlanta, GA.* (Sponsor: Erica Taylor, FACSM)
 Email: rmason@desu.edu
(No relationships reported)

ABSTRACT

The amount of time that older adults exercise is influenced by their fitness, physical function, and self-efficacy to participate in physical activity. As the population of older adults is continuing to increase and become more diverse, it will be important to recognize and investigate differences among them, including variance in exercise time. The usefulness of self-report instrumentation by older adults to determine the optimal amount of time spent exercising to enhance fitness components and physical function is still largely unknown.

Purpose: To investigate the relationship between self-reported exercise habits, fitness levels, and physical function among healthy older adult women. **Methods.** Two groups of older adult women (M_{age} = 69 years) were instructed to continue their normal routines of attending group exercise classes at the local YWCO for a 10-week period. Group 1 (n=15) self-reported a weekly average that was equal to or lower than 360 minutes of exercise per week. Group 2 (n=15) consisted of those participants who reported averaging more than 360 minutes of exercise per week. The Senior Fitness Test (SFT) was used to assess the overall fitness and physical function of both groups of participants at baseline, after five weeks, and again after 10 weeks of exercising. **Results.** Statistical analysis showed no significant interaction effect for time*group (p<0.05) for chair stands [F(2,52)=2.288, p=.112], arm curls [F(2,52)=2.138, p=.128], 2-min step [F(2,52)=1.048, p=.358], chair sit & reach [F(2,52)=1.290, p=.284], and back scratch tests [F(2,52)=1.102, p=.340]. However, a significant interaction effect existed for time*group for the 8-foot Up & Go test [F(2,52)=4.685, p=.013]. **Conclusion.** Study findings suggest that perhaps 360 minutes of exercise per week in a community-based setting such as the Athens YWCO is the threshold for considerably improving mobility, coordination, and dynamic balance as measured by the 8-foot Up & Go task in older adult women. Also, further consideration should be given to utilizing tests similar to the 8-foot Up & Go that are designed to be more sensitive and complex when assessing the physical fitness of older adults.

Preliminary Validation Of The Virtual Short Physical Performance Battery In Older Adults With Multiple Sclerosis
 Rachel Klaren-Bollaert¹, Robert W. Motl², Anthony P. Marsh³. ¹*University of Illinois Urbana-Champaign, Urbana, IL.* ²*University of Alabama at Birmingham, Birmingham, AL.* ³*Wake Forest University, Winston-Salem, NC.*
 Email: klaren2@illinois.edu
(No relationships reported)

Abstract

Purpose: There are relatively few measures for studying physical function involving older adults with multiple sclerosis (MS), including non-supervised outcomes administered within a patient's home. However, such measures are necessary considering the prevalence and associated consequences of MS and aging on physical function. The objective of this study was to perform a preliminary examination of the validity of the virtual Short Physical Performance Battery (vSPPB) and its associations with objectively-measured levels of moderate-to-vigorous physical activity (MVPA) and cognitive function.

Methods: A sample of 30 older adults with MS (≥60 years of age) underwent assessments of cognitive function, completed a battery of lower and upper extremity function assessments, including the vSPPB, and wore an accelerometer for a 7-day period. Spearman correlations (r) were conducted based on an expected differential pattern of associations with measures of upper and lower extremity function and for MVPA and cognitive function.

Results: vSPPB scores demonstrated strong associations with measures of lower extremity function (r=0.55-0.81), and weak associations with a measure of upper extremity function (r=0.16). The total SPPB (9.2 (2.3)) and vSPPB (6.9 (2.4)) scores were similar and moderately correlated (r=0.76) and the component scores of the SPPB and vSPPB were moderately to strongly correlated (r=0.41-0.58). Total vSPPB scores demonstrated moderate associations with minutes of MVPA per day (r=0.46). There were no significant associations between vSPPB scores and any of the cognitive measures.

Conclusion: We provide preliminary evidence that supports the validity of scores from the vSPPB as a measure of perceived lower extremity function that provides unique information for inclusion in clinical research and practice involving older adults with MS.

Beneficial Effects of Senior Functional Fitness to Manage Blood Pressure in Community-dwelling Older Adults
 Sz Ming Fang, Michael-S Lo, Linda L. Lin, Chiao-Hsin Chen, Yueh-Chang Tsai. *Institute of Physical Education, Health and Leisure Studies, Tainan, Taiwan.*
 Email: penguin811012@gmail.com
 (No relationships reported)

Purpose: To investigate the relationships and difference of senior functional fitness between varied levels of blood pressure (BP) and functional fitness assessments with community-dwelling older adults.

Method: 1003 community-dwelling residents aged 65 to 95 (Male, n=384, age =74yrs; female, n=615, age =69yrs) volunteered to participate in the study during 2010-2015. Participants completed 6 functional fitness tests, blood pressure measured and a health-screening questionnaire. The senior functional fitness including flexibility, muscle strength, muscle endurance, aerobic endurance, and body agility/dynamic balance. The **classification of Blood Pressure for Adults**: Normal systolic blood pressure (SBP) <120 and diastolic blood pressure (DBP) <80 mmHg (NOR); Prehypertension SBP 120-139 or DBP 80-89 mmHg (PRE); Stage 1 hypertension SBP 140-159 or DBP 90-99 mmHg (1st); Stage 2 hypertension SBP ≥160 or DBP ≥100 mmHg (2nd). One-way ANOVA and Pearson's product moment correlation were used to determine plasticity of functional fitness of individual BP.

Result: Senior functional fitness had the significant correlations with blood pressure ($p < .05$). In aerobic endurance, NOR is better than 2nd (1.36%) ($p < .005$). Furthermore, significant differences were observed in lower limbs muscle endurance, NOR is higher than 1st and 2nd (8.71%, 1.46%) ($p < .005$). In lower body flexibility, NOR is better than 2nd (98.51%) ($p < .005$). However, in upper body flexibility, NOR and PRE were better than 1st and 2nd ($p < .005$). In body agility/dynamic balance, NOR is faster than 1st and 2nd (9.87%, 16.4%) ($p < .005$).

Conclusion: The participants with better control of the blood pressure have better lower extremity muscle endurance, ability, balance, lower and upper extremity flexibility. The cardiovascular function and upper body flexibility were the most direct influence factors to prevent or manage hypertension.

Keywords: prehypertension, older adults, functional fitness

Effects of Resistance Training on Physical Exercise Capacity and Vascular Function Among Elderly Women
 Joyce E. Ballard, FACSM, Arturo A. Arce-Esquivel. *The University of Texas at Tyler, Tyler, TX.*
 (No relationships reported)

Aging is associated with a decline in physical exercise capacity and in limb blood flow that could lead to a reduction in overall functional capacity. Exercise training has emerged as an effective therapy to improve the decline in physical and vascular function. **PURPOSE:** The purpose was to examine the effects of whole-body resistance training (RT) on physical exercise capacity and microvascular function among elderly women.

METHODS: Fifteen women (age: 69 ± 7.45 years) were referred by physicians as apparently healthy and signed informed consents prior to testing. These women participated in whole-body RT program performed, 2 days/week for 8 weeks. Before and after training muscle strength [One repetition maximum (1RM) for chest press, biceps curl, leg extension, and leg curl], physical exercise capacity [i.e., six-minute walk test (6MW)], and microvascular function (i.e., vascular reactivity) were measured.

RESULTS: The 1RM for all the muscle strength outcomes increased significantly [chest press: 29.74%, pre = 8.64 ± 2.46 ; post = 11.21 ± 2.91 kg; biceps curl: 37.02%, pre = 9.02 ± 2.45 ; post = 12.36 ± 2.49 kg; leg extension: 19.95%; pre = 34.24 ± 11.76 ; post = 41.07 ± 14.53 kg; leg curl 25.33%; pre = 36.00 ± 8.92 ; post = 45.12 ± 8.52 kg]. The 6MW test increased significantly 15.76% [pre = 564.20 ± 90.83 ; post = 653.10 ± 50.78 m, ($p < .05$)]; and the vascular reactivity index [measured by fingertip digital thermal monitoring] also increased significantly 13.36% [pre = 2.17 ± 0.44 vs. post = 2.46 ± 0.36 , ($p < .05$)].

CONCLUSIONS: Clearly, these findings demonstrate that whole-body RT is capable of increasing physical exercise capacity and microvascular function among elderly women. This study underlies the importance of whole-body resistance exercise training as part of a healthy and active lifestyle in elderly women.

Fitness Correlates Of Golf Performance, Exercise Enjoyment, And Mood In Senior Women Golfers
 Lynn A. Darby, FACSM¹, Bonnie G. Berger¹, David R. Owen².
¹Bowling Green State University, Bowling Green, OH. ²Brooklyn College, CUNY, Brooklyn, NY.
 Email: ldarby@bgsu.edu
 (No relationships reported)

Senior golfers (≥ 50 yrs of age) constitute approximately 5 million of the 20 million "committed" U.S. golfers (National Golf Foundation, 2016). This number emphasizes that golf is a lifelong physical activity. **PURPOSE:** To investigate the relationships among golf-specific fitness measures, golf performance, exercise enjoyment, and mood alteration. **METHODS:** Female senior golfers completed golf histories, 17 golf-specific fitness screening tests (TPI-fit; *Tiltest Performance Institute*®), golf swing analyses, and the Physical Activity Enjoyment Scale (PACES). Heart rate (HR), ratings of perceived exertion (RPE), and Total Mood Disturbance (TMD) scores on the Profile of Mood States were measured before and after a 6-min walk test (6MWT). Pearson correlations were calculated. **RESULTS:** Descriptive characteristics, means \pm SD: Age (yrs) = 64.1 ± 8.0 ; Body weight (kg) = 71.1 ± 14.3 ; TPI-fit and golf swing analyses = 17.3 ± 4.4 , 13.1 ± 7.9 , "lower is better"; 6MWT (ft) = 1906 ± 213 (67th %ile), RPE = 13.1 ± 2.0 "somewhat hard", HR (b/min) = 127 ± 20 , %HRmax = 81 ± 15 "vigorous." Age was not correlated with any variables, except months of playing golf per year ($r = -0.56$, $p = 0.03$) with older golfers playing fewer months than younger golfers. Age when beginning golf participation was positively correlated with handicap, average scores for 9- and 18-holes, and number of golf swing errors ($r_s = 0.71$, 0.68 , 0.65 ; $p_s < 0.03$). Golfers' body weights were correlated with better TPI-fit scores ($r = -0.64$, $p = 0.01$) and average scores for 9- and 18-holes of golf ($r = -0.67$, -0.65 ; $p_s \leq 0.02$) representing greater strength or leverage during the golf swing. Golfers with better TPI-fit scores tended to have higher exercise enjoyment ($r = -0.42$, $p = 0.09$). TMD scores on the POMS improved (97.4 ± 13.9 , 89.5 ± 15.2 ; $p = 0.06$) after only 6-min of high intensity walking. Greater 6MWT HRs were correlated with greater TMD improvements ($r = 0.49$, $p = 0.05$). **CONCLUSIONS:** Senior women golfers with more years of golf experience, or who were heavier, performed better on TPI golf-specific fitness and swing tests. The women also reported enjoying exercise and desirable changes in mood after aerobic exercise. Future studies of senior women golfers are needed to continue examining the role of golf participation in seniors' fitness levels and overall subjective well-being.

Relationships Among and Differences between Muscle Quality and Functional Performance in Younger and Older Women
 Mitchel A. Magrini, Ryan J. Colquhoun, Alejandra Barrera-Curiel, Ryan M. Thiele, Tyler W.D. Muddle, Jason M. DeFreitas, Doug B. Smith, Nathaniel D.M. Jenkins. *Oklahoma State University, Stillwater, OK.*
 (No relationships reported)

The quality of skeletal muscle has been identified as an important factor that is used to describe intramuscular changes associated with muscle function in aging. Traditionally, muscle quality (MQ) has been calculated as maximal muscle strength expressed per unit of muscle mass. More recently, however, the echo intensity (EI) of skeletal muscle ultrasound images has been used as a surrogate measure of muscle quality. **Purpose:** The purpose of this study was to examine the relationships among and differences between commonly-used measures of MQ and functional performance in younger (YW) and older women (OW). **Methods:** 15 YW (mean \pm SD: 22 ± 2 yrs) and 15 OW (74 ± 5 yrs) completed this study. Muscle cross section area (mCSA) and EI of the rectus femoris were measured from ultrasound scans at the midpoint of the thigh. Each participant completed two maximal voluntary isometric knee extension contractions (MVICs) to determine MVIC strength. Each participant also completed three maximal velocity sit-to-stand movements, during which power and movement velocity were measured. MQ was calculated as MVIC strength \div mCSA. Independent samples t-tests were used to analyze differences between YW and OW and Pearson's correlation coefficients were also used to analyze the relationships among the dependent variables in the YW and OW. **Results:** MVIC strength (166 ± 37 vs 105 ± 28 Nm), mean velocity (0.6 ± 0.1 vs 0.4 ± 0.1 m/s), peak velocity (0.9 ± 0.2 vs 0.7 ± 0.1), mean power (435 ± 81 vs 299 ± 57 W), peak power (1070 ± 265 vs 597 ± 127 W) were greater and EI (39 ± 8 vs 52 ± 10 au) was lower in the YW than OW, respectively. There was no difference in muscle quality ($p = 0.96$). EI and MQ were not significantly related ($r = 0.12$) in the YW, but were significantly related in the OW ($r = 0.54$). EI was inversely related to mCSA in the YW ($r = -0.53$) and OW ($r = -0.54$). In addition, MVIC was significantly related to mCSA ($r = 0.75$) in the OW, and was not significantly related to EI or MQ in either the YW or OW. **Conclusion:** There were age-related differences in muscle strength, muscle size, echo intensity, and functional performance, but no age-related difference in traditionally measured MQ. EI was related to MQ in the OW, but not the YW. Although EI has been used as a surrogate for MQ, these data suggest that MQ and EI may reflect different qualities of skeletal muscle in aging.

Acute Neuromuscular Adaptations In Response To Low-intensity Blood-flow Restricted Exercise And High Intensity Resistance Training**

Pedro Mil-Homens, Joana F. Reis, Goncalo V. Mendonca, Tomás Freitas, Maria J. Valamatos, Pedro Fatela. *Faculdade de Motricidade Humana; PTDC/DTP-DES/5714/2014, Lisboa, Portugal.*
(No relationships reported)

Numerous studies have reported similar neuromuscular adaptations between low-intensity (LI) blood-flow restricted exercise (LI BFR) and high-intensity (HI) resistance training. Unfortunately, since none of these experimental designs individualized BFR levels to each participant, their findings are difficult to interpret. **PURPOSE:** To compare the acute effects of LI BFR (80% of absolute vascular occlusion pressure) with LI non-BFR and HI training on muscle torque, activation and neuromuscular fatigue. **METHODS:** Ten men (23.8 ± 5.4 yrs) exercised at 20 (LI) and 75% (HI) of 1 repetition maximum. LI consisted of 4 sets of knee extensions (30+15+15+15 repetitions) with and without BFR. HI included 4 sets of knee extensions (10+10+10+10 repetitions) without BFR. BFR pressure was determined individually using resting blood-flow measurements. Torque was determined during maximal voluntary contractions (MVC) before and after exercise. Surface electromyographic activity (root mean square - RMS and median frequency - MF) was recorded for the rectus femoris (RF) and vastus medialis (VM) muscles, before and after each session of training, during isometric contractions performed at 20% MVC. **RESULTS:** Torque decreased post-HI and LI BFR (-9.5 and -7.8%, respectively; p<.05), but not after LI without BFR. The MF was reduced following HI in the VM and the RF muscles (-5.3 and -12.5%, respectively; p<.05). Conversely, the impact of LI BFR on reducing MF was limited to the RF muscle (-10.7%, p<.05). The RMS values for the VM only increased after LI BFR (+26.3%, p<.05). In contrast, while RMS decreased by 19.0% post-HI (p<.05), this was not seen after LI with or without BFR. **CONCLUSION:** LI BFR is as effective as HI in decreasing post-exercise MVC. However, since our data unequivocally demonstrate that the neuromuscular impact of HI is more profound than that of LI BFR, it should be emphasized that the use of high mechanical loads represents a stronger stimulus for muscular adaptation.

Acute Effects of Blood Flow Restriction Cuffs During Aerobic Exercise on Hemodynamics in Females**

Margarita Gonzalez, Brittany Esparza, Patrick Murphy, Murat Karabulut. *University of Texas Rio Grande Valley, Brownsville, TX.*
Email: margarita_gonzalez_8@yahoo.com
(No relationships reported)

PURPOSE: The purpose of this study was to investigate the acute effects of a 20-minute walk/run at 40% VO₂ with and without blood flow restriction (BFR) cuffs on pulse rate (PR), stroke volume (SV), cardiac output (CO), cardiac ejection time (CET), systemic vascular resistance (SVR) and total vascular impedance (TVI) when compared to a 60-minute walk/run at 65% VO₂ without BFR in females. **METHODS:** Seventeen female subjects, between the ages of 18 and 40, were familiarized with the study protocol, had thigh circumference (THC) measured, and performed the Bruce protocol on the first day. BFR cuff inflation was based on THC. The three randomized sessions: 1) 40% VO₂ with BFR for 20 minutes (BFR-20min), 2) 40% VO₂ without BFR for 20 minutes (no-BFR-20min), and 3) 65% VO₂ without BFR for 60 minutes (no-BFR-60min). Each session began with the subject reaching a hydration status at or below 1.010. Once the hydration levels were reached, the subject would lie down, in the supine position, and have baseline hemodynamics measured. Following baseline measurements, the subject walked/run at a randomly predetermined intensity and time with or without BFR cuffs. BFR cuffs were taken off immediately after the 20-minute BFR condition. Post measurements of hemodynamics were taken at 10, 20, and 40 minutes following exercise. Conditions were separated by at least 48 hours. **RESULTS:** Significant condition main effects were found in PR (p<.01, BFR-20min vs. no-BFR-60min), SV (p<.01, BFR-20min vs. no-BFR-60min), CET (p<.04 no-BFR-20min vs. no-BFR-60min). Significant time main effects were found in PR (p<.01), SV (p<.01), CO (p<.04), CET (p<.01), SVR (p<.04), and TVI (p<.01). Significant condition*time interactions were found in PR (p<.01), SV (p<.01), CO (p<.02), SVR (p<.04), and TVI (p<.01).

CONCLUSIONS: The BFR-20min condition, at 40% VO₂, elicited higher SV and lower PR responses than the no-BFR-60min condition using 65% VO₂, which might be caused by the use of a lower intensity that produced a lower sympathetic nervous system response. Furthermore, the no-BFR-60min condition produced a lower response in SVR and TVI than the no-BFR-20min condition that may have been caused by a greater release of nitric oxide from the session length that was thrice as long.

Impact of Blood Flow Restricted Cycle Training in College-Aged Triathletes on Performance and Physiological Parameters**

Norio Hotta¹, Takafumi Shiono¹, Hisayoshi Ogata¹, Michael Kushnick². ¹Chubu university, Kasugai, Japan. ²Ohio University, Athens, OH.
Email: horinori@isc.chubu.ac.jp
(No relationships reported)

Aerobic exercise training with blood flow restriction (BFR) has been reported to increase aerobic capacity and muscle strength and volume. However, there is no evidence that such a training strategy increases performance in athletes. **PURPOSE:** To elucidate the effects of a 4 week BFR cycle training protocol on aerobic capacity, muscle function and performance variables in triathletes of a university club. **METHODS:** Eighteen healthy university triathletes were randomly assigned to BFR group (n = 12; 19 ± 1 yrs) or no BFR group serving as the control (CON; n = 6; 20 ± 1 yrs). Both groups trained by cycling for 30 minutes, 3 days/week for 4 weeks. BFR was performed for 15 minutes total during each session as 5 minutes with BFR followed by 5 minutes without BFR, by applying cuffs to the upper thighs. The BFR group was further subdivided into two groups: one group with compression set to 160 mmHg (constant pressure, BFR-CP, n = 6); in the other, the compression was gradually increased from 160 to 190 mmHg over 4 weeks (incremental pressure, BFR-IP, n = 6). All tests were performed before (Pre) and after 4 weeks of training (Post). Triathlon-specific performance tests were used: 5000-m run and 1500-m swim time trials and a 20-min bike distance trial, as well as the evaluation of peak oxygen uptake (VO_{2peak}), one legged knee extensor strength, and thigh muscle cross sectional area (CSA). Two-way repeated ANOVAs were used (BFR vs CON or BFR-CP vs BFR-IP and Pre vs Post) with significance accepted as p<0.05. **RESULTS:** VO_{2peak} significantly increased after the training (main effect of time) and significant group-by-time interactions were detected (3198 to 3449 mL/min and 3152 to 3212 mL/min in BFR and CON). However, a post-hoc analysis indicated no significant interaction in VO_{2peak} between BFR-CP (3137 to 3396 mL/min) and BFR-IP (3259 to 3501 mL/min). Although the 5000-m run time was significantly shorter after the training (main effect of time), no significant interaction were detected (20.3 to 19.8 min and 20.1 to 19.8 min in BFR and CON). Lastly, there were no significant effects of training on muscle strength or CSA, 1500-m swim time, or 20-min bike distance. **CONCLUSIONS:** In this group of university triathletes, 4 weeks of BFR cycle training increased aerobic capacity, but had no added effect on muscle strength and volume or performance test outcomes.

Influence Of The Degree Of Blood Flow Restriction On Muscular Activity During Bench Press Exercise**

Koji Kurita¹, Masanori Takemura², Mitusharu Kaya³, Junzo Tsujijita⁴, Yuichiro Katoh¹. ¹Univesity of East Asia, Shimomoseki, Japan. ²Ichihashi Clinic, Kobe, Japan. ³Hyogo University of Health Science, Kobe, Japan. ⁴Institute of Health & Sports Medical Science, Osaka, Japan.
Email: pcp1996@cotton.ocn.ne.jp
(No relationships reported)

Abstract; It has been reported that blood flow restriction (BFR) induced increases in muscle activation are correlated with decreased muscle blood flow resulting from external compression (i.e. higher relative pressures) (Sugaya M; 2011). However it has been reported that higher relative pressures may not be necessary with low-intensity exercise with BFR (Loenneke JP et al; 2015). **PURPOSE:** The purpose of this study was to compare the effects of resistance exercise with different degrees of BFR on muscle activation. **METHODS:** 15 healthy adults performed 3 sets of bench press exercise (30, 15, and 15 reps; load: 30% 1RM) during 4 different BFR conditions: non pressure (N-BFR), low pressure BFR (L-BFR), middle level pressure BFR (M-BFR), and high pressure BFR (H-BFR). Surface EMG was recorded from the pectoralis major muscle (PM), anterior deltoid muscle (AD), and the triceps brachii muscle (TB), EMG amplitude (RMS) normalized as the relative exercise intensity (%) was analyzed (2-way repeated measures analysis of variance, and multiple post hoc test). **RESULT:** During 3 sets of exercise, gradual increases in RMS were observed in all muscles. The RMS of AD were 44.0±9.4-52.4±12.1-54.7±13.2 (mean±SD, %, 1set-2set-3set, N-BFR), 47.4±11.6-57.4±15.9-61.9±17.4 (L-BFR), 42.1±8.0-58.3±12.2-65.4±15.7 (M-BFR), and 47.0±12.3-68.2±25.9-77.3±33.9 (H-BFR). Interactions

WEDNESDAY, MAY 31, 2017

between BFR conditions and sets for AD had significant effects ($F=2.53, p<0.05$). The main effect of BFR conditions was significant for PM, average of 3 sets (mean \pm SD, %), N-BFR: 46.8 \pm 7.6; L-BFR: 52.4 \pm 14.3; M-BFR: 52.2 \pm 11.7 < H-BFR: 61.5 \pm 21.1, $F=3.06, p<0.05$, but was not significant for TB (N-BFR: 46.5 \pm 14.7; L-BFR: 55.9 \pm 20.1; M-BFR: 50.5 \pm 10.8; H-BFR: 52.1 \pm 17.4, $F=0.86, p>0.05$). **CONCLUSION:** These findings indicate that muscle activation was affected by relative differences in applied pressure for non-restricted trunk muscles (i.e. PM and AD), but not affected for restricted limb muscle (i.e. TB). Previous studies have focused on restricted limb muscle following single-joint resistance training. Therefore, it is important that the influence of the degree of blood flow restriction on muscle activation is investigated in multi-joint exercise. :

260 Board #81 May 31 9:30 AM - 11:00 AM
Can Blood Flow Restriction Augment Post Activation Potentiation in College-Aged?

Karolina Koziol. *The University of Oklahoma, Norman, OK.*
 Email: karolina@ou.edu
 (No relationships reported)

It has been shown that blood flow restriction (BFR) can enhance muscular performance, however, it remains unknown if BFR can augment post activation potentiation (PAP). **PURPOSE:** To determine whether BFR can enhance PAP induced by either whole body vibration (WBV) or isometric maximal contractions (IMVC) as measured by jump performance in college-aged males. **METHODS:** Resistance trained men ($n=20$) ages 18-30 years participated in a randomized, crossover design with repeated measures. Subjects visited the lab on 4 occasions. The first visit was for familiarization, and the second visit was the control condition (CON - 3 vertical jumps (VJ) to calculate jump height and power, followed by 10 min rest, then 3 VJ). For visits 3 and 4, subjects performed 2 different treatment conditions (pre, treatment, post), separated by 30 minutes of rest on each day. The 4 treatment conditions included whole body vibration (WBV), whole body vibration with BFR (WBVK), maximal voluntary contractions (MVC) and maximal voluntary contractions with BFR (MVCK) both via deadlift. Repeated measures ANOVA compared conditions for percent changes in power and jump height as well as for the raw power and height values (time (2) x condition (5)). **RESULTS:** There were significant differences in percent change in jump height for 3 of the 4 interventions compared to CON (-1.5 \pm 1.0): WBV 3.0 \pm 9.9% ($p=.002$); WBVK 2.8 \pm 9 ($p=.002$); and MVCK 3.5 \pm 1.0 ($p=.006$) but not for the MVC condition 0.8 \pm 1.2 ($p=.145$). There were no significant differences in percent change in jump power for any condition. For raw jump height (inches), there was a significant condition x time interaction ($p=.001$) and a significant main effect for time ($p=.004$) or about a 1 inch increase from pre to post across all conditions) but no significant main effect for condition ($p=.100$). There were no significant main effects or interaction effect for jump power (W). **CONCLUSION:** The 4 conditions (not including CON) significantly improved jump height (but not power), however, the addition of BFR did not enhance PAP or jump performance. These findings suggest the BFR protocol may not have been a strong enough stimulus to enhance PAP since we used a constant restriction pressure for all subjects (160 mmHg) rather than individualizing the pressures based on total occlusion pressures.

Blood Flow Restriction Training Improves Functional Tests Associated with Return to Sport After Injury

Mia MacDonald, Kathryn Lucas, Maddie Marquez, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.*
 (No relationships reported)

Introduction:

Traditional strength training with high load resistance is not practical for patients with orthopedic injuries and often not tolerated well by sedentary individuals. Blood flow restricted training (BFRT) is an emerging way to increase muscle strength using low loads and high repetitions. However, whether this strength training method also transfers to functional outcomes used in rehabilitation, such as hop testing, is unknown. We hypothesized that BFRT would significantly improve muscle strength and hop test performance used in making return to sport decisions.

Methods:

4 healthy females and 7 males (24.5 \pm 7.25 years old) who were not currently participating in strength training completed the study. Kaatsu BFRT bands were placed on the subjects' thighs while they performed leg extension, calf raises, and leg press exercises starting at 30% of their 1 RM max, 3 times per week for 6 weeks. Resistance was adjusted every other training session. Isometric quadriceps strength was measured on a Biodex. Single leg hop and triple hop performance were measured before and after the study. Strength and hop distances were compared before and after KAATSU strengthening with a paired t-test.

Results:

Significant improvements were found for peak quadriceps strength (pre: 170.0 \pm 47.98 N, post: 197.1 \pm 57.2 N, $p=.037$), single leg hop (pre: 128.9 \pm 33.8cm, post: 154.2 \pm 33.4cm, $p=.007$), and triple hop (pre: 405.5 \pm 106.4cm, post: 428.4 \pm 104.1cm, $p=.025$).

Conclusions:

BFRT is associated with significant improvements in muscle hypertrophy and functional improvements in healthy subjects. There were significant improvements in hop testing distances, indicating the benefits of BFRT extend beyond improved strength. Subsequent studies should evaluate the possibility of creating BFRT programs that target injury-specific muscle groups when high load resistance training is contraindicated due to surgery or injury.

Acute Effects Of Aerobic Exercise With Blood Flow Restriction Cuffs On Arterial Compliance In Males

Magalie Sanchez, Margarita Gonzalez, Brittany Esparza, Patrick Murphy. *University at Texas Rio Grande Valley, Brownsville, TX.*
 Email: magalee717@yahoo.com
 (No relationships reported)

PURPOSE: The purpose of this study was to examine the acute effects a 20-minute run, at 40% VO₂, with and without blood flow restriction (BFR) cuffs has on systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial pressure (MAP), and pulse pressure (PP) when compared to a 60-minute run at 65% VO₂ without BFR in males. **METHODS:** On the first session, seventeen male subjects (between the ages of 18 and 50) were familiarized with the study protocol, measured for thigh circumference, and performed the Bruce protocol. Inflation of BFR cuffs was based on thigh circumference. Conditions were randomized into three sessions, 1) a 60-minute walk/run without BFR cuffs at 65% VO₂ intensity, 2) 20-minute walk/run at 40% VO₂ intensity with the BFR cuffs inflated, and 3) 20-minute walk/run at 40% VO₂ intensity without BFR. Participants were required to show up hydrated, reaching a status at or below 1.010, and with at least 8-hour fasted during the three separate randomized sessions. After the subject reached set hydration levels, they would lie down in a supine position and have baseline blood pressure measurements taken. After blood pressure was taken, subject would walk/run for 20 or 60 minutes at a moderate intensity (40% or 65% VO₂) with or without BFR cuffs. BFR cuffs were placed before condition three and were taken off immediately post exercise. Upon completion of the exercise, participants laid back into the supine position and had post measurements, of blood pressure, taken post 10, 20, and 40 minutes. Sessions were separated with at least 48 hours. **RESULTS:** Significant condition main effects were found in SPB ($p<.05$). Significant time main effects were found in SPB ($p<.02$) and PP ($p<.05$). Significant condition time main effects were found in SPB ($p<.01$) and DBP ($p<.01$). **CONCLUSION:** The results conclude that the 60-minute condition had lower post SBP measurements than the 20-minute BFR and non-BFR conditions, which can be caused by vasodilation, due to the possible increase in nitric oxide, that created less pressure in the arteries from the large difference in activity length when compared to the 20-minute sessions.

263 Board #84 May 31 9:30 AM - 11:00 AM

Differences in Neuromuscular Adaptations After Two Weeks of Conventional vs Blood Flow Restriction Resistance Training

Danny D. Dominguez, Patrick Gage Murphy, Brittany N. Esparza, Gabriela Soto, Roberto Osornio, IV, Ulku Karabulut, Murat Karabulut. *University of Texas at Rio Grande Valley, Brownsville, TX.*
 (No relationships reported)

PURPOSE: The purpose of the study was to determine the neuromuscular changes in the rectus femoris (RF) muscle as measured by electromyography (EMG) following short-term resistance training with and without blood flow restriction (BFR). **METHODS:** 12 males (age = 27.4 \pm 6.3 years; height = 171 \pm 7 cm; weight = 79.8 \pm 13.2 kg) performed six sessions of lower body unilateral resistance training using a leg extension machine. The leg on which BFR was applied was determined through randomization leg dominance. Each training session consisted of unilateral knee extensions with and without blood flow restriction. Electromyography data was recorded for each participant during two isometric maximum voluntary contractions (MVC) and two isokinetic knee extension tests (180°/s and 60°/s) using a Biodex System 4 Pro™. EMG was recorded from the RF during these tests. Resistance training consisted of six non-consecutive sessions of knee extension exercises performed in a time frame of two weeks. For the BFR group, subjects trained for a total of four sets (30, 15, 15, 15) at an intensity of 20% 1RM. The contralateral limb was trained with two sets of 11 repetitions at an intensity of 70% 1RM without BFR. The volume of exercises was similar for both conditions. **RESULTS:** No condition*time interactions or condition and time main effects were observed for root mean square (RMS), mean RMS (mRMS), yMax (yRMS), and median frequency (MDF) in both MVC and isokinetic 180°/s and 60°/s ($p>0.05$). **CONCLUSIONS:** Both training conditions resulted in insignificant changes and there was no significant difference found between time points. It could be concluded that this was not enough time or stimulus to note major differences across modalities in relation to neuromuscular adaptations of the RF as measured by EMG. Further studies should investigate the effects of higher volume load on neuromuscular adaptations.

Long-term Changes Following Weight Loss in Older Patients with Heart Failure with Preserved Ejection Fraction**

Thomas Becton¹, James Muller², Peter Brubaker, FACSM², Barbara Nicklas¹, Dalane W. Kitzman¹. ¹Wake Forest School of Medicine, Winston-Salem, NC. ²Wake Forest University, Winston-Salem, NC. (Sponsor: Peter Brubaker, FACSM)
Email: jbecton@wakehealth.edu
(No relationships reported)

Heart failure with preserved ejection fraction (HFpEF) is the most common form of heart failure among older persons, and >80% of patients are overweight/obese. Increased adiposity is associated with numerous systemic impairments that contribute to HFpEF pathophysiology, and is significantly correlated to severity of exercise intolerance, the primary symptom in HFpEF. Yet only one study has examined the effects of caloric restriction (CR) with or without aerobic training (AT) in older HFpEF patients. The Study of Caloric Restriction and Exercise Training (SECRET) demonstrated that a short-term (20-weeks) CR or AT+CR intervention resulted in significant weight loss and led to significant improvements in peak VO₂ and quality of life. However, whether these changes are sustained over time is not known.
PURPOSE: To evaluate long-term changes in exercise function and body composition in older HFpEF patients after completion of the SECRET interventions. **METHODS:** Sixteen patients, from CR or AT+CR groups (≥10 kg weight loss), underwent maximal treadmill exercise and DXA body composition assessment 29 ± 11 months (range 10-47 months) after completion of their SECRET trial participation. Paired t-tests were used to compare changes over time. Pearson correlations were used to explore the relationship between body composition measures. **RESULTS:** Compared to status at trial end, at follow-up, mean weight change was +5.2 ± 3.8 kg. There was a significant increase in fat mass (+4.9 kg, p<0.001), but not lean mass (+0.3 kg, p=0.67). There was a significant correlation between change in total mass and fat mass (r = 0.75, p=0.001), but only a trend between change in total mass and lean mass (r = 0.49, p=0.053). There was also a significant decrease in relative peak VO₂ (-2.2 ± 2.1 ml/kg/min, p=0.003) and exercise time (-2.4 ± 2.6 min, p=0.006), with a trend for absolute peak VO₂ (-87 ± 152 ml/min, p=0.062). **CONCLUSIONS:** While CR and AT+CR in older HFpEF patients produces significant improvements in exercise tolerance associated with improved body composition, these positive changes appear to diminish during long-term follow-up, and regained weight appears to be mostly fat. This suggests a need for long-term interventions to prevent weight regain and maintain improvements in physical function and body composition in older HFpEF patients.

PeakVO₂-cardiac Output Relationship During Exercise In Seniors Who Are Sedentary, Athletic, And HFpEF Patients**

Michinari Hieda, Sarma Satyam, Christopher Hearon Jr., Justin Lawley, Ashley Hardin, Mitchel Samels, Jose Martinez Diaz, Braden Everding, Dean Palmer, Lisa Hicklen, Margot Morris, Sheryl Livingston, Jeungki Yoo, Qi Fu, Rong Zhang, Benjamin D. Levine. *The Institute for Exercise and Environmental Medicine, Texas Health Presbyterian Hospital, Dallas, TX.*
Email: hieda_michinari_0119@yahoo.co.jp
(No relationships reported)

PURPOSE: The purpose of this study was to evaluate the relationship between O₂ uptake (VO₂) and cardiac output (Qc) during exercise in seniors who were sedentary, athletic, and Patients with HFpEF.
METHODS: Based on lifestyle physical activity level categorization, elderly-sedentary seniors (n=27, 69±5 yrs) and elderly-athletic seniors (n=25, 68±3 yrs), and patients with heart failure with preserved ejection fraction (HFpEF) (n=24, 71±7 yrs) were selected and underwent cardiopulmonary exercise testing. A modified Astrand-Saltin incremental treadmill protocol was performed to determine VO₂ and ventilatory gas exchange using the Douglas bag technique. Cardiac output (Qc) was measured with the C2H2 rebreathing method. Peak arterial-venous O₂ difference (peak AV-O₂ diff) was calculated by Fick equation (peak VO₂ divided by peak Qc). The slope of the relationship between changes in VO₂ and Qc during exercise was calculated by ΔQc/ΔVO₂.
RESULTS: Peak VO₂ and peak Qc was lower in HFpEF group than the other groups (peak VO₂: HFpEF: 13.1±3.6; vs. Sedentary: 23.5±4.4; vs. Athlete: 39.5±5.3 ml/kg/

min, P<0.001 (ANOVA) as was peak Qc: HFpEF: 12.7±4.1; vs. Sedentary: 14.8±4.1; vs. Athlete: 19.0±6.0 L/min, P<0.001 (ANOVA)). Peak AV-O₂ diff in HFpEF group was the smallest in the 3 groups (HFpEF: 9.7±2.3; vs. Sedentary: 12.2±3.0; vs. Athlete: 14.3±3.6 %, P<0.0001 (ANOVA)), and the Athlete group was greater than the Sedentary group (P=0.04 (Wilcoxon rank-sum)). The relationship between Qc and VO₂ (slope of ΔQc/ΔVO₂) is shown in Figure.
CONCLUSIONS: Both reduced Qc and AV-O₂ diff contribute significantly to the impairment of exercise capacity in HFpEF through Qc is augmented for a given VO₂. Lifelong exercise training enhances Qc and peak AV-O₂ diff in the elderly population and normalizes Qc/VO₂ relationship.

Relationship between Cardiac Output and VO₂

Self-Reported Screen Time is Independently Associated with Cardiometabolic Disease Risk Factors in Young Adults**

Kathleen R. Connor, 83843¹, Katrina Taylor², Devin Drummer³, Megan C. Nelson¹, Chantal Vella, FACSM¹. ¹University of Idaho, Moscow, ID. ²Eastern Washington University, Cheney, WA. ³Central Washington University, Ellensburg, WA.
(No relationships reported)

Research has shown that self-reported screen time is linked to cardiometabolic disease risk factors in children. Whether this association extends to young adults has not been investigated. **PURPOSE:** To determine the associations between self-reported screen time and individual cardiometabolic disease risk factors in young adults. **METHODS:** Sixty-six young adults volunteered for the study (mean±SD: age 20.6±1.4 y; BMI 24.3±3.6 kg/m²; body fat 22.7±8.8%; peak oxygen consumption [VO₂peak] 45.7±7.7 ml/kg/min). Sedentary behavior and screen time (television viewing, video games and computer games) were self-reported using the Sedentary Behavior Questionnaire. Moderate-to-vigorous physical activity (MVPA) was objectively measured by 7 d of accelerometer wear. Cardiometabolic disease risk factors were measured using standard procedures and included waist circumference, blood pressure, glucose, triglycerides (TG), high-density lipoprotein cholesterol (HDL) and low-density lipoprotein cholesterol (LDL). Body composition was estimated by BOD POD and VO₂peak was measured by indirect calorimetry using an incremental treadmill test to exhaustion. Multiple regression was used to analyze the independent associations between screen time and individual cardiometabolic disease risk factors with sedentary behavior, MVPA, age, and sex used as covariates in the models. **RESULTS:** On average, screen time (14.8±11.6 h/week) accounted for 25% of total sedentary behavior (59.0±25.8 h/week). Screen time was positively associated with BMI (R²=0.19, β=0.35, p=0.02), waist circumference (R²=0.19, β=0.43, p<0.01), fat mass (R²=0.39, β=0.34, p=0.01), and TG (R²=0.24, β=0.43, p<0.01), and negatively associated with VO₂peak (R²=0.66, β=-0.39, p<0.01). These associations were independent of total sedentary behavior, MVPA, age and sex. Screen time was not associated with blood pressure, glucose, HDL or LDL (p>0.05).
CONCLUSIONS: Our findings suggest that screen time is related to individual cardiometabolic disease risk factors in young adults. Screen time accounted for 25% of sedentary time and may be an important area to target for chronic disease prevention programs in young adults.

The Relationship Between CAD Risk Factors And Carotid Intima-media Thickness (cimt) In Children
 Daniel J. White. *University of New England, Biddeford, ME.*
 Email: dwhite18@une.edu
 (No relationships reported)

Increased carotid intima-media thickness (CIMT) is accepted as an early indicator for the development of atherosclerotic coronary artery disease (CAD). The presence of CAD risk factors is shown to have a negative influence on CIMT. As obesity rates increase in children which negatively alters CAD risk factors, it is unclear how this might alter CIMT. **PURPOSE:** The purpose of this study was to determine if there is a relationship between children's CIMT and CAD risk factors as well as number of CAD risk factors combined. **METHODS:** One hundred and nineteen children (age 10.51±0.52, height 147.2±7.05cm, and weight 46.51±12.21kg) took part in the CIMT assessment. Subjects were randomly selected from the Cardiovascular Health Intervention Program. Subjects had previously completed a fasting blood lipid and glucose profile, height, weight, and resting blood pressure to evaluate CAD risk factors. A licensed sonographer completed scans on the right and left common carotid using the ultrasound unit (Terason t3200) with a linear transducer probe. CIMT was measured using the software The Carotid Analyzer for Research Version 6. **RESULTS:** An increase in CIMT was observed in the right ($p<.05$), left ($p<.01$) and combined right and left CIMT ($p<.001$) in children with an elevated BMI ($>85^{th}$) Vs those with a healthy BMI. The children with elevated blood pressure ($>95^{th}$) had an elevated CIMT in both the left ($p<.001$) and combined left and right CIMT ($p<.05$). In respect to elevated blood glucose ($> 100\text{mg/dl}$), only an elevated CIMT was observed in the right CIMT ($p<.05$). When comparing CIMT to number of CAD risk factors, an increase in CIMT ($p<.05$) was observed in children with 2+ CAD risk factors Vs 0 CAD risk factors. **CONCLUSION:** It appears elevated BP, BMI and glucose have a negative influence on CIMT in children. Changes in CIMT (left VS right) appear to be different based on the CAD risk factor of interest. Children with 2+ CAD risk factors appear to have an adverse effect on CIMT, strongly suggesting the need for early healthy life-style intervention. This research supports previous research looking at CIMT in children with CAD risk factors. Funding provided by Clark Charitable Foundation (Subcontract from Children's National Medical Center, Washington, DC)

The Effect of Moderate Resistance Exercise on Arterial Stiffness With and Without the Valsalva Maneuver
 Nicole M. Fortunato, Christa Winter, Elizabeth O'Neill, Samuel A.E. Headley, FACSM. *Springfield College, Springfield, MA.*
 (Sponsor: Samuel Headley, FACSM)
 (No relationships reported)

Resistance exercise has been said to increase arterial stiffness. The Valsalva maneuver can be used while performing resistance exercise, and may also contribute to negatively altering arterial stiffness. **PURPOSE:** The study was designed to determine the effect of moderate intensity resistance exercise on arterial stiffness with and without the Valsalva maneuver. **METHODS:** Subjects ($N = 13$) consisted of males between 18-30 years old who were familiar with resistance training. All subjects completed one session of moderate intensity resistance exercise (60% of 1-RM) with the Valsalva maneuver, and a second session without the Valsalva maneuver in a counterbalanced order. Pulse wave velocity (PWV) was used to measure arterial stiffness before exercise, 10 min post, 30 min post, and 60 min post exercise. **RESULTS:** No significant interaction $F(3,36) = 0.74, p = .54$ was found between the condition of Valsalva maneuver, or no Valsalva maneuver, and the test occasion. No significant main effect $F(1,12) = 0.02, p = .89$ was found for the treatment condition of Valsalva maneuver and no Valsalva maneuver. Also, no significant main effect $F(1,96, 23.57) = 0.18, p = .84$ was found for test occasion (pre-exercise, 10 min post, 30 min post, and 60 min post exercise). **CONCLUSION:** Moderate intensity resistance exercise with and without the Valsalva maneuver did not negatively affect arterial stiffness.

Patterning Of Physiological And Perceptual Responses To Exercise: Effect Of Sympathetic Blockade
 Kade Davison, Braden L. Mitchell, Gaynor Parfitt, Simon Spedding, Roger G. Eston. *University of South Australia, Adelaide, Australia.*
 (No relationships reported)

The rating of perceived exertion (RPE), a subjective indicator of exercise intensity, is becoming increasingly popular for monitoring and prescribing exercise intensity in clinical populations. It remains unclear whether the relationship between RPE and oxygen uptake (VO_2) is affected by perturbations to the sympathetic nervous system.

Purpose: To determine whether acute sympathetic blockade alters the relationship between heart rate (HR), RPE and VO_2 during incremental exercise. **Methods:** Eleven healthy adults completed two graded exercise tests (GXT) on a motorized treadmill, under a β_2 receptor antagonist and placebo. Treadmill speed increased by 2 $\text{km}\cdot\text{h}^{-1}$ every 2 min and participants reported their RPE (Borg 6-20 RPE Scale) each min until exhaustion. The VO_2 and HR were measured continuously. Linear regression modelled the growth of individual participant relationships of RPE and HR with VO_2 . To account for differences in peak HR between conditions, values were expressed relative to the peak HR from each GXT. Paired sample t-tests assessed differences in the slope (b) of the individual regression models between conditions. **Results:** The $\text{VO}_{2\text{peak}}$ and HRpeak were lower during β -blockade (51.9 ± 5.3 vs 48.6 ± 7.5 $\text{mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$, $p<0.05$; 192.7 ± 8.2 vs 156.0 ± 23.1 $\text{b}\cdot\text{min}^{-1}$, $p<0.01$, respectively). As expected, the slope for the relationship between HR and VO_2 was greater during β -blockade (b 0.37 ± 0.03 vs 0.48 ± 0.07 , $p<0.01$), however, there was no significant difference in the slope of the RPE: VO_2 relationship (b 3.34 ± 0.71 vs 3.30 ± 0.77 , respectively $p>0.05$) and no significant difference in b when HR was expressed relative to the peak HR during the GXT (b 0.71 ± 0.07 vs 0.73 ± 0.07 , $p>0.05$). **Conclusion:** Despite a marginally lower $\text{VO}_{2\text{peak}}$, the relationship between RPE and VO_2 remains unchanged by sympathetic blockade, whereas the absolute HR: VO_2 relationship is significantly altered. This means that RPE can be used in place of HR to determine metabolic work or estimate fitness sub-maximally in individuals taking β -blockade.

Exercise-induced Change in Metabolites and Associations with Cardiometabolic Risk Factors
 Andrea M. Brennan¹, Mark Benson², Jordan Morningstar³, Robert E. Gerszten⁴, Robert Ross, FACSM¹. ¹Queen's University, Kingston, ON, Canada. ²Brigham and Women's Hospital, Boston, MA. ³Massachusetts General Hospital, Boston, MA. ⁴Beth Israel Deaconess Medical Center, Boston, MA.
 Email: 12ab87@queensu.ca
 (No relationships reported)

Exercise-induced improvement in risk for chronic disease is attributed to changes in body composition, cardiorespiratory fitness, blood pressure and glucose metabolism; however, the underlying mechanism is unclear. Metabolomics offers the technology needed to investigate large numbers of metabolites that may participate in biochemical pathways of exercise-induced improvement in cardiometabolic risk. **PURPOSE:** To investigate the impact of an exercise intervention on plasma metabolites and whether changes in metabolite levels are related to changes in cardiometabolic risk factors. **METHODS:** A secondary analysis was performed in 216 middle-aged abdominally obese men and women ([mean (SD)], 52.4 (8.0) years) originally recruited to participate in a 6-month randomized controlled trial examining the effects of exercise amount and intensity on cardiometabolic risk factors. 139 metabolites were profiled by liquid chromatography-mass spectrometry. Cardiorespiratory fitness (CRF) was assessed using standard open-circuit spirometry during a maximal graded exercise test. Waist circumference (WC) was measured at the superior edge of the iliac crest. 2-hour glucose was measured in response to a 2-hour 75-g oral glucose tolerance test. Systolic (SBP) and diastolic blood pressure (DBP) was measured using an automated BP monitor. **RESULTS:** Seven metabolites significantly changed in the exercise compared to control group ($p<0.05$). There were no significant associations at the adjusted p-value ($p<0.0004$) between change in metabolites and change in 2-hour glucose, SBP or DBP. Change in leucine ($B=-0.29$), isoleucine ($B=-0.30$) and UDP-N-acetylglucosamine ($B=-0.40$) were negatively associated and citric acid isocitric acid ($B=-0.29$) was positively associated with change in CRF. Change in UDP-N-acetylglucosamine ($B=0.46$) was positively associated with change in WC ($p<0.0004$). **CONCLUSION:** These findings represent a more global effort to uncover the biochemical pathways in which exercise elicits its cardiometabolic effects. These observations implicate several metabolites that may serve as biomarkers or have a direct regulatory role in pathways related to exercise and improved cardiometabolic status.

Time Course for Blood Pressure Changes with Aerobic Exercise in U.S. Veterans
 Shakeelah Sutton. *Veterans Affairs Medical Center, Washington, DC.* (Sponsor: Peter Kokkinos, FACSM)
 Email: Sutton.951@gmail.com
 (No relationships reported)

It is well-established that regular exercise training decreases resting blood pressure (BP). However, the length of exercise training necessary to lower resting BP is not well-defined.

PURPOSE: To assess the time course of exercise-induced BP changes in individuals with resting systolic BP ≥ 130 and/or diastolic BP ≥ 80 mm Hg.

METHODS: Veterans were enrolled in a 12-week hospital-based exercise program that consisted of aerobic exercise two to three times per week. Resting BP was taken manually at the beginning of each session. Exercise intensity was maintained at 60% -80% of heart rate reserve.

We assessed resting BP in 93 patients (61.5 ± 7.8 years) who completed the 12-week intervention. Qualifying resting BP was defined as systolic BP ≥130 mmHg and/or diastolic BP ≥80 mmHg at baseline. Baseline and post BP was obtained during stress tests administered before and after the intervention. Midpoint BP was comprised of the average BP obtained during week 6 of the intervention. Two sided paired sample t-tests were applied.

RESULTS: There was a significant decrease in mean resting systolic BP after 6 weeks of exercise from baseline (138.7 ± 14.6 vs. 130.3 ± 14.1 mmHg; p<0.001). A significant decrease was also found in resting diastolic BP between these two time points (79.9 ± 7.3 vs 74.9 ± 9.1 mmHg; p<0.001). No significant changes in resting BP were observed between midpoint and post-intervention time points. Post-intervention resting systolic BP (129 ± 13.6 mmHg; p<0.001) yielded a 9.7 mmHg decline from baseline while diastolic BP (73.6 ± 9.8 mmHg; p<0.001) yielded a 6.3 mmHg decline (Table).

CONCLUSION: Resting systolic and diastolic BP were significantly lowered after 6 weeks of aerobic exercise training. No additional changes were observed in BP at 12 weeks of exercise. Thus, exercise BP is lowered after just six weeks of aerobic exercise training or approximately 12-18 sessions.

Table.

Resting Blood Pressures During 12-Week Exercise Intervention

	Baseline	Midpoint	Post
Systolic BP (mmHg)	138.7 ± 14.6	130.3 ± 14.1	129 ± 13.6
Diastolic BP (mmHg)	79.9 ± 7.3	74.9 ± 9.1	73.6 ± 9.8

The Relationship Between Initiation of Cardiac Rehabilitation and Readmission Rates for Patients with Metabolic Syndrome

Lee Anne Siegmund, Mark McClelland, James Bena. *Cleveland Clinic, Cleveland, OH.*
 Email: siegmul@ccf.org
 (No relationships reported)

Phase II cardiac rehabilitation (CR) has been shown to be effective at reducing risk factors associated with cardiovascular disease (CVD). A delay in starting CR has been associated with poorer fitness outcomes. The risk of CVD more than doubles in the presence of metabolic Syndrome (MetS). The association between initiation of CR, and hospital readmissions in patients with MetS was previously unknown.

Purpose: We sought to determine the relationship between the length of time to the start of CR, and hospital readmissions in patients with MetS. Further, we aimed to determine if there was an association between demographic and clinical variables, and hospital readmissions in this patient population.

Methods: We examined the records of 353 CR patients at a quaternary medical center who had MetS. Continuous measures were imputed using predicted mean matching regression, while categorical measures were imputed based on logistic models. Readmissions prior to beginning CR were excluded.

Results: Patient readmissions within 90 days were more likely to be non-white (p=0.026) and have a time to CR initiation of ≤ 30 days (p<0.001). Patients readmitted at ≤ 6 months were more likely to be non-white (p<0.001) and have time to CR ≤ 60 days (p = 0.017). Of 54 patients readmitted within 6 months, 75.9% began CR within 60 days and 56.9% were non-white. In multivariable models for readmission within 6 months, those of white race (OR 0.42 [0.18, 0.97]; p=0.041) were less likely to be readmitted. Patients who began CR early were 2.47 times more likely to be readmitted by 6 months (OR 2.47 [1.22, 5.02]; p=0.012).

Conclusions: Patients with MetS were more likely to be readmitted if they were non-white. Early uptake to CR resulted in higher likelihood of readmission at ≥ 90 days. These results raise questions about the health status and other unique traits of patients with MetS who begin CR early. Future studies should focus on designing CR programs to meet the needs of non-whites and those who may be sicker at the onset of CR.

The Immediate Blood Pressure Lowering Effects of Acute Concurrent Exercise: A Meta-Analysis

Alyssa Jones¹, Lauren ML Corso¹, Hayley V. MacDonald², Blair T. Johnson¹, Jill Livingston¹, Linda S. Pescatello, FACSM¹.
¹University of Connecticut, Storrs, CT. ²The University of Alabama, Tuscaloosa, AL. (Sponsor: Dr. Linda S. Pescatello, FACSM)

(No relationships reported)

Our recent meta-analysis on the blood pressure (BP) lowering effects of concurrent exercise training (CET) found systolic BP (SBP) and diastolic BP (DBP) were moderately reduced an average of ~3 mmHg overall. However, large SBP/DBP (~9/8 mmHg) reductions were noted among adults with hypertension, indicating the potential clinical utility of CET as antihypertensive lifestyle therapy. **PURPOSE:** To perform a meta-analysis to determine whether acute concurrent exercise (CE) is also efficacious antihypertensive lifestyle therapy. **METHODS:** Databases were searched for controlled studies that included: adults (≥19 yr), a single bout of CE, and measured BP pre- and post-CE and control. Analyses followed random-effects assumptions.

RESULTS: 8 studies and 13 interventions (k) qualified. Subjects (N=109) were young to middle-aged (35.9±16.4 yr), overweight (26.7±3.1 kg/m²) men (34.6%) and women (65.4%) with a resting SBP/DBP of 122.3±11.9/76.6±7.2 mmHg. Among the total sample, 38.6% (N=42) had hypertension, 12.4% (N=14) prehypertension, and 49.0% (N=53) normal BP. Acute CE was performed at moderate-to-vigorous intensity (aerobic=65.6±17.5% maximum oxygen uptake, resistance=63.9±16.5% one-repetition maximum) for 55.0±6.1 min, with 53.9% of the interventions performing aerobic first. Aerobic exercise interventions included walking (38.5%, k=5), cycling (38.5%, k=4), running (15.4%, k=2), and step aerobics (7.7%, k=1) for 29.1±3.0 min. Dynamic resistance exercise interventions were performed on machines for 26.1±4.9 min, and consisted of 2.8±1.2 sets of 11.5±5.4 repetitions per set for 5.9±1.2 exercises. BP was measured in the laboratory for 89.2±45.4 min post-CE. Overall, acute CE elicited large reductions in SBP (d_i [95% CI]= -0.84 [-1.23, -0.44]; -9.2 mmHg), but not DBP (d_i [95% CI]= -0.08 [-0.27, 0.11]; -0.6 mmHg) compared to control. We observed significant heterogeneity for SBP (I² [95% CI]= 82.7% [71.6%, 89.4%]) and DBP (I² [95% CI]= 49.7% [4.9%, 73.43%]), but no significant moderators emerged. **CONCLUSION:** Similar to CET, acute CE leads to clinically meaningful reductions in SBP (~9 mmHg), but in contrast to CET, not DBP. The BP lowering patterns appear to differ between acute and chronic CE, findings that should be confirmed in future randomized CE trials.

Blood Pressure Reductions Following A 12-week Isometric Training Program: Lab-based Vs. Home-based Approach

Ben DH Gordon, Erin Vinoski, Caroline Jones, Jan Warren-Findlow, Reuben Howden. *University of North Carolina at Charlotte, Charlotte, NC.*
 Email: bgordo18@uncc.edu

(No relationships reported)

PURPOSE: The American Heart Association (AHA) identified isometric exercise training (IET) as a "potential" supplementary therapy for blood pressure management (Class IIB Level of Evidence C), highlighting a need for further investigation. Importantly, reductions in resting blood pressure (RBP) following IET have been reported in laboratory environments, but data regarding the use of IET in the community are lacking. **METHODS:** Fourteen hypertensive participants (24-60 years) were randomized to one of three conditions; standard laboratory face-to-face delivered IET, home administered IET (with instructional video), and a control condition. IET groups completed handgrip IET at 30% maximal voluntary contraction three days per week for twelve weeks. Changes in resting BP were assessed every six weeks during the training period and six weeks post-training. **RESULTS:** Twelve weeks of IET induced a clinically significant reduction in group mean SBP (class -8.77±6.34; home -8.10±6.13; control -5.77±6.41 mmHg; weeks: p=0.06; treatment p= 0.14). Interestingly, six weeks after training had ended, group mean blood pressure was further reduced in the class condition of IET and SBP was still lower compared to pre-training measures in the home condition, whereas control participants trended towards pre-study measures (class -11.00±7.05; home -6.90±5.68; control -4.55±3.04 mmHg). **CONCLUSIONS:** Twelve weeks of IET produced a clinically relevant reduction in RBP. Similar reductions were observed in both home and class IET conditions with continued reductions taking place post training. These data suggest that self-administered IET in a cohort of hypertensive participants was as effective compared to a laboratory-based setting. Therefore, IET may be an effective and practical intervention for self-management of RBP in the wider community. Additional research is needed, accounting for other factors that affect RBP, to further confirm, IET as an effective intervention for reducing RBP. Acute Electrical Muscle Stimulation Of The Lower Extremities Enhances The Vascular Endothelial Function

Hajime Miura¹, Yasuaki Tamura¹, Miduki Ishikawa¹, Ayako Azuma¹, Kenichi Deguchi². ¹Tokushima University, Tokushima, Japan. ²Naruto Hospital, Tokushima, Japan.
Email: hajime-m@tokushima-u.ac.jp
(No relationships reported)

The use of electrical muscle stimulation (EMS) has been shown to potentially improve or compensate for disadvantages in disabled or chronic patients with physical inactivity. However, little is known about the effects of EMS on the arterial function. **PURPOSE:** The aim of this study was to evaluate the effects of EMS to the lower extremities on the vascular endothelial function determined by flow-mediated vasodilation (FMD). **METHODS:** Eight healthy adult men were studied under two experimental trials (EMS and control without any stimulation) in the supine position. In the EMS trial, both lower leg and thigh muscles were sequentially stimulated at 4 Hz for 20 min. Before and after each trial, the brachial systolic and diastolic blood pressure (SBP and DBP) were measured. In order to measure the FMD, a forearm cuff was inflated to 50 mmHg over their SBP for 5 minutes with subsequent deflation. The right brachial artery diameter was measured using a high-resolution ultrasound device. The FMD was then estimated as the percent change in the arterial diameter over the baseline value at maximum dilation during reactive hyperemia. **RESULTS:** In the EMS trial, the FMD was significantly elevated immediately after (12.1±1.1%) and at 30 min after EMS (11.0±0.9%) compared with rest (9.2±0.8%). However, there were no significant changes in the control trial (9.3±0.9% at rest, 9.4±0.8% immediately after C trial, and 9.2±0.9% at 30min after C trial). Immediately after and 30min after each trial, significant differences in the FMD were found between the EMS and control trials ($p < 0.05$). No significant changes were found in the SBP/DBP in either trial. **CONCLUSIONS:** Acute EMS appears to improve the vascular endothelial function. These findings suggest that chronic EMS might be useful for reducing the risk of cardiovascular disease in people suffering from partial paralysis or arthritis as well as in healthy subjects.

Prolonged Sitting-Induced Lower Limb Vascular Dysfunction: The Effect of Oxidative Stress

Ryan Garten, Matthew Scott, Tiffany Zuniga, Austin Hogwood.
Virginia Commonwealth University, Richmond, VA.
Email: rsgarten@vcu.edu
(No relationships reported)

Prolonged sitting has been reported to result in significant vascular dysfunction due to increases in lower limb pressure and subsequent reductions in shear stress. Oxidative stress, a known modulator of vascular function, has been reported to increase in the vasculature in response to high pressures, but contrary findings exist when attempting to directly link the connection between increased pressure, oxidant production, and resulting vascular dysfunction. Therefore, the direct role of oxidative stress on the observed vascular dysfunction during prolonged sitting is currently unknown. **PURPOSE:** This study sought to examine the impact of oxidative stress on prolonged sitting-induced vascular dysfunction, measured via passive leg movement, by administering an acute oral antioxidant prior to the sitting session. **METHODS:** Seven young (24 ± 1 yrs) healthy males completed two 3-hour sessions of prolonged sitting. Subjects were given either an oral antioxidant (AO) containing 2 grams of vitamin C or a placebo (PL) pill. The supplementation took place following the baseline measures and immediately prior to the sitting session and all supplementation was double-blinded with at least 72 hours separated the two sitting sessions. Leg vascular function was assessed with passive leg movement (PLM) immediately prior to sitting, 1.5 hours, and 3 hours after the onset of the sitting session. **RESULTS:** Leg vascular function (assessed via PLM-induced hyperemia) was revealed to be significantly reduced following the three hours of prolonged sitting in the PL condition when evaluated as both Δ LBF (Baseline: 1214 ± 229; 3 hours: 904 ± 196 ml·min⁻¹; $p < 0.05$) and LBF area under the curve (AUC) (Baseline: 500 ± 158; 3 hours: 293 ± 99 ml·min⁻¹; $p < 0.05$). The AO condition resulted in a significant attenuation in lower limb vascular dysfunction after 3 hours of prolonged sitting expressed as both Δ LBF (Baseline: 1193 ± 330; 3 hours: 1040 ± 242 ml·min⁻¹; $p = 0.3$) and LBF area under the curve (AUC) (Baseline: 500 ± 158; 3 hours: 378 ± 99 ml·min⁻¹; $p = 0.2$). **CONCLUSION:**

Prolonged sitting-induced lower limb vascular dysfunction, assessed by PLM, was attenuated in response to an acute antioxidant supplementation. These findings implicate oxidative stress as a modulator of vascular function during prolonged sitting.

Tart Montmorency Cherries (prunus Cerasus L.) Acutely Modulate Vascular Function In The Absence Of Improvements In Cognition.

Karen M. Keane, Crystal F. Haskell-Ramsay, Rachel C. Veasey, Glyn Howatson, FACSM. Northumbria University, Newcastle Upon Tyne, United Kingdom. (Sponsor: Glyn Howatson, FACSM)
Email: karen.keane@northumbria.ac.uk
(No relationships reported)

Cerebral blood volume and metabolism of oxygen declines as part of human ageing and has been related to cognitive decline. There is some evidence to suggest that polyphenol-rich foods play an important role in delaying the onset or attenuating the progression of age-related health disorders such as cardiovascular and Alzheimer's disease, and to improve cognitive function. **PURPOSE:** The aim of this study was to assess the impact of Montmorency tart cherry juice consumption on pre-frontal cortical haemodynamics, cognitive function and blood pressure in middle-aged adults. **METHODS:** Twenty-seven healthy middle aged adults were recruited to take part in the study; the mean ± SD age, stature, mass and BMI were 50 ± 6 years, 170.7 ± 9.1 cm, 76.0 ± 16.0 kg and 26.1 ± 4.9 kg/m², respectively. Participants received either a 60 mL dose of a Montmorency tart cherry concentrate (MC) or a placebo (PLA) in a randomised, double blind, placebo-controlled, crossover design study with a >14 day wash-out period between conditions. Cerebrovascular responses (cerebral blood flow volume, total-, deoxy-, and oxy-haemoglobin), cognitive performance, mood and blood pressure were assessed at baseline and 1, 2, 3 and 5 h following consumption. Total-, deoxy- and oxy-haemoglobin were also continuously measured during the 60-min resting/absorption period immediately following supplementation. **RESULTS:** There were significant differences in concentrations of total and oxy-haemoglobin during the last three epochs of the resting/absorption period ($p \leq 0.05$) and during the cognitive task period 1 h post consumption ($p \leq 0.05$). Furthermore, MC consumption significantly lowered systole ($p \leq 0.05$) over a period of 3 h, with peak reductions of 6 ± 2 mmHg at 1 h post MC consumption relative to the placebo. Cognitive function and mood were not affected. **CONCLUSIONS:** The findings suggest that MC concentrate can acutely modulate CBF in the prefrontal cortex characterized by increased concentrations of both total- and oxy-haemoglobin. Despite this, the results do not translate to improvements in cognition or mood in the hours following consumption. Importantly, these data support previous findings observations that demonstrate a significant improvement in systole following MC supplementation.

Blood Flow in Humans During Low-Load Exercise with and without Blood Flow Restriction

J Grant Mouser¹, Gilberto C. Laurentino², Scott J. Dankel¹, Samuel L. Buckner¹, Matthew B. Jessee¹, Brittany R. Counts³, Kevin T. Mattocks¹, Jeremy P. Loenneke¹. ¹The University of Mississippi, University, MS. ²University of Sao Paulo, Sao Paulo, Brazil. ³University of South Carolina, Columbia, SC.
(No relationships reported)

Blood flow restriction (BFR) in combination with exercise has been well studied, however, little is known about the actual blood flow response to this type of exercise. The range of applied pressures in the research is wide, and previous studies have only examined the blood flow response using the same pressure for every individual independent of limb size, and have only done so at rest, after inflation of the cuff, and following exercise. No investigations have examined this response using relative applied pressures as a percentage of arterial occlusion pressure (AOP) nor have they investigated this within an exercise bout. **PURPOSE:** To measure blood flow before, during, and after low-load elbow flexion exercise combined with no restriction (NOBFR), 40% of AOP (40BFR), and 80% of AOP (80BFR). **METHODS:** 140 participants (women=75, men=65) were randomized into one of three conditions. After AOP and one-repetition maximum (1RM) measurement, ultrasound measures of standing blood flow at rest in the right brachial artery were taken. Participants performed four sets comprising 75 total goal repetitions of elbow flexion at 30% 1RM. Blood flow was measured between sets and at one and five minutes post-exercise. **RESULTS:** Blood flow decreased following inflation, with no difference between BFR conditions (40BFR: 38.1 ml·min⁻¹ vs. 80BFR: 36.3 ml·min⁻¹, $p=0.85$). Men had greater blood flow than women in all conditions at all time points (411.6 vs. 214.0 ml·min⁻¹,

respectively, $p < 0.001$). Maximum blood flow was decreased during exercise with pressure (NOBFR=406.7 ml·min⁻¹, 40BFR=311.1 ml·min⁻¹, 80BFR=188.5 ml·min⁻¹, $p < 0.001$). Blood flow tended to increase across sets regardless of condition. One minute following cuff deflation, blood flow was higher in 80BFR than in 40BFR for women only (372.2 vs. 253.1 ml·min⁻¹, $p = 0.005$). One minute following cuff deflation, there was no group difference in blood flow for men (NOBFR=675.2 ml·min⁻¹, 40BFR=715.4 ml·min⁻¹, 80BFR=666.3 ml·min⁻¹, $p = 0.75$).

CONCLUSIONS: The reduction in exercise-induced blood flow during BFR is pressure-dependent, with higher pressures eliciting a decrease in the magnitude of the hyperemic response. Blood flow increased above baseline during all BFR conditions; the use of relative applied pressures ensures that full occlusion does not occur during exercise.

Forearm Blood Flow Regulation Following Maximal Strength Training-induced Improvements in Work Efficiency

Ole Kristian Berg¹, Stian K. Nyberg², Tobias M. Windedal², Eivind Wang². ¹Molde University College, Molde, Norway. ²Norwegian University of Science and Technology, Trondheim, Norway.

(No relationships reported)

Maximal strength training (MST) improves submaximal work efficiency (WE) in the arms. However, since assessment of muscle oxygen uptake ($\dot{V}O_2$) during exercise is lacking, the behavior of MST-induced adaptations is unknown, and it remains elusive if metabolic and vascular responses in arms may contrast what has been observed in legs. **PURPOSE:** To investigate responses in arm blood flow and arteriovenous oxygen difference ($a-vO_{2diff}$) during steady state exercise following MST. **METHODS:** Thus, utilizing Doppler-ultrasound and a catheter placed in the subclavian vein for measurements of blood flow and $a-vO_{2diff}$, we assessed steady state WE and peak responses in seven young males (24±2(SD) years) following a six-week handgrip MST intervention. **RESULTS:** As expected, MST improved maximal strength (49±9 to 62±10kg) and rate of force development (923±224 to 1086±238N·s⁻¹), resulting in a reduced submaximal $\dot{V}O_2$ (31±9 to 25±10mL·min⁻¹) and concomitantly increased WE (8.8±2.3 to 11.7±3.6%) (all $p < 0.05$). In turn, the WE-improvement led to a reduced blood flow (486±102 to 395±114mL·min⁻¹), mediated by a lower heart rate (66±4 to 59±7beats·min⁻¹) and blood velocity (43±8 to 32±6cm·s⁻¹) (all $p < 0.05$). Conduit artery diameter and $a-vO_{2diff}$ remained unaltered. The peak test revealed increased time to exhaustion (948 to 1104seconds; $p < 0.05$), and a tendency towards increased peak work rate ($p = 0.06$), but no change in peak oxygen uptake. **CONCLUSION:** Despite arguments of metabolic and vascular limb-specific differences, these results reveal that the mechanisms responsible for WE adaptations following small muscle mass MST in the upper extremities is a direct reflection of what has been documented for lower extremities. Additionally, our data show that the advantageous reductions in blood flow is regulated through conduit artery blood velocity.

Cardiovascular, Perceptual and Metabolic Demands Associated with Low-intensity Blood Flow Restriction Cycling

Hannah J. Thomas, Female, Brendan R. Scott, Male, Jeremiah J. Peiffer, Male. Murdoch University, Murdoch, Australia. (Sponsor: Dr. Tim Fairchild, FACSM)
Email: hannahthomas755@hotmail.com

(No relationships reported)

The use of blood flow restriction (BFR) during very-low-intensity walking can improve aerobic and anaerobic capacity; however, no research exists which has examined BFR during more ecologically valid aerobic exercise, such as intensities consistent with the American College of Sports Medicine guidelines for low- to moderate-intensity. **PURPOSE:** To examine the acute cardiovascular, metabolic and perceptual responses to aerobic BFR exercise at intensities consistent with the American College of Sports Medicine guidelines. **METHODS:** Eighteen healthy males (23 ± 3 y) completed, in a randomized and counterbalanced order, low-intensity (LI), low-intensity with BFR (LI_{BFR}) and high-intensity (HI) interval cycling sessions. These included a standardized warm-up and three 2-min intervals with 2-min of recovery cycling (10W) between efforts. During HI, LI and LI_{BFR} sessions efforts were set to 85%, 40% and 40% of peak power, respectively. During LI_{BFR}, 80% arterial occlusion was applied to both legs during the efforts and removed during recovery. Continuous measures of heart rate (HR), cardiac output (CO) and oxygen consumption ($\dot{V}O_2$) were recorded. Blood pressure and rating of perceived exertion (RPE) were measured at the end of each interval. Lactate was measured pre- and post-session. **RESULTS:** Blood pressure, HR, CO, $\dot{V}O_2$, lactate and RPE were greatest during HI (range; $p = 0.01$ to $p = 0.04$). During the intervals, blood pressure,

HR and CO were greater during LI_{BFR} compared with LI (range; $p = 0.01$ to $p = 0.04$). $\dot{V}O_2$ measured during the recovery periods were greater in LI_{BFR} compared with LI ($p = 0.01$; for all time points). Post-session lactate was greater ($p = 0.01$) during LI_{BFR} (6.3 ± 0.49 mmol·L⁻¹) compared with LI (2.8 ± 0.29 mmol·L⁻¹). Importantly, mean arterial pressure during the third interval (124.2 ± 2.3 mmHg vs. 113.9 ± 2.5 mmHg) was greater ($p = 0.01$) in LI_{BFR} compared with HI. **CONCLUSION:** LI_{BFR} results in greater cardiovascular and metabolic stress compared with LI alone, and therefore could provide an alternative modality to increase aerobic fitness for individuals not able to perform exercise at high-intensity. However, LI_{BFR} may not be suitable for all populations, specifically those with vascular dysfunction.

Prior Aerobic Exercise Attenuates Prolonged Sitting-induced Leg Endothelial Dysfunction

Takuma Morishima, Robert M. Restaino, Lauren K. Walsh, Jill A. Kanaley, FACSM, Jaime Padilla. University of Missouri, Columbia, MO. (Sponsor: Jill Kanaley, FACSM)
(No relationships reported)

PURPOSE: Prolonged sitting leads to leg endothelial dysfunction; however, it remains unknown whether this impairment can be prevented with prior exercise. It is also unknown if, in the absence of exercise, standing is an effective alternative strategy to sitting for conserving leg endothelial function. Accordingly, the purpose of this study was two-fold: 1) to test the hypothesis that prior exercise prevents sitting-induced endothelial dysfunction; and 2) to test the hypothesis that standing is an effective substitute to sitting for maintenance of leg endothelial function. **METHODS:** Eleven young healthy subjects (7 men; 4 women) completed three experimental trials: sitting, prior exercise + sitting, and standing. Following baseline popliteal artery flow-mediated dilation (FMD) measurements, subjects maintained a supine position for 45 min in the sitting and standing trials or performed 45 min of self-paced cycling (71.3 ± 3.0% HR_{max}) in the prior exercise + sitting trial. Thereafter, subjects were immediately positioned into a seated or standing position, according to the trial, for 3 hours and then popliteal artery FMD measures were repeated. **RESULTS:** Popliteal artery FMD was impaired after 3 hours of sitting (3.75 ± 0.5% vs. 1.57 ± 0.71%, $P < 0.05$) and this impairment was attenuated by prior cycling exercise (3.95 ± 0.41% vs. 3.10 ± 0.83%, $P > 0.05$). Furthermore, 3 hours of standing did not have a significant impact on popliteal artery FMD (4.10 ± 0.45% vs. 3.97 ± 0.65%, $P > 0.05$). **CONCLUSIONS:** Prolonged sitting-induced leg endothelial dysfunction can be partially prevented by prior aerobic exercise. Moreover, in the absence of exercise, standing represents an effective substitute to sitting for maintaining normal leg vascular function.

Normobaric Intermittent Hypoxia Increases Middle Cerebral Arterial Blood Flow Velocity With No Systemic Hypertension

Xiangrong Shi, FACSM, Xiaoli Liu, Diqun Xu, Sarah Ross, James Hall, Sid O'Bryant. UNT Health Science Center, Fort Worth, TX. (Sponsor: Xiangrong Shi, FACSM)
Email: xiaoli.liu@unthsc.edu
(No relationships reported)

Purpose: To study vascular responses to intermittent hypoxia (IH) exposures. **Methods:** Six healthy men (26 ± 1 yr) were exposed to 5 IH bouts, each comprising 6-min breathing 10% O₂ interspersed with 4 min breathing room air. During IH, middle cerebral arterial blood flow velocity (V_{MCA} , Ez-Dop), blood pressure (BP, NIBP100D), O₂ saturation (SaO₂, Radiometer), breathing frequency (F_R), tidal volume (V_T , Universal Ventilation Meter), inspired and expired O₂ and CO₂ fractions (1100 Medical Gas Analyzer; Perkin-Elmer) were continuously monitored. **Results:** The SaO₂ was decreased during 6-min IH ($P < 0.001$), which was more significant in the 5th than the 1st bout of IH exposures ($P < 0.001$). The V_{MCA} was significantly increased by IH and its magnitude was greater in the 5th than the 1st bout of IH exposures ($P = 0.002$). IH did not change mean BP (MBP) from the baseline (min 0) during either the 1st or 5th bout (see Table). Minute ventilation (V_E) was stimulated by IH ($P = 0.023$) with no difference between the bouts. The increased V_E was driven by increases in V_T because f_R remained constant throughout IH exposures. There was a decrease ($P < 0.001$) in partial pressure of end-tidal CO₂ ($P_{ET}CO_2$) during IH, which was not different between the 1st and the 5th bouts of IH exposures.

Time (min)		0	1	2	3	4	5	6
SaO ₂ (%)	1 st bout	97.3±0.3	91.3±0.5	84.4±1.0	81.2±1.1	79.1±1.3	76.9±1.3	74.4±1.5
	5 th bout	94.6±0.5	86.6±0.8	78.9±0.5	74.3±1.2	71.7±1.4	70.2±1.6	69.2±1.7

	5 th bout	58.6±2.3	59.6±2.3	61.4±2.4	63.6±2.9	68.3±2.8	68.5±3.4	68.5±3.9
MBP (mmHg)	1 st bout	88±3	86±4	85±3	84±4	83±4	83±4	83±4
	5 th bout	86±3	85±3	83±3	83±3	83±4	83±3	83±3
V _T (L)	1 st bout	0.82±.10	1.06±.20	1.33±.36	1.26±.36	1.20±.28	1.11±.23	1.33±.29
	5 th bout	0.77±.13	0.95±.19	0.97±.21	0.99±.16	1.21±.29	0.96±.12	1.27±.18
F _{br} (br/min)	1 st bout	13.3±1.6	12.7±1.7	12.5±1.8	13.1±2.1	13.3±2.0	12.5±2.0	12.5±1.9
	5 th bout	12.6±1.7	12.5±1.9	13.1±2.0	13.1±1.8	13.5±2.3	13.0±2.2	12.9±2.1
P _{ET} CO ₂ (mmHg)	1 st bout	42.4±0.3	41.1±0.6	40.1±0.6	39.4±0.5	38.9±0.6	38.9±0.5	39.2±0.5
	5 th bout	42.6±0.5	40.4±0.7	39.8±0.6	39.4±0.8	38.8±0.7	38.7±0.9	38.4±0.9

Conclusion: Normobaric IH exposures enhance cerebral perfusion, which is mediated by a moderate hypoxemia. There is no hypertensive response during the IH exposures.

283 Board #104 May 31 11:00 AM - 12:30 PM
Skin Perfusion and Vascular Conductance during Steady State Exercise are Unaffected by Aging or Heart Disease

Graeme Carrick-Ranson, Megan Reyden, Paul B. Nolan, Stacey A. Reading. *University of Auckland, Auckland, New Zealand.*
(No relationships reported)

PURPOSE: To examine the effect of healthy aging and ischemic heart disease on skin perfusion (SkP) and vascular conductance (VC) during relatively short-duration (15 min), steady state, normothermic cycle exercise. **METHODS:** All participants were physically active at least 60 min per week at the time of recruitment. SkP was collected (laser-Doppler flowmetry) in 10 young (24±4 yrs) healthy men (YH), 10 older (58±6 yrs) healthy men (OH), and 9 older (61±8 yrs) men with documented ischemic heart disease (IHD) during seated rest and at 60±5% and 75±5% of peak oxygen uptake (VO_{2peak}). VC was calculated as perfusion units (p.u.)/mean arterial pressure, while maximal dilatory capacity was determined using iontophoresis of 3% sodium nitroprusside. A two-way ANOVA with repeated measures was used to determine aging (YH vs. OH) and IHD (OH vs. IHD) comparisons for SkP and VC across experimental conditions. **RESULTS:** VO_{2peak} was not significantly different between YH and OH (mean±SD, 46±6 vs. 44±6 ml.kg⁻¹.min⁻¹ respectively, p=0.535) but was ~34% lower in IHD (29±6 ml.kg⁻¹.min⁻¹, p<0.001 vs. OH). There were no significant aging or IHD interaction effects for SkP or VC across experimental conditions (all p≥0.153). Maximal dilatory capacity was ~12% lower in OH vs. YH (98±36 vs. 111±53 p.u. respectively, p=0.558) and ~25% lower in IHD vs. OH (73±28 p.u., p=0.096). SkP at 75% VO_{2peak} as a percentage of maximal dilatory capacity was not significantly affected by either aging (32±17 vs. 40±22% in YH and OH respectively, p=0.343) or IHD (47±39%, p=0.872 vs. OH). **CONCLUSION:** During relatively short-duration exercise at similar relative intensity, SkP and VC do not appear to be adversely affected in aging adults with and without IHD. However, older adults and people with IHD may utilise a higher percentage of their maximal dilatory capacity during exercise.

Hemodynamic Changes Following High-Velocity Circuit Resistance or Treadmill Training in Adults with Cardiometabolic Risk Factors

Kirk Roberson, Melanie Potiaumpai, Kayla Widdowson, Annmarie Jaghab, Sean Chowdhari, Catherine Armitage, Katherine McGriff, Kevin A. Jacobs, FACSM, Joseph F. Signorile. *University of Miami, Miami, FL.* (Sponsor: Kevin A Jacobs, FACSM)
 Email: kxr181@miami.edu
(No relationships reported)

Cardiometabolic syndrome (CMS) is classified as a combination of maladaptive cardiovascular and metabolic abnormalities that includes hypertension, dyslipidemia, and blood vessel dysfunction. These outcomes can negatively influence hemodynamics (HDYN) via a decrease in myocardial efficiency due to increased afterload and/or decreased vascular elasticity. Studies have reported changes in HDYN during and following acute exercise in clinical populations. However, there is a paucity of information on how high-velocity circuit resistance training (CRT) compared to continuous treadmill exercise (TM) affects these parameters at rest. **PURPOSE:** To compare the effects of CRT, TM and no exercise (CONT) on HDYN variables at rest in older adults with multiple CMS risk factors. **METHODS:** Eleven women (66.4 ± 6.4 years) participated in 12-weeks of CRT or TM. Stroke volume (SV), cardiac index (CI), systemic vascular resistance (SVR), end-diastolic volume (EDV), ejection fraction (EF), and oxygen consumption (rVO₂) were measured by impedance electrocardiography and indirect calorimetry before and after training. **RESULTS:** A within-group analysis revealed significant increases in CI (MD=0.257, SE=.092, p=.023) and EDV (MD=31.10, SE=11.96, p=.032), a trend towards an increase in SV (MD=8.63, SE=4.28 p=.07) and a decrease in SVR (MD=-154.15, SE=71.07, p=.06) for CRT. TM resulted in significant increases in CI (MD=.218, SE=.080, p=.026) and EDV (MD=26.16, SE=10.36, p=.035); however, increases were not comparative to those seen with CRT. The CONT group showed a significant decrease in rVO₂ (MD=-1.60, SE=.64, p=.03). No significant differences were observed for EF. At post-testing CONT resulted in a decrease in rVO₂ approaching significance compared to TM (MD=-3.10, SE=1.12, p=.07). CRT demonstrated more favorable changes in SV, CI, SVR and EDV than TM or CONT. However, these changes did not reach statistical significance. **CONCLUSION:** These preliminary results indicate that CRT and TM lead to significant favorable changes in CI and EDV, however, CRT showed greater improvements in each and a trend towards improvements in HDYN when compared to TM and CONT. It is expected that completion of testing on existing subjects will further strengthen our results.

Impact of Short-term Training Camp on Aortic Pressure in Collegiate Endurance Runners

Tsubasa Tomoto¹, Jun Sugawara¹, Ai Hirasawa², Tomoko Imai³, Shigehiko Ogoh, FACSM⁴. ¹*National Institute of Advance Industrial Science and Technology, Tsukuba, Japan.* ²*Kyorin University, Mitaka, Japan.* ³*Aichi Institute of Technology, Toyota, Japan.* ⁴*Toyo University, Kawagoe, Japan.* (Sponsor: Shigehiko Ogoh, FACSM)
(No relationships reported)

PURPOSE: Stiffening of the aorta may be a possible cause of increased aortic blood pressure (BP) reflecting increased cardiac workload. We have previously reported that in regularly highly-trained endurance athletes, arterial stiffness increases after a short-term training camp characterized by greater training volume. As a follow-up study, we investigated the effect of such exercise on aortic BP. **METHODS:** In a total of 36 regularly highly-trained collegiate endurance runners, pulse wave analysis was performed before and after a seven-day training camp for evaluating aortic BP and the round-trip travel time (TR) of the pressure wave which is a surrogate index of aortic stiffness. They underwent a group training (three sessions per day mainly consisted of long distance running and sprint training). Variables of interest were compared between two groups based on accomplishment of the task (running at least 26 km per day). **RESULTS:** In the accomplished group, TR significantly shortened after the camp. In addition, aortic systolic BP and pulse pressure slightly but significantly elevated despite no significant changes in brachial BP and pulse pressure. Such significant changes were not observed in the unaccomplished group. Additionally, there was a significant correlation between the training distance during the camp and the change in aortic systolic BP (r=0.490, P<0.001). **CONCLUSION:** These results suggest that, even in regularly highly-trained endurance athletes, aortic BP increases acutely after the short-term vigorous training camp, and it is partly due to stiffening of the aorta. In addition, the greater training volume could be a cause of increased aortic BP but not in brachial BP.

Time Course Of Acute Exercise-induced Impairment Of Endothelial Dependent Vasorelaxation

M. Brennan Harris, Morgan C. Bucknor, T. Hunter Embry, Rachel G. Denny, Justin P. Canakis, Christina L. Kontzias, Yuntian Guan, Katie M. Necochea. *College of William & Mary, Williamsburg, VA.* (Sponsor: Joseph W. Starnes, FACSM)
 Email: mbharr@wm.edu
 (No relationships reported)

Regular endurance exercise improves endothelium dependent vasorelaxation. However, the initial stress of acute exercise may impair vascular function prior to the beneficial adaptive response. **PURPOSE:** The purpose of this study is to examine the effects of acute exhaustive exercise on endothelial-dependent vascular function. **METHODS:** 7-9 mo old, male, Wistar rats were divided into four groups (n=6/group): sedentary (SED), 6h post-exercise (6h), 24h post-exercise, and 48h post-exercise. Exercise consisted of one bout of exhaustive treadmill exercise lasting between 30-40 min. Endothelium dependent vasorelaxation was assessed in ring segments of the aorta by constructing an acetylcholine dose response curve (10^{-10} - 10^{-5} M) in a wire myograph. **RESULTS:** Maximal vasorelaxation was impaired in 6h (70.1±5.2%) and 24h (76.2±4.4%) compared to SED (86.9±4.2%) and 48h (83.7±4.4%). EC_{50} for 6h (3.9e⁻⁷) was significantly (p<0.05) greater than SED (1.3e⁻⁷) and 48h (1.5e⁻⁷). **CONCLUSIONS:** These data suggest that acute, exhaustive treadmill exercise results in impaired endothelial dependent vasorelaxation up to 24h post-exercise and returns to sedentary levels within 48h.

The Effect Of Inorganic Nitrate And Exercise On Blood Pressure In Pre-and Hypertension Subjects.

Francisco J. Diaz¹, Humberto Guerrero¹, Magdalena Najera¹, Daniel Galvan², Jesui Garcia¹, Antonio Tovar¹, Luis Garcidueñas², Marina Trejo³, Guadalupe Diaz¹, Maciste Macias¹, Arturo Figueroa-Galvez, FACSM⁴, Fabiola Mendez¹. ¹Univ. de Guanajuato, Leon, Mexico. ²Comision de Deporte del Estado de Guanajuato, Leon, Mexico. ³Universidad Autonoma de Baja California, Baja California, Mexico. ⁴Florida State University, Florida, FL. (Sponsor: Figueroa Galvez Arturo, FACSM)
 Email: fisiol.ug@gmail.com
 (No relationships reported)

Dietary supplementation of inorganic nitrate (NO-3) reduces blood pressure (BP) in normal and hypertensive subjects. An acute bout of exercise also reduces BP in many normotensive and in most hypertensive individuals. The possible additive hypotensive effect of NO-3 plus exercise has not been investigated in pre- and hypertensives. **PURPOSE:** To assess whether intake of NO-3 followed by maximal exercise may potentiate the hypotensive effect of both procedures. **METHODS:** Ten pre- or hypertensive subjects participated in a randomized double-blind study one week apart. (7 men, 3 women) (BP ≥ 120/80mmHg) (Systolic Blood Pressure SBP/Diastolic Blood Pressure DBP). Subjects arrived in the fasting condition and without medications and ingested either a fruit and vegetables juice containing 250 g of NO-3 (8 mmol/L of NO-3) (N) or nitrate depleted juice (P). After 90 minutes post supplementation, they performed a MAXCAP-T treadmill test. BP was obtained 10 minutes post arrival (BP1), 90 minutes post dietary supplementation (BP2), immediately Post MAXCAP-T (BP3), 10 minutes after MAXCAP-T (BP4), and 150 minutes post MAXCAP-T (BP5). Statistics anova, paired t test, t test two groups. **RESULTS:** After ingestion of N, SBP and DBP were reduced by 11 and 6 mmHg, respectively. Meanwhile, after P, SBP decreased 3 mmHg while DBP did not change. Following MAXCAP-T, SBP increased less after N than P (26 vs 31 mmHg, P<0.05). DBP decreased 2 and increased 5 mmHg with N and P, respectively (P<0.05). Ten minutes after MAXCAP-T, SBP was 20 and 11 mmHg lower than BP1 for N and P respectively (P<0.05). The difference between N and P was significant (P<0.05). DBP was reduced 10 mmHg with N with no changes in P. After 150 minutes of MAXCAP-T, SBP was 24 and 16 mmHg lower than BP1 for N and P, respectively (p<0.05). Meanwhile, DBP was 8 mmHg lower than BP1 for N without significant changes for P. **CONCLUSIONS:** Ingestion of inorganic nitrate decreased SBP and DBP before exercise and prevented increases in SBP and DBP immediately after acute maximal exercise. The combination of NO-3 and exercise resulted in greater decreases in BP in pre- and hypertensive patients as compared with P.

Independent and Combined Effects of Heat Stress and Exercise on Arterial Stiffness

Aaron R. Caldwell, Forrest B. Robinson, Matthew A. Tucker, Cash H. Arcement, Cory L. Butts, Brendon P. McDermott, Matthew S. Ganio, FACSM. *University of Arkansas, Fayetteville, AR.*
 Email: ac039@email.uark.edu
 (No relationships reported)

Several studies have established that arterial stiffness, assessed via pulse wave velocity (PWV), is reduced following passive heat stress or exercise. Yet, no study to date has simultaneously investigated the cumulative effects of exercise and heat stress on measures of PWV. **PURPOSE:** Determine the independent and combined effects of heat and exercise on arterial stiffness. **METHODS:** Nine subjects (n=3 females, 46±11 years old; 24.1±2.8 kg/m²) completed four trials, with different interventions, in a randomized order. In a control trial subjects rested supine (CON). In order to independently test the effect of heat stress, subjects were passively heated (i.e. no exercise) in a hot environment (~40°C) while wearing a water perfusion suit with hot water (PH). In two other trials, subjects cycled at ~50% of VO_{2peak} in a hot (~40°C; HC) or cool (~15°C; CC) environment. Prior to interventions and in the hour following interventions, pulse wave velocity (PWV), via Doppler ultrasound, was assessed at the tibial, radial, femoral and carotid artery sites. Central PWV (C_{PWV}) was assessed using measures between the carotid/femoral artery sites, while peripheral stiffness was assessed using the radial/carotid (U_{PWV}), and tibial/femoral (L_{PWV}) artery sites. Mean body temperature (T_b) was measured with skin and rectal thermistors. **RESULTS:** No significant changes in T_b were observed during the CON and CC trials. However, the PH and HC trials elevated T_b 2.69±0.23°C and 1.67±0.27°C, respectively (p<0.01). No changes in any measure of PWV were observed in the CON, CC, or HC trials (p>0.05). However, in the PH trial U_{PWV}, but not C_{PWV} or L_{PWV} was reduced immediate post (-107±81 cm/s) and 15 minutes (-93±82 cm/s) post heating (p<0.05). **CONCLUSIONS:** Contrary to previous data, we did not observe changes in arterial stiffness following aerobic exercise (i.e., CC). Further, although heat stress alone reduced arterial stiffness (specific to the upper peripheral arteries), when combined with exercise in the heat, there was no change in arterial stiffness (i.e., HC). This suggests that heat stress has an independent effect on arterial stiffness that is obliterated when combined with exercise.

Atrial Natriuretic Peptide Augmented Following Aquatic Treadmill Exercise

Dustin P. Joubert¹, Jorge Z. Granados², James R. Rowe¹, Stephen F. Crouse, FACSM². ¹Stephen F. Austin State University, Nacogdoches, TX. ²Texas A&M University, College Station, TX. (Sponsor: Stephen F. Crouse, FACSM)
 Email: joubertd@sfasu.edu
 (No relationships reported)

Aquatic treadmill (ATM) exercise training has been shown to reduce blood pressure reactivity to exercise to a greater degree than land treadmill (LTM) exercise training. Furthermore, ATM exercise tends to elicit a greater post-exercise hypotensive response and an acute augmentation in flow-mediated dilation (FMD). However, the mechanisms for such changes are unclear, and previous research showed no differences in plasma nitrates or nitrites between modes. **Purpose:** To determine the effects of an acute bout of ATM and LTM exercise on atrial natriuretic peptide (ANP), norepinephrine (NE), and epinephrine (EPI) in pre-hypertensive men. **Methods:** Following BP screening and a maximal exercise test, 13 men (33 ± 11 years, 27.7 ± 10.6% fat, 39.3 ± 7.7 ml·kg⁻¹·min⁻¹ 130 ± 7/77 ± 7 mmHg) completed an acute bout of both ATM and LTM at 60% VO_{2max} for a duration required to expend 300 kcal (~30 minutes). Blood samples were obtained pre-exercise and immediately post-exercise. Blood samples were analyzed for ANP, NE, and EPI. **Results:** All results are displayed in the table. The percent increase in ANP was significantly greater (p<0.05) for ATM than LTM exercise. There were no significant differences in the change in NE or EPI between modes. **Conclusion:** ANP is released by the atria in response to increased volume load on the heart, and plays a role in blood pressure regulation through both vasodilatory effects and renal natriuretic/diuretic effects. Water submersion is known to increase venous return and preload on the heart. Increased ANP levels observed following ATM exercise in the present study may explain in part the previous findings of an augmented post-exercise hypotensive response and augmented FMD with ATM exercise.

	ATM				LTM				p-Value

Experimental Intermittent Ischemia Augments Exercise-Induced Inflammatory Cytokine Production

Daniel Shill, Kristine Polley, T. Bradley Willingham, Jarrod Call, Jonathan Murrow, Kevin McCully, FACSM, Nathan Jenkins. *University of Georgia, Athens, GA.* (Sponsor: Kevin McCully, FACSM)

(No relationships reported)

Acute exercise-induced transient increases in inflammatory cytokines are linked to the beneficial vascular effects of exercise, but the underlying mechanisms that promote appearance are contingent on numerous factors (e.g. muscle mass recruited, exercise intensity/duration, etc.). Evidence suggests that a lack of oxygen and/or blood flow to working muscle modifies cytokine appearance. However, little is known about the inflammatory response to intermittent ischemia in working muscle.

PURPOSE: Determine the extent to which local inflammation is involved in the response to ischemic exercise by reproducing the peripheral arterial disease (PAD)-associated phenomenon of intermittent claudication without the presence of potential confounding comorbidities frequently exhibited by patients with PAD.

METHODS: 14 healthy males performed unilateral isometric forearm contractions for 30 minutes with and without experimental ischemia. Blood was drawn at baseline, 5 and 10 minutes into exercise, at the end of exercise, and 30, 60, and 120 minutes after exercise.

RESULTS: Oxygen saturation levels, as measured by near-infrared spectroscopy, were reduced by 10% and 41% during non-ischemic and ischemic exercise, respectively ($P < 0.001$). Non-ischemic exercise did not affect cytokine values during exercise (all $P > 0.05$). Ischemic exercise enhanced concentrations of basic fibroblast growth factor, interleukin (IL)-6, IL-10, tumor necrosis factor- α , and vascular endothelial growth factor at the end of exercise by 148%, 197%, 129%, 154%, and 164% ($P < 0.05$), respectively, but IL-8 was not influenced by ischemic exercise ($P > 0.05$).

CONCLUSION: In conclusion, the present study demonstrates that ischemic, small muscle endurance exercise elicits local inflammatory cytokine production, compared to non-ischemic exercise. The effect of ischemic exercise with PAD-associated comorbidities may impact the inflammatory response during and after exercise.

FUNDING: This study was supported by funds from the Office of the Vice President for Research and the College of Education at the University of Georgia (to N.T.J.).

DISCLOSURES: J.R.M. is Chief Operating Officer and K.K.M. is President of Infrared Rx. The other authors report no conflicts of interest, financial or otherwise.

PURPOSE: To Discern Differences of Cardiovascular Response Over Four Rounds of a High-Intensity Functional Training (HIFT) Session. **METHODS:** Participants with at least four weeks of experience with HIFT were recruited ($n=100$; age= 31.25 ± 7.2 years; $\dot{V}O_{2peak} = 45.9 \pm 6.0$ ml/kg/min). Participants completed a graded exercise test to determine peak oxygen consumption ($\dot{V}O_{2peak}$) and heart rate (HR_{peak}). Participants returned to the laboratory after one week to perform as many rounds (1 round: 250-meter row, 20 kettlebell swings and 15 thrusters) of HIFT in 15 minutes. All repetitions were summed at the end and analyzed as a round. During the graded exercise test and HIFT, oxygen consumption and HR were measured via a Cosmed K4b2 portable metabolic system. Average $\% \dot{V}O_{2peak}$ and average $\%HR_{peak}$ of each

round was determined by taking the average heart rate and oxygen consumption of each round and dividing by HR_{peak} and $\dot{V}O_{2peak}$ of the treadmill test. Two-way (4×2) repeated measures analysis of variance was conducted with rounds as the within-subjects and physiological response ($\%HR_{peak}$ and $\% \dot{V}O_{2peak}$) as the between-subjects factor to determine whether $\%HR_{peak}$ and $\% \dot{V}O_{2peak}$ responded the same across rounds 1-4 of the HIFT workout (time \times HR and $\dot{V}O_2$ interaction). Independent samples t-tests were used to compare $\% \dot{V}O_{2peak}$ and $\%HR_{peak}$ for each round with an adjusted alpha of 0.0125. **RESULTS:** A significant interaction was found between the measure of cardiovascular response and round [$F(1,176) = 31.65$, $p < 0.001$] indicating $\%HR_{avg}$ and $\% \dot{V}O_{2avg}$ responded differently across rounds. A significant difference ($p < 0.001$) between $\% \dot{V}O_{2peak}$ and $\%HR_{peak}$ was found for all rounds [Round 1: $76.9 \pm 8.9\%$ vs. $83.1 \pm 8.4\%$; Round 2: $80.6 \pm 9.3\%$ vs. $86.8 \pm 8.7\%$; Round 3: $79.3 \pm 9.9\%$ vs. $89.3 \pm 5.8\%$; Round 4: $78.6 \pm 9.6\%$ vs. $91.5 \pm 6.5\%$]. **CONCLUSION:** Our results suggest that HR and $\dot{V}O_2$ did not respond the same over four rounds of HIFT; thus, simply estimating HR response during HIFT would overestimate the metabolic demands of the activity. The progressive increase in $\%HR_{peak}$ may be due to increases in thermoregulatory demands causing an increase in cardiac output, while metabolic demands remain relatively constant. Future investigations should aim to determine the mechanism underlying of the dissociation between HR and $\dot{V}O_2$ during HIFT.

Bench Press With and Without Blood Flow Restriction on Hemodynamics and Pulse Wave Reflection

Yu Lun Tai, Erica Marshall, Alaina Glasgow, J. Derek Kingsley. *Kent State University, Kent, OH.* (Sponsor: Dr. Ellen Glickman, FACSM)

(No relationships reported)

Hemodynamic and pulse wave reflection responses to upper-body resistance exercise (RE) with and without blood flow restriction (BFR) are unclear. **PURPOSE:** To evaluate the differences between bench press with and without BFR on hemodynamics and pulse wave reflection in resistance-trained men. **METHODS:** Sixteen resistance-trained men participated in the study. Hemodynamics and pulse wave reflection were assessed before and after low-intensity bench press with BFR (LI-BFR), traditional high-intensity bench press without BFR (HI), and control (CON). The LI-BFR utilized of 4 sets with repetitions of 30, 15, 15, and 15 at 30% 1-repetition maximum (1RM) and 30 seconds rest between sets. The HI consisted of 4 sets of 8 repetitions at 70% 1RM and 60 seconds rest between sets. The CON consisted of supine rest for 10 minutes. A repeated measures ANOVA was used to evaluate the conditions (LI-BFR, HI, CON) across time (rest, recovery) on hemodynamics and pulse wave reflection. **RESULTS:** There were significant ($p \leq 0.05$) increases in heart rate after LI-BFR (Rest: 57 ± 10 bpm; Rec: 62 ± 11 bpm) and HI (Rest: 57 ± 14 bpm; Rec: 69 ± 13 bpm) compared to rest and CON. There were no changes in aortic and brachial systolic blood pressure (BP) after any condition. However, there were significant ($p \leq 0.05$) reductions after HI-BFR in aortic (Rest: 66 ± 9 mmHg; Rec: 61 ± 6 mmHg) and brachial (Rest: 60 ± 5 mmHg; Rec: 65 ± 9 mmHg) diastolic BP compared to rest. There were significant ($p \leq 0.05$) condition by time interactions after LI-BFR and HI for augmentation index (AIx) (LI-BFR: Rest: $10.0 \pm 5.6\%$, Rec: $27.2 \pm 12.1\%$; HI: Rest: $12.2 \pm 9.0\%$, Rec: $22.3 \pm 8.1\%$), AIx at 75 bpm (LI-BFR: Rest: $1.1 \pm 7.6\%$, Rec: $21.6 \pm 14.5\%$; HI: Rest: $4.5 \pm 12.7\%$, Rec: $19.5 \pm 10.4\%$), augmentation pressure (LI-BFR: Rest: 3.9 ± 2.2 mmHg, Rec: 13.3 ± 6.9 mmHg; HI: Rest: 5.2 ± 3.9 mmHg, Rec: 9.6 ± 3.7 mmHg) and wasted left ventricular energy (LI-BFR: Rest: 838 ± 513 dynes s/cm², Rec: 2961 ± 1743 dynes s/cm²; HI: Rest: 1116 ± 849 dynes s/cm², Rec: 1983 ± 904 dynes s/cm²) such that they were augmented compared to rest and CON, with no differences between LI-BFR and HI. **CONCLUSION:** These data suggest that LI-BFR significantly decreases aortic and brachial diastolic BP. In addition, LI-BFR and HI significantly alter pulse wave reflection in a similar fashion.

Validity Of Forearm Oxygen Uptake During Handgrip Exercise: Assessment By Ultrasonography And Venous Blood Gas

Stian K. Nyberg, Ole K. Berg, Jan Helgerud, Eivind Wang. *NTNU, Trondheim, Norway.*

Email: stiankwak@gmail.com

(No relationships reported)

ABSTRACT:

Assessment of forearm oxygen uptake ($\dot{V}O_2$) during handgrip exercise is a keenly investigated concept for observing small muscle mass metabolism. Although a combination of Doppler-ultrasound measurements of brachial artery blood flow and blood gas drawn from a deep forearm vein has been utilized to calculate forearm $\dot{V}O_2$

for more than two decades, this experimental design has, somewhat surprisingly, not been validated. **PURPOSE:** To evaluate the reliability and accuracy of this technique following handgrip exercise. **METHODS:** Test-retest measurements were performed with ~0.25 watt (W) steady state increments in ten healthy young (24±3(SD) yrs.) males during handgrip exercise. **RESULTS:** $\dot{V}O_2$ and workload exhibited a linear relationship ($p < 0.01$) following all submaximal workloads (0.50W:43.8±10.1 mL·min⁻¹; 0.75W:53.8±14.1 mL·min⁻¹; 1.00W:63.4±16.3 mL·min⁻¹; 1.25W:72.2±17.6 mL·min⁻¹), while the final increment before exhaustion was non-significant, marking a $\dot{V}O_2$ -plateau (1.5W:79.2±18.6 mL·min⁻¹). In turn, blood flow exhibited a concomitant relationship ($p < 0.01$) with $\dot{V}O_2$ (0.50W:359±86 mL·min⁻¹; 0.75W:431±112 mL·min⁻¹; 1.00W:490±123 mL·min⁻¹; 1.25W:556±112 mL·min⁻¹; 1.50W:622±131 mL·min⁻¹) while arteriovenous oxygen difference ($a-vO_{2diff}$) remained constant following all workloads (123±11-130±10 mL·L⁻¹). The average $\dot{V}O_{2test}$ -retest difference was -0.4 mL·min⁻¹ with ±2SD limits of agreement (LOA) of 8.4 and -9.2 mL·min⁻¹, respectively, while coefficients of variation (CV) ranged from 4-7%. Accordingly, test-retest blood flow difference was 11.9 mL·min⁻¹ (LOA:84.1 mL·min⁻¹; -60.4 mL·min⁻¹) and again CV ranged between 4-7%. Test-retest difference for $a-vO_{2diff}$ was -0.28 mL·dL⁻¹ (LOA: 1.26 mL·dL⁻¹; -1.82 mL·dL⁻¹) with CV ranging from 3-5%. **CONCLUSION:** Our results reveal that forearm $\dot{V}O_2$ -assessment by Doppler-ultrasound and direct venous sampling is a valid experimental design across a range of exercise intensities, and suggest that this method can be applied for assessment of small muscle mass metabolism in occupationally relevant forearm musculature.

Cognitive Task Impairs Dynamic Cerebral Autoregulation During Normoxia And Hypoxia.

Shigehiko Ogoh, FACSM¹, Hiroaki Nakata², Tadayoshi Miyamoto³, Manabu Shibasaki². ¹Toyoy University, Kawagoe-shi, Saitama, Japan. ²Nara Women's University, Nara-shi, Nara, Japan. ³Morinomiya University of Medical Sciences, Osaka-shi, Osaka, Japan.
(No relationships reported)

Hypercapnia-induced cerebral hyper-perfusion or hypoxia attenuates dynamic cerebral autoregulation (CA). On the other hand, performing cognitive task increases both anterior and posterior cerebral blood flow via frontal and occipital lobe activation and this cognitive tasks-induced cerebral hyper-perfusion attenuates dynamic CA. **PURPOSE:** The aim of the present study was to examine whether cognitive task-induced impairment in dynamic CA was enhanced by hypoxia condition. **METHODS:** To test our hypothesis, we identified dynamic CA during the Go/No-Go task under normoxia and hypoxia conditions. This study examined the relationship between mean arterial pressure (MAP) and mean middle cerebral artery blood velocity (MCA V_{mean}) during the Go/No-Go task. Dynamic CA and steady-state changes in MCA V_{mean} in relation to changes in arterial pressure were evaluated using transfer function analysis. **RESULTS:** MCA V_{mean} increased with the Go/No-Go task ($P=0.022$), but the different response of MCA V_{mean} between normoxia and hypoxia conditions was not observed ($P=0.850$). In the transfer function analysis, the low frequency (LF) and very LF (VLF) phase shift decreased during the Go/No-Go task (LF and VLF; $P < 0.001$ and $P=0.01$). However, the decreases in LF and VLF phase shift during the Go/No-Go task was not modified by hypoxia condition ($P=0.617$ and $P=0.981$). **CONCLUSIONS:** Similarly with change in MCA V_{mean} , dynamic CA was attenuated during cognitive task. In contrast to our hypothesis, hypoxia did not affect this phenomenon.

Effects of Blood Flow Restriction Training on Vascular Reactivity & Morphology in Older Subjects. A Randomized Controlled Trial.

Karynne G. Lopes, Daniel A. Bottino, Paulo T.v. FARINATTI, Roberto A. Lourenço, ELIETE BOUSKELA, RICARDO B. OLIVEIRA. RIO DE JANEIRO STATE UNIVERSITY, Rio de Janeiro, Brazil.
Email: ricardobrandaojr@gmail.com
(No relationships reported)

The positive effects of low intensity blood flow restriction (BFR) training on muscle mass and strength are well documented. Less investigated, however, are the effects and safety of this intervention on the vascular health of older adults. **PURPOSE:** to compare the effects of low intensity resistance training (RT) with BFR and high intensity RT without BFR on body composition, muscle strength and vascular function in older adults. **METHODS:** Through a randomized controlled trial, 29 eutrophic, inactive elderly, aged 72±7 years old, weight 63.1±10.7 kg, body mass index 25.2±2.6 kg/m², were divided in three groups as follows: BFR - exercise intensity set at 30% of 1 repetition maximum (RM) with BFR promoted by a pressure cuff inflated throughout the session at 50% of the resting systolic blood pressure; Control (CON) - exercise intensity set at 30% of 1 RM without BFR; HI - exercise intensity set at 70% of 1 RM without BFR. All subjects performed two exercises for lower limbs and two for upper limbs, three days a week during three months. The RT included three sets of 10 RM

with one minute of resting between sets. All the results were presented as mean±SD. A one way ANOVA, followed by the Bonferroni post-hoc test were used to compare the relative gains (%Δ) among groups. **RESULTS:** Differently to HI, BFR significantly increased arm muscle mass ($P=0.03$) assessed by dual energy x-ray absorptiometry when compared to CON. Handgrip strength was higher in both BFR and HI groups ($P < 0.001$). Three months of either BFR or HI were not deleterious to vascular reactivity assessed by venous occlusion plethysmography ($P > 0.05$ when groups were compared) and microvascular morphology assessed by nailfold videocapillaroscopy ($P > 0.05$). **CONCLUSIONS:** BFR training was able to increase mass and strength of small muscles in older adults, with no deleterious effects in vascular function. Future studies should investigate the possible risks and benefits of this intervention in frail elderly with sarcopenia.

The Effects of Resistance Exercise on Forearm Blood Flow and Vasodilatory Capacity Between Sexes

J. Derek Kingsley, Erica Marshall, Alaina Glasgow, Yu Lun Tai. Kent State University, Kent, OH. (Sponsor: Ellen L. Glickman, FACSM)
Email: jkingsle@kent.edu
(No relationships reported)

An acute bout of resistance exercise (RE) has been suggested to have a negative effect on vascular function. However, no studies have evaluated differences between the sexes after free-weight resistance exercises. **PURPOSE:** To evaluate the effects of free-weight resistance exercises on forearm blood flow (FBF) and vasodilatory capacity between sexes. **METHODS:** Resistance-trained men (n=14) and women (n=13) between the ages of 18-30 yrs volunteered to participate. One-repetition maximum (1RM) was assessed on the squat, bench press and deadlift. FBF and vasodilatory capacity were assessed using venous occlusion plethysmography. FBF, mean arterial pressure (MAP) and forearm vascular conductance (FVC) were assessed at baseline and 15 minutes after each condition. Vasodilatory capacity was assessed at rest and followed by 5 minutes of circulatory occlusion (220 mmHg) to induce reactive hyperemia before and 20 minutes after an acute bout of RE. The RE consisted of 3 sets of 10 repetitions at 75% 1RM on the squat, bench press and deadlift. Two minutes of rest was given between sets and exercises. Each participant also completed a quiet control session of the same duration. Area under the curve (AUC) was also utilized to determine differences in blood flow. Data were analyzed by an ANOVA to examine the effects of gender by time by condition. Tukey HSD was used as a post-hoc test if the interaction was deemed significant. **RESULTS:** There were no significant sex differences at rest for any of the variables. Furthermore, there were no significant sex by time by condition interactions for any variable. There were significant increases in FBF (Rest: 8.4±6.0ml/100ml tissue/min; Recovery: 21.0±12.9ml/100ml tissue/min, p=0.0001), and FVC (Rest: 0.101±0.676ml/min/100ml/mmHg; Recovery: 0.273±0.180 ml/min/100ml/mmHg, p=0.0001) after the RE, but not the Control. A significant time by condition interaction was noted for MAP (Rest: 82±7mmHg; Recovery: 76±4mmHg, p=0.003) such that it was reduced after RE. While there was no increase in vasodilatory capacity, there was a significant increase in AUC (Rest: 149.0±81.0units; Recovery: 286.4±145.1units, p=0.0001) **CONCLUSION:** These data demonstrate that microvascular function is increased similarly between resistance-trained men and women after an acute bout of RE.

Calf Venous Compliance Differences in Male and Female Adults

Jocelyn C. Rothschild-Frey, Cody Yarnell, Juliane P. Wallace, FACSM. Southern Illinois University, Carbondale, IL.
Email: joce.7@siu.edu
(No relationships reported)

Similar to changes in arterial compliance with fitness and aging, venous compliance in the lower extremities of adults improves with higher fitness and declines with increasing age. In young adults, males have a higher venous compliance than females, a difference that does not appear related to hormonal fluctuations. Most previous studies have used small groups to make these comparisons. **PURPOSE:** To determine the calf venous compliance differences in males and females in a larger group of adults. **METHODS:** 71 females and 102 males volunteered for this

project. Participants underwent anthropometric assessment, a submaximal graded exercise test, and assessment of calf venous compliance. Utilizing venous occlusion plethysmography, calf pressure-volume relations were determined using the quadratic regression equation $[(\Delta\text{limb volume}) = \beta_0 + \beta_1 * (\text{cuff pressure}) + \beta_2 * (\text{cuff pressure})^2]$. Calf venous compliance was calculated as the first derivative of the pressure-volume relation during cuff pressure reduction. Sex differences in anthropometric variables, fitness, and compliance (β_1 , β_2 , and the slope of the pressure compliance relationship) were analyzed with a simple ANOVA. **RESULTS:** The males and females were of similar age [102 males (26±12 yrs), 71 females (28±17 yrs)] and fitness level (males 50.24±19.55 ml*kg⁻¹*min⁻¹ vs. females 47.84±16.03 ml*kg⁻¹*min⁻¹). The males were larger in size (BMI: 25.07±3.81 kg/m²; calf volume: 585.79±116.70 cm) than the females (BMI: 23.78±4.3 kg/m²; calf volume: 497.52±132.31cm). Females had significantly larger β_0 values than males, but males had significantly higher β_2 values than females indicating higher calf venous compliance [males; $\Delta\text{Limb Volume} = 0.6665 \pm 1.89051 + 0.0939 \pm 0.1119 (\text{Cuff Pressure}) - 0.0212 \pm 0.20587 (\text{Cuff Pressure})^2$ vs. females; $\Delta\text{Limb Volume} = 1.8384 \pm 5.28027 + 0.1083 \pm 0.12568 (\text{Cuff Pressure}) - 0.0009 \pm 0.00107$]. Compliance @ 20mmHg was significantly higher in males than females (0.28 ± 0.83mmHg vs. 0.06 ± 0.02 mmHg respectively). **CONCLUSION:** Consistent with previous research, this large data set found males to have higher calf venous compliance than females and females to have higher net capillary filtration than males.

Exaggerated Cardiovascular Response to Muscle Mechanoreflex Activation in Type 2 Diabetic Rats
 Masaki Mizuno, Jere H. Mitchell, FACSM, Scott A. Smith.
University of Texas Southwestern Medical Center, Dallas, TX.
 (Sponsor: Jere H. Mitchell, FACSM)
 Email: masaki.mizuno@utsouthwestern.edu
 (No relationships reported)

Evidence suggests that the cardiovascular response to physical activity is excessively heightened in patients with type 2 diabetes mellitus (T2DM). However, the mechanisms underlying this exaggerated circulatory responsiveness remain to be fully elucidated. The exercise pressor reflex (EPR) is a primary contributor to autonomic cardiovascular regulation during physical exercise. Mechanically (mechanoreflex) and metabolically (metaboreflex) sensitive components mediate EPR function. We have shown previously that the metaboreflex is overactive in T2DM whereas the function of the mechanoreflex remains undetermined in this disease. **PURPOSE:** To assess mechanoreflex activity in T2DM rats. It was hypothesized that the heightened cardiovascular response to exercise in T2DM is induced, in part, by functional alterations in the muscle mechanoreflex. **METHODS:** T2DM was induced in Sprague-Dawley rats by a combination of both a low-dose streptozotocin injection (30-35 mg/kg, ip) and a 14-16 wk high-fat diet. In control rats (normal diet; no streptozotocin; n=34) and T2DM (n=10) rats, the EPR was activated by electrically-inducing hindlimb muscle contraction via stimulation of spinal ventral roots. The mechanically-sensitive component of the EPR was selectively activated by passively stretching hindlimb muscle. **RESULTS:** Compared to control animals, sympathetic and pressor responses to EPR activation were significantly greater in T2DM rats (RSNA: $\Delta = 122 \pm 20$ vs. 61±8 %, P<0.05; MAP: $\Delta = 49 \pm 5$ vs. 20±2 mmHg, P<0.05). Passive stretch likewise evoked greater increases in RSNA ($\Delta = 81 \pm 16$ vs. 31±5 %, P<0.05) and MAP ($\Delta = 38 \pm 7$ vs. 13±2 mmHg, P<0.05) in T2DM rats compared to healthy controls. **CONCLUSIONS:** These data demonstrate the skeletal muscle mechanoreflex is overactive in T2DM. This is an important finding as it suggests that both the metaboreflex (as previously reported) and mechanoreflex contribute significantly to the generation of EPR overactivity in T2DM possibly accounting for the abnormally large cardiovascular response to exercise in this disease. *Supported by the Lawson & Rogers Lacy Research Fund in Cardiovascular Disease*

Peripheral and Central Blood Pressure Response to Handgrip Exercise Coupled with Blood Flow Restriction
 Jeffrey D. Miller, Edward T. Kelley, Daniel P. Credeur.
University of Southern Mississippi, Hattiesburg, MS.
 Email: Jeffrey.D.Miller@usm.edu
 (No relationships reported)

Low intensity exercise coupled with blood flow restriction (BFR) produces comparable strength gains and skeletal muscle hypertrophy, compared to non-BFR training at higher intensities. However, the cardiovascular response (e.g., blood pressure-BP) to this type of exercise remains controversial. **PURPOSE:** To examine peripheral and central BP responses to low and high-intensity, unilateral handgrip exercise performed with and without BFR. **METHODS:** Eight college-aged males (Age=24±5 yrs; BMI=30±7 kg/m², handgrip max voluntary contraction-MVC=52±8 kg) underwent three 5-minute bouts (counter-balanced, 10 mins rest) of rhythmic handgrip (1-2 sec duty cycle, 20 squeezes/min) performed at a low (40% MVC) and high-intensity (60%

MVC) with and without proximal occlusion (80-100mmHg, 50-80% arterial occlusion assessed via radial artery Doppler-ultrasound). Peripheral BP's (brachial artery) were obtained using the oscillometric method, and a proprietary transfer function was applied to the pulse waveform to estimate central aortic BP's [systolic, diastolic, mean arterial pressure (MAP) and rate-pressure product (RPP=heart rate x systolic BP)]. **RESULTS:** Peripheral systolic and diastolic BP, MAP and RPP were greater than central pressures at BL (e.g., peripheral systolic BP=130±6 vs. central systolic BP=113±5 mmHg; P<0.001), and across each handgrip bout (P<0.05). Compared to BL, both peripheral and central MAP increased, with the greatest change occurring during high-intensity handgrip with BFR (+17±4, P<0.001). Similar findings were observed for peripheral and central systolic and diastolic BP, and RPP (e.g., central RPP at BL=7296±621, vs. 40% BFR=8217±612, vs. 60% with BFR=9441±686, vs. 60% without BFR=9237±629; P<0.001). **CONCLUSION:** These preliminary findings indicate that low intensity, unilateral handgrip exercise performed with BFR produces a comparable BP response (i.e., magnitude increase for MAP) as high intensity handgrip without BFR; however, RPP was greater during high intensity handgrip both with and without BFR, compared to low intensity with BFR.

Post-Exercise Blood Pressure and Autonomic Balance Following Continuous and Intermittent Exercise Bouts
 C. Matthew Lee, Megan Robles, Marialice Kern, FACSM.
San Francisco State University, San Francisco, CA. (Sponsor: Marialice Kern, FACSM)
 Email: cmlee@sfsu.edu
 (No relationships reported)

PURPOSE: To examine the post-exercise response of blood pressure and cardiac autonomic balance following a continuous bout of exercise (CONT) compared to multiple intermittent bouts (INT) resulting in the same volume of exercise. **METHODS:** Participants (n=18; age: 23.8±3 yr; 12 females, 6 males) completed both 30 minutes of CONT and 30 min of INT cycling exercise (3, 10-min bouts) at 60% VO_{2max} on 2 separate days. The order of the conditions was randomized and the INT bouts were separated by ~4 hours. Systolic (SBP) and diastolic blood pressure (DBP) were assessed with a continuous noninvasive BP monitor before exercise (PRE) and at 5, 30, 60, and 120 min of seated recovery following CONT and the final INT bout. Spectral measures of heart rate variability, reported as high- (HF) and low-frequency (LF) power, were also obtained from an electrocardiogram at the same time points. LF/HF was reported as a measure of autonomic balance. A 2-way ANOVA was used to compare BP and measures of autonomic control between conditions and over time. A significance level of 0.05 was used for all tests. **RESULTS:** Table 1 shows the values for BP during the conditions. There was a main effect of time on SBP such that it was significantly lower at all post-exercise time points compared to PRE. There were no significant changes in DBP between conditions or over time. Furthermore, there was a main effect of time on LF/HF such that it was higher at 5 minutes post-exercise (CONT: 1.23±0.04; INT: 1.17±0.03) compared to PRE (CONT: 1.10±0.02; INT: 1.06±0.02) and 60 (CONT: 1.11±0.03; INT: 1.10±0.03) and 120 min (CONT: 1.10±0.02; INT: 1.07±0.02) post-exercise. **CONCLUSION:** Both CONT and INT resulted in similar post-exercise reductions in SBP and alterations in autonomic balance. Accumulating exercise in multiple bouts appears to result in a similar post-exercise BP response as the same volume of exercise done continuously.

Table 1.

		PRE	5 min	30 min	60 min	120 min
SBP (mmHg)	CONT	120.3 ± 2	111.0 ± 3*	108.0 ± 3*	105.4 ± 3*	108.5 ± 3*
	INT	121.2 ± 2	111.8 ± 3*	108.6 ± 3*	108.5 ± 4*	105.9 ± 3*
DBP (mmHg)	CONT	65.8 ± 2	65.9 ± 2	67.3 ± 2	65.7 ± 2	66.4 ± 2

Acute Hypotension After High-intensity Interval Exercise in Metabolic Syndrome Patients
 Miguel Ramirez-Jimenez, Felix Morales-Palomo, Juan Fernando Ortega, Ricardo Mora-Rodriguez. *UNIVERSITY OF CASTILLA-LA MANCHA, TOLEDO, Spain.*
 Email: PROFESOR.MRAMIREZ@UCLM.ES
 (No relationships reported)

PURPOSE: The purpose of this study was to compare the magnitude of post-exercise hypotension (PEH) after a bout of high intensity interval training (HIIT) in comparison to an isocaloric bout of traditional moderate intensity continuous exercise (CE). **METHODS:** After supine rest fourteen obese (31±1 kg·m⁻²) middle-age (57±2 y) metabolic syndrome patients (84% hypertensive) underwent a bout of HIIT (45 min)

and CE (70±5 min) in a random order and then returned to supine recovery for another 45 min. Exercise trials were isocaloric and compared to a no-exercise trial (CONT). Before and after exercise we assessed blood pressure (BP), heart rate (HR), cardiac output (Q), systemic vascular resistance (SVR), intestinal temperature (T_{INT}), forearm skin blood flow (S_kBF) and percent dehydration.

RESULTS: During CONT blood pressure and the rest of variables remained unchanged. HIIT produced larger PEH than CE (systolic BP -14±4 versus -4±2 mmHg; $P=0.024$) and larger increases in post exercise resting HR (27±2 versus 4±2 beats·min⁻¹; $P<0.005$). Post-exercise T_{INT} and S_kBF increased only after HIIT ($P<0.05$). PEH after HIIT correlated with the reductions in SVR ($r=0.58$; $P<0.030$) the increases in Q ($r=-0.91$; $P<0.001$) systolic BP prior to exercise ($r=0.60$; $P<0.023$).

CONCLUSIONS: Our findings suggest that HIIT is a superior exercise mode than CE to transiently reduce hypertension in MSyn subjects. PEH seems to be enhanced by some factor positively related the elevations blood pressure during the previous exercise bout.

Effects of Warm up and Cool Down on Wingate Anaerobic Power Test Hemodynamics

Ryan Page, Lauren Chandler, Luisa Echeverry, Kaitlin Monteith, Richard Happel, John Petruzzo, Robert M. Otto, FACSM, John W. Wygand, FACSM. *Adelphi University, Garden City, NY.* (Sponsor: John W. Wygand, FACSM)
Email: rpage@adelphi.edu

(No relationships reported)

The impact of warm-up (WU) and cool down (CD) on systemic vascular resistance (SVR[dyn.s/cm]) relative to high intensity exercise is limited. SVR (mean arterial pressure – central venous pressure ÷ cardiac output [CO]) is an index of change in vascular resistance of individual vascular beds and provides insight into local hemodynamic (H) function. **PURPOSE:** The purpose was to examine the effects of a WU and CD on power output and the cardiovascular (CV)/H response to the Wingate Anaerobic Power Test (WAPT). **METHODS:** Following familiarization with impedance cardiography and the WAPT, 20 subjects (21.9 ± 2.7 yr, 170.7 ± 10 cm, body mass 70.5 ± 10.9 kg, 7 ♂) were randomly assigned in a crossover design to the following trials: WU & CD (C1), WU & no CD (C2), no WU, but CD (C3), and no WU & no CD (C4) with 48 hours between trials. Both WU and CD were 3 min cycling @ 50 rpm @ 50 watts. No WU or no CD required 3 minutes of seated rest. All measures were monitored continuously until 5 min post-test. Blood pressure was measured immediately post exercise. **RESULTS:** Statistical analysis by ANOVA with repeated measures ($p<.05$) of combined data of WU trials (C1 & C2) vs no WU trials (C3 & C4) reveals a significant difference ($p<.05$) pre-WAPT between HR 102 vs 84 b/min, SV 95 vs 83 mL/b, CO 9.8 vs 7.0 L/min, and SVR 681 vs 950 dyn.s/cm, respectively. Combined data of CD trials (C1 & C3) vs no CD (C2 & C4) post-WAPT reveals significant differences ($p<.05$) in HR 141 vs 130 b/min, CO 16.0 vs 14.4 L/min, and SVR 415 vs 469 dyn.s/cm. SV of 114 vs 111 mL/b was not significantly different. No differences were found between trials performing the same type of WU or CD. Peak power and average power of all trials were 1131 ± 308 W and 583 ± 120 W with NSD among trials. **CONCLUSION:** Our data indicate that WU had no impact on Wingate Anaerobic Power Test performance. The differences in SV and HR were anticipated because of the protocol used with active and passive WU and CDs. The marked reduction in SVR of 39% from WU prior to WAPT substantiates improved local peripheral hemodynamic function and confirms the opportunity for improved metabolic exchange for a highly demanding anaerobic activity. The benefit of CD following intense exercise is demonstrated with a prolonged attenuation of SVR, which may enhance recovery.

304 Board #125 May 31 11:00 AM - 12:30 PM

The Hypotensive Effects of Isometric Training are Associated with Decreasing Daytime Sleepiness in Young Women

Takashi Yamagata, Takayuki Sako. *Japan Women's University, Tokyo, Japan.*
Email: yamagatat@fc.jwu.ac.jp

(No relationships reported)

Isometric exercise training (IET) has been conducted to reduce resting blood pressure; however, the underlying mechanisms are not fully understood. Sleep and sleepiness have been shown to be associated with cardiac risk factors including hypertension. In addition, although some studies indicate that exercise can improve sleep and sleepiness, it remains unknown whether IET can influence sleep, sleepiness, and their relationship with hypotensive effects. **PURPOSE:** To investigate whether IET influences sleep, sleepiness, and to determine their relationship with reduced resting blood pressure (BP). **METHODS:** Twenty-two normotensive young women were assigned to either control (n=11) or training (n=11) group. The training group

performed unilateral isometric handgrip (IHG) sessions three times per week for 8 weeks (wks). The training protocol consisted of four 2-min bouts of IHG exercise at 25 % of maximal voluntary contraction, separated by 3-min rest periods. Sleep and sleepiness were assessed using the Pittsburgh Sleep Quality Index (PSQI) and the Epworth Sleepiness Scale (ESS). Resting blood pressure was measured pre and post 8 wks of training. PSQI and ESS were measured at pre (0 wk), middle (4 wk), and post (8 wk) training. BP was compared between pre and post training, using paired T-test in each group. PSQI and ESS were analyzed by two-way analysis of variance (time x group), using post hoc Tukey HSD test. A Pearson correlation was determined between resting BP change ratio and change ratio for PSQI and ESS from pre to post training period. **RESULTS:** Following 8 wks, IHG training significantly reduced systolic BP (-4.5±6.3 mmHg, $p<0.05$) and mean BP (-3.8±4.6 mmHg, $p<0.05$), but not diastolic BP (-3.4±5.3 mmHg, $p=0.058$); no BP changes were noted in the control group. The PSQI scores were not significantly different among groups. A significant interaction effect was observed in ESS, which indicated that ESS significantly decreased from pre to post training period in the training group (10.3±3.7 to 8.4±4.6, $p<0.05$). ESS change ratio was significantly associated with the resting mean BP change ratio ($r=-0.732$, $p=0.01$). **CONCLUSION:** This study indicates that isometric exercise training could reduce resting blood pressure and was associated with daytime sleepiness in young women.

Balance Confidence Predicts Fall Frequency but not Physical Activity in Individuals with Parkinson's Disease.

Amanda Penko. *Cleveland Clinic, Cleveland, OH.* (Sponsor: Ellen Glickman, FACSM)
Email: penkoal@gmail.com

(No relationships reported)

Parkinson's disease (PD) is a neurodegenerative movement disorder that affects approximately one million Americans. Physical activity has been shown to be beneficial in the management of PD, however, motor symptoms associated with the disease may create a barrier to participating in exercise. The activities balance confidence (ABC) scale is an index of an individual's confidence in their balance during activities of daily living and is predictive of fall risk but the association between ABC scores and physical activity behavior in individuals with PD has yet to be determined.

Purpose: To assess the relationship between balance confidence and fall frequency, disease severity and objectively-measured physical activity in individuals with PD. **Methods:** Ten participants diagnosed with PD (63.5 ± 11.2 years old, $n = 3$ females) completed the validated ABC scale and gave self-report of their fall frequency over the past 12 months. Disease severity was assessed via the Unified Parkinson's disease ratings scale (UPDRS) by trained personnel. Finally, participants were given a wrist-mounted, physical activity monitor (Movband 3) to measure physical activity behavior over a one-week period. Physical activity during all waking hours and was recorded as the number of steps taken per hour of activity monitor wear. **Results:** Pearson's correlation analyses revealed significant negative correlations ($r \geq -0.59$, $p \leq 0.05$) between the ABC scale score and both the number of falls reported over the previous 12 months and UPDRS scores. In other words, as balance confidence increased, the number of falls reported and disease severity decreased. However, ABC scores were not ($r = -0.06$, $p = 0.85$) associated with physical activity.

Conclusion: While individuals with Parkinson's disease who had poor balance confidence did have more frequent falls and greater disease severity, their physical activity behavior was not different than those with greater balance confidence. Therefore, poor balance confidence may not decrease physical activity behavior in individuals with Parkinson's disease.

Effectiveness Of Multi-component Exercise On Physiological Function Among Older Adults With Diabetes And Hypertension

Nuo Yi¹, Kaili Meng², Yong "Tai" Wang, FACSM³, Xiaoyu Guo², Xiangren Yi², Xue Gao². ¹East Stroudsburg University, East Stroudsburg, PA. ²Shandong University, Jinan, China. ³The University of Texas at Tyler, Tyler, TX. (Sponsor: Yong "Tai" Wang, FACSM)

Email: nyi@live.esu.edu

(No relationships reported)

The increasing prevalence of older adults with diabetes and hypertension has resulted in a major public health issue and seriously challenged healthcare professionals in China. **PURPOSE:** The purpose of this study is to design a multi-component exercise program (MEP) with a randomized controlled trial and examine the effectiveness of the MEP on fitness and physiological function among older adults with diabetes, hypertension or mixed at a community sitting in China. **METHODS:** Seventy older adults (34 men, 36 women; M age= 66±5.5 year old) randomly assigned for the MEP participated in 60 minutes of supervised exercise consisting of various activities related to flexibility, strength, balance, and endurance three times per week for 12 weeks. An experimental pretest-posttest design was employed measuring physical fitness: strength, endurance, flexibility, balance and VO₂ peak, and physiological function: a systolic blood pressure (SBP), diastolic blood pressure (DBP), total cholesterol (TC), triglyceride (TG), high density lipoprotein (HDL), low-density lipoprotein (LDL), and fasting glucose (FG). Paired *t*-tests were utilized to analyze for within-group comparisons between baseline and the results after three months. **RESULTS:** The results revealed that fitness variables were improved significantly in strength (bench press, seated row, arm curl, knee extension, leg press), endurance (VO₂ peak), flexibility (hamstring flexion, knee flexion, shoulder flexion,) and balance (8 foot up and go and chair stand) ($P < 0.05$) after training, meanwhile, the results showed greater decrease in DBP ($t = 3.34 P = 0.00$) SBP ($t = 3.49 P = 0.00$). Biomarkers further demonstrated that the MEP had a significant effect on physiological function: TC ($t = 3.89 P = 0.00$), LDL ($t = 3.20 P = 0.00$), FG ($t = 2.85 P = 0.01$), but no significant effect emerged on TG ($t = -1.01 P = 0.34$), HDL ($t = -0.73 P = 0.56$) in pretest-posttest. **CONCLUSIONS:** The findings from this intervention indicated that this MEP has significant effects on physical fitness, aerobic capacity, blood pressure and biomarkers among older adults with diabetes and hypertension. Such intervention should be expanded to a larger older population.

Muscle Weakness and Diabetes Jointly Exacerbate the Rate of Functional Disability among Older Mexican Americans

Ryan P. McGrath¹, Brenda M. Vincent², Brad P. Dieter³, Kate A. Duchowny⁴, Kyriakos S. Markides⁵, Soham Al Snihi⁵, Mark D. Peterson, FACSM¹. ¹University of Michigan Medical School, Ann Arbor, MI. ²VA Ann Arbor Health System, Ann Arbor, MI. ³Providence Medical Research Center, Spokane, WA. ⁴University of Michigan, Ann Arbor, MI. ⁵University of Texas Medical Branch, Galveston, TX.

Email: mcgratry@med.umich.edu

(No relationships reported)

PURPOSE: Preserving muscle strength and avoiding chronic diseases such as diabetes may reduce the rate of developing a functional disability at an older age, especially among at risk populations. The purpose of this study was to determine the independent and joint contributions of muscle weakness and diabetes on the incidence of activities of daily living (ADL) disability in an older Mexican American cohort. **METHODS:** A subsample of 2,378 Mexican American males and females aged 65 years and older at baseline were followed for 17 years. Muscle strength was assessed with a handheld dynamometer and was normalized to body weight (normalized grip strength [NGS]). Male and female participants were considered weak if their NGS was ≤ 0.46 and ≤ 0.30 , respectively. The presence of diabetes, ADL disability, and the age of each diagnosis was self-reported by participants. Males and females were classified into four separate groups depending on their muscle strength and diabetes status. Sex-stratified Cox proportional hazard models were used to examine the independent and joint effects of muscle weakness and diabetes on incident ADL disability after adjusting for relevant covariates. **RESULTS:** Males and females that were weak and had diabetes at baseline had a 2.36 (95% confidence interval [CI]: 2.29-2.43; $p < 0.0001$) and 1.96 times higher rate (CI: 1.92-2.20; $p < 0.0001$) of ADL disability compared to males and females that were strong and did not have diabetes at baseline, respectively. Strong male and female participants that had diabetes at baseline had a 1.84 (CI: 1.76-1.93; $p < 0.0001$) and 1.36 times higher rate (CI: 1.33-1.40; $p < 0.0001$) of ADL disability than males and females that were strong and did not have diabetes, respectively. Weak males and females that did not have diabetes at baseline had a 1.36 (CI: 1.32-1.39; $p < 0.0001$) and 1.11 times higher rate (CI: 1.09-1.12; $p < 0.0001$) of ADL disability than males and females that

were strong and did not have diabetes, respectively. **CONCLUSION:** Preserving muscle strength and avoiding diabetes reduces the rate of incident ADL disability in older Mexican Americans. Older Mexican Americans should engage in behaviors and activities that are conducive to healthy aging in order to reduce future declines in physical functioning.

(No relationships reported)

PURPOSE: Examine the prevalence of self-reported leisure time physical activity (LTPA) participation by intensity using a representative sample of U.S. adults (18-64 years old) with a seizure disorder or epilepsy. **METHODS:** Data from the 2013 (n=587) and 2015 (n=647) National Health Interview Survey cycles were utilized to examine the prevalence of meeting the 2008 Physical Activity Recommendations for U.S. adults. **RESULTS:** In the 2013 NHIS, the prevalence of adults with a seizure disorder or epilepsy reporting insufficient (< 150 min), sufficient (150-300 min [meets rec]), or high volumes of LTPA (> 300 min [meets rec]) were 92.5%, 6.6%, and 0.9%, respectively. In the 2015 NHIS, the prevalence of adults with a seizure disorder or epilepsy reporting insufficient (< 150 min), sufficient (150-300 min [meets rec]), or high volumes of LTPA (> 300 min [meets rec]) were 92.4%, 7.1%, and 0.5%, respectively. An estimated 19.6% and 15.8% of those with a seizure disorder or epilepsy reported meeting the MSA recommendation during 2013 and 2015, respectively. **CONCLUSIONS:** Adults reporting a seizure disorder or epilepsy may not be impeded by their condition to participate in LTPA or MSA.

Patterns of Sedentary Behavior in The First Month After Acute Coronary Syndrome

Andrea T. Duran¹, Carol E. Garber, FACSM¹, Joseph E. Schwartz², Keith M. Diaz². ¹Teachers College, Columbia University, New York, NY. ²Columbia University Medical Center, New York, NY. (Sponsor: Carol Ewing Garber, FACSM)

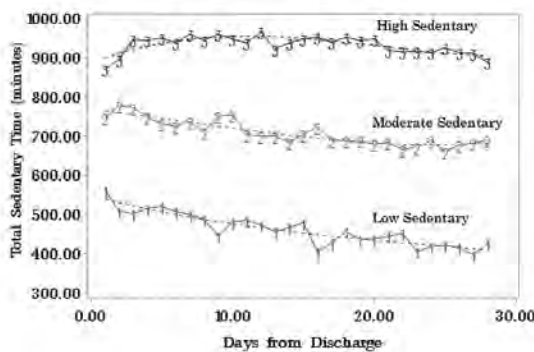

Email: atd2127@tc.columbia.edu

(No relationships reported)

Sedentary behavior (SED) is a key contributor to cardiovascular disease in the general population. Few data exist on objectively measured SED patterns in acute coronary syndrome (ACS) patients in the first month after an ACS event; a critical period when lifestyle behaviors are reformed.

PURPOSE: To characterize SED patterns and their correlates in ACS patients over the first month post-discharge. **METHODS:** Participants (n=177) with confirmed ACS (myocardial infarction or unstable angina) from a university hospital in Upper Manhattan were examined. SED was objectively measured for 28-days post-discharge via Actical wrist accelerometry. Group-based modeling at the day-level was used to characterize SED patterns (trajectories) over the 28-days. Logistic regression was used to determine correlates of SED trajectories. Correlates included sociodemographic, hospitalization, physical and psychosocial factors. Models were adjusted for age, sex, race and ethnicity. **RESULTS:** Participants spent a mean (SD) of 12.3±3.2 hrs/day in SED the first month post-discharge. Three distinct SED trajectory groups were identified (Fig 1). The high SED group (38%) spent a mean (SD) of 15.6±1.3 hrs/day in SED with no change in day-level SED. The moderate SED group (41%) spent a mean (SD) of 11.8±1.2 hrs/day in SED with little change in day-level SED. The low SED group (21%) spent a mean (SD) of 7.6±1.5 hrs/day in SED, with a gradual decline in SED from immediately post-discharge (~9 hrs/day) to 28-days post-discharge (~7 hrs/day). In multivariable models, left ventricular ejection fraction < 40 , length of hospital stay and coronary artery bypass grafting were identified as significant correlates of the high SED group ($p < 0.05$ for all). **CONCLUSION:** ACS survivors accrued alarmingly high volumes of SED during the first month post-discharge, with little to no change in day-level SED over time. ACS survivors with greater disease severity were more likely to accrue higher volumes of SED.

Figure 1. Trajectories of sedentary time post-discharge in ACS patients.

Association of Sedentary Behavior with Cardiovascular Disease Risk Factors in Osteoarthritis Patients.
 GARVITA THAREJA, JUNBAE MUN, MINSOO KANG, FACSM. MIDDLE TENNESSEE STATE UNIVERSITY, MURFREESBORO, TN. (Sponsor: MINSOO KANG, FACSM)
 Email: GT2G@MTMAIL.MTSU.EDU
 (No relationships reported)

INTRODUCTION: Cardiovascular disease has been a significant public health concern among US adults. Recently, great attention has been given to the sedentary behavior (SB) in relation to health indicators such as CD risk factors (CDRF); however, the relationship between sedentary behavior (SB) and CDRF has been little known in patients with osteoarthritis.

PURPOSE: The aim of this study was to investigate the association between leisure-related SB (LSB) time and CDRF among US adults suffering with osteoarthritis.

METHODS: Data from the 2004-2005 Osteoarthritis Initiative Database were analyzed for this study. 4,796 adults (male = 1,992; average age 61.16 ± 9.2 years), currently experiencing or at risk of developing severe osteoarthritis, were included in this analysis. LSB time was defined as leisure time sitting hours per day for past 7 days, categorized into less than 1 hour, 1 hour to less than 2 hours, 2-4 hours and more than 4 hours. Patients with CDRF were operationally defined as presence of any one of hyperlipidemia (blood cholesterol ≥240 mg/dl), obesity (BMI ≥30 kg/m²), hypertension (BP ≥140/90 mmHg), and diabetes (blood glucose ≥200 mg/dl). Logistic regression analysis was used to examine the association between LSB and CDRF with controlling covariates (i.e., age, sex, race, education, and marital status). Statistical analyses were conducted using SPSS (v.22). Significance level was set at 0.05.

RESULTS: 57.1% of participants had CDRF. 79.4% of the participants had leisure time sitting for more than 2 hours per day. The adjusted odds ratios (OR) were statistically significant between LSB time and CDRF for less than 1 hour (reference) vs 2-4 sitting hours (OR = 1.47, 95% CI: 1.01 - 2.13) and less than 1 sitting hour vs more than 4 sitting hours (OR = 1.80, 95% CI: 1.24 - 2.62). Sitting time for 1 hour but less than 2 hours was not significant.

CONCLUSIONS: The results of this study indicate that LSB time associates significantly with CDRF among osteoarthritis patients. This finding suggests that avoiding LSB may be beneficial for lowering the risk of CD in US adults with osteoarthritis.

Prevalence of Physical Activity and Sitting in People with Inflammatory Bowel Disease and Healthy Individuals
 Katrina Taylor¹, Chantal A. Vella, FACSM². ¹Eastern Washington University, Cheney, WA. ²University of Idaho, Moscow, ID.
 Email: ktaylor31@ewu.edu
 (No relationships reported)

Inflammatory bowel disease (IBD) is an autoimmune disease characterized by the cyclical nature of flare and remission periods, with little known about the prevalence of physical activity and sedentary behaviors, such as sitting, in this population.

PURPOSE: To determine the prevalence of physical activity and sitting in people with IBD (in remission and disease flare) compared to healthy individuals. **METHODS:** Participants with IBD (n=242; 96 in disease flare [IBD-flare] and 146 in disease remission [IBD-remission]), and healthy controls (n=265) participated in an online survey. Self-reported walking, moderate-to-vigorous physical activity (MVPA) and

sitting were collected using the International Physical Activity Questionnaire. Data were analyzed using analysis of covariance with age, sex, education status, disease history, and smoking habits as covariates. **RESULTS:** People with IBD reported lower levels of walking (329±422 minutes/week, p=0.03) and MVPA (279±412 minutes/week, p<0.01) than healthy individuals (477±536 min and 481±529 minutes/week, respectively). There were no differences between IBD-flare and IBD-remission participants for levels of walking (301±466 vs. 335±368 minutes/week, respectively) or MVPA (227±315 vs. 330±481 minutes/week, respectively, p>0.05 for both). Physical activity guidelines were met in 45% of people with IBD and 73% of healthy individuals (p<0.05). Although sitting was not different between groups, there was a trend for higher sitting in those with IBD (424±196 minutes/day) compared to healthy individuals (395±182 minutes/day, p=0.07). **CONCLUSION:** Our findings indicate that people with IBD report lower levels of physical activity than healthy individuals but report no differences in weekday sitting. Furthermore, there were no negative consequences of a disease flare on physical activity. Our findings suggest that people with IBD are able to participate in varying levels physical activity despite there being no guidelines for this population. Future research should aim to develop physical activity recommendations to benefit people with IBD and reduce the amount of time spent sitting.

Seasonal Variation in Physical Activity of Children with Disabilities during Physical Education
 Cindy H.P. Sit¹, Jane J. Yu¹, Wendy Y.J. Huang², Thomas L. McKenzie, FACSM³, Bik C. Chow², Ester Cerin⁴. ¹The Chinese University of Hong Kong, Hong Kong, China. ²Hong Kong Baptist University, Hong Kong, China. ³San Diego State University, San Diego, CA. ⁴Australian Catholic University, Melbourne, Australia.
 Email: sithp@cuhk.edu.hk
 (No relationships reported)

Children with disabilities are less physically active than their typically developing peers. Physical education (PE) is a primary school setting where children can accumulate health promoting physical activity (PA). Little is known about seasonal variation in PA of children with disabilities during PE in Hong Kong.

PURPOSE: To examine seasonal difference in PA of children with different types of disabilities in the context of PE in special schools.

METHODS: Nine schools designed for children with four disability types (i.e., sensory impairments, physical disabilities (PD), mild-to-moderate intellectual disabilities, and severe intellectual disabilities) in Hong Kong were recruited. Trained observers used SOFIT (System for Observing Fitness Instruction Time) to code PA levels (i.e., lying down, sitting, standing, walking, vigorous) of students during PE. Moderate-to-Vigorous PA (MVPA) was calculated by summing walking and vigorous codes. Observations were conducted on three normal school days in winter (December, mean 18°C) and summer (June, mean 28°C) respectively. Total session energy expenditure (TEE) and energy expenditure rate (EER) were calculated using standard formulae. Linear mixed models were used to determine difference in percentage of time spent in MVPA, TEE, and EER across disability types in two seasons, after adjusting for gender, grade level, duration of PE, and school-level clustering. Interactions among season, disability type, and gender were also examined.

RESULTS: A total of 179 PE classes (94 winter, 85 summer; mean length 38.5 minutes) were observed. Only main effects of *season* were significant for %MVPA (F=4.2, p=.042) and TEE (F=5.1, p=.026), with lower scores in winter (b=-5.1, 95% confidence interval [CI], -10.0 to -0.2 for %MVPA; b=-17.4, 95% CI, -32.7 to -2.1 for TEE) compared to summer.

CONCLUSIONS: PA of children with disabilities during PE varies with seasonality. Adaptation of the setting and program content is needed to promote year-round PA for children with disabilities.

Physical Activity Levels among Children with Physical Disabilities in Home and School Settings
 Ru Li¹, Cindy H. P. Sit¹, Jane J. Yu¹, Raymond K. W. Sum¹, Kenneth C. Cheng¹, Stephen H. S. Wong, FACSM¹, Thomas L. McKenzie, FACSM². ¹The Chinese University of Hong Kong, Hong Kong, Hong Kong. ²San Diego State University, San Diego, CA.
 Email: lirutracy@link.cuhk.edu.hk
 (No relationships reported)

Children with physical disabilities (PD) are less physically active than their peers with other types of disabilities. Homes and schools are important settings where children can accrue physical activity (PA).

PURPOSE: To examine PA levels of children with PD in school and home settings.

METHODS: Participants were 147 children with PD recruited from three special schools in Hong Kong. *Behaviors of Eating and Activity for Children's Health: Evaluation System* was used to document PA levels in four settings at school (before-class, recess, lunch break, after-class) and one home setting (before dinner) on four normal school days. Linear mixed models with repeated measures (four measurement days) were used to examine the percentage of time spent in moderate-to-vigorous PA (%MVPA) in the five settings across gender, grade level (4-6, 7-9, and 10-12), and mobility level (walking with or without assistance) after adjusting for school as random effects.

RESULTS: In the before-class setting, significant main effects were found for gender ($F = 5.5, p < .05$) and grade level ($F = 3.8, p < .05$), with boys having less %MVPA than girls ($b = -6.2, 95\% \text{ CI} = [-11.4, -0.9]$), and children in Grades 4-6 and 7-9 having higher %MVPA than those in Grade 10-12 ($b = 7.8, 95\% \text{ CI} = [1.7, 13.9]$; $b = 7.0, 95\% \text{ CI} = [0.4, 13.6]$). A significant main effect of mobility was found separately for recess, lunch break, and after-class settings ($F = 48.6, p < .001$; $F = 34.1, p < .001$; $F = 12.1, p < .01$), with children walking without assistance accruing higher %MVPA ($b = 16.9, 95\% \text{ CI} = [12.1, 21.7]$; $b = 12.7, 95\% \text{ CI} = [8.4, 17.0]$; $b = 47.8, 95\% \text{ CI} = [22.9, 72.7]$). Additionally, a significant *grade by mobility* interaction effect was found in %MVPA during the after-class period ($F = 3.8, p < .05$), whereby the %MVPA of Grade 10-12 children who walked without assistance was greater than counterparts needing assistance. No significant effects of gender, grade level, and mobility on %MVPA were found at home setting.

CONCLUSIONS: Children have low levels of PA across settings, with the most inactive pattern at home and slightly more PA accrual at recess and after-class setting. Future research should pay more attention to their low activity level at home. A multifaceted intervention that considers the contextual and personal factors may help promote PA in children with PD. Supported by GRF 14409514.

The Epidemiology of Injuries in Turkish Athletes at Rio Paralympics

Aynur Demirel¹, Tuğba Kocahan², Baran Yosmaoglu³, Emre Baskan⁴, Mahmut Calik⁵, Çiğdem Öksüz¹, Nevin Ergun, FACSM¹. ¹Hacettepe University, Ankara, Turkey. ²Ministry of Youth and Sports, Ankara, Turkey. ³Baskent University, Ankara, Turkey. ⁴Pamukkale University, Denizli, Turkey. ⁵Uskudar University, Istanbul, Turkey.
Email: aynurdemirel629@hotmail.com
(No relationships reported)

Purpose: The aim of the study was to determine the characteristics and incidence of medical condition or injuries of Turkish team participated to Rio Paralympics. **Methods:** Medical condition information was collected from assessment forms which recorded by 6 team physiotherapists and one doctor. The assessments included demographic characteristics of athletes (sport type, age, gender), injury related questions (time-type and region of injury). **Results:** 81 Turkish athlete (35 female/45 male) participated to Rio Paralympics. A total of 148 application (75 female/73 male application) in 50 athletes were documented during the Paralympic Games. Of the application 63% was musculoskeletal system disorders, 12.8% was urinary system disorders, 2.7% was ophtalmologic problems, 6.8% was gastro intestinal, 2% was ear and 2.1% was allergic problems. Of these injuries 37.1% occurred before the games started. 31 athletes injured more than one time. The most commonly injured region was shoulder and neck (17.6%, 16.9% respectively). Of the athlete 41.9% received medical treatment alone, 43.2% received physiotherapy alone, 14.9% received both physiotherapy and medical treatment. **Conclusion:** This is the first comprehensive epidemiologic report of Turkish paralympic team. It is important to determine the injury prevalence and develop prevention strategies in paralympic sports.

Identifying Predictors of Health in Adults with an Intellectual Disability

Jooyeon Jin¹, Joonkoo Yun², Stamatis Agiovlasis, FACSM³. ¹University of Seoul, Seoul, Korea, Republic of. ²Oregon State University, Corvallis, OR. ³Mississippi State University, Mississippi State, MS. (Sponsor: Agiovlasis, Stamatis, FACSM)

(No relationships reported)

Body mass index (BMI) and age are well-known predictors of an individual's health (Peter et al., 2015). However, many studies recently suggest that there should be additional factors between BMI and health to strengthen the relationship (McAuley et al., 2014). This complicated process might apply to adults with an intellectual disability (ID), but there have been limited understanding on what other factors influence health over BMI and age in this underserved population. **PURPOSE:** To identify health predictors in adults with ID, controlling for BMI and age. **METHODS:**

We employed secondary data analysis using 6814 adults with ID (age 18-96 years; 56% men) from the 2013-14 Adult Consumer Survey by National Core Indicators to reveal the potential predictors. Tested variables included personal, health, residence, employment, daytime activities, home, friends/family/staff support, service satisfaction, community participation, and choice-related variables. Considering a type of the outcome variable (i.e., four health categories from poor to excellent), a forward model selection method based on ordinal multiple regression was employed to find out the best model explaining health in adults with ID. **RESULTS:** Mobility, moderate physical activity (PA) engagement, tobacco use, staff support, having a job, eating out in the past month, and having a vacation in the past year were all significant predictors of health in this population ($p < .001$), and the model containing those predictors explained 17% of variance on health of adults with ID, after accounting for BMI and age. Those who moved without mobility aids, engaged in PA, didn't smoke, had a job, received less staff support, ate out, and had vacation were significantly healthier than their counterparts. For instance, the ordered logit for adults with ID who didn't routinely engage in moderate PA being a less healthy category is .49 more than their counterparts. The goodness-of-fit test (Pearson $\chi^2 = 20241.5, p > .05$) revealed that this model fits well. **CONCLUSION:** Apart from BMI and age, we have to consider various personal, social and environmental predictors to better explain health of adults with ID. Interestingly, the health predictors found in this study are closely aligned with the International Classification of Functioning, Disability and Health (WHO, 2001).

Associations Among Residential Settings, Physical Activity And Health Outcomes In Adults With Intellectual Disabilities

Joonkoo Yun¹, Jooyeon Jin², Stamatis Agiovlasis, FACSM³. ¹Oregon State University, Corvallis, OR. ²University of Seoul, Seoul, Korea, Republic of. ³Mississippi State University, Mississippi State, MS. (Sponsor: Stamatis Agiovlasis, FACSM)
(No relationships reported)

The impact of different forms of residential settings on the quality of life of people with intellectual disabilities (ID) has received considerable attention. Previous studies indicate positive effects of deinstitutionalization on social network, adaptive behavior, and many other behavioral outcomes. However, the relationship between residential settings and health-related outcomes in people with ID has not been adequately studied, despite the significance of health and health risk factors such as physical activity (PA). **PURPOSE:** To examine the relationships between perceived general health, PA engagement, body mass index (BMI), and types of residential settings in adults with ID. **METHODS:** We analyzed data from the 2013-2014 Adult Consumer Survey by National Core Indicators. Data were available from 13991 cases of adults with ID (8069 men; 5922 women) aged 18 to 96 years ($M = 43.35 \pm 14.97$ yrs). Perceived health, height, weight, BMI, mobility, engagement in moderate PA, age, and residential settings were extracted for secondary data analyses. Binary logistic regression, multinomial logistic regression, and univariate one-way ANOVA were used to answer the research questions. **RESULTS:** There were significant differences in BMI between adults with ID residing in different settings ($p < .001$). Individuals with ID who live in institutions have the lowest BMI, whereas those who live independently have the highest BMI. However, there are different results on perceived health and PA engagement. There are significant differences on PA engagement among adults with ID in different residential setting. People with ID living in institutions have approximately 38% of lower engagement in PA than those living with parents ($OR = .61; CI: .50 - .75$), after controlling for mobility. Individuals with ID who live in institutions are 4 times more likely to rate their health as poor than those who live with parents ($OR = 4.19; CI: 2.54 - 3.88$), after controlling for age. There are no significant differences on perceived health between those living independently and those living with parents. **CONCLUSION:** Although individuals with ID who reside in institutions have the lowest BMI, they are less likely to engage in moderate PA and to have lower perceived health than individuals who live independently or with their parents.

BMI Across Age-groups In Adults With Down Syndrome And Adults With Intellectual Disability

Stamatis Agiovlasis, FACSM¹, Jooyeon Jin², Joonkoo Yun³. ¹Mississippi State University, Mississippi State, MS. ²University of Seoul, Seoul, Korea, Republic of. ³Oregon State University, Corvallis, OR.
Email: sagiovlasis@colled.msstate.edu
(No relationships reported)

The age-associated response of body mass index (BMI) in adults with Down syndrome (DS) has not been thoroughly examined. DS is associated with faster biological aging; thus, BMI may change differently in response to age between adults with DS and adults with other intellectual disabilities (ID). Differences between these groups in the age-associated response of BMI may reflect differences in how weight and height change as these people age. **PURPOSE:** To examine if BMI, weight, and height differ

across age-groups between adults with DS and adults with ID. **METHODS:** We conducted secondary analyses of data from the 2013-2014 National Core Indicators Adult Consumer Survey, containing 14,237 cases (age 18-96 y; 8208 men). Of these cases, 1,343 persons had DS (age 41 ± 13 y) and 11,289 persons (age 44 ± 15 y) had ID, but not DS. We extracted weight, height, BMI, sex, and age, and generated age groups: 18-29; 30-39; 40-49; 50-59; 60-69; 70-79; 80-89; 90-99 y. There were no DS cases in the 70-79, 80-89, and 90-99 y age groups. We used 2-way ANOVA and follow-up tests to examine differences in BMI, height, and weight across age groups. Height and weight were analyzed by sex. **RESULTS:** The BMI age-associated response was different between adults with DS and adults with ID ($p < 0.001$ for interaction). Adults with DS had higher BMI than adults with ID ($p < 0.001$) at ages 18-29 (30 vs. 27 kg·m⁻²), 30-39 (32 vs. 28 kg·m⁻²), and 40-49 y (31 vs. 29 kg·m⁻²). BMI did not differ between groups at 50-59, 60-69, and 70-79 y. For adults with DS, BMI was not significantly different between the 3rd, 4th and 5th decades of life and decreased after age 49 y (from 31 kg·m⁻² at age 40-49 y to 26 kg·m⁻² at age 60-69 y; $p < 0.001$). For adults with ID, BMI increased between the 3rd and 4th decade of life and decreased after age 59 y (from 28 kg·m⁻² at age 50-59 to 25 kg·m⁻² at age 80-89 y; $p = 0.015$). For both sexes, weight declined at earlier ages in those with DS than those with ID ($p \leq 0.019$ for interactions). Height was lower across all ages for both women and men with DS than their sex counterparts with ID ($p < 0.001$); however, the age-associated response in height did not differ between those with DS and those with ID. **CONCLUSION:** The age-associated changes in BMI and weight are different between adults with DS and adults with ID, but no DS. The results indicate earlier onset of weight loss in adults with DS.

Effect Of A Physical Education Program On Motor Performance In Down's Syndrome Children By Mabcb2
 Isaac G. Pérez, Jorge A. Rassa, Esteban L. Loaiza, Yaira M. Barranco, Edda Lorenzo, Emilio Villa. *National University of Chimborazo, Riobamba, Ecuador.*
 Email: iperez@unach.edu.ec
 (No relationships reported)

PURPOSE: Previous studies suggest that children with Down's Syndrome, a genetically based neurodevelopmental disorder, demonstrate motor problems and cognitive deficits. Thus, the aim of study was to analyze the effect of an intervention based on a special physical education program on motor performance in children with Down's Syndrome. **METHODS:** A total of 16 participants (7 girls and 9 boys) from Riobamba (Ecuador) with Down's Syndrome aged between 7 and 10 years (7.00±1.47) participated in this study. A special physical education program was implemented during 6 month (3 time-week; 2 hour per session). Motor performance was assessed at baseline and post-intervention through the Movement Assessment Battery Children-2 (MABC2-checklist) evaluating the following variables: manual dexterity, accuracy and catches, and balance. A pair sample t-test was conducted to compare the differences between baseline and post-intervention on motor performance variables means. **RESULTS:** Time to perform the test of Manual Dexterity significantly decreased post-intervention (baseline=155.82±94.06-seconds vs post-intervention=149.29±90.19-seconds; $p < 0.001$). The number of successful attempts in the test of accuracy and catches significantly improve post-intervention (baseline=3.17±1.98 vs post-intervention=8.29±4.62; $p < 0.001$). In the balance test, children significantly increased the time in balance state post-intervention (baseline=11.23±10.18 seconds vs post-intervention=15.58 ±7.50 seconds; $p < 0.001$). **CONCLUSION:** 6-month physical education program could improve motor performance (manual dexterity, accuracy and catches, and balance) in children with Down's Syndrome.

 (No relationships reported)

The participation in sport activities is important in individuals with spinal cord injury, namely to counteract their sedentary lifestyle and the loss of hand and upper limb function. However, there is a lack of knowledge regarding the effects of sport in moderate-to-vigorous physical activity levels and shoulder muscle strength. **PURPOSE:** To compare shoulder muscle strength and physical activity levels in sportive and non-sportive individuals with spinal cord injury. **METHODS:** This is a cross-sectional study encompassing 14 sportive (41.07 ± 9.99 yrs.) and 4 non-sportive men (32.0 ± 6.97 yrs.) with spinal cord injury (between T5 and L1). Sports

participation was determined by questionnaire. Physical activity was measured with triaxial accelerometry worn on wrist during 7 consecutive days. Data was expressed as average of minutes per day in moderate-to-vigorous physical activity. Shoulder strength was assessed in an isokinetic dynamometer at 60°/second. Shoulder movements considered were flexion/extension (range 0 - 50°), external/internal rotation (range 0 - 45°), and abduction/adduction (range 25 - 75°). Non-parametric statistics (Mann-Whitney) was used to compare differences between sportive and non-sportive men. **RESULTS:** Total moderate-to-vigorous physical activity of sportive compared to non-sportive individuals was significantly higher (126.50 ± 53.26 and 61.82 ± 28.8 min/day, respectively; U=52.00; $p=0.008$), and the same pattern was observed when considering only weekday moderate-to-vigorous physical activity (131.81 ± 58.66 and 62.47 ± 30.29 min/day, respectively; U=52.00; $p=0.008$). Regarding to isokinetic strength, the peak torque of the right and left shoulder extension was significantly higher (U=49.00; $p=0.025$) in sportive (72.45 ± 11.8 Nm and 73.95 ± 12.0 Nm, respectively) compared to non-sportive men (59.97 ± 7.46 Nm and 62.90 ± 12.42 Nm, respectively). **CONCLUSIONS:** In men with spinal cord injury, the participation in sport activities can lead to an increment in moderate-to-vigorous physical activity and shoulder extension strength that might be important for independency in daily activities. Supported by the CNPQ under grant number 206862/2014-8; CAPES under grant number 6099/13-0; CIAFEL under grant number UID/DTP/00617/2013.

Workplace Wellness Exercises For Individuals Who Use Wheelchairs
 Stephanie L. Silveira¹, Dustin Dew², Kelly Bonner². ¹University of Houston, Houston, TX. ²UAB/Lakeshore Research Collaborative, Birmingham, AL.
 Email: slsilvei@central.uh.edu
 (No relationships reported)

Individuals who use wheelchairs for mobility face various barriers to physical activity during the workday. Worksite wellness exercises can be conducted during the workday to increase energy expenditure during sedentary time sitting at a desk. Research in the general population shows promising results for worksite wellness exercises conducted at specific intervals and intensities throughout the day increasing daily energy expenditure, which over an extended time period could have a significant impact on weight management. **Purpose:** To pilot test worksite wellness exercises for individuals who use wheelchairs for mobility. **Method:** Five worksite wellness exercises were chosen from surveys including: air punches, arm circles, chair push-ups, forward/lateral raises, and desk push-ups. The five exercises were pilot tested using the COSMED K4 portable metabolic cart in individuals who use wheelchairs of working age. Participants first rested for five minutes to measure resting energy expenditure. Exercises were performed for intervals of 60 seconds of work and 60 seconds of rest in a randomized order. Feasibility of worksite wellness exercise movement performance and trends in changes in energy expenditure were analyzed across the entire sample. **Results:** Participants included 14 individuals who use wheelchairs for mobility between 18 and 60. On average resting energy expenditure equaled 1.33(SD=0.35) Mets and 1.64(SD=0.39) Kcal/min and exercise energy expenditure equaled 2.38(SD=0.81) Mets and 3.08(SD=1.06) Kcal/min. Greatest increases shown in chair push-ups and desk push-ups. Three participants were unable to perform chair push-ups due to injuries or strength. Therefore, performing worksite wellness exercises for 13 minutes per workday could result in an extra 100 Kcal/week expended per week. **Conclusions:** Worksite wellness exercises are a feasible option for energy expenditure in the workplace for individuals in wheelchairs. Specific worksite wellness exercises are needed to suit their needs that could also be performed outside the workplace as an exercise regimen. This was a small, feasibility pilot study and larger studies need to be done to show reliability and validity of these exercises across diverse populations of individuals who use wheelchairs for mobility.

Using a Self Regulation Physical Activity Intervention to Improve Physical Function
 Kimberlee A. Gretebeck, Wan-Chin Kuo, Carly E. Babino, Katherine M. Mead, Cheyenne Mangan, Emily Hammer, Randall J. Gretebeck, FACSM. *University of Wisconsin-Madison, Madison, WI.*
 Email: kgretebeck@wisc.edu
 (No relationships reported)

Limitations in physical function are risk factors for subsequent disability, institutionalization, and loss of independence for older adults and are directly caused or exacerbated by physical inactivity. Getting older adults to adopt and maintain physical activity (PA) is a challenge. Use of self-regulation (SR) strategies may be useful, especially for overweight and obese older adults. **PURPOSE:** To examine the effect of a 10-week group exercise and lifestyle behavior change program on physical function in older community-dwelling adults. **METHODS:** Fifty two older adults (mean age=72.34 yrs ± 8.0, mean BMI=31.68 ± 6.53) completed the 10-week Physical Activity

for Life for Seniors (PALS) group exercise and lifestyle behavior change program. Ten exercises were performed in a circuit in 1 minute intervals over 40 minutes 3 days/week. The 30 minute lifestyle behavior change class included self-regulation problem solving strategies for staying active. Physical function was measured via the Physical Function Questionnaire (PFQ, 0=unable to do to 100=no difficulty in performing 6 functional tasks), Timed Up and Go (TUG, time in seconds to rise from a chair, walk 3 meters, return to chair and sit), 6 Minute Walk (6MW, feet) and Usual Gait Speed (UGS, meters/second to walk 6 m distance); PA via the CHAMPS questionnaire and SR via the Self-Regulation for Exercise Scale (1=never to 5=very often). Paired t-tests were used to examine mean differences in the variables pre and post intervention.

RESULTS: In this population of overweight and obese older adults, significant improvements ($p<.000$) were noted in physical function (PFQ: 72.85 ± 21.12 vs 79.31 ± 18.47 ; TUG: 10.89 sec ± 2.67 vs 9.45 sec ± 2.52 ; UGS: 1.19 m/s $\pm .22$ vs 1.26 m/s $\pm .22$; 6MW: 1112.06 ft ± 410.21 vs 1337.92 ft ± 361.04); PA (total PA: 2143.31 ± 2153.24 vs 4092.99 ± 2635.78 ; moderate PA: 742.84 ± 1476.00 vs 2366.96 ± 2112.94); and SR ($1.55 \pm .61$ vs $2.67 \pm .62$). **CONCLUSIONS:** These results suggest that a 10-week group exercise intervention that includes a SR behavior change component was effective in improving physical function and moderate intensity and total PA in this population of older adults. Participants indicated they liked the socialization the group format provided.

322 Board #143 May 31 9:30 AM - 11:00 AM
Determinants of Leisure-Time Physical Activity Participation in University Students with Physical Disabilities: A Multi-University Study

Jennifer Dysterheft¹, Gioella Chaparro², Ian Rice². ¹Hamline University, St. Paul, MN. ²University of Illinois, Urbana-Champaign, Urbana, IL. (Sponsor: Robert Pettitt, FACSM)
 (No relationships reported)

Purpose: The purpose of this study was to investigate the participation rates and determinants of physical activity (PA) participation of university students with physical disabilities (SWD).

Methods: 40 SWD from 16 U.S. universities completed a mixed-methods online survey regarding their LTPA practices and influences to participation on their campus. Surveys used to measure variables of interest included LTPAQ-SCI and PASIPD (PA), WHO QOL-BREF (quality of life), ESES (exercise self-efficacy), SCOPE (social inclusion opportunities), B-PEDS (barriers to exercise), and Self-Regulation (SR) questions (intent to exercise). Short answer questions were included to allow participants to expand on answers and provide more detailed information. Kruskal-Wallis tests were used to examine differences in survey outcomes between gender and sport participation. Spearman's rho and multiple regressions analysis were used to examine the extent of the relationships between variables of interest and participant PA levels. Short answer responses were analyzed using thematic analysis strategies.

Results: A strong correlation was found between PA and all variables of interest ($p<.05$). Variables found to have the strongest correlation with PA included ESES ($r_s=0.63$, $p<.01$), SR ($r_s=0.74$, $p<.01$), WHO QOL-BREF ($r_s=0.45$, $p<.01$), and perceived opportunities for LTPA on campus ($r_s=0.51$, $p<.01$). Multiple regressions analysis revealed gender, SR, and perceived social inclusion on campus were significant predictors of PA level ($F=19.43$, $p<.01$, adj. $R^2=0.61$). Short answer responses reflected quantitative findings and provided rich elaboration on these constructs.

Conclusions: Results indicated SWD may be more active than previously thought, yet still critically low relative to physical activity guidelines for aerobic health. Although all external and internal variables examined had significant relationships to PA level, internal variables had the strongest correlations to PA level. It was also found that significant internal variables had strong correlations to external variables, indicating a complex relationship between SWD external-environmental influences, internal-personal influences, and PA levels.

 (No relationships reported)

INTRODUCTION: There is a constant connection between mind and body in Dance/Movement Therapy (DMT). This connection promotes the integration of the emotional, cognitive and physical dimensions of a person.

PURPOSE: to evaluate the cognitive improvement after a DMT program in adults with intellectual disability (ID)

METHODS: 28 adults with moderate-severe ID (16 men, 40-66 yr), recruited from a workshop center, participated in the study after obtaining their legal/tutors and their own informed consent. They were divided into Intervention group (IG; n=15) and Control group (CG; n=13). The IG followed a DMT program of 26 sessions of 1 hour 2 day/w plus their regular work, meanwhile the CG continued with their regular activities. The sessions were structured as proposed by Chace (1953). Human Figure drawing test, Illinois test for Psycholinguistic aptitudes and Pictures memory test were applied before and after the DMT program. Descriptive for all variables were obtained. T-test was applied to study within-group differences. ANCOVA was applied to study between-groups differences.

RESULTS: Significant deterioration for evolutionary indicator (EI), word verbal expression fluency (WVEF) and body part expression fluency (BPEF) were found in the CG. The IG significantly improves EI and picture's memory (PM). When controlling for age, gender, ID level and baseline values, a significant difference ($p<.05$) between IG and CG in the EI was found.

CONCLUSIONS: Even only EI showed between-groups significant differences, there is a cognitive improvement in persons with ID after following a DMT program. More research is needed with a larger sample and/or a longer DMT program.

Validity Of The Maps Score As A Functional Measure In Adults With Incomplete Spinal Cord Injury

Heontae Kim, Don W. Morgan, FACSM, Sandra L. Stevens, John M. Coons, Minsoo Kang, FACSM. Middle Tennessee State University, Murfreesboro, TN. (Sponsor: Minsoo Kang, FACSM)
 Email: hk3m@mtmail.mtsu.edu
 (No relationships reported)

Current functional measures for adults with spinal cord injury are limited in their ability to assess person-environment interaction as defined by the World Health Organization. The Movement and Activity in Physical Space (MAPS) score, an objective functional measure encompassing physical activity and person-environment interaction, has been successfully applied to measure various patient populations. However, the validity of the MAPS score in adults with incomplete spinal cord injury (iSCI) has not been evaluated.

PURPOSE: To validate the MAPS score in adults with iSCI using evidence of convergent and known-group difference validity.

METHODS: 9 adults (48.1 ± 16.4 yrs) with iSCI wore a GT3X accelerometer and carried a LandAirSea model Tracking Key GPS receiver when outside of their residence to measure free-living physical activity and record location (latitude/longitude), respectively. In this analysis, participants who wore an accelerometer and GPS for at least 3 days were included ($n=9$; 5.8 ± 1.5 days). MAPS scores were calculated by combining data from the accelerometer and GPS to assess patient function. Functional ambulation measures included walking speed, 6-minute walk distance (6MWD), and Walking Index for Spinal Cord Injury (WISCI - II).

Convergent validity evidence was obtained by quantifying the relationship between MAPS score and the three functional ambulation measures using Pearson product moment correlations, and known-group difference validity evidence was assessed using an independent t-test to compare participants who displayed greater (n=7; ASIA Impairment Scale: B) and lesser (n=2; ASIA Impairment Scale: C and D) severity of functional impairment (GSFI vs LSF1).

RESULTS: The MAPS score was moderately correlated with walking index (r=.74), walking speed (r=.64) and 6MWD (r=.56). A significant difference in MAPS score was also observed between GSFI (5.27±7.12) and LSF1 (35.65±23.55) groups, t(6.47)=-2.97, p=.023.

CONCLUSIONS: Our findings provide support for using the MAPS score as a functional outcome measure in adults with incomplete spinal cord injury.

Sex Differences in Resting Heart Rate and Heart Rate Recovery in Low Back Pain Subjects

Alexyz Milian, Marlon L. Wong, Jessica Bolanos, Teresa Glynn, Neva Kirk-Sanchez, Magno F. Formiga, Lawrence P. Cahalin. *University of Miami, Miami, FL.* (Sponsor: Dr. Thomas Best, FACSM)
 (No relationships reported)

Resting heart rate (RHR) and heart rate recovery (HRR) are two easy to obtain measures providing a quick estimate of cardiovascular health (CVH). There is conflicting and inconclusive evidence regarding the association of CVH and low back pain (LBP), although it is known that deconditioning is prevalent in this population. **PURPOSE:** To examine sex differences in RHR and HRR, and the relationship between RHR and HRR in subjects with LBP. **METHODS:** RHR and 1 minute HRR were assessed via Polar heart rate monitoring in 31 patients (18 females) seeking therapy for chronic non-specific LBP. HRR was assessed after repeatedly lifting a 25-pound weight from a 1 foot stool to chest height in an erect posture (Rep Lift) for 1 minute at a self-selected cadence, using self-selected biomechanics, as well as after 15 minutes of steady state treadmill walking (TMW) at a self-selected brisk pace. **RESULTS:** Males and females were similar in age (55.4±14 years), BMI (28.6 ± 5.4 kg/m²), resting blood pressure (127/78 mmHg), pain intensity (2.8 ± 2.5), and self-reported disability (Oswestry score of 35.8 ± 17.1). Additionally, there were no significant differences between males and females in RHR (72.3±1.9 bpm), peak heart rate of Rep Lift and TMW (107.0 ± 20.0 and 96.0 ± 13.7 bpm respectively), and HRR after Rep Lift and TMW (18.0 ± 10.3 and 15.8 ± 6.4 beats, respectively). However, RHR predicted HRR after Rep Lift and TMW in males (p<.01, R²=.55 and .46 respectively) but not in females (R²=.05, p=.11 and R²=.03, p=.48 respectively). **CONCLUSIONS:** RHR is often measured and interpreted as a sign of CVH, or rather deconditioning, in patients with LBP. However, it appears that RHR predicts cardiac recovery after activity in males but not females with LBP. Thus, assumptions of exercise tolerance and CVH in females with LBP should not be based on RHR, but rather on HRR. The reason for the above findings in women compared to men is unclear and warrants further investigation. This study also highlights the potential value of HRR after functional tasks such as repetitive lifting and steady state walking.

The Success Rate of iCan Bike Participants with Multiple Diagnoses

Kelly D. Barns, 63701¹, Andrea L. Patrick², Nicolas J. Wilkins¹, Jessie N. Stapleton³, Thomas J. Pujol, FACSM¹, Jason D. Waggoner¹. ¹*Southeast Missouri State University, Cape Girardeau, MO.* ²*iCan Shine, Fairfax, VA.* ³*Missouri Baptist University, St. Louis, MO.* (Sponsor: Thomas J. Pujol, FACSM)
 Email: kdbarns1s@semo.edu
 (No relationships reported)

Individuals with cognitive and physical disabilities must endure daily challenges that may decrease overall well-being. The iCan Bike program, a subdivision of the iCan Shine organization, utilizes an individualized intervention for teaching mentally and physically challenged individuals how to ride a two-wheeled bicycle as a means to increasing well-being and self-confidence. **PURPOSE:** The purpose of this study was to investigate the relationship between the learning success rate in the iCan Bike program and the quantity of participant diagnoses. **METHODS:** Participants were 2,652 boys (n = 1,705) and girls (n = 947) with varying diagnoses. The amount of diagnoses per rider were as followed: one (n = 1896), two (n = 639), three (n = 100), and four (n = 17). Each participant attended a five day camp, 75 minutes per day. During the week, participants progressed through a series of interventions, adapted equipment, and typical two-wheeled bicycles. Successfully riding a two-wheeled bicycle was defined as riding unassisted for 75 feet. Descriptive statistics were conducted using IBM SPSS (v23). **RESULTS:** Overall, participants achieved a 67.7% rate of success (males = 70.2%; females = 60.4%) for learning to independently ride a two-wheeled bike. The participants' success rate per amount of diagnoses were as follows: one diagnosis = 67.9% (males = 70.3%; females = 63.5%), two diagnoses =

67.0% (males = 68.2%; females = 64.7%), three diagnoses = 71.0% (males = 81.4%; females = 56.1%), and four diagnoses = 58.9% (males = 63.6%; females = 50.0%). **CONCLUSIONS:** These findings support past research, indicating this teaching style is an effective way for individuals with any amount of diagnoses to learn how to ride a two-wheeled bicycle. Interestingly, participants with three diagnoses saw a higher success rate (primarily due to a higher male success rate) when compared to the participants that had one, two, or four diagnoses. More research needs to be conducted to better define the relationship between success rate, quantity/combination of diagnoses, and gender differences among iCan Bike participants.

Exercise Results in Physiological Improvements in Individuals Living with Disabilities

Lisa Sprod, Brandi Crowe, Jennifer Bell, Dan Johnson. *University of North Carolina Wilmington, Wilmington, NC.*
 Email: sprodl@uncw.edu
 (No relationships reported)

PURPOSE: Individuals who have a disability are at risk for becoming overweight or obese which has been associated with secondary health conditions including heart disease, stroke, diabetes, and cancer. In fact, individuals who have a disability triple their risk for these aforementioned conditions compared to adults without disabilities. This population is likely to become overweight due to physical inactivity or inadequate physical activity. Reasons cited for exercise barriers include residual physical impairments related to their health condition, or a lack of access to programs that provide appropriate accommodations. This study aimed to determine the effects of an exercise intervention on physical functioning, which may ultimately be linked to chronic disease development, in individuals with disabilities. **METHODS:** Participants were recruited from a group home through convenience sampling. At baseline and following the 6-week exercise intervention, participants underwent a battery of physiological and functional tests including body weight, resting heart rate (RHR), resting blood pressure, cardiorespiratory fitness, fall risk, muscular strength and endurance. The exercise intervention consisted of three 60 minute supervised sessions per week with two sessions held at the Miracle Field and one held at the group home. **RESULTS:** Participants included 12 group home residents, (n = 8 males) with an average age of 46 years old with varying degrees of cognitive impairments. Significant improvements were found in balance and muscular endurance. Fall risk scores improved from 37.42 ± 4.47 to 55.98 ± 6.82 (p = 0.02) and the number of repetitions performed on the lateral raise improved from 5.60 ± 0.93 to 8.10 ± 0.60 (p = 0.01) from pre- to post-intervention. Additional improvements, although not statistically significant, were found in RHR, systolic blood pressure, cardiorespiratory fitness, muscular strength, and number of push-ups performed. **CONCLUSIONS:** A supervised exercise intervention seems to be a safe and effective way to improve functional outcomes in individuals with disabilities living in a group home.

Sedentary Patterns In People with Intellectual Disability

Guillermo R. Oviedo¹, Casimiro Javierre², Jesús Fortuño-Godes¹, María Carbó-Carreté¹, Myriam Guerra-Balic¹. ¹*FPCEE Blanquerna - University Ramon Llull, Barcelona, Spain.* ²*University of Barcelona, Barcelona, Spain.*
 Email: groviedo77@gmail.com
 (No relationships reported)

Introduction: Adults and older adults with intellectual disabilities (ID) have low physical activity levels (PALs) and very little is known about the patterns of sedentary time (ST) among them. **Purpose:** To analyze ST patterns of adults and older adults with ID. **Methods:** A group of 42 adults and 42 older adults with mild to severe ID were recruited. A health screening questionnaire was completed by each participant and/or legal guardian. Height and weight were obtained to calculate BMI. ST patterns were assessed with ActiGraph accelerometers for 7 consecutive days. **Results:** Non-significant differences in ST throughout the week were observed. Non-significant differences between gender groups were found for ST. A significant difference was found for age groups where adults present a higher number of breaks per sedentary hour than older adults (P = 0.048) and the obese participants spent more time on SB than those participants with a normal BMI (P = 0.042). We also found that the number of bouts in SB per day increased in those participants with higher BMI values (P = 0.005). **Conclusions:** These groups of subjects with ID showed a high prevalence of ST (79.4% of monitoring time). Interestingly, when comparing age and/or gender groups, no differences were observed for ST. Our findings provide novel and valuable information to be considered in future interventions aiming to increase PAL and reduce ST. Well-designed interventions and preventive health strategies in this specific population are recommended.

and body composition in people with DS. **METHODS:** The design of the study was an experimental type. Twenty two children participated with DS. Thirteen in the experimental group (EG) and nine in the control group (CG), that did not present any history of heart diseases and which didn't practice any type of physical activity or sport. The isometric strength (manual hydraulic dynamometer model SH5001), the height (stadiometer SECA 213), weight (Tanite Scale Bc533) were measured and BMI was calculated. Also the triceps and the medial calf skinfolds (Slimguide Caliper) were measured. Later a physical activity program was implemented with a frequency of five times per week with sessions of 55 minutes of duration for a period of 16 weeks. **RESULTS:** In the EG the age was 12.3 + 2.06 years, while in the CG was 11.4 + 1.94 years. The height was 134.6 + 6.4 cm and 132.7 + 4.8 cm for the GE and GC respectively. The BMI in the EG was 22.2 + 2.5 kg/m² and 20.7 + 2.5 kg/m² at the beginning and at the end of the intervention, respectively ($p=0.0001$). Meanwhile in the CG the BMI was 23.29 + 4.9 kg/m² and 21.9 + 4.6 kg/m² during the pretest and posttest respectively ($p=0.001$). In regards to the calf skinfold in the EG was 14.9 + 5.5 mm at the beginning and 14.55 + 3.2 mm at the end ($p=0.008$), while in the CG no significant difference were found ($p = 0.39$). No significant differences for the triceps skinfold were found. Isometric strength in EG at baseline was 2.4 ± 4 kg and 9.2 ± 2 kg at the end ($p=0.0001$), while in the CG no significant difference were observed ($p = 0.1$). **CONCLUSION:** A physical conditioning program can improve the body composition and the isometric strength in people with DS. People with DS need to engage in physical activity because of their tendency to be overweight and obese, this would significantly improve their quality of life.

Ballroom Dance Improves Heart Rate Variability and Depression in Persons with Multiple Sclerosis
 Katelyn Anne Dato-on¹, Jimin Suh¹, Stephanie Raab¹, Kenneth Banting¹, Sheri L. Bunyan², Alexander V. Ng, FACSM¹.
¹Marquette University, Milwaukee, WI. ²Concordia University, Mequon, WI.
 Email: katelyn.ann.dato-on@marquette.edu
 (No relationships reported)

Multiple Sclerosis is a neurodegenerative disease of the central nervous system. Symptoms include fatigue, depression, gait disturbances, and cognitive changes, all which affect quality of life (QOL). Heart Rate Variability (HRV), an indication of cardiac autonomic balance, can be altered in persons with Multiple Sclerosis (PwMS) and has been associated with depression and other health risks in other populations. In turn, depression as well as HRV, can be improved with aerobic exercise. The relationships between depression, QOL, and other self-reported measures to HRV in PwMS are largely unknown. We previously showed that ballroom dance (BD) may improve physical fitness, cognition, fatigue, depression and QOL in PwMS. **PURPOSE:** The purpose of this study was to investigate the relationship of depression with HRV in PwMS and test whether BD can improve HRV concurrent with depression. **METHODS:** Thirteen PwMS participated in an 8-week BD program (MSD). Twelve PwMS served as a control group (C). BD classes were 1 hour/day, 2x/week and taught by a professional BD instructor. Each MSD subject was paired with a non-MS partner. All subjects were ambulatory, independent to modified independent. Patient Determined Disease Steps (PDDS) did not differ between groups (MSD=2.0(1.9), C=1.4(1.8)). Pre- and post- measures included QOL (PROMIS Global Well Being), Fatigue Impact Scale (FIS), Beck Depression Inventory (BDI), Heart Rate Variability (HRV), and 6-minute walk test (6MWT). Nonparametric and parametric statistics were used with $p \leq 0.05$. Data are mean (SD) or md (Q1,Q3) for self-report measures. **RESULTS:** In both MSD and C groups prior to BD, QOL correlated with FIS ($r_s = -0.63$) and BDI ($r_s = -0.70$). FIS correlated with BDI ($r_s = 0.72$). HRV correlated with QOL ($r_s = 0.47$) and BDI ($r_s = -0.56$) but not with FIS. ($r_s = -0.32$). No variables correlated with 6MWT. For the MSD group, HRV (pre = 31 (19) post = 38 (19) ms, $p = 0.03$) and 6MWT (pre = 432 (114) post = 462 (126) m, $p = 0.03$) increased. Of the self-report outcomes, BDI improved (pre= 9 (5,15) post = 4 (0,10), $p = 0.04$). There were no changes in any measured outcome for the C group. **CONCLUSION:** BD can lead to significant improvements in HRV and depression. Further, HRV but not 6MWT might mediate improvements in QOL through depression in pwMS. This study was supported by the Greater Milwaukee Foundation.

The Effect of Step Count Increase on Role Limitations for People Living with HIV/AIDS
 Olivia Estill¹, Camerra C. Miller¹, Gregory A. Hand, FACSM², Jason R. Jagers¹. ¹University of Louisville, Louisville, KY. ²West Virginia University, Morgantown, WV. (Sponsor: Dr. Ann Swank, FACSM)
 (No relationships reported)

Individuals living with HIV/AIDS experience many daily struggles beyond the complications associated with physical illness. These could include psychological stress, mood disorders, and depression, all of which can greatly impact an individual's

daily life. This secondary data analysis was conducted to examine a potential relationship between increase in physical activity and health-related quality of life for people living with HIV/AIDS (PLWHA).

Methods: Participants were recruited as part of a home-based PA intervention aimed to reduce risk factors of cardiovascular disease for PLWHA taking ART. A secondary data analysis was conducted by separating participants into groups according to increases in step count. Clinical and psychological assessments were conducted at baseline and 18 week follow-up. Self-reported mental health was measured using the SF-36 and its specific subscales were used. This analysis focuses on the subscale role limitations due to emotional wellbeing (RE). PA levels were measured via accelerometer. Accelerometer data was considered compliant if the participant had a total on-body time of at least 10 hours a day for 4 days. PA was determined by using the average step count per day. The comparison group consisted of those who increased daily steps by 10% or more.

Results: 34 females and 28 males with valid armband data were used for final data analysis. No significant differences were observed between groups at baseline. Those who increased their PA from baseline to follow-up had an average increase of 1502 steps/day and showed a significant increase in their self-reported RE score from 18.18 ± 6.84 at baseline to 40.91 ± 7.89 at 18 weeks on the SF-36 form ($p = 0.03$), whereas those with no changes in and/or who decreased daily PA by an average of 1195 steps/day showed no change.

In conclusion, people living with HIV/AIDs who increased their step count by 10% after 18 weeks showed a significant increase in RE. A relationship between physical activity and emotional well-being could provide a foundation for further study aimed to increase health-related quality of life for people with chronic disease, especially considering the impact it can have on activities or daily living. This project was supported by funding through the NIH/NINR R21 Grant 1R21NRO11281 and Theraband@

Exploring The Impact Of A Pilot Physical Activity Intervention On Youths With Type 1 Diabetes.

Fiona Mitchell, Alison Kirk, Kenneth Robertson, Louise Wilkie, John J. Reilly. *University of Strathclyde, Glasgow, United Kingdom.* (Sponsor: Dave Rowe, FACSM)
Email: fiona.c.mitchell@strath.ac.uk
(No relationships reported)

Purpose: Type 1 Diabetes (T1D) is rising globally. Youths with T1D have poorer health and lower levels of physical activity (PA) than those without diabetes. The ActivPals study aimed to support youths with T1D to increase PA levels. The intervention incorporated a PA consultation, key behaviour change techniques and a wearable PA self-monitoring device. The aim of this study was to qualitatively explore the impact of the ActivPals pilot PA intervention on youths with T1D.

Methods: Semi-structured interviews with participants and one of their parents (N=16) were carried out between May and July 2016. Participants were recruited after delivery of the ActivPals 4- week intervention. Interviews were recorded, transcribed verbatim and analysed thematically using a six-stage iterative process. Codes were applied to data extracts in an inductive manner as recurring ideas, events or beliefs were identified.

Results: Factors contributing to intervention effectiveness are presented as three main themes. Each main theme had two sub-themes. The themes were: 1) Intervention impact (sub themes: new ways to exercise and sustained exercise); 2) Intervention components (sub themes: behaviour change techniques and one to one consultation); and 3) Intervention technology (sub theme: barriers/issues and recommendations for future interventions). The ActivPals intervention had a positive impact on young people with Type 1 diabetes. Most notably, the PA consultation and behaviour change techniques were important for increasing PA levels. The intervention technology was seen as both a facilitator and a barrier to PA. Participants provided important feedback on the intervention. For example, role modelling and self-monitoring were seen as critical to the intervention and the wearable activity monitors were problematic and should be redesigned or an alternative used, for future work with this population.

Conclusion: This research will contribute to the development of evidence based, user informed and pragmatic interventions leading to healthier lifestyles in youths with T1D.

This study was funded by Yorkhill Children's Charity.

Increases In Physical Activity Improves HDL Cholesterol In People Living With HIV/AIDS Taking Antiretroviral Therapy

Camerra C. Miller¹, Olivia Estill¹, Gregory A. Hand, FACSM², Jason R. Jagers¹. ¹University of Louisville, Louisville, KY. ²West Virginia University, Morgantown, WV. (Sponsor: Dr. Ann Swank, FACSM)

(No relationships reported)

People living with HIV/AIDS (PLWHA) and taking antiretroviral therapy (ART) medications are at increased risk for cardiovascular disease (CVD) and metabolic disorders once they begin therapy. The presence of metabolic disorders, such as increased blood lipids, make it difficult to manage CVD. Physical activity (PA) has been shown to reduce modifiable risk factors of CVD. The purpose of this analysis was to compare the blood lipid profiles of PLWHA while being treated with ART who increased their daily step count compared to those who did not.

Methods/design: Participants were recruited as part of a home-based PA intervention aimed to reduce risk factors of cardiovascular disease for PLWHA taking ART. A secondary data analysis was conducted by separating participants into groups according to changes in step count. The comparison group consisted of those who increased daily steps by 10% or more, with the remaining participants serving as the reference group. Assessments conducted at baseline and 18 week follow-up included waist circumference and fasting blood lipids including total cholesterol and triglycerides, HDL-C, LDL-c, and glucose. Height, weight, and PA levels via accelerometer were also collected. Accelerometer data was considered compliant if the participant had a total on-body time of at least 10 hours a day for 4 days. PA was determined by using the average step count per day. Groups were determined by changes in step count from baseline to follow-up with an increase in PA by 10% or more as group 1.

Results: A total of 34 females and 28 males with valid armband data were used for final data analysis. No significant differences were observed between groups at baseline. Those who increased their PA at 18-weeks had an average increase of 1502 steps/day and showed a significant increase in HDL cholesterol from 44.10 ± 2.79 pre to 49.01 ± 3.51 post ($p = 0.03$), whereas those with no changes and/or decreased daily PA by an average of 1195 steps/day showed no change.

Conclusion: These data show that a small increase in daily step count of 10% or more increased HDL levels compared to those who did not. In conclusion, something as simple as increasing step count can improve blood lipid profile for PLWHA while being treated with ART.

10-Week Guanidinoacetic Acid Supplementation Affects Inflammatory Markers in Healthy Men and Women

Sergej M. Ostojic, Patrik Drid, Tatjana Trivic, Valdemar Stajcer. *University of Novi Sad, Novi Sad, Serbia.*
Email: sergej.ostojic@chess.edu.rs

(No relationships reported)

Cellular bioenergetics largely depends on guanidinoacetic acid (GAA, also known as glycoylamine or betacyamine), a natural metabolic precursor of creatine, and an investigational dietary supplement. Previous animal studies have shown that supplemental GAA could induce inflammatory responses yet no human studies so far evaluated possible pro-inflammatory effects of this compound. **PURPOSE:** To examine the effects of 10-week supplementation with 3 grams per day of GAA on serum and urinary inflammatory markers in apparently healthy men and women. **METHODS:** Twenty healthy volunteers (10 men and 10 women; age 22.0 ± 2.3 years, weight 75.5 ± 22.9 kg, height 173.3 ± 10.5 cm) participated in this open-label, repeated-measure interventional study. All participants were assigned to receive GAA for 10 weeks, and were evaluated at baseline, and following 10-weeks of ingestion. The primary endpoint was the change in serum levels of high-sensitivity C-reactive protein (hsCRP) assessed at baseline and at 10 weeks follow-up. Secondary outcomes included change from baseline to end of treatment in values for serum ferritin, white blood cell (WBC) count and differential, and urinary inflammation markers. **RESULTS:** Serum hsCRP levels increased non-significantly during GAA intervention (1.6 ± 1.0 mg/L at baseline vs. 1.8 ± 2.1 mg/L at 10-week follow-up; $P = 0.72$). Supplementation with GAA yielded a statistically significant increase (7.5%

corresponding to 4.1 g/L; $P = 0.012$) of the mean serum ferritin levels. In addition, WBC count tended to increase at post administration ($6.7 \pm 0.9 \cdot 10^9$ vs. $7.3 \pm 1.5 \cdot 10^9$; $P = 0.09$), while urinary markers were not affected by GAA intervention ($P > 0.05$).

CONCLUSION: It appears that dietary GAA might have a pro-inflammatory effect during medium-term intake in healthy humans. GAA-driven elevation in serum ferritin should be considered as a possible adverse effect of the intervention. This project was partly supported by the Serbian Ministry of Education, Science and Technological Development (Grant no. 175037), the Provincial Secretariat for Higher Education and Scientific Research (Grant No. 114-451-710/2016-03) and the Faculty of Sport and Physical Education, University of Novi Sad (2016 Annual Award).

Sprint Cycling Performance Improvement Post-Creatine Supplementation is Associated with Increase in Lean Body Mass

Daniel L. Crisafulli, Harsh H. Buddhadev, Lorrie R. Brilla, FACSM, Gordon R. Chalmers, David N. Suprak, Jun G. San Juan. *Western Washington University, Bellingham, WA.* (Sponsor: L. R. Brilla, FACSM)
Email: crisafd@wwu.edu

Reported Relationships: D.L. Crisafulli: *Contracted Research - Including Principle Investigator; Albion Laboratories, Inc., Clearfield, UT.*

Creatine supplementation is recommended as an ergogenic aid to improve repeated cycling sprint performance. Creatine absorption is increased in the presence of electrolytes. Research examining the effect of a creatine-electrolyte (CE) supplement on repeated sprint cycling performance failed to show post-supplementation improvement. These results can be attributed to inadequate recovery periods between repeated sprints. A recovery of 2-minutes is adequate for phosphocreatine resynthesis and may allow for maximal performance during repeated cycling sprints.

PURPOSE: To investigate the effect of a 6-week CE supplementation intervention on peak power and average work performed during repeated cycling sprints interspersed with 2-minute recovery periods.

METHODS: Peak power and average work performed by 38 recreational cyclists (CE group: $n = 17$; 23.4 ± 4.0 years; placebo (P) group: $n = 18$; 23.4 ± 4.0 years) were measured on a Velotron ergometer as they completed five, 15-s cycling sprints, with two minutes of recovery between sprints, pre- and post-supplementation. Peak power was the highest overall power measured across the sprints. Average work was the mean of total work performed across the five sprints. Participants' body composition was estimated using three site skinfold measurements. Mixed-model ANOVAs were used for statistical analyses.

RESULTS: For almost all participants, the peak power was generated during the first sprint. A supplement-time interaction showed a 4% increase in peak power (27 W; $p < 0.001$) and a 5% increase in average work (376 J; $p < 0.001$) from pre- to post-supplementation for the CE group. For the P group, no differences were observed in these variables from pre- to post-testing. Similarly, the lean body mass increased by 2% (1.4 kg; $p = 0.001$) from pre- to post-testing for the CE group, whereas no differences were found for the P group (supplement-time interaction; $p = 0.001$). For the CE group, a modest association ($r = 0.626$; $p = 0.007$) was observed between the increases in peak power and lean body mass from pre- to post-supplementation.

CONCLUSION: A CE supplement improves repeated short duration cycling sprint performance when sprints are interspersed with adequate recovery periods. Additionally, the ergogenic effect of CE supplement is associated with an increase in lean body mass.

The Effect of Bacillus Coagulans and HMB On Muscle Integrity and Inflammation During Military Training

Yftach Gepner¹, Jay R. Hoffman, FACSM¹, Elad Shemesh², Jeffrey R. Stout, FACSM¹, David D. Church¹, Alyssa N. Varanoske¹, Hila Zelicha³, Ilan Shelef⁴, Yacov Chen², Hagai Frankel², Ishay Ostfeld². ¹*Institute of Exercise Physiology and Wellness, Sport and Exercise Science; University of Central Florida, Orlando, FL.* ²*Israel Defense Force, Medical Corps, Tel Hashomer, Israel.* ³*Department of Public Health, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel.* ⁴*Soroka Medical Center, Beer-sheva, Israel.* (Sponsor: Jay R. Hoffman, FACSM)

(No relationships reported)

BACKGROUND: β -Hydroxy- β -methylbutyrate (HMB) is a derivative of the branched chain amino acid leucine, and has been demonstrated to enhance recovery and attenuate muscle damage from high intensity exercise. Recent evidence has suggested that the use of a probiotic may enhance protein absorption, as such the combination of a probiotic with HMB ingestion may be more beneficial during

field operations. **PURPOSE:** To compare the co-administration of the probiotic *Bacillus coagulans* (BC30) with HMB calcium (CaHMB) to CaHMB alone on the inflammatory response and muscle integrity during 40-days of intense military training. **METHODS:** Soldiers from the same unit were randomly assigned to one of two groups: CaHMB with BC30 (CaHMBBC30; $n=9$) or CaHMB with placebo (CaHMBPL, $n=9$). A third group of participants from the same unit served as a control (CTL; $n=8$). During the 40-day study, all participants performed the same daily protocol. During the first 28 days soldiers were garrisoned on base and participated in the same training tasks. During the final 2-weeks soldiers navigated 25-30 km per night in difficult terrain carrying ~35 kg of equipment. All assessments (blood draws and diffusion tensor imaging to assess muscle integrity) were conducted prior to and approximately 12-hours following final supplement consumption. Analysis of covariance was used to analyze all blood and muscle measures. **RESULTS:** Significant attenuations were noted in IL-1 β , IL-2, IL-6, CX3CL1, and TNF- α for both CaHMBBC30 and CaHMBPL compared to CTL. The response of plasma IL-10 concentrations was significantly attenuated for CaHMBBC30 compared to CTL only. A significant decrease in apparent diffusion coefficients was also observed for CaHMBBC30 compared to CaHMBPL. **CONCLUSION:** Results of this study provide further evidence that HMB supplementation may attenuate the inflammatory response to intense training, and that the combination of the probiotic *Bacillus coagulans* with CaHMB may be more beneficial than CaHMB alone in maintaining muscle integrity during intense military training.

The Physiological And Psychological Effects Of A Pre Exercise Amino Acid Supplement

Krystle K. Sanders¹, Kayla Berrios², Matthew Frazee¹, Yi-Hung Liao³, Jeffrey R. Bernard¹. ¹*California State University-Stanislaus, Turlock, CA.* ²*Saint Mary's College of California, Moraga, CA.* ³*National Taipei University of Nursing and Health Sciences, Taipei, Taiwan.*

(No relationships reported)

Purpose: The research literature suggests that amino acid supplementation may be beneficial for many different modes of exercise. Thus, the purpose of this study is to determine if a pre-exercise amino acid supplement improves performance of a 5 mile time trial test and to assess whether there are changes in cognition.

Methods: Eight recreationally active male college students were recruited for this repeated measures design study. Participants consumed either a commercially available BCAA supplement (BCAA) or placebo (CON) 15 minutes prior to performing a Wingate test, followed by a brief break and then a 5 mile time trial test. Blood samples were collected before, during and after exercise to measure glucose, lactate and insulin levels. The Go/No Go and Stroop tests were used to assess cognition before and after exercise.

Results: There were no significant performance differences between BCAA and CON treatments for the Wingate test (Pre-Exercise: BCAA 10.7 ± 0.5 W/kg vs. CON 11.1 ± 1.2 W/kg, Post-Exercise: BCAA 11.4 ± 1.1 W/kg vs. CON 10.8 ± 1.5 W/kg; $p < 0.05$). Also there were no significant difference in performance for the time trial test (BCAA 26.7 ± 0.9 min vs. CON 25.9 ± 1.4 min; $p < 0.05$). Furthermore, blood glucose, lactate and plasma insulin levels were similar at each time point for both treatments. Lastly, participants performed equally well on the cognitive tests both before and after exercise (Go/No Pre-Exercise: BCAA 93.2 ± 1.6 % correct vs. CON 93.6 ± 2.0 % correct, Post-Exercise: BCAA 92.8 ± 1.9 % correct vs. CON 93.0 ± 0.9 % correct; Stroop Pre-Exercise: BCAA 83.9 ± 4.5 % correct vs. CON 85.3 ± 4.6 % correct, Post-Exercise: BCAA 86.3 ± 2.7 % correct vs. CON 85.5 ± 3.2 % correct; $p < 0.05$).

Conclusion: Under these testing conditions BCAA supplementation does not appear beneficial for 5 mile time trial performance, on physiological markers or cognition. However, the effects of BCAA supplements under different conditions is warranted. Grant Funding:

Effects Of Branched-chain Amino Acids On Resting Metabolic Rate, Body Composition, And Satiety In Females

Erica J. Roelofs¹, Abbie E. Smith-Ryan, FACSM². ¹*Meredith College, Raleigh, NC.* ²*University of North Carolina, Chapel Hill, NC.* (Sponsor: Abbie E. Smith-Ryan, FACSM)
Email: ejroelofs@meredith.edu

(No relationships reported)

Branched-chain amino acid (BCAA) supplementation may have beneficial effects by raising amino acids in the blood, however, nearly all of the research has examined effects only in males. **PURPOSE:** To examine the effects of BCAAs on resting metabolism, body composition, and satiety in females. **METHODS:** Twenty four females (mean \pm SD; Age: 22.6 ± 5.3 y; Height: 166.4 ± 7.3 cm; Weight: 66.0 ± 11.4 kg) completed baseline testing, which assessed body composition, resting

energy expenditure (REE) and respiratory exchange ratio (RER). REE and RER were measured through indirect calorimetry for 20 minutes while participants laid in a supine position. Body composition was measured by seven site skinfolds and bioelectric impedance analysis to determine body fat percentage (%BF). Questionnaires using Likert scales were completed to evaluate hunger and satiety. Participants were then randomly stratified to either the treatment group of BCAAs (28.5 g/day) or placebo group (4 g/day non-caloric sweetener), and consumed the supplement three times daily mixed with 12 oz. of water, between meals (between breakfast and mid-day meal, between mid-day meal and evening meal, and between evening meal and sleep) for 21 days. After supplementation, participants repeated baseline testing. Prior to the first testing visit and during the last week of consuming the supplement, participants completed two separate 3-day diet logs. **RESULTS:** There were no significant differences pre- to post-testing in weight, %BF, or RER for either group ($p < 0.05$). There was no main effect for treatment ($p = 0.65$) or time ($p = 0.84$) for REE. There was a significant interaction between groups for REE ($p = 0.025$) with REE increasing after BCAA supplementation ($\Delta 85.5 \pm 142.2$ kcal) and REE decreasing after placebo consumption ($\Delta -74.5 \pm 139.5$ kcal). Confidence intervals (95% CI) demonstrated a significant increase in REE after BCAA supplementation ($p < 0.05$). The BCAA group reported feeling more satiated in the evening, according to 95% CI ($p < 0.05$). **CONCLUSIONS:** Supplementing with BCAAs between meals resulted in a higher resting metabolic rate and greater feelings of satiety in women. Initial results suggests consuming BCAAs between meals may have positive implications for weight maintenance or loss in women, due to increases in resting energy expenditure and satiety.

Effects Of A Combined Protein And Antioxidant Supplement On Muscle Recovery In College - Aged Males

Samuel I. Bloom, Alexs A. Matias, Noelle Morrow, Natalya Martins, Yookee Roh, Daniel Ebenstein, Gabriel O'Brien, Daniela Escudero, Kevin Brito, Leah Glickman, Stephen J. Ives, Paul J. Arciero, FACSM. *Skidmore College, Saratoga Springs, NY.* (Sponsor: Paul J. Arciero, FACSM)
 Email: sbloom1@skidmore.edu
 (No relationships reported)

Eccentric contractions (ECC) result in muscle fiber damage from mechanical stress and a pro-inflammatory, pro-oxidant response, leading to a decline in muscle function and rise in muscle soreness. Individually, protein (PRO) and antioxidant (AO) supplements have been shown to improve recovery after eccentric exercise-induced muscle damage, though have yet to be combined. **PURPOSE:** Determine if a combined protein and antioxidant supplement (PRO+AO) improves muscle soreness (MS) and muscle function (MF) following fatiguing eccentric contractions over PRO alone or a control. **METHODS:** 60 sedentary college-aged males participated in a randomized, single-blind, parallel design study. Peak isometric torque (PIT), peak isokinetic torque (PIKT), thigh circumference (TC), and muscle soreness (MS) were measured prior to 100 maximal ECC of the knee extensor muscles, immediately after the ECC, as well as at 1, 2, 6, and 24h post ECC. Immediately post ECC, 6h post ECC, and 2h prior to the 24h assessment, participants consumed one of three isocaloric supplements (~30 g, 120 kcal ea.) of either a carbohydrate control (CHO; $n = 14$), PRO ($n = 16$), or PRO+AO (dehydrated berry-mixture; $n = 17$). **RESULTS:** All groups had similar baseline MS, TC, MF, macro and micronutrient intakes, and performed a similar amount of total work during the ECC (all, $p > 0.05$). There was a significant effect for time ($p < 0.05$) for PIT (~25% decrease), PIKT (~25% decrease), TC and MS (~1 and 35% increase, respectively). There was an effect of group over time for PIKT (PRO and PRO+AO > CHO, $p < 0.05$). At the 24h time point, there was a trend towards improved relative MF for PRO and PRO+AO compared to CHO (~11% difference for PIT, ~17% difference for PIKT). For MS there was a group x time interaction indicating PRO+AO having the lowest MS ($p < 0.05$). **CONCLUSION:** These results suggest PRO facilitates recovery of muscle function and soreness within 24h following fatiguing ECC, however addition of AO ameliorates MS more than PRO alone. As eccentric contractions are a component of many types of physical activity, under circumstances requiring a short turn around to a subsequent bout (e.g. occupational, military, or sport), combined PRO+AO supplementation may better mitigate ECC-induced muscle soreness with equal restoration of performance. Effect of Creatine Supplementation on Exercise Performance following a Short-term Low Carbohydrate Diet

Stephanie A. Born, Timothy R. Rotarius, Barry W. Scheuermann. *The University of Toledo, Toledo, OH.*
 (No relationships reported)

Consumption of a low carbohydrate (low-CHO) diet typically leads to fatigue and decreases in exercise performance. **Purpose:** This study determined if a creatine supplement (CS) prevents the decrease in exercise performance associated with consuming a low-CHO diet. Compared to the placebo (PL) group, we hypothesized that CS would prevent the decline in performance as demonstrated by an equal or improved time to task failure (completed intervals). **Methods:** Fourteen healthy subjects (5 males, 9 females; 25.7 ± 5.4 yrs, (\pm SD)) were randomly assigned to either CS or PL group. Each subject performed 2 high intensity interval exercise sessions at 90% peak work rate. The test sessions were separated by a 10 day low-CHO diet and either CS or PL supplementation. Peak work rate was determined using a 25 W/min ramp test to volitional fatigue. Baseline aerobic fitness (as peak oxygen uptake (VO_{2peak})) was determined as the highest 10 s average obtained during the ramp test. The high intensity interval session (i.e. performance trial) consisted of a 1:1 ratio of 30 s exercise at 90% peak work rate followed by 30 s of loadless cycling. Heart rate was collected at baseline and during each interval of the performance trial using a standard electrocardiogram. Subjects consumed a loading dose of creatine monohydrate (20 g/day) or placebo, while adhering to a low-CHO diet of <25% CHO total daily consumption. Subjects kept detailed food and exercise logs for the duration of the study. **Results:** Results of the preliminary exercise test indicated that the baseline fitness of the CS group (36.1 ± 5.3 ml/kg/min) was similar ($p > 0.05$) to the PL group (36.9 ± 5.8 ml/kg/min). There was a significant improvement in the CS group compared to the PL group for the high intensity interval exercise performance pre- and post-diet ($p < 0.001$). On average, the CS group improved $20.8 \pm 27.7\%$ for the total number of exercise bouts performed, whereas the PL group demonstrated a $35.9 \pm 14.5\%$ decrease in the total number of bouts performed post-diet. No change in body composition (% body fat) was observed between groups (CS; $1.4 \pm 1.5\%$ vs PL; $1.3 \pm 0.8\%$, $p > 0.05$). **Conclusion:** Results of the present study suggest that creatine loading may effectively attenuate the fatigue associated with a low-carbohydrate diet, and may, in fact, improve high-intensity interval exercise performance.

Beta-hydroxy-beta-methylbutyrate Supplementation On Low-frequency Fatigue Following Fatiguing Exercise

T. Brock Symons¹, Jordon W. Macht², Mark G. Abel³, Jody L. Clasey, FACSM³. ¹University of Louisville, Louisville, KY. ²Campbellsville University, Campbellsville, KY. ³University of Kentucky, Lexington, KY. (Sponsor: Jody L. Clasey, FACSM)
 (No relationships reported)

Participation in any strenuous form of physical activity will result in a decline in skeletal muscle performance during and following the activity, this decline is commonly called fatigue. Low-frequency fatigue (LFF), a form of fatigue, is characterized by a loss of force at low frequencies of stimulation, a slow recovery of force and is reported following eccentric contractions. β -Hydroxy- β -Methylbutyrate (HMB) is a nutritional supplement that claims to prevent and improve skeletal muscle recovery following muscle damage producing contractions. **PURPOSE:** To determine if three weeks of HMB supplementation could attenuate the effects of LFF caused by eccentric muscle contractions in young healthy adults. **METHODS:** 33 participants (18 males, 15 females; 23.2 ± 4.3 yr.) completed the study. Participants performed 4 sets of 25 eccentric (ECC) contractions of the tibialis anterior muscle. Outcome measures were recorded prior, following, throughout a 20-minute recovery period, and at 48 and 96 hours following an ECC fatiguing protocol. Outcome measures included: isometric peak torque, 10 and 50 Hz peak torque, and 10/50 Hz peak torque ratio. Participants served as their own control and lower limbs were randomly assigned as control (CTL) or supplement (SUP). Following the pre-supplement test-day, participants completed 3 weeks of 3g/day of HMB supplementation. Post-supplementation, the ECC fatiguing protocol was completed and outcome measures were obtained. **RESULTS:** The ECC fatiguing protocol reduced isometric peak torque in both the CTL and SUP limbs by 49.3% and 48.4%, respectively ($p < 0.01$). Ten Hz peak torque (pre-ECC fatigue: 4.8 ± 2.2 Nm vs. 96-hr post-ECC fatigue: 4.2 ± 2.4 Nm) and the 10/50 Hz peak torque ratio (pre-ECC fatigue: 0.51 ± 0.14 vs. 96-hr post-ECC fatigue: 0.44 ± 0.14) in the CTL limb were reduced at the 96-hour time point ($p < 0.01$), indicative of LFF. The SUP limb displayed no LFF (pre-ECC fatigue: 0.49 ± 0.11 vs. 48-hr post-ECC fatigue: 0.47 ± 0.11) at the 48-hour time point ($p > 0.05$), suggestive of a faster recovery. The CTL limb showed a 19.2% reduction in isometric peak torque at the 48-hour recovery time point ($p < 0.01$); whereas, the SUP limb displayed only a 6.4% reduction in isometric peak torque. **CONCLUSIONS:** Three weeks of HMB supplementation attenuated LFF and force loss after an ECC fatigue protocol.

The Acute Effect of a Four-Main Ingredient Pre-workout Supplement on Lower Body Muscular Endurance
 Jay E. Maiava, Joel D. Reece. *Brigham Young University Hawaii, Laie, HI.*
 Email: jayemaiava40@gmail.com
 (No relationships reported)

Most pre-workout supplements have various ingredients that when ingested together claim to have positive ergogenic effects. However, many supplements lack scientific evidence from independent research. **PURPOSE:** To determine the acute effect of a pre-workout supplement on lower body muscular endurance in college aged males. **METHODS:** This study was a double-blind, crossover design. Twenty-five participants (23.8 ± 1.3 years) visited the University Fitness Center on two separate occasions. Each visit was one week apart. During both visits participants completed the same warm up and maximal repetition seated leg press test at 75% of their body weight. Treatment order for each participant was randomized prior to testing. The control treatment consisted of a placebo supplement and the experimental treatment included a pre-workout supplement. Both treatments consisted of consuming eight fluid ounces, 15 minutes prior to testing, as recommended by the manufacturer. The treatment supplement included four main ingredients comprising beta alanine, creatine nitrate, N-Acetyl L-tyrosine, and caffeine. **RESULTS:** No significant difference in maximum repetitions was observed between the control treatment supplement (56.56 ± 24.74) and the experimental pre-workout supplement (60.56 ± 26.20), $F(1,24) = 1.481, p=0.235$. **CONCLUSION:** Despite popularity for pre-workout supplements while weight training, acute positive effects may not be realized. Recommendations for future research may evaluate timing of consumption and long term effects of particular pre-workout supplements.

 (No relationships reported)

PURPOSE: We sought to determine if a multi-ingredient pre-workout supplement (PWS) given prior to resistance exercise was effective in increasing post-workout reactive hyperemia compared to placebo (PBO). **METHODS:** Thirty, recreationally trained males participated in this double-blinded, PBO controlled study. All participants reported for two visits, separated by one week. At visit 1, participants consumed a multi-ingredient PWS with seventeen active ingredients (including citrulline, norvaline, caffeine, creatine and anti-oxidant blends) or PBO. 45-min after consumption of PWS/PBO, participants performed four sets of leg extension resistance exercise to failure at 30 or 80% of their 1-RM. At visit 2, subjects consumed the same supplement as in visit 1, but exercised at the alternate intensity. Heart rate (HR), blood pressures, and femoral artery blood flow were assessed at baseline (BL), 45-min following PWS/PBO consumption (PRE), and at 5-min following the last set of resistance exercise (POST). Repeated measures ANOVA was performed with time, supplement, and training intensity as the independent variables. Data are reported as mean \pm sem. **RESULTS:** Significant main effects of time ($P < 0.01$), but no interactions were observed for blood pressures, femoral artery diameter, and retrograde femoral artery blood flow. A significant time*supplement interaction ($P < 0.05$) was observed for HR and antegrade and mean femoral artery blood flow. Change in HR from BL and PRE to the POST time point was significantly greater in the PWS group compared to the PBO group ($+27.3 \pm 2.5$ vs. $+19.8 \pm 2.2$ bpm and $+34.6 \pm 2.1$ vs. $+25.0 \pm 2.3$ bpm for change from BL and PRE, respectively; $P < 0.03$). Similarly, change in mean femoral artery blood flow from BL and PRE to the POST time point was significantly greater in the PWS group compared to the PBO group ($+590 \pm 56$ vs. $+404 \pm 52$ mL/min and $+687 \pm 60$ vs. $+484 \pm 50$ mL/min for change from BL and PRE, respectively; $P < 0.02$). **CONCLUSIONS:** The PWS did increase the reactive hyperemia response observed following resistance exercise though no specific interactions with the intensity of the resistance exercise were observed.

Nighttime Consumption of Whey and Casein Protein: Effects on Morning Metabolism and Resistance Exercise Performance
 Takudzwa A. Madzima, Jared T. Melanson, Jonas R. Black, Simon C. Locke, Svetlana Nepocatyč. *Elon University, Elon, NC.* (Sponsor: Paul Miller, FACSM)
 Email: tmadzima@elon.edu
 (No relationships reported)

Whey protein (WP) and casein protein (CP) consumed at night before sleep has been shown to have positive satiating and metabolic effects the next morning. No data exist regarding the effect of nighttime consumption of WP and CP on the ability to perform resistance exercise (RE) the following morning. **PURPOSE:** To determine the effect of WP and CP at two different doses, when consumed before sleep on next morning appetite, resting metabolic rate (RMR), and RE volume compared to a non-caloric placebo (PLA). **METHODS:** Eleven physically active men and women (age, 24 ± 5 yrs; body fat, $18.8 \pm 4.9\%$) participated in this randomized, double blind, crossover study. One-repetition maximums (1-RM) were performed on six exercise machines to determine RE intensity. A single dose of 24g WP, 48g WP, 24g CP, 48g CP, or PLA was consumed 30 minutes prior to sleep and each trial was separated by 48-72 hours. Measurements of appetite (visual analogue scales (VAS) for satiety, hunger, and desire to eat), RMR (indirect calorimetry), and RE volume were performed the next morning (0600-0900 hours). Appetite was assessed immediately before and after RMR measurements, and immediately after RE. RMR measurements were collected for 30 minutes and the last 25 minutes were analyzed. Outcome variables were oxygen consumption (VO_2), RMR, and respiratory quotient (RQ). RE was performed for 2 sets of 10 repetitions and a 3rd set to failure at 60% of 1-RM. Statistical analyses were conducted using 5×3 (group by time) repeated-measures ANOVA for appetite variables and one way ANOVA for metabolic variables and RE volume. All significance was accepted at $p < 0.05$. **RESULTS:** There were no time effects and no group \times time interactions in satiety, hunger, and desire to eat. There were no significant differences in VO_2 , RMR (24g WP: 1795 ± 517 kcal/d; 48g WP: 1810 ± 371 kcal; 24g CP: 1691 ± 351 ; 48g CP: 1858 ± 416 ; PLA 1775 ± 346 kcal; $p > 0.05$) and RQ. In addition, there was no significant difference in RE volume (24g WP: 11812 ± 2972 kg; 48g WP: 11913 ± 2575 kg; 24g CP: 12646 ± 3759 kg; 48g CP: 11753 ± 2456 kg; PLA: 11680 ± 2654 kg; $p > 0.05$). **CONCLUSION:** Varying doses of WP and CP prior to sleep did not have an effect on morning appetite, RMR, and RE volume. Nighttime consumption of WP and CP can be consumed without impeding next morning metabolism and training volume, but does not improve exercise performance.

Reported Relationships: V. Martin: Contracted Research - Including Principle Investigator; Study funded by Lactalis.

PURPOSE: Electrostimulation (ES) training can trigger muscular and nervous adaptations, leading to an improvement of muscular strength and power. However, this training modality generates a high fatigue level, that translates into training and recovery issues. However, it has been shown that a supplementation with native whey (NWH) can decrease neuromuscular fatigue during a strength-training session. Therefore, the purpose of this study was to assess if NWH supplementation could promote recovery and training gains after an ES training program. **METHODS:** This pilot, randomized, double-blinded trial, involved 50 moderately active men (21.5 ± 3.2 y). They were allocated into 3 groups, supplemented 5d/week, either with 15 g of NWH, or whey (WH), or placebo (PLA). All the groups underwent a 12-week ES training program. Maximal concentric power (Pmax) was evaluated before, immediately after, as well as 30', 60', 24h et 48h after the 1st, 4th and last ES training session. In addition, the maximal voluntary contraction force (CMV), the evoked twitch amplitude (Pt), anatomical cross-sectional area (CSA) and the maximal voluntary activation level (VA) of the knee extensors were measured before (T0), and after 6 (T1) and 12 weeks of training (T2). **RESULTS:** Pmax recovery kinetics differed between groups ($P < 0.01$). Pmax started to recover at 30' in NWH, 24h in WH and 48h in PLA. Training gains also differed between groups. CMV increased between T0 and T2 in NWH ($+11.8\%$, $P < 0.001$) and WH ($+7.1\%$, $P < 0.05$), but not PLA. Nevertheless, the adaptations kinetics differed: CMV increased in NWH and WH between T0 and T1, but a additional gain was only observed between T1 and T2 in NWH. In addition, VA was depressed at T1 and T2 in PLA (-3.9% , $P < 0.05$), at T2

in WH (-3.5%, $P < 0.05$), and was unchanged in NWH. Finally, Pt and CSA improved with training, but did not differ between groups. **CONCLUSIONS:** These results suggest that NWH initiate the power recovery process earlier than WH or PLA after an ES-training session. This quicker recovery seems associated with strength gains along the entire training period, that are accounted for by hypertrophy and VA preservation. Conversely, the VA decreases in WH and PLA could be indicative of overtraining. Thus, as compared to WH, NWH could promote recovery and neuromuscular adaptations after training.

Differently Formulated Creatine Effects On Fatigue, Work, And Power In Resistance-trained Subjects

D. R. Miller, L. R. Brilla, FACSM, J. G. San Juan, D. N. Suprak, H. H. Buddhadev. *Western Washington University, Bellingham, WA.* (Sponsor: Lorrie Brilla, FACSM)

Reported Relationships: D.R. Miller: *Contracted Research - Including Principle Investigator; Partially supported by Albion Laboratories, Inc.*

Creatine is an effective supplement for improving strength, power, and reducing fatigue, especially in high intensity, repeated activities. Various nutritional strategies have been utilized to enhance creatine efficacy, including concurrent intake of carbohydrates, electrolytes, and nutrients with alkaline quality, such as magnesium. **Purpose:** This study examined the effects of two differently formulated creatine supplements, creatine monohydrate (CM) or creatine-magnesium chelate (CC), compared to placebo (P) on fatigue, work, and power during knee extensions. **Methods:** The study evaluated effects in resistance-trained participants, repeating measures after six-weeks of supplementation. Subjects ($n=23$; 21.9 ± 1.8 years) maintained their regular resistance training program and had not supplemented creatine in the previous 6 months. Supplementation was 4 g creatine daily for CM and CC, plus 400 mg magnesium in CC. Maximum torque and fatigue of knee extensors at $180^\circ \text{ sec}^{-1}$ were determined using an isokinetic dynamometer for 2 sets of 30 repetitions each, with 2 minutes rest between sets. Fatigue was calculated by the ratio between the first 1/3 and the last 1/3 of work for each set. Body composition was determined with the three-site skin folds test. Statistical analyses were performed using mixed ANOVA. **Results:** Fatigue results demonstrated no significant differences ($p > 0.05$). For work and average power, there were no significant interaction effects ($p > 0.05$) in either set 1 or 2. However, there was a significant group effect for work (P: 1987.49 ± 617.65 J, CM: 1978.55 ± 723.21 J, CC: 2485.57 ± 677.58 J; $p < 0.05$; partial $\eta^2 = 0.371$) and average power (P: 165.4 ± 70.33 W, CM: 160.59 ± 56.28 W, CC: 186 ± 66.71 W; $p < 0.05$; partial $\eta^2 = 0.407$) in set 1; with no significant differences in set 2 ($p > 0.05$). There were no significant effects of time or group from pre- to post-test for body composition ($p > 0.05$). **Conclusion:** There were no significant differences for fatigue in either set. In the first set, CC demonstrated greater total work performed and greater average power. There were no significant differences in these variables for the second set in any group. The small improvement observed in work and power for CC indicates that the magnesium may enhance creatine's effects.

 β -alanine Supplementation To Improve Exercise Capacity And Performance: A Systematic Review And Meta-analysis

Eimear Dolan¹, Kirsty Elliott-Sale², Guilherme G. Artioli¹, Paul A. Swinton³, Hamilton Roschel¹, Craig Sale, FACSM², Bruno Gualano¹, Bryan Saunders¹. ¹University of Sao Paulo, Sao Paulo, Brazil. ²Nottingham Trent University, Nottingham, United Kingdom. ³Robert Gordon University, Aberdeen, United Kingdom.

Email: eimeardol@gmail.com

(No relationships reported)

PURPOSE: To conduct a systematic review and meta-analysis of the evidence on the effects of β -alanine supplementation on exercise capacity and performance. **METHODS:** This study was designed in accordance with PRISMA guidelines. A three level mixed effects model was used to model effect sizes, along with the influence of various moderators including participant training status, duration and type of exercise (capacity and performance). Three databases (PubMed, Google Scholar, Web of Science) were searched using a number of terms (" β -alanine" and " β -alanine" combined with "supplementation", "exercise", "training", "athlete", "performance", and "carnosine"). Inclusion/exclusion criteria limited articles to double-blinded, placebo-controlled studies investigating the effects of chronic β -alanine supplementation on an exercise measure. All healthy participant populations were considered. A single outcome measure was extracted from each exercise test and converted to effect sizes for meta-analyses. **RESULTS:** Forty individual studies employing 65 different exercise protocols and totaling 70 exercise measures in 1461 participants were included in the analyses. A significant overall effect size of 0.18 (95%CI: 0.08, 0.28) was shown. Meta-regression demonstrated that exercise duration significantly moderated effect sizes ($P=0.004$).

Subgroup analyses also identified the type of exercise as a significant ($P=0.013$) moderator of effect sizes within an exercise time-frame of 0.5-10 min with greater effect sizes for exercise capacity [0.4998 (95%CI: 0.246, 0.753)] vs. performance [0.1078 (95%CI: -0.201, 0.416)] based tests. There was no moderating effect of training status ($P=0.559$), intermittent or continuous exercise ($P=0.436$) or total amount of β -alanine ingested ($P=0.438$). Co-supplementation with sodium bicarbonate resulted in the largest effect size when compared to placebo [0.43 (95%CI: 0.22, 0.64)]. **CONCLUSIONS:** β -alanine supplementation had a significant overall effect while sub-group analyses revealed a number of modifying factors, including exercise duration and type. These data allow individuals to make informed decisions as to the likelihood of an ergogenic effect with β -alanine supplementation based upon their chosen exercise modality.

The Effects of Beta-Alanine and Sodium Bicarbonate Supplementation on Anaerobic Performance in Trained Males

Christopher Swart¹, Brian Thompson², Elizabeth Mullin², Vincent J. Paolone, FACSM². ¹Bridgewater State University, Bridgewater, MA. ²Springfield College, Springfield, MA.
 (No relationships reported)

PURPOSE: The study was designed to examine the effects of chronic beta-alanine supplementation and acute sodium bicarbonate supplementation on anaerobic performance using a cycle ergometer protocol. **METHODS:** Ten trained males (O_{2peak} $52.14 \pm 4.24 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$) performed an 8 minute anaerobic exercise cycling protocol before, after chronic beta-alanine supplementation, and after the combination of chronic beta-alanine and acute sodium bicarbonate supplementation. Subjects were instructed to take 6.4 grams of beta-alanine in 4 doses spread throughout the day at the same time each day for 4 weeks. At the completion of the beta-alanine experimental session each subject was given a sodium bicarbonate supplement to take acutely for 24 hours prior to the combination of chronic beta-alanine and acute sodium bicarbonate supplementation experimental session. Each subject took 0.5 grams of sodium bicarbonate per kilogram of bodyweight ingested in 4 doses evenly spread throughout the 24 hours prior to the final session. The 8 min intermittent cycling protocol used for each session included 30 seconds of maximum effort followed by 30 seconds of active recovery for 8 rounds. The performance variables measured every minute included lactate, RTW (relative total work), RAAP (relative average anaerobic power), TREPS (total repetitions), RPE, O_2 and RER. **RESULTS:** Significant interactions were found for RTW, RAAP, TREPS and RPE. RTW was significantly greater post supplement 2 ($M_{PS2} = 131.68 \pm 4.44$) compared to control ($M_C = 116.86 \pm 3.25$) at time point 3:30. RAAP was significantly greater post supplement 1 ($M_{PS1} = 4.42 \pm .19$) compared to control ($M_C = 4.05 \pm .21$) for time point 3:30. Although RTW and RAAP were only significant at one time point (3:30), a trend toward an increase in RTW and RAAP was found. **CONCLUSION:** A trend toward higher RTW and RAAP during the 8 min intermittent cycling protocol may indicate the benefit of chronic beta-alanine combined with acute sodium bicarbonate supplementation outside the widely studied exercise length of 60-240 seconds.

349 Board #170 May 31 11:00 AM - 12:30 PM
Twenty-four Weeks Of Beta-alanine Supplementation Increases Muscle Carnosine Content Despite Downregulation Of Beta-alanine Transporter Expression

Bryan Saunders¹, Vitor de Salles Painelli¹, Luana Farias de Oliveira¹, Vinicius da Eira Silva¹, Rafael Pires da Silva¹, Luiz Riani¹, Mariana Franchi¹, Livia de Souza Gonçalves¹, Roger Charles Harris², Hamilton Roschel¹, Guilherme Giannini Artioli¹, Craig Sale, FACSM³, Bruno Gualano¹. ¹University of Sao Paulo, Sao Paulo, Brazil. ²Junipa Ltd, Newmarket, United Kingdom. ³Nottingham Trent University, Nottingham, United Kingdom.
 Email: drbryansaunder@outlook.com
 (No relationships reported)

Skeletal muscle carnosine content can be increased via chronic beta-alanine ingestion, but the maximum increase achievable with supplementation is unknown. Additionally, the effects of prolonged supplementation on carnosine-related gene expression in humans are not known. Since athletes are likely to supplement for extended periods of time, determination of the long-term effects of beta-alanine supplementation is warranted. **PURPOSE:** To investigate the effects of 24-weeks of beta-alanine supplementation on muscle carnosine content and expression of genes related to carnosine metabolism. **METHODS:** Twenty-four males were supplemented with 6.4 g day⁻¹ of sustained release beta-alanine (BA; N=15) or placebo (PL; N=9) for 24 weeks. Every 4 weeks participants provided a muscle biopsy from the *m. vastus lateralis*, which was subsequently analysed for muscle carnosine content and gene

expression (*CARNS*, *TauT*, *ABAT*, *CNDP2*, *PHT1*, *PEPT2*, *PAT1*). **RESULTS:** Carnosine content was increased from baseline at every time point in BA (all $P < 0.0001$; Week 4: $+11.4 \pm 7.0$ mmol·kg⁻¹·dm, Week 8: $+13.9 \pm 7.8$ mmol·kg⁻¹·dm, Week 12: $+17.0 \pm 8.6$ mmol·kg⁻¹·dm, Week 16: $+17.6 \pm 8.4$ mmol·kg⁻¹·dm, Week 20: $+21.2 \pm 7.9$ mmol·kg⁻¹·dm, Week 24: $+20.2 \pm 7.6$ mmol·kg⁻¹·dm), but not PL (all $P > 0.05$). Maximal changes ranged from $+17.1$ to $+41.3$ mmol·kg⁻¹·dm, and absolute maximal content ranged from 31.8 to 63.9 mmol·kg⁻¹·dm. There was an effect of supplement ($P = 0.002$) on *TauT* with lower expression in BA (-36%, -39%, -27%, -57%, -46% and -35% at Weeks 4, 8, 12, 16, 20 and 24); no further differences in gene expression were shown. **CONCLUSION:** Twenty-four weeks of beta-alanine supplementation increased muscle carnosine content in all individuals at all time points, although absolute maximal changes were variable. Downregulation of the beta-alanine transporter *TauT* suggests it plays an important role in muscle carnosine accumulation with beta-alanine supplementation. These data demonstrate that individuals who supplement with beta-alanine for prolonged periods can maintain elevated muscle content throughout supplementation, despite downregulation of beta-alanine transporter expression.

350 Board #171 May 31 11:00 AM - 12:30 PM

The Effect of Six Weeks of Beta-Alanine Supplementation on Incremental Exercise Performance

Carol A. Weideman, Timothy J. Michael, FACSM, Krysten Binfet, Ashley Haldeman, Bret Gruden, Nicholas J. Hanson, Michael G. Miller. *Western Michigan University, Kalamazoo, MI.*

(No relationships reported)

Beta-alanine supplementation has been proposed as a means to improve exercise performance by increasing intramuscular buffering capacity. By increasing buffering capacity, exercise performance should improve by delaying the onset of fatigue. **PURPOSE:** The purpose of this study was to determine if beta-alanine supplementation is able to reduce fatigue associated with incremental exercise to exhaustion among males and females. **METHODS:** 25 (12 male and 13 female) healthy, recreationally active volunteers completed this study. Subjects were age 22.6 ± 3.5 years with a BMI of 24.4 ± 3.9 . A double blind study was conducted over a 6-week period. Each subject completed an incremental exercise bout on an electromagnetically braked cycle ergometer once every 2 weeks for 6 weeks. Timing of data collection was as follows: week 0 (no supplementation/ baseline measure), end of week 2, 4, and 6. Supplementation consisted of either a 400mg capsule of beta-alanine (treatment) or 400mg capsule of dextrose (placebo) taken 4 times per day for 6 weeks. **RESULTS:** Performance and physiological measures collected included time to exhaustion (TTE), maximum power output (PO max), VO_2 peak, Ventilatory Threshold (VT), and peak heart rate (HR peak). Results were analyzed using repeated measures ANOVA with significance set *a priori* at $p < 0.05$. There were no significant differences over time or within sex, therefore data is collapsed and is presented as treatment vs. placebo (mean \pm SE). TTE (seconds) 1051.1 ± 39.1 vs. 976.4 ± 37.6 ; PO max (Watts) 206.7 ± 6.7 vs. 195.5 ± 6.5 ; VO_2 peak (ml/kg/min) 34.1 ± 1.4 vs. 35.9 ± 1.3 ; VT (L/min) $1.84 \pm .08$ vs. $1.83 \pm .07$; and HR peak (beats/min) 180.3 ± 3.4 vs. 178.2 ± 3.3 . **CONCLUSIONS:** Assessed variables showed no significant differences ($p > 0.05$) between treatment and placebo at time points 2, 4, and 6 weeks. This finding was also found when isolating assessment to males and females. These results suggest that beta-alanine supplementation was not effective in improving exercise performance as used in this study.

Glutamine and Alanine Supplementation Improves Cytoprotective Parameters in Rats Submitted to Progressive Resistance Exercise

Julio -. Tirapegui, Thaís M. Hypólito, Raquel Raizel, Audrey Y. Coqueiro, Carlos E. C. Martins, Vanessa B. S. Lima, Henrique Q. T. Ribeiro, Andrea Bonvini. *University of São Paulo, São Paulo, Brazil.*

Email: tirapegu@usp.br

(No relationships reported)

Excessive exercise can lead to an inflammatory process and, recently described, liver dysfunction. Heat shock proteins, especially HSP70, have important anti-inflammatory properties by blocking the activation of the NF- κ B pathway, which is also suppressed by Sirtuin 1 (SIRT1). Glutamine availability is critical for the optimal regulation of HSP response and SIRT1 concentration, and its metabolism is compromised under catabolic situations, such as intense exercise. Glutamine and alanine supplementation, in their free form or as dipeptide, can increase the HSP70 response in heavy aerobic training. However, less is known about these cytoprotective effects in resistance exercise (RE). **PURPOSE:** Evaluate the effect of chronic oral supplementation with glutamine and alanine, in their free form or as dipeptide, on SIRT1 and HSP70 concentration and NF- κ B activation in liver of rats submitted to progressive RE. **METHODS:** Adult male Wistar rats (n 8/ group) were submitted to 8-week RE and

supplemented with L-alanine and L-glutamine, in their free form or as dipeptide (ALA, GLN+ALA and DIP groups, respectively), or water (SED and CTRL group). RE consisted to climb a ladder for 3 to 6 sets with progressive loads (25 to 100% of body weight). In the last 21 days of training, supplements were given in a 4% solution dissolved in drinking water. SIRT1 and HSP70 concentration and DNA binding activity of NF- κ B were determined in liver. **RESULTS:** RE slightly decreased HSP70 concentration in liver of CTRL group. However, all supplementations promoted a 3-fold increase in HSP70 levels ($P < 0.05$ v. CTRL group), denoting liver protection. Trained groups exhibited significantly increased level of SIRT1, consistent with the reduction of NF- κ B activation. Interestingly, DIP supplementation induced higher level of SIRT1 (by 280%, $p < 0.05$ when compared with trained groups), as well as greater cytoprotection demonstrated by suppression of NF- κ B activation (by 52%, compared with GLN+ALA and ALA groups) in liver of trained rats. **CONCLUSIONS:** Chronic oral supplementation with L-glutamine, given with L-alanine or as dipeptide, induced cytoprotective effects mediated by increased HSP70 and SIRT1 concentrations, which may have attenuated NF- κ B activation in liver of rats submitted to progressive RE. Financial support: FAPESP, CAPES and CNPQ.

CYP19A1 Gene Polymorphism of Aromatase is Associated with Arterial Stiffness in Healthy Japanese People

Koichiro Hayashi¹, Motoyuki Iemitsu², Haruka Murakami³, Kiyoshi Sanada², Hiroshi Kawano⁴, Yuko Gando⁵, Noriko Tanaka⁵, Ryoko Kawakami⁶, Motohiko Miyachi³. ¹*Kokugakuin University, Yokohama, Japan.* ²*Ritsumeikan University, Kusatsu, Japan.* ³*National Institute of Health and Nutrition, Tokyo, Japan.* ⁴*Kokushikan University, Tokyo, Japan.* ⁵*Nagoya University, Nagoya, Japan.* ⁶*Waseda University, Tokyo, Japan.*

Email: k-hayashi@kokugakuin.ac.jp

(No relationships reported)

INTRODUCTION: CYP19A1, the aromatase enzyme gene, is responsible for the biosynthesis of estrogens that have anti-arteriosclerotic effects. Previous studies have shown that the rs10046 genotype of CYP19A1 is associated with increased incidence of coronary artery disease. However, no studies have investigated whether this genotype is correlated with arterial stiffness. Additionally, it is unknown whether the rs10046 genotype is associated with a relationship between arterial stiffness and cardiorespiratory fitness. **PURPOSE:** To determine the effects of CYP19A1 gene polymorphism (rs10046) on arterial stiffness, and their associations with cardiorespiratory fitness in healthy Japanese people. **METHODS:** Nine hundred forty-seven healthy Japanese adults (Men: N=280, 43 \pm 17 years; Women: N=667, 46 \pm 17 years, Mean \pm SD) participated in a cross-sectional study. The rs10046 (C>T; transposition in the 3' untranslated region) genotype was determined by real-time PCR with Taqman probe. Arterial stiffness was measured by brachial-ankle pulse wave velocity (baPWV). Cardiorespiratory fitness was evaluated by peak oxygen uptake. Subjects were divided into high- or low-cardiorespiratory fitness groups based on the median value of peak oxygen uptake in each sex and decade of life. **RESULTS:** One-way ANOVA revealed that there were significant differences in age, weight, blood triglyceride level, and systolic blood pressure among the genotypes. After adjusting for these covariates, baPWV of individuals with the TT genotype of rs10046 were significantly lower than those of other genotypes (TT; 1211 \pm 195, TC; 1253 \pm 250, CC; 1251 \pm 257 cm/sec). For both sexes, the same pattern was observed, but these findings were not significant. The rs10046 genotype had no impact on differences of arterial stiffness associated with cardiorespiratory fitness level. **CONCLUSION:** CYP19A1 gene polymorphism (rs10046) of aromatase is related to arterial stiffness in healthy Japanese people but has no impact on the relationship between arterial stiffness and cardiorespiratory fitness.

Genes' Polymorphisms Related To Athletic Physical Performance: A Descriptive Study In Estonian Elite Athletes
 Agnes Mägi¹, Eve Unt¹, Ele Prans², Sulev Kõks². ¹Tartu University Hospital, Tartu, Estonia. ²University of Tartu, Tartu, Estonia.
 Email: agnes.magi@kliinikum.ee
 (No relationships reported)

Genetic predisposition has a substantial role in the development of athletic physical performance and is characterized by a large number of gene polymorphisms and the interaction of these variations.

PURPOSE: (1) to examine the prevalence of genotypes of 6 genes related to physical performance (*ACE1/D*, *ACTN3 R577X*, *PPARGC1A Gly482Ser*, *AGT Met235Thr*, *AMPD1 Gln12Ter*, *NOS3 786C/T*) in Estonian elite athletes; (2) to compare the distribution of gene variations between representatives of 2 sports groups (predominantly endurance-oriented and mostly for speed and/or power-oriented sports groups).

METHODS: the study group consisted of 130 elite athletes (23 females and 107 males); current and former Estonian national team members; in age range 28.3±5.6 years; involved in 19 different sports disciplines. There were 77 representatives of endurance-oriented sports (17 females and 60 males) and 53 representatives of speed and power-oriented sports (6 females and 47 males). 26 athletes of the study group were medallists or finalists in the Olympic Games, World or European championships. Peripheral venous blood samples were collected for DNA extraction and genotyping (6 candidate genes) from all study subjects. For statistical analysis, a descriptive analysis and χ^2 test were used to determine significant differences between the frequencies of gene variations. P-values of ≤ 0.05 were set as statistically significant.

RESULTS: the higher prevalence of the RR genotype of the *ACTN3* gene among athletes of endurance-oriented sports compared to athletes of speed and power-oriented sports was statistically significant ($p=0.025$). We did not find any significance in the distribution of other gene variations between the two sports groups. We observed the trend of a higher prevalence of the *NOS3* TT genotype ($p=0.076$) and a lower prevalence of the *AMPD1* TT genotype ($p=0.09$) in the endurance-oriented sports group compared to the speed and power-oriented sports group, but it was not statistically significant.

CONCLUSIONS: our study results reveal a significantly higher prevalence of the *ACTN3* RR genotype in athletes of the endurance-oriented sports group, which is in accordance with our previous study among young skiers and this may be an advantage for the explosive speed and power capacity in endurance sports.

Novel Genes Associated with Elite Athlete Performance Via Inflammatory Pathways
 Kylene Boka, Helen Piontkivska, Kenneth Sparks, Scott Habowski, Ellen Glickman, FACSM. Kent State University, Kent, OH. (Sponsor: Dr. Ellen Glickman, FACSM)
 (No relationships reported)

There is a known relationship between inflammation and its alteration in exercise performance. In addition, a number of inflammatory processes are linked to the major histocompatibility complex (MHC) on the short arm of chromosome 6. As our understanding of genetics expands, over 140 genes have been linked with exercise performance; however, the role of inflammatory pathways remains unclear. **PURPOSE:** The purpose of this study was to investigate whether 3 genes, unique to the elite athletes, and located on the short arm of chromosome 6 are connected to the immune/inflammation MHC genes cluster. **METHODS:** Eleven elite runners (VO₂max: 70-88.3 mL/kg, included Olympic Trial qualifiers and Olympic athletes) and eleven control athletes (VO₂max: 54-57 mL/kg, locally competitive cyclists and runners) had their genome sequenced. Exome reads were mapped to the hg19 using CLC Genomics ver. 8.5 with respective amino acid variants called and annotated. Variants shared by at least 75% of the respective groups (elites vs. controls) were further investigated using the Database for Annotation, Visualization, and Integrated Discovery (DAVID) v6.7. The top 3 functional groups of genes in each category were analyzed further and certain genes identified for further research. **RESULTS:** *GABBR1/OR2H2* (6p21.31), *OR14J1* (6p22.1), and *SLC17A4* (6p22-p21.3) were identified as genes, unique to the elite athletes, located close to an important immune cascade pathway on chromosome 6. The hypothesis is that the close proximity of these genes to the MHC cluster (6p21.2) is likely related to the inflammation pathways in the elites that influences their exercise performance ability.

CONCLUSIONS: These results indicate that there may be underlying genetic traits that are unique to elite athletes that allow for their extraordinary athletic performance and that are related to inflammatory markers.

 (No relationships reported)

PURPOSE: The genetic basis of physical activity has been firmly established through both animal and human studies. The purpose of this study was to examine genetic variation across the genome for association to quantitative measures of exercise dose, intensity, duration, and adherence.

METHODS: Young adults (18-35 y) underwent 15 weeks of aerobic exercise training while wearing computerized heart rate monitors. Exercise intensity was defined as age- and gender-specific percent heart rate reserve, and exercise dose was calculated as session duration adjusted for exercise intensity, summed over all exercise sessions. A total of 1,012 non-Hispanic white, 700 African American, and 332 Hispanic subjects were genotyped for ~200K genetic markers using the Illumina Metabochip, and genome-wide association analysis was performed using PLINK. Principal component analysis was used to control for racial/ethnic background and population substructure.

RESULTS: SNPs in 10 genes exceeded a genome-wide significance of $p < 10^{-4.5}$, including *FN3KRP*, *FAM148A*, *CUX2*, *RIPK2*, *ABC11*, *B3GNTL1*, *BRE*, *BDNF*, *ZHX3*, *IDE*, and *TBCD*. Pathways contributing to lipid metabolism, neural signaling, muscle contraction, and adiposity were significantly represented by SNPs with a nominal $p < 0.0001$. The brain-derived neurotrophic factor (BDNF) signaling pathway emerged as a central factor linking multiple other pathways, highlighting neural signaling as a target for exercise tolerance. Two SNPs in the *CEP112* gene were significantly associated with exercise adherence ($p < 10^{-6}$); this gene has previously been implicated in smoking cessation, suggesting a common genetic pathway for persistent behavior.

CONCLUSIONS: This study represents the first genome-wide analysis of exercise tolerance and adherence in a multi-racial sample of young adults; neural signaling pathways appear to be important in both outcomes.

Osteoarthritic Extracellular RNA Biomarkers in Synovial Fluid
 Anthony J. Griswold, Jose Perez, Karen Nuytemans, Thomas Strong, Liyong Wang, Hayley Ennis, Marvin Smith, Jeffery Vance, Margaret A. Pericak-Vance, Lee D. Kaplan. University of Miami, Miami, FL. (Sponsor: Thomas Best, FACSM)
 (No relationships reported)

The molecular mechanisms influencing the initiation and progression of osteoarthritis (OA) are unclear. Therefore, current clinical management of predominately involves symptomatic treatment of end-stage diagnosed OA. Understanding the pathogenesis of OA at the pre-clinical stage may aid in both diagnostic and preventative modalities in the management of this chronic disease. **PURPOSE:** To determine the synovial extracellular RNA (exRNA) changes associated with OA. **METHODS:** Synovial fluid was collected from the injured knee of a cohort of 14 individuals (ages 15-47, 10 males and 4 females) undergoing surgical repair following ACL and/or meniscus injuries. Each knee had arthroscopically graded OA and divided the cohort into 5 individuals in the OA group (OA in >1 knee compartment) and 9 individuals in the non-OA group (OA in ≤ 1 knee compartment). Total exRNA was extracted from the synovial fluid collected at the time of surgery, >30 million reads generated per sample using massively parallel sequencing, and differential abundance of RNA was calculated between the two groups. **RESULTS:** A total of 19 protein coding exRNAs were significantly different ($FDR \leq 0.05$) between the two groups: 13 increased in the OA group, 6 decreased. While no specific pathways were enriched, these genes included several genes known to influence OA pathways including *ADAM12* (metalloprotease-disintegrin 12) and *BMPRIA* (bone morphogenetic protein receptor type 1A). In addition, 3 miRNAs were different: 2 increased, 1 decreased. One of these increased miRNAs was mir30a which has a known role in promotion of extracellular matrix degradation. **CONCLUSIONS:** These data suggest that the profile of extracellular RNA molecules are dysregulated arthroscopically diagnosed OA. While the specific intercellular signaling role of these exRNA are yet to be elucidated, they offer intriguing biomarkers and suggestions of dysregulated molecular pathways in OA. Changes in the genes *ADAM12*, *BMPRIA*, and mir30a suggest that exRNA markers of extracellular matrix degradation are biomarkers for the initiation and/or progression of OA. These findings have the potential clinical utility to differentiate patients at risk for the development of OA, introducing the possibility for intervention at pre-symptomatic stages.

Acute Exercise Induced Changes of Gene-Specific DNA Methylation in Natural Killer Cells

Christina Koliyamitra¹, Wilhelm Bloch¹, Alexander Schenk¹, Walter Pulverer², Philipp Zimmer¹. ¹*Cardiovascular Research and Sports Medicine, Cologne, Germany.* ²*Austrian Institute for Technology, Vienna, Austria.* (Sponsor: Prof. Dr. Steinacker Jürgen Michael, FACSM)
Email: c.koliyamitra@dshs-koeln.de
(No relationships reported)

As part of the innate immune system, natural killer cells (NK cells) have the ability to detect and eliminate virus-infected and neoplastic cells. The amount of tumor infiltrating NK cells is connected with the prognosis of various tumor diseases. Acute physical exercise influences the mobilization of NK cells and increases their cytotoxicity. Previous studies indicate that a load-dependent variation of the NK cells is induced by epigenetic modifications.

Purpose: The aim of this investigation was to examine to what extent has the promoter methylation of activating (KIR2DS4) and inhibiting (KIR3DL1) NK cell receptors changed after acute exhaustive exercise.

Methods: A total of 18 healthy female subjects (age of 55, 2 ± 5, 7) were asked to perform a spirometry on a cycle ergometer. The spirometry protocol was a step test of 1 min rest measurement at the beginning, followed by a 3 min warm-up phase with 50 watts of power output and an increase of 25 watts for every 2 minutes of the test until exhaustion. Before (T0) and after (T1) spirometry test, venous blood was collected from which NK cells were isolated and DNA was extracted. Accordingly, the KIR2DS4 and KIR3DL1 NK cell receptors were examined through Targeted Deep Amplicon Sequencing.

Results: The promoter methylation of the activating KIR2DS4 receptor reduced after single exercise load (T0 vs T1). The significant changes were observed in two close (distance of 4 base pairs), identified CpGs (p=.007 and p=.008). No effects found on the inhibiting KIR3DL1 receptor. There was no correlation found between the promoter methylation and the maximum oxygen uptake of the subjects. However, the data showed a positive correlation of the promoter methylation between both genes at T0 and T1.

Conclusions: Acute exercise reduces the promoter methylation of the activating NK cell receptor KIR2DS4. This finding may be related to reduced KIR2DS4 gene expression by natural killer cells. The correlation between the methylation of both genes indicates that reduced methylation of the activating receptor proves to be reduced for the inhibiting receptor as well. However, only the activating receptor is sensitive to epigenetic modulations after exhaustive exercise. Therefore, high-load acute exercise represents a promising positive influence for the innate immune system.

Exercise Induced Natural Killer (NK) Cell Genomic Response in Pediatric Acute Lymphoblastic Leukemia (ALL) Survivors

Martin Perlsteyn¹, Leonard S. Sender², Fadia Haddad¹, Dan M. Cooper¹, Ronen Bar-Yoseph¹, Shlomit Radom-Aizik¹. ¹*University of California Irvine, Irvine, CA.* ²*CHOC Children's Hospital, Orange, CA.*
(No relationships reported)

Despite remarkable success in achieving remission, pediatric ALL survivors face increased risk of physical activity related metabolic, cardiovascular, and bone disease. The mechanisms of these threats to the healthspan are unknown. NK cells play a role in therapy and immune surveillance in ALL and along with other immune cells, are also involved in the molecular pathways by which exercise benefits health. NK cells increase in the circulation in response to brief exercise to a greater degree than any other leukocyte. **PURPOSE:** To examine the effect of brief exercise on NK cell gene expression (RNA seq), in children and adolescents who have survived ALL. **METHODS:** 9 ALL survivors and 9 sex and age-matched controls (14.8±0.7 & 15.0±0.9 y/o) performed 8, 2-min bouts of cycle ergometer exercise interspersed with 1-min rest at a constant work equivalent to 65±1% of peak $\dot{V}O_2$. RNA Seq was performed using standard techniques. The trimmed reads were aligned to Human hg19 reference genome. Differential analysis was performed using DESeq (v.1.18.0). Paired design was used to account for samples from same patient (FDR<0.05). Differential expression genes were classified into pathways using the Kyoto Encyclopedia of Genes and Genomes (KEGG) database (EASE score<0.05). **RESULTS:** 17 annotated genes were expressed significantly different from controls in ALL survivors at baseline (before exercise) and were enriched in MicroRNAs in Cancer KEGG pathway. Brief exercise significantly altered 4407 genes in control and 4126 genes in ALL. 220 genes were altered differently in response to exercise in ALL survivors compared to controls. Those genes were enriched in KEGG Pathways involved in immune surveillance; e.g., hematopoietic cell lineage, central carbon metabolism in cancer, HIF-1 signaling pathway, pathways in cancer and antigen processing and presentation which included 3 killer-cell immunoglobulin-like receptors (regulate the killing function of NK cells)

that had reduced response in ALL. **CONCLUSION:** Exercise altered the expression of thousands of NK cell genes in both ALL and controls with a distinct pattern in ALL. Among several possible health effects, exercise may improve NK cell function in immune surveillance in ALL survivors. FGF21 is Produced By Active Skeletal Muscle during Intense Exercise in Humans: Influence Of P_iO₂

Marcos Martin-Rincon¹, Alberto Perez-Lopez², Marco Azzinnari¹, Mercedes Said-Quintana¹, Alfredo Santana¹, David Morales-Alamo¹, Cecilia Dorado-García¹, Jose A L Calbet¹. ¹*University of Las Palmas de Gran Canaria. (No relationships reported)

Fibroblast growth factor 21 (FGF21) is a peptide produced mostly by the liver and other tissues as skeletal muscle. Recent work supports that the main source of circulating FGF21 during exercise is the hepato-splanchnic circulation. Nevertheless, increased FGF21 mRNA has been reported in human skeletal muscle after prolonged exercise. Given the great increase of skeletal muscle blood flow during exercise, a small amount of FGF21 released by active skeletal muscles could have escaped detection by a-v differences.

PURPOSE: to determine whether skeletal muscle produces FGF21 in response to exercise and the influence of muscle metabolism and oxygenation on this process. **METHODS:** Eleven volunteers performed incremental exercise (IE) to exhaustion in normoxia (Nx, P_iO₂:143 mmHg) and hypoxia (Hyp, P_iO₂:73 mmHg) while muscle metabolites and FGF21 protein expression (Western Blot) were measured before (control) and immediately after IE in Nx and Hyp. Immediately after IE, the circulation of one leg was instantaneously occluded (300 mmHg) and vastus lateralis muscle biopsies obtained after 10s from the occluded leg, and simultaneously from both legs at 60s.

RESULTS: At 10s muscle lactate ([La]) was increased and phosphocreatine (PCr) and ATP reduced in Nx and Hyp, without differences between conditions. Muscle [La] was increased by 25% from 10 to 60s in the occluded leg (P<0.05) and unchanged in the non-occluded leg (+5% P=0.71). After 60s, PCr was reduced by 94 and 48%, in the occluded and non-occluded leg, respectively (P<0.05). Compared to pre-exercise, FGF21 protein expression was increased in the occluded leg by 55 and 57% at 10s and 60s, respectively (time effect P=0.02) and by 10% (P=0.42) in the non-occluded leg at 60s, without influence of P_iO₂. No association was observed between metabolite accumulation and FGF21 expression.

CONCLUSIONS: FGF21 is produced during intense exercise in human skeletal muscle. The fact that FGF21 was not increased 60s after the end of exercise in the leg recovering with free circulation highlights the utility of total occlusion of the circulation to trap in the muscle myokines released in small amounts by the muscle during contractile activity.

(No relationships reported)

The effects of intermittent hypoxic exposure (live low train high) on skeletal muscle oxygenation kinetics remain poorly understood. However, recent developments in technology have meant that the monitoring of skeletal muscle blood flow in response

to training is possible. **PURPOSE:** The aim of the current study was to determine whether handgrip dynamometry (HGD) training in normobaric hypoxia (14% FiO₂) altered blood flow in the non-dominant flexor digitorum profundus (FDP) at rest and during exercise.

METHODS: Following institutional ethical approval, 7 healthy males who were not forearm trained (mean age: 20.7 ± 1.1 years; stature: 1.77 ± 0.08 m; body mass: 84.0 ± 14.2 kg) volunteered to take part in the study. In a randomized, crossover design participants completed four weeks of progressive HGD endurance training (0.3Hz in week one increasing to 1.2Hz in week 4) in both normoxia and hypoxia. There were four training sessions per week and each consisted of 30 min intermittent handgrip exercise at 30% of maximal voluntary contraction (MVC), followed by a 60s maximal 'sprint'. A six week washout period separated normoxic and hypoxic training. Before and after the training intervention, forearm muscle blood flow was determined at rest and during exercise (25% MVC) using near-infrared spectroscopy and the venous occlusion method. Forearm blood flow was calculated by evaluating the rate of increase in total haemoglobin (thb) during the first few seconds of venous occlusion (60 mmHg).

RESULTS: Two-way repeated measures ANOVA revealed a significant interaction (time x condition; *p* = 0.028) in blood flow during exercise at 25% MVC, but not during rest (*p* = 0.114); further there was no significant main effect for condition (*p* = 0.059) or time (*p* = 0.077). Follow up paired samples *t*-tests revealed that forearm muscle blood flow during exercise was greater than baseline following normobaric hypoxic training (*p* = 0.049, MD = 1.59, 95% CI = 0.24 - 3.21 ml·min⁻¹·100ml⁻¹), but not following normoxic training (MD = 0.05, 95% CI = -0.45 - 0.54 ml·min⁻¹·100ml⁻¹).

CONCLUSIONS: Thirty minutes of handgrip dynamometry training a day for 4-weeks in normobaric hypoxia has the potential to increase forearm muscle blood flow. Future studies should seek to determine whether these hypoxia induced changes translate to an enhanced endurance performance.

The Effect of Hypoxia on PGC-1α

Roksana Zak, Robert Shute, Dustin Slivka, FACSM. *University of Nebraska-Omaha, Omaha, NE.* (Sponsor: Dustin Slivka, FACSM)

(No relationships reported)

Markers for mitochondrial function in the skeletal muscle appear to be reduced after extended exposure to altitude. However, short term training at altitude enhances aerobic capacity. Further investigation is needed to determine the skeletal muscle response to altitude.

PURPOSE: The purpose of this study was to determine the impact of exposure to normobaric hypoxia after exercise on the gene expression and subcellular location of PGC-1α protein compared to a normoxic environment.

METHODS: Six male participants (age 25 ± 2, height 180 ± 4 cm, weight 82 ± 2 kg) completed two 90 min cycling trials in laboratory conditions followed by a 6 h recovery in either ambient conditions (975 m) or in a hypoxic environment (5000 m). Biopsies were taken from the *vastus lateralis* before exercise, after exercise, and following 6 h recovery. Samples were analyzed for PGC1-α gene expression using RT-qPCR and subcellular location using western blot on cytosolic and nuclear fractions.

RESULTS: Exposure to hypoxia following exercise resulted in significantly lower expression of PGC-1α (*p* = 0.014) but no significant differences were found in protein translocation between the cytosolic (*p* = 0.225) and nuclear (*p* = 0.211) fractions.

CONCLUSIONS: It appears that the post-translational events of PGC-1α are not altered by acute hypoxia after exercise, despite a reduced transcriptional response of PGC-1α. It is unclear if these cellular events would account for the deficit in mitochondrial function observed with extended exposure to a hypoxic environment. This project was funded by grants from the Department of Defense (W8IXWH-10-Z-0120) and NASA Nebraska Space Grant.

Exercise Induced Oxidative Stress During Normobaric And Hypobaric Hypoxic Exercise Recovery

John C. Quindry, FACSM¹, Roksana Zak², Robert Shute³, Tiffany Quindry¹, John Cuddy¹, Walter Hailles¹, Dustin R. Slivka, FACSM⁴, Brent Ruby, FACSM¹. ¹University of Montana, Missoula, MT. ²University of Nebraska - Omaha, Omaha, NE. ³University of Nebraska - Omaha, Omaha, NE. ⁴University of Nebraska - Omaha, Omaha, NE. Email: John.quindry@mso.umt.edu

(No relationships reported)

PURPOSE: Altitude exposure and exercise provoke an acute oxidative stress response in muscle and blood tissues. Prior work indicates that redox-sensitive exercise recovery responses are attenuated above 1500m, although the independent impact of hypobaric and hypoxia on these responses are unknown. Moreover, given that the wealth of existing exercise and altitude data are conducted primarily in males, the current study

was designed to understand exercise recovery responses in males and females exposed to various hypoxia and hypobaric conditions following a common bout of aerobic exercise.

METHODS: Sixteen active males (n=8) and females (n=8) between the ages of 18-40 performed cycle ergometer exercise for 60 minutes at 70% watts max at a base elevation of 975m. In a randomized counter-balanced crossover design subjects recovered in an environmental chamber for 4 hours in three conditions; 1000m normobaric normoxia (NN, 675mmHg, 18.8% FiO₂), a simulated 4400m normobaric hypoxia (NH, 675mmHg, 12% FiO₂), or a simulated 4400m hypobaric hypoxia (HH, 440mmHg, 12% FiO₂). Pulse oximetry was used to measure O₂ saturation throughout the exercise trials and to confirm hypoxia during recovery. Six muscle biopsies obtained from the vastus lateralis at baseline and following each exercise recovery were examined for hypoxia and redox sensitive transcripts including endothelial PAS domain protein-1 (EPAS-1), hemoxygenase-1 (HMOX1), superoxide dismutase-2 (SOD2), and nuclear factor erythroid-derived 2-like 2 (NFE2L2).

RESULTS: No sex-dependent differences in gene transcripts were observed for any markers examined (*p*>0.05). No differences were observed for EPAS-1 (variable 2 fold increase, *p*>0.05) or NFE2L2 (1.29 fold increase, *p*>0.05). Time-, but not trial-, dependent differences existed for HMOX1 (8.4 fold increase, *p*<0.000) and SOD2 (1.4 fold increase, *p*=0.017) and indicate a similar redox stimulus was present 4 hours post exercise in all three recovery condition.

CONCLUSIONS: These data suggest exercise recovery in simulated conditions of NH and HH do not impact EPAS-1, HMOX1, SOD2 or NFE2L2. Additional redox-sensitive markers in blood and muscle should be examined to determine whether additional adaptive responses are impacted by NH and HH recovery conditions.

363 Board #184 May 31 9:30 AM - 11:00 AM

Hypoxic Training Promotes Apelin Expression In Skeletal Muscles Of High Fat Diet-induced Obese Mice

ying zhang. *Beijing Sport University, Beijing, China.* Email: zhyi9256@126.com

(No relationships reported)

PURPOSE: To investigate the effects of hypoxia, exercise, and hypoxic exercise training on the expression of apelin and APJ in skeletal muscle of obese mice.

METHODS: 60two-month oldC57BL/6Jmice were randomly divided into two groups: 10 in normal diet group(N) and 50 in the high fat diet (HFD) groups. After two months of feeding, the HFD mice whose body weight 20% higher than the average weight of N group were selected as obese mice and were further allocated into four groups: Control (C), Exercise (E), Hypoxia (H), and Exercise plus Hypoxia (E+H), at 8-9 mice/group. Besides body weight, measured variables in skeletal muscle were protein/mRNA levels of apelin/APJ, AMPKα-Thr172 phosphorylation, hypoxia inducible factor-1α(HIF-1α),mRNA levels ofperoxisome proliferator-activated receptorα (PPARα), estrogen-related receptor (ERRα),and nuclear respiratory factor1 (NRF1).

RESULTS: Obese mice had significantly lower mRNA and protein expressions of apelin/APJ in skeletal muscles than the normal body weight mice. After four weeks of interventions, hypoxic exercise training decreasedbody weight andincreased mRNA and protein expressions of apelin and APJ, mRNA expression of ERRα, and protein expression of HIF-1α.

CONCLUSIONS: These results indicate that changes of body weight may be associated with the levels of apelin/APJ expressions in skeletal muscle.

Metabolomic Analysis Of Skeletal Muscle In Horses Trained In Hypoxia.

Hajime Ohmura¹, Kazutaka Mukai¹, Yuji Takahashi¹, Toshiyuki Takahashi¹, James H. Jones². ¹Japan Racing Association, Shimotsuke-shi, Japan. ²University of California, Davis, Davis, CA.

(No relationships reported)

Hypoxic training is effective for improving athletic performance. In horses, hypoxic training increases maximal oxygen consumption (VO₂max) more than normoxic training. However, the effects of hypoxic training on well-trained horses is unclear, and its effects on muscle metabolism have not been investigated. We hypothesized that VO₂max of well-trained horses would increase and muscle metabolomics would differ before and after hypoxic training. **PURPOSE:** To determine the effects of hypoxic training on VO₂max and muscle metabolomics of well-trained horses.

METHODS: We studied 5 well-trained horses in which VO₂max had not increased over 3 consecutive weeks of supramaximal treadmill training in normoxia twice a week. Horses trained with hypoxia (15% O₂) twice a week. Before and after 3 weeks of hypoxic training, VO₂max was measured on the treadmill and biopsy samples for metabolomics analyses were taken from the gluteus medius muscle at rest. Data were analyzed with Welch's t-test. **RESULTS:** VO₂max increased after 3 weeks of hypoxic training (176 vs. 194 ml/(kg×min), *p* < .05) even though all-out training in normoxia had not increased VO₂max. From metabolomic analysis, Acetyl CoA (0.150 vs.0.048

nmol/g, $p < .05$), ATP (8.3 vs. 7.6 $\mu\text{mol/g}$, $p < .05$), and pyruvic acid (141 vs. 116 nmol/g, $p < .05$) decreased after hypoxic training. However, BCAAs (302 vs. 407 nmol/g, $p < .05$) and methionine (33 vs. 41 nmol/g, $p < .05$) increased after hypoxic training. **CONCLUSION:** Hypoxic training may increase $\text{VO}_{2\text{max}}$ even though it is not increased by normoxic training. Finding changes in muscle metabolomics in hypoxia may suggest a mechanism for potentially increasing racing performance by increasing $\text{VO}_{2\text{max}}$.

365 Board #186 May 31 9:30 AM - 11:00 AM Physical Discomfort And Relationship To Performance During A 12-mile March In US Army Soldiers

Stephen A. Foulis, Jan E. Redmond, Peter N. Frykman, Edward J. Zambraski, Marilyn A. Sharp. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*
Email: stephen.a.foulis.civ@mail.mil
(No relationships reported)

Long road marches carrying heavy loads are a common military task. While it is anecdotally accepted that discomfort related to physical pain and soreness increases during long marches, there is little data available which has quantified this discomfort or determined its effect on march performance. **PURPOSE:** To quantify pain and soreness (P&S) during a 12-mile march and determine how it affects pacing. **METHODS:** While carrying a load weighing ~46.4 kg, 46 male and 26 female Soldiers performed a 12 mile foot march. A mandatory rest break of 10 minutes was enforced at the 3 and 9 mile marks, and a 30 minute break was enforced at the 6 mile mark. Time splits were taken every 3 miles. At the start, each rest point, and finish, soldiers rated their P&S from 0 (No Discomfort) to 3 (Extremely Uncomfortable) using an image of the body mapped into 21 regions (scale adapted from Dimov et al, *AIHAJ*, 2000). Increases in P&S over time were assessed using rmANOVA. Correlations were examined between changes in P&S (finish-start) for each site and load carried per body mass and with changes in pace (time for last 3 miles – time for first 3 miles). **RESULTS:** Total march time was 244 ± 35 minutes (mean \pm SD). Average overall P&S of the 21 body regions increased during the march from 0.13 ± 0.11 prior to the march to 0.46 ± 0.24 at the end ($p < 0.01$ for trend), and did not significantly differ by sex ($p = 0.24$). Of the 71 soldiers, 64 (90%) reported a P&S of 2 or 3 for at least one body region, with 36 (51%) reporting a P&S of 3. The sites of the greatest soreness were the shoulders (End P&S 1.99 ± 0.96) and the feet (End P&S 1.36 ± 1.20) ($p < 0.05$ for both). Significant increases in P&S were observed in the neck, shoulders, mid-to-lower back, hips/waist, thighs, legs/feet, and ankles ($p \leq 0.05$ for trends). Load carried per body mass correlated with changes in neck P&S ($r = 0.24$, $p = 0.04$). Increases in P&S of the hips/waist were associated with decreasing their pace ($r = 0.32$, $p = 0.01$). **DISCUSSION:** Due to the high load over a long distance, P&S increased over the march and may have interfered with performance. These data provide quantitative evidence of the changes in reported physical discomfort during long marches. To minimize soldier discomfort and improve performance, improvements in road march policy, equipment ergonomics, and training of proper gear fitting should target these body regions.

366 Board #187 May 31 9:30 AM - 11:00 AM Relationship Between Soldier Performance on the Two-Mile Run and Beep Test: Ability to Predict $\text{VO}_{2\text{max}}$

Maria C. Canino, Stephen A. Foulis, Jan E. Redmond, Edward J. Zambraski, Marilyn A. Sharp. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*
Email: maria.c.canino.ctr@mail.mil
(No relationships reported)

Aerobic fitness is vital for military personnel to perform their physically demanding job tasks. The Army currently uses a two-mile run (TMR) as part of the Army Physical Fitness Test to measure aerobic fitness levels. The Beep Test (BT) is also currently being used by the Army as a pre-enlistment screening test. Both tests have been validated to predict an individual's aerobic capacity. An advantage of the BT is that it can be performed indoors, offering an alternative to the TMR when outdoor conditions could affect performance. A comparison of the results of these two tests has not been made. **PURPOSE:** To determine the relationship between the TMR and BT and to compare their $\text{VO}_{2\text{max}}$ estimations. **METHODS:** 404 male and 128 female soldiers participated in this study. The TMR results were self-reported from their most recent APFT. To screen for maximal effort, all soldiers included reached a post BT heart rate within 10 bpm of their age-predicted maximal heart rate (220-age). Correlations and

simple linear regression were used to analyze the relationship between TMR and BT. **RESULTS:** The regression model obtained for predicting TMR time (min) from BT shuttles (#) was $\text{TMR} = 19.101 - 0.067 * \text{BT}$, $R^2 = 0.53$ ($p < 0.001$), $\text{SEE} = 1.137$ min. For example, completing 60 and 30 shuttles would be similar to TMR times of 15.08- and 17.09 min, respectively. The mean TMR time was 15.01 min (range: 10.9-22.2 min). The mean BT score was 61 shuttles (range: 16-113 shuttles; test duration: 2.2-12.2 min). There is a significant moderate correlation between the TMR and BT estimated $\text{VO}_{2\text{max}}$ ($R^2 = 0.64$; $p < 0.001$), with mean $\text{VO}_{2\text{max}}$ values for TMR and BT 50.5 ± 5.1 and $39.4 \pm 6.1 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$, respectively. **CONCLUSIONS:** A significant moderate relationships exist between both TMR times and BT shuttles and TMR and BT estimated $\text{VO}_{2\text{max}}$. Further, in the same individuals TMR estimated $\text{VO}_{2\text{max}}$ was 22% higher than what was predicted by BT performance. Reasons for this large discrepancy could include inflation of their performance on the TMR due to subject recall, motivational differences to perform to their maximum, and/or significant differences in the ability of these two tests to actually estimate $\text{VO}_{2\text{max}}$. Additional studies are needed to concurrently measure TMR, BT, and a laboratory measure of $\text{VO}_{2\text{max}}$ in the same individual.

367 Board #188 May 31 9:30 AM - 11:00 AM The Physiological Demands of a 16 km Loaded Patrol

Gemma S. Milligan¹, James J. Treweek², Michael J. Tipton¹.
¹University of Portsmouth, Portsmouth,, United Kingdom. ²Royal Air Force, High Wycombe, United Kingdom.
Email: gemma.milligan@port.ac.uk
(No relationships reported)

The Royal Air Force (RAF) Regiment (Regt) is a close combat unit, their primary role is to secure the safety of an operational airfield. One of the critical tasks of the RAF Regt is a patrol, this can last approx. 4.5 hours, covering a distance of 16 km. **PURPOSE:** To determine the physical demand of a simulated 16 km loaded patrol in RAF Regiment Regt personnel, specifically if differences occurred between the first and fifteenth km. **METHODS:** 26 participants from the RAF Regt performed a 16 km loaded (31.50 kg) patrol over 4 hrs 28 min. Participants received 2 x 10 min breaks at 1 hr 25 min and 3 hrs 20 min and a 20 min break at 1 hr 54 min. Rating of Perceived Exertion (RPE) was recorded at the first and second break and on completion. Walking speed was paced at 4.20 km.h⁻¹ for the duration of the patrol. Heart rate (HR) was measured for the duration of the patrol. Oxygen consumption (O_2) was measured using Douglas bag collections of 1 min at 1 km, 3 km, 5 km, 10 km and 15 km. O_2 was calculated as $\text{mL} \cdot \text{kg}^{-1} \cdot \text{metre}^{-1}$ to allow for the variations in actual marching speed (3.80 km.h⁻¹ to 4.92 km.h⁻¹). **RESULTS:** No differences were reported in O_2 between the first, third, fifth or tenth km in comparison with 15 km. A meaningful significant increase in O_2 was observed at 10 km compared to the first km (0.24 ± 0.03 vs $0.22 \pm 0.02 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{metre}^{-1}$; $p = 0.002$; Cohen's d effect size (ES) 0.60; Post hoc power (PhP) = 0.92; $n = 25$) and 10 km compared to the third km (0.24 ± 0.03 vs $0.22 \pm 0.03 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{metre}^{-1}$; $p = 0.006$; ES 0.65; PhP = 0.85; $n = 19$). Significantly higher ($p \leq 0.0125$) O_2 was reported at 5 km compared to 3 km, however low ES and power were observed. During periods of work a linear cardiac drift was observed; mean \pm SD HR of $93 \pm 12.03 \text{ b} \cdot \text{min}^{-1}$ at 1 km to $110 \pm 14.98 \text{ b} \cdot \text{min}^{-1}$ at 16 km. RPE remained the same for the first and second breaks (median (range): 7 (6 to 13), increasing to 8 (6 to 14) on completion of the patrol. **CONCLUSION:** The metabolic, cardiovascular and perceived demands were low and remained low for the duration of the patrol. These data highlight that whilst the metabolic demand remained constant from the first to last km, HR increased linearly during the active element of the patrol. This suggests that HR should not be used to predict or estimate the metabolic workload of long duration activities such as the patrol.

368 Board #189 May 31 9:30 AM - 11:00 AM Neuromuscular Responses to Consecutive Day Military Load Carriage.

James F. Scales, Damian A. Coleman, Mathew Brown.
Canterbury Christ Church University, Canterbury, United Kingdom.
Email: j.scales895@canterbury.ac.uk
(No relationships reported)

Previous research has shown that lower limb peak torque (PT) is reduced up to 72 hours after treadmill load carriage. PT can occur at a range of muscle lengths and as such are unable to define the changes in muscle function, which may occur because of load carriage. **PURPOSE:** To determine changes in lower limb neuromuscular output, in responses to consecutive day military load carriage on a treadmill compared to an unloaded control group. **METHODS:** 12 participants (10 males: $88.8 \text{ Kg} \pm 16.8 \text{ Kg}$, $188.72 \text{ cm} \pm 8.5 \text{ cm}$; 2 females: $63.4 \text{ kg} \pm 12 \text{ kg}$, $164.2 \text{ cm} \pm 8 \text{ cm}$) walked on a level treadmill carrying 32kg across webbing, backpack and rifle, at a speed of 5.4 km-h⁻¹ for two hours on two consecutive days. 8 participants (6 males: $92.8 \text{ Kg} \pm 11.8 \text{ Kg}$, $187.22 \text{ cm} \pm 8.5 \text{ cm}$; 2 females: $64.2 \text{ kg} \pm 12 \text{ kg}$, $154.1 \text{ cm} \pm 8 \text{ cm}$) completed the protocol without the military equipment. Neuromuscular output of the ankle and knee flexors and extensors were studied by observing changes in torque by isokinetic dynamometry.

Knee extensor and flexor muscles were studied at 0, 60, 180 °-s-1. Ankle dorsi and plantar flexors were observed at 0, 60, 120 °-s-1. Measurements were taken pre and post load carriage on day one and day two. Torque was recorded as PT and at 5° intervals during isokinetic contraction. **RESULTS:** Statistically significant reductions in PT were observed post load carriage on day one and two in the dorsiflexors at 60 and 180°-s-1 (P<0.05) and knee flexors and extensors at 60 and 0°-s-1 (P<0.05), these are supported by torque reductions throughout the movement (70° to 0°)(P<0.05). PT returned to baseline 24 hours post exercise while torque at serial muscle lengths remained reduced. No changes were observed between unloaded and loaded walking. **CONCLUSIONS:** Findings indicate that two hours of treadmill load carriage causes a bimodal change in neuromuscular function of the knee extensors and flexors and the ankle dorsiflexors, characterised by a reduction in the PT and torque over two days of repeated exercise. However, no significant difference was observed between loaded and unloaded groups. While temporal results find support in the previous literature, the inclusion of an exercising control group, that demonstrates no significant change, suggests that they fail to observe that load carriage causes no greater reduction in neuromuscular function than unloaded walking.

369 Board #190 May 31 9:30 AM - 11:00 AM
Optimal Number of Practice Sessions for Performance of Heavy Loading Tasks in Soldiers

Marilyn A. Sharp¹, Stephen A. Foulis¹, Jan E. Redmond¹, Peter N. Frykman¹, Bradley J. Warr¹, Edward J. Zambraski². ¹USARIE/M, Natick, MA. ²ORISE, Baltimore, MD. (Sponsor: Edward J. Zambraski, FACSM)

 (No relationships reported)

All U.S. Army soldiers must perform the physically demanding tasks of their job prior to graduation from initial entry training. Armored personnel are required to conduct a tank ammunition loading task (TAL), while Field Artillery (FA) personnel perform the FA Ammunition Supply Vehicle reloading task (FAR). As these are graduation requirements, it is important to determine the influence of practice on performance of the TAL and FAR to guide training. **PURPOSE:** To determine the number of practices needed to optimize performance and pass rates of the TAL and FAR in soldiers unfamiliar with the tasks. **METHODS:** A sample of 43 soldiers (22 men, 21 women) performed the TAL 4 times and 41 (23 men, 18 women) also performed the FAR 4 times. Tasks were performed on four different days over a two week period with ≥48 hours rest between trials (T). To perform the TAL a soldier lifted and carried 18, 25 kg rounds a distance of 5 m, and handed them to another crewmember standing on the deck of the tank (lift height=1.63 m). The rate of loading was calculated in rounds·min⁻¹ with a passing rate of ≥ 2.4 rounds·min⁻¹ (18 rounds in 10 min). To perform the FAR 30, 45 kg rounds were lifted from the vehicle tailgate, carried 3 m and loaded into a rack with openings from floor to shoulder height. Soldiers had 15 min (3 5-min bouts, with 2.5 min of rest between each bout) to load 30 rounds. A passing score for the FAR was ≥ 2 rounds·min⁻¹ (30 rounds in 15 min). Repeated measures ANOVA were used to examine the effects of repeated trials. The number of soldiers failing the standard at each T was determined. **RESULTS:** The scores were significantly improved (p<0.01) from T1 to T4 for TAL (T1= 3.54 and T4=5.36 rounds·min⁻¹) and from T1 to T3 for FAR (T1=2.45 and T3= 3.47 rounds·min⁻¹). FAR plateaued T3 to T4 at 3.64 rounds·min⁻¹. The number of failures decreased with each trial on the TAL (T1=17, T2=14, T3=10, T4=6) and on the FAR (T1=19, T2=16, T3=11, T4=10). **CONCLUSIONS:** For trainees, it is important to provide 2-3 trials on each of these tasks to maximize the number passing, while not utilizing an inordinate amount of training time. Soldiers who are unable to perform to standard after 3 practices may need remedial progressive resistance training to be successful.

370 Board #191 May 31 9:30 AM - 11:00 AM
Body Composition and Physical Determinants of Physiological and Musculoskeletal Readiness in Marines

Katelyn Fleishman Allison¹, Karen A. Keenan¹, Qi Mi¹, Mita T. Lovalekar¹, Kim Beals¹, Lawrence C. Coleman², Bradley C. Nindl, FACSM¹. ¹University of Pittsburgh, Pittsburgh, PA. ²United States Marine Corps, Quantico, VA. (Sponsor: Bradley C. Nindl, FACSM)
 (No relationships reported)

Combat arms are now open to women across all Armed Forces. Identifying physicality of men and women with enhanced, cumulative physiological and musculoskeletal fitness may optimize Force Readiness. **PURPOSE:** To assess body composition and physical characteristics of male and female Marines from the Marine Corps' Ground Combat Element Integrated Task Force classified by performance clusters. **METHODS:** 302 Marines (age=22.0±2.7 yrs, height=1.5±0.1 m, mass=76.1±12.2 kg) underwent body composition testing (air displacement plethysmography); arm span and leg length; and a battery of laboratory and field strength, aerobic/anaerobic,

balance, biomechanics, and flexibility tests. A k-means cluster analysis was performed to characterize Marines with similar lab and field characteristics, regardless of sex, body composition or physicality. Twenty-three clustering validity indices were calculated to determine the optimal cluster number using R. One-way ANOVA or Kruskal Wallis tests were utilized to test for group differences, as appropriate, followed by Bonferroni adjusted pair-wise comparisons (p<0.05, two-sided). **RESULTS:** Three clusters (C) were identified: C1 with the best strength and aerobic/anaerobic characteristics, C3 with the worst strength and aerobic/anaerobic characteristics, and C2 between C1 and C3; clusters were then stratified by sex (Men: C1M, C2M, C3M; Women: C2W, C3W). C1M, C2M, and C3M had significantly less BF% than C2W and C3W. Fat free mass was significantly different among all groups. C1M and C2W had significantly greater fat mass than C3M. C1M and C2M had significantly greater arm span and leg length than all other groups. (Table 1) **CONCLUSIONS:** Fat free mass may have a stronger association with performance on strength, aerobic, and anaerobic tests than BF% or fat mass. These results can assist in developing tools to identify Marines with enhanced physiological and musculoskeletal readiness.

Distribution Of Cardiorespiratory Fitness Levels Of US Army Recruits From 2010-2013 By State

George L. Grieve¹, Morgan Clennin¹, Alexander C. McLain¹, Keith G. Huret², Bruce H. Jones², Mark A. Sarzynski, FACSM¹, Daniel B. Bornstein³. ¹University of South Carolina, Columbia, SC. ²US Army Public Health Center, Aberdeen Proving Ground, MD. ³The Citadel, The Military College of South Carolina, Charleston, SC.
 Email: grieveg@email.sc.edu
 (No relationships reported)

PURPOSE: To characterize the cardiorespiratory fitness (CRF) levels of US Army recruits by state. **METHODS:** Data on US Army recruits from all 50 states and Washington, DC who entered basic combat training (BCT) between 2010-2013 were provided by the US Army Public Health Center. CRF was assessed in a subset of recruits from their first diagnostic Army Physical Fitness Test during BCT by two-mile run time (run time) in minutes. States were ranked into quartiles based on median run times of recruits from that state aged 17 - 35 yrs in the total sample and stratified by sex. **RESULTS:** A total of 168,160 recruits (79.46% male) were analyzed. Median age, BMI, and run time were 20.0±3.6 years, 24.4±3.6kg/m², and 16.2min (range of 8.1-60.0 min), respectively. There were significant (p<0.0001) differences in median run time between males (16.0±2.2 min) and females (19.3±2.8 min). The distribution of median run times across states, with states ranked into one of three groups: 1) top 25% (lowest run times/highest CRF), 2) middle 50%, and 3) bottom 25% (highest run times/lowest CRF); is shown for the overall sample and by sex in Figure 1. Of the 14 states in the bottom 25% of median CRF in the total sample (Figure 1A), 11 of them were from the southern/southeastern regions (AL, AR, FL, GA, LA, MS, NC, OK, SC, TN, TX). These 11 states remained in the bottom 25% of median CRF in models stratified by sex (Figure 1B-C), with the exception being KY replacing OK in models restricted to male recruits (Figure 1C). **CONCLUSION:** The CRF levels of US Army recruits entering BCT differ by state. Our results show that recruits from the southern and southeastern states tended to have lower CRF compared to recruits from the rest of the country. This is relevant given previously established associations between CRF and training-related injuries sustained during BCT. Investigating state level factors contributing to the fitness of Army recruits (and theoretically all state residents of a given age-range) is an important next step.

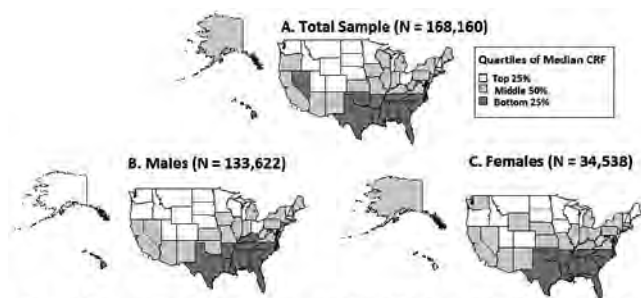

Figure 1. States ranked by quartiles of cardiorespiratory fitness based on median 2-mile run times of US Army recruits entering basic training from 2010-2013 (A-total sample), as well as separately in male (B) and female (C) recruits.

Dose Dependent Increases in Electrodermal Activity During Exercise in Military Men: Absolute Versus Relative Workloads

Shiloh Fuller. *Naval Health Research Center/Leidos, San Diego, CA.* (Sponsor: Dr. Marcus K. Taylor, FACSM)
 Email: shilohfuller@gmail.com

(No relationships reported)

Preliminary evidence suggests that electrodermal activity (EDA) is a prospective surrogate marker of sympathetic nervous system (SNS) activity during exercise. However, the validity of EDA in the context of aerobic exercise must be established before its translational potential can be realized. **PURPOSE:** To evaluate the validity of EDA as a measure of SNS activity during exercise and the moderating effects of aerobic fitness utilizing absolute (AW) and relative (RW) workloads. **METHODS:** Forty healthy, U.S. Navy active duty males (age: 36.2±6.9 yrs) completed a graded exercise test to assess maximal oxygen consumption (VO_{2max}). EDA was recorded at baseline, during exercise, and seated recovery. Relative changes were compared with baseline. A median split established the high-fit (AW: n=11, VO_{2max} 48.9±1.9; RW: n=20, VO_{2max} 50.5±4.3) and low-fit groups (AW: n=13, VO_{2max} 43.6±2.1; RW: n=20, VO_{2max} 41.1±2.7). A 2 (group) x 6 (stage) repeated measures ANOVA evaluated EDA changes across stages of exercise, as well as between fitness levels. To evaluate validity, EDA responses of high-fit and low-fit men measured by AW and RW were then compared to the established literature characterizing plasma catecholamine responses during exercise. **RESULTS:** Mean percent changes from baseline for AW were +71.1 to +107.4% from stages 1-4, with a decrease in seated recovery (+88.3%) ($p<0.001$, $\eta^2=0.38$), and for RW were +78.1 to +120.3% from 25% to 100% VO_{2max} , with a decline in seated recovery (+105.5%) ($p<0.001$, $\eta^2=0.24$). A significant interaction between fitness and workload was observed for RW ($p=0.003$, $\eta^2=0.11$). Specifically, high-fit showed a linear increase in EDA from 25 to 100% VO_{2max} , with a steady decrease into seated recovery. By contrast, low-fit maximal EDA response occurred at 75% VO_{2max} , followed by a blunted decline in seated recovery. This interaction did not prevail using AW ($p>0.05$). **CONCLUSION:** Similar dose dependent increases in EDA were observed utilizing AW and RW, although RW alone captured a rise in high-fit EDA above low-fit at maximal exertion. The noted differences between high-fit and low-fit men measured by AW and RW emulate the established literature characterizing plasma catecholamine responses during exercise. These findings imply that EDA is a potentially valid proxy of SNS activity during exercise.

Identifying The Critical Tasks Of The Raf Regiment
 James Treweek¹, Gemma Milligan², Mike Tipton², Sam Smithson¹. ¹Royal Air Force, High Wycombe, United Kingdom. ²Portsmouth University, Portsmouth, United Kingdom.
 Email: james.treweek@outlook.com
 (No relationships reported)

The Royal Air Force Regiment (RAF Regt) delivers the ground close combat role for the RAF, protecting airfield assets and personnel. There is a requirement for a Physical Employment Standard for the RAF Regt and identifying the critical tasks is the essential first step in this process.

PURPOSE: To identify the critical tasks of the RAF Regt including the method of best practice (MOBP) and minimum acceptable standard (MAS) for undertaking these tasks. **METHOD:** Task Analysis Questionnaires (TAQ), were sent to 13% (n=530) of the RAF Regt. SME focus groups were conducted to describe the critical tasks in a realistic scenario and identify a MOBP and MAS. A Military Judgement Panel (MJP) was asked to review the proposed critical tasks. The authorised critical tasks were presented to a further focus group of SME to finalise the scenario for each task, the MOBP and MAS. **RESULTS:** 279 TAQ were returned providing 1849 task descriptions, allocated to 22 generic task categories. SME identified the most physically demanding critical tasks, which were presented to the MJP for endorsement. A final SME focus group provided the following description, including a MOBP and MAS, for each endorsed task as follows:

Tactical Advance to Battle: Carrying total weight 47.1 kg, walk over mixed terrain for 16 km at 2-4 km.h⁻¹ moving tactically including pausing to make observations and taking regular navigation checks.
 Point of Entry: climb over/through 1.2 m wall/window unaided.
 React to Effective Enemy Fire: assault and withdraw, conduct fire and movement over 200 m in 5-10 m bounds, zig-zag movement.
 Casualty Evacuation (CASEVAC) - One person drag under fire: sprint to casualty 15 m away then drag casualty (total weight 116.5 kg), for 15 m to a point of cover.
 CASEVAC - Fireman's carry: after removing casualty's daysack, lift with assistance a casualty weighing 107.9 kg, then fireman carry 100 m out of immediate danger area.
 CASEVAC by stretcher: in a team of 4, carry a casualty (total weight 107.9 kg) on a stretcher over difficult terrain for 1 km.
 Construct a defensive position: as part of a section, for 6 hr period construct a sangar on the second floor of a building, including lift, lift and carry sandbags.
CONCLUSION: The critical tasks of the RAF Regt have been established. The MOBP and MAS are currently being established for these tasks.

 (No relationships reported)

The first stage to develop role-related, gender-free Physical Employment Standards (PES) is to identify and describe the physically demanding tasks undertaken in a role. **Purpose:** To identify the essential physically demanding tasks undertaken by Royal Marines (RM). **Methods:** 158 male RM volunteered and data were collected in two parts. Part 1: A facilitated two-day focus group where subject matter experts (SMEs; from ranks of Private to Major) generated a list of essential physically demanding tasks undertaken in the RM role. Part 2: 149 participants (5% of each rank in the incumbent RM force) were presented the SME tasks list and identified if they had completed the task, the task importance (1-6 scale, not applicable - critical) and physical demands (1-6 scale, very light - maximum). **Results:** The focus group participants identified 23 tasks and the task completion rate, importance and physical demands were rated in the survey (Table 1).

Table 1 - RM tasks with survey data [data presented as mode (range)]

TASK DESCRIPTION	COMPLETED THE TASK? (%)	IMPORTANCE (1-6)	PHYSICAL DEMAND (1-6)
Battle Preparation – Moving Stores and Equipment	89	6 (5)	4 (5)
Establish a Company Defensive Position	89	5 (5)	5 (5)
Reconnaissance Patrol from a Harbour Area / Defensive Location	100	6 (2)	4 (6)
Establish an Observation Point (OP) Screen	81	6 (5)	5 (4)
Company Attack	96	6 (4)	5 (4)
Casualty Drag from Point of Wounding to Point of Cover	91	6 (3)	5 (5)
Casualty Evacuation – Fireman’s Carry	97	6 (4)	5 (3)
Casualty Evacuation by Light Weight Stretcher	95	6 (3)	5 (3)
Movement Through Ship With Load	79	5 (5)	4 (5)
Amphibious Transit by Small Craft	83	6 (5)	3 (5)
Re-embark an Offshore Raiding Craft from the beach	97	6 (5)	3 (5)
Vertical Assault	95	6 (5)	5 (5)
Ski March	37	5 (5)	5 (4)
Snow Shoe March	34	5 (5)	5 (3)
Ski-joring (on skis, pulled by vehicle)	30	5 (5)	4 (4)
Long Distance Insertion March	98	6 (5)	5 (5)
Boarding Operations – Surface to Vessel	41	5 (5)	4 (5)
Boarding Operations – HELO to Vessel	42	5 (5)	3 (4)
Barrel Change in a Jackal	30	6 (5)	4 (5)
Lift HMG on to Viking/ Jackal	37	5 (5)	3 (5)
River crossing	98	5 (5)	3 (5)
Ice Breaking	33	5 (5)	4 (5)
Urban Operations	98	6 (5)	4 (5)

Conclusion: The essential physically demanding tasks identified in this study can be used to select those most critical to the RM role, and underpin the development of future relevant role-related PES.

375 Board #196 May 31 9:30 AM - 11:00 AM
The Potential for Sex Bias in Physical Employment Test Design
 Piete E.H. Brown¹, Sophie E. Britland¹, Jules Stevenson², Barry Sloan², Dean Simpson², Fran Gunner¹, Joanne L. Fallowfield¹.
¹Institute of Naval Medicine, Gosport, United Kingdom. ²Royal Navy, Portsmouth, United Kingdom.
 Email: NAVYINM-EMSAP2@mod.uk
 (No relationships reported)

Physical employment tests often simulate job-related tasks. The implementation of such tests can be constrained by cost, ease, and simplicity, which may unintentionally create a sex bias. **PURPOSE:** To investigate potential sex bias in prototype UK Royal Navy (RN) physical employment tests. **METHODS:** One hundred and fifty RN personnel volunteered (men n=75, women n=75). Physical characteristics, mean ± SD were (men vs. women): age 32 ± 8 vs. 29 ± 6 years; stature 1.77 ± 0.06 vs. 1.65 ± 0.05 m; body mass 81.0 ± 10.7 vs. 67.5 ± 9.8 kg. Five tests were developed with cylindrical, sand-filled Powerbags that simulated manual handling tasks performed onboard RN warships. Tests included two variants of an Aft Casualty Carry (35.0 kg and 41.5 kg, 10 m), Fore Casualty Carry (27.0 kg, 10 m), Foam Drum Carry (2 × 21.6 kg, 60 m), and Damage Control Timber Carry (28.4 kg, 50 m). Loads and distances were derived from equipment, infrastructure, Subject Matter Expert opinion, and anthropometric norms. Tests were performed as quickly as possible. A sub-sample

of women (n=19) also performed a modified Aft Casualty Carry test using a *Barbell* (circumference 0.08 m) instead of a *Powerbag* (circumference 0.91 m). Cut-scores were developed for all tests. **RESULTS:** All men (100%) passed all tests. Compared to men the pass rates of women were above 80% in three tests (Fore Casualty Carry (88%), Foam Drum Carry (92%), Damage Control Timber Carry (89%)), but lower than 80% in both Aft Casualty Carry tests (29% 35.0 kg test; 8% 41.5 kg test). The lifting phase accounted for the majority of Aft Casualty Carry failures (49% 35.0 kg test; 77% 41.5 kg test). Within the sub-sample (n=19), 100% of women successfully lifted the *Barbell* Aft Casualty Carry loads, but markedly less lifted the same loads in the *Powerbag* version of the test (58 % and 32 % in the 35.0 kg and 41.5 kg tests, respectively). **CONCLUSIONS:** The larger circumferential girth of the *Powerbag* in the Aft Casualty Carry test was not representative of the anthropometric dimensions of a casualty, and appeared to create a sex bias against women. This highlights the potential risk of sex bias if physical employment test implementation considerations are prioritised above the faithful replication of simulated job-based tasks.

Fitness Trumps Gender; Next Fit Soldier Up
 Todd A. Crowder¹, Michael F. Kloepper², Ian B. MacPherson².
¹US Military Academy, West Point, NY. ²173rd Airborne Brigade, Vicenza, Italy.
 Email: todd.crowder@usma.edu
 (No relationships reported)

The full integration of women into combat arms & relatively limited force structure demands every Soldier be a premium physical performer. **PURPOSE:** Investigate the role of fitness & gender integration of unit Soldier Performance Index (SPI) scores of a “mock” Airborne unit. **METHODS:** 71 subjects; 69 Airborne men; 26 officers (Rock LT), 43 soldiers (Rock S), 2 selected U.S. Service Academy female cadets (FC); tested on the SPI: Strength: Cadence Pull-ups {CPU}; 155-lb Bench Press {155BP}; Muscular Endurance: 65-lb BP {65BP}; 45-lb Dumbbell Squat {45SQ}; Endurance/Mobility: 2 Mile Run {2MR}; 300-Meter Forward/Backward Run (300M). APFT: (2-Min. Push-ups, Sit-ups, 2MR). Composite scores tabulated SPI scoring, age-gender scoring (APFT). Ten member mock units were created with highest Officer & different combinations of 9 highest Soldiers (HOS), 8 highest soldiers & highest female (H8F) 7 highest soldiers & 2 highest female soldiers (72F), 9 lowest male soldiers (LOS). **RESULTS:** Using SPI as true indicator of robust fitness profile, group affiliations & mean performances revealed HOS as highest physical performance. No significance was found between 3 groups (HOS, H8F, 72F), LOS group was significantly lower (p = .001) versus all 3 former groups. APFT paralleled SPI measure (p = .002). Objectively examining a multitude of physical indices, LOS achieved 78% of HOS, H8F achieved 98.5% of HOS ability & 72F achieved 96.7% HOS ability. Importantly H8F & 72F had only mean 80.7% of strength ability of HOS group. FC were only 68.4 % of SPI ability of the mean Rock LT group yet 17.6% greater ability than Rock LT group on APFT. **DISCUSSION:** Universal indicators of fitness, (i.e. SPI) are more critical to predicting performance in ground combat units than gender as a single variable. SPI indicated 2 FC were 19.1% higher than 9 LOS, however related to strength (155BP), the fit 2 FC had 0 reps compared to mean of 5.2 reps for the LOS. APFT, devoid of a strength measure, indicates FC to be 29.4% greater than LOS. **CONCLUSIONS:** In physical performance of ground combat units, SPI is more illuminative than either gender or current APFT. Integration of Airborne units should be based on an index similar to the SPI; minimally, the index should include valid measures of endurance, mobility & perhaps most importantly a strength metric.

Gender Differences in British Army Infantry Representative Military Task Performance
 Sam D. Blacker¹, Sarah L. Coakley¹, Ella Walker¹, Beverly Hale¹, Sarah Jackson², Julie P. Greeves², Russ Roberts², Stephen D. Myers¹.
¹University of Chichester, Chichester, United Kingdom. ²Army HQ, Andover, United Kingdom.
 Email: s.blacker@chi.ac.uk
 (No relationships reported)

British Army Infantry personnel must currently pass three Representative Military Tasks (RMTs) at the of end training: (1) A Loaded March (LM; 12.8 km, carrying 25 kg, <2 h); (2) A Jerry Can Carry (JCC; two 20 kg jerry cans for 150 m); and a Single Lift (SL; 40 kg Powerbag™ from the floor on to a 1.45 m platform). Female personnel have not previously been permitted to serve in Infantry roles in the British Army. Therefore, differences in RMT performance between serving male and female British Army personnel to an Infantry standard have not been examined. **Purpose:** To evaluate differences in RMT performance between male and female British Army personnel to an Infantry standard. **Methods:** 135 participants [48 female (age; 27 ± 5 y; body mass; 66.5 ± 8.4 kg; 2.4 km run time 11:11 ± 01:01 min:s) and 87 male (age; 25 ± 4 y; body mass; 78.8 ± 10.1 kg; 2.4 km run time 09:43 ± 00:42 min:s)] completed two sessions separated by at least 7 days. Session 1: Height, body mass, and body composition measured using dual energy X-ray absorptiometry (DXA). Participants

also completed the SL and JCC RMTs and a 2.4 km run to an individual best effort. Session 2: Participants completed a 12.8 km LM carrying 25 kg (6.4 km paced in 60 min and 6.4 km individual best effort). Participants wore a heart rate monitor during all physical tests. Differences between genders were compared using independent sample t-tests. Data are presented as the mean \pm SD and significance set at $p < 0.05$. **Results:** Compared to female participants, male participants had faster 2.4 km run times ($p < 0.01$), greater body mass ($p < 0.01$), greater total lean body mass ($p < 0.01$), higher SL scores ($p < 0.01$), achieved greater JCC distances ($p < 0.01$) and faster LM times ($p < 0.01$). All male participants and 13 % of female participants achieved the Infantry standard across all three RMTs. A greater proportion of male compared to female participants achieved the Infantry RMT standards for the SL (97 vs 15 %), Carry (99 vs. 58 %) and LM (100 vs. 83 %). **Conclusion:** Male personnel had higher RMT performance scores than females, however some women outperformed the men. The greatest gender differences in meeting Infantry RMT pass standards was for the SL. Therefore, future physical training programmes to support female personnel to meet Infantry RMT standards should focus on developing muscle strength.

378 Board #199 May 31 9:30 AM - 11:00 AM
Sex Differences in Training Load During British Army Phase One Training

Stephen J. McGuire, Samantha C. Saunders, Thomas J. O'Leary, Rachel M. Izard. *HQ Army Recruiting and Training Division, Ministry of Defence, UK, Upavon, United Kingdom.*
 Email: ARTD-OccMed-RA2@mod.uk
 (No relationships reported)

The initial weeks of British Army Phase One training are characterised by unaccustomed exercise and rapid increases in training load. Quantifying training load can aid in managing fatigue and minimising the risk of developing illness and injury whilst maximising training adaptation. Women are at increased risk of musculoskeletal injury during British Army Phase One training compared to men, however the differences in absolute external and relative internal training loads between sexes during the first few weeks of training is unknown. **PURPOSE:** Quantify the sex differences in external (distance and speed) and internal (ratings of perceived exertion [RPE] and heart rate [HR]) training loads during the first two weeks of British Army Phase One training. **METHOD:** Following completion of an initial medical assessment, 26 female (21 ± 4 yrs, 61.8 ± 8.4 kg, 1.64 ± 0.05 m, $12:29 \pm 1:01$ min 1.5 mile run time) and 24 male recruits (22 ± 4 yrs, 77.6 ± 9.7 kg, 1.78 ± 0.08 m, $10:30 \pm 1:03$ min 1.5 mile run time) were fitted with a combined HR and GPS device (Polar Team Pro, Polar Electro Oy, Finland) and monitored during waking hours (06:00 – 22:00 hrs) for the first 10 days of training. Daily self-reported RPE, muscle soreness and fatigue (all 0-10) were recorded. Independent samples t-tests were conducted to examine sex differences. **RESULTS:** Male recruits covered significantly more distance per day than female recruits (13.31 ± 0.83 km vs. 10.85 ± 0.70 km, $P < .001$) and at a greater mean speed (0.88 ± 0.05 km·h⁻¹ vs. 0.74 ± 0.03 km·h⁻¹, $P < .001$). Mean % HR reserve (%HRR) and RPE were not significantly different between men and women (%HRR: men 31 ± 3 vs. women 32 ± 4 , RPE: men 4 ± 1 vs. women 4 ± 1). However, female recruits reported significantly greater physical fatigue (men: 4 ± 1 , women: 6 ± 2 , $P < .001$) and muscle soreness (men: 4 ± 1 , women: 5 ± 2 , $P < .05$). **CONCLUSION:** Despite a lower absolute external training load and similar internal training loads, women reported greater fatigue and muscle soreness, which could be linked to a higher injury risk. Future work should examine the links between fatigue and muscle soreness with injury risk during the first few weeks of initial military training.

This research has been sponsored by the UK MOD (Army).

Diurnal Pattern of Salivary C-Reactive Protein and Associations with Biobehavioral Correlates in Military Men

Lisa M. Hernández, Marcus K. Taylor, FACSM. *Naval Health Research Center, San Diego, CA.* (Sponsor: Marcus K. Taylor, FACSM)
 Email: lisa.m.hernandez75.ctr@mail.mil
 (No relationships reported)

C-reactive protein (CRP), a systemic inflammatory biomarker, is positively associated with the development of disease and inversely correlated with regular physical activity. CRP has been previously reported to have a diurnal rhythm with higher levels upon awakening and lower levels thereafter.

PURPOSE: To characterize the pattern of salivary CRP and evaluate associations with sedentary and active behaviors in U.S. Navy men. **METHODS:** Healthy, active duty men ($n = 17$; mean \pm SD age = 36.1 ± 6.0 yr) self-collected samples in a free-living setting using oral swabs on 2 consecutive workdays at Wake, Wake + 30 min, Wake + 60 min, 1600, and 2100 for a total of 10 samples. Following our prior published study, CRP variables and summary parameters were computed. Stability across both days was evaluated via Pearson product-moment correlational analyses. Stable measures

were then correlated to self-reported percent time (%time) spent sedentary, or active, in a typical workday for the previous week. Three non-responders, defined as having an absolute reactivity (AR) > 0 , were excluded from analyses. **RESULTS:** Stability was high between both days at all time points (r value range = $.75-.92$, all $p \leq .001$). CRP was highest at Wake, decreased on average by $42.8 \pm 5.7\%$ at Wake + 30, and then plateaued for the rest of the day. The stabilities of Wake mean ($r = .89$, $p < .001$) and AR [(Wake + 30) - Wake], a measure of CRP pattern ($r = .48$, $p = .053$), were determined. Mean \pm SE of Wake mean was $12,460 \pm 3968$ pg/mL and AR was -8298 ± 3123 pg/mL. Wake mean was strongly associated with %time walking ($r = -.57$, $p < .01$). Wake mean also showed an intuitive yet nonsignificant positive association with %time sitting, and a negative association with both %time standing and %time performing heavy labor. Hypothesized associations between %time and AR were not performed due to the borderline stability of AR. **CONCLUSIONS:** In a military population, the salivary CRP pattern was described as diurnal with robust stability across 2 consecutive days. The negative correlation between Wake mean and %time walking suggests that walking is a powerful modality to reduce systemic inflammation. Subsequent analyses will comprehensively characterize the CRP pattern (area under the curve and other summary parameters) and evaluate additional biobehavioral correlates.

380 Board #201 May 31 9:30 AM - 11:00 AM
The “Yin and Yang” of the Adrenal and Gonadal Systems in Elite Military Men

Marcus K. Taylor¹, Lisa M. Hernández¹, Shiloh A. Kviatkovsky¹, Matthew R. Schoenherr¹, Michael S. Stone², Paul Sargent³. ¹Naval Health Research Center, San Diego, CA. ²Purdue University, San Diego, CA. ³Naval Special Warfare Center, San Diego, CA.
 Email: marcus.k.taylor2.civ@mail.mil
 (No relationships reported)

We recently established daily, free-living profiles of the adrenal hormone cortisol (Cort), the (primarily adrenal) anabolic precursor dehydroepiandrosterone (DHEA), and the (primarily gonadal) anabolic hormone testosterone (Testo) in elite military men. A prevailing view is that adrenal and gonadal systems reciprocally modulate each other; however, recent paradigm shifts prompted the characterization of these systems as parallel, cooperative processes (i.e., the “positive coupling” hypothesis). **PURPOSE:** To test the positive coupling hypothesis in elite military men by evaluating associations between adrenal and gonadal biomarkers across the day. **METHODS:** Fifty-seven healthy, active duty men (mean \pm SE age = 33.4 ± 1.0 yr) self-collected salivary hormone samples in a nondeployed, free-living setting on two consecutive midweek workdays upon waking, +30 min, +60 min, 1600, and 2100 (10 samples total). Hypotheses were tested using correlational and linear regression models. **RESULTS:** DHEA was positively coupled with Cort (r range: $0.28 - 0.30$, all $p < .05$) as was Testo (r range: $0.43 - 0.59$, all $p < .01$). Anabolic processes (i.e., DHEA, Testo) were also positively and reliably coupled across the day (r range: $0.31 - 0.39$, all $p < .05$). In multivariate models, DHEA and Cort combined to account for 27 - 43% variance in Testo across the day, which was driven primarily by DHEA. DHEA and Testo modestly and less robustly predicted Cort concentrations; this was confined to the morning (area under the curve, ground $F(3,51) = 2.9$, $p < .05$), and Testo was the primary predictor ($\beta = 0.38$, $p < .05$). **CONCLUSION:** To our knowledge, this is an unprecedented test of the positive coupling hypothesis in elite military men, a group at an elevated risk for chronic stress exposure. This study showed that adrenal and gonadal systems were positively coupled. Altogether, top-down co-activation of adrenal and gonadal hormone secretion may complement bottom-up counter-regulatory functions to foster anabolic balance and neuronal survival; hence, the “yin and yang” of adrenal and gonadal systems. This may be an adaptive process that is amplified by stress, competition, and/or dominance hierarchy.

 (No relationships reported)

BACKGROUND: Vitamin D has been implicated in modulating innate immunity and may confer protection against upper respiratory tract infections (URTIs) during periods of arduous training. **PURPOSE:** Determine whether vitamin D status in Marine Corps basic training recruits is associated with URTIs, and whether daily vitamin D supplementation decreases the incidence of URTIs as a result of augmented innate immunity. **METHODS:** A double-blind RCT was conducted with male and female recruits entering Marine Corps basic training. Subjects were randomized to

either 1000 IU vitamin D₃-d¹ (n=73) or placebo (n=76) for 12-weeks. At baseline, weeks 4, 8 and 12 (post-training) subjects provided saliva samples (passive drool) to determine secretory immunoglobulin A secretion rates (SIgA-SR) by indirect ELISA. The incidence of URTIs was assessed by administering a survey at weeks 4, 8 and 12. Serum vitamin D status (25(OH)D) was measured by radioimmunoassay. Longitudinal linear models were created using a simple-effects model to estimate symptoms. To determine whether supplementation altered SIgA-SR during training, a two-way repeated measures ANOVA was used. **RESULTS:** The proportion of recruits reporting URTI symptoms at any time during training was 72%. Baseline SIgA-SR were similar between placebo (65.4 ± 52.0 µg·min⁻¹) and vitamin D groups (51.9 ± 41.9 µg·min⁻¹). The relative changes in SIgA-SR were significantly greater with vitamin D supplementation at weeks 4 (5.1 ± 29.8%) and 8 (12.3 ± 31.0%) compared to placebo at the same time points (week 4; -6.5 ± 22.9% and week 8; 1.3 ± 22.9%), *p* = 0.001. Baseline 25(OH)D was significantly lower during winter (59.2 ± 22.5 nmol·L⁻¹) compared to summer (80.4 ± 21.0 nmol·L⁻¹), *p* < 0.001. When accounting for treatment, season and sex, there was no association between 25(OH)D and reported URTIs. **CONCLUSION:** We report that a high proportion of Marine Corps recruits experience URTIs during 12-weeks of basic military training, and although daily vitamin D supplementation led to a modest increase in SIgA-SR, this did not result in a reduction in the incidence of reported URTIs. A-50 Free Communication/Poster - Muscle and Mitochondria

Wednesday, May 31, 2017, 7:30 AM - 12:30 PM
Room: Hall F

382 Board #203 May 31 11:00 AM - 12:30 PM Alterations of Mitochondrial Dynamics Proteins in Primary Human Myotubes Following Roux-en-Y Gastric Bypass Surgery

Kai Zou¹, J. Matthew Hinkley², Sanghee Park², Donghai Zheng², G. Lynis Dohm², Joseph A. Houmard, FACSM¹. ¹University of Massachusetts Boston, Boston, MA. ²East Carolina University, Greenville, NC.
Email: kaizou1@gmail.com
(No relationships reported)

Mitochondrial dynamics including mitochondrial fission (e.g., Dynamin-related protein 1 (Drp1) and Fission 1 (Fis1)) and fusion (e.g., Mitofusin 2) regulates mitochondrial homeostasis. Defects in mitochondrial dynamics are suggested to contribute to skeletal muscle mitochondrial dysfunction and insulin resistance associated with obesity and Type 2 Diabetes. Roux-en-Y gastric bypass (RYGB) surgery markedly improves metabolic health as indicated by enhanced substrate oxidation and insulin action in skeletal muscle. However, the underlying cellular mechanisms responsible for these improvements are not clear and could possibly be due to the improvement of mitochondrial dynamics. **PURPOSE:** The purpose of this study was to determine whether RYGB surgery improves mitochondrial dynamics proteins in primary human myotubes derived from severely obese humans. **METHODS:** Primary human skeletal muscle cells were isolated from muscle biopsies obtained from six lean subjects (BMI = 23.4 ± 0.6 kg/m²) and six RYGB patients prior to, 1-month and 7-months after surgery (BMI = 50.2 ± 2.0, 43.2 ± 2.8 and 35.7 ± 2.2 kg/m², respectively) and were differentiated to myotubes. On day 7 of differentiation, myotubes were harvested for immunoblot analysis in order to assess the expressions of mitochondrial dynamics proteins. **RESULTS:** Before surgery, Drp1 Ser⁶¹⁶ phosphorylation and Fis1 protein expression were significantly higher in primary myotubes derived from severely obese patients when compared to lean controls (41% and 26%, respectively, *P* < 0.05). While there were no significant improvements at 1-month post-surgery, Drp1 Ser⁶¹⁶ phosphorylation and Fis1 protein expression were significantly decreased in primary myotubes from severely obese humans at 7-months post-surgery (Pre vs. 7-months post: 0.046 ± 0.004 vs. 0.035 ± 0.003; 0.023 ± 0.008 vs. 0.014 ± 0.003 AU; respectively, *P* < 0.05), and not statistically different from lean controls. However, MFN2 protein expression did not change in primary myotubes derived from severely obese patients at any timepoint post-surgery in comparison to pre-surgery. **CONCLUSION:** These data suggest that RYGB surgery reduces obesity-induced rise in mitochondrial fission, but not fusion, protein expression in primary human myotubes derived from severely obese humans.

383 Board #204 May 31 11:00 AM - 12:30 PM Osteocalcin Does Not Increase Insulin Sensitivity or Mitochondrial Biogenesis in Palmitate Treated C2C12 Myotubes

Hailey A. Parry, Roger A. Vaughan, Kyle L. Sunderland. *High Point University, High Point, NC.*
Email: parryh13@highpoint.edu
(No relationships reported)

PURPOSE: Osteocalcin (OC) is a bone matrix protein that has been shown to regulate systemic glucose homeostasis and increase mitochondrial mass in mice fed a high-fat diet, however the mechanisms by which OC stimulates metabolic adaptations in lipid overloaded muscle remain underexplored. This study examined the effects of OC on regulators of insulin signaling, glucose handling, and mitochondrial biogenesis *in vitro* using palmitate treated C2C12 myotubes.

METHODS: C2C12 myotubes were treated with control media, or media containing undercarboxylated OC (100ng/ml) both with and without 2mM palmitate-BSA conjugate (PA+OC and PA, respectively) for 24 hours. Insulin signaling (IRS-1, pIRS-1, Akt, pAkt, and PTP1B), glucose handling (GLUT-4 and AS160) and mitochondrial biogenesis (PGC-1 α and Citrate Synthase) were measured via western blot. One-way ANOVAs with Tukey's post-hoc tests performed to determine between treatment differences.

RESULTS: IRS phosphorylation and PTP1B protein content remained unchanged. Surprisingly, phosphorylation of Akt significantly increased (52% ± 33%) with PA+OC compared to OC. Additionally, GLUT4 content decreased significantly in all treatments (≥50%) compared to control with no differences between the treatments. GLUT4 regulator AS160 was significantly elevated (300% ± 158%) following PA+OC compared to OC. No changes in PGC-1 α or Citrate Synthase protein content were observed.

CONCLUSIONS: Overall, treatment with OC was unable to improve markers of insulin signaling and mitochondrial biogenesis in palmitate-treated C2C12 myotubes. Moreover, GLUT4 content and possibly translocation may be negatively affected by OC treatment in PA-treated cells.

384 Board #205 May 31 11:00 AM - 12:30 PM MKP-5 Establishes Skeletal Muscle Metabolic Quiescence by Negatively Regulating MAPK-dependent Mitochondrial Function

Kisuk Min, Anton M. Bennett. *Yale University, New Haven, CT.*
Email: kisuk.min@yale.edu
(No relationships reported)

Purpose: The mitogen-activated protein kinases (MAPKs) represent a central signaling pathway in the regulation of skeletal muscle function. It is also known that MAPKs are required to promote mitochondrial biogenesis in skeletal muscles. Mitochondrial dysfunction underlies numerous diseases including those of skeletal muscle. The MAPKs are negatively regulated by MAPK phosphatases (MKPs). We have demonstrated that MKP-5 regulates regenerative myogenesis and rescues muscle degeneration by inactivating and dephosphorylating both p38 MAPK and JNK. However, the physiological and molecular roles of MKP-5 in regenerative myogenesis and progression of skeletal muscle degeneration have remained unclear. We tested the central hypothesis that MKP-5 regulates mitochondrial function and thus contributes to enhanced myogenesis and regeneration in mice lacking MKP-5. **Methods:** To test our hypothesis, we induced skeletal muscle damage by cardiotoxin (CTX) injection into both *mkp-5^{+/+}* and *mkp-5^{-/-}* mice. Mitochondrial respiratory function in permeabilized muscle fibers was assessed in regenerating skeletal muscles from *mkp-5^{+/+}* and *mkp-5^{-/-}* mice. Mitochondrial biogenesis was determined by quantitative PCR for mRNA. The amount of mitochondrial DNA (mtDNA) copy number was also quantified by qRT-PCR. **Results:** Our data show that MKP-5-deficient mice exhibited 49% enhanced ADP-stimulated mitochondrial respiratory function in regenerative skeletal muscle compared with *mkp-5^{+/+}* mice (*P* < 0.05). Furthermore, expression of genes associated with mitochondrial biogenesis such as PGC1- α , NRF-1, Tfam, and subunits of complex I were significantly increased in regenerating skeletal muscles of animals lacking MKP-5. The amount of mitochondrial DNA copy number was also significantly increased in *mkp-5^{-/-}* mice, compared with *mkp-5^{+/+}* mice (*P* < 0.001). **Conclusions:** Collectively, these results demonstrate that MKP-5 negatively regulates mitochondrial function and biogenesis in skeletal muscle during myogenesis and regeneration.

385 Board #206 May 31 11:00 AM - 12:30 PM
Mitochondria Content In Rat Ankle Extensor Muscles Following Chronic Endurance Exercise

Peter Christopher, Joseph W. Starnes, FACSM, Douglas J. Oberlin, Mariel Fecych, Coleman Murray, Lauren Vervaecke, Anthony Bocchine, J Lee Beverly. *University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Joseph W. Starnes, FACSM)

(No relationships reported)

Endurance exercise studies involving animals typically measure muscle mitochondria content to verify intensity of training. Most use one of the three calf ankle extensor muscles, which vary in fiber type. The soleus is all slow twitch fibers (SO) while the plantaris and gastrocnemius are a mixture of fast twitch glycolytic (FG) and fast oxidative glycolytic (FOG) fibers. **PURPOSE:** To compare mitochondria content changes in the soleus, plantaris, and gastrocnemius in response to a widely used moderate intensity exercise program. **METHODS:** Male, 8-wk-old, Sprague-Dawley rats were divided into two groups: sedentary (S) and exercised (E) on a treadmill 5 d/wk for 6 wks. Exercise duration and intensity were progressively increased to 1 hr at 30 m/min up a 10.5% incline (75-80% VO_2max). Whole muscles plus specific FG and FOG regions of gastrocnemius were homogenized (9-10 for each muscle or fiber type) and cytochrome *c* oxidase activity, a marker of mitochondria content, was determined using a Clark-type oxygen electrode. **RESULTS:** E significantly increased cytochrome *c* oxidase compared to the same S muscle ($P<0.05$) and the amount of increase was similar for all muscles ($P>0.05$). On a relative basis (% above mean S value), the increases were 60.7 ± 13.3 (mean \pm standard error) in soleus, 72.3 ± 6.8 in plantaris, and 78.7 ± 12.4 in gastrocnemius. On an absolute basis ($\mu\text{Mol O}_2$ consumed/min/gram muscle), the increases were 28.5 ± 6.3 in soleus, 35.0 ± 3.3 in plantaris, and 25.7 ± 3.8 in gastrocnemius. E was also greater than S in all fiber types considered ($P<0.05$), but there were considerable differences in the amount of increase. On a relative basis (%), the increase in FOG fibers (115.5 ± 17.0) was significantly greater ($P<0.05$) than those in SO (60.7 ± 13.3) or FG (42.8 ± 12.0). On an absolute basis, all fibers differed from each other with FOG increasing the most and FG the least ($P<0.05$). Specifically, FOG increased by 53.4 ± 7.9 , SO by 28.5 ± 6.3 , and FG by only 5.1 ± 1.4 . **CONCLUSION:** All three whole muscles increase by similar amounts in response to a moderate intensity (75-80% VO_2max) exercise program, thus all are appropriate for verifying training status. Caution is advised when using small portions of plantaris and gastrocnemius because of differences in responses of FOG and FG fibers.

(No relationships reported)

Myokine/Cardiokine Follistatin-like Protein 1 Promotes Oxidative MyHC Expression and Mitochondrial Function in Myogenic Cells

Follistatin-like Protein 1 (FSTL1) is a glycoprotein secreted by cardiac and skeletal muscle tissues under stressful conditions. An elevated level of plasma FSTL1 has been observed after a single bout of exercise suggesting its potential myokine-like role involved in the crosstalk between muscle and other organs. **PURPOSE:** To investigate autocrine effects of FSTL1 on myotube differentiation, myosin heavy chain expression and mitochondrial respiration in various myogenic cells. **METHODS:** Primary myoblasts were isolated from canine gastrocnemius muscle. Myotube differentiation was induced by a low serum condition for 4 days. Immunostainings were performed using MF20 antibody (rod-like tail region of myosin) and DAPI (nuclei); and fusion index was determined by calculating the ratio between total number of nuclei and number of nuclei within myotubes formed. RT-PCR assays were performed using primer sets precisely designed to amplify each fiber type-associated myosin heavy chain isoforms. Oxygen consumption of intact cells were measured using a Clark-type oxygen sensor; and mitochondrial respiration was measured using Seahorse XF96 analyzer. **RESULTS:** During canine myotube formation, FSTL1 treatment (300 ng/ml, 4 days) significantly enhanced myogenic potential determined by fusion index (~2-fold increase). There was a significant increase in MyHC7 expression (~1.5 fold) in myotubes treated with FSTL1 during differentiation compared to non-treated myotubes. Acute FSTL1 treatment (up to 500 ng/ml) had no significant effect on mitochondrial respiration in canine myoblasts. Acute FSTL1 treatments (250 ng/ml) significantly increased mitochondrial respiration in L6 myotubes (~1.5 fold) and human rhabdomyosarcoma cells. Chronic FSTL1 treatments (250 ng/ml, 64 hours) significantly increased oxygen consumption in intact canine myoblasts and myotubes. **CONCLUSION:** Our preliminary data suggest that FSTL1 enhances differentiation

potential and increases oxidative metabolism in myogenic cells suggesting that FSTL1 may be an important cellular mediator of the beneficial effects of exercise in the context of skeletal muscle adaptation.

Exercise Preconditioning Improves Mitochondrial Morphology and Function in Rat Loubus Fromatis after Heavy Exercise

Lu Wang, Wenqian Deng, Xue Li, Qiongjia Yuan. *Chengdu Sport Institute, Chengdu, China.* (Sponsor: Tongjian You, FACSM)

Email: 21379183@qq.com

(No relationships reported)

Our previous work has demonstrated that exercise preconditioning can ameliorate the apoptosis in Loubus Fromatis of rats induced by one-time heavy exercise.

PURPOSE: To investigate whether exercise preconditioning affects the morphology and function of mitochondria by influencing the expression of dynamin-related protein 1(Drp1) and mitofusin 2(Mfn2) in rat loubus fromatis following an acute heavy load exercise.

METHODS: Thirty-six male Sprague-Dawley rats were randomly assigned into a control group (C, n=12), an exercise group (E, n=12) and an exercise preconditioning group (EP, n=12). Groups C and E received conventional feeding for four weeks, and then group E completed a one-time heavy load swimming exercise; group EP received feeding and swimming training for four weeks, 60 min/day, 6 days/week, and also completed a one-time heavy load swimming. Some indicators were detected, such as the apoptosis index (AI), the mRNA of Drp1 and Mfn2, index related to the function of mitochondrial respiratory chain (ATP, ADP/O, V3, V4, RCR, OPR). The experimental data are reported as mean \pm SE, and *P* values<0.05 were considered significant.

RESULTS: According to the TUNEL test, the apoptosis index (AI) (C:0.06 \pm 0.01; EP:0.58 \pm 0.17; E:0.89 \pm 0.16; respectively, $P<0.05$) were significantly elevated after heavy load exercise, mRNA of Mfn2 (C:0.25 \pm 0.09; E:0.95 \pm 0.08; EP:1.24 \pm 0.07; respectively, $P<0.05$) and Drp1 (C:0.34 \pm 0.08; EP:1.23 \pm 0.14; E:1.35 \pm 0.07; respectively, $P<0.05$) were also increased. However, the ATP content, ADP/O, RCR, V3 and OPR of the loubus fromatis were significantly lower in group E and EP than C ($P<0.05$), and those index in Group EP were higher than Group E ($P<0.05$) indicates that the function of mitochondrial respiratory chain in Group EP are better after carrying out an acute heavy load exercise.

CONCLUSIONS: Results from this study suggest that one-time heavy load swimming can induce cell apoptosis in rat loubus fromatis by increasing the expression of Drp1.

Four weeks of exercise preconditioning can ameliorate the apoptosis and the function of mitochondrion via increasing the expression of Mfn2.

Energy Balance During A Self-sufficient, Multistage Ultramarathon: a Case Study

Paul Hough, James Earle. *St Mary's University, Twickenham, United Kingdom.*

Email: Paul.hough@stmarys.ac.uk

(No relationships reported)

For optimal performance, endurance athletes are recommended to ingest sufficient energy to maintain energy balance (EB) and ensure adequate energy availability (EA).

PURPOSE: Describe and evaluate the EB of an athlete competing in a self-sufficient, multistage ultra-marathon (SSMU). **METHODS:** A male endurance athlete (Age 35 yrs; Ht 183.0 cm; Body mass 78.4 kg; VO_2max 66 ml/kg/min) volunteered to take part in this observational case study prior to competing in the Marathon des Sables 2016. The participant self-reported energy intake (EI) by reviewing his dietary plan after each of the five competitive event stages. The food diary was used to calculate energy and macronutrient intake using dietary analysis software. Basal metabolic rate (BMR) was estimated prior to the MdS based on fat free mass. Distance and moving speed were recorded using a GPS device (Garmin Forerunner 920XT) throughout the race. Exercise energy expenditure (EEE) was calculated using the GPS device algorithm. Total energy expenditure (TEE) was calculated by adding the participant's RMR to

the recorded EEE. EB was calculated by subtracting IE from TEE. EA was calculated as follows: EI - EE / fat free body mass. RESULTS: Mean daily EI was 2946 ± 358 kcal (38 ± 4.6 kcal/kgBM/day). Mean daily EEE was 3006 ± 1030 kcal (62 ± 13 kcal/kgBM/day). This resulted in a total energy deficit of 9609 kcal with a mean daily energy deficit of 1922 ± 952 kcal/day. Mean EA was -0.97 ± 15.4 kcal/kg/FFM/d. The participant did not report any subjective feelings of hunger at any point during the event. CONCLUSIONS: The athlete was unable to consume enough food/fluid to meet estimated energy requirements during all five days of the SSUM, resulting in sub optimal EA and EB throughout the event. Relying on subjective perception of hunger to modulate energy intake is not an effective strategy during a SSUM. Athletes competing in a SSUM are likely to benefit from a strategic diet plan to minimise daily energy deficit and maximise performance.

Nutrition Education Improves Nutrition Knowledge, Not Dietary Habits In Female Collegiate Distance Runners

Marissa Bongers, Bryce M. Abbey, Kate A. Heelan, FACSM, Janet E. Steele, Gregory A. Brown, FACSM. *the University of Nebraska Kearney, Kearney, NE.* (Sponsor: Gregory A. Brown, FACSM)
 (No relationships reported)

BACKGROUND. In order to meet the physical demands of training for and competing in sports, athletes need to fuel their body adequately on a daily basis. Previous research, however, has indicated that the dietary habits of athletes are often insufficient regarding total energy and carbohydrate intake. Furthermore, athletes often do not know what or how much food they should eat in order to meet the nutritional demands of their sport. **PURPOSE.** The purpose of this study was to assess the effect that nutrition education focusing on total energy, carbohydrate, fat, and protein requirements has on the nutrition knowledge and dietary intake of female collegiate distance runners. **METHODS.** Eleven female collegiate Division II cross-country runners (age: 19.4 ± 1.1 years, mass: 56.65 ± 4.90 kg, height: 163.50 ± 5.22 cm) completed a nutrition knowledge for athletes survey consisting of 10 background information questions and 76 true/false statements and recorded a 3-day diet record prior to the start of the intervention. Participants were then presented with four 1-hour nutrition education sessions covering energy balance, carbohydrates, proteins, fats, and hydration. After the nutrition education intervention, participants completed the same nutrition knowledge survey and 3-day diet record. **RESULTS.** The nutrition education sessions increased (P<0.05) the participants' correct answers on the nutrition knowledge survey regarding dietary carbohydrate (45.5 ± 24.5% vs. 68.2 ± 29.8%), fat (57.6 ± 21.6% vs. 72.7 ± 20.1%) and protein (76.6 ± 9.6% vs. 93.5 ± 9.8%) intake (for pre vs. post, respectively). Although the participants were not meeting recommendations regarding total energy and carbohydrate intake before the nutrition education sessions, there were no changes in dietary composition following the nutrition education sessions. **CONCLUSION.** The present data are in agreement with previous findings indicating that enhanced nutrition knowledge does not always translate to enhanced dietary practices, even when improved dietary practices could result in improved sports performance.

In Race Nutritional Strategies Comparing Ironman Wisconsin Athletes to Ironman World Championship Athletes

Stephanie Harpenau, Elaina Biechler, Lauren Sutton. *Loras College, Dubuque, IA.* (Sponsor: Vincent Paolone, FACSM)
 Email: stephanie.harpenau@loras.edu
 (No relationships reported)

PURPOSE: The purpose of the current investigation was to compare the nutritional plans of Ironman Wisconsin athletes to elite Ironman World Championship athletes and to determine if differences exist between the two groups. **METHODS:** Athletes competing in Ironman triathlons were surveyed at Ironman Wisconsin (N=73) and the Ironman World Championships (N=79) to determine their in-race nutrition plans. Unpaired t-tests were run to examine the differences in overall finish time, calories consumed per hour on the bike, fluid consumed while biking, and caffeine consumption during the biking portion of the race. **RESULTS:** Athletes participating at the Ironman World Championships consumed significantly more (p < .01) calories per hour on the bike compared to Wisconsin Ironman athletes (299.9 kcal +/- 126.6; 239.5 kcal +/- 130.5, respectively). Ironman World Championships athletes consumed significantly (p < .01) more fluid on the bike compared to Wisconsin Ironman athletes (3827 mLs +/- 1693; 3327 mLs +/- 1874, respectively). Ironman World Championship athletes consumed significantly more (p < .01) caffeine while biking in comparison to Ironman Wisconsin athletes (110.7 mg +/- 172; 65.9 mg +/- 100.8, respectively). **CONCLUSIONS:** Ironman World Championships athletes consumed higher amounts of calories per hour, fluid, and caffeine during the bike in comparison to the Ironman

Wisconsin athletes. This suggests that elite Ironman athletes consume more calories, caffeine, and fluids during their races when compared to average Ironman athletes, and hence increased calorie and caffeine consumption may contribute to faster performances for the elite athletes.

Vitamin D Awareness and Intake in Collegiate Athletes

John S. Fitzgerald¹, Bennett A. Leitch¹, Patrick B. Wilson², Tanis J. Walch¹, Sandra E. Short¹, Kelsey Uffholz³, James N. Roemmich, FACSM³. ¹University of North Dakota, Grand Forks, ND. ²Old Dominion University, Norfolk, VA. ³Grand Forks Human Nutrition Research Center, USDA, Grand Forks, ND. (Sponsor: James Roemmich, FACSM)
 Email: John.s.fitzgerald@und.edu
 (No relationships reported)

Approximately 56% of athletes worldwide are vitamin D deficient which may negatively influence health and physical performance. Lack of knowledge about the importance of vitamin D may be contributing to the high prevalence of deficiency. **PURPOSE:** To assess vitamin D awareness in NCAA athletes and examine its association with total dietary vitamin D intake. **METHODS:** 52 women (mean ± SD: age = 20.0 ± 1.5 yr, 4 cross country, 4 golf, 8 hockey, 14 soccer, 6 softball, 8 swim and dive, 6 track and field, 2 tennis) and 29 men (age = 22.1 ± 1.9 yr, 4 baseball, 3 cross country, 9 football, 1 swim and dive, 7 track and field, 5 tennis) competing at the University of North Dakota completed an online survey between November 1, 2015 and January 30, 2016. Vitamin D awareness was assessed using five vitamin D-specific questions related to the following: 1) familiarity with vitamin; 2) concern about levels; 3) risk of deficiency; 4) importance for health; and 5) importance for physical performance. Responses were scored using a 5-point Likert Scale. Total dietary vitamin D intake was assessed using the vitamin D-specific Diet and Lifestyle Questionnaire. Spearman's rank order correlation coefficients were used to evaluate the association between Likert scores for each awareness question and total dietary vitamin D intake. **RESULTS:** Overall, 21% of athletes reported "rarely" hearing anything about vitamin D. The majority of athletes responded that vitamin D "probably" or "definitely" will play a role in their health (88.9%) and physical performance (71.6%). However, only 23.4% and 28.4% of athletes reported concern for their vitamin D levels or believed they were at risk for deficiency, respectively. The RDA for vitamin D was met by 30% of women and 62% of men. Familiarity with vitamin D in women (r = 0.33, p = 0.02) and concern about vitamin D levels in men (r = 0.45, p = 0.02) were positively associated with total dietary vitamin D intake. **CONCLUSIONS:** The majority of collegiate athletes believed vitamin D plays a role in their health and physical performance; however, most expressed low concern for their vitamin D levels. Increased familiarity with vitamin D and concern for vitamin D levels were associated with increased total intake of vitamin D, and thus, interventions addressing these factors could reduce the prevalence of vitamin D deficiency in athletes.

Food Servings Habitually Ingested By Mexican Varsity Athletes Depending On The Type Of Sport

Sayra Nataly Muñoz-Rodriguez, Alejandro Gaytan-Gonzalez, Sergio Alejandro Copado-Aguila, Juan R Lopez y Taylor, Roberto Gabriel Gonzalez-Mendoza, Brenda Guadalupe Sanchez-Conchas, Clara Yunuen Rodriguez-Ramirez, Marisol Villegas-Balcazar, Juan Antonio Jimenez-Alvarado. *Universidad de Guadalajara, Guadalajara, Mexico.*
 (No relationships reported)

Several studies have reported the macronutrient intake in different types of sports, however, the type and amount of food that is needed for achieve these quantities is not commonly reported. **PURPOSE:** To describe the habitual amount of food servings ingested in varsity athletes depending on the type of sport performed. **METHODS:** 365 varsity athletes were polled. They were asked about their habitual food intake by trained nutritionists using a food frequency questionnaire. This includes 75 common local foods divided in 9 food groups (Table 1). Each athlete described how many days per week he/she usually ate each food and the usual amount they consume in those days. Then the servings' amount were calculated for each food weekly and a total weekly servings per food group as a daily average was calculated. Servings' size were determined according to the Mexican System for Equivalent Foods. The sample was divided by the type of sport as team (soccer, basketball, baseball, volleyball, handball, n= 184) or individual (weightlifting, tennis, athletics, wrestling, gymnastics, karate, taekwon-do, judo, n=181). For each group, the servings' amount were analyzed as quartiles. **RESULTS:** Analyzing the 50th centile, cereals were the most consumed food group, followed by animal source foods (ASF) and fats. Legumes were the less consumed food group (50th centile: 0 servings; 75th centile: 1 serving) and wasn't included in the table. Foods had a very similar amount of servings per group per type of sport.

WEDNESDAY, MAY 31, 2017

CONCLUSIONS: In our population, the amount of food servings commonly ingested by varsity athletes were very similar between these two types of sport classification. These data could help as a reference for comparing the habitual amount of food serving's ingested (25th to 75th centile) in different types of sports.

Table 1. Amount of food servings ingested per type of sport.

Food group	Quartile					
	25th		50th		75th	
	Team	Individual	Team	Individual	Team	Individual
Cereals	8	9	10	13	16	16
ASF	5	6	7	8	10	12
Fats	4	4	6	7	9	10
Fruits	3	3	5	5	8	8
Dairy	2	2	3	4	5	5
Veggies	2	2	3	3	4	4
Sugars	2	2	3	3	5	5
Seeds	0	0	1	1	2	2

 (No relationships reported)

There is huge evidence regarding the macronutrient intake in athletes, however there is little research about the food groups and amount of food servings ingested by athletes. **PURPOSE:** To describe the habitual amount of food servings by food group ingested in male and female varsity athletes.

METHODS: 365 (206 males, 159 females) varsity athletes were evaluated anthropometrically and for dietary habits. They were asked about their habitual food intake by trained nutritionists using a food frequency questionnaire, which includes 75 common local foods divided in 9 food groups (Table 1). Each athlete described how many days per week he/she usually ate each food and the usual amount they consumed on those days. The servings' amount were calculated for each food weekly as a total weekly servings per food group, finally a daily average was calculated. Servings' size were determined according to Mexican System for Equivalent Foods. The sample was divided by sex and then the servings were calculated as quartiles.

RESULTS: Subjects' age, body weight and stature were 21 ±2 and 21 ±2 years old, 76 ±15 and 61 ±11 kg, 177 ±7 and 163 ±7 cm, for males and females respectively. Considering the 50th centile, the most ingested food groups were cereals, animal source foods (ASF) and fats. The less consumed food group was legumes (its quartile analysis revealed 0 serving/day at the 50th centile and 1 servings at 75th centile). Veggies group were repetitive in centile 25th and 50th in male athletes.

CONCLUSIONS: Male and female varsity athletes had the same pattern of food intake, but in different amount. Further research is needed for assessing if these servings are enough to achieve the macronutrient daily needs.

Table 1. Amount of food servings habitually ingested by male and female varsity athletes.

Food group	Quartile					
	25		50		75	
	Males	Females	Males	Females	Males	Females
Cereals	10	7	14	9	19	12
ASF	6	5	9	6	12	9
Fats	4	4	7	6	9	10
Fruits	3	3	6	4	8	7
Dairy	2.5	2	4	3	6	4
Sugar	2	2	4	3	6	4
Veggies	2	2	2	3	4	4
Seeds	0	0	1	1	2	2

394 Board #215 May 31 11:00 AM - 12:30 PM
Dietary Characteristics In Medalist Versus No Medalist Varsity Combat Ahtletes

Andrea Patricia Rohan-Lopez, Alejandro Gaytan-Gonzalez, Roberto Gabriel Gonzalez-Mendoza, Juan R Lopez y Taylor, Edtna E Jauregui-Ulloa, Ana Gabriela Gutierrez-Muñiz. *Universidad de Guadalajara, Guadalajara, Mexico.*
 (No relationships reported)

Nutrition is an important factor for achieving sports success. Some dietary characteristics could lead to sporting advantage. Therefore, analyzing the dietary characteristics of successful athletes could help to better understand their nutritional practices that lead them to an advantage over their competitors.

PURPOSE: To compare the dietary characteristics between medalist and non-medalist varsity combat athletes.

METHODS: The nutritional characteristics of 58 varsity combat (wrestling, judo, karate, tae-kwon-do) athletes were evaluated one month before a national collegiate sport tournament. After the tournament, subjects were classified as medalist if they earned a medal (first four places, n=28) or non-medalist (n=30). Their dietary characteristics were evaluated with a 24-h dietary recall applied by trained nutritionists. These characteristics were daily food servings, energy and macronutrient intake (g/day and g/kg/day). All variables are expressed as median and interquartile range. Dietary characteristics were compared between groups by U Mann-Whitney test.

RESULTS: For food groups, medalist athletes ingested lower amounts of dairy and fats than non-medalist. Similarly, total fat intake (g/day) were lower in medalist. The relative macronutrient intake (g/kg/day) was significantly lower for fat (1.3 [1.0-1.7] vs 1.8 [1.4-2.0], p=0.003) but not for protein (1.8 [1.5-2.6] vs 2.0 [1.8-3.0], p=0.07) nor carbohydrates (6.0 [3.8-7.5] vs 6.6 [4.7-8.7], p=0.11) in medalist vs non-medalist, respectively. Despite didn't reached statistical significance, sugars' servings, energy intake, and relative protein intake tended to be lower in medalist group.

CONCLUSIONS: In this study, medalist athletes tended to ingest less food groups (dairy, fats, sugars), energy, fat and relative protein one month before an important competition. Perhaps because they were trying to keep their competition weight as controlled as possible in this lapse.

Table 1. Daily dietary characteristics for medalist and non-medalist varsity combat athletes.

	Medalist [Median (interquartile range)]	Non-medalist [Median (interquartile range)]	p-value
Animal source foods (servings)	8.5 (6.0-10.5)	8.5 (6.4-12.5)	0.46
Dairy (servings)	3.5 (2.5-5.0)	5.0 (3.0-6.0)	0.05
Legumes (servings)	0.5 (1.0-1.5)	1.0 (0.6-1.5)	0.71
Cereals (servings)	12.0 (8.5-16.0)	12.8 (10.8-20.0)	0.18
Veggies (servings)	3.0 (1.5-4.5)	2.0 (1.3-3.8)	0.31
Seeds (servings)	1.0 (0.5-1.5)	1.0 (0.4-2.5)	0.54
Fats (servings)	4.5 (2.5-9.5)	7.7 (5.0-12.0)	0.04
Fruits (servings)	5.0 (3.0-8.5)	5.5 (3.5-9.9)	0.36
Sugars (servings)	3.0 (1.5-6.0)	3.7 (2.7-6.3)	0.09
Energy (Kcal)	2891 (1998-3741)	3360 (2592-5050)	0.08
Protein (g)	137 (103-168)	151 (122-206)	0.12
Fat (g)	82 (62-123)	113 (92-158)	0.01
Carbohydrates (g)	396 (231-493)	389 (314-670)	0.25

Body Composition and Performance Capabilities Based on Level of Protein Intake in Collegiate Female Dancers

Katelyn R. Peterson¹, Ann F. Brown¹, Christopher W. Bach², Guiliana De Amelidea³, Shawn M. Leonard³, Tom Welsh³, Michael J. Ormsbee, FACSM³. ¹University of Idaho, Moscow, ID. ²University of Nebraska, Lincoln, NE. ³Florida State University, Tallahassee, FL. (Sponsor: Dr. Michael J. Ormsbee, FACSM)
 (No relationships reported)

The aesthetic nature of dance places pressure on dancers to have low body weight and fat, which often leads to disordered eating. Despite data showing higher protein intake improving body composition in numerous populations, a paucity of data exists on dancers. **PURPOSE:** To examine associations between protein intake, body

composition and performance among dancers. **METHODS:** Female dancers ($n = 25$; age 20.7 ± 1.8 years; mean \pm SD) were recruited to complete a 3-day food log, body composition analysis (DXA), and performance testing for muscular endurance, power and strength. Protein was expressed as g/kg/day and three equal groups were created (Low protein: LP, <1.2 g/kg/day; Moderate protein: MP, 1.2 - 1.6 g/kg/day; High protein: HP, >1.6 g/kg/day). Data were analyzed using one-way ANOVA to compare group means (SPSS v.21.0, Chicago, IL). Significance was set at $p < 0.05$. **RESULTS:** Total caloric intake was significantly greater in HP when compared to LP only (LP: $1,883.5 \pm 500.1$ kcal; HP: $2,439.8 \pm 348.5$ kcal; $p = 0.01$). Protein consumption was greater in HP compared to MP and LP, and for MP compared to LP ($p < 0.05$). Additionally, 22 participants (88% of all participants) fell below the protein recommendation (2.3 g/kg/day) for athletes to maintain lean mass during weight loss. There were no differences between LP, MP, and HP for all body composition and performance measurements. Although not significantly different, HP had lower body weight compared to LP despite consuming more calories. Additionally, although not significant, fat mass (%) was lower and lean mass (%) was greater in HP compared to both LP (fat: -8% ; lean: $+3\%$) and MP (fat: -4% ; lean: $+0.5\%$). **CONCLUSIONS:** Tertiles of protein intake in the female collegiate dancers participating in this study were not significantly associated with more desirable body composition and performance. However, trends for improved body composition observed with HP may be physiologically relevant for dancers. Further research should focus on achieving adequate protein spread between groups to determine the impact higher protein intake may have on dancers' body composition and performance.

396 Board #217 May 31 11:00 AM - 12:30 PM

Protein Intake Per Meal in Varsity Athletes with Low and High Lean Body Mass Index

Alejandro Gaytan-Gonzalez¹, Roberto Gabriel Gonzalez-Mendoza¹, Juan R Lopez y Taylor¹, Brenda Guadalupe Sanchez-Conchas¹, Sayra Nataly Muñoz-Rodríguez¹, Juan Antonio Jimenez-Alvarado¹, Marisol Villegas-Balcazar¹, Francisco Torres-Naranjo². ¹Universidad de Guadalajara, Guadalajara, Mexico. ²Centro de Investigacion Osea y de Composicion Corporal, Guadalajara, Mexico.
Email: lnalejandrog@outlook.com
(No relationships reported)

PURPOSE: To compare the protein intake per meal in varsity athletes with low and high lean body mass index (LBMI). **METHODS:** Protein intake per meal and LBMI were assessed in 94 varsity male athletes. Protein intake was evaluated with a 24-h dietary recall by trained nutritionists. The protein amount per meal was estimated for each subject and was classified as inadequate if it contained lower than 20 g of protein. Lean body mass was evaluated with bioelectrical impedance and LBMI was calculated (lean body mass [kg]/height² [m]). Then the sample was divided per LBMI tertiles, and the lower and higher tertiles defined as low (LLBM) and high (HLBM) lean body mass groups, respectively. Median intake for total (g/day), relative (g/kg/day) and per meal (g) protein as well as prevalence of inadequate protein intake (INPI) per meal were calculated for each group. We made comparisons between groups for protein intake (U Mann-Whitney test) and INPI prevalence (two samples t-test), we also analyzed within groups per meal protein intake (Friedman ANOVA, Dunns post hoc) and per meal INPI prevalence (one sample t-test). **RESULTS:** HLBM group had a higher total but not relative protein intake compared with LLBM group. The per meal protein intake analysis didn't show significant differences between groups. The INPI prevalence was similar in both groups, but one comparison reached statistical significance. LLBM group ingested the majority of their protein at lunch being higher than dinner ($p < 0.05$) and the INPI prevalence was lower at lunch ($p > 0.05$). HLBM also ingested the majority of their protein at lunch, being higher than breakfast and dinner ($p < 0.05$) and the lowest prevalence of INPI was showed in lunch compared with dinner ($p < 0.05$) but not for breakfast ($p > 0.05$). **CONCLUSIONS:** INPI per meal is common in varsity athletes, independently if they are LLBM or HLBM. Despite an adequate daily protein intake, efforts should be addressed to provide adequate amounts of protein on a per meal basis.

Table 1. Protein intake (daily and per meal) and prevalence of inadequate protein intake per meal.

	LLBM [Median (interquartile range),n=31]	HLBM [Median (interquartile range),n=31]	p-value (between groups)
Total protein intake (g/day)	105.5 (90.0-128.7)	129.7 (93.3-197.5)	0.04
Relative protein intake (g/kg/day)	1.8 (1.3-2.3)	1.5 (1.2-2.6)	0.55
Breakfast protein intake(g)	22.3 (12.0-35.3) ^{AB}	28.0 (16.4-35.9) ^A	0.28
Lunch protein intake (g)	31.8 (16.9-52.1) ^A	42.2 (27.4-66.9) ^B	0.13
Dinner protein intake (g)	21.9 (8.0-28.1) ^B	19.6 (12.6-40.5) ^A	0.29
INPI at breakfast (%)	45.2 ^a	35.5 ^{ab}	0.44
INPI at lunch (%)	25.8 ^a	12.9 ^a	0.20
INPI at dinner (%)	48.4 ^a	51.6 ^b	0.80

Different capital letters mean significant differences ($p < 0.05$) in protein intake between meals within groups.
Different lower case letters mean significant differences ($p < 0.05$) in INPI prevalence between meals within groups.

Dietary Analysis and Body Composition of Male and Female Costa Rican College Soccer Players

Natalia Sojo-Rodríguez, Mariángela Cordero-Vargas, Anne Chinnock, Yamileth Chacón-Araya, José Moncada-Jiménez. *University of Costa Rica, San José, Costa Rica.*
Email: natisojo14@gmail.com
(No relationships reported)

Soccer is a worldwide popular sport and research on several aspects related to performance are available; however, there are only a few studies reporting dietary analysis and body composition of Latin American college players. **PURPOSE:** To determine macronutrient consumption and body composition in male and female college competitive soccer players. **METHODS:** Participants were 22 male (mean age = 21.4 ± 1.9 yr.) and 19 female (mean age = 20.1 ± 1.7 yr.) varsity team soccer players who were interviewed for dietary assessment using a 7-day diet history questionnaire. Body composition was obtained by a full-body dual-energy X-ray absorptiometry (DXA) scan. Total energy and macronutrient analysis was performed following the nutritional interview, and body height, weight, lean mass, fat mass (%), and intermuscular adipose tissue-free skeletal muscle mass (IMAT-SMM) were obtained from the DXA scan. Gender differences were obtained by independent samples t-tests. **RESULTS:** Energy intake was higher in males ($19,377 \pm 5,514$ kJ) than in females ($13,066 \pm 4,610$ kJ; $p \leq 0.001$). Carbohydrate intake was higher in males (10.3 ± 3.2 g/kg) than in females (7.9 ± 3.8 g/kg; $p = 0.010$). Protein intake was higher in males (2.2 ± 0.8 g/kg) than in females (1.6 ± 0.5 ; $p = 0.031$). Fat consumption was similar between males (1.9 ± 0.8 g/kg) and females (1.7 ± 0.6 g/kg; $p = 0.117$). Body height (176.0 ± 6.1 vs. 160.4 ± 3.4 cm), weight (69.3 ± 7.7 vs. 59.2 ± 6.5 kg), lean mass (26.0 ± 2.0 vs. 16.9 ± 1.4 kg), and IMAT-SMM (31.0 ± 2.3 vs. 20.2 ± 1.6 kg) mean values were higher in males than in females ($p \leq 0.001$ for all). Fat mass was higher in females ($31.4 \pm 6.4\%$) than in males ($14.8 \pm 5.2\%$; $p \leq 0.001$). **CONCLUSIONS:** An excessive energy and carbohydrate intake was found in both genders. Protein and fat intake were appropriate for both genders. Body composition in males showed similar values compared to previously reported literature; however, females showed poor body composition compared to international values.

Weight Loss Practices Of Youth Taekwondo Athletes

Cosme F. Buzzachera¹, Natalia F. Silva¹, Andreo F. Aguiar¹, Stephanie L. S. Leal¹, Juliano M. Gabardo¹, Fernando M. Mitamura¹, Andrea G. Bernardes¹, Renata S. B. Januário¹, Laura Guidetti, FACSM². ¹North University Of Parana, Londrina, Brazil. ²University Of Rome, Rome, Italy.
Email: cosme.buzzachera@unopar.br
(No relationships reported)

Taekwondo athletes traditionally compete at the lowest weight class possible in order to gain a competitive advantage. To be eligible in lighter weight classes, competitors use a combination of potentially harmful weight loss practices, which may adversely

WEDNESDAY, MAY 31, 2017

affect one's physical and mental health. **PURPOSE:** The present study examined the weight loss practices of youth Taekwondo athletes. **METHODS:** Participants were 280 Taekwondo competitors aged 12 to 18 yrs (116 boys; mean age \pm SD 15.4 \pm 1.6 yr) who completed a previously validated questionnaire developed to evaluate rapid weight loss in combat sports athletes, which provides a score. The higher the score obtained by the competitor, the more aggressive his/her weight management strategies tend to be. Frequency and summary statistics were calculated on all variables. To compare the overall magnitude of weight management behaviours between boys and girls, a Mann-Whitney U Test was conducted with the scores obtained by both genders. A general linear model one-way ANOVA with Tamhane post hoc test for unequal variances was used to compare the scores obtained by the three following groups: regional-, national-, and international-level competitors. The same procedure was used to compare scores between athletes from different weight classes ($P < 0.05$). **RESULTS:** Seventy-five percent of youth Taekwondo athletes reported that have already lost weight to compete. Most of them reported reductions of up to 5% of body weight (mean \pm SD 2.2 \pm 1.9%). The reductions usually occurred within 8 \pm 4 d. Increased exercise and restricted food and/or fluids and training with plastic or rubberized suits, were cited as the most common rapid weight loss strategies. One-third of the athletes reported they took diet pills, diuretics, and/or laxatives to lose weight. No significant differences were found in the score obtained by male versus female as well as by athletes from different weight classes. International- and national-level athletes scored significantly higher in the questionnaire than regional-level athletes ($P < 0.05$). **CONCLUSION:** These results suggest that rapid weight loss is highly prevalent in youth Taekwondo athletes. The level of aggressiveness in weight management behaviors seems to be influenced by the competitive level.

Sources Of Nutrition Information And Knowledge In Ultra-runners (the SNIKR Study): A Qualitative Analysis

Sara E. Mahoney, Thomas R. Wojcicki, Kathleen Fitzgerald, Julia Zalmanoff. *Bellarmino University, Louisville, KY.*
 Email: smahoney@bellarmine.edu
 (No relationships reported)

With the recent increase in ultra-endurance competitions, the role of nutrition in performance has garnered significant attention. While the ACSM, AND, and DC have a joint position stand on nutrition for endurance performance, recent data has demonstrated that many ultra-endurance athletes do not meet the recommendations for athletic performance. **PURPOSE:** The purpose of this study was to understand common sources of nutrition information among recreational ultra-endurance athletes, and determine how this information is used in their training. **METHOD:** Recreational ultra-endurance athletes were recruited to participate in one of two focus groups (N = 8, mean age = 38.2 years), which followed pre-scripted questions to guide discussion. Participants also completed a demographic questionnaire. Focus group data was transcribed and reviewed by multiple researchers, and common themes were identified. **RESULTS:** The sample was 50% female, 100% white or non-Hispanic, 68% attained a college degree or higher, and 62.5% are married/partnered. Regarding their perception of the ideal diet for an ultra-endurance athlete, 87.5% of respondents discussed a "whole foods" diet with little processed food. Most of the participants (62.5%) were aware of the ACSM recommendations, but did not follow them. The most common reason was a belief in individual responsiveness to diet (50%) or the perception that it was too difficult to follow (50%). The most commonly used sources of nutrition information were through experienced athletes (87.5%) or personal relationships (62.5%), followed by magazines and non-academic books (50%). **CONCLUSION:** Overall, the focus group discussion revealed that recreational athletes, while aware of the dietary recommendations, do not believe they are accessible or worth their effort. As many participants look to personal relationships and successful athletes for advice, researchers and dietitians may reconsider how nutritional information is most effectively disseminated.

Inadequacy Of Food-Energy Supplying To The Energy Requirements Of Female Ballet Dancers

Caroline Bernardino¹, Rodrigo M. Manda¹, Nailza Maestá², Roberto C. Burini, FACSM¹. ¹UNESP Medical School, Botucatu/SP, Brazil. ²Piracicaba Methodist University, Piracicaba/SP, Brazil. (Sponsor: Roberto Carlos Burini, FACSM)
 Email: Caa.bernardino@hotmail.com
 (No relationships reported)

PURPOSE: Nowadays athletes use to control strictly their body weight focusing on convenient body weight-dependent competing categories or simply for their sports performance, as commonly seen in dancers. Usually this procedure lead to eating disorders with unfavorable outcomes. To investigate the energy balance of ballet dancers in association with their food intake pattern and anthropometric profile. **METHODS:** The resting energy expenditure (Fitmate), food intake (Food Frequency and 24-h recall questionnaires) pattern and anthropometric (Bioelectrical Impedance

data of ballet dancers was crosssectionally studied in 17 girls (19.1 \pm 7.1 yrs.). Statistical analysis was done by Pearson's correlation and Multiple Stepwise Regression ($p < 0.05$).

RESULTS: The availability of energy (22.48 \pm 13.1 kcal/kgFFM/d) was inadequate for 82.3% of the dancers once their energy intake (1248 \pm 385 kcal/d) achieved only 56% of the total energy expenditure. However, 24.5% showed high body fatness although 52.9% referred episodes of amenorrhea. Overall, their diet was classified as low quality (HEI score 67.9 points).

CONCLUSIONS: The existence of a presently energy-insufficient diet intake was confirmed by the energy expenditure measurements and the self reports of amenorrhea. On the other hand, the found rate of high body fatness would mean some earlier long lasting positive energy-balance in those girls. Supported by CNPq.

Twelve-weeks Oral Spray Vitamin D₃ Supplementation Does Not Alter Bone Turnover Markers In Collegiate Gaelic Footballers

Sharon M. Madigan¹, Joshua Todd², Emeir McSorley², L. Kirsty Pourshahidi², Eamon Laird³, Martin Healy⁴, Mark Kilbane⁵, Malachi McKenna⁵, Pamela Magee². ¹Sport Ireland Institute, DUBLIN, Ireland. ²Ulster University, Coleraine, United Kingdom. ³Trinity College, DUBLIN, Ireland. ⁴St. James's Hospital, DUBLIN, Ireland. ⁵St. Vincent's University Hospital, DUBLIN, Ireland. (Sponsor: Dr. Giles Warrington, FACSM)
 Email: smadigan@instituteofsport.ie

Reported Relationships: S.M. Madigan: Intellectual Property; none. Honoraria; none. Ownership Interest (Stocks, Bonds); none.

Vitamin D deficiency is associated with increased bone remodelling activity. Quantification of reference-standard bone turnover markers total procollagen type I N-terminal propeptide (PINP) (bone formation) and beta C-terminal telopeptide of type I collagen (β -CTX) (bone resorption) therefore enable detection of subtle perturbations in bone remodelling that may result from vitamin D inadequacy and indicate an increased risk of stress fracture in athletes. **PURPOSE:** To investigate the effect of wintertime vitamin D₃ supplementation using an oral spray on bone turnover markers in Irish athletes compared to placebo. **METHODS:** Stored samples from a randomised, double-blind, placebo-controlled trial conducted in Gaelic footballers (3000IU (75 μ g) vitamin D₃ daily versus placebo for 12-weeks, n=42) were analysed for PINP and β -CTX. Dietary vitamin D and calcium intake as well as total 25-hydroxyvitamin D (25(OH)D) data were available from the previous study. **RESULTS:** Overall, 72% of athletes presented with a 25(OH)D concentration $<$ 50nmol/L, and 5 exhibited vitamin D deficiency ($<$ 30nmol/L) at baseline. Dietary vitamin D and calcium intakes averaged 5.9 \pm 4.3 μ g/day and 1037 \pm 651mg/day respectively. Daily supplementation with 3000IU (75 μ g) vitamin D₃ significantly increased mean \pm SD 25(OH)D compared to no significant change in the placebo group (vitamin D; 47.37 \pm 13.29 to 83.68 \pm 32.98nmol/L (+79%) vs. placebo; 43.10 \pm 22.00 to 49.22 \pm 25.40 (+14%) $P=0.006$). However, ANCOVA revealed no significant difference in mean \pm SD change from baseline for PINP (-8.72 \pm 18.83 vs. -5.04 \pm 21.13 μ g/L, $P=0.413$) or β -CTX concentrations (-0.09 \pm 0.18 vs. -0.10 \pm 0.21 μ g/L, $P=0.627$) when compared to placebo. **CONCLUSION:** In this study, 12-weeks vitamin D₃ supplementation using an oral spray solution did not influence bone turnover when compared to placebo, despite increasing mean 25(OH)D concentration by 79%. Vitamin D inadequacy ($<$ 50nmol/L) is apparent in collegiate Gaelic footballers however future interventions, aiming to test change over time in bone turnover as a primary outcome, should consider a longer intervention in athletes with vitamin D deficiency ($<$ 30nmol/L).

402 Board #223 May 31 11:00 AM - 12:30 PM
Anxiety and Stress Predict Gastrointestinal Symptoms during One Month of Running

Patrick B. Wilson. *Old Dominion University, Norfolk, VA.*
 Email: pbwilson@odu.edu
 (No relationships reported)

PURPOSE: To investigate dietary, training, demographic, anthropometric, pharmacological, and psychological predictors of gastrointestinal (GI) symptoms in distance runners. **METHODS:** A total of 150 runners (74 men) completed a prospective journal recording daily running duration and intensity (Rating of Perceived Exertion [RPE]), as well as GI symptoms experienced during each run. At month's end, participants completed a survey inquiring about demographics, anthropometrics, running experience, analgesic use, antibiotic use, probiotic consumption, fluid/food intake during runs, caffeine intake before and during runs, stress, and anxiety. Stress and anxiety were measured via the Perceived Stress Scale (PSS) and Beck Anxiety Inventory (BAI). Substantial GI distress was defined as a run with at least one GI symptom ≥ 3 on a 0 to 10 scale. **RESULTS:** On average, participants reported experiencing substantial GI distress during 44.1% of runs. Age ($\rho = -0.30$, $p < 0.01$) and years of running experience ($\rho = -0.17$, $p = 0.04$) were negatively correlated

with the percentage of runs with substantial GI distress. Mean run RPE ($\rho = 0.23$, $p < 0.01$), frequency of probiotic food consumption ($\rho = 0.20$, $p = 0.02$), PSS scores ($\rho = 0.29$, $p < 0.01$), and BAI scores ($\rho = 0.27$, $p < 0.01$) were positively associated with the percentage of runs with substantial GI distress. **CONCLUSIONS:** Several factors are associated with substantial GI distress over one month of running, including perceived stress and anxiety, which have largely been neglected in previous research.

403 Board #224 May 31 9:30 AM - 11:00 AM The Physiological Responses of Specialist-Role Paramedics Undertaking a Simulation Treating Casualties Exposed to Hazardous Materials

Jane ES Thompson¹, Mark Rayson², Ella F. Walker¹, Carla A. Gallagher¹, Julianne Doherty¹, Stephen D. Myers¹, Sam D. Blacker¹. ¹University of Chichester, Chichester, United Kingdom. ²Mark Rayson Consulting Limited, Bristol, United Kingdom. Email: j.thompson@chi.ac.uk
(No relationships reported)

The National Ambulance Resilience Unit (NARU) works on behalf of each National Health Service Ambulance Trust in England to strengthen national resilience and improve patient outcome in challenging pre-hospital scenarios. Specialist ambulance responders (HART) are trained to deal with mass casualty incidents, during which they may need to wear Breathing Apparatus (BA) inside fully encapsulated Gas Tight Suits (GTS) to treat casualties in a hazardous area. **PURPOSE:** To measure the physiological strain of paramedics during a simulated task to treat casualties exposed to hazardous materials. **METHODS:** Six participants (5 male / 1 female; age 39 ± 8 y; body mass 80.1 ± 7.9 kg; VO_{2max} 38.05 ± 4.31 ml·kg⁻¹·min⁻¹) wearing BA and GTS (36.7 ± 1.3 kg) undertook a 30 min simulated task, which included walking 200 m to an incident, moving casualties and administering CPR for approximately 14 min. Participants' urine osmolality was measured before the task. Sweat losses during the task were estimated by changes in body mass, with participants unable to drink due to the BA. Participants wore a heart rate monitor, rectal thermistor, and skin thermistors (neck, hand, scapular and shin). The day before the simulation, participants completed an incremental shuttle run test to measure VO_{2max} and maximum heart rate (HR_{max}). Data are presented as the mean \pm SD; differences were compared using paired sample t-tests with significance set at $p < 0.05$. **RESULTS:** Mean urine osmolality at the start of the task was 380 ± 150 mOsm·kg⁻¹. Total estimated sweat losses during the simulation were 0.47 ± 0.39 L. Mean heart rate during the simulation was 75 ± 15 % HR_{max} . During the simulation both rectal (start and end; 37.45 ± 0.03 to 38.13 ± 0.19 °C, $p < 0.05$) and mean skin temperature (31.57 ± 0.02 to 34.04 ± 0.06 °C, $p < 0.05$) increased. The range of peak rectal temperatures were $37.8 - 38.3$ °C. **CONCLUSION:** Participants started the simulated task in a hydrated state and sweat losses were unable to be matched by fluid intake. Although cardiovascular strain during the task was 'moderate' to 'very hard' and body temperature increased, all participants successfully completed the 30 min simulation. These data can be used to inform interventions to enhance physical performance and to develop physical competency assessments for specialist ambulance responders.

404 Board #225 May 31 9:30 AM - 11:00 AM The Physiological Responses of Specialist-role Paramedics Treating Casualties in a Simulated Firearms Incident

Carla A. Gallagher¹, Mark P. Rayson², Ella F. Walker¹, Jane ES Thompson¹, Julianne Doherty¹, Stephen D. Myers¹, Sam D. Blacker¹. ¹University of Chichester, Chichester, United Kingdom. ²Mark Rayson Consulting Limited, Bristol, United Kingdom. Email: C.Gallagher@chi.ac.uk
(No relationships reported)

The National Ambulance Resilience Unit (NARU) works on behalf of each National Health Service Ambulance Trust in England to strengthen national resilience and improve patient outcome in challenging pre-hospital scenarios. Specialist ambulance responders are trained to deal with hazardous or difficult situations, particularly incidents such as situations involving firearms and mass casualties. **PURPOSE:** To measure the physiological strain of paramedics during a scenario to treat multiple casualties in a simulated firearms incident. **METHODS:** Six participants (5 male / 1 female; age 27 ± 3 y; body mass 80.4 ± 11.8 kg; VO_{2max} 46.5 ± 1.6 ml·kg⁻¹·min⁻¹) wearing ballistic personal protective equipment (19.1 ± 1.0 kg) undertook a 120 min

scenario, which included a 400 m approach walk, casualty drags, sprints, and stretcher drags. Participants' urine osmolality was measured before the scenario. Sweat losses during the scenario were estimated by changes in body mass with ad libitum fluid intake measured. Participants wore a heart rate monitor, rectal thermistor and skin thermistors (neck, hand, scapular and shin). The day before the simulation participants completed an incremental shuttle run test to measure predicted VO_{2max} and maximum heart rate (HR_{max}). Data are presented as the mean \pm SD; and analysed with paired sample t-tests with significance set at $p < 0.05$. **RESULTS:** Urine osmolality at the start of the simulation was 450 ± 160 mOsm·kg⁻¹. Total estimated net sweat losses during the scenario were 2.23 ± 0.34 L which was not different to fluid intake of 2.43 ± 0.42 L ($p > 0.05$). Mean heart rate during the scenario was 73 ± 11 % HR_{max} . During the simulation both rectal (start to end; 37.54 ± 0.29 to 38.34 ± 0.51 °C, $P = 0.24$) and mean skin temperatures (32.04 ± 1.08 to 30.85 ± 0.68 °C, $P = 0.78$) did not change significantly. The range of peak rectal temperatures was $37.10 - 39.15$ °C. **CONCLUSION:** Participants started the scenario in a hydrated state and sweat losses were matched by fluid intake. Although cardiovascular strain during the simulation was 'moderate' to 'hard', body temperature did not rise significantly and all participants successfully completed the two-hour scenario. These data can be used to inform interventions to enhance physical performance and develop physical employment standards for specialist ambulance responders.

405 Board #226 May 31 9:30 AM - 11:00 AM The Physiological Response of Specialist-role Paramedics Undertaking a Casualty Decontamination Scenario.

Julianne Doherty¹, Mark P. Rayson², Ella F. Walker¹, Jane ES Thompson¹, Carla A. Gallagher¹, Stephen D. Myers¹, Sam D. Blacker¹. ¹University of Chichester, Chichester, United Kingdom. ²Mark Rayson Consulting Limited, Bristol, United Kingdom. Email: j.doherty@chi.ac.uk
(No relationships reported)

The National Ambulance Resilience Unit (NARU) works on behalf of each National Health Service Ambulance Trust in England to strengthen national resilience and improve patient outcome in challenging pre-hospital scenarios. Specialist ambulance responders are trained to wear Powered Respirator Protective Suits (PRPS) to move, treat and decontaminate casualties exposed to hazardous materials. **PURPOSE:** To measure the physiological strain of paramedics during a scenario to move and decontaminate multiple casualties exposed to hazardous materials. **METHODS:** Eight participants (7 male / 1 female; age 38 ± 10 y; body mass 90.4 ± 16.2 kg; VO_{2max} 34.5 ± 5.6 ml·kg⁻¹·min⁻¹) undertook a 193 min scenario involving erecting a decontamination tent, then donning PRPS (11.9 ± 0.4 kg) to work for ~120 min to move and decontaminate multiple casualties. Urine osmolality was measured before the scenario. Sweat losses during the scenario were estimated from changes in body mass, with ad libitum fluid intake recorded. Participants wore a heart rate monitor, rectal thermistor, skin thermistors (neck, hand, scapular and shin). The day before the scenario participants completed an incremental shuttle run test to measure VO_{2max} and maximum heart rate (HR_{max}). Data are presented as the mean \pm SD; differences were compared using paired sample t-tests with significance set at $p < 0.05$. **RESULTS:** Urine osmolality at the start of the scenario was 350 ± 170 mOsm·kg⁻¹. Estimated sweat losses during the scenario were 1.40 ± 0.36 L which were less than fluid intake 2.54 ± 0.96 L ($p < 0.05$). Mean heart rate during the scenario was 64 ± 11 % HR_{max} . During the scenario rectal temperature increased (start to end; 37.51 ± 0.32 to 37.88 ± 0.19 °C, $p < 0.05$) and mean skin temperature was unchanged (31.16 ± 0.10 to 31.67 ± 1.23 °C, $p > 0.05$). The range of peak rectal temperatures was $37.95 - 38.60$ °C. **CONCLUSIONS:** Participants started the scenario in a hydrated state and sweat losses were lower than fluid intake. Cardiovascular strain during the scenario was 'moderate' and body temperature increased slightly. One participant was withdrawn during the scenario by the investigators due to becoming excessively fatigued. These data can be used to inform interventions to enhance physical performance and develop physical employment standards for specialist ambulance responders.

406 Board #227 May 31 9:30 AM - 11:00 AM A Case Report: The Physiological Strain Incurred by Electrical Utility Workers During Consecutive Work Days

Andrew W. D'Souza¹, Robert D. Meade¹, Lovely Krishen², Martin P. Poirier¹, Glen P. Kenny¹. ¹University of Ottawa, Ottawa, ON, Canada. ²Electrical Power Research Institute, Knoxville, TN. Email: adsou102@uottawa.ca
(No relationships reported)

Heat strain in electrical utilities workers has been assessed in a single work day and it has been shown that workers can experience high levels of thermal and cardiovascular strain. However, the impact of consecutive work shifts performed in hot conditions on the level of physiological strain remains unclear. **PURPOSE:** To examine the influence

of working consecutive shifts in hot conditions on the physiological strain experienced by electrical utility workers. **METHODS:** Four male electrical utility workers (age 38 ± 12 years) were monitored as they performed their normal work duties over two consecutive work days in hot conditions (average: 34°C , 60% relative humidity). Hydration was assessed using urine specific gravity (USG) prior to and following the participants regularly scheduled work shift. The proportion of work spent at various levels of physical effort as defined by the American Conference for Governmental and Industrial Hygienists (i.e., rest, light, moderate, and heavy effort) was determined using video analysis. Body core temperature (T_{core}) and heart rate (HR; presented as a percentage of maximal heart rate, HR_{max}) were measured continuously throughout the work shifts. **RESULTS:** Based on the ACSM guidelines, the workers were considered dehydrated ($\text{USG} \geq 1.020$) prior to (Day 1: 1.025 ± 0.005 ; Day 2: 1.029 ± 0.004) and following (Day 1: 1.027 ± 0.015 ; Day 2: 1.032 ± 0.004) each work shift. On day 1, workers spent 50, 25, 21, and 4% of the work period at rest and performing tasks considered as light, moderate and heavy physical exertion, respectively; whereas, 65, 19, 11, and 5% of the work shift was spent in these physical exertion categories during the second day. The proportion of the work shift at rest was higher on the second day compared to the first ($P=0.07$). Peak T_{core} tended to be greater on the second (Day 2: $38.4 \pm 0.2^{\circ}\text{C}$; range: $38.2\text{--}38.7^{\circ}\text{C}$) relative to first work shift (Day 1: $38.1 \pm 0.2^{\circ}\text{C}$, range: $37.8\text{--}38.2^{\circ}\text{C}$; $P=0.08$), whereas the peak HR response was similar between days (Day 1: $91 \pm 7\% \text{HR}_{\text{max}}$; range: $83\text{--}100\% \text{HR}_{\text{max}}$; Day 2: $87 \pm 11\% \text{HR}_{\text{max}}$; range: $74\text{--}98\% \text{HR}_{\text{max}}$; $P=0.57$). **CONCLUSION:** Our case report findings suggest that despite the fact that work effort is decreased over consecutive work shifts, thermal strain continues to be elevated in electric utility workers. (No relationships reported)

Current evidence demonstrates that the planet's climate is warming and that extreme heat waves are occurring more frequently. Outdoor workers are vulnerable to climate changes and are subject to risk of heat-related illness. Sugar cane cutters represent a labor force that is at high risk of heat-related illness due to high physical demands, long labor hours, and use of uniforms that dissipate heat poorly. **PURPOSE:** To investigate heat stress, dehydration and cardiovascular responses of sugar cane cutters during a typical work shift. **METHODS:** Eight male sugar cane workers (27 ± 7 years) volunteered for the study. Data collection occurred on a sugar cane plantation during the spring season. An ingestible telemetric temperature sensor and a heart rate monitor were used for measuring core temperature (T_{core}) and heart rate (HR), respectively, continuously. Oxygen consumption (VO_2) was measured using a portable metabolic cart during the first and second half of the work shift. Urine samples were collected pre- and post-work shift. Total sweat loss was calculated using body weight change and adjusting for water ingestion and urine output. A wet-bulb globe temperature (WBGT) station was used to monitor environmental heat stress. **RESULTS:** Total work shift time was $6:55 \pm 0:18$ hr with physical work duration of $5:28 \pm 0:21$ hr and rest time of $1:27 \pm 0:09$ hr. Mean and peak T_{core} during the work shift were 37.82 ± 0.31 and $38.60 \pm 0.41^{\circ}\text{C}$, respectively. All subjects achieved T_{core} above 38°C . Mean and peak HR during the work shift were 137 ± 18 and 165 ± 11 bpm, respectively. VO_2 was, on average, $21.2 \pm 5.4 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ and was not different ($p=0.296$) between the first ($22.6 \pm 3.4 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) and second half ($21.2 \pm 5.4 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) of the work shifts. Volunteers ingested 6.0 ± 1.0 L of fluid and experienced a total sweat loss of 7.6 ± 2.3 L. WBGT index was on average $26.8 \pm 2.3^{\circ}\text{C}$ and above the permissible heat exposure threshold of 25°C for 1 hour of heavy work. **CONCLUSIONS:** Sugar cane cutting is a physically demanding occupation performed in a hot environment and associated with high T_{core} and fluid loss. Preventative actions such as water ingestion, adequate rest, access to shade, and physiological monitoring should be implemented to reduce the risk of heat illness, particularly with the warming global climate. 408 Board #229 May 31 9:30 AM - 11:00 AM

Thermal Exposure Limit for Mine Refuge Chambers: A Pilot Study

Candi D. Ashley, Rebecca M. Lopez, FACSM, Danielle Aguillar, Thomas E. Bernard. University of South Florida, Tampa, FL.
(Sponsor: Marcus Kilpatrick, FACSM)
(No relationships reported)

Refuge chambers (RCs) provide shelter to miners trapped during a disaster. Industry standards mandate that RCs not exceed a Steadman Apparent Temperature (AT) (also known as Heat Index) of 95°F (35°C). This limit is designed for adults performing moderate work and maintaining thermal equilibrium at a core temperature $\leq 37^{\circ}\text{C}$. However, occupants in a RC spend most of their time at rest, and are able to maintain thermal equilibrium at a core temperature $> 37^{\circ}\text{C}$. Thus, the temperature limit may be unnecessarily restrictive. **PURPOSE:** To determine the upper limit of sustainable heat stress that is protective for most individuals during long-term heat exposure at rest. **METHODS:** In Phase 1, five men (age = 23.6 ± 3.2 ; BMI = 23.6 ± 2.5) underwent five 4-hr trials in a semi-recumbent position (mean $\text{VO}_2 = 0.43 \text{ L/min}$) at ATs of 39.4, 40.0, 42.8, 45.6 and 49.0°C , rh 90%. In phase 2, five men (age = 23.6 ± 3.2 ; BMI = 25.1 ± 2.2) underwent five 8-hr trials in a semi-recumbent position (mean $\text{VO}_2 = 0.44 \text{ L/min}$). The starting AT for phase 2 was 3°C below the highest AT from Phase 1, and increased in a stepwise fashion (ATs = 45.6, 50.8, 51.7, 54.4 and 56.1°C ; 90% rh). In all trials, gastrointestinal temperature (T_{gi}) and heart rate (HR) were assessed every 15 min. Oxygen uptake was assessed at the midpoint of each trial. Fluids were offered ad libitum. Sweat rate (SR) was determined from pre- and post-body weights. Repeated measures ANOVA was used to assess differences between trials. T-tests were used to assess pre- to post-trial differences. Significance was set at 0.05. **RESULTS:** Maximum AT of 56.1°C had an ending HR of 76 ± 1 bpm and ending T_{gi} of $37.5 \pm 0.3^{\circ}\text{C}$; well below the assumption of the Steadman AT limit. There were no differences ($p>0.05$) in T_{gi} at 45.6°C at 4 hrs in Phase 1 ($T_{\text{gi}} = 37.0 \pm 0.6^{\circ}\text{C}$) or Phase 2 ($T_{\text{gi}} = 37.2 \pm 0.1^{\circ}\text{C}$) or at 8 hrs in Phase 2 ($T_{\text{gi}} = 37.1 \pm 0.3^{\circ}\text{C}$). As AT increased, the difference in T_{gi} from 4 to 8 hrs increased ($p<0.05$). There was no difference in HR ($p>0.05$) and no between-phase difference in SR ($p>0.05$). **CONCLUSION:** As there were no differences in T_{gi} at 4 hrs and a greater difference from 4 to 8 hrs as AT increased, 4 hrs may not be long enough to detect a change in T_{gi} . The effect of climate evidenced by increasing T_{gi} which occurred between 43.3 and 46°C -AT provides support for sustainable exposures greater than 35°C -AT with a likely ceiling below 46°C -AT.

409 Board #230 May 31 9:30 AM - 11:00 AM

The TLVs Fail to Maintain Body Core Temperature within Safe Limits in Older Adults

Glen P. Kenny, Dallan T. Lamarche, Robert D. Meade, Andrew W. D'Souza. University of Ottawa, Ottawa, ON, Canada.
Email: gkenny@uottawa.ca
(No relationships reported)

Industries rely on the American Conference of Governmental Industrial Hygienists Threshold Limit Values (TLVs) to manage the health and safety of workers in hot conditions. A key shortcoming of the TLVs is the assumption that the guidelines are generalizable to broad population groups and do not consider age-related impairments in heat dissipation. **PURPOSE:** To evaluate core temperature and change in body heat storage during work in the heat using the TLVs, which are designed to ensure that a stable core temperature (and therefore heat balance) is achieved and remains below 38°C . **METHODS:** Nine older (58 ± 5 yrs) males performed three 120-min work bouts consisting of cycling at a fixed rate of heat production (360 W) under increasing ambient temperatures. Based on the TLVs, each protocol consisted of different work-to-rest (WR) ratios performed at different wet-bulb globe temperatures (WBGT). The first was 120-min of continuous (CON) cycling at 28°C WBGT while two protocols consisted of intermittent work bouts (15-min duration) adjusted for increases in WBGT: i) WR of 3:1 at 29°C (WR3:1) and ii) WR of 1:1 at 30°C (WR1:1) (equivalent exercise time of 90 and 60-min, respectively). Rectal (T_{re}) and mean skin temperatures were measured continuously and used to calculate the change in mean body temperature (ΔT_{b}). The change in body heat storage was determined via direct calorimetry and subsequently used to calculate ΔT_{b} . **RESULTS:** Heat balance was not achieved during exercise in any work conditions as the rate of change in T_{re} was greater than $0^{\circ}\text{C}\cdot\text{min}^{-1}$ (all $P \leq 0.05$). As a consequence, mean T_{re} exceeded 38°C ; albeit, time for T_{re} to exceed 38°C decreased as total exercise time increased (CON: 53 ± 7 ; WR3:1: 79 ± 12 ; and WR1:1: 100 ± 29 min). Moreover, a greater ΔT_{b} was observed with calorimetry relative to thermometry in all work protocols during the first 15-min of exercise [thermometry vs. calorimetry; CON: 0.21 ± 0.07 vs. $0.45 \pm 0.06^{\circ}\text{C}$ ($P<0.01$); WR3:1: 0.18 ± 0.05 vs. $0.51 \pm 0.06^{\circ}\text{C}$ ($P<0.01$); and WR1:1: 0.20 ± 0.06 vs. $0.50 \pm 0.09^{\circ}\text{C}$ ($P<0.01$)]. **CONCLUSION:** We show that the TLVs do not adequately protect older workers from potentially dangerous increases in core temperature during moderate work in the heat. Supported by the Ontario Ministry of Labour, Electric Power Research Institute and Natural Sciences and Engineering Research Council of Canada

410 Board #231 May 31 9:30 AM - 11:00 AM
Uncompensable Heat Stress Improves Manual Dexterity, But Does Not Affect Risk Propensity
 Rebecca L. Stansbery, Zachary J. Schlader, Jennifer L. Temple, Lindsey N. Russo, David Hostler, FACSM. *University at Buffalo, BUFFALO, NY.* (Sponsor: David Hostler, FACSM)
 Email: rlstansb@buffalo.edu
 (No relationships reported)

PURPOSE: Healthcare workers in the West African Ebola Treatment Units experienced substantial heat stress from wearing personal protective equipment (PPE) while performing light activities in a hot environment. It is unknown if uncompensable heat stress alters risk propensity or manual dexterity, which could impact the health of the worker and/or patient. We tested the hypothesis that uncompensable heat stress increases risk-taking propensity and impairs manual dexterity. **METHODS:** Fifteen healthy subjects (2 women) aged 22 ± 2 y completed a single experimental trial in 40°C and 60% relative humidity while wearing a hooded Tyvek chemical resistant coverall, an N95 respirator mask, goggles, gloves, boots, and an autopsy apron. Subjects walked on the treadmill for 30 min at 60% of their age predicted maximal heart rate, which was followed by 15 min seated rest. This cycle was repeated until participants reached 120 min, the subject terminated the test, or their physiological measures exceeded safe parameters. Subjects completed the Balloon Analogue Risk Task (BART) and two dexterity tasks (Tool Dexterity and Minnesota Manual Dexterity) pre and post the exercise while in the hot environment. **RESULTS:** Core temperature ($1.8 \pm 0.6^\circ\text{C}$; $p < 0.01$), mean skin temperature ($3.8 \pm 0.7^\circ\text{C}$; $p < 0.01$), and heart rate (55 ± 21 bpm; $p < 0.01$) increased during exercise, while body mass decreased ($1.1 \pm 0.4\%$; $p < 0.01$). Core-to-skin temperature gradient decreased from pre to post ($1.1 \pm 0.02^\circ\text{C}$ vs. $1.0 \pm 0.02^\circ\text{C}$; $p < 0.01$). During exercise, perceived exertion ($p < 0.01$), thermal sensation ($p < 0.01$), thermal comfort ($p < 0.01$), sweating sensation ($p < 0.01$), and dyspnea ($p < 0.01$) ratings increased. There was no change in the number of balloon explosions on the BART, an objective measure of risk propensity, from pre to post ($p = 0.43$). Time to complete the Tool Dexterity task did not differ between pre and post ($p = 0.49$). Time to complete the Minnesota Manual Dexterity task decreased from pre to post for both placing (270.4 ± 29.6 s vs. 252.0 ± 27.7 s; $p = 0.03$) and turning (230.2 ± 25.7 s vs. 204.9 ± 33.3 s; $p < 0.01$). **CONCLUSION:** Despite considerable thermal strain, light exertion in the heat while wearing encapsulating healthcare PPE did not alter risk propensity, but improved aspects of manual dexterity.

Selection into Shipbuilding Occupations when Dealing with Missing Data
 Deborah L. Gebhardt, FACSM, Todd A. Baker. *HumRRO, Alexandria, VA.*
 Email: dgebhardt@humrro.org
 (No relationships reported)

Building battle ships involves transforming sheets of steel into many shapes and joining the segments using welding, brazing, torquing, and other methods. **PURPOSE:** To design and validate selection tests for 30 jobs (e.g., shipfitter, joiner). One of the challenges was prevalence of missing data due to intermittent availability of the workers in the shipyard. Thus, this research used alternative methods to identify statistically the tests predictive of job performance for 30 occupations. **METHOD:** A job analysis survey completed by 629 workers identified the essential tasks for each job. Research staff identified the physical abilities required to perform essential job tasks. Researchers conducted a criterion-related validity study that included ten predictor tests and five criterion measures. The criterion measures included performance of tasks onboard a ship, along with supervisor evaluations of physical job performance. The sample included 197 men and 47 women across 24 of the 30 jobs. **RESULTS:** Validation data yielded a model ($R^2 = .59$) that consisted of lift/carry climb stairs, arm endurance, container lift, and plank. Further analysis showed the test battery was fair to protected groups (e.g., sex, age). Due to varying shift schedules, missing data occurred for the predictor tests and criterion measures for many subjects. Listwise deletion in the regression analysis resulted in a final sample of 155. Although statistical power was high for this sample, we conducted a Full Information Maximum Likelihood (FIML) analysis to determine whether the missing data affected the conclusions. FIML used a maximum likelihood approach to estimate the missing data based on all available information for a subject in an unbiased manner, rather than not replace or impute missing data. **CONCLUSIONS:** Comparison of squared multiple Rs for all ten tests for the FIML (0.61) and original (0.59) analyses found a small difference with FIML accounting for 1.3% more variance. The FIML standardized beta coefficients with the highest values were the same as the original regression analysis, thus confirming the original results. We established separate passing scores by job and test using information from the validation and job analysis results. Each job's test battery contained only tests and passing scores relevant to the job.

Flow-resistive Inspiratory Muscle Training Improves Running Time To Exhaustion With Thoracic Load Carriage
 Ren-Jay Shei, Robert F. Chapman, FACSM, Allison H. Gruber, Daniel P. Wilhite, Timothy D. Mickleborough, FACSM. *Indiana University, Bloomington, IN.* (Sponsor: Timothy D. Mickleborough, FACSM)
 (No relationships reported)

Exercise while carrying an external load upon the thoracic cavity imposes extra stress on the cardiopulmonary and limb locomotor systems. This in turn, negatively impacts exercise tolerance and performance, as well as pulmonary and respiratory muscle function. Thoracic load carriage exercise (LC) has been shown to induce global respiratory muscle fatigue as assessed by volitional mouth pressures, with a concomitant impairment in running time-trial performance. Inspiratory muscle training (IMT) has been shown to improve performance in a running time-trial with thoracic LC. However, in many occupational and recreational activities that require thoracic LC, the capacity to sustain prolonged exercise may be of equal or greater importance than performance in a time-trial. **PURPOSE:** To determine the efficacy of 6 weeks of flow-resistive IMT on running time to exhaustion with thoracic LC; and to determine whether 6 weeks of flow-resistive IMT moderates diaphragmatic fatigue that may occur following a thoracic LC running time to exhaustion test. **METHODS:** Twelve recreationally active males completed two runs to exhaustion (T_{lim}) at a fixed speed eliciting 70% of $\dot{V}O_{2max}$ while carrying a 10 kg backpack. Visits were completed at baseline and after 6 weeks of either IMT or placebo-IMT. Exercise metabolic and ventilatory measures were recorded and diaphragm strength was measured using bilateral phrenic nerve stimulation in conjunction with esophageal balloon-tipped catheters to measure intrathoracic pressures. Twitch transdiaphragmatic pressure amplitude was recorded pre-exercise and immediately post-exercise in both trials. Maximal volitional mouth pressures (P_{imax}) were recorded at baseline and post-IMT. **RESULTS:** 6 weeks of IMT significantly improved T_{lim} ($p = 0.029$, $\% \Delta +29.3 \pm 6.4\%$ IMT, $-8.8 \pm 11.1\%$), but did not alter the change in diaphragm strength following a run to exhaustion ($p > 0.05$). The $\% \Delta$ in P_{imax} from pre- to post-training was significantly correlated with the $\% \Delta$ in T_{lim} from pre- to post-training ($p = 0.031$, $r = 0.622$). No changes were observed in minute ventilation or breathing mechanics (all $p > 0.05$). **CONCLUSIONS:** IMT improves exercise tolerance with thoracic LC, but does not attenuate the severity of diaphragmatic fatigue following a running time to exhaustion test.

Assessment of the Physical Requirements Related to the Basic Training Program in Police Patrolling
 Sébastien Poirier¹, Annie Gendron², Louis Laurencelle¹, Joany Badeau¹, Claude Lajoie¹. *¹Université du Québec à Trois-Rivières, Trois-Rivières, QC, Canada. ²École Nationale de Police du Québec, Nicolet, QC, Canada.* (Sponsor: François Trudeau, FACSM)
 Email: Sebastien.Poirier@uqtr.ca
 (No relationships reported)

PURPOSE: To evaluate the demands of the basic training program in police patrolling (BTPPP) at the École Nationale de Police du Québec in order to develop a job-related physical test (JRPT). The aims were to: 1. quantify the physiological demands of the training and 2. identify and analyze the physically demanding and critical tasks of the training. **METHODS: AIM #1:** To determine the physiological demands, 56 cadets were recruited (27 M, 26 F). Their $\dot{V}O_{2max}$ and maximal heart rate (HR_{max}) were directly assessed ($\dot{V}O_{2max} = 48.9 \pm 6.8$ mlO₂ · kg⁻¹ · min⁻¹) using an incremental treadmill test. The physiological demands of the BTPPP were later quantified by recording the HR of participants during the physically demanding classes and then $\dot{V}O_2$ was extrapolated using a personalized regression function. Video sequences were also taken during those classes to allow further analyses. **AIM #2:** To identify the critical tasks of the BTPPP, 12 police training-experts participated in an advisory activity in which they were asked to individually rate the critical aspect of various tasks using a seven point Likert-like scale. A ranking of the most critical physically demanding tasks was established based on the scores given by the experts. The tasks scored as the most critical were later analyzed by 4 experts in kinesiology in order to identify the physical abilities needed to execute those tasks. **RESULTS: AIM #1:** HR analysis showed participants spent very little (Avg. = 0.62%) of their time in class at a HR > 90%; the most difficult classes required $\dot{V}O_2$ averaging only 35.2 mlO₂ · kg⁻¹ · min⁻¹ for females and 43.1 mlO₂ · kg⁻¹ · min⁻¹ for males. **AIM #2:** Critical tasks identification by police training-experts allowed the creation of a rank order list of 11 tasks of which the 7 most critical were, in order: reactive shooting, wrestling, self-defence with a baton, pursuing a suspect, force open a door, crowd control, and moving an unconscious person. Analysis of these 11 tasks by experts in kinesiology allowed the ranking of the most essential physical abilities, the first four being lower body power, coordination, upper body power and agility.

CONCLUSION: The assessment of the physical demands of the BTPPP allowed the creation of a JRPT based on the proper abilities and tuned to the energy expenditure and critical physically demanding tasks taught during the training.

414 Board #235 May 31 9:30 AM - 11:00 AM
Development of a New Job-Related Physical Test for the Basic Training Program in Police Patrolling
 Claude Lajoie¹, Sébastien Poirier¹, Annie Gendron², Louis Laurencelle¹. ¹UQTR, Trois-Rivières, QC, Canada. ²École Nationale de Police du Québec, Nicolet, QC, Canada. (Sponsor: Francois Trudeau, FACSM)
 Email: claudelajoie@uqtr.ca
 (No relationships reported)

Purpose: Based on previous observation and analyses of the basic training program in police patrolling, the main physical abilities required to successfully accomplish the critical and essential tasks of the program were identified. The objective of the study was then to develop and validate a new physical test for the École Nationale de Police du Québec (ENPQ) based on a job related approach sustaining the bona fide occupational requirements criteria. **Methods:** Our approach focused both on job task simulation and assessment of specific motor and physiological abilities. Seventeen tasks representing the main physical abilities elicited in the training program were evaluated throughout the test circuit, especially: lower and upper limb power, upper limb strength, global coordination and agility. To validate the test, 184 male and 56 female police students were recruited. Students executed the new ENPQ test and also a series of six 'convergent' measures (C): Edgren agility test (C1), dynamometer test for strength (C2), seated medicine ball throw for upper body power (C3), vertical (C4) and horizontal (C5) jump tests for lower limb power, and a maximal aerobic power estimation (C6). Among the experimental group, 39 male and 9 female police students did twice the ENPQ test for establishing test-retest reliability. **Results:** The new ENPQ test consists of a time circuit including various tasks in continuity, separated by 3 laps: lap 1 (8 tasks), lap 2 (7 tasks) and lap 3 (7 tasks). Mean completion time was significantly different (p<0.001) between male (210 ± 25 sec) and female participants (282 ± 52 sec). Correlation between the ENPQ test time and the six convergent tests were all significant (p<0.01) and moderately high: C1 (r=-0.43), C2 (r=-0.62), C3 (r=-0.59), C4 (r=-0.50), C5 (r=-0.71) and C6 (r=-0.49). Test-retest reliability (n=48) was r=0.81. **Conclusion:** The construction design used for the development of the new test insures *per se* its content (face) validity. On the other hand, the correlations obtained between the independent six 'convergent' ability measures and the new test's time performance confirm its multi-faceted concurrent validity. As for its predictive, or practical, usefulness for the tightening and betterment of the training standards of future police officers, this remains to be investigated.

415 Board #236 May 31 9:30 AM - 11:00 AM
DEXA Body Composition and Cardiovascular Risk Factors are Weakly Related in Police Officers
 Alison McGuire, Stephen F. Crouse, FACSM, Steven Martin, Allison Donnell, Daniel Mohnke, John S. Green, FACSM. *Texas A&M University, College Station, TX.* (Sponsor: Dr. Stephen Crouse, FACSM)
 (No relationships reported)

There is currently little research on whether fat mass and distribution are predictors for cardiovascular risk. **PURPOSE:** To determine if obesity measures, such as fat mass and distribution (e.g. android vs gynoid), could be used to predict cardiovascular risk, particularly lipid levels, systolic blood pressure (SBP) and blood glucose. **METHODS:** 182 police officers (166 males, 16 females; age 37.6±8.1 yrs; ht 1.7±0.1 m; wt 92.2±17.8 kg; BMI 28.9±4.8) were part of an annual cardiovascular risk profile testing group. We measured resting blood pressure and body composition via DEXA scan (SBP 127.16±10.33 mmHg; fat mass 26.85±9.99 kg; lean mass 62.01±9.90 kg; percent android fat 35.5±10.1; percent gynoid fat 29.7±6.9). Fasting blood samples were drawn and analyzed by a clinically certified lab to determine total blood cholesterol (TC) (192±37 mg/dL), LDL (119±35 mg/dL), HDL (46±10 mg/dL), triglycerides (129±99 mg/dL), and glucose (87±19 mg/dL). Correlations were determined by using a bivariate Pearson correlation matrix, significance was set at and p<0.01**. **RESULTS:** As fat mass increased, total cholesterol and LDL increased and HDL decreased. Triglycerides, glucose, and SBP also increased as fat mass increased. There were also significant increases in total cholesterol, LDL, triglycerides, glucose and SBP as android fat percentage increased. HDL decreased significantly as android fat percentage increased.

		Lean Tissue Mass	Fat Tissue Mass	Android Fat %	Gynoid Fat %	BMI
Cholesterol	Pearson	-.068	.193**	.242**	.196**	.211**
	R ²	.005	.037	.059	.038	.045
HDL	Pearson	-.258**	-.252**	-.262**	-.030	-.233**
	R ²	.067	.064	.069	.001	.064
LDL	Pearson	-.017	.169*	.178*	.154*	.168*
	R ²	.000	.029	.032	.024	.028
Triglycerides	Pearson	.075	.240**	.302**	.134	.215**
	R ²	.006	.058	.091	.018	.046
Glucose	Pearson	.152*	.150*	.153*	.024	.215**
	R ²	.023	.023	.023	.001	.046
Resting SBP	Pearson	.246**	.258**	.196**	.073	.299**
	R ²	.061	.067	.038	.005	.089

CONCLUSION: Fat mass and distribution are significantly, but weakly related to blood lipids/lipoproteins and blood pressure. We suggest that factors other than fat mass affect these cardiovascular disease risk markers, such as genetics, lifestyle, and diet. More research is needed to see if this correlation holds or is stronger in similar and different populations.

DXA Body Composition Is Weakly Related To Blood Lipids, Blood Pressure, And Glucose In Firefighters
 Kalen A. Johnson, Daniel Mohnke, Allison Donnell, Steven E. Martin, John S. Green, FACSM, Stephen F. Crouse, FACSM. *Texas A&M University, College Station, TX.* (Sponsor: Stephen F. Crouse, FACSM)
 Email: kjohns15@tamu.edu
 (No relationships reported)

Current published data are inconclusive regarding whether DXA body composition measures of fat, lean, and regional fat mass are predictive of other CVD risk factors. **PURPOSE:** To determine if DXA measures can be used in a cardiovascular risk-predictive manner to indicate unhealthy levels of circulating lipoproteins in firefighters. **METHODS:** 256 male firefighters (age=35±10; ht=179±6.6 cm; wt=94±16 kg; BMI=29.9±4.6; fat mass=27.5±10.4 kg; lean mass=63±7.5 kg; gynoid%fat=28.7±6.5%; android%fat=36±11.3%; glucose=85±12.9 mg/dL; SBP=128±9 mmHg) underwent an annual cardiovascular risk profile screening and DXA scan; resting BP was also measured. We collected fasted blood samples and a clinically certified lab analyzed them to determine glucose, HDL, LDL, total cholesterol, and triglycerides. Statistics included simple statistics and Pearson's correlations. **RESULTS:** Table (*=p<.01)

		Percent Fat	Lean Mass	Fat Mass	Android % Fat	Gynoid % Fat	BMI
Cholesterol	Pearson	.262*	.003	.212*	.281*	.197*	.180*
	R ²	.069	.000	.045	.079	.039	.032
HDL	Pearson	-.203*	-.228*	-.253*	-.251*	-.070	-.286*
	R ²	.041	.052	.064	.063	.005	.082
LDL	Pearson	.248*	.002	.206*	.266*	.191*	.185*
	R ²	.062	.000	.042	.07	.036	.034
TRIG	Pearson	.284*	.166*	.285*	.322*	.128	.277*
	R ²	.081	.028	.081	.104	.016	.077
Glucose	Pearson	.287*	.044	.271*	.277*	.238*	.208*
	R ²	.082	.002	.073	.077	.057	.043
Resting SBP	Pearson	.126	.201*	.178*	.130	.102	.176*
	R ²	.016	.040	.032	.017	.010	.031

CONCLUSIONS: Though the correlations were statistically significant, none of the DXA body composition measures explained a physiologically relevant portion of the variance in the CVD risk markers measured. We suggest that factors other than body fat contribute to lipid and blood pressure profiles in firefighters, a population at high risk for CVD.

Analysis of Dietary Intake in Volunteer Firefighters
 Kelly C. McLaughlin¹, Lauren N. Chavis¹, Rachel Dickinson¹, Emily Reeve¹, Christian K. Roberts, FACSM², Deborah L. Fearheller¹. ¹Ursinus College, Collegeville, PA. ²Occidental College, Los Angeles, CA. (Sponsor: Christian Roberts, FACSM)
 (No relationships reported)

Cardiovascular disease remains the leading cause of death in the United States. Dietary patterns can influence many risk factors for cardiovascular disease, such as blood pressure, lipid levels, body composition and glucose metabolism. Cardiac events are the leading line-of-duty deaths in firefighters. Due to the fast-paced and unpredictable

nature of the work as well as lack of proper kitchen equipment, firefighters often rely on quick, easy meals that may not be optimally nutritious. Limited research has examined firefighter's dietary intake and preferences. **PURPOSE:** To analyze the dietary intake of volunteer firefighters. **METHODS:** Seemingly healthy male volunteer firefighters (n=18, 34.1 ± 11.7 years of age) participated in a dietary workshop. Height and weight of each participant was measured. Participants were asked to collect a three-day diet recall which was analyzed using Diet Analysis Plus. **RESULTS:** The BMI of study participants was 32.4 ± 4.9 kg/m². On average, the participants consumed 1753 ± 503 kcals daily. The macronutrient breakdown was 197.8 ± 83.8 g (45.1%) carbohydrates, 71.6 ± 19.6 g (36.8%) fats and 75.6 ± 18.3 g (17.2%) protein. Types of fat intakes were: saturated fat (24.8 ± 6.7 g), monounsaturated fat (20.5 ± 7.8 g), polyunsaturated fat (11.5 ± 6.9 g), and trans-fat (2.0 ± 5.5 g) per day. In addition, 14.1 ± 6.2 g of dietary fiber, 70.9 ± 57.6 g of sugar, and 3008 ± 1231 mg sodium was consumed. Furthermore, the firefighters reported intakes of 10.0 ± 6.0 g linoleic acid, 1.0 ± 0.7 g linolenic acid, 735 ± 466 mg calcium, 170 ± 78 mg magnesium, 1775 ± 850 mg potassium, and 3 ± 2 µg vitamin D. **CONCLUSION:** Our results suggest volunteer firefighters do not consume diets in line with the 2015 Dietary Guidelines for Americans; however, additional data is needed to completely understand the dietary preferences of firefighters.

The Body Mass Index And Its Relationship With Cardiovascular Risk in Québec Firefighters

Philippe Gendron, François Trudeau, FACSM, Claude Lajoie, Louis Laurencelle. *Université du Québec à Trois-Rivières, Trois-Rivières, QC, Canada.*
Email: philippe.gendron@uqtr.ca
(No relationships reported)

Firefighting tasks in emergency conditions impose high physiological and psychological demands, which can be particularly deleterious to the health and safety of firefighters. According to the *National Fire Protection Association*, 51% of the deaths that occurred among U.S. firefighters in 2015 while on duty were sudden cardiac deaths. Therefore it is essential for firefighters to maintain a healthy body weight throughout their career in order to reduce the risk of on-duty death. Body mass index (BMI) is very likely associated to a higher cardiovascular disease (CVD) risk in firefighters. Misclassifying mesomorphic firefighters as obese by using BMI occurred infrequently in a U.S. firefighters' cohort (Poston et al. 2011, *J Occup Env Med*, 53(3), 266-273). **PURPOSE:** To document CVD risk among Québec firefighters according to their BMI. **METHODS:** Seven hundred and seventy nine (779) male firefighters (age: 41.6 ± 10.4 years; BMI: 28.0 ± 3.6 kg/m²) answered an online questionnaire evaluating the presence of CVD risk factors and symptoms. All data collected were self-reported. Three groups were formed based on the BMI; Group 1 (G₁): 18.5 kg/m² ≤ BMI < 25 kg/m², Group 2 (G₂): 25 kg/m² ≤ BMI < 30 kg/m², Group 3 (G₃): BMI ≥ 30 kg/m². **RESULTS:** Prevalence of overweight (25 kg/m² ≤ BMI < 30 kg/m²) and obesity (BMI ≥ 30 kg/m²) is 59.9% and 23.6% respectively. The number of modifiable risk factors (diabetes, hypertension, physical inactivity, smoking and dyslipidemia) is higher among firefighters with higher BMI before adjusting for age (G₁: 0.70 ± 0.71, G₂: 0.94 ± 0.78, G₃: 1.32 ± 1.00, P ≤ 0.001) and after (G₁: 0.77 ± 0.70, G₂: 0.94 ± 0.75, G₃: 1.23 ± 0.93, P ≤ 0.001). The BMI of participants who didn't have any cardiovascular symptom (n=463) was lower than that of participants who did report at least one cardiovascular symptom (n=285) before adjusting for age (27.35 ± 2.94 vs 28.44 ± 3.97, P ≤ 0.001) and after (27.37 ± 2.85 vs 28.44 ± 3.83, P ≤ 0.001). **CONCLUSION:** These results show the important prevalence of overweight and obesity among Québec firefighters based on BMI. They also show the relationship between BMI and CVD risk factors and symptoms. These relationships suggest that the BMI is an important indicator of CVD in Québec firefighters.

P. Gendron was supported by a doctoral research scholarship from Fonds de recherche du Québec en santé.

Efficacy of a Goal Setting Intervention on Firefighters' Cardiorespiratory Fitness: A Pilot Randomized Controlled Trial

Dierdra Bycura, Natalia Dmitrieva, Anthony Santos, Kelsey Waugh, Kamiko Ritchey. *Northern Arizona University, Flagstaff, AZ.* (Sponsor: Timothy K. Behrens, FACSM)
Email: dierdra.bycura@nau.edu
(No relationships reported)

PURPOSE: The purpose of this study was to assess the effectiveness of a goal setting and implementation planning intervention on cardiorespiratory fitness among firefighters. **METHODS:** Male career firefighters (N=18) from a large municipal fire department with nine or more years on the job were randomized to an intervention arm (n=10) or passive control arm (n=8) of a 14-week study involving cardiorespiratory exercise. The intervention consisted of a goal setting and implementation planning coaching toward improving cardiorespiratory fitness at baseline, as well as support

throughout the 14 weeks of the study (i.e., midpoint goal coaching, surveys on goal adherence). Cardiorespiratory fitness was assessed through a standardized physical protocol for firefighters (Candidate Physical Ability Test; CPAT) at baseline, 6 week, at 14 week time points, using the Cosmed K4b2 portable metabolic system to measure physiological variables. Using intention-to-treat principles, we employed a 2-level multilevel model to examine the effect of intervention group on intercept and change over time on primary outcomes of interest: oxygen transport and utilization (VO₂), heart rate (HR), and respiratory exchange ratio (R). **RESULTS:** The intervention and control groups both exhibited a significant increase in VO₂ (B=0.1414, SE=0.0253, p<.0001), and a decline in R (B=-0.0026, SE=0.0008, p<.01) over the course of the study. However, there were no significant effects of randomization group on intercepts or slopes of any of the three outcomes, indicating that there were no significant differences in cardiorespiratory fitness when intervention group was compared to the control group. **CONCLUSION:** Although both groups exhibited improvements on two of the three cardiorespiratory outcomes, the addition of goal setting and planning implementation intervention did not convey additional benefits over the effect of a control group. The current study was the first to directly measure cardiorespiratory demands of actual firefighter job tasks (CPAT), as measured by using a portable metabolic system. Importantly, the results of this intervention provided estimates that will be used to appropriately power a larger future trial testing the effect of goal setting and planning implementation in improving cardiorespiratory health.

The Effect of Age on Cardiorespiratory and Muscular Fitness Measures in Female Firefighters

Lauren K. Kirlin¹, Jeanne F. Nichols, FACSM², Katie Rusk³, Richard A. Parker³, Mitchell J. Rauh, FACSM¹. ¹San Diego State University, San Diego, CA. ²University of California San Diego, La Jolla, CA. ³San Diego Firefighters' Regional Fire Wellness Center, San Diego, CA. (Sponsor: Jeanne Nichols, FACSM)
Email: lkirlin@gmail.com
(No relationships reported)

The profession of firefighting is physically demanding, requiring a high level of both cardiorespiratory and muscular fitness. However, few studies have examined these fitness components among female firefighters (FF) and it remains unclear if this population is meeting minimum standards adopted by the National Fire Protection Association (NFPA). **PURPOSE:** To describe cardiorespiratory and muscular fitness of female career FF, and to determine if ageing affected their achievement of recommended profession standards. **METHODS:** A cross-sectional analysis of age groups (25-34, 35-44, 45-54, >55 yr) was conducted on 96 female FF over a ten-year span. Outcomes included cardiorespiratory fitness (CRF) expressed as maximum METs achieved during graded exercise to volitional fatigue, and muscular fitness (push-ups, sit-ups, and Sorenson back endurance). A one-way analysis of variance (ANOVA) with Bonferroni post-hoc comparisons was used to determine mean (± SD) differences (alpha level of 0.05) between age groups. **RESULTS:** The mean maximum METs achieved was significant across age groups, decreasing from 14.0 ± 2.2 in the 25-34 age group to 12.8 ± 1.4 in the 55+ age group (p<0.0001). The mean maximum number of push-ups was significant across age groups, decreasing from 34.0 ± 13.8 in the 25-34 age group to 31.6 ± 16.1 in the 45 to 54 age group, but increased to 35.8 ± 13.2 in the 55+ age group (p=0.02). Mean differences between age groups for sit-ups and the Sorenson test were not significantly different (p>0.05). **CONCLUSION:** While the mean values for age-groups consistently met or exceeded the 12-MET minimum CRF standard of the NFPA, the percentage of FF that fell below this cut-off ranged from 13% in the 25-34 age group to 39% in the 45-54 age group. Strategies to maintain fitness among all female FF are needed to ensure safe and effective job performance.

Heart Rate Recovery As Part Of Firefighters' Selection Process?

Jean-Guy Handfield¹, Vincent Gosselin Boucher², Alain Steve Comtois². ¹Optimum Consultants, Montréal, QC, Canada. ²Université du Québec à Montréal, Montréal, QC, Canada. (Sponsor: Jean-Pierre Boucher, FACSM)
Email: vincent.gosselin.boucher@gmail.com
(No relationships reported)

During a fire response, firefighters must carry out interventions that can vary in time followed by pauses for recovery. Thus, the ability to assay effort recovery is essential for firefighters to perform the requested task several times. **PURPOSE:** The objective of this study was to observe the heart rate (HR) recovery after a firefighter task simulation course test and rank their performance. **METHODS:** During the session, three groups of participants were asked to pass the course test, totalling n=48. Participants had an average of 23 ± 2.6 years, body weight 82 ± 8.7 kg and height 177 ± 6.4 cm (BMI of 26.2 ± 2.2 kg / m²). The course included seven tasks: fire hose handling, obstacles course with equipment, climbing up and down a 5 stair

staircase with hose, forced entry simulations with a sledgehammer, portable ladder manipulation, exploration work with a gaff pole and transporting an unconscious victim. Each participant was equipped with a HR monitor. A performance index, using heart rate at minute two of a 4 minute recovery period sitting down immediately after the course test and time of completion, was created to determine if a participant could in theory pass to the next stage of a hiring process. **RESULTS:** The maximal heart rate was 197 ± 2.6 bpm and represented the HR reached during the course test. The percentage of HR recovery after 2 min was $30 \pm 4.1\%$ for participants who passed ($n=40$) and $20 \pm 2.6\%$ for participants who did not pass ($n=8$) ($p<0.001$). Decrease of relative recovery was significantly different for the participants who passed or did not pass ($p < 0.05$), between 8 and 10 %. The index identified the overall performance with discrimination ($p<0.001$) for the two groups (7.79 ± 0.52 and 6.14 ± 0.52 , respectively). **CONCLUSIONS:** The evaluation of firefighters reveals the high intensity of effort required during intervention situations and the need to consider the moments of pauses, duration of pauses and aerobic fitness.

Policing is a dangerous activity with intense physical and psychological demands that might impact police officers (PO) quality of life **PURPOSE** To evaluate physical fitness (PF), body composition (BC) and the quality of life (QL) among Brazilian male military police officer recruits **METHODS** Participants were 219 male PO recruits of a northern state of Brazil engaged on a mandatory 6-month training course before admission in the Police Department. The course is a 6-month full-time activity that includes 3 sessions of physical training/week and other police tasks. During the early part of the course, cardiorespiratory fitness (CRF) and muscle strength (MS) were evaluated by means of the Cooper running test (CRF), curl up, pull up and push up tests (MS). BC was evaluated by BMI, body fat percentage (BF% - Jackson & Pollock 3 skin fold) and waist circumference (WC). In the same evaluation, QL was assessed by the WHOQOL-Bref, that ascertains the QL in four domains: physical, psychological, social, and environmental. We compared the QL by BMI categories (normal vs overweight+obese) using Mann-Whitney test. We also evaluated the correlation between PF tests and QL (Spearman test), always applying 5% level of significance **RESULTS** Mean (\pm SD) PO age and BMI were 25.5 ± 3.6 years and 24.4 ± 2.5 kg/m². PO showed high level of PF and reduced QL (Table 1). There was no association between all PF components and all QL domains ($r < 0.1$, $p > 0.12$). Using BMI, 33% of PO would be classified as overweight and 2.7% as obese, but all participants were in the normal range for BF% and WC ($< 20\%$ and < 94 cm, respectively) **CONCLUSION** We observed high levels of PF and a relatively impaired QL among young PO recruits. Contrarily to previous findings, QL was not correlated to PF which may be related to high demands during the course. Therefore, considering BF% and WC values, the adequacy of using BMI for BC evaluation in this population (young well fit PO recruits) needs further

Table 1 Descriptive values of physical fitness, BC and QL among 219 Brazilian male PO recruits	
	mean \pm sd
Push up (repetitions)	30.4 \pm 2.32
Curl up (repetitions)	34.4 \pm 3.58
Pull up (repetitions)	7.7 \pm 3.68
CRF (VO ₂ max-mL.kg ⁻¹ .min ⁻¹)	48.5 \pm 3.65
BF (%)	11.2 \pm 3.8
WC (cm)	80.3 \pm 5.5
QL Physical domain	66.5 \pm 15.17
QL Psychological domain	75.6 \pm 17.06
QL Social domain	69.5 \pm 18.33
QL Environmental domain	54.4 \pm 13.48

 (No relationships reported)

The central governor theory (CGT) states that metabolites that act through sensory feedback mechanisms act on the brain and spinal cord, allowing the nervous system to decide the extent of skeletal muscle recruitment during exercise. This ensures that homeostasis is maintained throughout exercise, regardless of the conditions of the exercise. Few studies have examined the role of the CGT and teleoanticipation during resistance training. **PURPOSE:** Examine the role of the CGT and teleoanticipation during resistance training, while completing the bench press (BP) during a known and unknown load. **METHODS:** A convenience sample of 26 participants (age=21.31 + 1.99 yrs, ht 175.08 + 9.15 cm; mass 81.04 kg + 13.16 kg) completed three testing sessions: 1) 1 RM BP determination; 2) Submaximal BP reps to fatigue known weight (KW); 3) Submaximal BP reps to fatigue unknown weight (UW). KW and UW sessions were randomized and completed at 70% 1RM. **RESULTS:** One-way ANOVA revealed no significant effects for testing order. Repeated measures t-tests revealed no significant differences in number of repetitions (KW 14.23+ 2.76 v. UW 14.73 + 2.24; t = 1.18, df = 25, p = .25), RPE (KW 13.37 + 1.40 v. UW 13.00 + 1.66; t = 1.26, df = 25, p = .22) or attentional focus (% associative v. % dissociative) (KW 68.46 + 12.87 v. UW 68.85 + 13.36, t=0.15, df = 25, p = .88). **CONCLUSIONS:** While completing the BP participants used more associative rather than dissociative attentional strategies. RPE, reps to fatigue, and attentional did not differ across KW and UW conditions. Load knowledge did not influence performance.

Evaluating Instructions For Use Of The Rate Of Perceived Exertion Scale: A Pilot Study

Olivia Henderson, Melissa Powers. University of Central Oklahoma, Edmond, OK.
 Email: mcurtis3@uco.edu
 (No relationships reported)

PURPOSE: The purpose of this study was to determine if there is a difference in understanding of Rate of Perceived Exertion (RPE) with two types of instructions. **METHODS:** Older adults that lived independently at a life care community participated in this study (N = 18). Two interviews took place more than seven days apart from each other. One participant only attended the first interview. At the first interview, participants signed the necessary paperwork and randomly chose which script (Brief or Modified Borg) would be read. At the second interview the remaining script was read. Identical sets of description, scenario and feedback questions were asked after each script. Participants were asked to describe the feeling of RPE's 6,9,13, 17, and 20. In addition, scenarios were said and they were asked to label the situations RPE level for themselves. Scenarios included gate closing at the airport (Airport Scenario), playing with children, and a typical trip to the grocery store. Responses were rated 'Good,' 'Needs Improvement,' and 'Exact.' Situations were analyzed by script and frequency. **RESULTS:** The Modified Borg instructions had a higher number of 'Good' descriptions for 6 (n = 13 vs. n = 12), 9 (n = 14 vs. n = 11), 13 (n = 9 vs. n = 4), and 17 (n = 12 vs. n = 3). RPE of 20 had equal (n = 10) participants with 'Good' descriptions for both scripts; however, the Modified Borg had two more participants that 'Needed Improvement.' The Airport scenario for the Brief instructions ranged from 13 to 20 RPE and 8 to 17 RPE for the Modified Borg. The most common answers were 13 (n = 5) and 15 (n = 5) for the Brief, and the Modified Borg's were 12 (n = 4) and, 11, 13 and 14 (n = 3). Playing with children scenario resulted in 11 and 12 being the most common answer given for both scripts (n = 3 - 6). The children scenario ranged from 7 to 18 for the Brief Script and 6 to 13 for the Modified Borg. Most answered response was 11 (n = 6) to the grocery store scenario for both scripts ranging from 8 to 14 and 6 to 14 for the Brief and Modified Borg. **CONCLUSION:** Perception widely varies between the participants for the different scenarios. The longer more descriptive instructions were helpful but were possibly too long for the adults to be more accurate than the brief script.

The Effect of an Energy Harvesting Backpack on Perceived Exertion during Locomotion

Andrew Tweedell¹, Courtney Haynes¹, Maria Talarico¹, Julianne Douglas², Jose Collazo². ¹Army Research Laboratory, Aberdeen Proving Ground, MD. ²Communications-Electronics, Research, Development, and Engineering Center, Aberdeen Proving Ground, MD.
 Email: andrew.tweedell.ctr@mail.mil
 (No relationships reported)

Biomechanical energy harvesting from elastically-suspended load carriage is a promising source of power for Soldiers, who often march with heavy loads at varying speeds on various terrains. An energy harvesting backpack (EHB) has been developed which generates power from vertical oscillations during locomotion. Ideally, the EHB should not increase psycho-physiological burden compared to the standard military assault pack (AP). **PURPOSE:** To compare ratings of perceived exertion (RPE) while walking with an EHB and an AP at different speeds on different grades. **METHODS:** 16 subjects (M±SD; 28.6±4.9 years; 173.4±10.6 cm; 78.7±16.4 kg) walked on a treadmill with each pack for 5 minutes at each of three grades (+5%, 0%, and -5%) and each of two speeds (1.34 m/s and self-selected faster speed). Both the AP and EHB contained a 15.9 kg load, but the design of the EHB made it 4.4 kg heavier than the AP. A Borg RPE score was taken during the last 10 seconds of walking at each grade and speed. A within-subjects ANOVA was used to determine effects of pack, grade, and speed on log-transformed RPE. Alpha level was set a priori at p<0.05. Post-hoc comparisons were explored using Bonferroni corrections. **RESULTS:** There were main effects for pack, speed, and grade ($F_{1,152}=14.3$, $F_{1,152}=100.1$, and $F_{1,152}=346.3$, respectively; p<0.001) with no interaction effects. Subjects reported a greater sense of exertion with the EHB (11.9±2.8) than with the AP (11.2±2.6) regardless of speed and grade. Faster speeds elicited higher RPE scores than slower speeds (13.1±2.4 and 10.1±2.1, respectively), while the incline grade produced higher RPE scores (13.1±2.5) than decline and level grades (10.3±2.3 and 11.2±2.5, respectively). **CONCLUSIONS:** The EHB caused greater levels of perceived exertion that were not altered by walking speed or grade. This may be due to the extra stabilization required or the extra weight cost of the EHB. Kinematic variables (trunk lean) related to this research suggest potential non-linear effects of EHB use, which may also be related to the increased perceptions of exertion found here. This may affect trade-offs between power generation, perceived exertion, and metabolic cost that warrants further research and may ultimately affect user-acceptance of suspended-load energy harvesting systems in the field.

Validity And Reliability Of Borg's 6-20 RPE Scale Among Chinese Mandarin Speaking Young Healthy Adults

Weiyang Ding¹, Tongjian You, FACSM², Phil Gona², Laurie Milliken, FACSM². ¹Northern Jiangsu People's Hospital, Yangzhou, China. ²University of Massachusetts Boston, Boston, MA. (Sponsor: Laurie Milliken, FACSM)
 Email: dingwy2002@yahoo.com
 (No relationships reported)

The validity and reliability of the Borg's 6-20 Rating of Perceived Exertion (RPE) scale has not been tested among Chinese people from Mainland China. Leung and Wang each have published a Chinese version RPE scale but neither has been validated in Chinese speaking people from Mainland China. **PURPOSE:** This study assessed: 1. The validity of Leung Chinese version (n=22) and Wang Chinese version (n=23) of the Borg 6-20 scales; 2. The reliability of Wang Chinese version (n=11) of RPE scale; and 3. The agreement of these two Chinese versions (n=21) of the RPE scales during the Bruce treadmill protocol testing among young healthy adults from Mainland China. **METHODS:** A total of 26 subjects (11 males, and 15 females), age 22.7±3.0 yr., volunteered to participate. They performed one (n=3), two (n=14), or three trials (n=9) of the identical Bruce treadmill protocol exercises within a time span of 9.0±5.1 days (validation trials), and 30.4±27.9 days (reliability trials). The objective measures of exercise intensity (power output, heart rate, and oxygen consumption) and the subjective measure of effort (RPE) were observed during the incremental exercise. **RESULTS:** Significant (p<0.01) Pearson linear correlations coefficients (r) were found where RPE values were strongly correlated with power output (Leung version $r_{s\geq 0.75}$, Wang version $r_{s\geq 0.73}$), heart rate (Leung version $r_{s\geq 0.84}$, Wang version $r_{s\geq 0.87}$), and oxygen consumption (Leung version $r_{s\geq 0.80}$, Wang version $r_{s\geq 0.81}$). The overall test-retest interclass correlation coefficient (ICC) was 0.94. All the Bland-Altman plots for stage 1 to 3 showed that at most 1 data point was outside of the limits of agreement. Fisher z-transformation test found no significant differences in correlation (all $p>0.05$) between trials for the reliability test of Wang version scale, and found no significant difference (p>0.05) in correlation with objective measures between the two Chinese versions of RPE scale. **CONCLUSIONS:** Both Leung and Wang Chinese versions Borg's 6-20 RPE scales are valid psychophysiological tools to measure perceptions

of exertion during controlled Bruce treadmill protocol exercise among young healthy Chinese adults. The Wang scale is reliable, and the Leung and Wang scales show good agreement with each other.

Perceptual Responses Of High Intensity Interval Training Among Overweight And Obese Individuals

John T. Halvorson, Carmen Byker-Shanks, John G. Seifert, FACSM, Mary P. Miles, FACSM. Montana State University, Bozeman, MT. (Sponsor: Mary Miles, FACSM)
 (No relationships reported)

INTRODUCTION: Poor exercise adherence is resulting in a rise of chronic diseases. High intensity interval training (HIIT) may improve adherence as it takes less time and is less monotonous. Beneficial physiological effects have been measured, but perceptual responses to HIIT have not been researched in overweight and obese (OW/OB) individuals. **PURPOSE:** To analyze whether participants prefer HIIT in comparison to continuous aerobic exercise (CON). **METHODS:** OW/OB individuals (30-55 years old) completed, in a randomized order: CON) a 45 minute walk at 65% of the age predicted maximal heart rate (APMHR), HIIT60) a 20 minute exercise in which the intensity alternated between 80% AMPHR and 60% APMHR every 60 seconds, and HIIT90) a 21 minute exercise in which the intensity alternated between 80% AMPHR and 60% APMHR every 90 seconds. Heart rate (HR), ratings of perceived exertion (RPE), and exercise enjoyment were measured during the exercise. Feeling scale (FS) and physical activity enjoyment scale (PACES) was measured 5 and 35 minutes post exercise. A qualitative (QUAL) interview was conducted 35 minutes post exercise. **RESULTS:** HIIT was more preferred than CON as evidenced by a higher (p<0.05) Friedman's rank score in HIIT90 and HIIT60 compared to CON. Post exercise PACES was higher (p<0.05) in HIIT60 and HIIT90, and FS was higher with HIIT60. Higher HR during HIIT60 and HIIT90 (p<0.05) indicate higher intensities during the exercise. Perceived exertion was higher (p<0.05) in HIIT90 and HIIT60, as evidenced by Friedman's rank scores of 2.36, 2.29, and 1.36 in HIIT90, HIIT60, and CON. QUAL data showed a feeling of passive exercising among CON compared to dynamic exercising among HIIT. Inability to self-regulate and safety concerns were felt in regards to HIIT. Lack of time and energy were factors for not exercising; HIIT was seen to be an effective method for time compared to CON for lack of energy. **CONCLUSIONS:** HIIT was a more preferred exercise, both during and after the exercises, regardless of the higher intensities. Greater challenges as well as dynamic changes in intensity were referenced as positive exercise perceptions. Both exercises were seen to be utilized in different scenarios such as lack of time for HIIT and a family activity for CON. Thus, HIIT is a preferred exercise within those who are OW/OB.

Impact of Using Perceptually Regulated Recovery Periods During Repeated Sprint Work

Matt Laurent¹, Danilo Tolusso², Adam Fullenkamp¹, Stephanie Douglas¹, Justin Kraft, FACSM², Matt Green, FACSM⁴. ¹Bowling Green State University, Bowling Green, OH. ²University of Alabama, Tuscaloosa, AL. ³Missouri Western State University, St Joseph, MO. ⁴University of North Alabama, Florence, AL. (Sponsor: Matt Green, FACSM)
 Email: cmlaure@bgsu.edu
 (No relationships reported)

Work-to-rest ratios (W:R) are designed to allow optimal recovery in sequential exercise bouts with particular consideration of intensity and duration. Emerging evidence supports the use of perceptual measures of recovery as valuable training tools in human performance. However, the efficacy of a perceptual measure of recovery compared to pre-established W:R during bouts of repeated sprint work has not been explored. **PURPOSE:** To compare performance during identical bouts of repeated sprints using either traditional W:R methodology vs. the use of a perceptual measure to gauge recovery. **METHODS:** Eight sprint-trained individuals completed two repeated sprint trials consisting of 3 sets of 8, 30-meter sprints on a non-motorized treadmill. Between each set of sprints, participants were given either a standard 5-min recovery whereupon the next set of sprints began or they were allowed to gauge recovery using a previously tested 0-10 Perceived Recovery Status (PRS) Scale. When using the PRS, once a participant estimated a recovery level '5' they began their next set of sprints. Performance measures included power (watts), decrements in power (DEC), recovery of power between sets (REC), and acute RPE estimated per sprint, but averaged to represent RPE in a set. **RESULTS:** When using the PRS, individuals self-selected longer recovery times than the standard 5 minutes (on average 24 sec longer between sets 1 and 2 and 1 min 54 sec longer between sets 2 and 3). A 2 (trial) x 3 (sets of sprints) repeated measures ANOVA revealed no significant differences (p > 0.05) in performance measures. However, performance was improved, albeit not significantly, when participants used the PRS method vs. the traditional W:R. In general, when using

the perceptually-regulated recovery strategy, improvements (~8-12%) were observed in power, DEC, REC, and RPE vs. a set 5-min recovery period. **CONCLUSIONS:** Results indicate that perceptually regulated recovery periods were longer but produce, at a minimum, statistically similar repeated sprint performance results. In addition to greater convenience associated with subjective markers, increased adherence to exercise associated with this form of training is plausible when using perceptual markers to set intensities during exercise.

Comparison Of Different Instructional Sets For Patient-Generated Indexes Of Pain Severity

Erin A. Dannecker, Ajay Aggarwal, James A. Kenney. *University of Missouri-Columbia, Columbia, MO.* (Sponsor: Marybeth Brown, FACSM)
 Email: dannecker@missouri.edu
 (No relationships reported)

Patient-Generated Indexes (PGIs) are a form of individualized patient-reported outcome measure that request patients to self-identify a predetermined number of health concerns and then rate the severity of the concerns. PGIs have been used to measure such concerns as quality of life, physical function, disability, and pain. The instructional sets of PGIs vary, but no studies were located that have tested the impact of different PGI instructional sets on severity ratings. **PURPOSE:** This study directly compared a PGI instructional set that requested painful activities (PGI-pain) to a PGI instructional set that requested activities from which the respondent most wanted less pain (PGI-painrelief). **METHODS:** The sample consisted of cohorts of patients with knee osteoarthritis (OA) who were either non-surgically managing their OA (n = 31, 62 yrs old (SD = 10.18), 64.5% women) or scheduled for their first joint replacement/s (n = 30, 56 yrs old (SD = 6.45), 70.0% women). During a single visit, patients completed both PGIs without any activity prompts. Also, they completed a numeric pain scale for rating the highest pain in the most painful knee. **RESULTS:** Both PGIs correlated with the numeric pain ratings ($r^2 = .76 \text{ \& } .80, p < .01$). No significant differences in the patients' pain ratings were detected between the two PGIs ($t_{60} = 0.35, p > .05$), but the pre-surgical patients' pain ratings were higher than the non-surgical patients using both PGIs ($t^*_{59} = -6.94 - -5.55, p < .01$). The importance of the activities that the patients identified for the PGI-painrelief was higher than for the PGI-pain ($t_{60} = -4.28, p < .01$) and the pre-surgical patients' ratings of activity importance were higher than the non-surgical patients using both PGIs ($t^*_{59} = -4.56 - -3.31, p < .01$). **CONCLUSIONS:** The results support the construct and concurrent validity of both PGIs. Although ratings of pain severity did not differ between the two PGIs, the importance of the self-selected activities varied between them. Thus, the instructional set of PGIs may influence the criteria respondents use for identifying their concerns. These findings contribute to previous reports from qualitative studies that people prefer to assess activities they view as important. Future studies should test the impact of PGI instructional sets on responsiveness to change across time.

Predicting Affective Exercise Responses from a Submaximal Exercise Test Using the Feeling Scale

Emilee Traxler¹, Robert W. Pettitt, FACSM¹, Mark Hartmann², Cherie D. Pettitt¹. ¹Minnesota State University-Mankato, Mankato, MN. ²Iowa State University, Ames, IA. (Sponsor: Robert W. Pettitt, FACSM)
 (No relationships reported)

The feeling scale (FS), rated -5 to +5, where -5 is an affective state of very bad and +5 is very good, has been validated across the moderate to severe exercise domains during incremental exercise; however, little has been reported on constant-load exercise. **PURPOSE:** To examine the FS during the Mankato submaximal exercise test (MSET) and predict FS responses at intensities above and below gas exchange threshold (GET). **METHODS:** A total of 8 women and 6 men (age 21 ± 1) completed the MSET using stages of 35 and 65% of estimated maximal work capacity (W_{peak}). Participants returned for 10-minute constant-load bouts at 50 and 70 or 72% estimated W_{peak} . FS was assessed at the end of each minute of the MSET and constant-load bouts. Linear regression from the MSET was used to predict FS at 50 and 70% W_{peak} . Actual and predicted values were compared using the Wilcoxon test. **RESULTS:** Actual ratings declined in the 50% W_{peak} trial reaching the lowest FS rating of 0.63 ± 2.84 , a value not differing from the estimate of 0.64 ± 2.43 ($z = 0.11, p = 0.92$). Six participants failed to complete the entire 70% W_{peak} trial. Continual time-dependent decreases in FS were reported by the remaining participants. The actual end-exercise value (-1.00 ± 2.06) did not differ from the predicted (0.21 ± 2.06) ($Z = 1.40, p = 0.16$). **CONCLUSION:** Affective responses using the FS can be predicted for exercise below GET; however, it may be limited in predictability above GET.

431 Board #252 May 31 11:00 AM - 12:30 PM
Caffeine but not Low-Carbohydrate Improves Exercise Capacity in Sedentary Adults Similar to Endurance Trained Athletes

Namrita Kumar¹, Gordon L. Warren, FACSM², Teresa Snow¹, Mindy Millard-Stafford, FACSM¹. ¹Georgia Institute of Technology, Atlanta, GA. ²Georgia State University, Atlanta, GA. (Sponsor: Mindy Millard-Stafford, FACSM)
 Email: namritak@gmail.com
 (No relationships reported)

Caffeine (CAF) and small amounts of carbohydrate (CHO) ingested or simply exposed to the oral cavity appear to delay fatigue during prolonged exercise, possibly through central nervous system mechanisms. However, this has been primarily documented in endurance trained (ET) athletes. **PURPOSE:** To determine if: 1) CAF and/or a low dose of CHO (equivalent to CHO contained in ergogenic mouth rinse and insufficient to trigger a peripheral metabolic response) improves endurance capacity in sedentary adults (SED) similar to ET and 2) potential ergogenic mechanisms differ based on fitness status. **METHODS:** Using a double-blind crossover design, ET and SED (n=12 each) completed four exercise trials consisting of 30 min cycling at 90% lactate threshold followed by cycling time to fatigue (TTF) at 105% lactate threshold. The following solutions were ingested after standardized 43 g CHO breakfast: CAF (3 mg/kg), low (<1%) CHO (LCHO), combined CAF+LCHO, and placebo (PLA). **RESULTS:** ET and SED did not differ in overall mean (\pm SD) TTF (23.8 ± 8.1 vs. 24.1 ± 11.3 min) but TTF improved ($p < 0.05$) in CAF+LCHO versus LCHO. When averaging across both CAF treatments (CAF+LCHO and CAF), perceived exertion was lowered and TTF was increased by 21% (26.3 ± 10.4 vs. 21.7 ± 9.9 min) compared to the two no-CAF treatments (PLA and LCHO), but CAF did not alter muscle strength/activation. Blood glucose, lactate, and CHO oxidation were higher with CAF vs. no-CAF treatments. Fat oxidation was higher in ET compared to SED, but CAF did not alter fat oxidation. **CONCLUSIONS:** The ergogenic benefit and action of CAF appears to be independent of fitness status. The addition of LCHO ingestion, previously observed to act centrally, did not further augment benefits of CAF in the fed state.

432 Board #253 May 31 11:00 AM - 12:30 PM
Fatigue as a Rehabilitation Strategy to Reduce Quadriceps Inhibition Following Anterior Cruciate Ligament (ACL) Reconstruction

Timothy Lowe¹, Qi Zhang², Xuanliang Dong¹. ¹University of Texas at Tyler, Tyler, TX. ²Tsinghua University, Beijing, China. (Sponsor: Yong Tai Wang, FACSM)
 (No relationships reported)

Arthrogenic muscle inhibition (AMI), an inability to fully activate the quadriceps muscles, has been consistently observed in patients with anterior cruciate ligament reconstruction (ACLR) surgery. Reductions in quadriceps activation may be partly due to the flexion reflex pathway, which includes the activation of the hamstrings and reciprocal inhibition of the quadriceps. Central fatigue has been shown to reduce muscle activation, change movement strategy, and shift loading to other muscles. Therefore, we hypothesized that the fatigue of the hamstrings could be used to alleviate the quadriceps muscle inhibition by counteracting the flexion reflex. **Purpose:** To determine the effects of fatigue on reducing quadriceps muscle inhibition after ACLR reconstruction. **Methods:** A total of nine adult athletes (19.9 \pm 1.7 years old) with unilateral ACLr and nine control athletes (24.0 \pm 2.4 years old) with no previous history of knee injury were recruited. Fatigue was induced in subjects by performing tempo squats, in which the ACLr group tended to use hamstrings for more hip flexion and trunk forward flexion than the control group. Quadriceps inhibition was assessed through the central activation ratio (CAR), measured by twitch interpolation, before and after the fatigue for each subject. A Mixed ANOVA was performed to examine the effect of fatigue on the CAR between pre- and post-fatigue, and among ACLr and control groups. **Results:** The CAR of the quadriceps was significantly greater post-fatigue than pre-fatigue for the ACLr group (96.0 \pm 7.6% vs. 81.2 \pm 15.8%, $p=0.010$); whereas no significant differences were observed for the control group between post-fatigue and pre-fatigue (96.9 \pm 9.6% vs. 97.0 \pm 17.1%, $p=0.969$). Additionally, in pre-fatigue trials the ACLr group had marginally significant less CAR (81.2 \pm 15.8% vs. 97.0 \pm 17.1%, $p=0.067$) than the control group; after fatigue trials no significant differences of CAR were observed between the ACLr and control groups (96.0 \pm 7.6% vs. 96.9 \pm 9.6%, $p=0.838$). **Conclusion:** These results suggest that fatigue training can be used as a rehabilitation strategy to restore normal quadriceps function at the knee joint following ACL reconstruction by relaxing the hamstrings and overcoming the inhibition of the quadriceps.

Recreationally-Trained Subjects are Unable to Attenuate VO₂ Slow Component During Severe Exercise Using RPE
 Slater K. Powell¹, Emilie M. Hauser¹, Nathan D. Dicks², Robert W. Pettitt, FACSM¹, Cherie D. Pettitt¹. ¹Minnesota State University, Mankato, Mankato, MN. ²North Dakota State University, Fargo, ND. (Sponsor: Robert W. Pettitt, FACSM)
 Email: slater.powell1923@gmail.com
 (No relationships reported)

Previous research indicates that recreationally-trained subjects are able to attenuate the slow component of oxygen uptake (VO₂) during heavy intensity exercise using rating of perceived exertion (RPE). Little is known, however, about the use of RPE to attenuate the slow component when exercising in the severe exercise domain. **PURPOSE:** The present study examined the degree to which recreationally-trained subjects could attenuate the VO₂ slow component while cycling in the severe exercise domain. **METHODS:** A total of 15 volunteer subjects, 9 males, and 6 females (mean age ± SD = 22.3 ± 1.8), completed a 3-minute all-out exercise test for the determination of critical power (CP) and the curvature constant (W'). Subjects then returned and completed two separate bouts at 10% >CP. The constant bout required subjects to sustain their preferred cadence until exhaustion. The regulated bout involved subjects attempting to maintain their RPE from 2-min into the bout by adjusting power output until their power output declined to a value ≤ CP. **STATISTICAL ANALYSIS:** Paired t-tests were conducted. **RESULTS:** The constant bout evoked a VO₂ value (43.3 ± 7.3 ml·kg⁻¹·min⁻¹) that was not different from VO_{2max} (43.1 ± 7.4 ml·kg⁻¹·min⁻¹) (t = 0.17, p = 0.87), confirming that the intensity was in the severe exercise domain. In the regulation bout, there was a significant gain (~7 ml·kg⁻¹·min⁻¹) in VO₂ between 2 min and the end of exercise (t = 6.25, p < 0.01). A wide range of utilization for the work capacity above CP was observed (2.0 - 13.7 kJ). **CONCLUSION:** In contrast to exercise in the heavy domain, recreationally-trained subjects are unable to attenuate the VO₂ slow component using their RPE in the severe domain. Future research is needed on fitter subjects and/or different psychometric scales.

Acute Affective Responses To High-Intensity Interval Training In Trained and Untrained Men
 Yuriko Higaki, Hisashi Mori, Chihiro Kojima, Kazushige Goto. *Ritsumeikan University, Kusatsu, Japan.*
 Email: sh0063ip@ed.ritsumei.ac.jp
 (No relationships reported)

Although exercise has been shown to alter transiently affective variables, the impact of fitness levels on affective response to high-intensity interval training (HIT) remains unclear. **PURPOSE:** The present study was designed to compare affective responses between HIT and continuous exercise at low-intensity in trained and untrained men. **METHODS:** Twenty male subjects (21.2 ± 0.34 years) were divided into trained group (TR, n=10, maximal oxygen uptake (VO_{2max}) 55.6 ± 1.1 ml/kg/min) or untrained group (UT, n=10, VO_{2max}: 40.5 ± 1.0 ml/kg/min). All subjects completed two trials in random order, consisting of HIT (10 × 1 min pedaling at 90% of VO_{2max}) with 1 min of active rest at 30% of VO_{2max}) or 60 min of pedaling at 50% of VO_{2max} (LOW). Scores of muscle soreness, fatigue, vitality and desire for exercise were evaluated using visual analog scale before exercise and during 60 min of post-exercise period. Moreover, two-dimensional mood scale (TDMS) was conducted to assess vitality, stability, pleasure and arousal. Blood samples were also collected to determine blood lactate glucose concentrations. During exercise, heart rate (HR) and rating of perceived exertion (modified 10 scale) were recorded. **RESULTS:** Exercise-induced blood lactate elevation was significantly greater in the TR group than in the UT group (group × time, P < 0.05). The results of TDMS revealed that exercise altered significantly arousal, vitality, stability and pleasure (main effect for time, P < 0.05) after HIT and LOW. However, scores of vitality, stability and pleasure were significantly (P < 0.05) elevated 60 min after HIT in the UT group, whereas the TR group did not show similar change. **CONCLUSIONS:** These findings suggest that exercise improves acutely affective variables. However, the affective response to exercise appears to be particularly influenced by fitness levels, and HIT augments vitality, stability and pleasure during post-exercise period only in untrained men, not in trained men.

The Validity of Oxygen Uptake Efficiency Measures in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome
 Stephanie M. Van Riper¹, Jin-Mann S. Lin², Elizabeth R. Unger², Ryan J. Dougherty¹, Multisite Clinical Assessment of ME/CFS (MCAM) Workgroup², Dane B. Cook, FACSM¹. ¹University of Wisconsin, Madison, WI. ²Centers for Disease Control and Prevention, Atlanta, GA. (Sponsor: Dane B. Cook, FACSM)
 Email: smvanriper@gmail.com
 (No relationships reported)

Maximum oxygen uptake is often used to evaluate cardiopulmonary function in patients with Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). However, many ME/CFS patients may not be capable of giving the level of effort required for a valid test. Oxygen uptake efficiency slope (OUES) has been proposed as an effort independent measure to assess aerobic fitness in populations where maximal exercise is contraindicated, but has not been assessed in ME/CFS. **PURPOSE:** To determine the validity of OUES as a measure of aerobic fitness in ME/CFS. **METHODS:** Maximal exercise testing was performed using a ramped protocol on a cycle ergometer in a clinical sample of ME/CFS patients as part of the CDC multi-site study. Oxygen consumption (VO₂), carbon dioxide production (VCO₂) and pulmonary ventilation (VE) were directly measured using a metabolic cart. Ventilatory equivalents for O₂ (VE/VO₂) and CO₂ (VE/VCO₂) were calculated. Peak effort was determined using American College of Sports Medicine criteria. Anaerobic threshold was determined using the Vslope method. OUES was determined by VO₂ = a*log VE + b, where a = OUES, b = intercept. Linear regression was used to determine the relationship between VO_{2peak} and OUES. Group comparisons were analyzed using Independent t-tests and Mann-Whitney tests with an alpha = 0.05. **RESULTS:** A total of 180 tests were evaluated including 135 (39 male) ME/CFS patients and 45 (18 male) controls (CO). Over 80% of the sample achieved peak exercise effort. Anaerobic threshold occurred at similar percentages of peak VO₂ (ME/CFS: 54%; CO: 53%, p > 0.05) and peak Watts (ME/CFS: 39%; CO: 45%, p > 0.05). Maximum VO₂ correlated with OUES in both groups (CFS: Rho = 0.695, p < 0.01; CO: Rho = 0.709, p < 0.01). OUES values were significantly lower for ME/CFS patients (ME/CFS Median 1.77, interquartile range (IQR) 0.86; CO Median 2.3, IQR 1.29, p < 0.05). Ventilatory equivalent measurements were significantly higher in ME/CFS at anaerobic threshold compared to CO (VE/VO₂: ME/CFS Median 25.8, IQR 7.8; CO Median 24.0, IQR 3.8; VE/VCO₂: ME/CFS Median 30.1, IQR 9.2; CO Median 28.5, IQR 4.1, p < 0.05). **CONCLUSION:** These data demonstrate the validity of OUES to predict aerobic capacity and might discriminate ME/CFS patients from healthy controls, thereby encouraging future research using submaximal effort tests.

A-54 Free Communication/Poster - Preparticipation and Injury Risk Assessment

Association of Interrelated Neuromechanical Factors with Injury Occurrence among College Football Players
 Gary B. Wilkerson. *University of Tennessee at Chattanooga, Chattanooga, TN.* (Sponsor: Daniel C. Herman, FACSM)
 Email: Gary-Wilkerson@utc.edu
 (No relationships reported)

PURPOSE: The purpose of this prospective cohort study was to assess the predictive value of injury risk screening methods that collectively assess aspects of environmental awareness, cognitive processing of neural input, and motor control, as well as any persisting effects of previous injuries. **METHODS:** Prior to participation, 43 NCAA Division I-FCS college football players (20.2 ± 1.2 years; 185.7 ± 5.8 cm; 105.4 ± 20.6 kg) completed the 10-item Sport Fitness Index (SFI) survey and performed both a 60-second Reactive Peripheral Response (RPR) test and a 10-second Unilateral Forefoot Squat (UFS) test of postural stability. The 0-100 SFI score quantified perceptions of persisting effects of previous injuries. The RPR represented the number of outermost target hits (rings 4 and 5 of 64 target buttons arranged in a pattern of 5 concentric rings on a 1.2 m x 1.2 m board) while simultaneously reciting text that scrolled across a centrally located screen. The UFS test utilized a smartphone accelerometer to quantify the root mean square (RMS) of instantaneous change in body mass acceleration (Jerk) on the dominant extremity. All sprains, strains, and head injuries sustained from the beginning of practice sessions to the end of the 13-game season were documented, along with the number of player appearances in games.

RESULTS: Injuries were sustained by 14 of 43 players (33%). Univariable associations of binary risk classification with injury occurrence were: SFI ≤ 86 (OR=1.77), UFS Jerk RMS ≥ 0.06 (OR=4.19), RPR ≤ 11 Hits (OR=2.95), and Games Played ≥ 8 (OR=3.16). A large SFI X UFS X RPR interaction effect was identified (OR=11.20). Logistic regression results for the combination of the 3-way interaction (Adjusted OR=21.32) with Games Played ≥ 8 (Adjusted OR=6.19) yielded a strong prediction model ($\chi^2_2 = 9.04$, $p = .011$; $R^2 = .265$). Cox regression results for a binary SFI X UFS X RPR risk classification, adjusted for the potentially confounding effect of differential game exposure among players (0-13 games), demonstrated a strong association with time to injury occurrence (HR=4.65; 90% CI: 1.74, 12.44).

CONCLUSIONS: The findings support the potential for reduction of football injury risk through targeted interventions that address modifiable deficiencies in peripheral visual awareness, reaction time, and postural stability.

437 Board #258 May 31 11:00 AM - 12:30 PM
Relationships Among Lower Extremity Range Of Motion, Postural Control, And Power Generation Asymmetries: The FPPE Project

Daniel R. Clifton, Cambrie Starkel, James A. Onate. *The Ohio State University, Columbus, OH.*
 Email: dclifton88@gmail.com
 (No relationships reported)

Lower extremity (LE) musculoskeletal (MSK) injury risk factors are often examined in isolation without regard to how their interrelationships may influence injury risk. Developing a better understanding of relationships among MSK injury risk factors may help inform future injury risk assessment models. **Purpose:** Identify relationships among LE range of motion (ROM), postural control and power generation asymmetries. **Methods:** Prior to the start of their competitive sports seasons, high school football, soccer, basketball and lacrosse athletes completed the ankle dorsiflexion weight-bearing lunge (DF), single leg anterior reach (SLAR), and anterior single leg hop for distance (SLHOP) tests as part of the Functional Pre-Participation Physical Evaluation project. These tests were used as assessments of LE ROM, postural control, and power generation, respectively. DF measurements were recorded in centimeters while SLAR and SLHOP distances were recorded in centimeters and normalized to the participants' leg lengths. Limb symmetry indices (LSI) were calculated for all tests as the minimum score of the two legs divided by the maximum score. Linear regression was used to assess direct effects of DF LSI and SLAR LSI on SLHOP LSI. A linear regression-based mediation analysis was performed to determine if DF LSI was indirectly related to SLHOP LSI through an effect on SLAR LSI. Statistical significance of the indirect effect was assessed using a 95% bias-corrected bootstrapped confidence interval (CI) with 50,000 samples. A 95%CI that did not include 0.00 was considered statistically significant. Alpha level was set *a priori* at $p < 0.05$. **Results:** 3,765 male (15.65 \pm 1.23 years, 1.77 \pm 0.09m, 74.34 \pm 16.38kg) and 1,874 female (15.51 \pm 1.17 years, 1.65 \pm 0.07m, 60.26 \pm 9.94kg) high school athletes participated in this study. DF LSI (coefficient: 0.03, 95%CI=0.02-0.04; $p < 0.001$) and SLAR LSI (coefficient: 0.21, 95%CI=0.17-0.24; $p < 0.001$) were directly related to SLHOP LSI. DF LSI was indirectly related to SLHOP LSI (coefficient: 0.005, 95% bootstrapped CI=0.003-0.007) through its effect on SLAR LSI. **Conclusions:** LE ROM, postural control, and power generation asymmetries are related through a combination of direct and indirect effects. Future research should examine how these interrelationships influence LE MSK injury risk.

The Comprehensive High-level Activity Mobility Predictor-Sport (CHAMP-S): A Performance-Based Outcome Measure to Quantify High-level Mobility and Assist with Return to Sport for Division I Collegiate Football Players

Ignacio A. Gaunaud, Michele Raya, Luis Feigenbaum, Christopher L. Bennett, David Viggiano, Lee Kaplan, Robert Gailey. *University of Miami, Coral Gables, FL.*
 Email: igunaud@med.miami.edu
 (No relationships reported)

The Comprehensive High-level Activity Mobility Predictor (CHAMP) is a reliable and valid outcome measure that assesses high-level mobility in Service Members (SM) with traumatic lower limb loss. The CHAMP has the potential to be used to assess current high-level mobility capabilities in healthy, athletic individuals, to determine those athletes that may be at risk for injury, can be administered throughout rehabilitation process, and can assist with return to play decision making for collegiate athletes that suffer lower limb injuries.

Purpose: To develop the reliability and validity of the Comprehensive-High-Level Activity Mobility Predictor-Sport (CHAMP-S) in Division I Collegiate Football Players. **Method:** 206 student athletes participated in the study. 97 were tested at one time by three testers (two using the paper format and one using a mobile

device application) to determine CHAMP-S interrater reliability. 115 had completed CHAMP-S, anthropometric measures, upper and lower limb power, speed, and agility measures and underwent correlation analysis. 206 underwent ANOVA followed by post hoc analysis to determine differences between CHAMP-S scores between different football positions. Twenty athletes who underwent season ending injury were administered the CHAMP-S every 4-5 weeks throughout rehabilitation to assess change in high-level mobility and determine return to sport.

Results: The ICC's for the CHAMP-S items ranged from 0.90 (95% Confidence Interval, CI: [0.85, 0.93]) to 0.98 (95% Confidence interval, CI: [0.97-0.99]) for Single Limb Stance, Four-meter side step test, L-Test, and Illinois Agility Test. The CHAMP-S was significantly correlated with BMI, % Body Fat, Vertical Jump, Broad Jump, 40-yard dash, and shuttle run. The CHAMP-S demonstrated differences between linemen and skilled position players in all planes of movement. All 20 athletes returned to play safely and have not suffered re-injury to the ipsilateral or contralateral lower extremity. The athletes achieved 103% \pm 5% (95-109%) of their baseline CHAMP-S score ($p = 0.09$). **Conclusion:** The CHAMP-S is a reliable and valid measure of high-level mobility in Division I Collegiate Football Players that can help determine differences by position and assist return to sport following lower limb injury.

Predicting Knee and Thigh Injury Risk Using Scaled Vertical Jump and Standing Long Jump Power

Suzanne M. Konz. *Marshall, Huntington, WV.*
 Email: konz@marshall.edu
 (No relationships reported)

Movement tests, such as the VJ and SLJ, are used to determine power, athlete development, and quantify training protocol effectiveness. An idea exists to compare the power outputs from a VJ and a SLJ to give a picture of lower extremity injury risk. The ability to use easy and cost-efficient common movement tests could greatly enhance the capabilities of allied health care professionals.

PURPOSE: to examine the ability to predict knee and thigh injury based upon an allometrically scaled ratio of VJ and SLJ power.

METHODS: Participants included 26 female NCAA-I athletes from soccer and volleyball teams. The study examined testing data on the athletes before an off-season training cycle. Previous thigh or knee injury was compared to scaled Avg. power ratio, scaled peak power ratio, and z-scores for Avg. power and peak power. Correlation and ROC curves analyzed the relationships. Significance was set at the .01 level.

RESULTS: There were no correlations between the variables of interest and an athlete's past injury history. The individual team variables also revealed no correlation. ROC curves indicated: VJ Avg. power (.631), VJ peak power (.663), SLJ Avg. power (.622), and the VJ/SLJ peak power ratio (.663) indicated individuals who are at risk for injury.

CONCLUSIONS: Correlation indicates that ratios of power output for VJ and SLJ are not effective for predicting injury potential. A reason for the lack of correlation could be due to the crossover in vertical and horizontal components of VJ and SLJ success. The crossover of the horizontal components in the VJ jump is not as impactful as the vertical pieces of the SLJ. Each sport has different skills involved. The ROC curves do not provide strong specificity or sensitivity for predicting injury risk. The peak power ratio does not provide a solid means to predict injury risk. The z-scores of the Avg. power ratio and the peak power ratio failed in sensitivity and specificity. However, using the individual outputs of each revealed interesting information. VJ Avg. power, VJ peak power, and SLJ Avg. power provide a degree of prediction capability. The data confirms that the two sports are different from each other in power needs. Using the performance tests of the VJ and the SLJ to determine injury risk does seem to predict the possibility of a knee or a musculoskeletal thigh injury.

Test-Retest Reliability of Functional Tasks in Healthy High School Athletes: The FPPE Project

Cambrie Starkel¹, Daniel R. Clifton¹, Thomas M. Best, FACSM², James Borchers, FACSM³, Ajit Chaudhari, FACSM¹, R. Dawn Comstock³, Nelson Cortes⁴, Jay Hertel, FACSM⁵, Xueliang Pan¹, Bonnie Van Lunen⁶, James Onate¹. ¹The Ohio State University, Columbus, OH. ²University of Miami, Miami, FL. ³University of Colorado-Anschutz, Denver, CO. ⁴George Mason University, Manassas, VA. ⁵University of Virginia, Charlottesville, VA. ⁶Old Dominion University, Norfolk, VA. (Sponsor: James Borchers, FACSM)

(No relationships reported)

The 4th edition of the Pre-Participation Physical Evaluation (PPE) recommends functional testing for the musculoskeletal portion of the examination. However, limitations exist concerning currently recommended functional test components and the feasibility of implementing this test battery in the secondary school setting. In particular, test-retest reliability for recommended functional tests across secondary school settings has yet to be established.

PURPOSE: Determine test-retest reliability of three functional tests utilized in the Functional Pre-Participation Physical Evaluation (FPPE) project.
METHODS: A convenience sample of four high schools currently enrolled in the FPPE project participated. Prior to the start of their competitive sports seasons, high school athletes completed a weight-bearing lunge to assess ankle dorsiflexion range of motion (DF) as well as the single leg anterior reach (SLAR) and anterior single leg hop for distance (SLHOP) tests as part of the FPPE project. Athlete testing was conducted by the head Certified Athletic Trainer (AT) at each high school and was repeated one week after the initial test date. Intraclass correlation coefficients (ICC) using a two-way mixed effects model and an absolute agreement definition were calculated for each functional test. Separate ICCs were calculated for each AT. ICC(3,1) values were interpreted as: excellent (>0.75), fair to good (0.40-0.75), and poor (<0.40).
RESULTS: 40 athletes (m/f= 23/17, 16.4±1.1 y, 1.78±0.11 m, 70.1±13.1 kg) participated in this study (10 athletes per high school). Test-retest reliability was excellent for all raters for both the DF (ICC(3,1) range: 0.817-0.975) and SLHOP tests (ICC(3,1) range: 0.832-0.963). Test-retest reliability of the SLAR was found to be excellent for two raters (ICC(3,1): 0.813, 0.876) and fair to good for two raters (ICC(3,1): 0.583,0.693).
CONCLUSIONS: Test-retest reliability for functional tasks utilized in the FPPE project was generally excellent across a sample of high school ATs, supporting the utility of these tasks in longitudinal assessments in secondary school settings. Supported by NIH Grant 5R01-AR062578-02.

Injury And Illness Profiles During The 2014 South African Ironman Ultra-distance Triathlon
 Louis J. Holtzhausen, FACSM, Charles R. Smit, Gina Joubert, Konrad Von Hagen. *University of the Free State, Bloemfontein, South Africa.*
 Email: holt.louis@gmail.com
 (No relationships reported)

PURPOSE: High physiological demands on ultra-endurance triathletes and potentially serious medical complications require scrutiny of illness and injury profiles. Accurate data are required for planning of medical services. The aims of the study were to record medical history, illness and injuries of athletes receiving medical attention during the 2014 Ironman South Africa (IMSA) triathlon, and to investigate the temporal presentation of medical encounters, to optimise deployment of medical services for IMSA events.
METHODS: A retrospective, cross-sectional study of all medical encounters and associated factors during the 2014 IMSA was conducted.
RESULTS: The incidence of medical encounters was 7.8%. A significantly higher percentage of younger participants encountered medical problems (p=0.04). The majority of patient encounters (80.1%) occurred after completion of the race, and 49.2% of patient encounters occurred during the last eight hours of the event. The median duration of treatment was 26 minutes (2-126 minutes). Medication was used by 35.1% of patients during the race, and 36.2% in the three preceding days. The most common medical encounters were exertion-related (71.2%), followed by gastro-intestinal (16.4%), dermatological (11.9%), musculoskeletal (9.6%) and cardiorespiratory conditions (2.4%).
CONCLUSION: Medical encounters occurred more frequently in later stages of the 2014 IMSA, as recorded elsewhere. The majority of medical conditions were exertion-related. Potential higher risk has been associated with medication use, recent illness, and in younger participants. Temporal stacking of medical personnel and resources, planning of resources according to expected conditions, preventative measures for high-risk behaviour, and on-going data collection are recommended.

Adding BMI to Electrocardiographic Criteria improves Accuracy of Predicting Left Ventricular Mass in Football Athletes
 Stephen F. Crouse, FACSM¹, John P. Erwin, III², Stephanie White³, Thomas H. Meade⁴, Steven E. Martin¹, John S. Green, FACSM¹, Jonathan M. Oliver², Dustin P. Joubert⁶, Bradley S. Lambert¹, Joe P. Bramhall¹, Kory Gill¹, David Weir¹, Homer Tolson¹. ¹Texas A&M University, College Station, TX. ²Texas A&M University College of Medicine, Bryan, TX. ³SSM Heart Institute/Clayton, St. Louis, MO. ⁴Baylor Scott and White, College Station, TX. ⁵Texas Christian University, Fort Worth, TX. ⁶Stephen F. Austin State University, Nacogdoches, TX.
 Email: s-crouse@tamu.edu
 (No relationships reported)

Electrocardiographic (ECG) measurements are commonly used to diagnose left ventricular (LV) hypertrophy in men, yet the validity of this practice has seldom been appraised in American-style football (ASF) athletes. **PURPOSE:** Evaluate the accuracy of five commonly used ECG criteria for LV hypertrophy – Murphy (AJC, 1984), Sokolow (AHJ, 1949), Gruber (Arch Intern Med, 1943), Cornell (Casale, JACC, 1985), and Cornell voltage-duration product (C-VDP) (Malloy, JACC,

1992) – to predict echocardiographically (ECHO) measured LV mass (LVM) in ASF athletes. **METHODS:** Resting 12-lead ECG and ECHO procedures were performed on 62 collegiate ASF players first entering an NCAA Football Bowl Subdivision university; age=18±1 yr., ht=186±7 cm, wt=99.9±22.6 kg, BMI=28.6±5.0 kg·m⁻², and BSA=2.23±0.26 m². Regression was used to predict ECHO-derived LVM and LVM/BSA from the five ECG criteria, and from the ECG criteria with BMI (+BMI) added to the model. **RESULTS:** Table (*p<0.01 for regression)

R ² for Model ECG Criteria	LVM r ²	+BMI R ²	LVM/BSA r ²	+BMI R ²
Murphy	.001	.169*	.039	.039
Sokolow	.010	.200*	.052	.052
Gruber	.001	.164*	.030	.034
Cornell	.006	.160*	.018	.022
C-VDP	.000	.159*	.021	.026

None of the ECG criteria alone were predictive of LVM or LVM/BSA in ASF athletes. Adding BMI to the regression significantly improved the predictive accuracy for LVM but not for LVM/BSA. **CONCLUSION:** ECG criteria alone are not useful in diagnosing LVH in ASF athletes. Our results suggest that adding demographic measures to the predictive model may improve diagnostic accuracy. Thus, new algorithms for evaluating LVM and LVH in ASF athletes should be explored using demographic, body habitus, cardiovascular, and other ECG criteria.

Effect of Previous Injury on Functional Movement Screening Outcomes
 Joshua Hoffman¹, Michael Krill¹, Toren Moore¹, James Borchers, FACSM¹, Timothy Hewett, FACSM². ¹The Ohio State University, Columbus, OH. ²Mayo Clinic, Rochester, MN.
 (Sponsor: Timothy Hewett, FACSM)
 Email: Joshua.Hoffman@osumc.edu
 (No relationships reported)

To improve player safety, medical professionals use questionnaires, pre-participation physicals, screening tests, biomechanical analyses, and strength testing to describe characteristics of high risk athletes. The seven-test Functional Movement Screening (FMS) is widely used in current practice, and research efforts have demonstrated the efficacy of the FMS to predict future injury. However, the effect of previous injury on FMS scores has not been defined. Because previous injury is a significant predictor of subsequent injury, an understanding of the effects of previous injury on total FMS score is critical to assess the efficacy of the screening tool to predict future injury. **PURPOSE:** Determine the efficacy of the FMS evaluation to assess prior musculoskeletal injury. **METHODS:** From 2012-2015, 58 incoming football athletes completed the FMS and a medical history questionnaire. Trained sports medicine researchers performed the screens and distributed questionnaires. Descriptive statistics were calculated to assess the effectiveness of total FMS results to predict previous injury. The previously established ≤ 14 score cut-off was utilized to establish the two groups' at-risk levels. The established cut-off was reported to indicate football players at-risk for serious injury defined as out of physical participation for > 2 weeks. **RESULTS:** 46 athletes reported a prior musculoskeletal injury compared to 12 that denied prior injury. The group of 46 athletes was equally split on FMS scores with 23 athletes that recorded a score of ≤ 14 and 23 athletes that recorded a score > 14. The group that denied previous injury (N=12) was also evenly split with 6 athletes that recorded of score of ≤ 14 and 6 with a score > 14. The FMS with a cut-off score of 14 recorded a sensitivity and specificity of 0.500. The positive predictive value was 0.793 with a negative predictive value of 0.207. **CONCLUSIONS:** Prior history of musculoskeletal injury as reported on the incoming medical questionnaire did not affect total score on the FMS with specificity or sensitivity. Future studies should evaluate the effects of previous injury on other clinical screening tools. In addition, better screening tools could be developed that assess the incidence of previous injury and risk of future injury.

High School Preparticipation Evaluation Screenings: Do States Include Mental Health Recommendations?
 Jacey Keeney¹, Josh Kaplan², Kristin L. Schneider¹. ¹Rosalind Franklin University of Medicine & Science, North Chicago, IL. ²Wittenberg University, Springfield, OH.
 Email: Jaelyn.Keeney@my.rfums.org
 (No relationships reported)

7.7 million high school students participate in sports annually and are required to have a physical. Given the focus on illness and injury, physicians may be more likely to focus on physical health than mental health. ACSM recommends the *Preparticipation Evaluation, 4th Edition* (PPE-4), which is the standard assessment tool and includes

guidelines for assessing mental health. However, little is known about the inclusion of mental health recommendations in state PPE forms. Screening mental health among athletes may prevent psychological and performance-related difficulties. **PURPOSE:** This study examines the inclusion of mental health in PPE forms in the US. We describe the mental health content of state PPE forms and consistency with the PPE-4. The content of the PPE-4 suggests that eating disorder symptoms be assessed using yes/no questions and other topics (e.g., mood, anxiety, stress, home safety, and substance use) be included as physician reminders (e.g., open-ended). **METHODS:** PPE forms were retrieved via the National Federation of State High School Associations website (n=47; 4 states did not have forms). Two raters independently coded PPE forms to evaluate adherence to the PPE-4. PPE forms were coded as whether mental health issues were not addressed, addressed as a question, or addressed as a reminder. **RESULTS:** There was acceptable agreement between coders (kappa range: 0.7-1.0; M=0.9). 55.3% of forms included a question about history of an eating disorder, 83.0% included a question pertaining to worry about weight, 83.0% included a question about presence/frequency of menstrual period, and 70.2% included a question about attempts at weight loss/gain. The physician reminders were used in less than 60.0% of forms. 46.8% of forms provided a reminder to physicians to assess substance use and safety at home. Stress was included as a reminder on 59.6% of forms. 59.6% of states included a reminder to assess for sad, hopeless, depressed, or anxious mood, with only 8.5% including a question about mood or anxiety. **CONCLUSIONS:** The PPE-4 is used to ensure safe participation in high school sports, but most state forms omit questions related to mental health. Future studies should examine physician assessment of mental health during PPE, as well as the course of treatment following a positive screen for mental health issues.

Predicting Musculoskeletal Injuries from Psychological, Neurocognitive and Physical Factors in Collegiate Athletes Without Injury History

Monique Mokha, 33128, Peter Sprague, 33128, Dustin Gatens, Steve Orris, Steve Russo. *Nova Southeastern University, Ft. Lauderdale, FL.*
 Email: gm588@nova.edu
 (No relationships reported)

Musculoskeletal injury (MSI) risk in athletes is thought to be multifactorial in nature and to include psychological, neurocognitive and physical sources. However, most researchers lack the time and resources to assess these multiple factors in large groups of athletes. Examining multiple factors at once may yield improved injury prediction. **PURPOSE:** To determine if body fat percentage (high or low BF%), ImPACT reaction time (RT in sec), ImPACT visual motor speed (VMS in sec), Functional Movement Screen (FMS) scores, Beck's depression indices (BDI), and/or Beck's anxiety indices (BAI) could predict MSI in athletes without MSI history. **METHODS:** Seventy-one [(males, n=35; age, 19.9±1.5 yrs; height, 1.77±0.08m; mass, 73.2±14.6kg) (females, n=36; age, 19.1±1.1 yrs; height, 1.68±0.06m; mass, 70.1±9.4kg)] NCAA Division II athletes without MSI history participated in this prospective cohort study. Data were collected during pre-participation examinations as part of standard protocol. Injuries were tracked for an academic year by each team's certified athletic trainer via computer software. Pearson Chi-square analyses were used to determine if MSI could be predicted by BF%, RT, VMS, BDI, BAI, presence of a "1" on the FMS, or presence of an asymmetry on the FMS, $p < .05$. BF% was dichotomized as high or low for males (>15%) and females (>25%). **RESULTS:** Twenty-seven athletes (38.0%) sustained a total of 54 MSI. Two of the 7 independent variables were statistically significant predictors of MSI. Athletes with asymmetry on any of the FMS tests ($\chi^2=12.299$, $p < .001$) or high BF% ($\chi^2=5.820$, $p < .015$) were more likely to sustain a MSI. The relative risks for an FMS asymmetry and high BF% were 1.89 (CI: 1.22-2.94, $p = .001$) and 1.99 (1.06-3.75, $p = .015$), respectively. **CONCLUSION:** Athletes without a history of MSI may be at risk of MSI if they have high BF% or an asymmetry on any of the FMS tests. The neurocognitive and psychological test components may not yield significant injury prediction value in this group. Since BF% and FMS scores are modifiable risk factors clinicians may justify their assessment during pre-participation examinations.

446 Board #267 May 31 11:00 AM - 12:30 PM
The Efficacy Of Performance On Clinical Hop Tests To Predict Previous Lower Extremity Injury

Toren Moore. *The Ohio State University, Columbus, OH.*
 (No relationships reported)

Background: Clinical hop tests, such as the 6-meter timed hop (6TH) and single-leg triple crossover hop (TXH) evaluate strength and neuromuscular coordination in athletes' lower extremities. Clinicians use symmetry in performance of these tests as a return to sport criteria after an injury, such as an anterior cruciate ligament (ACL) rupture. In addition, symmetries have been identified as a risk factor for lower extremity injuries. However, the efficacy of clinical hops to identify athletes with a history of previous injury is not well defined.

Purpose: Determine the efficacy of performance on 6TH and TXH to predict previous lower extremity injury.

Methods: 51 and 52 male division I football players performed a 6TH and TXH, respectively. All athletes completed a medical history questionnaire. Players were categorized as either self-professing to have a previous lower extremity injury, or not having a previous lower extremity injury. Bilateral asymmetry was defined as a greater than 10% difference in performance on the 6TH and TXH between limbs. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated to evaluate the efficacy of symmetry to predict previous injury history. Results: of the 51 players that performed the 6TH, 14 reported a previous lower extremity injury. 14 of the 52 players that performed the TXH reported previous lower extremity injury. Sensitivity, specificity, PPV, and NPV are reported for the 6TH (Figure 1a) and TXH (Figure 1b).

a.	Injury (+)	Injury (-)
Symmetry $\geq 10\%$	7	11
Symmetry $< 10\%$	7	26
Sensitivity	0.500	
Specificity	0.703	
PPV	0.389	
NPV	0.788	
b.	Injury (+)	Injury (-)
Symmetry $\geq 10\%$	2	11
Symmetry $< 10\%$	12	27
Sensitivity	0.143	
Specificity	0.711	
PPV	0.154	
NPV	0.692	

Figure 1. Analysis of previous injury history and performance on the a. 6TH and b. TXH tests.

Conclusion: Bilateral asymmetry does not predict previous injury incidence. The efficacy of additional clinical tests, such as the single-leg hop, should be evaluated.

Effects of Previous Lower Extremity Injury on Functional Movement Screening Results

Michael K. Krill¹, Joshua T. Hoffman², Toren Moore², James R. Borchers, FACSM², Timothy E. Hewett, FACSM³. ¹Florida Atlantic University Charles E. Schmidt College of Medicine, Boca Raton, FL. ²The Ohio State University Wexner Medical Center, Columbus, OH. ³Mayo Clinic, Rochester, MN.
 Email: krill.11@buckeyemail.osu.edu
 (No relationships reported)

Background: Functional movement screening (FMS) is a seven-movement screening test frequently utilized as a component of pre-season physicals. Individual tests evaluate movement patterns to identify athletes potentially predisposed to injury and previous research has established a cut-off for football athletes at high risk for serious injury defined as out of physical participation for > 2 weeks.

Purpose: To examine the effects of previous lower extremity injury on functional movement screening scores, specifically the lower extremity FMS tests.

Methods: All incoming freshman football student-athletes for the 2012-2015 seasons completed functional movement screening performed by FMS trained sports medicine researchers. All incoming athletes completed a past medical history questionnaire to document any previous injury history. Descriptive statistics were calculated to measure the effect of lower extremity injury on the FMS scores for deep squat, hurdle step, active straight leg-raise, rotary instability and inline lunge tests. The established ≤ 8 lower extremity cut-off was utilized to establish the two groups' level of risk.

Results: 60 incoming football athletes completed both the medical questionnaire and functional movement screening from 2012-2015. 36 athletes reported a previous lower extremity injury and 17 of those athletes demonstrated scores below the lower extremity cut-off (Sensitivity: 0.472). The 24 remaining athletes reported no prior lower extremity injury and 12 scored above the cut-off (Specificity: 0.500). Previous lower extremity injury had a higher positive predictive value (0.586) than negative predictive value (0.387) on lower extremity functional movement screening scores.

Conclusion: The self-reported previous lower extremity injury history of our incoming football student-athletes was not specific or sensitive for prediction of score on the functional movement screening evaluation to identify high risk lower extremity movement patterns. Future work should continue to evaluate variables that may affect results of screening tests for athletes at high risk of injury to continue to optimize athlete safety.

Identifying Metabolic Syndrome Risk Factors in Division 1 and Division 3 Football Players: a Pilot Study

Janet T. Peterson, FACSM¹, Garth J. Babcock², Annika Vahk², Wendy ES Repovich, FACSM². ¹Linfield College, McMinnville, OR. ²Eastern Washington University, Cheney, WA.
 (No relationships reported)

Retired NFL football players are at an increased risk for Metabolic Syndrome (MetS). Cross sectional studies in high school and college football players suggest an increased risk even at this level. It is not clear when MetS risk factors (RF) develop and if certain markers can be used to assess risk for early intervention. **PURPOSE:** The purpose of this pilot study was to identify MetS risk factors using the NCEP ATP III standards and measures of abdominal obesity in freshmen football players from a Division 1-FCS and a Division 3 team. Additionally, this study sought to identify if risk differed by player position and/or by college division. **METHODS:** Fifty freshmen (Division 1, n = 18, Division 3, n = 32) football players volunteered to be tested before the start of the competitive season. Testing for MetS risk factors included fasting Triglyceride (TG), High Density Lipoprotein (HDL), blood glucose (BG), blood pressure (BP), and waist circumference (WC). Additional measures included percent body fat (%BF) and subcutaneous (SCAT) and visceral fat (VAT) depth. Descriptive statistics and comparison between schools related to MetS RF were analyzed. A Pearson Correlation was used to determine the relationship between the clinical markers. **RESULTS:** Ten players (20%) met the criteria for MetS (n = 2 with 3 RF, n = 6 with 4 RF, and n = 2 with 5 RF). Division 1 had a higher percentage of players (n = 5, 27.8%, 3 offensive linemen) meeting the criteria for MetS compared to the Division 3 players (n = 5, 15.6%, 1 offensive lineman). All NCEP ATP III risk factors except BG were positively correlated with meeting the criteria for MetS, with the WC being the highest (r = 0.766, p = 0.000). Using non NCEP ATP III risk factors positive correlations were found between the %BF (r = 0.645, p = 0.000), SCAT (r = 0.352, p = 0.013), and VAT (r = 0.489, p = 0.000). Lineman meeting the criteria for MetS had a %BF > 21. **CONCLUSIONS:** This data suggests that freshmen football players have a high incidence of MetS RF. Waist Circumference and %BF should be included in pre-season evaluation with follow up for early intervention as necessary.

449 Board #270 May 31 11:00 AM - 12:30 PM
Examination of Y-Balance Performance in Chronic Ankle Instability

HYUNGPIL JUN, 83844-2401¹, Russell Baker¹, Lindsay Warren¹, Young-min Chun², Jin-Ah Kim², Smokey Fermin¹, Jeffrey Seegmiller¹, Sae Yong Lee². ¹University of Idaho, Moscow, ID. ²Yonsei Institute of Sports Science and Exercise Medicine, Yonsei University, Seoul, Korea, Republic of.
 (Sponsor: Lee Brown, FACSM)
 (No relationships reported)

Chronic ankle instability (CAI) is associated with reduced proprioception and range of motion, which often results in postural control deficits. The Y-Balance Test has been used to assess lower extremity mobility, functional performance, and risk of injury. An inability to maintain single leg stance, a component of the Y-Balance Test, is associated with CAI. The Y-Balance Test has not been examined to determine performance differences in cases of CAI. **PURPOSE:** To assess maximum reach distance (MRD) differences of the Y-Balance Test in CAI participants and healthy controls. **METHODS:** A case control study of 28 subjects (14 healthy [age: 27.57±3.23 years; height: 169.61±8.33 cm; weight: 76.98± 17.95 kg], 14 CAI [age: 24.07±4.46 years; height: 175.06±5.09 cm; weight: 82.24± 10.38 kg]); CAI participants were recruited per International Ankle Consortium guidelines using the Foot and Ankle Ability Measure (FAAM) and Cumberland Ankle Instability Tool (CAIT). Subjects performed three trials in each direction (Anterior [ANT], Postero-medial [PM], Posterolateral [PL]) of the Y-Balance Test. The trials were averaged and normalized for limb length to produce a MRD value for each direction. Independent sample t-tests were used to compare MRD differences between groups. Alpha was set at p ≤ .05; an effect size above .3 was considered clinically meaningful. **RESULTS:** Significant differences were not found for MRD in the ANT (mean difference = -1.23, p = .61, Cohen's d = 0.20, 95% CI for Cohen's d = -0.94 - 0.55), PM (mean difference = 4.03, p = .27, Cohen's d = 0.43, 95% CI for Cohen's d = -0.32 - 1.17), or PL (mean difference = 4.21, p = .26, Cohen's d = 0.43, 95% CI for Cohen's d = -0.32 - 1.18) directions. The control group exhibited higher scores in the PM (106.77 vs. 102.73) and PL (105.16 vs. 100.96) directions, while the CAI group produced a higher score (61.62 vs. 60.39) in the ANT direction. **CONCLUSION:** Statistically significant differences were not found between groups on the Y-Balance Test; however, the differences in the PM and PL directions may be clinically meaningful. Clinicians may need to consider PM and PL MRD deficiencies on the Y-Balance Test when treating CAI patients; however, further research is needed to determine the sensitivity of the Y-Balance Test for identifying CAI.

A-55 Free Communication/Poster - Resistance Training

Effects of Rest Interval Duration on the Volume Completed During a High-Intensity Bench Press Exercise

Dennis J. Hernandez, Gil Spitz, Anna M. Welch, Young Sub Kwon. Humboldt State University, Arcata, CA.
 Email: youngsubkwon@hotmail.com
 (No relationships reported)

Between set rest intervals (RI) are one of the most important variables in resistance training; however, no known research has investigated the effects of RIs greater than 5-min during strength training (> 85% of 1RM). **PURPOSE:** The purpose of this research was to examine the effects of three different RIs (2, 5, and 8-minute) on training volume (TV) (kg, sets x reps x resistance) completed during a high-intensity bench press exercise (> 85% of 1RM). **METHODS:** 15 resistance trained males (mean± sd, age = 26+ 5 yr, height = 161+ 6 cm, body mass = 79+ 6 kg, bench press 1RM ratio = 1.39+ 0.1) completed 3 experimental sessions, during which 4 sets of the bench press were performed with 85% of a 1RM load. During experimental sessions, the bench press was performed with a 2, 5, or 8-minute RI in a randomly counterbalanced design. Data was analyzed using a one-way ANOVA with repeated measures. **RESULTS:** The greatest TV (p < 0.05) was attained when subjects used an 8-min RI between sets (table 1). Additionally, TV completed using the 5-min RI was significantly greater (p < 0.05) when compared to the 2-min RI (table 1). **CONCLUSIONS:** Resistance trained males, with the goal of greater volume during strength training, would benefit from longer RIs. Specifically, using an 8-min RI between 4 consecutive sets of a bench press allows for a greater TV.

	2-min	5-min	8-min
Volume(Kg)	1448 + 215*#	1793 + 315*	2207 + 372

* p < 0.05, value significantly different from 8-min RI
 # p < 0.05, value significantly different from 5-min RI

Evaluation Of Strength And Conditioning With On-court Success In Division I Collegiate Volleyball: A Retrospective Study

Jennifer Bunn¹, Gregory Ryan, FACSM², Gabriel Button³, Sidong Zhang¹. ¹Campbell University, Buies Creek, NC. ²Georgia Southern, Statesboro, GA. ³North Carolina State University, Raleigh, NC. (Sponsor: J.W. Yates, FACSM)
 Email: bunnj@campbell.edu
 (No relationships reported)

Strength, fitness, and athleticism are often emphasized in sport, but there is little evidence addressing the relationship of these variables to performance. **PURPOSE:** To assess relationships between strength and conditioning (SC) measures and game performance in Division I volleyball. **METHODS:** Five years of data, were collected from one women's Division I collegiate team, n = 76. All game and SC stats were normalized to z-scores. SC measures included: T-drill, 18.3 m sprint, squat, hang clean, sprint recovery test, vertical jump, and broad jump. ANOVA was used to assess performance differences by position, and multiple stepwise regression was used to assess relationships between game and SC stats. **RESULTS:** There was a significant difference by position for broad jump (p = .002), 18.3 m sprint (p = .036), vertical (p < .001), and total strength (p = .019). Overall, there was a significant correlation between on-court performance and SC measures (r = .439, p < .001). Significant position-specific correlations (p < .05) are as follows: defensive specialist, total strength with digs (r = .798); setters, hang cleans with assists (r = .818) and digs (r = .886), broad jump with block assists (r = .846) and total game performance (r = .801); outside hitters, vertical with digs (r = .444) and total game success (r = .529), and total strength with kills (r = .660) and errors (r = .577); middle blockers, broad jump with kills (r = .694), errors (r = .736), block assists (r = .705), block solos (r = .691), and total game success (r = .594).

CONCLUSIONS: These data indicate that some SC measures correlate well with on-court performance and are specific by position. A prudent training approach may be for SC coaches to focus on improving specific measures by position, which could then translate to improved game performance.

452 Board #273 May 31 9:30 AM - 11:00 AM
Effects Of Barbell-based, Full-body Resistance Training On Muscular Strength, Lean Body Mass, And Cardiometabolic Biomarkers.

Robert S. Santana, Carol Johnston. *Arizona State University, Phoenix, AZ.*
(No relationships reported)

Resistance training improves muscular strength and hypertrophy, as well as cardiometabolic biomarkers. However, results in the literature have been inconsistent which may relate to the heterogeneity in training protocols. **PURPOSE:** This single-group pilot study defined a standardized barbell-based linear periodization full-body resistance training program and assessed its effect on muscular strength and biomarkers. **METHODS:** Ten healthy, untrained males (26.4±7.5 y) underwent 4 weeks of a barbell-based, full-body, linear periodization program 3x/week. Exercises included the squat, standing press, bench press, and deadlift. Participants performed 3 sets of 5 repetitions on the squat, bench press, and standing press and 1 set of 5 repetitions on deadlift. Weight was incrementally added each training session. Maximum dynamic strength was assessed by 5-repetition maximum (5RM), and biomarkers (lipids, insulin, HOMA-IR, CRP, and glucose) were assessed. The study was IRB approved. **RESULTS:** 5RM increased on squat (79.4%; $p=0.005$), bench press (25.9%; $p=0.004$), standing press (45.3%; $p=0.004$), and deadlift (52.9%; $p=0.05$). The sum of four lifts also increased after 4 weeks of training (50.3%; $p=0.005$). Over the 4 weeks, lean body mass (LBM) increased (1.5%; $p=0.025$). Total and HDL cholesterol decreased significantly (-14.4% and -11.7% respectively) and LDL cholesterol trended downward (-15.8%) but the total:HDL cholesterol ratio was unaltered. **CONCLUSION:** It appears that untrained males can increase body strength on a 4-week full-body, barbell-based linear periodization training program. Changes in LBM occurred sooner than previously reported. A standardized resistance training protocol for building strength would facilitate research interpretation in this field. Randomized control trials with larger samples over longer time periods are needed to further investigate the effects of full-body barbell exercise training on changes in muscular strength, LBM, and cardiometabolic biomarkers.

Eccentric Resistance Training in Adults with and without Spinal Cord Injuries

Whitley J. Stone, Sandra L. Stevens, Dana K. Fuller, Jennifer L. Caputo. *Middle Tennessee State University, Murfreesboro, TN.*
 Email: wjs3c@mtmail.mtsu.edu
(No relationships reported)

Following incomplete spinal cord injuries (iSCI), individuals lose motor control, muscle fiber cross sectional area, and contractile force capacity, ultimately resulting in compromised functional independence. An innovative exercise modality for populations with impaired functional capacity is eccentric resistance training (ERT). **PURPOSE:** The purpose of this study was to examine the effects of active lower body ERT using a seated eccentric ergometer in individuals with iSCI and controls (CON). Specifically, the study was designed to determine if those with iSCI adapt similarly to ERT as CON participants, as well as the overall safety and efficacy of ERT in this population. **METHODS:** This pilot investigation involved the recruitment of persons with iSCI ($n=3$) and age- and sex-matched able-bodied CON ($n=3$). The 8-week intervention focused on building lower extremity eccentric strength by progressively increasing the duration and intensity of the three training sessions per week. Control participants completed the same training intervention. Main outcome measures were eccentric strength (eccentric ergometer), isometric strength (hand held dynamometer), and leg muscle mass (DEXA). **RESULTS:** All participants completed all sessions of the ERT. At posttest, eccentric strength improved from pretest ($p=.044$, $\eta_p^2=.68$) with similar changes between groups ($p>.05$). The percent improvement in isometric strength for those with iSCI (41.5%) was different than CON (-2.8%) after training ($p=.044$). Neither group demonstrated a change in grams of muscle mass in the legs at posttest ($p>.05$). **CONCLUSION:** Active lower body ERT is well tolerated and effective at increasing lower extremity strength in those with iSCI. These adaptations are likely attributable to neuromuscular development rather than a hypertrophic response.

Bench Press Strength Changes Over 23 Years in Police Recruits with Gender Comparisons

Elizabeth H. Seldomridge¹, Robert W. Boyce, FACSM¹, Austin C. Smith¹, Haley O. Norris¹, Glenn R. Jones², Michele A. Parker¹. ¹*University of North Carolina Wilmington, Wilmington, NC.* ²*City of Charlotte Police Department, Charlotte, NC.*
 Email: ehs3188@uncw.edu
(No relationships reported)

Strength is a vital component in the performance of police duties to ensure the safety of officers and those they serve. Therefore, the initial strength the officers brings to the training program predicts the level of strength they will maintain throughout their careers. **PURPOSE:** To evaluate bench press strength changes that occur in police recruits from 1990 to 2013 with gender comparisons. **METHODS:** During the first week of police recruit training in a large southeastern metropolitan area, bench press strength and bench press weight ratio were evaluated in 2,460 recruits. ANOVA and Bonferroni post hoc procedures were used to evaluate data. **RESULTS:** The initial ANOVA indicated significant differences in males for both variables at $p\leq 0.05$. Males tended to increase in bench press strength from 1990 to 2007 (83.7±2.0 kg to 95.9±2.1 kg, $p\leq 0.01$). Male bench press strength tended to plateau after 2007. No discernible pattern was seen in females for both variables and little change in males was observed in bench press weight ratio. **CONCLUSIONS:** Overall, males had a tendency to become stronger over time when considering their initial test scores in recruit school. However, females tended to remain at approximately the same muscular strength across the 23 years.

Testosterone And Cortisol Responses To Superslow And Traditional Resistance Exercise In College-aged Males

Pragya Sharma Ghimire, Eonho Kim, Daeyool Kim, Michael Bemben, FACSM, Debra Bemben, FACSM. *The University of Oklahoma, Norman, OK.* (Sponsor: Dr. Debra Bemben, FACSM)
 Email: pragya@ou.edu
(No relationships reported)

Recent evidence suggests that Superslow resistance training (SS), involving low intensity workloads and slow repetitions, has potential to produce improvements in muscular strength similar to traditional high intensity resistance training (TR). Few studies have compared endocrine responses to SS and TR protocols. **PURPOSE:** To compare acute hormonal responses to two resistance exercise protocols that have similar exercise volumes, but differ in intensity and contraction speed. **METHODS:** Thirteen males (18-35 years) participated in this randomized crossover study. Participants performed two protocols in random order separated by 3-week washout periods. For TR, participants completed 3 sets of 8 reps at 80% 1-RM for four upper and lower body exercises with 1.5 seconds of concentric and eccentric contraction speeds. For SS, participants performed 1 set of each exercise to voluntary failure at 50% 1-RM with 10 seconds concentric and 5 seconds eccentric contraction speeds. Fasting morning blood draws were taken before (Pre), immediately post exercise (IP), and 15 min post exercise (15P). Serum samples were analyzed for testosterone (TES) and cortisol (Cor) concentrations using ELISA. Lactate and hematocrit were also measured for each condition. **RESULTS:** There were no significant differences in baseline values between the two conditions. There was a significant ($p<0.05$) time effect for raw concentrations of TES and Cor. TES significantly ($p<0.05$) decreased from IP to 15P for both conditions (SS- 8.25 ± 1.37 ng/ml to 7.38 ± 1.26 ng/ml; TR- 8.50 ± 1.25 ng/ml to 6.94 ± 0.88 ng/ml). There was a trend ($p=0.059$) for Cor to increase from Pre to IP for both conditions (SS - 166.66 ± 15.15 ng/ml to 216.08 ± 18.16 ng/ml; TR- 157.55 ± 8.77 ng/ml to 201.03 ± 19.84 ng/ml). TES % change showed a significant time effect as it increased from Pre to IP (SS- 0.95 ± 4.39%; TR- 15.39 ± 7.73%) and decreased from Pre to 15P (SS- -5.48 ± 6.70%; TR- -5.41 ± 3.79%). Cor % change was not different between the two conditions. Correcting for hemoconcentration eliminated the significant responses. **CONCLUSION:** Both protocols showed similar patterns of hormonal responses, which may have been mediated by plasma volume shifts. This finding supports that SS exercise could be a beneficial alternative for those unable to perform high-intensity resistance exercise.

456 Board #277 May 31 9:30 AM - 11:00 AM
Comparison Of Peak Power In The High Bar And Low Bar Squat Across Eight Loads
 Jacob R. Goodin, Caleb D. Bazyler, Jake R. Bernards, Joseph Walters, Satoshi Mizuguchi, Michael H. Stone. *East Tennessee State University, Johnson City, TN.*
 (No relationships reported)

PURPOSE: To examine differences in peak power output between high bar (HBS) and low bar back squats (LBS).

METHODS: Six trained males (25.0 ± 3.1 years, 1.78 ± 0.04 m, 87.6 ± 7.5 kg) with previous squatting experience (experience: 7.5 ± 4.1 years, HBS 1RM: 157.0 ± 15.3 kg, squat/bodyweight: 1.8 ± 0.18) completed the study using a crossover design. Subjects completed a 4-week familiarization phase with both conditions. Peak power data was collected over 2 sessions using dual uniplanar force plates synchronized with 2 string potentiometers on each side of the bar collecting at a sampling frequency of 1000 Hz using a BNC 2110 connector with an analog to digital converter. Subjects were randomly assigned to the HBS or LBS for 1 set of 3 repetitions at 20, 30, 40, 50, 60, 70, 80, and 90% of their most recent HBS training 1RM with 3 to 5 minutes' rest between sets and >72 hours between testing conditions. A 2x8 repeated measures analysis of variance was used to determine interactions and main effects for condition and load with post-hoc tests conducted for statistical main effects.

RESULTS: Analysis revealed significant main effects for load ($p < 0.01$) but not for condition. Peak power output was greatest at 70% of HBS 1RM for the LBS, and 80% of HBS 1RM for the HBS.

CONCLUSIONS: According to this pilot data, athletes seeking to increase power production ability should choose a squatting style in which they feel most proficient and comfortable. Furthermore, either the HBS or LBS can be used as the primary squatting movement, or as a secondary movement to provide variation and remove linearity from the training program. However, based on previous research it is likely that sport specific biomechanical parameters will influence the squatting style selection for the majority of athletes who participate in sports that involve jumping, sprinting, and change of direction. Training with loads between 70% and 80% of HBS 1RM may be optimal for increasing power production ability. Further research using a larger population of well-trained athletes is suggested in order to more precisely compare HBS and LBS power outputs.

Increased Performance of Upper-Body Strength Exercise: Effect of Leg Induced Increase in Blood Lactate Concentration
 Philipp Birnbaumer¹, Alexander Müller¹, Gerhard Tschakert¹, Serge P. von Duvillard, FACSM², Peter Hofmann, FACSM¹.
¹Institute of Sports Science, Graz, Austria. ²Institute of Sports Science, Salzburg, Austria. (Sponsor: Serge P. von Duvillard, FACSM)
 Email: pbirnbaumer@gmx.at
 (No relationships reported)

Studies have shown that high systemic blood lactate concentrations led to inhibition of glycolysis and an increase of oxidative metabolism in subsequent anaerobic exercise. **PURPOSE:** The aim of this study was to examine the effect of increased blood lactate (La) concentration induced by high intensity leg exercise on net lactate production and performance in subsequent dynamic arm pull-ups. **METHODS:** Nine trained sport students (age: 25.1 ± 1.9 yr; BMI: 21.7 ± 1.4) performed arm pull-ups on a horizontal bar with legs placed on a box either with or without pre-load (PRE) in a randomized order. PRE was a 26.6±2s all out shuttle run to increase La to ~8 mmol.l⁻¹. Each testing was preceded by a 15 min standardized warm up. Time between warm-up and testing was 14 min. During testing, heart rate (HR) and respiratory gas exchange measures ($\dot{V}O_2$, $\dot{V}CO_2$, \dot{V}_E) were monitored and La levels were measured at specific time points. Respiratory gas exchange measures were compared via the area under the curve (AUC). **RESULTS:** In pull-ups without PRE, La increased from 1.24 ± 0.4 to 6.4 ± 1.4 mmol.l⁻¹, whereas in conditions with PRE, La increased from 9.28 ± 1.98 to 10.89 ± 2 mmol.l⁻¹. In PRE conditions net La accumulation was significantly reduced by 75.5%. Performance was significantly increased by 1 rep (4%) after PRE. In PRE, net oxygen uptake $\dot{V}O_2$ (50% AUC), pulmonary ventilation \dot{V}_E (34% AUC) and carbon dioxide $\dot{V}CO_2$ production (26% AUC) were significantly increased during pull-ups but net respiratory exchange ratio (RER) was significantly decreased during work and recovery. **CONCLUSION:** Increased La induced by anaerobic leg exercise, inhibits glycolysis and increases oxidative metabolism in subsequent anaerobic dynamic upper body exercise. Increased oxidative metabolism during strength endurance exercise leads to superior performance outcome. This concept may be beneficial in sports climbing, due to a shift to an increased oxidative metabolism. However, this aspect needs to be evaluated further and in greater detail.

University of North Carolina at Chapel Hill, Chapel Hill, NC.
 (Sponsor: Claudio Battaglini, FACSM)
 (No relationships reported)

PURPOSE: The aim of this study was to examine the effect of two-weeks of lower body resistance training on cardiopulmonary capacity ($\dot{V}O_{2peak}$) as well as its impact on muscle strength/size in sedentary middle-aged females. **METHODS:** After familiarization, $\dot{V}O_{2peak}$ was assessed via maximal cardiopulmonary exercise testing (CPET), leg extensor strength via isokinetic dynamometry, and muscle size of the vastus lateralis (VL) via cross-sectional area (CSA) using a B-Mode ultrasound. **RESULTS:** $\dot{V}O_{2peak}$ significantly improved by 10.8% ($2.1 \text{ mlO}_2 \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$; $p=0.002$). Leg extension peak torque (PT) significantly improved by 6.1% (5.9 Nm ; $p=0.027$), while EMG amplitude did not change (-3.69% ; $p=0.388$). Similarly, VL CSA did not increase in response to training (0.17 cm^2 ; $p=0.456$). No significant relationships were observed between changes in $\dot{V}O_{2peak}$ and selected strength variables (PT/Amplitude). **CONCLUSIONS:** These results suggest that strength training appears to have had a positive effect on $\dot{V}O_{2peak}$ and strength in middle-aged females. However, future studies including a control group are warranted to confirm or refute the results of this current study.

Effect of Three Different Muscle Action Training Protocols on Hamstrings-to-Quadriceps Muscle Size Ratio
 Cassio V. Ruas¹, Lee E. Brown, FACSM², Camila D. Lima³, Pablo B. Costa², Megan A. Wong², Ronei S. Pinto¹. ¹Federal University of Rio Grande do Sul, Porto Alegre, Brazil. ²California State University, Fullerton, Fullerton, CA. ³Memorial University of Newfoundland, St. Johns, NL, Canada.
 (No relationships reported)

Hamstrings-to-quadriceps (H:Q) muscle size ratio measured by muscle thickness (MT) is a measure of muscle balance, which can identify risk of lower-extremity injuries during sports. However, the most advantageous muscle action training protocol to elicit optimal H:Q is unknown. **PURPOSE:** To compare 3 different training protocols on H:Q muscle size ratio. **METHODS:** Forty untrained males (age 22.87 ± 2.28 yrs, mass 70.66 ± 11.04 kg, ht 174.29 ± 6.9 cm) performed 6 weeks (2 sessions per week) of training of their dominant leg H and Q on a Biodex isokinetic dynamometer. They were randomly assigned to one of 4 groups; concentric Q and concentric H (CON/CON), concentric Q and eccentric H (CON/ECC), eccentric Q and eccentric H (ECC/ECC), or no training (CNTRL). Training began with 1 set of 10 maximal repetitions at 210°/s concentrically and 60°/s eccentrically. Intensity of training was increased every week by decreasing the angular velocity for concentric and increasing it for eccentric in 30°/s increments. Volume of training was increased by adding 1 set each week. MT measurements were taken 72h before and after training in the transverse plan of Q rectus femoris (RF), vastus intermedius (VI), vastus lateralis (VL) and vastus medialis (VM), and H biceps femoris long head (BF), semitendinosus (ST) and semimembranosus (SM) using a real-time portable B-mode ultrasound device. H:Q muscle size ratio was calculated as H MT/quadriceps Q MT. **RESULTS:** A 7x2x4 (muscle x time x group) ANOVA showed interactions of muscle x time and time x group. They were followed up with seven paired t-tests, one for each muscle, and two paired t-tests, one for each group. MT post was greater than pre for VL ($8.05 \pm 4.78\%$), VM ($5.71 \pm 31.79\%$), BF ($7.93 \pm 10.87\%$), ST ($8.99 \pm 15.88\%$) and SM ($6.09 \pm 7.65\%$), while there was no difference for RF ($2.98 \pm 7.43\%$) or VI ($4.23 \pm 10.95\%$). MT post was also greater than pre for CON/CON ($7.75 \pm 8.92\%$), ECC/ECC ($11.81 \pm 0.76\%$), and CON/ECC ($6.68 \pm 1.68\%$), while CNTRL (-1.38 ± 15.22) was not different. **CONCLUSIONS:** These findings suggest that all training protocols may increase MT of H and Q similarly, which may not lead to improvements in H:Q muscle balance. A greater volume of training may need to be performed for H to elicit greater H:Q muscle size balance.

PURPOSE: The purpose of this study was to evaluate the reliability of open-handed and pinch-grip weight-assisted pull-ups in recreationally-trained rock climbers. **METHODS:** Recreationally-active volunteers (n = 9) completed four counterbalanced trials. Trials (two grips each test-retest) were used to determine the reliability of the grips. Each trial included one set of open-handed or pinch-grip weight-assisted pull-ups until failure. Each trial used one of two grips each repeated twice. Sets consisted of either the open-handed or pinch-grip pull-ups assisted by 50% reduction of body weight. **RESULTS:** Heart rate, ratings of perceived exertion (RPE), perceived recovery scale and session-RPE were not significantly different (p > 0.05) among trials. Intra-class Rs for test-retest of the open-handed (R = 0.99) and pinch-grip (R = 0.96) weight-assisted pull-ups evidenced reliable values. However, Bland-Altman analysis (BA) revealed large errors indicating weight-assisted pull-ups using open-handed (95% error range: upper limit 6.34, lower limit -3.90) and pinch-grip (95% error range: upper limit 5.35, lower limit -6.91) were only somewhat reliable. **CONCLUSIONS:** Based upon the ICCR's measurement was reliable, however the BA indicated the device was only somewhat reliable.

Strength Training Between Science and Practice

Alessandro L. Colosio, Georgia Spigolon, Federico Y. Fontana, Silvia Pogliaghi, FACSM. University of Verona, Verona, Italy.
Email: alessandro.colosio@univr.it

(No relationships reported)

Evidence-based ACSM guidelines provide a comprehensive framework for the design of strength training interventions. Yet, a variety of practice-based approaches are used in gyms, clubs and sport federations based on empirical evidence, fashion and tradition while their scientific validation remains elusive. **PURPOSE:** We developed a practice-based strength training (*pST*) and tested its performance against an evidence-based (*eST*) intervention. **METHODS:** 18 young healthy males with minimal ST experience were randomly assigned to *eST* (#6), *pST* (#6) or *Control* (C, #6) group. *eST* and *pST* trained for 4 weeks (three, one-hour sessions per week composed of a warm-up, three main exercises -squat, chest press and deadlift- and two complementary exercises -pull-ups and push press- and a cool-down). Interventions differed in: 1) periodization strategy (linear vs. daily undulating); 2) intensity target (Repetition Maximum (RM) vs. % of maximum load) and volume (repetition range vs. exact number of repetitions); 3) amount of within-session and between-sessions variation of intensity and volume (small vs. large). *Pre* and *post* training, we measured 1RM tests (squat and deadlift) and maximal isometric force (IF_{peak}) and maximal rate of force development ($IRFD_{peak}$) through a whole-body isometric-strength test (mid-tight pull test) on a force platform. Groups were compared by a 2-way ANOVA. **RESULTS:** Groups were not different *pre* training. The ability to produce force significantly increased in the *post* condition (15±5% for 1RM squat and deadlift, 14±5% in IF_{peak} , 33±14% in $IRFD_{peak}$) in *pST* group while *eST* showed a significant improvement only in the 1RM Squat (10±5%) that was significantly smaller than that observed for *pST*. No changes occurred in C. **CONCLUSIONS:** In young healthy subjects who trained three times per week for 4 weeks with the same type of exercises, *pST* improved the ability to produce force to a larger extent compared to *eST*. Although further studies are warranted to investigate the amount and time course differences between the two interventions, it seems that the periodization strategy, intensity and volume prescription and the large within-session and between-sessions modulation of training volume and intensity that characterize *pST* may offer an advantage in strength outcome compared to *eST*.

Effects Of Full-body Barbell-based Linear Progression Resistance Training Program On Healthy Untrained Participants

John Petrizzo, Jordan Feigenbaum, Ryan Page, John W. Wygand, FACSM, Robert M. Otto, FACSM. Adelphi University, Garden City, NY. (Sponsor: Robert M. Otto, FACSM)
Email: JPetrizzo@adelphi.edu

(No relationships reported)

Resistance training (RT) has been shown to have numerous health and performance benefits across varied populations; however the majority of the research conducted on the general population has focused on machine-based RT protocols. **PURPOSE:** To evaluate the chronic effects of a standardized whole body barbell training program on healthy participants. **METHODS:** 51 subjects (age 21.4 ± 4.7 yrs, ht. 170.3 ± 10.6 cm, body mass 69.6 ± 15.2 kg, waist 73.6 ± 9.3 cm, and hip 96.1 ± 8.0 cm, 22 ♂) were familiarized and a five repetition training load was titrated to the point the subject reached a load that they could lift safely 5 times without any degradation of form. Subjects performed the barbell squat (BS) (50.5 ± 28.8 kg), standing shoulder press (P) (26.2 ± 10.1 kg), barbell deadlift (DL) (60.2 ± 31.3 kg), and the barbell bench press (BP) (56.1 ± 29.5 kg). Following warm-up, all exercises were performed for 3 sets of 5 repetitions except DL was performed for a single set of 5 repetitions. Subjects were asked to perform a full-body resistance training protocol two or three times per week. BS was performed at each session, the P and BP alternated at each session, and the DL was performed a minimum of once per week. The training load was increased at each session that followed the attainment of 5 repetitions for each set. The progression continued until the subject was unable to make linear progress on the BS exercise. **RESULTS:** The mean duration of the intervention was 11.1 ± 3.46 weeks. Statistical analysis by t-test (P<.05) was applied to both the anthropometric and RT data. Despite no significant difference between anthropometric measurements, strength showed dramatic improvement across all lifts. Final BS (80.9 ± 33.6 kg) improved an average of 60.2%, P (38.2 ± 17.1 kg) improved an average of 45.8%, DL (87.4 ± 40.6 kg) improved an average of 45.2%, and BP (56.2 ± 29.5 kg) improved an average of 32.2%. No subjects suffered an acute injury throughout the duration of the intervention. **CONCLUSION:** A barbell-based, full-body RT protocol utilizing a linear approach to loading can be a safe and effective means of rapidly improving strength in a novice population.

The Effect of Knee Sleeves on Muscle Function During the Squat Exercise

Laurie Batchelder, Christopher Palladino, John Petrizzo, Robert M. Otto, FACSM, John W. Wygand, FACSM. Adelphi University, Garden City, NY. (Sponsor: Robert M. Otto, FACSM)
Email: lauriebatchelder@mail.adelphi.edu

(No relationships reported)

Knee sleeves (KS); made of neoprene; provide compression around the knee without restricting flexibility. KS are commonly used by weightlifters, powerlifters, and fitness competition athletes, who report attenuated knee discomfort and increased performance. Purportedly the use of KS helps to stabilize the knee, improve strength performance, and reduce the risk of injury during lower body resistance training. **PURPOSE:** To assess the impact of KS use on muscle activity and power output during the performance of the squat exercise, 19 subjects (age 26.0 ± 2 yr, ht 172.9 ± 3.6 cm, body mass 74.8 ± 3.7 kg, 13 ♂), with a minimum of six months training with squat exercise were randomly assigned to KS or no KS (NKS) trials with a repeated-measures design. **METHODS:** EMG data were obtained on the vastus lateralis (VL), semitendinosus (S) and gluteus maximus (G) muscles with a baseline obtained by two isometric maximal voluntary contractions (MVC) for five seconds, using an immovable and secure barbell at mid-range of the squat position. A warm-up of 10 reps of unloaded barbell and 5 reps @ 65% of self-reported 1RM preceded (5 min) the trial (KS or NKS) of 5 reps @ 85% 1RM (94.1 kg). Following an 8 minute rest, subjects completed the cross over trial. EMG normalized to MVC was recorded for each trial. Peak power (PP) and average power (AP) were determined by measuring the bar speed with a micro-computer system. Statistical analysis by ANOVA (p<.05) was applied to the data. **RESULTS:** VL: 65.0 ± 44.7 & 64.5 ± 46.0, S: 71.6 ± 35.0 & 69.9 ± 37.9, and G: 48.4 ± 25.3 & 49.7 ± 24.2 for K and NKS, respectively, revealed no significant difference between conditions. In addition, %MVC for VL: 171.9 ± 126 & 180.9 ± 111, S: 215.1 ± 160 & 230.2 ± 166, and G: 145.6 ± 96 & 147.8 ± 111 for K and NKS, respectively were not significantly different. PP(watts): 624.1 ± 216 and 638.5 ± 229 and AP: 349.3 ± 100 and 345.7 ± 113 for KS and NKS trials, respectively were not significantly different. **CONCLUSION:** The use of KS during the squat exercise required almost identical motor unit recruitment and provided comparable power output, thus the use of KS is a subjective decision.

 (No relationships reported)

Despite significant progress, cardiovascular (CV) disease remains the leading killer in the US, with lack of physical activity being a primary risk factor. Research suggests that 4 weeks of exercise training reduces blood pressure (BP) and fat mass, as well as improves fitness; yet it is unclear whether circuit training (CT) or resistance training (RT) yields better short-term improvements. **PURPOSE:** To compare changes in CV and fitness measures after a 4-week CT or RT program. **METHODS:** Eighteen middle-aged adults (CT: N = 9, 49.7±8.4 yrs; RT: N = 9, 49.3±11.7 yrs) completed 4 weeks of either CT or RT exercise. Pre- and post-intervention, CV health measures, including fasting glucose, blood lipids, carotid artery intima media thickness (IMT), body composition by bioelectrical impedance analysis (BIA) and central and brachial BP were determined. Fitness testing involved measurement of maximum oxygen consumption ($\dot{V}O_{2max}$), and indices of balance and strength. **RESULTS:** Between group analyses revealed no differences between groups with exercise training, although several variables tended to improve in both groups. In the CT group, we noted improvements in central BP (SBP: 108.9±11.6 to 104.9±7.8; DBP: 76.1±8.2± to 72.3±5.6 mmHg, p<0.05). No changes in body weight, lean mass or fat mass occurred in the CT group; however, body weight (84.5±20.7 to 83.8±20.7 kg), lean mass (57.5±15.8 to 59.5±15.8 kg), and body fat (31.9±8.6 to 29.0±7.9 %) all changed in the RT group (p<0.05). For fitness measures, the CT group improved balance (right leg: 78.3±70.4 to 152.2±122.1; left leg: 41.2±39 to 167.9±206.6 sec) and 2-min stair climb (266.1±37.8 to 314.1±46.7 stairs), while the RT group improved 12-step sprint (3.3±0.5 to 2.7±0.4 sec) and maximum strength measures (leg press: 164.3±91.0 to 178.9±92.9 kg; bench press: 29.1±43.3 to 32.9±43.9 kg) (all p<0.05). Both groups improved wall sit (CT: 44.5±18.2 to 96.4±56.9; RT: 69.6±42.5 to 100.1±65.7 sec, p<0.05). No changes in lipids or glucose were found in either group. **CONCLUSION:** Our results suggest that 4 weeks of CT or RT improves CV health and fitness measures, with no differences between these two types of training.

Acute Effects of the Power Snatch on Vertical Jump Performance
 Nick Diaz, Courtney Jensen, J. Mark VanNess. *University of the Pacific, Stockton, CA.*
 Email: n_diaz4@u.pacific.edu
 (No relationships reported)

Postactivation potentiation can increase a muscle's ability to generate force. In practical terms, this may mean that acute weight lifting could improve vertical jump performance. **PURPOSE:** To examine vertical jump performance after performing prior power snatch exercises. **METHODS:** Following a standardized warm up, ten trained Olympic-style weight lifters performed power snatch exercises at increasing intensities (40% 1 repetition max [RM], 60% 1RM, and 80% 1RM) followed by vertical jump performance. Their vertical jump was measured using a Vertec in a control condition and following each power snatch intensity. Each condition was counterbalanced and separated by at least 48 hours. Two-way repeated measures ANOVA analyzed each lift intensity using vertical jump height as the dependent variable. Also, vertical jump performance in every post-power snatch condition was compared to control using a Student's t-test. **RESULTS:** There was no statistical difference in jump height in the repeated measures ANOVA or the t-test. However, there were small improvements across group means (0.3 to 0.6 inches) in the power snatch conditions. Power analysis for that effect size showed that 58 subjects would be needed to demonstrate significance. **CONCLUSION:** Power snatch exercise may be either inappropriate for eliciting postactivation potentiation or the effect was not large enough to demonstrate improvement in vertical jump performance. Future studies could examine this effect using different exercises, a single gender, or more experienced weight lifters.

 (No relationships reported)

INTRODUCTION: The vertical jump is one movement used to train and assess power output of the legs. Specifically, loaded vertical jumps have been proven to increase vertical jump performance in a training environment. **PURPOSE:** The purpose of this study is to evaluate three loaded vertical jump training methods: the barbell back squat jump (BB), the goblet squat jump (GB) and the dumbbell squat jump (DB) on lower limb, peak joint powers. **METHODS:** Nine male volunteers (age: 22.1 ± 1.2 yrs; Ht: 1.75 ± 0.05 m; Wght: 76.0 ± 10.0 Kg) with at least 2 yrs experience in weight lifting performed 5 trials in each condition of the goblet, back and dumbbell squat jumps (randomized order) utilizing 10% of their 1-RM back squat as the experimental weight. Ten infrared cameras (200Hz) and an AMTI force plate (1,000Hz) collected a full body, 3-marker per segment model and ground reaction force data. All data were smoothed using a 4th order Butterworth filter of 20Hz. GRF data were interpolated down to 200Hz to temporally align camera and force data. Commercial software was used to calculate 3D lower limb joint angles, moments and powers via inverse dynamics. Differences in peak ankle, knee and hip power values during the jump were compared with RMANOVA (alpha ≤ 0.05) with Bonferroni post hoc tests. **RESULTS:** DB resulted in greater COM maximal jump height compared to BB (p < .0001) and GB (p = .005). No differences were noted for peak hip joint power (p = .23). Peak knee power was larger for DB compared to BB (p = .01) but not GB (p = .06). At the ankle, DB produced greater power than BB (p = .01) and GB (p < .001); but no differences were noted between GB and BB (p = .40). **CONCLUSION:** DB produced a greater COM maximal jump height, and greater knee and ankle powers. DB may be a superior training tool to produce increased knee and ankle joint powers.

A proposed method of increasing warm-up intensity without inducing muscular fatigue is using a respiratory training mask to provide breathing resistance. Despite the lack of research-based evidence and equivocal anecdotal evidence, this particular warm-up strategy does appear to be of increasing popularity among both athletes and active individuals. **PURPOSE:** The purpose of this study was to investigate sprint performance following the use of training masks during dynamic warm-up in Division I American football athletes. **METHODS:** Seventeen male (mean±SD: age = 17.94±.75 years, weight = 104.43±23.02 kg, height 184.93±7.06 cm) NCAA Division I, American football athletes from a Midwestern university were recruited to participate in this study. Athletes were informed of risks, and completed 3 testing sessions separated by 7 days each. All testing sessions took place at the same time of day on artificial turf in the university's indoor training facility. Testing sessions began with a warm-up (WU) under the instruction of a member of the university's Strength and Conditioning staff. The WU consisted of dynamic exercises targeting the lower body musculature. During the initial visit, participants completed the dynamic WU and tested on 5x10-meter sprints without a respiratory training mask and all data collected during the initial visit were used to establish baseline measurements. During the second and third visits, participants were randomly selected to complete the WU with the respiratory training mask set to simulate an altitude 3,657.6 (EXP) m or 914.4 m (SHAM). Upon completion of the WU, participants removed the mask and performed 5 × 10-meter sprints. A one-way repeated measures analysis of variance (ANOVA) design was used to assess differences between control and experimental results. All statistical analyses were performed using SPSS (Version 21.0 for Windows; SPSS, Chicago, Illinois) with statistical significance set at p < .05. **RESULTS:** No significant differences were found between control, sham, and experimental measures (P = 0.7-0.874). **CONCLUSION:** These findings suggest that the use of respiratory training masks during WU does not improve sprint times in Division I football athletes.

Decrease of Muscle Performance After Two Different Load Protocols in Well-Trained Men: a Pilot Study

Ana Luiza M. Correia, Filipe Dinato de Lima, Andrew C. da Fonseca, Martim Bottaro, Amilton Vieira, Ricardo M. Lima.
University of Brasilia, Brasilia, Brazil.
 Email: analuiza.matias2@gmail.com
 (No relationships reported)

To study muscle damage recovery, firstly muscle damage has to be induced by an exercise. A specific drop jumps protocol has been largely used in previous studies. However, all participants studied were untrained.

PURPOSE: To assess muscle strength, muscle power and muscle swelling after two different load drop jump protocols in well-trained athletes.

METHODS: Eighteen strength and/or power-trained male athletes (4.31±2.75 years of training experience) were randomly assigned into one of two groups. DJ100 consisted in 5 sets of 20 drop jumps from a 60-cm box with 2-minute rest interval (n=9, 23.00±2.74 years). DJ140 consisted in seven sets of 20 drop jumps also (n=9, 22.89±3.37 years). Volunteers performed a maximally explosive vertical jump. Both groups performed the assessment of indirectly markers of muscle damage before and immediately after exercise protocol. Muscle thickness of knee extensors was measured using B-mode ultrasound. Maximal isometric muscle strength (PT) was measured by 2 sets of 4 seconds maximal isometric knee extension at 60°. For vertical jump, the athletes performed three countermovement jumps as high as possible, with one-minute rest between jumps. After normal distribution confirmed by Shapiro-Wilk tests, independent samples T-tests were used to compare the magnitude of changes of muscle thickness, isometric strength and vertical jump between groups. A p-value of ≤ 0.05 was adopted.

RESULTS: There was no significant difference (p>0.05) in sample's baseline characteristics between groups. There was no significant difference in the increase of muscle thickness (DJ100: 6.47 ± 1.67 (16.50%) vs. DJ140: 7.51 ± 2.31 mm (17.82%); p = 0.286). The decrease of isometric strength was significantly greater in DJ140 than DJ100 (DJ100: 34.24 ± 22.30 (11.20%) vs. DJ140: 67.06 ± 38.79 N.m (22.41%); p = 0.043; ES = 1.037). The decrease of vertical jump was also significantly greater in DJ140 than in DJ100 (DJ100: 0.48 ± 2.88 (0.95%) vs. DJ140: 7.72 ± 7.44 cm (17.42%); p = 0.015; ES = 1.283).

CONCLUSIONS: The main finding of this study was that an exercise protocol composed by 100 drop jumps did not decrease lower limb muscle power in well-trained athletes. Furthermore, 140 drop jumps induced a decrease in muscle performance greater than 100 drop jumps in well-trained athletes.

Heavy And Light Training Days Attenuates Decline In Force Output During 3-weeks High-volume Resistance Training

Kevin M. Carroll, Jake R. Bernards, James L. Miller, Kimitake Sato, Brad H. DeWeese, Michael H. Stone. *East Tennessee State University, Johnson City, TN.*
 Email: carrollk@etsu.edu
 (No relationships reported)

High volume resistance training is employed by coaches during training emphasizing enhanced body composition, hypertrophy, and work capacity. However, high volume training may cause levels of fatigue that impact strength and power performances. It is not well known if using fatigue-management strategies such as heavy and light days affect these performances.

PURPOSE: To compare changes in kinetic variables following high volume resistance training employing heavy and light days. **METHODS:** Eight strength trained males (age = 27.4 ± 4.2 years, body mass = 90.8 ± 11.8 kg, isometric peak force = 4397.1 ± 636.9) participated in the study. Pre- and post-training each subject was evaluated for isometric peak force (IPF), allometrically-scaled isometric peak force (IPFa), and rate of force development at 90 ms (RFD90) during an isometric mid-thigh pull test on a dual force platform sampling at 1000Hz. The training protocol consisted of resistance training 3 days/wk with each week progressing in intensity. Each 3rd training day was a light day (10% lighter than day 1). Paired-samples t-tests were calculated pre-post the 3 weeks to assess changes associated with training. Magnitudes of change were examined using percent change and effect size using Cohen's *d*. **RESULTS:** The change in body mass (BM) was significantly higher (90.8 ± 11.8 kg to 92.5 ± 11.7 kg) (p = 0.03) while no statistical differences were observed in IPF (4397.1 ± 636.9 N to 4380.4 ± 432.9 N), IPFa (218.0 ± 25.5 N/kg^{0.67} to 215.5 ± 23.2 N/kg^{0.67}), or RFD90 (10155.6 ± 5511.3 N·s⁻¹ to 9208.3 ± 4547.3 N·s⁻¹) (p > 0.05). Percent change for BM, IPF, IPFa, and RFD90 were as follows: 1.9%, -0.4%, -1.2%, -9.3%, respectively. Effect sizes for BM (*d* = 0.15), IPF (*d* = 0.03), IPFa (*d* = 0.10), and RFD90 (*d* = 0.19) indicated trivial effects pre-post high volume training. **CONCLUSIONS:** High volume resistance training is often concomitant with reductions in strength performance. The results of the study indicate that force outputs were spared following 3-wks high volume training when employing heavy and light days. Although not significant, a

reduction in RFD90 of 9.3% is practically significant for athletes. It seems that while strength variables were largely unaffected, explosiveness (i.e. RFD90) may be more sensitive to high training volumes regardless the fatigue management strategies used.

Differences In Power And Velocity During The Back Squat In Resistance-trained Men And Women.

Jonathan M. Neddo¹, Jonathan M. Oliver², Jason D. Stone², John D. Mata², Margaret T. Jones, FACSM¹. ¹George Mason University, Fairfax, VA. ²Texas Christian University, Fort Worth, TX. (Sponsor: Margaret T. Jones, FACSM)
 Email: jneddo@gmu.edu
 (No relationships reported)

Muscular power is vital to success across sport and competitive level. Determination of the load that optimizes power varies by exercise, gender, and training status. For example, the load that maximized peak power for the power clean in men has been proposed to occur at 80% one-repetition maximum (1RM); whereas the ideal load for the squat is equivocal. Further, one study reported differences between men and women in peak power at differing loads during ballistic exercise. However, few data exist on the differences in men and women relative to power and velocity, and no study has examined the differences in men and women relative to power and velocity, and no study has examined the differences in men and women relative to power and velocity development. **PURPOSE:** To determine whether differences exist between resistance-trained (RT) men and women in regard to the loads that maximize average power (AP), peak power (PP), average velocity (AV), and peak velocity (PV) in the back squat (BS). **METHODS:** Forty-one RT (n = 41) men (m = 20; 21 ± 1 y; 183.0 ± 7.8 cm; 82.5 ± 8.0 kg) and women (w = 21; 20 ± 1 y; 166.5 ± 6.9 cm; 63.1 ± 7.7 kg) had their 1RM determined (m: 147.0 ± 28.0 kg; f: 89.1 ± 12.3 kg). On a second day, they performed two repetitions at BS loads corresponding to 30%, 40%, 50%, 60%, 70%, 80%, and 90% 1RM as explosively as possible for determination of AV, PV, AP and PP. The repetition with the highest value was used for comparison. Repeated measures analysis of variance for AV, PV, AP, and PP were run. **RESULTS:** Men were older (p = 0.022), taller (p < 0.001), heavier (p < 0.001), stronger (p < 0.001), and had a greater 1RM to body weight ratio (m: 1.8 ± 0.3; w: 1.4 ± 0.1; p < 0.001). Men also produced higher velocities (PV, AV) and power (PP, AP) across all loads. The highest PP occurred at 90% 1RM for both, though no difference was noted between 80% 1RM and 90% 1RM in either sex. The highest AP occurred at 70% 1RM in men, though AP at 60% and 80% 1RM were not different. The highest AP in women was observed at 80% 1RM, though no difference was noted between that intensity and 50% - 70% 1RM. AV and PV occurred at the lowest intensity (30% 1RM) in both sexes. **CONCLUSION:** These data suggest that load for PP, PV, and AV does not differ. However, differences did exist in the load that resulted in the highest AP. Whether this would be observed across all sports is unknown. Further study is required to determine if sex differences exist in load among different sports and training status.

Effect of Different Types of Circuit Resistance Training on Total and Regional Muscle Mass

Chin-chueh Tsai¹, Nien-chieh Liu². ¹National Taiwan Sport University, Taoyuan, Taiwan. ²Chien Hsin University of Science and Technology, Taoyuan, Taiwan.
 Email: ccttsai@ntsus.edu.tw
 (No relationships reported)

PURPOSE: The purpose of this study was to compare the training effects on total and regional muscle mass with different types of circuit resistance training among sedentary healthy adults.

METHODS: 36 participants (18 female; 28.19 ± 5.30 yr; 168.50 ± 8.93 cm; 66.33 ± 14.17 kg) were randomly assigned to three groups: machine circuit training group (MCT, n = 12), dumbbell circuit training group (DCT, n = 12), and control group (n = 12). MCT and DCT performed 3 sessions per week for 8 weeks resistance-type circuit training (10 exercise x 30 sec x 3 set; 25-30 min). Muscle mass of trunk and limbs were measured pre and post intervention for all subjects using bio-electric analyzer. One-way ANCOVA and least significant difference (LSD) were used for the analysis. Significant level was set at α = .05.

RESULTS: There were no significant difference in body mass (MCT: -2.19%; DCT: -1.55%; CON: -0.43%) before and after 8-wk intervention in any group. Changes in total skeletal muscle mass (MCT: + 3.44%; DCT: +4.67%; CON: -1.18%) was not different between MCT and DCT. Both training groups demonstrated significant difference with control group (p<.05). Significant changes in arms and legs muscle mass were found after training in MCT and DCT. Upper limb showed higher rate of increase in both group. For trunk muscle mass (MCT: + 0.88%; DCT: +1.83%; CON: -0.53%), both training group were significant difference with control group after intervention (p<.05). DCT showed better training effect on trunk muscle mass than MCT (p<.05).

CONCLUSIONS: The findings of present study verify the effectiveness of 8-week circuit resistance training on body composition and muscle mass for sedentary healthy

adults. Training effects was equivalent using machine or dumbbell as equipment for limb muscle mass. Circuit training with dumbbell required core stability lead to more hypertrophy of trunk muscle than training with machine.

Effects of Different Resistance Training Protocols on Performance, Metabolic and Perceptual Responses in Trained Men

André Santos Martorelli¹, Nathália Dias², Vitor Cleto², Sávio da Silva², Andrew Fonseca², Amilton Vieira², Rodrigo Silva³, Carlos Ernesto⁴, Martim Bottaro². ¹Federal Institute of Goiás, Valparaíso de Goiás, Brazil. ²University of Brasília, Brasília, Brazil. ³Federal University of Ouro Preto, Ouro Preto, Brazil. ⁴Catholic University of Brasília, Brasília, Brazil.
 (No relationships reported)

Monitoring the intensity of resistance training (RT) is essential for the effectiveness of training periodization. Athletes have been using power, hypertrophic and strength trainings protocols to improve performance. However, the effects these protocols on physiological stress are still unknown. **PURPOSE:** To compare the effects of three different protocols of RT on total volume (TV), session rate perceived exertion (SRPE) and lactate concentration (LAC). **METHODS:** Nine resistance trained men (22 ± 3.87 years, 79.53 ± 13.28 kg and 176.59 ± 7.53 cm) performed three training sessions on different days separated by at least 72 hours in a counterbalance fashion. After determining one maximum repetition (1-RM) on a squat (SQ) and bench press (BP) exercises, each volunteer performed three different training protocols: 1) power training session (PTS, performed 6 sets of 6 reps on SQ and 6 sets of 6 reps on BP at 50% of 1-RM), 2) hypertrophy training session (HTS, performed 5 sets of maximum repetitions on SQ and 5 sets on BP at 75% of 1-RM) and 3) strength training session (STS, performed 5 sets of maximum repetitions on SQ and 5 sets on BP at 90% of 1-RM). The three sessions were performed with 2-min rest interval between sets and 5-min between the two exercises. The SRPE was measured 15-min after each training session by the CR-10 RPE scale. Statistical analysis was done by means of repeated measures ANOVA. The probability level of statistical significance was set at $p < 0.05$ in all comparisons. **RESULTS:** The STS showed lower TV (2493.00 \pm 948.79 kg) in comparison with HTS and PTS (5169.75 \pm 1340.20 and 4428.00 \pm 701.94 kg, respectively). However, the STS and HTS showed higher SRPE (6.33 ± 1.87 and 7.89 ± 1.17 , respectively) when compared to PTS (4.33 ± 1.66). In all protocols volunteers showed higher LAC at the end of the sessions ($p < 0.05$). Moreover, in the HTS the LAC was higher (1.15 ± 0.36 to 11.77 ± 2.07 mM) when compared to STS (1.02 ± 0.36 to 6.53 ± 2.87 mM) and PTS (1.10 ± 0.40 to 4.00 ± 2.47 mM). **CONCLUSION:** Our data suggest that the magnitude of physiological stress resulting from the exercise (internal load) is more dependent on the magnitude of the effort (maximum or submaximal repetitions) than the TV or load lifted (external load) in different protocols of RT. Further studies are needed to investigate the effects of other RT protocols.

Intra- And Inter-set Velocity Characteristics During High- And Low-load Resistance Training To Failure

Carlos A. Estrada, Ryan J. Colquhoun, Mitchel A. Magrini, Allie G. Speer, Bert H. Jacobson, FACSM, Jason M. DeFreitas. Oklahoma State University, Stillwater, OK. (Sponsor: Bert H. Jacobson, FACSM)
 (No relationships reported)

INTRODUCTION: Recent investigations have examined the effects of high- and low-load resistance training on skeletal muscle hypertrophy and strength. However, few investigations have examined the velocity parameters between these two conditions. **PURPOSE:** The purpose of this study was to examine the velocity characteristics during high- and low-load barbell back squatting to failure. **METHODS:** Eleven resistance-trained males (Age: 22 ± 3 years, Body Mass: 83.7 ± 10.5 kg, Squat 1RM: 157.1 ± 25.8 kg) were recruited to participate in this study. During the initial visit participants completed a one-repetition maximum (1RM) testing session to assess lower extremity muscular strength. Following 1RM testing, participants were asked to return for two additional sessions scheduled no more than eight days apart. Following a designated warm-up, subjects were randomly assigned to squat either 80% (high-load) or 30% (low-load) of their squat 1RM for three sets to failure with 3 minutes' rest between sets. Mean velocity (MV) was recorded during each set using a linear position transducer (GymAware, Canberra, Australia). **RESULTS:** Independent samples t-tests were conducted to assess differences between conditions. Initial analysis displayed a significantly higher MV for the low-load condition (0.66 ± 0.08 m/s) when compared to the high-load condition (0.40 ± 0.12 m/s; $p < 0.001$) across all time points. Follow-up analysis revealed a significant decrease in MV during each set during both conditions ($p = 0.000 - 0.008$), with no significant differences between groups ($p > 0.05$ for each set). No significant differences ($p > 0.05$) in percent decline of intra-set MV (Low-load: 30.3-34.8%; High-load: 30.4-37.4%) were observed between the conditions at each time point. Additionally, there were no significant differences in MV

between the first and last reps of each set in either condition ($p > 0.05$ for each time point). **CONCLUSION:** Although high-load resistance training leads to significantly higher MV's than low-load resistance training, percent decline during and between sets was similar in both conditions, indicating similar levels of fatigue were accumulated during the bouts. Given the vast difference in MV between conditions, future research into the mechanisms of fatigue during each condition may be warranted.

 (No relationships reported)

Researchers and practitioners have used the resistance training-specific rating of perceived exertion (RPE) scale to individualize load prescription. **PURPOSE:** To compare changes in muscle thickness (MT) of the vastus lateralis at 50% (VL50) and 70% (VL70) and vastus medialis at 70% (VM70) femur length between percentage-based training (PBT) and autoregulated-based training (ABT) via RPE. **METHODS:** Eleven males (age: 23 ± 4 yrs, body mass: 77.4 ± 7.7 kg, body fat: $9.5 \pm 3.8\%$) with at least two yrs. of training experience and a minimum one-repetition maximum (1RM) of 1.5 and 1.25x bodyweight on the squat and bench press respectively, were assigned to one of two groups: PBT (n=6) or ABT (n=5) for 8 weeks. Forty eight hours following pre-testing MT via ultrasound, both groups performed the squat and bench press 3x/wk. on non-consecutive days (i.e. Mon., Wed., Fri.) using the same number of sets and repetitions following an undulating resistance training program, which linearly increased load and decreased repetitions throughout. Weeks 1-3 consisted of 8, 6, and 4 repetitions on Mon., Wed., and Fri., while weeks 4-5 consisted of 7, 5, and 3 repetitions, with 6, 4, and 2 repetitions being performed during weeks 6-7. Week 8 served as a taper with 4 and 3 repetition days on Mon. and Wed. and post-testing on Fri. Load increased during each week in PBT from 65, 70 and 75% in week 1 to 82.5-92.5% of 1RM in week 7. In ABT there was no prescribed load but subjects were instructed to select a load in which the set ended with a 5-7 RPE in week 1 and progressed to an 8-10 RPE in week 7. A 2x2 repeated measures ANOVA was used with significance set at $p \leq 0.05$. **RESULTS:** There was a significant time effect for VL50 (25.4 ± 3.28 to 28.1 ± 4.64 mm; $p=0.04$; $+10.42\%$) in PBT but not in ABT (26.72 ± 3.75 to 28.45 ± 3.42 mm; $p=0.16$; $+6.47\%$). The time effect for VL70 in PBT approached significance (23.69 ± 3.42 to 26.81 ± 2.89 mm; $p=0.06$; $+13.17\%$), and there was no significant change for VL70 in ABT (24.61 ± 3.59 to 26.31 ± 4.06 mm; $p=0.33$; $+6.91\%$). There was a significant time effect for VM70 in PBT (17.93 ± 3.25 to 19.25 ± 3.36 mm; $p=0.05$; $+7.36\%$), but not in ABT (19.63 ± 4.30 to 20.50 ± 4.00 mm; $p=0.17$; $+4.43\%$). Additionally, there were no group differences (VL50: $p=0.72$; VL70: $p=0.92$; VM70: $p=0.54$). **CONCLUSION:** Our findings indicate that PBT and ABT strategies produce similar lower body hypertrophy.

Inter-limb Differences When Using A Passive-dynamic Ankle-foot Orthosis For Running

Elizabeth Russell Esposito, Jason M. Wilken. Center for the Intrepid, Fort Sam Houston, TX.
 (No relationships reported)

Recent advancements in surgical care have improved the ability to salvage, versus amputate, severely injured limbs but many patients are still left with severe functional impairments. Passive-dynamic ankle-foot orthoses (PD-AFO) have enabled some injured individuals to regain many of their functional abilities, including a return to running. The PD-AFO's semi-rigid structure provides the external support that is essential for many of these activities, but it limits motion and affects movement mechanics. There is a paucity of information on running with PD-AFOs and how their use impacts the unaffected limb. **Purpose:** To identify limb loading and footstrike patterns during running in PD-AFO users. **Methods:** Fifteen male Service Members (29 ± 5 years, 1.8 ± 0.1 m, 84.3 ± 7.6 kg) who had undergone unilateral lower limb salvage and who were prescribed custom PD-AFOs (Intrepid Dynamic Exoskeletal Orthosis)

participated. Kinematic and kinetic data were recorded as subjects ran through a 17m data capture area at a self-selected speed (3.4±0.7 m/s). Between limb differences in footstrike patterns and loading rates were assessed between the PD-AFO and unaffected limbs via paired t-tests. **Results:** Mean loading rates were 43% greater on the unaffected limb than on the PD-AFO limb (60.4±25.6 vs. 34.6±11.8 BW/sec, p<0.001). These differences were largely due to distinct footstrike asymmetries. Eleven patients used a heel strike on the unaffected limb and a forefoot contact on the PD-AFO limb. One subject attempted to run with a heel strike on both limbs and 3/15 subjects were able to run with mid-forefoot footstrike classification on each limb. **Conclusion:** Participants were able to run with the PD-AFO following traumatic lower limb salvage, but distinct asymmetries were observed. Loading the forefoot of the PD-AFO creates a larger lever for patients to utilize its energy storage and return properties and is viewed as desirable. Heel strike and higher loading rates on the unaffected limb could contribute to overuse-type injuries if these running mechanics are maintained long term. Thus, training interventions that focus on achieving a forefoot strike pattern on both limbs may promote the desired changes in running mechanics for this patient cohort.

Sport-specific Comparisons of Lower Extremity Joint Work during Running

Jacqueline Morgan, Bhushan Thakkar, Kathryn Harrison, Gregory Crosswell, D. S. Blaise Williams, III, FACSM. *Virginia Commonwealth University, Richmond, VA.* (Sponsor: D. S. Blaise Williams III, FACSM)
 Email: morganj3@mymail.vcu.edu
 (No relationships reported)

Running involves unique contributions of joint work in order to absorb forces and subsequently propel the body forward. When compared to the hip and knee, the ankle contributes the greatest negative (W^-) and positive (W^+) work during running. Changes in work have been linked to increases in velocity (sprinting) and intensity (incline). The mechanics of running has been examined primarily in athletes who are runners. However, other athletes utilize running during their practice and competition. The specific movements of these sports may result in different mechanical demands on the lower extremities and therefore different running mechanics. **PURPOSE:** To compare differences in individual joint work and total work (W^0) during steady state running in a group of female athletes from 3 different sports (running=RN, lacrosse=LX, basketball=BB). **METHODS:** Forty-eight female athletes volunteered (RN: n=12, ht=1.68±0.1m, mass=62.1±9.8kg; LX: n=24, ht=1.64±0.1m, mass=64.1±6.6kg; BB: n=12, ht=1.76±0.1m, mass=72.3±13.4kg). Sagittal plane kinematics and kinetics were assessed while running on an instrumented treadmill (Treadmetrix, Park City, Utah) at a constant speed using a 5 camera motion analysis system (Qualysis, Goteborg, Sweden). Joint powers and joint work for the hip, knee and ankle were calculated using Visual 3D (C-Motion Inc., Bethesda, MD). W^0 was defined the absolute value of $W^- + W^+$. Independent variables included W^- , W^+ , W^0 at the hip, knee and ankle. Two-factor analyses of variance (ANOVA) were employed using SPSS 24.0 for W^- , W^+ and W^0 . Post-hoc analyses (Tukey HSD) were performed as appropriate. All significance levels were set at $\alpha<0.05$. **RESULTS:** A significant interaction between sport and joint existed with W^- (p<0.01) and with W^0 (p=0.01) at the ankle. Specifically, RN had more W^- (0.71±0.29) than LX (0.50±0.12, p=0.02) at the ankle. W^0 at the ankle was greater in RN (1.31±0.05) compared to both LX (0.96±0.21, p<0.01) and BB (0.97±0.23, p=0.02). **CONCLUSION:** Overall, W^- and W^0 at the ankle is greater in RN compared to LX and BB. The contribution of the ankle to the lower extremity is 60% in RN compared to 54% in LX and 45% in BB. These differences in work may result in possible inefficient gait patterns. Implications of altered mechanics are possible increases in energy demand or neuromuscular fatigue.

Changes in Joint Work across Consecutive Seasons in Collegiate Cross Country Runners

Mikel R. Stiffler, Bryan C. Heiderscheid. *University of Wisconsin - Madison, Madison, WI.*
 Email: stiffler@ortho.wisc.edu
 (No relationships reported)

Running mechanics are known to change with age and years of experience, however the extent to which mechanics may change more acutely from one year to the next is uncertain. In particular, refinements of running mechanics may occur which benefit an individual's performance or reduce injury risk. **PURPOSE:** To assess changes in lower extremity joint work during running across two consecutive seasons among healthy collegiate runners.

METHODS: Pre-season data from the 2015 and 2016 cross country seasons were reviewed for 14 NCAA Division I runners (men, 7; age: 20.1±1.1 yr; height: 1.7±0.1 m; mass: 61.6±8.8 kg). Athletes were healthy at both testing sessions. Ground reaction forces and kinematic data were recorded during treadmill running (4.47m/s). Sagittal

plane positive (PW) and negative work (NW) were calculated for the hip, knee, and ankle during stance phase and averaged across gait cycles. PW and NW at each joint were then compared across seasons using paired t-tests. Training programs and injuries occurring between testing sessions were also reviewed.

RESULTS: No differences between limbs were observed (p > 0.13); analyses are reported for the right limb. At the start of the 2015 season, PW at the hip, knee, and ankle was 0.26±0.10, 0.33±0.08 and 1.31±0.21 J/kg, respectively, and NW was -0.04±0.04, -0.45±0.11, and -0.83±0.29 J/kg, respectively. At the start of the 2016 season, PW at the hip, knee, and ankle was 0.38±0.14, 0.25±0.25 and 1.30±0.23 J/kg, respectively, and NW was -0.05±0.05, -0.39±0.09, and -0.86±0.31 J/kg, respectively. Hip PW increased significantly and both knee PW and NW decreased significantly (p < 0.006) across seasons. No significant differences between seasons were observed in ankle PW or NW (p > 0.42) or in hip NW (p = 0.43). Results remained consistent when comparing those who did and did not sustain an injury between 2015 and 2016, and no changes in training programs were noted. **CONCLUSIONS:** Hip PW and knee PW and NW changed significantly between seasons, indicating an alteration in running mechanics that may affect performance. In the absence of injury and training-related modifications, the mechanism responsible for these changes requires further exploration.

The Effect of Small Perturbations in Running Velocity on Measures of Coordination Variability

Kristyne Wiegand, Julia Freedman Silvernail. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: John Mercer, PhD, FACSM)
 Email: bartel@unlv.nevada.edu
 (No relationships reported)

Running research aims to replicate movement that occurs outside the laboratory and may represent daily life. One factor commonly manipulated and constrained within the laboratory is running velocity. Outside the laboratory, velocity is often varied within a runner's training regimen. Though running velocity is regularly altered in both settings, little is known about how these small changes may affect the organization of movement. **PURPOSE:** This study aimed to determine whether small deviations from preferred velocity led to changes in coordination variability (CV). **METHODS:** Nine healthy runners (age 22 ± 2 years) were recruited from the Las Vegas community. Kinematic and kinetic analyses were performed while participants ran at 85%, 90%, 95%, 100%, 105%, 110%, and 115% of their preferred velocity. Movement CV was calculated for the segment couples of thigh-shank and shank-foot during early, mid, and late stance using a modified vector coding technique. The joint couples analyzed included: thigh flexion-shank rotation, thigh flexion-shank flexion, shank rotation-foot eversion, and shank flexion-foot flexion. CV values were averaged across trials and compared between conditions using repeated measures ANOVA ($\alpha<0.05$). **RESULTS:** No statistically significant differences in CV were found between velocity conditions for any couplings of interest during any phase of stance (Table 1). **CONCLUSION:** Small perturbations in running velocity from preferred do not influence CV of thigh-shank and shank-foot couplings during stance phase. It is possible that larger deviations from preferred velocity would result in changes, and this effect has been shown in previous research. However, the goal of this project was to assess how slight changes, such as what would be seen in day-to-day training or from constraints in the laboratory, would influence CV.

Table 1: Mean movement coordination variability of segment couples during early, mid and late stance

	Early Stance (0-20%)				Mid Stance (21-60%)				Late Stance (61-100%)			
	Thigh-Shank		Shank-Foot		Thigh-Shank		Shank-Foot		Thigh-Shank		Shank-Foot

Maximalist Shoes Do Not Reduce Impact Loading During Level And Downhill Running

Roy T.H. Cheung, Fannie O.Y. Lau, Eric Ching, Zoe Y.S. Chan, Janet H.W. Zhang, Ivan P.H. Au. *Hong Kong Polytechnic University, Hong Kong, China.* (Sponsor: Prof. Irene S. Davis, FACSM)
 Email: Roy.Cheung@polyu.edu.hk
 (No relationships reported)

A new running shoe design called 'maximalists', which claims to provide maximal cushioning with its oversized midsole and thus lower the impact loading, becomes more popular among trail runners. Downhill running is an essential component of trail races but it may lead to a greater loading than level running. However, the effects of maximalists on the running biomechanics, especially during downhill running, remain unexamined.

Purpose: To compare vertical loading rates, stride length and footstrike angle in runners with traditional running shoes (TRS) and maximalists (MAX) during level and downhill running. **Methods:** Twelve regular shod runners (9 males, 32.5±8.9 years) were asked to run on a self-paced instrumented treadmill at 0% and 10%-declination with TRS (Adizero boost, Adidas) and MAX (Clifton 3, Hoka) in a randomized sequence for 5 minutes. Kinematics and force data were sampled at 200 and 1,000 Hz respectively. The average (AVILR) and instantaneous vertical loading rates (VILR), along with the stride length and footstrike angle, were extracted and averaged over the last minute in each condition. **Results:** VALR, VILR, stride length, and footstrike angle were similar between TRS and MAX during both level and downhill running ($p>0.372$, Table 1). **Conclusion:** These findings suggest that additional cushioning of maximalist running shoes do not lower impact loading. In addition, maximalists do not change the stride length and footstrike pattern in shod runners.

	Level running				Downhill running			
	MAX Mean (SD)	TRS Mean (SD)	Cohen's d	P-value	MAX Mean (SD)	TRS Mean (SD)	Cohen's d	P-value

Is Variability Of Stride Frequency A Factor That Determines Preferred Stride Frequency During Running?

Kendell S. Galor, Joshua Bailey, Jared Joerger, John Mercer, FACSM. *University of Nevada Las Vegas, Las Vegas, NV.* (Sponsor: Dr John Mercer, FACSM)
 (No relationships reported)

Purpose: The purposes of this study were 1) to quantify and describe variability of stride frequency during running, and 2) to determine if the variability of stride frequency is minimized at the preferred stride frequency. **Methods:** The participants (n=8; 24.88±4.16 years; 173.19±9.33 cm; 72.81±14.27 kg) performed seven 5-minute run conditions on an instrumented treadmill (Bertec FIT, USA). The seven runs were a function of their preferred stride frequency (PSF, PSF±5%, PSF±10%, PSF±15%). Participants matched each foot fall with a metronome set to the stride frequency for each condition. Data were collected during four 30-second trials per condition. Variability of stride frequency was determined using coefficient of variation ($CV_{SF} = \text{standard deviation}/\text{mean} \times 100$). CV_{SF} were each compared between conditions using a repeated measures ANOVA. **Results:** CV_{SF} was different across SF conditions ($F=14.672$, $p<0.001$). Using pairwise comparisons, it was determined that CV_{SF} at PSF (0.991) was significantly less than during PSF+10% (1.262; $p=0.016$), PSF+15% (1.454; $p<0.001$), PSF-10% (1.362; $p=0.028$), and PSF-15% (1.652; $p<0.001$). The CV_{SF} during PSF+5% (1.025) was different from all other SF perturbations ($p<0.05$). CV_{SF} during PSF+10% (1.262) was less than during PSF-15% (1.652; $p=0.025$). CV_{SF} during PSF+15% (1.454) was greater than PSF-5% (1.209; $p=0.016$). CV_{SF} during PSF-5% (1.209) and PSF-10% (1.362) were less than PSF-15% (1.652; $p=0.001$,

$p=0.028$, respectively). **Conclusion:** CV_{SF} was influenced by large changes in SF. Stride frequency variability increased as stride frequency increased further from the preferred stride frequency. It may be that decreased variability of SF is a factor determining the preferred stride frequency during running.

Influence Of Stride Frequency Manipulation On Muscle Activity During Running At Reduced Body Weight

Kenji Masumoto¹, Jared Joerger², John A. Mercer, FACSM.
¹*Kyushu University, Kasuga, Japan.* ²*University of Nevada, Las Vegas, NV.*
 (No relationships reported)

Running with body weight support (BWS) (e.g., running on a lower positive pressure treadmill) has been used for physical fitness enhancement. Nevertheless, gait mechanics of running with BWS is not fully understood. **Purpose:** To investigate influence of stride frequency (SF) manipulation on muscle activity during running at different BWS conditions. **Methods:** Nineteen subjects (23.8±4.1 years) ran on a lower body positive pressure treadmill at their preferred running speed (PS) for different BWS conditions (i.e., 0%, 50%, and 80% of BWS conditions). The SF conditions consist of running at preferred SF (PSF), PSF+10%, and PSF-10%. Muscle activity from the rectus femoris (RF), biceps femoris (BF), tibialis anterior (TA), and gastrocnemius (GA) were measured. In addition, rating of perceived exertion (RPE) and SF were measured. Muscle activity, RPE, and SF were analyzed using a 3 (mode) x 3 (BWS) repeated measures analysis of variance (ANOVA) ($\alpha = 0.05$). PS was analyzed using a one-way repeated measures ANOVA ($\alpha = 0.05$). **Results:** Muscle activity (RF, BF, TA, and GA), RPE, and SF were not influenced by the interaction of BW support and SF ($P>0.05$). Muscle activity from the RF, TA, and GA were different between BWS conditions ($P<0.001$). Specifically, muscle activity from the RF, TA, and GA were lower with increasing BWS (e.g., a decrease of 26%~46% between 80%BWS and 0%BWS conditions). Muscle activity from the RF, BF, and TA were different between SF conditions ($P<0.05$). For example, RF muscle activity during running at PSF was 11%~18% lower than when running at PSF+10%. Additionally, BF muscle activity during running was higher with increasing SF (e.g., a 20% increase in SF resulted in 12%~27% increase in the BF muscle activity). RPE was not different between BWS conditions ($P>0.05$) and between SF conditions ($P>0.05$). SF was different between BWS conditions ($P<0.001$) and between SF conditions ($P<0.001$). For example, SF was lower with increasing BWS (e.g., a decrease of 15% between 80%BWS and 0%BWS conditions). PS was higher with increasing BWS (9.8±2.1 km/h, 11.0±2.6 km/h, and 11.8±2.8 km/h for 0%, 50%, and 80% of BWS conditions, respectively; $P<0.001$). **CONCLUSION:** These observations suggest that a change in SF may influence muscle activity (i.e., RF and TA) during running, regardless of BWS.

 Email: dswilliams@vcu.edu
 (No relationships reported)

Age-related changes in bone structure and mechanics may increase the risk of injury when performing exercise such as running. Joint-related injury such as osteoarthritis is a primary concern for older runners. A contributing factor to bony injury is joint loading. However, it is not known whether increased loading exists in older runners. **Purpose:** To compare anteroposterior and compressive joint reaction forces (JRFs) in the lower extremities during running in healthy young and older runners. **Methods:** Nine healthy young runners (YA) and 10 healthy older adult runners (OA) performed fifteen over ground running trials at a fixed velocity (3.35 m/s). Running velocity was maintained (+5%) using an infrared timing gate. Three-dimensional kinematics and ground reaction forces were recorded simultaneously using an 8-camera motion capture system (240 Hz, Qualisys, Inc.) and force platform (960 Hz, AMTI, Inc.), respectively. Visual 3D was used to calculate ankle, knee and hip JRFs (compressive and anterior/posterior) during the stance phase of the gait cycle. Independent samples t-tests were used to compare mean JRFs in both directions. **Results:** YA exhibited significantly larger mean JRFs at the ankle ($p=0.04$; YA: -13.2±1.0 BW; OA: -12.6±0.7 BW) and knee ($p=0.04$; YA: -13.0±0.9 BW; OA: -12.3±0.9 BW) while no differences were observed at the hip ($p=0.08$; YA: -12.0±1.0 BW; OA: -11.1±1.4 BW). In the anterior/posterior direction, older adults had significantly smaller ankle JRFs compared to young adults ($p=0.01$; YA: 5.1±0.7 BW; OA: 4.5±0.4 BW) while no differences were observed at the knee ($p=0.20$; YA: -3.0±1.2 BW; OA: -2.7±0.8 BW) or hip ($p=0.37$; YA: 2.4±2.0 BW; OA: 2.2±1.9 BW). **CONCLUSIONS:** These data demonstrate that OA have smaller compressive JRFs and anteroposterior shear forces than YA. Therefore, it can be suggested that the greater incidence of bony and cartilage injuries experienced by older runners is not due to greater forces applied to the lower extremity joints during running.

Sagittal Plane Peak Knee Angle Variability During Distance Running Training And Race SpeedsChristopher T. Robertson, Jaclyn O'Loughlin, Jeffrey T. Wight.
Jacksonville University, Jacksonville, FL.

Email: crobert17@ju.edu

(No relationships reported)

PURPOSE: To analyze peak knee angle variability during distance running to determine if significant differences exist between the stance and swing phases at training and race paces. **METHODS:** Twenty-six highly-trained (30-80 miles per week) adult runners participated in the study (9 females, 17 males, 36.1±10.8 years). For gait analysis, 9mm spherical retro-reflective markers were applied according to Pohl et al., (2010). Data were collected at 200 Hz for 25 seconds using 6 Vicon Bonita cameras. Ten strides were analyzed and normalized to 100 points for the both the stance and swing phases. To assess variability, standard deviation (SD) was calculated across the 10 strides for each of the 100 data points. Peak variability was identified by taking the maximum value of the 100 SDs. The occurrence of peak variability in each phase was extracted as a percentage of each normalized phase. A 2 by 2 repeated measures factorial ANOVA was used to test for main effects and interaction (phase x velocity) at $p=0.05$ for both variables. **RESULTS:** There were significant phase main effects ($p<0.001$) for both variables. Peak knee angle variability was significantly greater in the swing phase compared to the stance phase (7.88° vs 4.22° , respectively). Peak knee angle variability occurred at 74% of the swing phase compared to 19% of the stance phase. **CONCLUSION:** Peak knee angle variability is greater throughout the swing phase compared to the stance phase and this peak occurs at specific, but different, percentages of each phase regardless of running speed. Peak knee angle variability occurs just before and after foot contact so it is likely relevant to consistency of landing mechanics during running and therefore may be an important factor in the occurrence and/or prevention of running injuries.

(No relationships reported)

Biomechanics of the stance phase of running is of interest in relation to injury development. Studying the stance phase requires proper detection of foot contact (FC). The onset of vertical ground reaction force (GRF) is considered the gold standard in a laboratory setting to detect FC. In the absence of GRF data, motion analysis can be used to measure peak downward velocity of the pelvis (PDVP) with a 15ms offset which showed good relation with FC during treadmill running at one speed (1). Inertial sensors can measure kinematic parameters like PDVP outside the laboratory setting. Peak tibial acceleration (PTA) is a parameter of interest in running injury development which can be measured with inertial sensors and may also be used to detect FC outside the laboratory.

PURPOSE: To assess the effectiveness of these kinematic methods using inertial measurement units (IMUs) to detect FC during running at different speeds. **METHODS:** 3 male runners (28 ± 8.5 yrs) ran on an instrumented treadmill at 6 speeds (10-15 km/h) for 1 minute each, wearing a suit equipped with IMUs at the tibia and sacrum. FC was determined based on GRF data of the treadmill (1000 Hz; threshold of 20N) and IMU data (240Hz). PDVP was obtained from a single integration of pelvic acceleration in the global frame. PTA was determined from the acceleration data measured in the local tibia frame. The 95% limits of agreement were used to compare each method to the gold standard (i.e., GRF).

RESULTS:**Table 1: The offset and 95% limits of agreement for the two kinematic methods with respect to the gold standard for 6 running speeds.**

Running Speed	Kinematic method	Offset		95% limit of agreement			
				Lower		Upper	
10 km/h	PDVP	5 frames	(21.0 ms)	1 frame	(4.2 ms)	6 frames	(25.2 ms)
	PTA	5 frames	(21.0 ms)	2 frames	(8.4 ms)	9 frames	(37.8 ms)
11 km/h	PDVP	6 frames	(25.2 ms)	1 frame	(4.2 ms)	8 frames	(33.6 ms)
	PTA	6 frames	(25.2 ms)	2 frames	(8.4 ms)	10 frames	(42.0 ms)
12 km/h	PDVP	7 frames	(29.4 ms)	1 frame	(4.2 ms)	7 frames	(29.4 ms)
	PTA	7 frames	(29.4 ms)	0 frames	(0 ms)	13 frames	(54.6 ms)
13 km/h	PDVP	8 frames	(33.6 ms)	1 frame	(4.2 ms)	8 frames	(33.6 ms)
	PTA	8 frames	(33.6 ms)	2 frames	(8.4 ms)	13 frames	(54.6 ms)
14 km/h	PDVP	6 frames	(25.2 ms)	1 frame	(4.2 ms)	7 frames	(29.4 ms)
	PTA	6 frames	(25.2 ms)	2 frames	(8.4 ms)	11 frames	(46.2 ms)
15 km/h	PDVP	6 frames	(25.2 ms)	2 frames	(8.4 ms)	6 frames	(25.2 ms)
	PTA	6 frames	(25.2 ms)	3 frames	(12.6 ms)	9 frames	(37.8 ms)

CONCLUSION: This study showed that a novel IMU-based method of detecting FC using PTA and PDVP showed good similarity with FC detection based on GRF at all running speeds. The different time offsets among running speeds should be considered when implementing these kinematic methods to detect FC. This opens up new possibilities for studying running mechanics outside the laboratory.

Superficial Sensory Feedback Is Not Responsible For Gait Alterations Associated With Barefoot RunningMelissa A. Thompson¹, Kristine M. Hoffman², ¹Fort Lewis College, Durango, CO. ²Denver Health Medical Center, Denver, CO.

Email: mathompson@fortlewis.edu

(No relationships reported)

Of the many sensory modalities, cutaneous sensory feedback is thought to play a primary role in locomotor patterns. It has long been proposed that gait alterations, when changing from shod to barefoot, are mediated by alterations in sensory feedback. While the theory of sensory mediated gait adaptations associated with barefoot running is plausible, there has been no data to support this claim. **PURPOSE:** To examine the role of superficial plantar cutaneous feedback in barefoot and shod running in order to substantiate the claim that sensory feedback triggers the gait alterations associated with barefoot running. **METHODS:** 10 healthy active subjects (6 male, 4 female); mass: 65.2±9.7 kg; age: 27±7.1 years participated in this study. 10 over-ground running trials were completed in each of the following conditions: barefoot (BF), shod (SHOD), anesthetized barefoot (ANEST BF) and anesthetized shod (ANEST SHOD). For the anesthetized conditions 0.1-0.3 mL of 1% lidocaine was injected into the dermal layer of skin on the plantar foot below the metatarsal heads, lateral column and heel. 3-dimensional motion analysis and ground reaction force (GRF) data were captured as subjects ran over a 20m run way with a force plate at 12m. Kinematic and kinetic differences were analyzed via two-way repeated measures ANOVAs. **RESULTS:** The differences in gait between the BF and SHOD conditions were consistent with previous research with subjects exhibiting decreased stride length (BF: 2.07±0.24m, SHOD: 2.21±0.24m, $p<0.001$) and changing from rear footstrike when SHOD to fore/mid footstrike when BF (BF: -5.5±5.1°, SHOD: 7.5±3.8°, $p<0.001$). Similarly, BF running was associated with decreased peak vertical GRFs and impact peak magnitudes (vGRF BF: 2.19±0.24 BW, SHOD: 2.32±0.19 BW, $p=0.02$; impact peak BF: 1.65±0.22 BW, SHOD: 1.89±0.25 BW, $p<0.001$). Despite anesthetizing the plantar surface, there was no difference between the BF and ANEST BF conditions in terms of stride length (BF: 2.07±0.24m, ANEST BF: 2.01±0.27m, $p>0.05$), footstrike (BF: -5.5±5.1°, ANEST BF: -3.8±3.2°, $p>0.05$) or GRFs (vGRF BF: 2.19±0.24 BW, ANEST BF: 2.15±0.28 BW, $p>0.05$; impact peak BF: 1.65±0.22 BW, ANEST BF: 1.59±0.25 BW, $p>0.05$). **CONCLUSION:** Superficial cutaneous sensory receptors are not primarily responsible for the gait changes associated with barefoot running.

The Ability of Sagittal Plane Kinematic Variables to Predict Loading in Different Populations of RunnersKathryn Harrison, Bhushan Thakkar, Gregory Crosswell, Jacqueline Morgan. *Virginia Commonwealth University, Richmond, VA.* (Sponsor: D. S. Blaise Williams III, FACSM)
Email: harrisonk3@mymail.vcu.edu*(No relationships reported)*

It is known that sagittal plane kinematics are able to predict loading in runners. This may be of use to clinicians who don't have access to force measurement devices. However, running biomechanics differ between genders and age groups. Thus it may be that models used to predict loading in demographically distinct groups of runners need to be specific to age and gender. **PURPOSE:** To determine if kinematic predictors of kinetic variables during running apply across genders and age groups. **METHODS:** Sagittal plane kinematics and kinetics were assessed in young male (YM: n=13, age=23.1 ± 2.3 yrs, mass=77.0 ± 12.1 kg, height=1.79 ± 0.08 m, velocity=3.32 ± 0.48 m/s) and middle-aged female runners (MF: n=28, age=47.3 ± 7.0 yrs, mass=63.7 ± 7.8 kg, height=1.66 ± .07 m, velocity=2.55 ± 0.37 m/s) using a 5 camera motion analysis system (Qualysis, Goteborg, Sweden) running on an instrumented treadmill (Treadmetrix, Park City, Utah) at their preferred running pace. Kinematics (knee flexion at initial contact, foot angle at initial contact, step position, peak knee flexion and COM excursion) were the independent variables; kinetics (average vertical loading rate, braking impulse, knee power absorption and peak knee extension moment and peak vertical ground reaction force) were the dependent variables. Linear regression models were developed to predict loading in both groups ($\alpha=0.05$). **RESULTS:** In both YM and MF, sagittal plane kinematics were useful in predicting peak knee moment (YM: $R^2=0.56$, $p=.002$; MF: $R^2=0.47$, $p=.0002$), knee power absorption (YM: $R^2=0.78$, $p=.0002$; MF: $R^2=0.55$, $p<.0001$), braking impulse (YM: $R^2=0.66$, $p=0.01$; MF: $R^2=0.67$, $p<.0001$), and peak vertical ground reaction force (YM: $R^2=0.31$, $p=0.03$; MF: $R^2=0.23$, $p=0.02$). Peak knee flexion appeared in the most models (peak knee moment, knee power absorption and braking impulse for both men and women), and thus may be the most useful single kinematic variable to assess loading across age groups and genders. In all models, greater knee flexion was associated with increased magnitude of loading. Average vertical loading rate could not be predicted using the chosen kinematics in either group. **CONCLUSIONS:** When equipment for kinetic assessment is not available, sagittal plane gait analysis may be a useful tool for clinicians to estimate loading in runners.

The Differential Effects of Footwear on Sample Entropy of Ground Reaction Force during RunningShuqi Zhang¹, Yumeng Li², Li Li, FACSM³. ¹Northern Illinois University, Dekalb, IL. ²California State University Chico, Chico, CA. ³Georgia Southern University, Statesboro, GA.
Email: szhang3@niu.edu*(No relationships reported)*

Maximum cushioned shoes could reduce the peak vertical Ground Reaction Force (GRF) during running, but it may increase the foot instability in horizontal directions, especially at the initial foot contact. Sample entropy (SampEn) has been adopted to define the irregularity to quantify levels of complexity of movement and examine the fluctuations in GRF within a time series. The foot instability would be better represented by the index of SampEn within a stance phase instead of variation among different stance phases viewing instability as errors. **PURPOSE:** this study was aimed at examining the complexity of GRF while running on the treadmill with different types of footwear through SampEn.

METHODS: 19 experienced runners were recruited and ran on the treadmill at 7.8 mph wearing different types of running shoes: max cushioned shoe, minimalist shoe, and regular shoe. GRF of 10 consecutive steps were collected by the instrumented Tandem treadmill. GRF data were further analyzed to calculate sample entropy for both the first 20% stance phase and entire stance phase. Two-way MANOVA was used to examine the effects of independent variables (shoe, step) on sample entropy measures at first 20% stance phase (SampEn_{20%-MI}, SampEn_{20%-AP}, SampEn_{20%-VT}) and entire stance phase (SampEn_{MI}, SampEn_{AP}, SampEn_{VT}). Post hoc Tukey test was applied as needed.

RESULTS: a significant shoe effect was observed on the association among dependent variables listed above ($P < .05$). Cushioned shoes displayed a higher SampEn_{AP} (.1162 ± .01558) than regular shoes (.1094 ± .0258) and a greater SampEn_{20%-AP} (.1953 ± .1556) than minimalist shoes (.1546 ± .0932). Minimalist shoe exhibited greater SampEn_{VT} (.0614 ± .01310) and SampEn_{20%-VT} (.0636 ± .0688) than cushioned shoes (.0577 ± .1002; .0448 ± .0305) respectively. No other significant difference was observed.

CONCLUSIONS: in general, cushioned shoes displayed more fluctuations of GRF in the anterior-posterior (AP) direction compared to minimalist and regular shoes, which indicates cushioned shoes may increase the foot instability in AP direction

during running. Greater fluctuations of vertical GRF when wearing minimalist shoes may indicate a reduced foot stability that could affect the impact absorption at foot touchdown and force generation in push-off.

Is Muscle Activity a Factor that Determines Preferred Stride Frequency During Running Outdoors?Krizzel Galvez, Jared Joerger, Kendell Galor, John A. Mercer, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.**(No relationships reported)*

Purpose: The purpose of this study was to determine if muscle activity is affected by different stride frequencies (SF) at preferred running velocity while running outdoors. **Methods:** Participants (n=10, 26.4±8.7 years, 72.6±18.3 kg, 170±8.7 cm) were given a self-selected warm-up after signing an informed consent. Wireless electromyography sensors (sample rate = 1926 Hz) were attached to four muscles on the right side: the rectus femoris (RF), biceps femoris (BF), tibialis anterior (TA), and gastrocnemius (GA). Maximum voluntary contractions were performed for five seconds prior to moving outside for data collection. Preferred running velocity and preferred stride frequency (PSF) were determined outdoors. Participants performed seven randomized conditions, each at their preferred running velocity, consisting of a specific SF. The conditions were 115%, 110%, 105%, 100%, 95%, 90%, and 85% of their PSF. SF was controlled by having participants match a metronome. Absolute value of EMG were averaged across a 5-second window for each SF for each muscle. A repeated measures analysis of variance was used to compare muscle activity between SF conditions.

Results: There was no significant difference in BF between SF conditions ($p=0.352$). There was no significant difference in RF between SF conditions ($p=0.229$). There was no significant difference in TA between SF conditions ($p=0.342$). There was no significant difference in GA between SF conditions ($p=0.758$). **Discussion:** Despite large changes in SF, average muscle activity was not different for any of the muscles tested when running a set speed outdoors. It does not seem that average muscle activity is a factor determining preferred stride frequency.

This project was made possible by a grant from the National Institute of General Medical Sciences (P20GM103440) from the National Institutes of Health. This project's contents are solely the responsibility of the authors and do not necessarily represent the official views of NIH.

Comparison Of Intrinsic Foot Muscle Size And Strength Between Gymnasts And Shod RunnersSarah Ridge, Mark Olsen, Kelsey Garner, J William Myrer, Dustin Bruening, A Wayne Johnson. *Brigham Young University, Provo, UT.* (Sponsor: J Ty Hopkins, FACSM)
Email: sarah_ridge@byu.edu*(No relationships reported)*

Purpose: Wearing supportive footwear during athletic activity may decrease the activity of the intrinsic foot muscles (IFM), leading to weaker muscles and suboptimal foot function. The purpose of this study was to compare the IFM size and strength of two athletic populations - gymnasts who train barefoot and runners who wear cushioned running shoes during training.

Methods: IFM size and toe flexor strength were measured from 13 female gymnasts (age: 19.8 ± .9 years; height: 158.9 ± 4.98 cm; weight: 56.9 ± 4.27 kg) and 21 female runners (age: 22.1 ± 2.95 years; height: 167.4 ± 8.88 cm; weight: 63.0 ± 9.38 kg). Strength was assessed from the big toe individually, and the 2nd, 3rd, and 4th toes together. During testing, the subject was seated with the knee flexed at 90° and the foot on the floor. The toes were aligned with a customized dynamometer. The subject gripped an S-beaner (great toe flexion) or a bar (lateral toe flexion) with their toe(s) and flexed to a maximal contraction for 3 seconds. The average of 3 trials was used for analysis. . Ultrasound images (10 MHz GE LogiqP6) were recorded of the abductor hallucis (ABDH), quadratus plantae (QP), flexor digitorum brevis (FDB) and flexor hallucis brevis (FHB). Measurements included the cross-sectional areas of the ABDH, QP, FDB and thickness of the FHB. ANCOVAs (with height and weight as covariates) were run to compare the IFM size and flexor strength between the groups of subjects. **Results:** Gymnasts had larger FDB and FHB, as well as stronger great toe flexion than runners (see table).

Conclusion: The IFM responsible for toe flexion and great toe flexion strength were greater in gymnasts than runners. Based on these data, training without cushioned footwear, in a task that requires finer control of the foot, has resulted in increased great toe flexion strength. Though it's difficult to separate training task from footwear in this study, these findings lend support to the idea that training in cushioned footwear may hinder optimal IFM function.

Group	Muscle Size				Muscle Strength	
	ABDH (cm ²)	QP (cm ²)	FDB (cm ²)	FHB (cm)	Great Toe (kg)	Lateral Toes (kg)
Gymnasts	2.16 ± .57	1.73 ± .26	1.87 ± .27	1.57 ± .07	5.44 ± 3.68	3.76 ± 1.41
Runners	1.82 ± .50	1.52 ± .35	1.62 ± .27	1.38 ± .17	4.34 ± 1.37	4.28 ± 2.05
p-value	.321	.061	.043*	.006*	.012*	.969

Relationship of Footstrike Pattern and Landing Impacts During a Marathon Race

Matthew Ruder¹, Steve T. Jamison¹, Adam Tenforde¹, Marian Hannan², Irene Davis, FACSM¹. ¹Spaulding National Running Center, Cambridge, MA. ²Institute for Aging Research, Hebrew SeniorLife, Boston, MA. (Sponsor: Irene Davis, FACSM)
 (No relationships reported)

Landing impacts during running are influenced by footstrike pattern (FSP) in rearfoot strikers (RFS) in laboratory studies. These impacts have been linked with running injuries. Landing impacts are highest in RFS, lower in midfoot strikers (MFS) and lowest in forefoot strikers (FFS). In RFS, impacts are positively correlated with speed. However, these relationships have only been examined in a laboratory setting, limiting the ecologic validity of the data.

PURPOSE: 1. To compare landing impacts between FSP during a marathon. 2. To assess the interaction effect of FSP and speed on landing impacts during a marathon.

METHODS: 226 runners (118 M, 108 F; 44.3±11.1 yrs) running a marathon were recruited for this study. Subjects were initially filmed running on a treadmill to determine their habitual FSP (169 RFS, 32 MFS, 23 FFS). During the marathon, an accelerometer, secured to the distal medial tibia, recorded continuous data. Average peak tibial shock (TS) was calculated for the first 10km of the marathon. An ANOVA (p<0.05) was used to determine FSP differences. The interaction effect of FSP and speed on TS was determined using an ANCOVA (p<0.05).

RESULTS:

Peak TS was significantly higher in the RFS compared with the FFS runners. TS in the MFS group was 20% higher than in FFS group. While not significant, this difference was associated with a large effect size, suggesting it is clinically meaningful. TS was positively correlated to speed for RFS and MFS groups (p<0.05), but not for the FFS group (p>0.05).

CONCLUSION: When running in their natural environment, FFS runners have the lowest impacts of all FSPs. In addition, unlike the RFS and MFS groups, FFS runners appear to have the ability to maintain lower impacts at faster speeds.

Supported by Vibram USA.

Table 1: Means and Standard Deviations for subject groups and intra-group comparisons

	FFS	MFS	RFS
Mean Peak Tibial Shock (g)	10.03	12.13	12.23
Standard Deviation	2.47	3.01	3.95
Number of Subjects	23	32	169
Standard Error	0.52	0.53	0.30
	FFS-MFS	MFS-RFS	FFS-RFS
Absolute Value of Average Difference	2.10	0.10	2.20
Pooled Standard Deviation	2.80	3.82	3.81
Effect Size	0.75	0.03	0.58
P-Value	0.095	0.99	0.021

Ground Reaction Forces During Running in Extreme Cushioning Running Shoes

Miles Mercer. University of Nevada, Las Vegas, Henderson, NV.
 (No relationships reported)

The extreme cushioning running shoe has recently emerged on the market and it is unclear whether this unique shoe design affects the way people move compared to a regular running shoe. **PURPOSE:** To compare ground reaction forces (GRF) while running in extreme cushioning shoes (ES) vs. normal cushioning shoes (NS) at different speeds. **METHODS:** Subjects (n=5, 1 Female and 4 Males; 74.11kg±11.8kg, BMI: 23.45±1.76 kg/m², 1.69m±0.050m) completed a 1 day testing session consisting of establishing the subject's preferred running speed (PRS) and running at three speed conditions: PRS, PRS+5%, PRS+10%. Subjects were instructed to run over a force platform embedded in the middle of a 5-m runway while wearing ES (Hoka, Bondi 4) or their self-selected shoes (SS) with three speeds (PRS, PRS+5%, PRS+10%)

per shoe condition. Running velocity was measured using infrared timing gates with velocity controlled within ±5% target velocity with three trials completed per condition. Discrete vertical GRF parameters of impact peak (F1), maximum peak (F2), and average (Favg) were recorded and averaged across the three trials per condition. A 2 (shoe) x 3 (velocity) repeated measures analysis of variance (α=0.05) was used for analysis. **RESULTS:** Neither F1, Favg, nor F2 were influenced by the interaction of shoe and velocity (p>0.05) and none had a main effect of shoe (F1: ES 1.78±0.4 BW, SS 1.85±0.3 BW; Favg: ES 1.57±0.1 BW, SS 1.55±0.1 BW; F2: ES 2.68±0.2 BW, SS 2.67±0.2 BW; p>0.05). Favg did increase with velocity (p<0.05) but F1 and F2 did not (p>0.05). **CONCLUSION:** F1 was observed less than 30% of the ES trials for two subjects. Nevertheless, as a group, there were no differences in GRF parameters analyzed between shoe conditions.

492 Board #313 May 31 9:30 AM - 11:00 AM
The Effect Of Speed, Incline, And Distance On Impacts During A Marathon Road Race

Steve T. Jamison¹, Matthew C. Ruder¹, Adam S. Tenforde¹, Marian T. Hannan², Irene S. Davis, FACSM¹. ¹Spaulding National Running Center, Cambridge, MA. ²Harvard University, Cambridge, MA. (Sponsor: Irene Davis, PhD, PT, FACSM, FACSM)
 (No relationships reported)

The majority of running studies are conducted in controlled laboratory settings. The advent of mobile technology has allowed the study of running impacts outside in a more natural environment enhancing the ecologic validity of these investigations. A marathon provides an excellent opportunity to examine the effect of a variety of naturally occurring, race-related factors on running impacts which have been related to injury.

PURPOSE: To determine the association between course incline, speed, and race progression (an indication of fatigue) on running impacts (tibial shock) during a marathon.

METHODS: 226 individuals (118 males, 108 females; 44.3±11.1 yrs) running the same marathon (42.2km) were included. They each wore a triaxial accelerometer, recording at 1,000Hz, secured on their distal, medial tibia throughout the race. Peak resultant acceleration, tibial shock (TS), for each step was determined. Run times for each 5km, and the last 2.2 km, were provided by the race organizers. TS and course incline were averaged over matching race intervals. A linear mixed effects model was used to determine the relationship between tibial shock and the independent variables of course incline, speed, and race progression.

RESULTS: Mean resultant tibial shock was 15.2±1.1g. Course incline, speed, and distance were significantly related to TS (p<0.05). TS association between course incline was negative, while speed and distance were both positive.

CONCLUSIONS: Our results suggest that higher resultant tibial shock is associated with decreases in incline, increases in speed, and race progression (increased fatigue). Supported by Vibram USA.

Figure Caption: Population average resultant tibial shock [in units of gravity, g] relative to each independent variable (speed, incline, and distance). Grey numbers represent the total distance traveled after each race interval used [in km].

The Influence of Footwear on Running Mechanics, Impact, and Plantar Loading in Habitual Rearfoot Strikers

Camden S. Marshall, William J. McDermott, James Walker. The Orthopedic Specialty Hospital, Murray, UT.
 (No relationships reported)

Running overuse injuries are related to the magnitude of impact forces and shocks, loading rates, and the distribution of forces underfoot. Minimalist shoes and barefoot running might reduce or eliminate running impacts by encouraging softer landings. However, reduced cushioning could increase plantar loading and some runners may not alter their habitual running mechanics to account for less cushioning.

PURPOSE: To examine the acute effects of a cushioned neutral shoe (CN), minimal shoes (MN), and neoprene socks (BF) on running mechanics, impact, and plantar pressure.

METHODS Forty habitual rearfoot strikers ran on an instrumented treadmill while 3D kinematics, ground reactions forces (GRF), tibial accelerations (TA), and plantar pressure were recorded. Variables examined included: foot and knee angle at contact, vertical GRF loading rate (VLR), the isolated impact component of vertical GRF (IP), and the magnitude of peak positive to negative TA. Peak plantar pressure was compared for the forefoot (FFP), midfoot (MFP), and rearfoot (RFP). Differences were compared with a RMANOVA and post hoc t-tests ($\alpha=0.05$).

RESULTS With less cushioning the foot was less dorsiflexed at contact BF $8.6\pm 5.3^\circ < MN 11.30\pm 5.0^\circ < CN 16.0\pm 4.4^\circ$ ($p<0.01$). The knee was more extended at contact in CN $13.3\pm 6.6^\circ$ than MN $14.8\pm 5.9^\circ$ and BF $15.2\pm 5.8^\circ$ ($p<0.001$). VLR was less in CN 670 ± 212 N/kg/s compared to MN 980 ± 268 N/kg/s and BF 975 ± 371 N/kg/s ($p<0.001$) as was IP 4.1 ± 16 N/kg vs 6.8 ± 2.6 N/kg & 6.7 ± 3.2 N/kg ($p<0.001$). TA was lower in CN 9.4 ± 4.2 g than BF 12.6 ± 6.7 g and MN 11.4 ± 5.5 g ($p<0.01$). FFP increased with less cushioning: CN 330 ± 70 kPa $< MN 430\pm 87$ kPa $< BF 561\pm 76$ kPa ($p<0.001$). MFP was less in CN 144 ± 35 kPa compared to MN 212 ± 58 kPa and BF 224 ± 108 kPa ($p<0.05$). RFP was lower in CN 253 ± 52 kPa vs MN 272 ± 81 kPa and BF 396 ± 170 kPa ($p<0.001$).

CONCLUSION Less cushioning resulted in a more compliant configuration of the limb at ground contact, which agrees with previous research. However, the CN shoe reduced VLR, IP, and TA compared to MN and BF despite a more extended knee and dorsiflexed foot. Lower peak plantar pressures in CN suggest that cushioning better distributes plantar forces of a less compliant limb particularly in the rearfoot. These results highlight the importance of both cushioning and mechanics on injury related variables.

Six Week MFS Drill Training with Proprioceptive Resistance Device Influences Conversion of RFS to MFS

Connie Sol, Joseph F. Signorile, Afton D. Seeley. *University of Miami, Coral Gables, FL.* (Sponsor: Arlette C. Perry, Ph.D, FACSM)
 Email: consolfla@gmail.com
 (No relationships reported)

Recent literature suggests a transition from rear-foot striking (RFS) to mid-foot striking (MFS) may lower injury potential; but transition is difficult. Using a resistive proprioceptive device may facilitate the change. No study has quantified the impact of such a device on foot-strike conversion. **PURPOSE:** To examine the effectiveness of a 6-week MFS drill training program in converting recreational RFS to MFS with and without the use of a proprioceptive resistive device (EZ Run Belt) using changes in cardiovascular, biomechanical, and neuromuscular assessments. **METHODS:** 19 RFS runners were randomly assigned to control (C: M4, F1), drills only (DO: M3, F4), or drills plus belt (DB: M6, F1) groups. Both DO and DB received drill sessions using MFS training over 6 weeks with DB using a resistive belt (EZRB) during training runs. Physiological (VO₂max, anaerobic threshold, heart rate, running economy, timed performance), biomechanical (knee flexion and dorsiflexion angles at initial contact (KFA, DFA), cadence (CAD), stride length) and electromyographic (EMG) measures of 5 right-leg muscles (rectus femoris (RF), vastus lateralis, biceps femoris (BF), semitendinosus (ST), and lateral gastrocnemius (LG), were recorded as subjects ran under 3 conditions: submaximal (85% lactate threshold heart rate) on a treadmill (TM85) and overground for 400m (OUT85), maximal overground (OUTMAX), before and after training. **RESULTS:** In all 3 conditions, outcomes reflected significant within-group increases for DO and DB in CAD and EMG and decreases in KFA, DFA consistent with an RFS to MFS conversion, but no significance was detected between DO and DB, except for the RF EMG during TM85 increasing for DO and decreasing for DB (-.014±.005 μV, $p<.05$). Greatest changes in DO were observed at OUT85: RF (+66%, $p=.045$), BF (+70%, $p=.008$), LG (+49.6%, $p=.05$), KFA (-3.9%, $p=.001$) and DFA (-34.3%, $p<.001$). Greatest changes in DB were observed at OUTMAX: BF (+84.4%, $p=.003$), ST (+85.5%, $p=.015$), CAD (+5.3%, $p<.001$), KFA (-4.9%, $p<.001$). **CONCLUSIONS:** Changes in biomechanics and muscle activation observed in DO and DB indicate a significant shift from RFS to MFS after 6 weeks of MFS drill instruction, unique effectiveness of the proprioceptive device could not be established, but differences warrant further investigation.

A Comparison Of The Effects Of Forefoot Striking And Cadence On Vertical Load Rates

Erin Futrell¹, Douglas Gross¹, Darcy Reisman², Irene S. Davis, FACSM³. ¹*MGH Institute of Health Professions, Boston, MA.* ²*University of Delaware, Newark, DE.* ³*Harvard Medical School, Cambridge, MA.* (Sponsor: Irene Davis, FACSM)
 Email: efutrell@mghihp.edu
 (No relationships reported)

High vertical load rates have been linked to common running injuries. Interventions to reduce load rates have developed to reduce impact related injuries. Two popular approaches are increasing cadence (CAD) and using a forefoot strike (FFS) pattern. However, the effects of these interventions have not been compared in the same study. **Purpose:** To compare the effects of increasing CAD and transitioning to a FFS pattern to reduce impact loading in healthy recreational runners.

Methods: 35 habitual rearfoot strike runners, ages 19-42 yrs, running 5-15 mi/wk, with a CAD of < 170 steps/min were randomized to a FFS group ($n=16, 5M$) or increased CAD group ($n=19, 5M$). All subjects performed 4 wks of strengthening exercises. This was followed by 8 sessions of gait retraining (GR) over 3 wks using auditory feedback specific to each group. Run time was increased from 10-30 min over the 8 sessions, and feedback time was faded over the last 4 sessions. An instrumented treadmill assessment was done at baseline, at 1wk post GR, and at 1 mo follow-up. Variables of interest were vertical average and instantaneous load rates (VALR, VILR) measured in bodyweights (BW)/s.

Results: Groups were similar in all variables at baseline (Figure 1). FFS group reduced VALR by 58% and VILR by 44%. CAD group reduced VALR by 26% and VILR by 24%. At 1 mo, load rates for both groups were significantly lower than baseline, but FFS maintained reductions to a greater extent. A 5.6% increase in cadence occurred in both groups following GR. At 1 mo follow-up cadence remained higher in both groups, but to a greater extent in FFS group.

Conclusion: These data suggest that transitioning to a FFS results in greater reduction of vertical load rates and greater persistence of these changes over time.

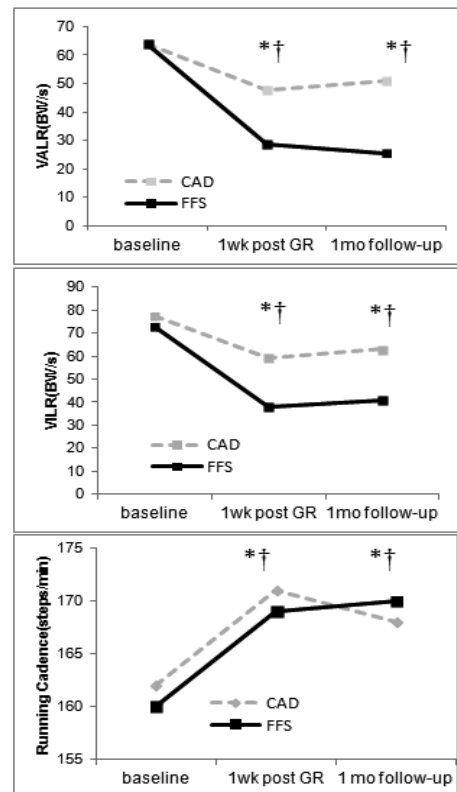

Fig 1. Comparison of results between groups across time from baseline. * significant difference for CAD group; † significant difference for FFS group

Perturbing Stride Frequency Has No Effect On Average Muscle Activity

Andrew Craig-Jones, Joshua Bailey, Kendell Galor, John A. Mercer, FACSM. *UNLV, Las Vegas, NV.* (Sponsor: Dr. John A. Mercer, FACSM)
 (No relationships reported)

Running is a popular and widely used mode of exercise in the world today. Preferred stride frequency (PSF) is the stride frequency (SF) a runner selects for a given speed. Changes in SF may influence metabolic costs while running (Meardon & Derrick, 2009, *MSSE*, 41, 512-513), but it is not clear if muscle activity is minimized at PSF compared to running with other SFs. **PURPOSE:** To determine if muscle activity is minimized while running at PSF. **METHODS:** 10 healthy participants (24.7±3.8 years; M=7, F=3) ran on a treadmill at PSF-15%, PSF-10%, PSF-5%, PSF, PSF+5%, PSF+10%, PSF+15%. Conditions were randomized for each subject to account for task adaptation. Treadmill running speed was determined initially by each participant instructing the tester to increase or decrease the speed until felt like a speed representative of a 30-minute run. During preferred running condition, PSF was calculated by visually identifying the time to complete 20 strides. Target SFs were then calculated for all other conditions. Participants ran for 5-minutes at each condition with 1-minute rest between conditions. SF was controlled by having the participants match foot strikes to the beat of a metronome set to each desired SF for 15 sec of every minute. Data were collected 4 times throughout each trial for 30s every minute of the condition. The first collection was used for this analysis. EMG sample rate was 2000Hz from the Rectus Femoris (RF), Biceps Femoris (BF), Tibialis Anterior (TA), and Gastrocnemius (GA). Average and root mean squared (RMS) EMG data were analyzed via repeated-measures ANOVA ($\alpha=0.05$). Data were normalized to %PSF to assess minimization. **RESULTS:** PSF RMS EMG were not minimized in any muscle across all SF conditions. Average EMG for BF ($F(1.24, 11.19) = 7.32, p>0.05, \eta_p^2 = 0.45$) and GA ($F(1.49, 1.71) = 21.38, p>0.05, \eta_p^2 = 0.70$) were both influenced by SF, but PSF EMG were not minimized for either of those muscles. Normalized EMG for BF were 103.90±27.02%, 90.83±26.02%, 98.37±16.19%, 104.20±29.61%, 103.42±42.59%, 109.48±48.37% and for GA were 112.73±25.02%, 90.77±24.90%, 95.33±27.33%, 108.35±36.24%, 90.89±19.40%, 106.68±20.33% for PSF -15%, -10%, -5%, +5%, +10%, +15% respectively. **CONCLUSION:** Muscle activity was not minimized while running at PSF compared across all conditions.

Does Preferred Running Velocity Vary with Variations in Running Condition?

Julia Freedman Silvernail, Miles Mercer. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: John Mercer, FACSM)
 Email: jfs@unlv.edu
 (No relationships reported)

Running form is often studied within the laboratory. During these studies, researchers must make the difficult decision to capture runners at a set velocity, which allows for straight forward comparisons between participants, or at their preferred velocity (PRV). Although theoretically we are capturing natural movement when we ask runners to move at a PRV, it is unknown how a laboratory PRV over-ground or on a treadmill may differ from each other or from running on a longer course outdoors. **PURPOSE:** The purpose of this study was to determine a PRV for two groups of runners (recreational and competitive) over-ground in the laboratory, on a laboratory treadmill, and outside on a track. **METHODS:** Healthy competitive (n=10) and recreational (n=9) runners completed running trials in each of three conditions: (1) over-ground, where PRV was determined as the average of five trials; (2) on the treadmill, where PRV was determined over five trials where participants were blinded to the velocity but asked to alter the velocity until they were comfortable; and (3) around a track where the split times of two laps were taken as two separate trials. **RESULTS:** There was not a significant interaction between group and condition ($p=0.468$) but there were significant main effects for both group ($p<0.001$) and condition ($p<0.001$). The competitive runners had a faster PRV (3.1 m/s) than recreational runners (2.7 m/s). Treadmill PRV was significantly slower (2.5 m/s) than over-ground PRV (3.1 m/s; $p<0.001$) and track PRV (3.1 m/s; $p<0.001$), which were similar to each other ($p=0.618$). **CONCLUSIONS:** Environment can change a runner's perception of preferred velocity, which was demonstrated in this study with a significantly slower preferred velocity while running on a treadmill. Therefore, one should take caution when interpreting or collecting running data that utilizes a preferred running velocity, and the environment in which the data were collected should be considered.

Decreased Metabolic Running Efficiency After One Week Of Practicing Improved Running Mechanics

Jacob Lee, 84058, Ashton Hudspeth, Ellis Jensen, 84058, FACSM. *Utah Valley University, Orem, UT.*
 (No relationships reported)

PURPOSE: A more efficient runner is a more comfortable, prolific, and competitive runner. At the same work rate, more efficient running technique should lead to decreased respiratory exchange ratio (RER), oxygen consumption (VO₂), exercise intensity (MET), and rating of perceived exertion (RPE). Such physiological changes should lead to performance improvements such as delayed onset of fatigue and decreased recovery time. We analyzed how improving arm movement and cadence could increase running efficiency. **METHODS:** Seven novice runners, aged 18-50, participated in the study (5 males, 2 females). Thirty-nine 3D-reflective motion sensors were placed on the upper body of each subject. Movement was analyzed by Coaches Eye. Trial 1 consisted of an uncoached 5-minute running bout at a pre-determined heart rate (calculated using the Karvonen formula) that corresponded to 50% of VO₂max. Exercise intensity, VO₂, RER, and HR were measured. After the first trial, subjects were coached on proper running mechanics and were encouraged to practice employing their enhanced technique for one week. Trial 2 was similar to trial 1 except that participants ran with proper mechanics. Paired t-tests were performed for each set of values to compare trial 1 with trial 2. **RESULTS:** Exercise intensity, VO₂, RER, and HR were all significantly greater in trial 2 than trial 1. Shoulder movement decreased in all axes. **CONCLUSIONS:** While subjects reduced their upper body movement and reported working less intensely to run at the same rate with improved mechanics, greater VO₂, RER, HR, and MET indicated that, after only one week of familiarization with new mechanics, they were actually running less efficiently. This could be the case because runners didn't practice the new mechanics sufficiently, or because with any change in running technique, even improvements, temporary lack of coordination due to under-developed neural and muscular control, leads to temporarily-decreased running efficiency. Further research with longer study duration would likely show that increased cadence and decreased upper-body movement result in more efficient running.

Effect of Running Speed on Achilles Tendon Injury Potential: Use of a Weighted Impulse Measure

Michael Baggaley, W. Brent Edwards. *University of Calgary, Calgary, AB, Canada.* (Sponsor: Joe Hamill, FACSM)
 Email: michael.baggaley1@ucalgary.ca
 (No relationships reported)

ABSTRACT
 Previous literature has suggested that increasing running speed is associated with a reduction in cumulative load per distance traveled and thereby a decrease in injury risk. However, the tissue damage incurred by a bout of loading is a function of its stress-life (S-N) behavior which describes the exponential relationship between loading magnitude and cycles to failure. Current cumulative loading measures do not consider the S-N relationship which may in fact lead to erroneous conclusions about tissue damage and injury risk. **PURPOSE:** The purpose of this study was to examine the influence of running speed on an S-N weighted impulse measure at the Achilles tendon. **METHODS:** Ten participants ran overground at 2.5, 3.5, and 4.5 m/s while force and motion capture data were recorded. An inverse dynamics analysis was used to calculate joint moments and AT force was calculated from the ankle joint moment and the AT moment arm which was a function of ankle joint angle. AT impulse per step was calculated as the time integral of the AT force curve. A weighted impulse measure was quantified where AT force was raised to the power of 9. This value was derived from *in vitro* tendon testing and describes the slope of the S-N tendon curve. Impulse and weighted impulse per km were calculated as the respective impulse per step measures multiplied by the number of steps necessary to run 1km. A Friedman test examined the main effect of speed followed by Bonferroni adjusted pair-wise comparisons. **RESULTS:** A significant main effect of speed was observed for impulse per step ($p=0.003$), impulse per km ($p<0.001$) and weighted impulse per km ($p<0.001$). In general, the impulse per step and impulse per km decreased with running speed ($p\leq 0.013$); however, no significant differences were observed between 3.5 and 2.5 m/s ($p\geq 0.047$). On the other hand, the weighted impulse per km increased with running speed ($p=0.005$). **CONCLUSION:** Using a traditional measure of cumulative impulse suggests that running faster may decrease the risk of Achilles tendon injury. This counterintuitive conclusion is not reached when using a weighted impulse measure that considers the S-N behavior of the tendon.

Risk Factors Associated With Foot Pain In Runners
 Joseph Wasser. *University of Florida, Gainesville, FL.* (Sponsor: Dr. Heather Vincent, FACSM)
 Email: wassejg@ortho.ufl.edu
 (No relationships reported)

Purpose: Repetitive stresses of running can contribute to the onset of musculoskeletal pains, such as those in the foot. The presence of foot pain in one site along the kinematic chain may alter running motion and cause pain to develop in other areas but this is not well-studied. The purpose of this study was to determine the differences in key running motion parameters in runners with and without foot pain, and identify significant contributors to the onset of foot pain.

Methods: This was a cross-sectional study of runners with foot pain (n=24) and age-sex matched runners without foot pain (n=20). Runner characteristics were: 173cm±9 cm; 70kg±14.5 kg; 77.3% long-distance trained. Running experience, history of joint pain and recent changes in training and shoe wear were collected. Foot pain was reported as presence of pain of any severity. A 12 optical camera 3-dimensional motion capture system with a force-plated treadmill were used to collect running motions and forces. Key variables included cadence, stride length, stance time and ground reaction force, rate of development of impact forces.

Results: Foot pain was classified as 33% plantar fasciitis, 8% metatarsal stress fracture, 17% other and 42% had undiagnosed foot pain. In runners with foot pain, 62.5% started running in a new shoe type within the past 6 months (p<0.001). Compared to runners without foot pain, those with pain reported additional musculoskeletal pain at sites along the kinematic chain in the knee, hip, low back and shoulder pain (62.5% versus 15%; p<0.001). 46% of runners with reported foot pain attempted to run with a new foot strike, compared to 25% of runners without pain (p=0.10). Logistic regression revealed that the strongest contributor to onset of foot pain was the use of a new running shoe type within the previous six months (β coefficient=-2.265; p=0.003) Temporal spatial measures were not different in runners with without foot pain.

Conclusion: For injury prevention, proper adaptation to new shoes should be a priority. Running with a chronic foot pain can ultimately become a more systemic problem with the onset of other musculoskeletal pains. If a runner wishes to change shoe type, a slow proper introduction and progression of these changes over a period of time is recommended.

Preliminary Analysis: Variability Between Healthy and Injured Individuals during Running
 Amanda Estep¹, Steven Morrison², Shane Caswell¹, Jatin Ambegaonkar¹, Nelson Cortes¹. ¹George Mason University, Manassas, VA. ²Old Dominion University, Norfolk, VA.
 Email: ncortes@gmu.edu
 (No relationships reported)

Reduced motor variability has been associated with increased risk of lower extremity running-related injuries, such as patellofemoral pain syndrome. Further investigation of lower extremity variability in populations with current lower extremity injury (LEI) is needed to determine the relationship between variability and running-related injuries.

PURPOSE: To compare lower extremity kinematic variability between healthy individuals (HE) and individuals currently experiencing LEI (knee, hip, pelvis, and thigh) during a running task.

METHODS: Thirty-four individuals (17 HE, 17 LEI) volunteered for this study. 3D kinematic data during running was captured at 200Hz using reflective markers placed on lower body. A single 25-second trial was collected. Variables of interest included knee flexion/extension angle, knee abduction/adduction angle, hip flexion/extension angle, and hip abduction/adduction angle; all were measured in degrees. Linear measures of variability including standard deviation (SD) and coefficient of variation (CV) were calculated for each dependent variable during the stance phase. A multivariate analysis of variance (MANOVA) was used to assess differences in SD and CV between the healthy and LEI groups.

RESULTS: The average running speed was 2.52±.24 m/s. There were no statistically significant differences between groups (injured and non-injured) when assessing linear measures of variability ($F_{1,32}=.624$, p>.05). Means and SD for each DV are as follows: knee FLEX SD (HE=6.48±13.07, LEI=1.83±.67), knee FLEX CV (HE=23.33±46.48, LEI=6.97±3.42), knee ABD SD (HE=1.06±1.52, LEI=.53±.18), knee ABD CV (HE=25.81±36.74, LEI=12.08±5.80), hip FLEX SD (HE=6.01±13.08, LEI= 1.39±.45), hip FLEX CV (HE=46.67±96.56, LEI=7.88±3.32), hip ABD SD (HE=1.37±1.60, LEI=.91±.34), hip ABD CV (HE=69.23±61.53, LEI=205.46±454.20)

CONCLUSIONS: Overall, no differences in lower extremity kinematic variability were found between groups. It is plausible that LEI is not manifested by significant changes in the amplitude of lower extremity kinematic variability demonstrated in the sagittal and frontal planes. Future studies should incorporate measures that capture the time-dependent nature in movement variability, rather than restrict analysis to simply assessing magnitude changes.

Is There a Predictable Value of the Drop Vertical Jump Test for Running Gait Injury Risk?
 Ravi Kumar, 32611-2727, Trevor Leavitt, 32611-2727, Cong Chen, Heather K. Vincent, 32611-2727, FACSM, Daniel C. Herman, 32611-2727, FACSM. *University of Florida, Gainesville, FL.* (Sponsor: Heather K. Vincent PhD, FACSM)
 Email: rakumar@ufl.edu
 (No relationships reported)

Purpose: A three-dimensional (3D) motion analysis of running gait is often used to identify modifiable lower extremity biomechanical risk factors, but can be time consuming and costly. The Drop Vertical Jump (DVJ) test when combined with the Landing Error Scoring System (LESS) can easily be done in the field to assess lower extremity coordination and injury risk. The purpose of this study was to determine if correlations existed between biomechanical variables of the DVJ and a 3D gait analysis. Positive findings would indicate that the DVJ may serve as a simple surrogate for the running analysis to quickly screen for lower extremity injury risk.

Methods: 24 runners (26.1 ± 8.6 yrs; 27.7 ± 11.3 miles/wk; 16 Male, 8 Female) participated. During one testing session, a 3D motion analysis and an instrumented treadmill were used to capture and determine lower extremity kinematics, ground reaction forces (GRF) and knee moments during the gait cycle. Subjects completed five DVJs and a gait analysis at a self-selected running speed (6.7 ± 0.9 mph). Data were gathered on the dominant leg for both the DVJ and the gait analysis (1 left dominant). LESS scores were calculated through frontal and sagittal plane videos of the DVJ using a score from 22 items. Individual LESS items were selected based on similar measures that could be captured in the 3D gait analysis: asymmetric motion of feet and knees in the sagittal and frontal planes, foot contact patterns and overall impression.

Results: Significant associations existed between maximal knee flexion angle (sagittal plane 3D running) and overall LESS score (r=-.791; p<0.001). There were no other significant associations between lower extremity kinematics, GRFs and knee moments and LESS items and overall score. There were also no significant associations between DVJ biomechanical variables and the 3D gait measures.

Conclusion: Contrary to our expectation, associations between 3D gait, DVJ and LESS were minimal. A possible explanation could be that the dual-leg DVJ test may not be able to account for factors of balance and stability that are critical for the single-leg nature of running. A single-leg DVJ may be a more accurate field test when predicting running-related injuries.

Trunk Kinematics Displayed During Running By Individuals with Adolescent Idiopathic Scoliosis: A Pilot Study
 Rumit S. Kakar¹, Joshua Tome¹, Tyler J. Denn-Thiele¹, Jamie Kronenberg¹, Kathy J. Simpson, FACSM². ¹Ithaca College, Ithaca, NY. ²University of Georgia, Athens, GA.
 (Sponsor: Kathy J. Simpson, FACSM)
 Email: rkakar@ithaca.edu
 (No relationships reported)

Decreased spinal motions in walking have been reported for Adolescent idiopathic scoliosis (AIS) individuals but how AIS produce the spinal rotations needed during high-effort running and thus compensate for the loss of spinal flexibility is not known.

PURPOSE: To compare trunk kinematics displayed by AIS and matched controls (CON) during a perceived maximal effort treadmill running.

METHODS: Five skeletally mature AIS individuals (thoracolumbar structural curve with neutral pelvis; primary Cobb angle = 35.3°±13.6°) and 5 CON (respectively: age: 21.3±1.3 yrs, 20.6±1.1 yrs; height 1.7±0.1m, 1.59±0.1m; mass 52.7±9.4 kg, 57.0±10.8 kg; level of physical activity (IPAQ SF): 7.3±2.6 hrs/wk, 6.67±3.06 hrs/wk) were recruited. Spatial locations of the 24 reflective markers on the trunk and pelvis were captured (Vicon®, 120 Hz) during self-selected maximal running speed for 15 sec on treadmill (BORG RPE > 13). Angular displacements (AngDisp) of the 3 trunk segments (upper trunk [UT: C7-T8], middle trunk [MT: T9-T12] and lower trunk [LT: L1-L5]) for each rotation plane were compared between the groups via Analysis of covariance (running speed = covariate, p<.05).

RESULTS: Running speeds were not different between the 2 groups (p=0.63). LT lateral flexion AngDisp relative to pelvis was significantly lower (p=.049) for AIS (7.7°±2.7°) compared to CON (14.0°±3.4°). AIS group (14.7°±5.0°) showed a tendency for clinical significance (p=.065) for greater sagittal plane AngDisp compared to CON (8.9°±2.8°) but no other significant differences were observed (p=.194-.814).

CONCLUSION: Minimal differences were observed between the groups contrary to those reported in literature for walking. One clinical explanation could be the presence of compensatory secondary spinal curve leading to a neutral pelvis. Magnitudes of the group differences observed were very low, and thus may not be clinically relevant when compared to the total available trunk ranges of motion. These could be a result of high inter-participant variability in running technique and low statistical power, and

not necessarily as an effect of scoliotic spine. Physically active AIS individuals have the potential to demonstrate typical trunk mechanics to achieve performance goals of high intensity physical activities like running.

A Prospective Study on Medial Tibial Stress Syndrome in Runners

James Becker¹, Mimi Nakajima², Will Wu². ¹Montana State University, Bozeman, MT. ²California State University, Long Beach, Long Beach, CA.
(No relationships reported)

Medial tibial stress syndrome (MTSS) is one of the most common overuse injuries in runners. Previous studies have indicated hip muscle strength, passive range of motion (ROM), and running kinematics as possible contributing factors. However, to date, no studies have combined measurements of all these areas into a single prospective study. **PURPOSE:** To prospectively examine differences in muscle strength, ROM, and kinematics between runners who do and do not develop MTSS. **METHODS:** 24 runners (sex: 13 male, 11 female; age: 20.1 ± 1.2 years; weekly mileage: 53.2 ± 20.8 miles) participated in this study. Participants underwent a clinical exam documenting lower limb alignment and ROM; were evaluated for hip abductor, external and internal rotator, and extensor strength using a hand held dynamometer; and completed a 3D running gait analysis during which a 12-camera motion capture system was used to record kinematics while they ran on a treadmill. Participants were followed for two years during which time any injuries were diagnosed and recorded by the teams' athletic trainer. Independent *t*-tests were used to compare differences between runners who did (INJ) and did not (CON) develop MTSS. Logistic regression was used to evaluate which variables were best predictors of group membership. **RESULTS:** After two seasons 8 of the 24 athletes developed MTSS. There were no differences in ROM measures between INJ and CON groups, however, the INJ group demonstrated weaker hip abductors than the CON group (16.0 ± 3.6 vs 21.9 ± 6.0 % body weight, *p* = 0.01, ES = 1.4). Compared to the CON group, the INJ group had higher contralateral pelvic drop (6.4 ± 1.4 vs. 4.5 ± 2.0°, *p* = .02, ES = 1.1), higher peak rearfoot eversion (8.2 ± 4.3 vs. 4.6 ± 1.9°, *p* = .02, ES = 1.1), and longer durations of rearfoot eversion (79.4 ± 8.5 vs. 55.5 ± 10.3 % stance, *p* < .001, ES = 2.5) during stance phase. The logistic regression ($\chi^2 = 18.1$, *p* < .001) revealed every 1% stance increase in duration of rearfoot eversion increased odds of being in the INJ group by 1.26 (*p* = .015, 95% CI 1.04 - 1.54). **CONCLUSION:** Both proximal and distal biomechanics appear to contribute to MTSS development. Thus, screening for individuals at risk of developing this common overuse injury should include evaluation of both regions, with particular attention to the duration of rearfoot eversion.

Do Female Runners with Large Peak Hip Adduction Angles Lack Hip Strength and Control?

Richard A. Brindle, Clare E. Milner, FACSM. Drexel University, Philadelphia, PA. (Sponsor: Clare Milner, FACSM)
Email: brindle@drexel.edu
(No relationships reported)

Large peak hip adduction angles in women are prospectively linked to patellofemoral pain and iliotibial band syndromes. Deficits in hip abductor eccentric strength and lower extremity neuromuscular control (NMC) may contribute to the large peak hip adduction angles in female runners. **PURPOSE:** To compare hip abductor eccentric strength and NMC between female runners with large and small peak hip adduction angles. **METHODS:** We recruited 11 female runners for this study (26 ± 4 years; 1.65 ± 0.06 m; 58.9 ± 4.0 kg; 19 ± 9 miles per week). Three-dimensional position data were collected during running. Hip abductor eccentric strength was measured using a hand held dynamometer during a break test. NMC was measured using the hip control test, based on Fitts law. A higher score on the hip control test indicated better NMC. Runners were separated into "large" and "small hip adduction" groups based on their peak hip adduction angle. Hip abductor eccentric strength and NMC were compared between groups and interpreted according to minimal detectable differences (MDD). Effect sizes (ES) were used to interpret the magnitude of differences. **RESULTS:** The large and small hip adduction groups were separated by more than the MDD in peak hip adduction angle (MDD = 2.7°), indicating a true difference (17.0° ± 0.9° and 12.6° ± 1.5°; ES = 3.7). The large hip adduction group had slightly less hip abductor eccentric strength (11.9 ± 1.7 (Nm/Bw*ht)*100⁻¹) than the small hip adduction group (12.4 ± 2.6(Nm/Bw*ht)*100⁻¹; ES = 0.2). Similarly, the large hip adduction group had less NMC (21 ± 2 taps) than the small hip adduction group (22 ± 4 taps; ES = 0.3). However, group differences did not exceed MDD for hip abductor eccentric strength (MDD = 2.5(Nm/Bw*ht)*100⁻¹) and NMC tests (MDD = 5 taps). **CONCLUSION:** Our findings suggest that female runners with large and small peak hip adduction angles have similar hip abductor eccentric strength and NMC. Thus, differences in peak hip adduction angle in female runners are not due to underlying hip abductor eccentric strength or NMC deficits.

Association of Body Composition with the Performance Level and Running Mileage among Long Distance Runners

Norimitsu Kinoshita¹, Tokita Masaya¹, Kenta Okuyama², Tomoo Tsubota¹, Michihiko Narita¹. ¹Hosei University, Tokyo, Japan. ²Colorado Department of Public Health and Environment, Denver, CO.
Email: sportsmed.kinoshita@hosei.ac.jp
(No relationships reported)

PURPOSE: To assess the association between leanness and running performance and training volume among highly trained Japanese long distance runners. **METHODS:** Body composition was measured by dual energy X-ray absorptiometry in 54 Japanese male long distance runners who belonged to a university track and field team (19.8 ± 1.3 yrs). The training volume was assessed by the average running mileage (km/month) during 5 months prior to the measurement. The runners were routinely divided into 4 categories by the coach of the team according to their performance level and the category of the period was used as the performance level of the runners; team A (n=15), B (n=17), C (n=11), and D (n=11) in the order of the level. Team D included runners who had injuries and restricted their training. Questionnaire survey was performed regarding weight control practices and complaints of fatigue. Written informed consent was obtained from each runner. **RESULTS:** The mean running mileage of the 54 runners was 606 km/month. Height, body mass, BMI, percent body fat, bone mineral density (BMD), z-score of BMD, and lean soft tissue mass were 172.0 ± 5.2 cm, 57.3 ± 4.4 kg, 19.4 ± 1.0 kg/m², 6.1 ± 1.3%, 1.175 ± 0.057 g/cm², -0.524 ± 0.677, and 51.1 ± 4.0 kg, respectively. The mean running mileage was not significantly correlated with any of those variables (*p* > 0.05). The mean running mileage of each category (A, B, C, & D) were 709, 600, 606, and 475 km/month, respectively (*p* < 0.01). Percent body fat were lowest in A (5.7%) and highest in D (6.4%) whereas z-score of BMD were -0.447 and -0.664, respectively. However, ANOVA showed no significant differences in those variables among the categories. Fisher's exact tests of questionnaire survey revealed significant between-categories differences in percentages of runners attempting weight reduction practices (8.3, 13.3, 53.8, and 38.5%, respectively, *p* < 0.05) and those complained of frequent fatigue (25.0, 53.3, 53.8, and 69.2%, respectively, *p* < 0.05). **CONCLUSIONS:** The runners had exclusively lean bodies regardless of their performance level and running mileage. The runners with the lowest performance level and the least training volume likely attempted weight reduction practice and complained of fatigue. It was concerned that they might pursue the lower level of percent body fat by restricting energy intake.

Ischemic Preconditioning Improves Marathon Trail Running Performance in Endurance-Trained Men

Samuel S. Van De Velde, Isaiah St. Pierre, Devan E. Haney, Christina A. Buchanan, Lance C. Dalleck. Western State Colorado University, Gunnison, CO.
Email: samuel.vandeveld@western.edu
(No relationships reported)

PURPOSE: Muscle ischemia and reperfusion induced by ischemic preconditioning (IPC) has recently been demonstrated to improve performance across various physical activities; however, its effectiveness in real-world athletic settings is less understood. Therefore, the purpose of this study was to examine the effects of IPC on lactate and overall time during the Moab Trail Marathon. **METHODS:** Six (all men) well-trained and experienced trail runners (age = 22.4 ± 6.3 yr, ht = 173.4 ± 8.4 cm, body mass = 64.2 ± 7.4 kg, VO₂max = 56.5 ± 7.1 mL·kg⁻¹·min⁻¹) participated in this study. Participants were matched based on VO₂max and in randomized, single-blind fashion received either an IPC or sham treatment protocol 48 hours prior to a 26.2 mile trail marathon race in Moab, UT. Experimental procedures were performed bilaterally on the lower limbs with a treatment protocol of 4×5-min compression/5-min reperfusion cycles at 220 mmHg for IPC or the same procedure at 20 mmHg for the sham protocol. Blood lactate measurements were obtained at mile 9.7 and at the marathon finish. Probabilistic magnitude-based inferences were determined to assess the likelihood that the true value of the effect represents substantial change. **RESULTS:** Relative to the sham treatment, IPC produced likely beneficial effects for marathon run time (mean ± 90% confidence limits (CL): 1.7 ± 1.5%). Mean marathon times for IPC and sham treatment groups were 3hr 57min 34sec and 4hr 37min 7sec, respectively. Blood lactate values were significantly lower (*p* < 0.05) in the IPC vs. sham group at 9.7 miles (2.4 ± 1.7 vs. 3.3 ± 1.3 mmol·L⁻¹) and finish (2.2 ± 0.6 vs. 3.8 ± 1.6 mmol·L⁻¹).

CONCLUSION: IPC treatment elicited improvements in marathon trail running performance in experienced men trail runners. Moreover, we found that IPC was associated with an attenuated rise in blood lactate concentration. Therefore, utilizing IPC may allow for higher work rates and improved performance in trail marathon running.

Performance and Energy Balance during a 439 Mile Endurance Run

Serina J. McEntire¹, Rebecca L. Stansbery², Dharini M. Bhammar¹, Sarah F. Thomas¹. ¹Valdosta State University, Valdosta, GA. ²University of Buffalo, Buffalo, NY. (Sponsor: Michael J Webster, FACSM)
Email: sjmcentire@valdosta.edu
(No relationships reported)

Running for extreme distances or time has become increasingly popular, however, energy balance and its effect on performance is of great concern. **PURPOSE:** This case study examined the physical performance and energy balance in a 51 year old firefighter completing an 11-day, 439 mile solo run across Texas. **METHODS:** All food and drink consumed during the 11 day run were recorded to assess energy intake during the run. Energy expenditure and exercise data were recorded via a heart rate/GPS monitor during each run. Nude body weight was recorded each morning. **RESULTS:** Daily, the subject completed 39.98±2.61 miles (range 33.26-42.98 mi) in 11.2±1.2 hrs (range 9.74-12.97 hrs) at a 16.8±1.3 min/mi pace (range 15.17-18.45 min/mi). Subject consumed 4398±811 kcals per day (range 3280-5617 kcals/day) and expended 3804±271 kcals per run (range 3280-5617 kcals/run). Over the 11 days, the subject lost 2.6 kg of body weight. Total energy expenditure (5397 ± 271 kcal) was greater than energy intake (4398 ± 812 kcal; p=0.005). Over the 11 days, there was a trend towards a slower mile pace (r=0.832, p=0.001). Heart rate was also lower across the 11 days (range: 95 - 137 bpm; p=0.045). There was no change in core body temperature throughout each run (p=0.125 Time x Day interaction) or across the 11 days (p=0.078). On average, capillary lactate levels increased from 2.3 ± 1.3 mmol/L to 6.5 ± 2.3 mmol/L pre to post run (p=0.005). **CONCLUSION:** Energy balance is important for sustaining the high training and performance levels required for ultra-endurance events. However, the athlete was not able to consume enough calories to remain in energy balance. Nutritional needs assessments during training and competition should be an integral part of the preparation for participation in an ultra-endurance event. Assessment of Oxygen Deficit in Collegiate Runner during Steady State Exercise

Mark E. Northuis, Rachael N. Webb, Cameron B. Jones. *Hope College, Holland, MI.* (Sponsor: Arthur S. Leon, FACSM)
Email: northuis@hope.edu
(No relationships reported)

Oxygen deficit (OD) for the same absolute workload intensity decreases with aerobic training through improved aerobic metabolism and likewise increases with detraining. It is unclear if the amount of increase in OD with detraining is the same in middle distance (MD) and long distance (LD) runners and what training related OD changes occur in these groups with subsequent retraining.

PURPOSE: To compare and contrast the changes in OD values of collegiate MD and LD runners which accompany a post-competitive season cessation of training and subsequent endurance retraining. **METHODS:** Fourteen members of the collegiate track team (7 MD and 7 LD) runners completed a steady-state treadmill test (SS) at their gender-specific mean 5k velocity (15.3 kph for females and 18.5 kph for males) at the conclusion of their track season followed by 3 additional SS tests at 2-week intervals. Participants did not train between SS1 and SS2 and performed identical prescribed training programs between SS2 and SS4. VO₂ steady state was identified as the breakpoint of the second phase of the OD curve. OD area under the curve comparisons were made using a 2x4 repeated measures ANOVA. **RESULTS:** MD demonstrated a significant decrease in VO₂ at SS pace over the 6-week study resulting in a reduction in their mean OD (6.4%) versus LD (-0.5%) (P<.01). Mean anaerobic contributions to reach SS were greater in LD than MD (36.9% vs. 32.2%) at the end of 4-weeks of retraining (P<.01). **CONCLUSION:** There are differences in OD patterns that accompany both detraining and endurance retraining in collegiate MD and LD runners. LD runners were more aerobically challenged than MD to maintain SS velocity after detraining and may require a greater volume of anaerobic training than MD runners during the early retraining phase in order to retain a faster training pace.

Is There an Oxygen Pulse Threshold During Treadmill Running?

Haley C. Bergstrom¹, Terry J. Housh, FACSM², Joel E. Eastman¹, M. Travis Byrd¹, Nathaniel D.M. Jenkins³, Kristen C. Cochrane-Snyman⁴, Richard J. Schmidt², Glen O. Johnson, FACSM². ¹University of Kentucky, Lexington, KY. ²University of Nebraska-Lincoln, Lincoln, NE. ³Oklahoma State University, Stillwater, OK. ⁴California State Polytechnic University Pomona, Pomona, CA.
Email: hbergstrom@uky.edu
(No relationships reported)

It has been suggested there are two separate breakpoints in the oxygen pulse (O₂ pulse = VO₂/heart rate) versus workload relationship during incremental cycle ergometry, corresponding to the first and second turn points in the blood lactate response. It is still unclear if these O₂ pulse breakpoints can be detected during treadmill running, and if detected, where these thresholds may be located relative to the gas exchange threshold (GET) and respiratory compensation point (RCP). **PURPOSE:** This study examined the relationship between O₂ pulse and exercise intensity to determine if O₂ pulse thresholds could be detected during treadmill running, and, if detected, to compare these O₂ pulse thresholds to the GET and RCP. **METHODS:** Twelve, moderately trained runners (6 men and 6 women; age = 23 ± 3 years; height = 175 ± 8 cm; weight = 71 ± 12 kg) completed an incremental treadmill test to exhaustion for the measurement of gas exchange, ventilation, and heart rate parameters, as well as the determination of VO₂ peak. The GET and RCP were determined from the breakpoint in the VCO₂ versus VO₂ and V_E versus VCO₂ relationships, respectively. The O₂ pulse was plotted against VO₂ for each subject and the relationship between these two variables was examined using polynomial regression models (linear and quadratic) at an alpha level of p ≤ 0.05. **RESULTS:** The mean (± SD) VO₂ peak was 3.475 ± 0.959 L·min⁻¹ (48.33 ± 7.30 mL·kg⁻¹·min⁻¹). The GET (2.289 ± 0.617 L·min⁻¹) and RCP (3.029 ± 0.867 L·min⁻¹) occurred at 67 ± 5% and 88 ± 4% of VO₂ peak, respectively. The O₂ pulse versus VO₂ relationship was best explained by a linear fit (r² = 0.976 - 1.000) for 9 and a quadratic fit (R² = 0.985 - 0.996) for 3 of the 12 subjects. Only 1 of the 3 subjects with a quadratic fit for the O₂ pulse versus VO₂ relationship displayed a response consistent with a plateau in the O₂ pulse. **CONCLUSIONS:** The highly linear relationship between O₂ pulse and VO₂ for 75% of the subjects indicated that O₂ pulse thresholds could not be detected during treadmill running using the O₂ pulse versus VO₂ relationship. These findings do not support the use of the O₂ pulse as a non-invasive measure of fatigue thresholds.

Email: ribeiro@augsborg.edu
(No relationships reported)

The mean maximum oxygen uptake (VO₂ max) from laboratory testing protocols of elite female long distance runners has been described as 68.4 ml·kg⁻¹·min⁻¹ for 3K to 10K runners (Daniels and Daniels, 1992) and 63.2 ml·kg⁻¹·min⁻¹ for elite female triathletes (Schabert et al, 2000). It is not known how NCAA Division III female cross-country runners compare to these groups.

PURPOSE: To describe the pre-season maximum oxygen uptake of NCAA Division III female cross-country runners
METHODS: Eighteen female cross-country runners were recruited from two NCAA Division III teams. After consenting to participating in the study, the subjects completed a progressive protocol to exhaustion. VO₂ max and respiratory exchange ratio (RER) were measured at peak.
RESULTS: Mean age of subjects was 19.4 years (SD=1.2) and mean VO₂ max was 52.2 ml·kg⁻¹·min⁻¹ (SD=5.9). The VO₂ max range was from 40.3 to 63.5 ml·kg⁻¹·min⁻¹ and the median was 52.4 ml·kg⁻¹·min⁻¹. The interquartile range was 49.6 to 56.8 ml·kg⁻¹·min⁻¹. Mean RER at VO₂ max was 1.08 (SD=0.06) and ranged from 1 to 1.21.
CONCLUSIONS: Mean pre-season VO₂ max of Division III cross-country runners was 23.7% lower than reported mean elite distance runners levels and 17.4% lower than mean elite triathlete levels. This is the first pilot study to describe NCAA Division III female cross-country runners, future studies should also describe ventilatory and anaerobic thresholds for this population.

Analysis of critical speed derived from "all-out" shuttle and continuous running
 Luke Krynski, Nicholas A. Jamnick, Mark Kramer, Robert W. Pettitt
Abstract

Time limits associated with short and middle-distance running performances are estimated validity using the critical speed (CS) concept; however, little is known about applications for shuttle running, a feature of team sports. **PURPOSE:** To evaluate the CS of shuttle versus continuous running. **METHODS:** A total of 20 varsity, male soccer players wearing global positioning sensors (GPS) engaged in a shuttle 3-min all-out running test (i.e., 70 m switch-backs) followed shortly by a 90 s continuous all-out running test on a 400 m track. Intermittent CS (CSi) and true CS were calculated using the last 30 s of each test and the running capacity at speeds exceeding CSi (D') was calculated using: (speed of 150 s - CS) * 150 s. **RESULTS:** There was a moderate effect size difference (Cohen $d = 0.72$) between true CS (3.78 ± 0.61) and CSi (3.40 ± 0.46) ($t = 6.44$, $p < 0.01$); however, the two parameters were positively, correlated ($r = 0.92$, $p < 0.01$), where true CS (m/s) could be predicted from $y = (CSi \times 1.24) - 0.43$ (standard error of estimate = 0.25 m/s). Poor correlations were observed between true CS and CSi versus D' (144 ± 46 m) ($r = -0.43$, $p = 0.07$ and $r = -0.32$, $p = 0.18$, respectively). **CONCLUSION:** Shuttle running evokes a consistent, predictable decline in CS. The CSi method likely reflects the same physiological variables mediating true CS, and the D' measure appears as a distinct metric.

Longitudinal Study of Changes in 1.5 Mile Run Times of Police Recruits Over 18 Years

Austin C. Smith¹, Robert W. Boyce, FACSM¹, Elizabeth H. Seldomridge¹, Haley O. Norris¹, Glenn R. Jones², Michele A. Parker¹. ¹University of North Carolina Wilmington, Wilmington, NC. ²City of Charlotte, Charlotte, NC.
 Email: acs7105@uncw.edu
 (No relationships reported)

Cardiovascular endurance is an important aspect in the performance of police duties. Departments have a need to assess ability to run as it is important not only for the officer's health but also to protect citizens. **PURPOSE:** To evaluate patterns in cardiovascular fitness of police recruits upon entry into the police academy over 18 years including gender differences. **METHOD:** During the first week of police recruit training in a large southeastern metropolitan area, physical fitness levels were evaluated. This study's variable of interest was: 1.5 mile run. ANOVA, and Bonferroni post hoc procedures were used to evaluate data. **RESULTS:** Initial ANOVA comparisons were significant between years for both males and females ($p \leq 0.001$). The post hoc analysis of males indicated that in the first four years 1990 to 1994, there was a significant decrease in run times (min:sec) from ($12:32 \pm 1:30$ to $11:14 \pm 1:17$, $p < 0.05$). There was an increase in run times from 1994 to 2007, ($11:14 \pm 1:17$ to $12:11 \pm 1:38$, $p \leq 0.001$). As in the males, there was a significant decrease in run times for females from 1990 to 1996, ($15:15 \pm 2:32$ to $12:25 \pm 1:20$, $p \leq 0.01$). **CONCLUSION:** Overall, it appears in this metropolitan police department males are tending to have lower cardiovascular fitness levels as time progresses with little change in females. These recruits may be mirroring the lower cardiovascular fitness levels of the society from which they came.

Marathon Training Improves Aerobic Capacity, Running Performance, and Reduces Body Fat in Men and Women

Christopher J. Lundstrom, Austin M. Miller, Morgan R. Betker, Katelyn E. Uithoven, Eric M. Snyder. University of Minnesota, Minneapolis, MN. (Sponsor: Dr. Michael Joyner, FACSM)
 Email: lund0982@umn.edu
 (No relationships reported)

Introduction: Training for a 42.2-km marathon run consists of high volume aerobic training, which may increase VO_{2MAX} , reduce percent body fat (BF) and body mass (BM), and improve running performance. Previous research has produced mixed results with respect to sex differences in response to training. We hypothesize that in a

relatively large population following the same training program, men and women will see similar improvements in 2-mile time trial (2TT), reduce BF and BM, and increase VO_{2MAX} after completing a 20-week marathon training program, and that changes in all 4 variables will be significantly correlated with each other. **Purpose:** To assess sex differences in response to marathon training and to determine the relationship between changes in running performance, aerobic capacity, and body composition in this population. **Methods:** Students in a marathon training class ($n=147$, 111 females; 21.0 ± 1.7 years) completed the following before and after a 20-week marathon training program: 2-mile time trial (2TT) on an indoor 200-m track, underwater weighing (average of 3+ trials calculated with the Brozecz equation) for percent body fat (BF), and a VO_{2MAX} test using a graduated protocol on a treadmill with a Medgraphics Ultima system. Mixed-design ANOVA was used to assess changes and sex differences. Percent change was calculated for 2TT, BF, VO_{2MAX} , and BM, and Pearson's r was used to assess correlations between the changes. **Results:** Subjects improved in VO_{2MAX} (men: 54.0 ± 7.5 to 56.5 ± 7.0 ml \cdot kg $^{-1}$ \cdot min $^{-1}$; women: 46.8 ± 5.4 to 48.1 ± 5.3 ml \cdot kg $^{-1}$ \cdot min $^{-1}$; $P \leq 0.001$), and 2TT (men: 14.5 ± 1.8 min to 13.1 ± 1.6 min; women: 16.8 ± 1.6 to 15.5 ± 1.4 min; $P \leq 0.001$), reduced BF (men: 15.3 ± 5.2 to $14.3 \pm 5.6\%$; women: 25.0 ± 4.7 to $23.8 \pm 4.7\%$; $P \leq 0.001$), and did not change in BM (men: 75.0 ± 10.4 to 74.5 ± 10.3 kg; women: 63.1 ± 7.7 to 63.3 ± 7.8 kg; $P=0.378$). No sex-by-time interactions were found for any of the measures. Changes in all measures were significantly correlated with each other (VO_{2MAX} and BF: $r=-0.178$, $P=0.033$; VO_{2MAX} and 2TT: $r=-0.311$, $P \leq 0.001$; VO_{2MAX} and BM: $r=-0.279$, $P=0.001$; BF and 2TT: $r=0.341$, $P \leq 0.001$; BF and BM: $r=0.419$, $P \leq 0.001$; 2TT and BM: $r=0.208$, $P=0.012$). **Conclusion:** In a healthy, young population following the same marathon training program, both men and women improve 2TT and VO_{2MAX} and decrease BF with no change in BM.

The Effect Of ACTN3 Genotype On Self-reported One-mile Running Time In Young, Recreationally Active Women

Christopher A. Martinez¹, Andreas Kreutzer¹, McKensie Kreutzer², Jason D. Stone¹, Joel Mitchell, FACSM¹, Jonathan M. Oliver¹. ¹Texas Christian University, Fort Worth, TX. ²University of Texas Southwestern Medical Center, Dallas, TX. (Sponsor: Joel Mitchell, FACSM)
 Email: c.martinez27@tcu.edu
 (No relationships reported)

Alpha-actinins form a crosslink between actin filaments and adjacent sarcomeres, and play a role in signaling and energy metabolism. Alpha-actinin-3, is encoded by the ACTN3 gene and only presents in Type II muscle fibers. Homozygosity for the 577X allele (XX) results in complete deficiency of α -actinin-3 and a compensatory upregulation of α -actinin-2, whereas heterozygosity (RX) and homozygosity for the 577R allele (RR) provide for the production of α -actinin-3. Research has reported a greater proportion of elite female distance runners are homozygous for the 577X allele compared to controls. However, no study to date has examined that apparent relationship in recreational women runners. **PURPOSE:** To examine the effect of ACTN3 genotype on self-reported one-mile running personal records (PR) in young, recreationally active women. **METHODS:** Thirty nine participants, grouped by the presence (RR+RX: $n=27$, age: 21.7 ± 3.8 years, BMI: 22.9 ± 3.3 kg/m 2) or absence (XX: $n=12$, age: 21.2 ± 3.2 years, BMI: 21.5 ± 1.8 kg/m 2) of the 577R allele, reported one-mile running PR. Genotype effects were examined using independent-sample t-tests and magnitude-based inference (MBI). **RESULTS:** A trend ($p=0.065$) toward faster one-mile times was observed in XX genotypes (415.7 ± 78.9 s) when compared to the RR+RX group (480.3 ± 104.8 s). MBI revealed a mechanistically beneficial effect of XX genotype (mean difference; $\pm 90\%$ CI; -65 s, ± 57 s). Similar observations were made among a subset of thirteen faster runners, who reported a one-mile PR of less than seven minutes (RR+RX: $n=7$, age: 21.9 ± 5.0 years, BMI: 20.9 ± 3.4 kg/m 2 ; XX: $n=6$, age: 19.5 ± 0.5 years; BMI: 21.8 ± 1.5 kg/m 2). Though not statistically significant ($p=0.378$), those in the XX group (355.8 ± 46.5 s) reported 5.4% faster times than those in the RR+RX group (376.3 ± 33.6 s). MBI revealed a mechanistically beneficial effect of XX genotype (-20 s; ± 40 s). **CONCLUSION:** These findings suggest a potential benefit of XX genotype on middle-distance endurance performance. This is in agreement with prior investigations that have linked XX genotype to endurance capabilities in elite female athletes.

Performance Changes in Consecutive Day Marathon Runners

James W. Roberts, Jr, FACSM. Edinboro University of PA, Edinboro, PA.
 Email: jroberts@edinboro.edu
 (No relationships reported)

Over the last five years, the popularity of marathon running to complete a marathon in each of the 50 states has grown. As such, new businesses have arisen to accommodate completing this faster. There are now multiday marathon series that cover two to seven

states (i.e. seven days, seven marathons, seven different states). There is currently very little in the literature about these types of events and a lack of analyses of the finish times for participants that complete multiple days of marathons. **PURPOSE:** To determine the performance changes across the multiday marathon events.

METHODS: 145 runners completed between one and seven marathons over a seven day period at the 2016 Mainly Marathons New England Series. Data for all finishers were retrieved after the completion of the series from the series website. Descriptive analyses and a comparison of means were performed on participants who completed one marathon (1MAR, n=63) and those that completed all seven marathons (7MAR) covering the seven different days (n=20).

RESULTS: Descriptive statistics, a paired t-test and independent t-test were performed using IBM SPSS version 21 with significance set at p<0.05. There was no significant difference in age between 1MAR and 7MAR (49.3±13.7 vs. 50.9±14.4 yrs, p=0.653). In addition, no statistically significant difference was found between 1MAR and day one of 7MAR finish times (350.4±96.7 vs. 362.1±80.0 min, p=0.625). However, 7MAR ran 11.7 minutes slower on average for day one. Finally, day one versus day 7 finish times for the 7MAR group were significantly different (362.1±80.0 vs. 390.8±60.2 min, p=0.006).

CONCLUSIONS: Even though the day one finish times were close to six hours on average, the toll of seven daily marathons still resulted in a significant decline in performance.

A Mile Trail Run Can Predict Performance for a 5K Trail Race

Grace A. MacDonald¹, Jeffrey Montes¹, Elizabeth A. Tanner¹, Nathaniel G. Bodell¹, Jacob W. Manning², James W. Navalta, FACSM¹. ¹University of Nevada Las Vegas, Las Vegas, NV. ²Southern Utah University, Cedar City, WV. (Sponsor: James Navalta, FACSM)
 (No relationships reported)

PURPOSE: A common desire and strategy for many runners is to predict race time off of a shorter time trial. It is unknown whether these strategies apply to trail races. The purpose of this study was to determine if a 1-mile trail run could predict performance on a 5K trail race. It was hypothesized that a significant correlation would be present between a timed 1-mile run and 5K run time.

METHODS: Thirteen participants [Female: 3, Male: 10, Age:23±5 yr, Height:175±9 cm, Mass:74±12 kg, BMI: 24±4] reported to the trailhead (Practice Loop, Three Peaks Recreation Area, Cedar City, UT) and completed a 1-mile and a 5K timed trail run one day apart in a counterbalanced order. Elevation at the trailhead was 1,641 m (5,385 feet) with a rise of 17 m (56 feet) throughout the marked 1-mile course, and 61 m (201 feet) on the 5K course. Testing was completed between 1500 and 1700h on both days. Environmental measures of temperature (23.9°- 25.6° C; 75°-78° F), humidity (13%-15%), and wind speed (4-9 mph) varied throughout the testing days. Data were analyzed using a Pearson product moment correlation coefficient with significance accepted at the p<0.05 level.

RESULTS: A significant correlation was observed between 1-mile time and 5K performance (r=0.987, p=0.0001, R²=0.974). The equation to predict 5K time from the mile time trial was: 5K time (expressed as a decimal) = 4.2881*mile time (expressed as a decimal) - 4.5521. The average running velocity during the 1-mile trail run was 3.94±0.9 m.sec⁻¹, and 3.4±1.0 m.sec⁻¹ for the 5K.

CONCLUSIONS: Our results show that a 1-mile trail run time trial can be used to predict performance for a 5K trail race. Also, based on these data, 5K trail running velocity is approximately 15% less than during a 1-mile trail run bout.

Standardized MET Overestimates Resting VO₂ And Underestimates Energy Cost Of Running In Low Cardiorespiratory Fitness Men

Felipe Amorim da Cunha¹, Helouane Ázara², Adrian Midgley³, Fabrício Vasconcellos¹, Patrícia Vigário², Paulo Farinatti¹. ¹Rio de Janeiro State University, Rio de Janeiro, Brazil. ²Augusto Motta University Center, Rio de Janeiro, Brazil. ³Edge Hill University, Ormskirk, United Kingdom. (Sponsor: Prof. Lars Mc Naughton, FACSM)
 Email: felipeac@globo.com
 (No relationships reported)

Multiples of the metabolic equivalent (MET) are widely used to prescribe exercise intensity and quantify the energy cost of physical activities. A growing body of empirical evidence, however, suggests the standardized 1-MET value, represented by a resting oxygen uptake (VO₂) of 3.5 mL.kg⁻¹.min⁻¹, significantly overestimates observed resting VO₂ in populations with lower cardiorespiratory fitness (CRF).

PURPOSE: Compare the standardized MET and resting VO₂ with respect to these two applications and explore the association between CRF and resting VO₂. **METHODS:** A heterogeneous cohort of 114 healthy men, aged 18 to 38 yr, volunteered to

participate in two studies. First, 100 men [lower CRF: n = 48, VO_{2max} < 50.0 mL.kg⁻¹.min⁻¹; higher CRF: n = 52, VO_{2max} ≥ 50.0 mL.kg⁻¹.min⁻¹] visited the laboratory twice to explore the association between directly assessed VO_{2max} and resting VO₂. Second, 14 men performed a 30-min bout of running at 8.0 km.h⁻¹ (8.3 METs according to the Compendium of Physical Activities) to investigate the use of the MET to quantify the energy cost of treadmill running. **RESULTS:** The VO_{2max} was strongly positively correlated with resting VO₂ (R = 0.68, P < 0.001). The mean observed resting VO₂ values of 3.28 (n = 100) and 3.07 (n = 14) mL.kg⁻¹.min⁻¹ were significantly lower than the standardized value of 3.5 mL.kg⁻¹.min⁻¹ (P < 0.001 and P = 0.005, respectively). When compared to the standardized value, groups with lower CRF demonstrated significantly lower mean observed resting VO₂ values of 3.06 (1st part of the study; P < 0.001) and 2.67 (2nd part of the study, P < 0.001) mL.kg⁻¹.min⁻¹. However, no significant difference was observed between standardized and observed resting VO₂ values for the groups with higher CRF (1st part of the study; P = 0.87; 2nd part of the study; P = 0.78). Hence the observed values for the energy cost of treadmill running were significantly underestimated when calculated using the standardized resting VO₂ value of 3.5 mL.kg⁻¹.min⁻¹ (P = 0.005 to P < 0.001) only for the groups with lower CRF. **CONCLUSION:** The standardized MET value considerably overestimated observed resting VO₂ in men with lower CRF. Direct determination of resting VO₂ is therefore preferred to improve the accuracy of the aforementioned applications in this population.

An Evaluation of Time-Trial Based Predictions of VO₂max and Recommended Training Paces For Collegiate and Recreational Runners

Eric M. Scudamore, Vaughn W. Barry, John M. Coons. Middle Tennessee State University, Murfreesboro, TN. (Sponsor: J. Matt Green, FACSM)
 Email: eric.scud@gmail.com
 (No relationships reported)

PURPOSE: Determine the accuracy of Jack Daniels' VDOT Running Calculator for the prediction of VO₂max, and recommendations of interval and threshold training paces (pIN & pTH) in samples of NCAA Division I track athletes (ATH, n = 11) and recreational runners (REC; n = 9). **METHODS:** Predicted variable data were obtained using results from indoor 5km time-trials. Data from the VDOT calculator was compared to laboratory tested VO₂max, pace at VO₂max (VO₂max_{pace}), and lactate threshold pace (LT_{pace}). **RESULTS:** VDOT underestimated VO₂max in ATH (t (10) = -6.00, p <.001, d = 1.75) and REC (t (8) = -8.96, p <.001, d = 3.44). Follow up between-groups analysis indicated that the difference between VDOT and VO₂max was significantly greater in REC than ATH (p = .0031, d = 1.59). pIN was slower than VO₂max_{pace} in REC (t (8) = -4.26, p = .003, d = 1.76), but not different in ATH (t (10) = 0.52, p = .614, d = 0.14). Conversely, pTH was faster than LT_{pace} in ATH (t (8) = -4.17, p = .003, d = 1.49), but not different in REC (t (8) = 1.64, p = .139, d = 0.57). **CONCLUSIONS:** Practically, pTH can be confidently used for threshold training regardless of ability level. pIN also appeared to be accurate for ATH, but may be not be optimal for improving VO₂max in REC. Practitioners should interpret VDOT with caution as it may underestimate VO₂max.

Table 1. Descriptive characteristics of subjects.

Variable	Whole Group (n = 20)		ATH (n = 11)		REC (n = 9)	
	Mean	SD	Mean	SD	Mean	SD
Age (years)	21.44	2.21	20.96	0.92	22.78	2.64
Height (cm)	173.42	10.99	177.48	9.23	170.67	11.46
Body mass (kg)	67.06	8.98	67.46	8.31	66.63	10.20
5 km (interval) time	20.63	3.93	18.22	2.11	23.01	3.61

ATH = NCAA Division I track athletes; REC = recreational runners

Table 2. Predicted and actual test data and difference scores by group.

	Mean ± SD	p	Cohen's d
NCAA Division I Athletes (n = 11)			
VO ₂ max (mL.kg ⁻¹ .min ⁻¹)	61.05 ± 6.61		
VDOT (mL.kg ⁻¹ .min ⁻¹)	56.33 ± 7.17		
VDOT - VO ₂ max	-4.72 ± 2.61	<.001	1.754
VO ₂ max _{pace}	5.75 ± 0.77		
pIN	5.79 ± 0.64		
pIN - VO ₂ max _{pace}	0.04 ± 0.26	.614	0.037
LT _{pace} *	6.75 ± 0.94		
pTH*	6.37 ± 0.75		
pTH - LT _{pace} *	-0.38 ± 0.28	.003	1.480
Recreational Runners (n = 9)			
VO ₂ max (mL.kg ⁻¹ .min ⁻¹)	51.41 ± 6.83		
VDOT (mL.kg ⁻¹ .min ⁻¹)	42.17 ± 7.54		
VDOT - VO ₂ max	-9.24 ± 3.10	.001	3.437
VO ₂ max _{pace}	6.89 ± 0.84		
pIN	7.40 ± 1.08		
pIN - VO ₂ max _{pace}	0.51 ± 0.36	.003	1.762
LT _{pace} *	7.88 ± 1.38		
pTH*	8.03 ± 1.16		
pTH - LT _{pace} *	0.15 ± 0.27	.139	0.574

VDOT = predicted VO₂max; pIN = predicted interval pace; VO₂max_{pace} = pace corresponding with velocity at VO₂max; LT_{pace}* = pace corresponding with velocity at lactate threshold; pTH = predicted threshold pace
 Units for all pace times are in min/mile

Effects of Footwear on Running Economy and Preferred Foot Strike Pattern in Collegiate Distance Runners
 Donovan S. Conley, FACSM¹, Shane A. Warehime², Kevin L. Hill¹, Tammy K. Evetovich, FACSM¹. ¹Wayne State College, Wayne, NE. ²University of Nebraska Omaha, Omaha, NE.
 (No relationships reported)

The influence of foot strike pattern on running performance has produced inconsistent results (Kasmer et al., Int. J. Sports Physiol. Perform. 29:286-292, 2013; Larson et al., J Sports Sci 29:1665-73, 2011) as has the effect of footwear and foot strike pattern on running economy (Perl et al., Med. Sci. Sports Exerc. 44:1335-1343, 2012). **PURPOSE:** To examine the effects of varying footwear on running economy and preferred foot strike pattern in collegiate distance runners. **METHODS:** Ten (5 female, 5 male) healthy, trained National Collegiate Athletic Association Division II distance runners were randomly assigned to 3 footwear conditions: 1) barefoot (BF), 2) minimally shod (MS) and 3) traditionally shod (TS). For each condition, running economy (VO_2), heart rate (HR), rating of perceived exertion (RPE), and preferred foot strike (PFS) pattern (forefoot, mid-foot, rear foot) were measured between the 5th and 6th min of treadmill running at 0% grade, 3.35 m/s. **RESULTS:** Repeated measures ANOVA analysis revealed no significant difference ($p > 0.05$) across BF, MS and TS footwear conditions for VO_2 (41.2 ± 2.5 , 40.7 ± 1.9 , 41.6 ± 2.2 ml/kg/min), HR (168.6 ± 17.5 , 166.7 ± 15.8 , 168.6 ± 16.1 bpm) and RPE (9.6 ± 1.8 , 9.3 ± 2.1 , 9.5 ± 1.8). The PFS data were analyzed using a Friedman's test followed by a Wilcoxon signed rank test. The Friedman's test showed a significant difference ($p < 0.05$) in PFS patterns across footwear treatments. Subsequently, the Wilcoxon test indicated the PFS pattern for BF was forefoot and, in contrast, for both MS and TS conditions the PFS was rearfoot. **CONCLUSION:** There is no metabolic advantage to BF, MS, and TS footwear in collegiate male and female distance runners and, although PFS varies with footwear, it has no effect on running economy. This suggests collegiate distance runners can select footwear of their choice without sacrificing running performance.

522 Board #343 May 31 11:00 AM - 12:30 PM
Decreasing Total Training Time Efficient In Improving Speed and Aerobic Cost in Competitive Runners
 Hillary D. Dickey, Daniel J. Larson, Ann M. Dunn, John W. Farrell, III, Greg S. Cantrell, David J. Lantis, Michael G. Bemben, FACSM, Rebecca D. Larson. University of Oklahoma, Norman, OK. (Sponsor: Michael G. Bemben, PhD, FACSM)
 (No relationships reported)

In addition to overall volume, an essential variable in an optimal endurance training program is the distribution of exercise intensity. Training intensity distribution (TID), which is the percentage of time an athlete spends training in low, moderate, and high intensity efforts, has been used to prescribe training programs and monitor athletes. Training based on a demarcation of high intensity at onset of blood lactate (OBLA) of 4mM has been suggested to provide a more precise stimulus to yield optimal metabolic and peripheral adaptations. Adaptations which shift OBLA allow an individual to exercise at higher work rates for longer periods, translating into better overall endurance performance. **PURPOSE:** Identify TID related factors that delay OBLA for competitive runners. **METHODS:** Sixteen University of Oklahoma Cross Country athletes (8 males and 8 females) initially performed two lactate threshold (LT) tests to determine training intensity zones (TIZ) based on heart rate (HR) and blood lactate. TIZ categories consisted of: low (Z1) = LA < 2 mM, moderate (Z2) ≥ 2 mM and ≤ 4 mM, and high intensity (Z3) > 4 M. Subjects subsequently wore GPS HR monitors (blinded) to practice every day for the next 5 weeks, including all training runs and races, while concluding the study with a final LT test. Total training time and TID parameters were recorded as well as the performance metrics of both running speed and aerobic cost at OBLA (S4 and AC4). Correlational analysis and multiple regression estimation were used to analyze the data. **RESULTS:** Bivariate correlations were not significant between most TID variables and the performance variables. However, when using multiple regression ($\alpha = 0.05$) to control for gender differences, total training time emerged as having a statistically significant ($p < 0.01$) negative relationship with performance changes ($\Delta S4$, $\Delta AC4$) over the time frame examined. Additionally, the coefficient analysis suggested that the proportion of training time in Z3 might be positively related to $\Delta S4$ ($p = 0.089$) and $\Delta AC4$ ($p = 0.062$). **CONCLUSION:** This study shows that improvements in an athlete's S4 and AC4 may be achieved by decreasing overall training time and potentially increasing the proportion of time in Z3. From a practical point of view, this could be achieved by elimination of training time in Z1 and/or Z2.

Effect of Short-term Altitude Training on Sprint Running Performance
 Yasuhiro Suzuki¹, Hirohiko Maemura², Toshiyuki Ohya¹, Masahiro Hagiwara¹. ¹Japan Institute of Sports Sciences, Kitaku, Tokyo, Japan. ²International Pacific University, Okayama, Japan.
 Email: yasuhiro.suzuki@jpnpsport.go.jp
 (No relationships reported)

It is suggested that intermittent hypoxic training (IHT) improved repeated sprint ability and maximal 30-s cycling sprint (Faiss et al., 2013; Hamlin et al., 2010; Kasai et al., 2015). Therefore, IHT may be suitable for enhancing sprint performance. However, IHT and/or altitude training have not yet been conducted in track events sprinters. **PURPOSE:** The purpose of the present study was to determine the effects of short-term altitude high intensity training on sea level sprint running performance in well-trained 400-m runners. **METHODS:** Eighteen college male 400-m runners were assigned to either a Hypoxic group ($n = 9$) or a Normoxic group ($n = 9$) and performed high intensity running training twice a day for 5 days. Both groups trained same high intensity training program in all weather running track. Hypoxic group trained and rested in Hida-Ontake Kogen Highland Training Area (1,700-1,800m). Before and after the training, subjects were completed 60-m and 400-m maximal running test, and vertical jump test. The post-training test periods were conducted 2, 7, 14, 21, 28 days after the final training session. **RESULTS:** After the 5 days of high intensity training, no significant changes in 400-m running time in both groups. However, percentage changes of 400-m running time were significantly higher in Hypoxic group (2.1 ± 1.0 %) than in Normoxic group (1.0 ± 0.9 %). 30-m time during the latter half of 60-m running was significantly increased in 7-days after training (Hypoxic: 3.15 ± 0.04 vs 3.23 ± 0.03 sec, Normoxic: 3.16 ± 0.03 vs 3.22 ± 0.03 sec) and significantly decreased in 21-days after training (Hypoxic: 3.08 ± 0.03 sec, Normoxic: 3.11 ± 0.03 sec) compared to before training. There were no significant changes in vertical jump in both groups. **CONCLUSIONS:** These results suggest that altitude high intensity training is effective for 400-m runners.

524 Board #345 May 31 11:00 AM - 12:30 PM
The Effects of a Medicine Ball Training Program on Running Economy
 Veronica Rasicci, Kyle L. Timmerman, Julie M. Cousins. Miami University, Oxford, OH. (Sponsor: Helaine Alessio, FACSM)
 Email: rasiccvm@miamioh.edu
 (No relationships reported)

Running economy (RE) has been shown to improve with the addition of concurrent explosive strength training, plyometrics, and heavy load resistance training. However, there is little research to date on the effects of RE with functional resistance training. **PURPOSE:** To determine the effect of a medicine ball training program on running economy. **METHODS:** At this time, 7 runners (age = 22.86 ± 6.23 years) have completed the pre- and post push-up, curl-up, running economy at 187 m/min and 204 m/min, and a maximal oxygen consumption test, with 10 additional runners in the process of completing the protocol. Following the pre-test, participants were matched for gender and $\text{VO}_{2\text{max}}$ and randomly assigned to either the intervention (I) or control (C) group. The intervention group completed a 6-week progressive medicine ball training program. Statistical analysis was performed using independent t-tests and Pearson product-moment correlations. Significance was set to $p < 0.05$. **summary of RESULTS:** The following is preliminary data on the 7 participants (4 I, 3 C) that have completed the protocol. The number of push-ups completed following the post testing increased by 6.8 ± 4.1 for the I group and 6.3 ± 9.5 for the C group. The I group increased the number of curl-ups completed by 21.0 ± 19.0 while the C group decreased by 3.3 ± 10.2 . Running economy at 187 m/min, decreased by 2.07 ± 1.0 ml/kg/min and 0.7 ± 0.4 ml/kg/min for the I and C groups, respectively. At 206 m/min running economy, decreases by 1.9 ± 1.3 ml/kg/min for the I group and increased by 0.5 ± 2.4 for the C group. $\text{VO}_{2\text{max}}$ decreased by 0.2 ± 1.2 ml/kg/min for the I group and increased by 0.8 ± 0.7 ml/kg/min for the C group. Independent t-test analyses are not currently showing statistically significant changes in the preliminary data ($p < 0.05$). Although not statistically significant, the Δ in push-ups and Δ in curl-ups are showing a positive correlation with RE at both speeds (187m/min: $r = 0.762$, $p = 0.238$; 204 m/min: $r = 0.871$, $p = 0.129$; 187 m/min: $r = 0.262$, $p = 0.738$; 204 m/min: $r = 0.420$, $p = 0.580$, respectively). **CONCLUSION:** These preliminary data suggest that the inclusion of a medicine ball training program may help improve abdominal endurance (curl-up) and running economy in trained endurance runners.

525 Board #346 May 31 11:00 AM - 12:30 PM
Effects of Replacing Run Training with Elliptical Bicycle Training in Experienced Runners
 Jordan Oddis. *Ohio University, Athens, OH.*
 (No relationships reported)

Run training can improve fitness and performance. Many runners have seen high rates of injury, which can lead to detraining. Cross-training methods attempt to attenuate detraining. A novel outdoor elliptical bicycle (EBIKE) has been designed to emulate the running motion without impact forces. **PURPOSE:** To determine the effectiveness of replacing 50% run training with elliptical bicycling on maximal oxygen consumption ($\text{VO}_{2\text{max}}$), ventilatory threshold (VT), respiratory compensation point (RCP), and 5,000 m time trial (TT) over a 4-week training period. **METHODS:** Fourteen male ($n=9$) and female ($n=5$), experienced runners (age=22.1 \pm 3.6 y, running experience=9.6 \pm 4.2 y) were classified as healthy and experienced via a health history screening, body composition assessment (skin fold method), and a graded $\text{VO}_{2\text{max}}$ test (GXT) on a treadmill during an initial testing session. The TT was performed on an indoor 300m track 24-72 hours following the GXT. Each participant was then randomly assigned to either the RUN group (100% normal run training) or COMBINED (COM) group (50% normal run training/50% elliptical bicycle training). An identical testing session was conducted following the 4-week training period. **RESULTS:** All results are reported as mean \pm SD. Paired *t*-tests ($\alpha<0.025$) were utilized to compare the physiological variables before and after training separately for each group. A Bonferroni correction was performed in order to adjust the alpha value to avoid statistical error. Before training values for $\text{VO}_{2\text{max}}$ (ml/kg/min) (RUN [59.94 \pm 3.92] and COM [62.67 \pm 6.41]) were not significantly different ($p>0.025$) compared to after training values of $\text{VO}_{2\text{max}}$ (RUN [60.59 \pm 4.61] and COM [63.17 \pm 7.97]). There also were no significant differences for VT, RCP, or TT values ($p>0.025$) before and after training for both the RUN and COM groups. No significant differences were seen when VT and RCP were expressed as a percent of relative $\text{VO}_{2\text{max}}$. **CONCLUSIONS:** In this novel investigation replacing 50% of run training with elliptical bicycle training over a 4-week period was able to maintain physiological and performance variables similar to 100% run training in this population of experienced runners. Coaches and runners should consider the EBIKE as a viable cross-training option for replacing up to 50% of run training.

526 Board #347 May 31 11:00 AM - 12:30 PM
Improvement in 3200-m Running Performance following Acute Inspiratory Muscle Training
 Allie Ludge, Kyle Barnes. *Grand Valley State University, Allendale, MI.*
 Email: barnesk@gvsu.edu
 (No relationships reported)

Prior high-intensity exercise has been shown to augment the oxidative energy contribution to subsequent exercise and enhance competitive performance. Inspiratory muscle training (IMT) is a form of resistance training for the muscles primarily involved in the processes of breathing using a resisted respiratory breathing trainer, which has also been shown to modify VO_2 kinetics and enhance performance. The potential impact of acute IMT as part of a warm-up on competitive performance, however, has not been investigated. **PURPOSE:** To compare the effects of acute resisted IMT (EXP) to sham IMT (CON) as part of a warm-up on running performance. **METHODS:** In a randomized cross-over design, 17 trained distance runners (age 20.1 \pm 1.4 yr, body mass 62.2 \pm 8.1 kg, height 1.73 \pm 0.09 m) completed two 3200-m performance trials on separate days, preceded by two different warm-up procedures. Prior to each 3200-m trial, subjects performed a warm-up which consisted of a 20 min self-paced run and standardized mobility drills, followed by either EXP or CON in a randomized order and 4x 80m strides. Inspiratory muscle function was measured pre and post IMT. Heart rate (HR), rating of perceived exertion (RPE), rating of perceived dyspnea (RPD) and expired gases were collected using a metabolic analyzer during each trial. **RESULTS:** 3200-m run performance was significantly faster after EXP (11.3 \pm 1.1 vs. CON 11.8 \pm 1.5 min, $p = 0.01$). Baseline inspiratory muscle function characteristics were not different between groups. Following each warm-up condition peak volume (EXP, 3.30 \pm 0.85 vs CON 2.99 \pm 0.68 L, $p < 0.01$), peak flow (EXP, 7.20 \pm 1.77 vs CON 6.81 \pm 1.73 L, $p = 0.03$), and peak strength index (EXP, 134 \pm 39 vs CON 127 \pm 34 cmH₂O, $p = 0.03$) were significantly higher after EXP. HR was not different between conditions (EXP, 183 \pm 9 vs CON 182 \pm 11), but VO_2 at each 800-m interval (EXP, 800-m 3.55 \pm 0.65, 1600-m 3.63 \pm 0.67, 2400-m 3.72 \pm 0.70 vs CON 800-m 3.43 \pm 0.66, 1600-m 3.54 \pm 0.67, 2400-m 3.64 \pm 0.70 L/min, $p > 0.05$) as well as peak VO_2 attained (EXP, 3.83 \pm 0.73 vs CON 3.74 \pm 0.76 L/min, $p = 0.25$) tended to be greater after EXP. RPE (EXP, 14.6 \pm 1.1 vs CON 14.8 \pm 0.9, $p > 0.05$) and RPD (EXP, 5.1 \pm 1.2 vs CON 5.7 \pm 1.6, $p = 0.06$) tended to be lower following EXP. **CONCLUSION:** These data indicate that acute resisted IMT as part of a warm-up enhances 3200-m time-trial performance in trained runners.

Body Composition, Bone Density, Metabolic Rate and Dietary Intakes of Collegiate Synchronized Swimmers
 Paula Borges Costa, Bradley T. Gieske, Richard A. Stecker, Charles R. Smith, Kyle E. Witherbee, Kimi M. Peterson, Scott R. Richmond, Kathryn A. Tessmer, Chad M. Kerksick, FACSM. *Lindenwood University, St. Charles, MO.*
 (No relationships reported)

Synchronized swimming is a physiologically demanding sport that requires strength, endurance, power, and artistic grace. Currently, limited information exists that outlines various physiological and dietary attributes surrounding the sport. **PURPOSE:** This study's aim was to identify physiological characteristics and dietary habits of collegiate synchronized swimmers. **METHODS:** Twenty-one female collegiate synchronized swimmers (20.4 \pm 0.3 yrs, 168.0 \pm 1.1 cm, 64.4 \pm 1.9 kg) were tested. Maximal oxygen uptake ($\text{VO}_{2\text{max}}$) was measured using indirect calorimetry during a graded treadmill exercise test. Resting metabolic rate (RMR) was assessed using indirect calorimetry with standardized criteria. Body composition was determined using skinfolds (4-site and 7-site) and dual-energy X-ray absorptiometry (DEXA). Dietary intake was assessed using four-day dietary records using Vitabot software. Data is presented as means \pm SD. Pearson correlation coefficients were used to determine significant relationships. **RESULTS:** $\text{VO}_{2\text{max}}$ was 43.8 \pm 1.0 mL/kg/day while absolute and relative (normalized to body mass in kg) RMR values were determined to be 1,702 \pm 52 kcal/day and 26.5 \pm 2.5 kcal/kg/day, respectively. DEXA determined fat mass (17.7 \pm 5.3 kg), lean mass (43.0 \pm 4.4 kg) and percent body fat (28.7 \pm 4.8 % fat) were computed. Percent fat values using 4 and 7-site skinfolds (25.7 \pm 4.8 % fat and 25.3 \pm 4.7 % fat, respectively) were similar but both values were different from DEXA determined percent body fat values ($p>0.05$). Total lumbar (1.03 \pm 0.11), trochanteric line (0.79 \pm 0.08), intertrochanteric line (1.14 \pm 0.12), femoral neck (0.96 \pm 0.12) and Ward's triangle (0.91 \pm 0.24) bone mineral density values were determined (in g/cm²) using DEXA. Relative daily calorie (29.0 \pm 10.1 kcal/kg), carbohydrate (3.6 \pm 1.1 g/kg), protein (1.3 \pm 0.4 g/kg) and fat (1.2 \pm 0.5 g/kg) were computed. No significant correlations were reported between any of the bone mineral density, body composition and dietary intake data ($p>0.05$). **CONCLUSION:** Synchronized swimmers have similar aerobic fitness, body composition and training habits as other competitive aquatic athletes. Reported energy intakes indicate low levels of energy availability; future work should explore menstrual complications and female athlete triad development.

528 Board #349 May 31 11:00 AM - 12:30 PM
Gender Differences in Water-Based Aerobic Capacity During Freestyle Swimming to Exhaustion
 Takashi Nagai¹, Anne Z. Beethel¹, Christopher Connaboy¹, Mita T. Lovalekar¹, John P. Abt, FACSM², Elizabeth F. Nagle, FACSM¹, Scott M. Lephart, FACSM². ¹University of Pittsburgh, Pittsburgh, PA. ²University of Kentucky, Lexington, KY.
 (Sponsor: Elizabeth F. Nagle, FACSM)
 Email: tnagai@pitt.edu
 (No relationships reported)

Aerobic capacity plays an essential role in physical performance. Females have been shown to have lower aerobic capacity during land-based incremental testing when compared to their male counterparts. However, there have been few studies on gender differences in aerobic capacity during water-based incremental swimming. Understanding the gender differences is an important step in coaching/training. **PURPOSE:** The purpose of this study was to examine aerobic capacity gender differences. **METHODS:** A total of 15 males (23.6 \pm 6.7yrs, 179.3 \pm 6.4cm, 75.2 \pm 11.5kg) and 15 females (22.6 \pm 6.3yrs, 167.6 \pm 6.4cm, 65.7 \pm 9.5kg) participated in the study and completed an incremental swimming test to exhaustion. The protocol involved swimming a minimum of 250 meters (10 lengths) using the freestyle stroke. Rest periods following each 22.9 meter length decreased from 10 seconds to 3 seconds throughout the test. Following 9 lengths, subjects continuously swam at maximal velocity until $\text{VO}_{2\text{max}}$ had been achieved or until exhaustion occurred. Aerobic capacity was measured with a portable metabolic system suspended above the swimmer using a cable pulley system, enabling a standard freestyle stroke with continuous measure of VO_2 . Ratings of perceived exertion (RPE), blood lactate (BLA), and maximal heart rate (HR_{max}) were also measured at the end of the test. Data were tested for normality, and independent samples *t*-tests or Mann-Whitney *U* tests were used, as appropriate ($p<0.05$). **RESULTS:** Males had significantly higher aerobic capacity (males: 48.4 \pm 7.4ml/kg/min, females: 39.8 \pm 5.3ml/kg/min, $p=0.001$) and lower HR_{max} (males: 173.3 \pm 6.9bpm, females: 180.7 \pm 7.7bpm, $p=0.032$) compared to females. There were no gender differences in RPE (males: 9.6 \pm 0.7, females: 9.5 \pm 0.7, $p=0.689$) or BLA (males: 11.3 \pm 3.5mmol/L, females: 9.9 \pm 2.9mmol/L, $p=0.269$). **CONCLUSIONS:** The current results have revealed significant gender differences in aerobic capacity at the maximal effort (with similar RPE scale and BLA values). These findings are in accordance with other land-based gender studies on aerobic capacity,

largely due to smaller stature/lung in females. Future studies should examine the effects of gender-specific and customized land/water-based training on their aerobic capacity. Supported by ONR: N00014-14-1-0022/N00014-15-0069

529 Board #350 May 31 11:00 AM - 12:30 PM
Gender Differences In Mean And Peak Swimming Force, Validity, Reliability, Of A Tethered Swimming Test

Jacquelyn Nagle¹, Elizabeth Nagle, FACSM², Takashi Nagai², Mita Lovlekar², Christopher Connaboy², John Abt, FACSM³, Scott Lephart, FACSM³, Scott Lephart, FACSM³. ¹John Carroll University, University Heights, OH. ²University of Pittsburgh, Pittsburgh, PA. ³University of Kentucky, Lexington, KY. Email: jnagle@jcu.edu
 (No relationships reported)

Consistent differences between males and females have been shown in land based measurements of anaerobic performance. Evidence shows that a 30-second max tethered swim (TST) is a valid and reliable measure of anaerobic power (F_{peak}) and capacity (F_{mean}) in swimmers. However, gender differences have not been investigated. **PURPOSE:** To explore gender differences for anaerobic performance, reliability, and validity of a TST. **METHODS:** 14 males and 14 females completed 4 sessions: Wingate cycling anaerobic test (WAnT), a performance swim (PS) session, and 4 TST over 2 sessions. Gender differences were determined using independent t-tests. Reliability was determined using an ICC (2, 1) for F_{peak} and F_{mean} . Criterion validity of the TST was determined using Pearson's Correlation analysis among F_{peak} and F_{mean} obtained during the TST and WAnT, and the swim velocity obtained during the PS. **RESULTS:** Gender differences are shown in Table 1. For males/females respectively, intercession for F_{peak} (0.764/0.696) and for F_{mean} (0.965/0.985), and intrasession for F_{peak} (0.645/0.786) and F_{mean} (0.920/0.990), were statistically significant ($p < 0.05$). Criterion validity is shown in Table 2.

Table 1.

	Males		Females		T-test
	Mean	SD	Mean	SD	
TST F_{peak}	277.43	54.51	191.58	37.56	0.000
F_{mean}	99.31	24.58	74.30	19.67	0.006
WAnT F_{peak}	1005.53	188.89	724.87	104.12	0.000
F_{mean}	707.47	99.81	443.27	96.42	0.000

Table 2.

Criterion Validity: TST F_{mean}	Pearson	Criterion Validity: TST F_{peak}	Pearson
Males:			
WAnT F_{mean}	0.280	WAnT F_{peak}	0.396
PS 25yd	0.666*	PS 25yd	0.636*
PS 50yd	0.746*	PS 50yd	0.336
PS 100yd	0.763*	PS 100yd	0.566
Females:			
WAnT F_{mean}	0.775**	WAnT F_{peak}	0.698*
PS 25yd	0.931**	PS 25yd	0.679*
PS 50yd	0.906**	PS 50yd	0.710*
PS 100yd	0.869**	PS 100yd	0.684*

CONCLUSIONS: Although gender differences exist for anaerobic performance of swimmers, the TST is still considered a reliable method with moderate/strong association with swim velocity. Results of this study further solidify the need for a mode specific measure of anaerobic power and capacity, due to the lack of association between the TST and land based measures in males. Supported by ONR: N00014-14-1-0022/N00014-15-0069

530 Board #351 May 31 11:00 AM - 12:30 PM

Reliability and Validity of Swimming Pool Protocol to Measure Maximal Aerobic Power of Healthy Adults

Elizabeth F. Nagle, FACSM¹, Takashi Nagai¹, Anne Beethe¹, Mita T. Lovlekar¹, Jaquelyn A. Nagle-Zera², Christopher Connaboy¹, John P. Abt, FACSM³, Robert J. Robertson, FACSM¹, Scott M. Lephart, FACSM³. ¹Univ. of Pittsburgh, Pittsburgh, PA. ²John Carroll University, Cleveland, OH. ³University of Kentucky, Lexington, KY. Email: nagle@pitt.edu
 (No relationships reported)

A modality specific swimming protocol to assess maximal aerobic power (MAP) is essential to accurately prescribe and monitor swimming conditioning programs. However, variable hydrodynamics properties can alter propulsive forces of a freestyle swimming stroke, and consequently impede the ability to consistently and accurately perform a MAP swimming protocol. **Purpose:** To assess: 1) reliability of a swimming pool maximal oxygen consumption ($VO_{2max_{sw}}$) (i.e. MAP) protocol; and 2) validity of a $VO_{2max_{sw}}$ test using swimming pool performance swim (PS) tests as the criterion. **Methods:** Thirty healthy males (n=15) and females (n=15) (age, 23.1+6.5 yrs; height, 173.4 + 8.6 cm; weight, 70.4 + 11.4 kg) performed two swimming pool $VO_{2max_{sw}}$ tests ($VO_{2max_{sw_A}}$ and $VO_{2max_{sw_B}}$), and two PS tests [50 yard (31.20 + 4.5 seconds) and 200 yard (159.2 + 25.5 seconds)]. Test-retest reliability of $VO_{2max_{sw}}$ ($ml \cdot kg^{-1} \cdot min^{-1}$), HRMax ($b \cdot min^{-1}$), cardiorespiratory efficiency (O₂ pulse) ($VO_{2max_{sw}} / HRMax$), maximal respiratory exchange ratio (RERMax), and ventilation (VeMax) ($L \cdot min^{-1}$), data was assessed calculating ICC's (2,1). Test validity was determined by correlating $VO_{2max_{sw_A}}$ with PS swims using Pearson's coefficients. **Results:** Intra-subject reliability (ICC) cardiorespiratory responses during the $VO_{2max_{sw_A}}$ and $VO_{2max_{sw_B}}$ tests are presented in Table 1.

Table 1.

Variable	N	$VO_{2max_{sw_A}}$	$VO_{2max_{sw_B}}$	ICC	p-value
$VO_{2max_{sw}}$ ($ml \cdot kg^{-1} \cdot min^{-1}$)	29	44.2 + 7.7	42.9 + 8.5	0.899**	<0.001
HRMax, ($b \cdot min^{-1}$)	19	177.5 + 8.5	178.1 ± 9.0	0.586**	.004
O ₂ pulse($ml \cdot b^{-1}$)	19	0.2 + 0.0	0.2 + 0.0	0.833**	<0.001
Peak RER	29	1.0 ± 0.1	1.0 ± 0.1	0.538**	.001
VeMax ($l \cdot min^{-1}$)	29	95.2 + 20.7	94.3 + 21.2	0.785**	<0.001

**p<0.01

For validity, moderately strong correlations were found between $VO_{2max_{sw_A}}$ and 50 (r = -0.543; p<0.05), and 200 (r=-0.486; p<0.05) swim performance time. **Conclusions:** The $VO_{2max_{sw}}$ test employed presently was found to be a reliable and functionally valid test of MAP. Future studies should consider the suitability of a pool-based $VO_{2max_{sw}}$ test for military, clinical populations, or injured athletes. Supported by ONR: N00014-14-1-0022/N00014-15-0069

Empirical Model Of Lane Bias Suggests Different Finish Order At 2016 Olympic Swimming Competition

Chris Brammer¹, Andrew Cornett², Joel Stager, FACSM¹. ¹Indiana University, Bloomington, IN. ²Eastern Michigan University, Ypsilanti, MI. (Sponsor: Joel Stager, FACSM) Email: brammerc@indiana.edu
 (No relationships reported)

Distance freestyle (FR) swimmers at recent elite-level competitions were shown to be faster swimming in one direction versus the other dependent on lane assignment (LA). These observations were consistent with a subsequent analysis of the 50-m FR events in that the change in performance from prelim (p) to semifinal (sf) to final (f) was also dependent on the swimmers' LA. Although some swimmers were concluded to have been advantaged over others, the extent to which the race outcomes were affected was not quantified.

PURPOSE: To determine if the 2016 Olympic swim performances were biased due to LA, and if so, to quantify the effect of the bias on 50-m FR race outcomes. **METHODS:** 800-m, 1500-m, and 50-m FR results from the 2016 Olympic Games were obtained from online sources. A linear model estimated the interaction effects between distance FR swimmers' LA and their Direction (toward or away from finish end) on 50-m splits. Each 50-m FR performance was adjusted using model estimates of the Direction effect for each lane, and the change in adjusted performance from p to sf to f heats calculated. Linear regression with the change in adjusted 50-m performances (input) and the change in actual 50-m performances (response) was used to re-adjust sf and f 50-m performances. Actual ranks minus ranks based on re-adjusted performances in a given lane was tested using the Wilcoxon signed-rank test.

RESULTS: The change in adjusted 50-m FR performance significantly predicted the actual change ($F(1,46) = 186, p < .01, R^2 = .79$). Corrected rank was different than

actual rank for lanes 1-3 and 6-8 ($p < .05$); median difference in rank (interquartile range) for Lanes 1-8 was 1 (0.5 to 1.5), 1 (0.5 to 1.5), 3 (2.5 to 3.5), 0.5 (0.5 to 1), 0 (0.5), -1.5 (-2 to -1), -2 (-2.5 to -1.5), and -3 (-3.5 to -2.5), respectively.

CONCLUSIONS: This analysis provides evidence that 2016 Olympic swimmers' performances were affected by their LA. Use of model estimates of the effects of LA and Direction on distance FR splits to estimate unbiased 50-m FR performances is a practical, post-hoc tool to quantify the lane bias effect on race outcomes. 50-m swimmers in Lanes 6-8 benefitted the most, finishing 1 to 3 places higher than they would have without the bias. That some athletes may have won medals simply due to factors of the pool environment should be very alarming to all swim stakeholders.

532 Board #353 May 31 11:00 AM - 12:30 PM
Maturational Timing and Performance in Collegiate Female Swimmers

Andrew C. Cornett¹, Alan Duski¹, Sierra Wagner¹, Samantha White¹, Brian Wright², Joel Stager, FACSM³. ¹Eastern Michigan University, Ypsilanti, MI. ²DePauw University, Greencastle, IN. ³Indiana University, Bloomington, IN. (Sponsor: Joel Stager, FACSM)
 Email: acornet2@emich.edu
 (No relationships reported)

Although it's well documented that top-performing swimmers are relatively late maturers, it's not well understood why this is so. One explanation is that there are certain physical traits common to later maturers that contribute to better swim performance. And as a result, later maturers are more likely to be 'selected' for continued sport participation. **PURPOSE:** To determine if: (1) top-performing swimmers are later maturers than lower-performing swimmers; (2) later-maturing swimmers perform better than earlier-maturing swimmers; and (3) there are physical traits common to both top performers and later maturers. **METHODS:** Maturational timing was estimated using age at menarche (AaM), which was determined retrospectively in collegiate swimmers ($N = 273$). Each swimmer's best performance during the 2015-2016 NCAA season was obtained from the USA Swimming database and selected based on Power Point Score (PPS), a standardized score given to all performances in the database. Independent samples t tests were used to compare (1) AaM and BMI (from self-reported height and weight) between bottom-performing (lowest 25% of PPS) and top-performing (highest 25% of PPS) swimmers and (2) PPS and BMI between earlier-maturing (youngest 25% of AaM) and later-maturing (oldest 25% of AaM) swimmers. **RESULTS:** The top performers were later maturers than the bottom performers (AaM 14.0 vs. 13.4 years, $t = 2.48$, $P = 0.02$, $d = 0.46$) and had lower BMIs (22.5 vs. 23.5 kg/m², $t = 2.30$, $P = 0.02$, $d = 0.41$). The later maturers performed better than the earlier maturers (PPS 802.6 vs. 753.4, $t = 2.11$, $P = 0.04$, $d = 0.39$) and had lower BMIs (22.5 vs. 23.4 kg/m², $t = 2.29$, $P = 0.02$, $d = 0.40$). **CONCLUSION:** Previous research has shown that top-performing swimmers and later-maturing women are more linear in body shape than their low-performing and earlier-maturing counterparts. Our results pertaining to weight per height (i.e., BMI) are consistent with these reports. And taken together, they provide evidence that there are physical traits common to top-performing swimmers and later-maturing women. So it's certainly possible that later maturers are being selected (by themselves or others) for continued swim participation on the basis of these traits. But additional longitudinal research is required to determine the extent to which this is the case.

533 Board #354 May 31 11:00 AM - 12:30 PM
Age-associated Changes In Training Volume And Athletic Performance: Cross-sectional and Longitudinal Analyses of Masters Swimmers

Stephanie Lapiere, Brett Baker, Hirofumi Tanaka, FACSM. *The University of Texas at Austin, Austin, TX.* (Sponsor: Hirofumi Tanaka, FACSM)
 Email: stephlapierre@utexas.edu
 (No relationships reported)

Masters athletes make every effort to maintain or even improve the athletic performance they accomplished when they were young. However, a decline in athletic performance is one of the inevitable consequences of aging. Precise physiological mechanisms of age-related decrease in athletic performance are not known but it is thought to be driven by decreases in exercise training stimuli. **PURPOSE:** We determined the influence of changes in training volume with aging on swimming performance by using both cross-sectional and longitudinal approaches. **METHODS:** Competitive swimmers who were members of the US Masters Swimming association were included if they had logged their yearly training volume and had participated in 50m freestyle events at a USMS meet between 2011 and 2015. A total of 692 and 98 swimmers aged 20-88 years were studied in the cross-sectional and longitudinal analyses. Multiple regression and mixed effects multiple regression models were used with gender as a covariate. The longitudinal data was then centered around different ages to find the age at which training is a significant predictor of performance. **RESULTS:** Both cross-sectional and longitudinal analyses showed no significant

associations between swimming training volume and age. In the longitudinal analyses, training volume was not significant as a predictor in swimming performance for younger swimmers (53 years and younger). In middle-aged swimmers (54-79 years), increases in training volume resulted in mildly better swimming performance (i.e., 3 miles/month increases in training volume were related to .05 sec better swimming time). Increases in training volume with advancing age had more significant effects on swimming performance in older swimmers (80 years and older) (i.e., 3 miles/month increases in training volume were associated with .27 sec better swimming time). **CONCLUSION:** In younger swimmers, changes in training volume did not have any significant impact on swimming performance. However, in middle-aged and older swimmers, there was a graded relationship between yearly increases in training volume and swimming performance such that the impact of training volume on swimming performance appears to become greater with advancing age.

Associations between Land-Based Laboratory Measures and Freestyle Swimming Performance: A Comparison between Males and Females

Anne Z. Beethe¹, Elizabeth Nagle, FACSM¹, Christopher Connaboy¹, Mita Lovalekar¹, John Abt, FACSM², Takashi Nagai¹, Scott M. Lephart, FACSM². ¹University of Pittsburgh, Pittsburgh, PA. ²University of Kentucky, Lexington, KY.
 (Sponsor: Elizabeth Nagle, FACSM)
 (No relationships reported)

Swimming requires technical proficiency to perform effectively and efficiently. Directly analyzing technique and performance is expensive and time consuming. Understanding underlying factors and characteristics which relate to swimming performance is of benefit. To quantify, land-based laboratory measures (LM) can be used, but associations between the LM and swimming times must be established. Further, it is unknown if technique and performance characteristics are equal in both sexes. **PURPOSE:** To examine associations of LM to swimming performance (SP) in female and male swimmers. **METHODS:** Fifteen female (22.6 ± 6.3 years, 167.6 ± 6.4 cm, 65.7 ± 9.5 kg) and 15 male (23.6 ± 6.7 years, 179.3 ± 6.4 cm, 75.1 ± 11.5 kg) recreational and competitive swimmers completed LM (body anthropometrics/composition, passive shoulder range of motion, shoulder laxity, and isokinetic scapular strength), and 50 and 200 yd freestyle SP. Spearman correlations were performed comparing LM with SP for each female/male group. Females and males were then split by a median cut point (fastest and slowest) for the 50 (Female = 32.6s; Male = 30.5s) and 200 (Female = 168.6s; Male = 159.3s) yd swims. After testing for normality, Mann-Whitney tests compared group means ($p < 0.05$). **RESULTS:** Correlations were found between female fat free mass (FFM) and 50 yd (-0.713; $p = 0.003$) and 200 yd (-0.724; $p = 0.002$) freestyle SP. Compared to the slower female, the faster female had greater height ($p = 0.021$) and leg length ($p = 0.015$) in relation to 50 yd SP, and greater FFM for both 50 yd ($p < 0.001$) and 200 yd ($p = 0.005$) SP. Males showed no sig. correlations in LM, nor sig. associations in LM between the faster and slower swimmers during the SP tests. In both sexes, shoulder girdle LM were not associated with SP. **CONCLUSION:** Time to completion was the only measure of SP. Therefore, an increase in relative female height may act to reduce the magnitude of wave drag encountered, allowing for faster speeds in relation to a specific propulsive impulse. Correlation between FFM and faster SP demonstrates that females with more muscle mass can compete at higher levels. To predict capabilities for future SP, and assess associations between LM and SP, studies should examine shoulder biomechanical measurements during the freestyle stroke. Supported by ONR: N00014-14-1-0022/N00014-15-0069

535 Board #356 May 31 11:00 AM - 12:30 PM
Predicting Performance: The use of Nonlinear Regression Models to Predict Olympic Performance in Swimmers

Joel T. Greenshields, Joel M. Stager, FACSM. *Indiana University, Bloomington, IN.* (Sponsor: Joel Stager, FACSM)
 Email: jtgreens@indiana.edu
 (No relationships reported)

PURPOSE: Due to recent external biases shown to have influenced the ability of a nonlinear regression model to predict Olympic performance, the purpose of this study was to employ additional statistical analytics as a means to characterize the progression of performances at future Olympic swim competitions. **METHODS:** Nonlinear regression models were fit for each swimming event for men (m) and women (w) at the Olympic Games ($n=26$) from 1948 to 2012. From these, and based upon predicted and observed performances, a 'best fit' model including 7 Olympic Games from 1988 to 2012 was selected. To predict future performances (2016), 1454 championship finals swim performances from this time frame were utilized. The mean time of the 8 swimmers in each final was used as the dependent variable to fit the model [$\text{time} = a \times \text{year}^b$]. A 95% percent confidence interval was

calculated using a Monte Carlo simulation method. Residual squared error (RSE), r-squared (r^2), confidence interval (CI) length, and absolute difference between observed and predicted of each regression model were compared.

RESULTS: Average RSE_m (1.24 ± 1.25), RSE_w (1.39 ± 1.15). Average r^2_m (0.76 ± 0.09), r^2_w (0.72 ± 0.12). There were no statistically significance differences in average RSE ($p=0.35$) or average r^2 ($p=0.35$) between sex models. Average length of the 95% CI_m (3.07 ± 3.13), CI_w (3.44 ± 2.86). No difference existed between length of CI between sex ($p=0.76$). Absolute difference in time between observed and predicted for men (0.79 ± 0.73 s), women (1.56 ± 1.89 s). No differences existed between the absolute difference in observed and predicted between the men and women models ($p=0.19$). 92.3% ($n=12$) of observed men and 69.2% ($n=9$) observed women mean performances for 2016 fell within the 95% confidence interval of the predicted model value.

CONCLUSIONS: In general, the nonlinear regression prediction models produce a valid and accurate approximation of Olympic performance progression as reflected by the 2016 Games. However, it is unclear why there is a different accuracy of 'fit' for the men and women predictions. Further study is needed to evaluate the potential factors apparently allowing the women to out-perform the 'best fit' model.

Nutrition and Physiological Recovery in Smith College Swimmers
 Devi Dearmon-Moore, 01063. *Smith College, Northampton, MA.*
(No relationships reported)

Nutrition and Physiological Recovery in Smith College Swimmers
 Devi Dearmon-Moore¹, Barbara Brehm-Curtis²
 Smith College, Northampton, MA

Athletes have an increased requirement for nutrients such as protein and carbohydrates in order to facilitate recovery. However, female athletes don't often receive a thorough nutritional education and often focus on maintaining a specific body weight to ensure peak performance. As a result, many women and girls do not consume enough food to satisfy the physical demands of their sports, increasing their risk of long term health problems later in life.

PURPOSE: To determine if members of the Smith College swim team meet their recommended dietary intake guidelines, and to explore the relationship between dietary intake, non-nutritional requirements, and physiological recovery. **METHODS:** Participants filled out an anonymous questionnaire daily for 7 days. The questionnaire included questions regarding daily food intake, total hours of sleep, any changes in caffeine intake and/or health, and their level of fatigue. Recovery was evaluated using the REST-Q, a 7-question survey that attempts to measure perceived exertion, perceived recovery and recovery effort in order to determine if the athlete is exhibiting signs of overtraining. Each question on the REST-Q is evaluated based on a scale from 0-6. Dietary intake was evaluated using MyFitnessPal, a free online website that allows the user to enter the name of a food item into a database and determine its nutritional content. Nutritional analysis was restricted to four nutrients: protein, carbohydrates, fat and calories. Recommended intake guidelines for each athlete were based on the values described in the literature and calculated by hand. **RESULTS:** Less than half of the participants met guidelines for the intake of at least two of the four nutrients studied. The two most common deficit nutrients were carbohydrates and calories. All but one participant met or exceeded guidelines for protein consumption. All participants reported on average low recovery scores and workouts that required significant effort to complete. **CONCLUSION:** Based on average dietary consumption during this study, none of the participants met all of their recommended dietary intake guidelines.

Role of Dryland Resistance Training on Musculoskeletal Injuries and Healthcare Costs in Masters Swimmers
 Brett Baker, Stephanie Lapierre, Hirofumi Tanaka, FACSM. *The University of Texas at Austin, Austin, TX.* (Sponsor: Hirofumi Tanaka, FACSM)
 Email: brett.baker@utexas.edu
(No relationships reported)

An increased incidence of orthopedic injuries with age interfere with Masters athletes to pursue better performance and place economic burden on these athletes. **PURPOSE:** We determined the prevalence and economic impact of swimming-related musculoskeletal injuries in Masters swimmers. **METHODS:** A comprehensive questionnaire was administered to the United States Masters Swimming (USMS) membership. A total of 498 swimmers (304 female and 194 male) aged 20-86 years responded. The swimmers had been swimming for 13.3 ± 11.5 years, and 67% of them participated in resistance training. Economic impact was determined by their total healthcare costs. Healthcare costs were costs associated with a doctor's visit, healthcare visit or another healthcare professional. Binary logistic and linear multiple regression tests using age, sex and years of swimming as covariates were run to

determine predictors for both injuries and healthcare costs. **RESULTS:** Thirty one % of the swimmers reported swimming-related musculoskeletal injuries. Prevalence of swimming-related injuries and healthcare costs were not different between females and males and was not related to aging. Accumulating years of dry-land resistance training were significantly associated with reductions in the prevalence of injuries. Yet they were also related to increases in healthcare costs ($p<0.05$). Resistance training participation was associated with an increase in the length of injuries ($p<0.05$), which predicted an increase in healthcare costs ($p<0.05$). **CONCLUSIONS:** Years of dry-land resistance training are associated with lower prevalence of swimming-related injuries but act to increase healthcare costs with elevating major injuries requiring lengthy recovery.

538 Board #359 May 31 11:00 AM - 12:30 PM
Ergogenicity Of Inspiratory Muscle Training Is Affected By Weekly Training Distance In Swimmers
 Mitch Lomax¹, Jernej Kapus², Peter Brown³, Mark Fahgy⁴.
¹University of Portsmouth, Portsmouth, United Kingdom.

(No relationships reported)

PURPOSE. The aim of this study was to examine the impact of weekly swimming training distance on the ergogenicity of inspiratory muscle training (IMT). **METHODS.** Thirty-three well trained youth swimmers were recruited and separated into a LOW (age: 16 ± 3 years; mass: 65.9 ± 6.6 kg; stature: 1.76 ± 0.12 m; $n = 18$) and HIGH (age: 16 ± 1 years; mass: 65.2 ± 8.3 kg; stature: 1.75 ± 0.11 m; $n = 15$) group based on weekly training distance (LOW: $15\text{-}31$ km \cdot wk $^{-1}$; HIGH: $42\text{-}56$ km \cdot wk $^{-1}$). The LOW and HIGH groups were further subdivided into control and IMT groups for a 6-week pressure-threshold IMT intervention giving a total of four groups: LOW_{con}, LOW_{IMT}, HIGH_{con}, HIGH_{IMT}. Before and after the intervention period, swimmers completed maximal effort 100 m and 200 m front crawl swims, with maximal inspiratory and expiratory mouth pressures (P_{imax} and P_Emax, respectively) assessed before and after each swim. **RESULTS.** Before IMT, 100 m and 200 m swimming times were on average 19.1 s and 20.8 s faster, respectively, in the HIGH_{con} and HIGH_{IMT} groups than the LOW_{con} and LOW_{IMT} groups ($P < 0.001$). IMT increased P_{imax} (but not P_Emax) by 36% in LOW_{IMT} and HIGH_{IMT} groups ($P < 0.001$) but 100 m and 200 m swims were faster only in the LOW_{IMT} group (3% and 7% respectively, $P < 0.05$). **CONCLUSION.** Performance benefits only occurred in those training between $15\text{-}31$ km \cdot wk $^{-1}$ and indicate that the ergogenicity of IMT is affected by weekly training distance. Consequently, current/anticipated training distances are important considerations when deciding whether or not to supplement swimming training with IMT.

Muscle Damage, Soreness And Stress Over 6-weeks Of Pre-season Training In Ncaa D1 Male Swimmers
 Mario Rusnak¹, Melissa VanderMeulen¹, Brigid Byrd², Gregory Byrd³, Raychel Rusnak¹, Tamara Hew-Butler, FACSM¹.
¹Oakland University, Rochester, MI. ²Wayne State University, Detroit, MI. ³Michigan State University College of Osteopathic Medicine, East Lansing, MI. (Sponsor: Tamara Hew-Butler, FACSM)
 Email: mrusnak@oakland.edu
(No relationships reported)

In 2014, three of our male swimmers were hospitalized for symptomatic exertional rhabdomyolysis (Stanfa M et al 2016). **PURPOSE:** To serially monitor and assess relationships between skeletal muscle damage, upper and lower body soreness, and physiological stress during the first six weeks of high volume training in collegiate male swimmers. **METHODS:** Seventeen male NCAA D1 swimmers presented to the lab six times during pre-season training. Blood was drawn weekly for measurement of serum creatinine kinase (CK), myoglobin (MYO) and a complete metabolic panel. Serum cortisol (C), testosterone (T) and T/C ratio were assessed at Weeks 1 (baseline), 4 and 6. Upper body soreness (US) and lower body soreness (LS) were assessed weekly via a visual analogue scale (0-10-inch unmarked scale). Repeated measures ANOVA with a Bonferroni correction were performed, with data reported as means \pm SD. Correlation analyses performed with significance set at $p<0.05$. **RESULTS:** Weekly training load consisted of: 88% swimming, 6% running, and 6% weight training which gradually increased from 16 hours to 20 total training hours/week over the first six weeks of training. Significant changes in CK (174 ± 2 ; 438 ± 259 ; 358 ± 309 ; 274 ± 112 ; 276 ± 127 ; 301 ± 126 U/L; $p<0.0001$), MYO (38 ± 16 ; 47 ± 18 ; 38 ± 18 ; 33 ± 12 ; 31 ± 10 ; 30 ± 7 ng/mL; $p=0.001$), US (1.5 ± 1.6 ; 3.5 ± 2.0 ; 3.7 ± 2.2 ; 5.1 ± 1.7 ; 5.4 ± 2.5 ; 4.8 ± 2.5 ; $p<0.0001$), LS (1.7 ± 2.0 ; 5.5 ± 2.5 ; 3.9 ± 2.0 ; 4.9 ± 1.7 ; 4.6 ± 2 ; 5.5 ± 2.2 ; $p<0.0001$), cortisol (15 ± 6 ; 10 ± 3 ; 9 ± 4 ng/dL; $p=0.0004$), and T/C ratio (37 ± 17 ; 48 ± 21 ; 58 ± 32 ; $p=0.04$) were noted while

changes in testosterone were not significant over time (456 ± 127 ; 438 ± 119 ; 416 ± 111 ng/dL; $p=0.38$). Significant correlations noted between CK vs. MYO ($r=0.36$), cortisol ($r=0.39$), alanine aminotransferase ($r=0.22$), and aspartate aminotransferase ($r=0.48$) when all data were combined. **CONCLUSION:** Muscle damage in collegiate male swimmers was modest despite cumulative training which peaked at 20hrs/week. A disconnect was noted between muscle damage (CK, MYO) and (upper and lower) body soreness, at moderate (~5/10) degrees of muscle soreness. Serum cortisol decreased over time, while testosterone remained unchanged, which promoted an anabolic hormonal environment despite gradual increases in high volume training at the commencement of the new (Fall) academic year.

540 Board #361 May 31 11:00 AM - 12:30 PM
Muscle Damage, Soreness, and Stress Over 7-weeks Of Pre-season Training In Ncaa Female Swimmers

Melissa VanderMeulen¹, Mario Rusnak¹, Brigid Byrd², Gregory Byrd³, Raychel Rusnak¹, Tamara Hew-Butler, FACSM¹.

¹Oakland University, Rochester, MI. ²Wayne State University, Detroit, MI. ³Michigan State University College of Osteopathic Medicine, East Lansing, MI. (Sponsor: Tamara Hew-Butler, FACSM)

Email: mjvander@oakland.edu

(No relationships reported)

In 2014, three female swimmers were hospitalized with symptomatic exertional rhabdomyolysis (Stanfa M et al 2016). **PURPOSE:** To serially monitor and assess relationships between skeletal muscle damage, upper and lower body soreness, and physiological stress during the first seven weeks of high volume training in collegiate female swimmers.

METHODS: 23 female NCAA D1 swimmers presented to the lab six times during 7-weeks of pre-season training. Blood was drawn at six timepoints for measurement of serum creatinine kinase (CK), myoglobin (MYO) and a complete metabolic panel. Serum cortisol (C), testosterone (T) and T/C ratio were assessed at Weeks 1 (baseline), 4 and 7. Upper body soreness (US) and lower body soreness (LS) were assessed, at the six timepoints that blood was drawn, using a visual analogue scale (0-10-inch unmarked scale). A repeated measures ANOVA with a Bonferroni correction were performed, with data reported as means \pm SD. Correlation analyses performed with significance set at $p<0.05$. **RESULTS:** Weekly training load consisted of: 88% swimming, 6% running, and 6% weight training which gradually increased from 16 hours to 20 total training hours/week over the first seven weeks of training. Significant changes were noted in CK (135 ± 68 ; 446 ± 723 ; 171 ± 83 ; 202 ± 80 ; 180 ± 100 ; 206 ± 170 U/L; $p=0.01$), US (1.5 ± 1.8 ; 3.9 ± 1.7 ; 3.3 ± 1.8 ; 5.4 ± 1.6 ; 6.1 ± 1.8 ; 3.7 ± 2.0 ; $p<0.0001$), LS (1.3 ± 1.5 ; 5.0 ± 2.2 ; 3.4 ± 1.8 ; 5.0 ± 1.9 ; 4.8 ± 1.8 ; 4.1 ± 2.0 ; $p<0.0001$), cortisol (19 ± 10 ; 15 ± 6 ; 11 ± 5 ng/dL; $p<0.0001$), and T/C ratio (2.4 ± 2.3 ; 3.0 ± 1.8 ; 4.1 ± 2.8 ; $p=0.0003$) but not in MYO (39 ± 20 ; 63 ± 141 ; 29 ± 18 ; 30 ± 17 ; 24 ± 4 ; 29 ± 14 ng/mL; $p=0.32$) or testosterone (33 ± 14 ; 37 ± 14 ; 36 ± 14 ng/dL; $p=0.29$). Significant correlations noted between CK vs. MYO ($r=0.84$), alanine aminotransferase ($r=0.21$), and aspartate aminotransferase ($r=0.49$) when data were combined, but largely driven by an outlier with CK= 3558 U/L and MYO= 691 ng/mL at Week 2 (first training week). **CONCLUSION:** Muscle damage in collegiate female swimmers remained largely within the normal range (CK <200 U/L) on average, but was highly variable between individuals. No correlations noted between muscle damage (CK, MYO) and (upper and lower) body soreness, at moderate (2-6) ratings of muscle soreness. Serum cortisol declined over training, promoting an anabolic hormonal environment.

Strenght Of Shoulder Rotators After A Swimming-training (inside And Outside Of The Pool) And Detraining

Stephane M. Ribeiro, Manoela S. Machado, Dênis B. da Silva, Elisângela da Silva, Wagner Z. de Freitas, Wonder P. Higino, Renato A. de Souza, Daniela G.M. Bueno. *IFSU/LEMINAS, Muzambinho, Brazil.*

(No relationships reported)

It is known that in the same way the training provide several adaptations, the interruption or change the types of physical activities can lead to the decline of skills developed. However, there are limited researches that indicate these effects on swimmers. **PURPOSE:** To evaluate the strenght of shoulder rotators of recreational swimmers after a swimming activities program, after a similar swimming-training program outside of the pool and after 8-week detraining. **METHODS:** Ten recreational swimmers (age: 44.0 ± 19.0 years) were evaluated using isokinetic dynamometry applied to dominant shoulder rotators: peak torque (PT) for external and internal rotation at velocity of 60°/s and 180°/s. The evaluations were performed after a swimming activities program inside of the pool (SWI: 28 weeks); after a swimming activities program outside of the pool (OUT: 8 weeks); after 8 weeks detraining (DET). These three experimental moments happened sequentially over the time. Both programs consisted of 60-minute sessions twice a week targeted mainly

upper limb strenght muscles. For statistical analysis a two-way ANOVA with repeated measures with Tukey-Kramer post hoc was carried out. **RESULTS:** It was showed a PT-decrease ($p<0.05$) after OUT (22.3 ± 7.7 N.m) and DET (21.1 ± 7.1 N.m) when compared with SWI (25.4 ± 7.7 N.m) for external rotation at 60°/s; Only DET (16.9 ± 5.7 N.m) showed significant difference when compared with SWI (21.4 ± 7.7) for external rotation at 180°/s. No significant differences were showed for internal rotation. **CONCLUSION:** Swimming activities program outside of the pool did not produce positive effects to maintain strenght level acquired after a swimming activities program inside of the pool only for external rotation at 60°/s, indicating that decline of skills previously developed may be muscle and velocity-dependent. Also, 8 weeks detraining was deleterious for strenght profiles of the shoulder rotators in recreational swimmers.

The Influence of an Educational Intervention on Hydration Status in Collegiate Swimmers.

Kelley Holmes¹, David Bacharach, FACSM². ¹University of Minnesota Duluth, Duluth, MN. ²St. Cloud State University, St. Cloud, MN. (Sponsor: John Keener, FACSM)

Email: holmesk@d.umn.edu

(No relationships reported)

Much research and many guidelines exist relating hydration and sport, yet many athletes don't understand the role it plays with training and performance. Athletes often come to practice or competition dehydrated. Hydration education has been shown to reduce dehydration in land-based athletes, but hasn't been studied in swimming. **PURPOSE:** The purpose of this study was to determine if an educational intervention improves the hydration status of collegiate swimmers.

METHODS: Participants (N=14) were collegiate level swimmers (n=6 female, n=8 male). Hydration status was determined using urine specific gravity (USG), urine osmolality (UO), and change in body mass. Measurements were taken before and after practice during week one. Athletes deemed dehydrated by any of the measures (n=9) were given an educational intervention during week two. The intervention provided information based on position statements from the American College of Sports Medicine and the National Athletic Training Association. The same hydration measures were made in week three after the educational intervention. A dependent t-test was used to determine any significant differences in pre-post intervention hydration measurements using the dehydrated swimmers to determine the program's effectiveness.

RESULTS: There was no significant difference in USG or UO ($p>0.05$). Pre and post-practice USG and UO values from week one were compared to week three.

CONCLUSIONS: While no significant differences were present as a result of the educational intervention, previous research has suggested educational interventions can improve the understanding of hydration and how it impacts performance and elicits positive performance outcomes. (Cleary et al., 2012; McDermott et al., 2009) In the present study, daily fluctuations in hydration and practice time, subjects misunderstanding/disregarding information provided during the intervention, or using a single determinant of hydration status, may be possible reasons for no change. Further investigations may want to both account for these variables and extend the educational intervention.

Associations Of Heart Rate Variability Measured During Orthostatic Test And During Daily Routine Activities

Ricardo Mesquita¹, Heikki Kyröläinen, FACSM¹, Daniela S. Olstad². ¹University of Jyväskylä, Jyväskylä, Finland. ²Polar Electro Oy, Kempele, Finland.
Email: rnamesquita@hotmail.com

(No relationships reported)

Measuring resting heart rate variability (HRV) indices constitutes an interesting, non-invasive and simple tool to monitor fatigue and performance responses. The orthostatic test (OT) where heart beat-to-beat (RR) intervals are measured is widely used to measure HRV. The feasibility in daily use would, however, increase considerably if vagal related HRV indices could be analysed from free living physical activity. **PURPOSE:** To determine the reliability and validity of HRV indices during daily routine situations. **METHODS:** Eight white-collar workers were recruited to participate in this study. RR intervals were recorded using a personal HR monitor (V800, Polar Electro Oy, Kempele, Finland). Data was collected every morning at home upon awakening and at work during routine situations on 16 different days. A total amount of 127 cycles of sitting periods followed by walking breaks were included for consecutive pairwise analysis of trials for reliability[SD1] (coefficient of variation (CV) and typical error (TE) with confidence limits of 95% were calculated). When reliability was found, the values from the morning OT were plotted against the corresponding routines at work. **RESULTS:** Mean RR-interval and HR values at work showed high levels of repeatability [CV during sitting and walking was 4.71 and 3.99, respectively, with a TE of 3.73 (3.34-4.25) and 3.65 (3.31-4.09)]. Although reliable, HR data recorded in the morning did not correlate with the corresponding routines at work ($r = 0.28$ for supine vs. sitting and $r = 0.05$ for standing vs. walking, $p > 0.05$). The root-mean-square difference of successive normal RR (RMSSD) was revealed not to be repeatable in those routine situations [CV during sitting and walking was 19.99 and 29.05, respectively, with a TE of 7.9 (7.15-8.85) and 9.43 (8.53-10.57)]. Furthermore, RMSSD values analyzed from the HRV recordings during standing did not correlate ($r = 0.138$, $p > 0.05$) with the respective values during walking in the morning upon awakening. **CONCLUSION:** Analyzing RMSSD from daily routine activities was not reliable or valid. To monitor training status, RMSSD should therefore be calculated from recordings in standardized conditions such as the OT in the morning. It would be much more feasible to get this information from free living activities but it does not seem to be a valid procedure.

The Relationship Between Lifelong Exercise Volume and Coronary Atherosclerosis

Vincent L. Aengevaeren¹, Arend Mosterd², Thijs L. Braber³, Niek HJ Prakken⁴, Paul D. Thompson, FACSM⁵, Thijs MH Eijssvogels⁶, Birgitta K. Velthuis³. ¹Radboud University Medical Center, Nijmegen, Netherlands. ²Meander Medical Center, Amersfoort, Netherlands. ³University Medical Center Utrecht, Utrecht, Netherlands. ⁴University Medical Center Groningen, Groningen, Netherlands. ⁵Hartford Hospital, Hartford, CT. ⁶Liverpool John Moores University, Liverpool, United Kingdom.
Email: Vincent.Aengevaeren@radboudumc.nl

(No relationships reported)

Higher levels of physical activity are associated with a lower risk of cardiovascular events. Nevertheless, there is debate on the dose-response curve of exercise and cardiovascular outcomes and whether high volumes of exercise may accelerate coronary atherosclerosis. **PURPOSE:** To determine the relationship between lifelong exercise volumes and atherosclerotic coronary artery disease (CAD) characteristics. **METHODS:** Middle aged men engaged in competitive or recreational leisure sports underwent a non-contrast and contrast-enhanced computed tomography scan to assess coronary artery calcification (CAC) and plaque characteristics. Participants reported lifelong exercise history patterns. Exercise volumes were multiplied by Metabolic Equivalent of Task (MET) scores to calculate MET-min/week. Participants were allocated to <1000 MET-min/week, 1000-2000 MET-min/week or >2000 MET-min/week. **RESULTS:** 284 participants (55±7 years) were included. CAC was present in 150/284 (53%) participants with a median CAC score of 35.8 [9.3-145.8]. Athletes

with a lifelong exercise volume >2000 MET-min/week (n=75) had a significantly higher CAC score (9.4 [0-60.9] versus 0 [0-43.5], $p=.02$) and prevalence of CAC (68%, OR=3.2 (95%CI: 1.6-6.6)) and plaque (77%, OR=3.3 (95%CI: 1.6-7.1)) compared to <1000 MET-min/week (n=88, 43% and 56% respectively). Among participants with CAC>0, there was no difference in CAC score ($p=.20$), area ($p=.21$), density ($p=.25$) and regions of interest ($p=.20$) across exercise volume groups. Among participants with plaque, the most active group had a lower prevalence of mixed plaques (48% versus 69%, OR=0.35 (95%CI: 0.15-0.85) and more often had only calcified plaques (38% versus 16%, OR=3.57 (95%CI: 1.28-9.97)) compared to the least active group. There was no difference in location of CAC or plaque. **CONCLUSION:** Participants in the >2000 MET-min/week group had a higher prevalence of CAC and atherosclerotic plaques. The most active group did however have a more benign composition of plaques, with fewer mixed plaques and more often only calcified plaques. These observations may explain the increased longevity typical of endurance athletes despite the presence of more coronary atherosclerotic plaque in the most active participants.

High Intensity Interval Training in a Rat Model of Severe, Angioproliferative Pulmonary Arterial Hypertension

Mary Beth Brown¹, Gary Long¹, Andrea Frump², Andrew Wiseman¹, Matthew Owens¹, Jamie Blessinger¹, Taylor Kurzhall¹, Spenser Studebaker¹, Kelly Jay¹, Ashley Troutman¹, Tim Lahm². ¹Indiana University, Indianapolis, IN. ²Indiana University School of Medicine, Indianapolis, IN.
Email: brownmb@iu.edu

(No relationships reported)

PURPOSE: We previously demonstrated superior benefit of high intensity interval training (HIIT) over continuous exercise training (CET) in a monocrotaline rat model of mild pulmonary arterial hypertension (PAH). Here we investigate HIIT in a model that elicits a more severe, angioproliferative PAH. **METHODS:** SD rats (~200g, male) received Sugden5416 (20mg/kg), followed by 3 wks of hypoxia ($P_{\text{atm}} = 362$ mmHg) and 4 wks of room air to induce PAH (SuHx, n=33). Subgroups of SuHx then underwent 6 wks of treadmill training performed as either HIIT (2 min at ~80-90% $\dot{V}O_{2R}$ reserve [$\dot{V}O_{2R}$] + 3 min at 30% $\dot{V}O_{2R}$, for 4-5 cycles, n=12), or low intensity CET (45-60 min at 50% $\dot{V}O_{2R}$, n=11), with the remainder untrained (SED, n=10). Values are mean±SE. **RESULTS:** Mortality in SuHx was unexpectedly worse for HIIT (4 deaths at 56, 60, 68, and 71 days), vs. CET (2 deaths at 60, and 73 days), and SED (2 deaths at 66 days). While all animals had similar baseline echocardiographic measures of cardiac output (CO, in μL) and stroke volume (SV, in mL/min), SuHx that died prematurely (n=8) had greater impairment in CO (141±19) and SV (424±52) following PAH induction (at pre-training) compared to surviving SuHx (n=25, 235±26, 598±38). Final CO and SV were higher for both HIIT (239±49, 540±58) and CET (207±41, 529±51) vs. SED (122±12, 405±35) SuHx rats, and were similar to untrained healthy controls (CON, n=6, 268±59, 548±71). SuHx-induced elevation in right ventricular (RV) systolic pressure (mmHg) and RV hypertrophy (as RV mass/LV+septum mass, and as RV thickness on echo in mm) were not improved by training with HIIT (61±7; 0.60±0.07, 2.2±0.2) or CET (60±8; 0.47±0.04, 2.0±0.2), vs. SED (55±8; 0.52±0.06, 2.2±0.2), and were higher than CON (28±3; 0.24±0.01, 1.3±0.1). Final $\dot{V}O_{2\text{max}}$ (mL/kg/min) in SuHx was also not improved for either HIIT (44±1.9) or CET (46±1.7) vs. SED (46±3.8). **CONCLUSION:** Both HIIT and CET promoted better RV function in SuHx rats despite no amelioration of RV hypertrophy, PAH, or exercise impairment. However, in contrast to previous findings in a mild PAH rat model, exercise training, particularly with HIIT, increased mortality for animals with poorer cardiac function prior to training onset and suggests that further investigation is needed to optimize training approach for patients with more severe RV dysfunction.

The Impact of Menopausal Status on Cardiac Responses to Exercise Training and Acute Moderate-Intensity Exercise

Amanda Q.x. Nio, Eric J. Stöhr, Samantha Rogers, Rachel Mynors-Wallis, Jane M. Black, Rob Shave. *Cardiff Metropolitan University, Cardiff, United Kingdom.*
Email: anio@cardiffmet.ac.uk

(No relationships reported)

The menopause is generally associated with lower cardiovascular function. However, most investigations have only assessed resting function, and the impact of the menopause on functional capacity and cardiac plasticity is poorly understood. **PURPOSE:** To investigate the impact of menopausal status on left ventricular (LV) function and rotational mechanics in response to exercise training and acute exercise.

METHODS: Eleven pre-menopausal (Pre-M) and 14 post-menopausal (Post-M) middle-aged women (age 45–58 years) completed 12 weeks of exercise training (3 sessions/week consisting of 4 × 4 min intervals at 90–95% maximum heart rate). Maximal aerobic capacity on an upright cycle ergometer was assessed before and after exercise training. LV function was assessed via echocardiography at 20, 40 and 60% peak power output during supine cycling. Due to poor image quality, data on LV rotational mechanics are only reported for 8 pre- and 10 post-menopausal women. **RESULTS:** Peak power output and maximal aerobic capacity increased after exercise training ($P < 0.01$), but this increase was greater in pre-menopausal than post-menopausal women (mean±SD; Pre-M-before 147±29 vs. after 179±28, Post-M-before 145±26 vs. after 169±24 W; Pre-M-before 29±5 vs. after 37±5, Post-M-before 29±6 vs. after 34±5 mL/min/kg; respectively, both $P < 0.05$). General hemodynamics, and LV function and rotational mechanics both at rest and up to 60% exercise were mostly similar in pre- and post-menopausal women in response to training (interaction effects $P > 0.1$). Specifically, the increase in peak basal rotation during exercise was smaller in post-menopausal women after training (three-way interaction $P < 0.01$; mean increase from rest to 60%: Pre-M-before 4.0; Pre-M-after 3.9; Post-M-before 3.7; Post-M-after 2.6°).

CONCLUSION: Middle-aged pre-menopausal women showed greater adaptability to 12 weeks of interval training than middle-aged post-menopausal women. The functional cardiac reserve up to 60% exercise was largely similar in pre- and post-menopausal women. Future work investigating LV function and mechanics at higher exercise intensities will likely provide further insight into the impact of menopausal status on training adaptations.

Amanda Nio is the beneficiary of a doctoral grant from the AXA Research Fund.

Assessment Of Myocardial Mechanics In Renal Transplant Recipients Using Speckle Tracking Echocardiography

Gianni Pedrizzetti¹, Laura Stefani², Stefano Pedri³, Enrico Minetti⁴, Benedetta Tosi², Giorgio Galanti². ¹University of Trieste -Italy, Trieste, Italy. ²Sports and Exercise Medicine, Florence, Italy. ³Esaote Spa -Italy -Medical Affairs Manager, Florence, Italy. ⁴University Hospital Careggi, Florence, Italy, Florence, Italy.

Email: laura-stefani@tiscali.it

(No relationships reported)

PURPOSE: Renal transplant recipients (RTR) have a high risk of cardiovascular mortality, despite surgical treatment and physical exercise is normally allowed to reduce the global morbidity risk. Quantitation of myocardial function by Global Longitudinal Strain (GLS) from 2-dimensional images based on speckle tracking echocardiography plays an important role in detecting the early myocardial dysfunction in many diseases. The aim of this study was to analyze the changes in myocardial strain during 12 months of exercise as prescription model. **MATERIALS AND METHODS:** We studied 17 renal transplant recipients, mean age 56 ± 8 y, submitted to the exercise prescription model followed ACSM guidelines. Longitudinal peak systolic strain were determined by velocity vector imaging from apical 4- and 2-chamber views (MyLab seven -Esaote). All the other standard 2D echo parameters (LVDD, LVSD, CMI, IVS, PW; EF) and the diastolic parameters were evaluated. **RESULTS:** Mean heart rate and systolic and diastolic blood pressure and the LV systolic and diastolic parameters maintain normals during the follow up. After training, GLS and Longitudinal peak systolic strain at basal and mid-segments of the lateral wall were significantly higher after 6 months (GLS^{TO} -20.7±4% vs GLS^{T6} -23.7 ±4.1% with $p < 0.05$) and after 12 months of exercise (GLS: -24.4±3%) in RTR with respect of the values of the onset of the protocol ($p < 0.01$). Average longitudinal systolic strain from the 4-chamber view and GLS was normal in controls (-22.3±2.6%^{TO}; -21.8±3.6%^{T6}; -23.4±4.2%^{T12}) and not significantly different if compared to RTR during all the time of the protocol. **CONCLUSIONS:** Differences in myocardial function in patients renal transplant recipients submitted to the exercise prescription can be found and it can be quantified by strain imaging. Any possible other differences comparing subjects with end-stage renal or before the transplantation and RTR will need further studies.

Non-targeted Metabolomics Identifies Exercise-induced Cardioprotective Metabolic Pathways That Negate Ischemia Reperfusion Injury.

(No relationships reported)

The effects of exercise on the heart and its resistance to disease are well-documented. Recent studies have identified exercise-induced resistance to arrhythmia is due to the preservation of mitochondrial membrane potential. **PURPOSE:** To identify novel metabolic changes that occurred parallel to these mitochondrial alterations, we performed non-targeted metabolomics analysis on hearts from sedentary (Sed) and exercise-trained (Ex) rats challenged with isolated heart ischemia-reperfusion injury (I/R). **METHODS:** Eight week old Sprague-Dawley rats were treadmill trained five days/week for six weeks (exercise duration and intensity progressively increased to 1 hour at 30 m/min up to 10.5% incline, 75-80% VO₂mx). **RESULTS:** The recovery of pre-ischemic function for sedentary rat hearts was 28.8±/5.4% (N=12) compared to exercise trained hearts which recovered 51.9%±/5.7 (N=14, $p < 0.001$). Non-targeted GC-MS metabolomics analysis of 1) Sedentary rat hearts; 2) Exercise-trained rat hearts; 3) Sedentary rat hearts challenged with global ischemia-reperfusion (I/R) injury; and 4) Exercise-trained rat hearts challenged with global I/R (10/group) revealed 20 statistically significant metabolites between groups by ANOVA using Metaboanalyst ($p < 0.001$). Enrichment analysis of these metabolites for pathway-associated metabolic sets indicated a >10 fold enrichment for ammonia recycling and protein biosynthesis (L-Glutamic acid; L-Proline; L-Histidine; L-Serine; L-Aspartic acid; L-Glutamine) ($p < 4.05E-05$, FDR=0.0024). Subsequent comparison of the sedentary hearts post-I/R and exercise-trained hearts post-I/R further identified significant differences in metabolites related to Aminoacyl-tRNA biosynthesis and nitrogen metabolism (4) ($p < 1.24E-05$, FDR≤5.07E-4). **CONCLUSION:** These studies shed light on novel mechanisms in which exercise-induced cardioprotection occurs in I/R which complement both the mitochondrial stabilization and antioxidant mechanisms recently described. These findings also link protein synthesis and protein degradation (protein quality control mechanisms) with exercise-induced cardioprotection and mitochondrial susceptibility for the first time in cardiac I/R.

(No relationships reported)

Maximal fat oxidation (FOX_{Max}) is the exercise intensity at which the highest caloric expenditure is attributed to fat metabolism and appears to be influenced by aerobic capacity and obesity. Determining, directly or indirectly, FOX_{Max} holds relevance with respect to optimal intensity for exercise prescription for weight loss and maintenance. **Purpose:** To determine if FOX_{Max} is sex-dependent and its agreement with the anaerobic threshold (AT), another intensity at which exercise can be prescribed to improve aerobic conditioning. **Hypothesis:** We hypothesized that: 1) FOX_{Max} in obese men and women is similar; 2) FOX_{Max} is not concordant with AT; and 3) heart rate (HR) at FOX_{Max} relative to real peak HR (HR_{pk}) is equivalent to that relative to HR_{pk} predicted from a recognized prediction formula ($208-0.7 \times \text{age}$). **Methods:** Forty obese adults (BMI: $40.3 \pm 1.1 \text{ kg} \cdot \text{m}^{-2}$), women (OW, $n=20$) and men (OM, $n=20$), aged 20 to 45 years, underwent a cardiopulmonary exercise test (CPX). Oxygen uptake (VO_2), carbon dioxide production (VCO_2), respiratory exchange ratio (RER) and heart rate (HR) were measured at FOX_{Max} , AT and at the peak of the test (HR_{pk}). Fat oxidation rates were calculated ($FOX-R = 1.67 \times VO_2 - 1.67 \times VCO_2$) and the highest value was set as the FOX_{Max} . AT was defined according to the V-Slope method. T-test, MANCOVA and partial correlations were applied. α level was set at 0.05. **Results:** VO_2 at AT and FOX_{Max} were identified at 77.4 ± 1.4 and $58.6 \pm 1.2\%$ of VO_{2pk} and HR at $80.5 \pm 1.2\%$ and $68.6 \pm 1.0\%$ of HR_{pk} , respectively. Although VO_2 and HR at FOX_{Max} differed from AT for both groups ($p < 0.01$), sex-adjusted positive correlations between them were observed (FOX_{Max} vs AT for VO_2 [$r = -0.78$] and for HR [$r = -0.61$], < 0.01). Sex-based comparisons showed that OW had higher $FOX-R$, and at the AT higher HR, VO_2 percent of HR_{pk} and VO_{2pk} ($p < 0.05$). However, OM had a higher percent of VO_{2pk} at FOX_{Max} . Similar HR_{pk} , HR at FOX_{Max} and percent of HR_{pk} were observed in both groups. HR at FOX_{Max} relative to the predicted HR_{pk} from the formula $208-0.7 \times \text{age}$ were $66 \pm 1\%$ in OM and $67 \pm 1\%$ in OW. **Conclusions:** Sex differences exist at AT and FOX_{Max} for VO_2 . Meanwhile, chronotropic responses (HR) at FOX_{Max} are equal for both and can be inferred from a usual formula when CPX is unavailable. **Funding:** Fundação de Amparo à Pesquisa do Estado de São Paulo (2009/01842-0, 2013/15681-3), SP, Brazil.

582 **Board #2** May 31 1:00 PM - 3:00 PM
The Combined Effects Of Regular Activity Breaks And Physical Activity On Postprandial Metabolism

Meredith C. Peddie, Ashleigh R. Homer, Stephen P. Fenimore, Claire M. Cameron, Murray Skeaff, Nancy J. Rehrer, FACSM, Tracy L. Perry. *University of Otago, Dunedin, New Zealand.*
Email: meredith.peddie@otago.ac.nz
(No relationships reported)

Regularly interrupting sedentary behavior with short bouts of activity lowers postprandial glycemia, however, the effects on lipid responses are inconsistent. Additionally, little is known about how the effects of regular activity breaks and continuous physical activity may combine to affect postprandial metabolism. **Purpose:** To compare the effects of prolonged sitting and regular activity breaks with or without 30 min of continuous physical activity on postprandial metabolism. **Methods:** A randomized, crossover study was conducted; 36 adults (mean age 25 y (SD 3.9), BMI 23.9 (SD 3.9), VO_{2max} 36.2 (SD 9.2) $\text{mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$) completed the following four two-day interventions: Prolonged sitting on both days, without (SED+SED) or with (PA+SED) a 30 min bout of continuous walking ($60\% VO_{2max}$) at the end of day 1; sitting on both days interrupted with regular activity breaks (2 min walking every thirty minutes at $60\% VO_{2max}$), without (RAB+RAB) or with (PA+RAB) a 30 min bout of continuous walking ($60\% VO_{2max}$) at the end of day 1. Postprandial metabolic responses to a standardized test meal (0.71 g/kg CHO, 0.70 g/kg FAT, 0.32 g/kg PRO,

43.24 kJ/kg) were measured in venous blood samples over 5 h on day 2 - at baseline, 30 and 45 min, and then hourly. Plasma glucose, insulin, and triglycerides were used to calculate total area under the response curve (AUC). Mixed model regression was used to compare the effects of interventions on AUC.

Results: There was no effect of intervention on glucose AUC ($p=0.26$). Compared to SED+SED, insulin AUC was significantly lower in PA+SED (-15%; 95% CI -4, -24%; $p=0.01$), RAB+RAB (-11%; 95% CI 0, -20%; $p=0.05$) and PA+RAB (-23%; -12, -31%; $p<0.001$). PA+RAB lowered insulin AUC more than PA+SED (-13%; 95% CI -4, -22%; $p=0.01$). Neither PA+SED nor RAB+RAB alone affected triglyceride AUC. However, PA+RAB significantly lowered triglyceride AUC compared to both SED+SED (-0.74 $\text{mmol} \cdot \text{L}^{-1} \cdot 5\text{h}$; 95% CI -1.28, -0.20; $p=0.01$) and PA+SED (-0.67 $\text{mmol} \cdot \text{L}^{-1} \cdot 5\text{h}$; 95% CI -1.15, -0.19; $p=0.01$). **Conclusions:** The results indicated that all patterns of physical activity cause an acute improvement in insulin sensitivity. Regular activity breaks and physical activity combined provides the greatest improvements in insulin sensitivity, while also lowering postprandial lipids. Obesity is a major public health issue in the United States (US), affecting an estimated 78 million US adults. Aerobic exercise (AE) is recommended by the American College of Sports Medicine to prevent and treat obesity, yet the effect of AE on circulating hunger hormones, including ghrelin and its biological catalyst, ghrelin-o-acyltransferase (GOAT), are less known. **PURPOSE:** To determine the influence of AE on circulating GOAT in normal-weight (NW) and obese (OB) adults. **METHODS:** A preliminary power analysis was performed to detect a medium to large effect size with 80% power. A sample size of nine was determined to be able to detect a medium effect size of 0.50 with 84% power and was used as the pilot sample for this study. Of the pilot sample, four were NW (body mass index [BMI] = $21.3 \pm 1.3 \text{ kg/m}^2$) and five were OB (BMI = $38.9 \pm 6.2 \text{ kg/m}^2$). Physical characteristics were measured at baseline with a health fitness assessment. Participants then returned to the laboratory on three separate occasions, separated by 48 hours to perform AE and control sessions in a randomly counterbalanced order. AE sessions were performed on cycle ergometers at 30% and 60% oxygen uptake reserve for 40 minutes. Control sessions were performed with seated rest and no AE for 40 minutes. Fifteen mL of blood was taken pre-and-post-AE and pre-and-post-control and were assayed in duplicate. Mixed factorial analysis of variance (ANOVA) was used to determine whether mean differences existed between NW and OB for GOAT in response to AE and control. Alpha levels were set *a priori* at $p < 0.05$. **RESULTS:** No significant mean difference was found between NW and OB ($F[1, 4] = 0.66, p = 0.44$) AE and control ($F[2, 4] = 0.05, p = 0.96$), or the interaction between body weight and treatment condition ($F[1, 8] = 0.75, p = 0.49$). **CONCLUSION:** We found the change in GOAT to be similar between NW and OB across treatment and control conditions in this pilot study. Our findings indicate that further investigation of GOAT is warranted in combination with other appetite regulating hormones in response to exercise. Such investigations should expand upon our findings and implement study designs that include larger samples of men and women to better understand the role GOAT may play as a biological catalyst in the suppression of hunger. Two Weeks of Interval Training Improves Metabolic Flexibility and Glucose Tolerance in People with Prediabetes

Nicole M. Gilbertson, Natalie ZM Eichner, Jacquelyn R. Moxey, Julian M. Gaftan, Zhenqi Liu, Eugene J. Barrett, Arthur Weltman, FACSM, Steven K. Malin. *University of Virginia, Charlottesville, VA.* (Sponsor: Arthur Weltman, FACSM)
Email: nmg4xk@virginia.edu
(No relationships reported)

PURPOSE: Impaired metabolic flexibility is associated with hyperglycemia. Although exercise improves metabolic flexibility, the optimal exercise dose is unclear. Thus, we tested the effect of a 2-week interval (INT) vs. continuous (CONT) training intervention on fuel selection in relation to glucose tolerance in adults with prediabetes.

METHODS: Subjects (Age: 57.8±2.2y, BMI: 34.5±2.2kg/m²) were screened for prediabetes using the American Diabetes Association criteria (75g OGTT and HbA_{1c}). Subjects were randomized to 60 min/d of supervised INT (n=7; 90% HRmax for 3 min and 50% HRmax for 3 min) or work matched CONT (n=6, 70% HRmax) exercise for 12 bouts. Fitness (VO_{2max}), body composition (BIA), and glucose tolerance (180 min 75g OGTT) were assessed pre- and post-intervention. Respiratory exchange ratio (RER; indirect calorimetry) was measured at 0, 60, 120 and 180 min of the OGTT to assess fasting and post-prandial (average of 60-180 min) metabolic flexibility. **RESULTS:** INT and CONT training increased VO_{2max} (+2.06±0.53 vs. +0.48±1.06 mL/kg/min, P=0.04), decreased skeletal muscle mass (SMM; -0.51±0.12 vs. -0.33±0.15 kg, P=0.001), and reduced fasting RER (-0.05±0.02 vs. -0.03±0.01 a.u., P=0.01). However, only INT exercise lowered 2-hr plasma glucose (-10.43±6.10 vs. +9.50±12.55 mg/dL, P=0.03) and increased post-prandial RER (+0.003±0.02 vs. -0.051±0.02 a.u., P=0.10) when compared with CONT training. Decreased SMM was significantly correlated with increased 2-hr glucose (r=-0.59, P=0.04) and enhanced post-prandial RER (r=-0.61; P=0.04). **CONCLUSION:** Independent of fitness and despite reductions in muscle mass, INT training favorably shifts fasting fat oxidation and post-prandial carbohydrate use in people with prediabetes. This suggests that exercise dose may be important for glycemic control and type 2 diabetes prevention.

Rate of Response in Insulin and Glucose Measures to Different Exercise Amounts and Intensities

Louise de Lannoy, John Clarke, Paula Stotz, Robert Ross, FACSM, *Queen's University, Kingston, ON, Canada.* (Sponsor: Robert Ross, FACSM)
 Email: 13ldl2@queensu.ca
 (No relationships reported)

Variability in glucose and insulin response to exercise is a largely neglected phenomenon. Here we analyze this variability by measuring the rate of response, defined as the number of individuals with an improvement in glucose and insulin values beyond the day-to-day variability of measurement.

Purpose: To determine the separate effects of exercise amount and intensity on the rate of response for glucose and insulin variables.

Methods: Participants were 171 sedentary, middle-aged abdominally obese adults who completed at least 90% of 5 weekly exercise sessions prescribed over a 24-week intervention. Participants were randomly assigned to (1) no-exercise control (n=51), (2) low-amount, low-intensity exercise (LALI; n=38), (3) high-amount, low-intensity exercise (HALI; n=52), or (4) high-amount, high-intensity exercise (HAHI; n=30). Two-hour glucose level, insulin area under the curve (AUC), and fasting insulin were measured at 16 and 24 weeks in response to a 2-hour, 75g oral glucose tolerance test. Biological variability for these measures was calculated to be ±2.2 mmol/L, ±940.2 pmol/L, and ±38.9 pmol/L, respectively.

Results: At 24 weeks, the rate of response for 2-hour glucose was 2.0%, 13.2%, 5.8%, 13.3% in the control, LALI, HALI, and HAHI groups, respectively. The rate of response for insulin AUC was 12.0%, 21.6%, 25.0%, 20.0% in the control, LALI, HALI, and HAHI groups, respectively. The rate of response for fasting insulin was 11.8%, 15.8%, 15.4%, 6.7% in the control, LALI, HALI, and HAHI groups, respectively. The rate of response was not different between control and any of the exercise groups for 2-hour glucose, insulin AUC, and fasting insulin (p>0.05). Exposure to exercise did not affect the rate of response for 2-hour glucose or fasting insulin between 16 and 24 weeks (p>0.05). Exposure data was not available for insulin AUC.

Conclusion: There was substantial variability of response for all measures of insulin and glucose that was not reduced by increasing exercise amount or intensity, where a maximum of 25% of participants improved in these measures beyond the day-to-day variability. This observation underscores the importance of accounting for the variability of measurement when interpreting treatment efficacy for a given individual.

Interventions to Change Physical Activity Behavior in Type 2 Diabetes: A Systematic Review and Meta-analysis

Marjan Mosalman Haghghi, Yorgi Mavros, Maria A. Fiatarone Singh, *The University of Sydney, Sydney, Australia.* (Sponsor: Professor Glen Davis, FACSM)
 Email: mmos4344@uni.sydney.edu.au
 (No relationships reported)

Low physical activity (PA) is a modifiable risk factor for health outcomes in individuals with type 2 diabetes (T2D). Sustained increases in PA are required to improve metabolic health and cardiovascular risk in this cohort, but have been difficult to achieve or poorly measured.

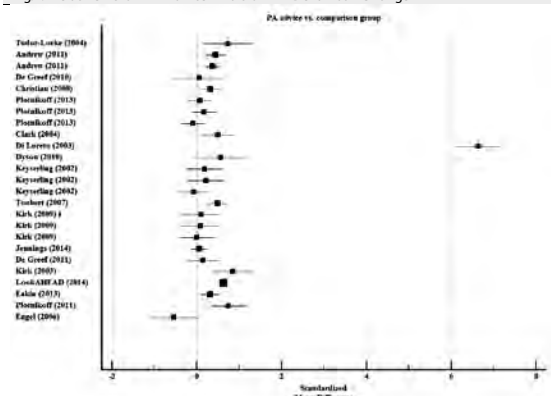

Purpose: To systematically review the effects of supervised exercise or lifestyle intervention including PA advice on long term PA in individuals with T2D.

Method: An electronic search of the literature was performed from earliest record to September 2016. Eligible trials were RCTs in T2D which included an objective or subjective measure of PA at baseline and at least one follow-up time point ≥ 6 months after enrolment. Mean differences, relative effect sizes (ES; Hedge's) and heterogeneity statistics (I²) were calculated using a random effects model.

Results: Among 107799 citations retrieved, 23 RCTs (including 18 RCTs of lifestyle advice and 5 RCTs of exercise) met the inclusion criteria (n=11673, 46.1% men, age 60.0 ± 4.0). All 5 exercise trials demonstrated increased PA relative to control [2/5 reported stable habitual PA plus an additional 3 d/week structured exercise; 3/5 reported moderate to large increases in total PA (relative ESs 0.6 to 1.5)]. The relative ESs for PA advice trials are shown in Fig 1 (pooling not appropriate; I² = 96%). Only 10/18 trials demonstrated significantly increased total PA (ES ranging from 0.3 to 0.8 and one very large ES of 6.6.) Subjective PA measurement was used in 60% of trials that reported significant increases in PA, vs. only 12.5% of non-significant trials.

Conclusion: Supervised exercise was associated with increased overall PA (inclusive of study-related and habitual activity levels) in T2D in 5/5 trials. By contrast, only 55% of PA advice trials reported significant increases in PA. This heterogeneity, plus reliance on subjective reporting methods, limits confidence in the efficacy and consistency of unstructured/unsupervised PA advice in T2D.

Fig.1. Relative ES of PA Advice Trials on PA Behaviour Change

 (No relationships reported)

PURPOSE: Muscle power declines with age and disease and predicts functional impairment. Although effective in some other cohorts, the benefits of high intensity, high velocity progressive resistance training (power training) on muscle strength, power, contraction velocity and lower limb function in older adults with type 2 diabetes has not been investigated.

METHODS: 103 overweight/obese older adults (>60 years) were randomized to receive high intensity power training [80% peak strength (1RM)] or sham-exercise, 3 days per week for 1 year. Peak muscle power, peak contraction velocity and 1RM were measured on Keiser knee extension (KE) and chest press (CP) machines before and after the intervention. Lower limb function was assessed using habitual and maximal gait speed, repeated chair stand and stair climb power. **RESULTS:** KE and CP 1RMs significantly increased following power training compared to sham-exercise [mean difference (CI) = 28.97 (5.17, 52.77) Nm and 75.99 (40.25, 111.74) N respectively]. Similar results were observed for KE and CP peak power [mean difference = 75.83 (35.82, 115.84) W and 26.77 (6.30, 47.24) W, respectively]. No effects were observed for changes in contraction velocity for KE or CP (p<0.05). Both groups showed similar improvements in habitual and maximal gait speed and chair stand time (p<0.05). Increases in KE peak power were explained by increases in KE 1RM (r=0.32, p=0.003), but not changes in KE contraction velocity (r=0.12,

$p=0.26$). In contrast, increases in CP peak power were explained by increases in CP contraction velocity ($r=0.52$, $p<0.001$) but not increases in CP 1RM ($r=0.17$, $p=0.26$). Neither changes in KE 1RM nor peak power were associated with changes in lower limb function. **CONCLUSIONS:** 1 year of power training significantly improved upper and lower body strength and power in older adults with type 2 diabetes. Improvements in lower limb power were associated with increases in strength but not contraction velocity. Conversely, improvements in upper limb power were associated with increases in contraction velocity but not strength. Unexpectedly, improvements in lower extremity function were not associated with changes in lower leg strength or power, suggesting that unaddressed factors such as obesity may have attenuated the benefits of power training on functional performance.

Randomized Controlled-Trial of Milk and High-Intensity Interval Training on Metabolic Health in Type 2 Diabetes

Monique E. Francois, Cody Durrer, Jonathan P. Little. *University of British Columbia, Kelowna, BC, Canada.*
 (No relationships reported)

Milk consumption post-exercise may provide additional lean mass gains and body fat loss. Such favorable body composition changes could promote further improvements in glycemic control and quality of life (QoL) in exercising older adults with type 2 diabetes (T2D).

Purpose: To determine if the addition of post-exercise low-fat milk to high-intensity interval training (HIIT) improves metabolic health more than HIIT and isolated milk-protein, or HIIT alone.

Methods: In a proof-of-concept, randomized double-blind controlled trial, 47 adults with physician-diagnosed T2D (58 ± 10 y, A1c: $7.1 \pm 0.8\%$, BMI: 35 ± 7 kg/m²) were randomly assigned to one of three nutritional beverages (500 mL skim-milk, milk-protein isolate or flavored water placebo) after HIIT exercise (2x cardio- and 1x resistance-based / wk) for 12 weeks. Body composition (dual-energy X-ray absorptiometry), glycemic control (hemoglobin A1c, continuous glucose monitoring) and QoL (SF-36) were measured before and after the intervention. Inferential analyses for clinical chances were performed using the spreadsheet at www.newstats.org.

Results: There were main effects of time but no group X time interactions. All results are therefore presented as main effects of time with groups collapsed, with probability of change being clinically beneficial shown for select variables. Body mass was unchanged (-0.8 ± 3.2 kg, $p=0.13$), however, lean mass ($+1.3 \pm 2.9$ kg, $p<0.01$, *likely beneficial*) and percent body fat ($-0.85 \pm 1.6\%$, $p<0.01$, *possibly beneficial*) were improved in all groups. Hemoglobin A1c ($-0.2 \pm 1.6\%$, $p<0.01$, *most likely trivial*), 24-h mean glucose (-0.4 ± 1.2 mmol/L, $p=0.04$) and glycemic variability (MAGE: -1.1 ± 2.9 , $p=0.02$) were reduced. QoL also increased (95%CI: $+5.3-17\%$, *most likely beneficial*) after HIIT.

Conclusion: The consumption of milk or protein after HIIT does not result in additional benefits for metabolic health compared to HIIT alone. In line with current evidence, HIIT is a potent stimulus for improving several aspects of metabolic health in patients with type 2 diabetes.

Leisure Time Physical Activity Among U.S. Adults with Elevated Symptoms of Attention Deficit Hyperactivity Disorder

Kathryn Fritz, 30606, Ashlyn Powell, Patrick J. O'Connor, FACSM. *University of Georgia, Athens, GA.* (Sponsor: Patrick O'Connor, FACSM)
 Email: kmfritz@uga.edu
 (No relationships reported)

Physical activity in adults with elevated ADHD symptoms is understudied. **PURPOSE:** This study surveyed U.S. adults with elevated ADHD symptoms for the purpose of (i) describing their leisure time physical activity (LTPA) and (ii) quantifying relationships between LTPA and ADHD symptoms. **METHODS:** 3,111 Amazon Mechanical Turk workers reported their age online and completed the six-item Adult ADHD Self-Report Scale-V1.1 Screener (ASRS). 228 adults screened positive for ADHD and completed

45 questions about demographics, health and physical activity. 221 individuals were included in the final analysis because 7 were excluded as outliers (≥ 5 SD above mean) or for responding incorrectly on the Godin. **RESULTS:** The sample was 56% female and 82% Caucasian with 83% between the ages of 18 and 59 years; 33% had some college and 30% were college graduates. Most respondents reported no current ADHD diagnosis (75%) or medication use to treat ADHD symptoms (83%). ADHD medication use was unrelated to the LTPA (all p values $> .40$). Past week physical activities were: walking (88% of sample), home activities (63%), stretching (35%), jogging (34%), weight lifting (30%), yardwork (27%), bicycling (22%), home repair (20%), yoga/mind-body (19%), gardening (16%), swimming (15%), sports (14%), playing music (9%), social dance (5%), aerobic dance (4%) and fishing/hunting (4%). Compared to men, women reported significantly less strenuous ($t=3.43$, $p=.001$) and overall LTPA ($t=2.886$, $p=.004$), including less engagement in home repair activities ($t=2.493$, $p=.014$), jogging ($t=2.204$, $p=.029$), sports ($t=2.188$, $p=.03$), music ($t=2.119$, $p=.036$) and bicycling ($t=2.012$, $p=.046$). Log transformed total LTPA scores were significantly ($p<.05$) related to ASRS question 2 (difficulty getting organized, $r=-.18$), the inattention subscale ($r=-.18$) and total ASRS scores ($r=-.17$). **CONCLUSION:** In a sample of U.S. adults with elevated symptoms of ADHD, LTPA is low and physical activity modes are similar when compared to U.S. samples of adults without ADHD. ADHD symptoms are negatively related to LTPA and unrelated to ADHD medication use.

Effects Of Aerobic Exercise Intensity On Acute Serum Levels Of Bdnf In Patients With Depression

Jorn Heggelund¹, Ole Christian Mehlum², Andreas Brabrand², Mona Nygaard², Einar Vedul-Kjelsaas¹, Ismail Cüneyt Güzey¹.
¹St. Olavs University Hospital, Trondheim, Norway. ²Norwegian University of Science and Technology, Trondheim, Norway.
 Email: jorn.heggelund@ntnu.no
 (No relationships reported)

Serum level of brain-derived neurotrophic factor (BDNF) is reduced in patients with depression and improved BDNF has been linked to antidepressant response. Aerobic endurance training increases BDNF levels but it is unknown whether this response is intensity dependent in patients with clinical depression.

Purpose: To examine the changes in serum BDNF levels after high aerobic intensity training (HIT) compared to long slow distance training (LSD). **Methods:** In an intraindividual design, 16 patients (6 women/10 men; 36 ± 11 yrs) with depression (ICD-10: F32-F33) performed the LSD and HIT with an interval of one week. HIT was warm up at 60-70 % of HR_{max} for 10 min, followed by 4x4 min intervals at 85-95 % of maximal heart rate (HR_{max}), intermitted by 3 min active rest periods at 60-70 % of HR_{max}. LSD was continuous running or walking for 45 min at 60-70 % of HR_{max}, with similar caloric expenditure as HIT. Blood samples were taken 5-10 min before each training session and within 3 min after completing the last 4 min interval (HIT) or upon completion of the LSD session. **Results:** Increase in serum BDNF after HIT was more pronounced compared to LSD ($p < 0.001$; Cohen's $d = 2.81$). Baseline BDNF levels were 32.11 ± 6.24 ng/mL and 30.62 ± 5.61 ng/mL in LSD and HIT, respectively. **Conclusion:** The serum BDNF response to aerobic exercise is intensity dependent in patients with clinical depression.

The Effects of Exercise Training on Anxiety in Fibromyalgia Patients: A Quantitative Synthesis

Cillian P. McDowell¹, Dane B. Cook, FACSM², Matthew P. Herring¹. ¹University of Limerick, Limerick, Ireland. ²University of Wisconsin, Madison, WI. (Sponsor: Dr Dane Cook, FACSM)
 Email: cillian.mcdowell@ul.ie
 (No relationships reported)

Physical inactivity and comorbid anxiety symptoms are prevalent among fibromyalgia (FM) patients. Exercise training may be an effective alternative therapy to reduce these symptoms. **Purpose:** To evaluate the effects of exercise training on anxiety symptoms in patients with FM, and to examine whether variables of theoretical or practical importance moderate the estimated mean effect. **Methods:** Twenty-five effects were derived from 10 articles published before June 2016 located using Google Scholar, MEDLINE, PsycINFO, PubMed, and Web of Science. Trials involved 2,914 patients with FM and included both randomization to exercise training or a non-active control condition and an anxiety outcome measured at baseline and during and/or after exercise training. Hedges' d effect sizes were computed, data for moderator variables were extracted, and random effects models were used to estimate sampling error and population variance for all analyses. Meta-regression quantified the extent to which patient and trial characteristics moderated the mean effect. **Results:** Exercise training significantly reduced anxiety symptoms by a mean effect Δ of 0.28 (95%CI: 0.16-0.40). No significant heterogeneity was observed ($Q_w=30.79$; $P=0.16$; $I^2=25.29\%$). Program duration ($\beta=1.44$; $z=2.50$; $p \leq 0.01$) was significantly related to the overall effect, with significantly larger anxiety improvements resulting from programs lasting greater

than 26 weeks ($\Delta=0.35$; 95%CI, 0.05-0.66) compared with those lasting less than 26 weeks ($\Delta=0.26$; 95%CI, 0.13-0.39). Session duration ($\beta=-0.53$), frequency ($\beta=-0.25$), intensity ($\beta=0.23$), control ($\beta=0.66$), anxiety recall time frame ($\beta=0.07$), and exercise setting ($\beta=0.45$) were not significantly related to effect size (all $p \geq 0.07$). **Conclusion:** Exercise training improves anxiety symptoms among FM patients. Thus, in addition to the physical benefits of exercise, persons with FM should be encouraged to exercise as a potential low-risk, adjuvant treatment for anxiety symptoms. The findings also suggest that larger anxiety symptom reductions will be achieved by focusing on longer exercise programs while promoting long-term adherence. Future well-designed investigations are required to examine the potential moderating effect of pain-related improvements in FM patients.

Comparison of Physical Activity and Sports Participation in Children With and Without Autism Spectrum Disorder

Jeanette M. Garcia¹, Kayla M. Baker¹, David J. Rice², Sean Healy³. ¹University of Central Florida, Orlando, FL. ²Florida Southern College, Lakeland, FL. ³Humboldt State University, Arcata, CA.
 Email: jeanette.garcia@ucf.edu
 (No relationships reported)

PURPOSE: To compare psychosocial factors associated with physical activity and participation in sports between children with Autism Spectrum Disorder (ASD) and typically developing (TD) children.
METHODS: The sample consisted of 49 nine-year old children with ASD (85% male) and 70 nine-year old TD children (85% male) who were part of a large, national study, the Growing Up in Ireland Study, which examined a series of demographic, behavioral, and psychosocial variables in children. Children and parents completed questionnaires that asked about their physical activity (PA), participation in sports, social factors (friends, bullying), and psychological variables (perception of intelligence, popularity, happiness, anxiety). T-tests compared differences between activity and psychosocial variables in children with ASD and TD children, while multiple regression examined which factors were associated with PA and sports participation.
RESULTS: Independent samples t-tests revealed that children with ASD had lower amounts of PA ($p=.01$), spent less time with friends ($p=.0001$), had fewer close friends ($p<.0001$), viewed themselves as less popular ($p<.0001$), reported greater feelings of anxiety ($p=.01$), and were less likely to participate in sports ($p=.002$). Regression analyses indicated that being a victim of bullying ($\beta=-.28$, $p=.03$) was associated with lower levels of PA in TD children, with a trend towards greater perceptions of popularity ($\beta=.1$, $p=.08$) associated with greater levels of PA. Children who were victims of bullying also reported less sports participation ($\beta=-.23$, $p=.03$). In children with ASD, greater time spent with friends ($\beta=.45$, $p=.0006$) and greater perceptions of intelligence ($\beta=-.2$, $p=.004$) were associated with greater levels of PA, while none of the psychosocial variables were associated with sports participation.
CONCLUSIONS: Children with ASD have lower levels of PA and sports participation than TD children. Interventions aimed to increase PA in children with ASD need to take into account differences in psychosocial factors associated with PA compared to TD children.

594 Board #5 May 31 1:00 PM - 3:00 PM
Exercise Induced Analgesia in Survivors of Cancer

Briana Clifford¹, Benjamin Barry¹, David Simar¹, David Goldstein². ¹University of New South Wales, Sydney, Australia. ²Prince of Wales Hospital, Sydney, Australia.
 Email: b.clifford@unsw.edu.au
 (No relationships reported)

PURPOSE: Chronic pain of varying origins is experienced by potentially greater than 50% of cancer survivors. Associated with reduced physical function and reduced health-related quality of life, it is a significant barrier to initiating and continuing exercise for cancer survivors. Aerobic exercise has been shown to have an acute analgesic effect demonstrated by a reduction in subjectively reported pain, or an increase in pain thresholds, for 10 to 30 minutes immediately following exercise. The hypoalgesic effect of exercise has been well demonstrated in healthy populations as well as some chronic diseases, but has not yet been investigated for cancer survivors. The aim of the current study is to investigate if cancer survivors experience an analgesic response to an acute bout of exercise, and if this response changes after repeated exercise sessions.
METHODS: Participants ($n = 6$) who had a diagnosis of breast, colorectal or prostate cancer who were 3-12 months post completion of primary treatment (hormone therapy excepted) were included in this study. Six participants completed individualised test bout of exercise (30-70% HRR, duration 15-20min). Pain thresholds were measured using an algometer over the rectus femoris muscle of the leg before and after the exercise. Five participants repeated the test exercise bout following a 2-week training period of 6 exercise sessions. Questionnaire measures of pain were also recorded using pain specific subscale from the SF-36 (0-100, 100=best).

RESULTS: The participants variously reporting being impacted by pain (SF-36 bodily pain 59.4 ± 8.1 range: 22.5 - 100) during the 4 weeks before testing commenced. Following two weeks of training, bodily pain was reported as 41.9 ± 23.8 out of 100. Pressure pain thresholds increased after exercise on day 1 (Mean diff \pm SD: 0.54 ± 0.40 kg/cm²; Cohens d (95% CI): 0.2 (0.04 - 0.49), $p<0.05$), indicative of exercise-induced hypoalgesia. This response was similar following 2 weeks of training (mean \pm SD: 0.52 ± 0.09 kg/cm²; Cohens d (95% CI): 0.43, $p<0.001$). **CONCLUSIONS:** Cancer survivors experienced an analgesic response to a single bout of exercise. This response was stable across a 2 week training period, despite higher levels of self-reported bodily pain.

595 Board #6 May 31 1:00 PM - 3:00 PM
Physical Activity and Brain Responses during Pain Modulation in Gulf Veterans with Chronic Muscle Pain

Aaron J. Stegner¹, Laura D. Ellingson², Stephanie M. Van Riper¹, Dane B. Cook, FACSM³. ¹University of Wisconsin-Madison, Madison, WI. ²Iowa State University, Ames, IA. ³William S. Middleton Memorial Veterans Hospital, Madison, WI. (Sponsor: Dane B. Cook, FACSM)
 (No relationships reported)

Chronic medically unexplained muscle pain (CMP) is a primary complaint among the more than 200,000 US Gulf War Veterans (GVs) currently suffering from debilitating multisymptom illnesses. Veterans of the more recent Iraq War are also dealing with CMP. Previously our lab demonstrated a positive relationship between physical activity (PA) and brain responses to pain modulation (PM) in civilian CMP patients. We also reported significant correlations between PA and behavioral indices of PM in healthy GV's. The relationship between PA and the underlying brain responses during PM, however, has not been thoroughly explored. **PURPOSE:** To examine the association between brain responses during PM and objectively-measured PA in GV's with and without CMP. **METHODS:** Twenty two GV's (12 CMP; 10 healthy) underwent thermal pain testing with and without distraction during an fMRI scan. Veterans were exposed to 15 heat stimuli (20 s) relativized to 'slightly intense' pain. Stimuli were administered alone or with distraction (i.e., congruent [CS] and incongruent versions [IS] of the Stroop Task). Pain intensity and unpleasantness ratings were collected for each stimulus. PA was assessed with hip-mounted accelerometers worn for a week. Brain responses during PM were modeled using SPM12 and correlated to six PA indices derived from the PA data. Voxel-level significance was set to 0.005 with a minimum cluster size of 330 mm³. **RESULTS:** Ratings of pain with distraction, CS and IS, were significantly ($p<0.01$) reduced compared to without for both groups. During CS, healthy GV's exhibited a positive correlation between activity in the right precentral gyrus during PM and sedentary minutes, while activity in the middle and prefrontal cortices was negatively related to PA at light, moderate and vigorous intensities. For IS, positive correlations were found between activity in the contralateral insula and indices of low intensity PA. GV's with CMP had only a negative correlation between activity in the right anterior cingulate cortex during CS and minutes spent in activities of daily living. **CONCLUSIONS:** Pain modulation during distraction appears uncompromised in GV's with CMP. However, the influence of PA on modulatory responses seems diminished in GV's with CMP compared to their healthy peers. Supported by Dept. of Veterans Affairs grant: 561-00436

Associations Between Physical Activity, Flourishing, Bullying And Emotional Difficulties In Children Autism

Stephanie M. McCoy, Joann Judge. University of Southern Mississippi, Hattiesburg, MS.
 (No relationships reported)

Physical activity (PA) is a significant indicator of present and future health in adolescents. However, it is unknown whether engaging in regular PA is associated with measures of child flourishing as well as bullying and emotional difficulties in children with autism spectrum disorder (ASD). **PURPOSE:** To examine associations between physical activity levels and measures of child flourishing as well as bullying and emotional difficulties. **METHODS:** Analyses include 1,363 (82% male) aged 6-17 (mean 11.54 ± 3.29 years) with ASD from the 2011-12 National Survey of Children's Health. Adolescents were grouped into two categories: those who engaged in regular PA (≥ 3 days/week) and those who did not engage in regular PA. Outcomes included emotional difficulties (excessive arguing and unhappiness) bullying or being cruel to others, and measures of flourishing (finishing tasks, staying calm and in control when faced with a challenge, showing interest in learning new things, and caring about doing well in school). Logistic regression models, adjusted for age, sex, gender, household income, and education assessed the odds of each outcome comparing those who engaged in regular PA to those who did not. **RESULTS:** Unadjusted prevalences showed that 69% of those with ASD were regularly physically active (≥ 3 days/week). Regular physical activity was not associated with excessive arguing, bullying or being cruel to others, or unhappiness. Those with ASD who participated in regular PA were 58% more likely to finish tasks (OR=1.58; $p=0.001$) compared to those who did not

WEDNESDAY, MAY 31, 2017

engage in regular PA. Additionally, those who engaged in regular PA were 44% more likely to stay calm and in control when faced with a challenge (OR=1.44; $p=0.007$). Furthermore, those who engaged in regular PA were 75% more likely to show interest and curiosity in learning new things (OR=1.75; $p=0.006$), and 65% more likely to care about doing well in school (OR=1.65; $p=0.004$) compared to those who did not engage in regular PA. **CONCLUSIONS:** Children with ASD that engaged in regular PA were significantly more likely to finish tasks, stay calm when faced with a challenge, show interest and curiosity in learning new things, and care about doing well in school. These findings suggest engaging in regular PA may increase flourishing in children with ASD.

Acute Exercise Effects on Mood Among Young Adults with Worry Symptoms Indicative of Generalized Anxiety Disorder
 Matthew P. Herring¹, Mats Hallgren², Mark J. Campbell¹.
¹University of Limerick, Limerick, Ireland. ²Karolinska Institutet, Stockholm, Sweden.
 Email: matthew.herring@ul.ie
 (No relationships reported)

Evidence supports the effects of exercise training on clinical severity, associated signs and symptoms, dimensions of sleep quality and quantity, and health-related quality of life among individuals with Generalized Anxiety Disorder (GAD). However, little is known about the acute effects of exercise among individuals with clinical or subclinical GAD.

Purpose

This study quantified mood responses to either acute aerobic exercise or quiet rest, examined potential sex-related differences in response, and explored potential moderators of response among young adult men and women with worry symptoms indicative of GAD.

Methods

Twenty-five young adults (8 males; 17 females; 21.1±1.3y) with Penn State Worry Questionnaire scores ≥45 (58±8) completed two 30-min conditions in counterbalanced order: vigorous treadmill running or seated quiet rest. Outcomes included worry symptoms, state anxiety, feelings of tension, depression, anger, energy, fatigue, and confusion, and total mood disturbance. RM-ANOVA examined differences across condition and time and between males and females. Hedges' *d* effect sizes (95%CI) were calculated to quantify and compare the magnitude of change in response to exercise compared to control. Regression explored potential moderators of mood response.

Results

Average heart rate was 163±5.4 bpm and participants reported an average session RPE of 13±2 (range: 9 to 17). Compared with control, acute exercise significantly improved state anxiety, feelings of depression, anger, energy, fatigue, and confusion, and total mood disturbance (all $p\leq 0.04$). Moderate-to-large improvements were found for anger ($d=0.57$, 95%CI: 0.01, 1.13), fatigue ($d=0.67$, 95%CI: 0.10, 1.24), confusion ($d=0.87$, 95%CI: 0.29, 1.45), and energy ($d=0.87$, 95%CI: 0.29, 1.45), and total mood disturbance ($d=1.10$, 95%CI: 0.50, 1.69). The magnitude of improvements were greater (i.e., larger effect sizes) among men for all outcomes except feelings of energy and fatigue and worry symptoms. High trait anxiety, depression, and poor sleep did not moderate exercise effects (all $p>0.10$).

Conclusion

Findings provide initial support for both the positive effects of acute aerobic exercise on mood and potential sex-related differences in exercise effects among young adults with worry symptoms indicative of GAD.

B-10 Thematic Poster - Growing Up Active: Physical Activity in Youth

Wednesday, May 31, 2017, 1:00 PM - 3:00 PM

Using Accelerometry To Measure Physical Activity Opportunities During The School Day In Rural Elementary Schools.
 Evan Hilberg¹, Patrick Abi Nader², John M. Schuna, Jr¹, Deborah John¹, Katherine B. Gunter, FACSM¹. ¹Oregon State University, Corvallis, OR. ²Université de Moncton, Moncton, NB, Canada.
 (Sponsor: Katherine Gunter, FACSM)
 (No relationships reported)

Physical activity (PA) guidelines for children recommend accruing 60 minutes or more of moderate to vigorous physical activity (MVPA) per day. Rural children accumulate the majority of their PA at school, so PA opportunities, such as physical education (PE), recess, and classroom-based PA (CBPA) in the rural school environment are critical for this population. There is limited research exploring these PA opportunities in the rural elementary school setting to understand which opportunities provide the most MVPA. **PURPOSE:** To determine the proportion of time rural children spend at different intensities during three specific PA opportunities available during the school day: PE, recess, and CBPA. **METHODS:** Objectively measured PA levels were collected over a period of four school days at six rural elementary schools using research-grade accelerometers. Accelerometers were worn on the waist during school hours by 292 children (grades 1-5). Daily wear times and school schedules were provided by teachers and were matched to the children's accelerometer data to determine the amount of time spent at different intensities during each PA opportunity. ANOVA was used to detect differences with an alpha level of 0.05. **RESULTS:** The average duration for each PA opportunity was 44 minutes of recess, 32 minutes of PE, and 19 minutes of CBPA. Children in our sample of rural elementary schools spent 18 ± 14% (M±SD) of recess time in MVPA, 16 ± 15% of PE in MVPA, and 11% ± 15% of CBPA in MVPA. Boys engaged in higher levels of MVPA than girls across all PA opportunities ($p<0.001$). First grade children accrued more time in MVPA across domains when compared to their fifth grade counterparts ($p<0.001$). Sedentary and light intensity activities were higher for older children and girls ($p<0.001$). **CONCLUSION:** Scheduling PA opportunities with the highest proportion of MVPA may be an effective method to increase activity in rural elementary school children. This sample of children are not meeting the recommendations of 50% for proportion of time spent in MVPA during recess and PE. Targeting approaches to increase MVPA during these already scheduled opportunities may help children reach daily recommendations. Supported by a grant from the National Institute of Food and Agriculture, U.S. Department of Agriculture, under award number 2011-68001-30020.

Infancy Weight Gain And Fat Mass In Youth- Does Physical Activity Modify The Association?
 Guro P. Bernhardsen, Trine Stensrud, Ulf Ekelund, FACSM.
 Norwegian School of Sport Sciences, Oslo, Norway. (Sponsor: Jorunn Sundgot-Borgen, FACSM)
 Email: g.p.bernhardsen@nih.no
 (No relationships reported)

Rapid weight gain in infancy has been linked to increased risk of obesity in youth. Hence, an increased knowledge on possible strategies to prevent excessive total fat mass (total FM) and trunk fat mass (trunk FM) is important to avoid development of obesity. One possible strategy could be moderate-to-vigorous physical activity (MVPA) or vigorous physical activity (VPA), since MVPA and VPA has been associated with lower levels of adiposity. However, it is unknown whether physical activity may modify the association between rapid infant weight gain and later adiposity. **PURPOSE:** To examine whether MVPA and VPA modifies the associations between weight gain the first year of life and total FM and trunk FM in youth. **METHODS:** We used data from a sub-cohort of the Norwegian Mother and Child Cohort Study (MoBa), including assessment of total FM and trunk FM by dual-energy X-ray absorptiometry (DXA), and MVPA (≥2296 cpm) and VPA (≥4012 cpm) assessed by Actigraph accelerometers. Weight gain was calculated as change in weight z-scores between birth and 1 year. We used multiple regression analyses to examine the association between infancy weight gain and total FM and trunk FM (with adjustments for sex, birth weight, gestational age, height and family income), and included the interaction term weight gain x MVPA and weight gain x VPA to

examine the modifying effect of MVPA and VPA (adjustments for monitor wear time included). **RESULTS:** The mean age (sd) of the 147 participants (45.6% girls) were 11.0 (0.61) years. There was a positive association between infancy weight gain and total FM (B=1.1, 95%CI= 0.40, 1.8) and trunk FM (B=0.5 95%CI= 0.16, 0.89). MVPA did not modify the association between infancy weight gain and total FM (p=0.157) and trunk FM (p=0.116), whereas VPA modified both total FM (B (gain x VPA) = -0.061, p=0.026) and trunk FM (B(gain x VPA)= -0.034, p=0.014). **CONCLUSION:** These findings indicate that VPA, but not MVPA, modifies the associations between weight gain during the first year of life and total FM and trunk FM in youth. Vigorous intensity PA may be considered as one of many public health strategies to curb childhood obesity, especially in those who are prone to obesity due to rapid infant weight gain.

Physical Activity And Markers Of Inflammation In Children

Runar Solberg¹, Sigmund Alfred Anderssen, FACSM¹, Elin Kolle¹, Ulf Ekelund, FACSM¹, Jostein Steene-Johannessen².

¹Norwegian School of Sports Sciences, Oslo, Norway.

²Kristiania, Universit College, Norwegian School of Sports Sciences, Oslo, Norway. (Sponsor: Jorunn Sundgot Borgen, FACSM)

Email: runar.barstad.solberg@gmail.com

(No relationships reported)

Inflammatory markers have been linked to adiposity, atherosclerosis and risk factors for development of cardiovascular disease. Regular physical activity (PA) is associated with potential benefits for many health outcomes. However, few studies have examined the associations between objectively assessed PA and inflammatory markers in healthy children. Moreover, these studies often include small sample sizes and few inflammatory markers.

PURPOSE: To examine the associations of objectively measured overall PA (counts per minute, CPM), moderate-to-vigorous PA (MVPA) and vigorous PA (VPA) with markers of inflammation in children.

METHODS: Of the 1467 children invited in 2005-2006, 1306 children participated, giving an overall participation rate of 89%. Inflammatory markers were; C-reactive protein (CRP), leptin, adiponectin, plasminogen activator inhibitor-1 (PAI-1), tumor necrosis factor α (TNF α) and interleukin-6 (IL-6). PA was assessed objectively by accelerometry (ActiGraph 7164). Outcomes variables were overall PA (CPM) as well as time spent in MVPA (> 2000 CPM) and VPA (> 6000 CPM). We used linear regression analysis to examine the association between PA and inflammatory markers, and one-way analysis of variance to analyze differences between groups. **RESULTS:** Time spent in VPA was negatively associated with CRP (β = -0.162), PAI-1 (β = -0.138) and leptin (β = -0.208) ($p < 0.001$ for all) after adjustment for sex. Further, there was a significant negative association between overall PA (CPM) and MVPA with CRP, PAI-1 and leptin ($p < 0.05$ for all), although the magnitude of association was less pronounced compared with VPA. We observed a graded association of CRP, PAI-1 and leptin across tertiles of VPA ($p \leq 0.01$ for all). **CONCLUSIONS:** Our results show that PA were negatively associated with inflammatory markers in Norwegian nine-year old children. Despite this being a cross-sectional study, the results indicate the importance of overall PA level. The association was most pronounced for VPA, suggesting that vigorous intensity activity may be more beneficial than moderate intensity in relation to inflammatory markers.

Moderate-to-vigorous Physical Activity Predicts Change In Clustered Cardio-metabolic Risk In 10-year-old Children

Turid Skrede¹, Mette Stavnsbo¹, Eivind Aadland¹, Katrine Nyvoll Aadland¹, Sigmund Alfred Anderssen², Geir Kåre Resaland¹, Ulf Ekelund, FACSM². ¹Sogn og Fjordane University College, Sogndal, Norway. ²Norwegian School of Sport Sciences, Oslo, Norway.

Email: turid.skrede@hisf.no

(No relationships reported)

PURPOSE: Examine the independent, prospective associations between objectively measured sedentary time and sub-components of physical activity with individual and clustered cardio-metabolic risk factors in 10-year-old healthy children.

METHODS: We included 700 boys and girls in which sedentary time, and physical activity were measured by accelerometry. Systolic blood pressure, waist circumference and fasting blood sample (total cholesterol, high-density cholesterol, triglycerides, glucose, fasting insulin) were measured by standard clinical methods and analysed individually and as a clustered cardio-metabolic risk score standardized by age and sex (z score). Exposure and outcome variables were measured at baseline and at follow-up seven months later.

RESULTS: Sedentary time was not associated with any of the individual cardio-metabolic risk factors nor clustered cardio-metabolic risk in prospective analyses. Moderate physical activity at baseline predicted higher levels of triglyceride (β -0.086 (-0.160 - -0.013, $p=0.021$) and insulin resistance (β -0.070 (-0.132 - -0.008, $p=0.027$) at follow-up independent of sex, socio-economic status, Tanner stage, monitor wear time, and waist circumference. One SD increase in moderate-to-vigorous physical activity predicted 0.056 SD lower clustered cardio-metabolic risk at follow-up ($p=0.043$). However, these associations were attenuated following adjustment for waist circumference.

CONCLUSIONS: Physical activity, but not sedentary time, is prospectively associated with cardio-metabolic risk in healthy children. Public health strategies aimed at improving children's cardio-metabolic profile should strive for increasing levels of physical activity of at least moderate intensity rather than reducing sedentary time.

603 Board #5 May 31 1:00 PM - 3:00 PM

High And Low Impact Physical Activity Substitution And Pediatric Bone Density

Jonathan A. Mitchell¹, Diana L. Cousminer¹, Alessandra Chesi¹, Shana E. McCormack¹, Heidi J. Kalkwarf², Joan M. Lappe³, Vicente Gilsanz⁴, Sharon E. Oberfield⁵, John A. Shepherd⁶, Andrea Kelly¹, Struan FA Grant¹. ¹Children's Hospital of Philadelphia, Philadelphia, PA. ²Cincinnati Children's Hospital Medical Center, Cincinnati, OH. ³Creighton University, Omaha, NE. ⁴Children's Hospital of Los Angeles, Los Angeles, CA. ⁵Columbia University Medical Center, New York, NY. ⁶University of California San Francisco, San Francisco, CA.

Email: mitchellj2@email.chop.edu

(No relationships reported)

PURPOSE: To determine if substituting time spent in high and low impact physical activity (PA) associated with changes in pediatric bone mineral density (BMD) and content (BMC).

METHODS: We analyzed data from the longitudinal Bone Mineral Density in Childhood Study (N=1,856 with up to 7 visits). Spine, total hip, and femoral neck areal BMD (aBMD) and total body less head (TBLH) BMC were measured by DXA, with sex and age specific Z-scores, adjusted for height calculated. Hours per day (h/d) spent in total, high impact, and low impact PA were self-reported. Partition and isotemporal substitution-modeling frameworks were applied to linear mixed models; the latter framework to test how substituting high for low impact PA (and vice versa) affects bone health in an observational study. Statistical interactions with sex, self-reported race (Black or non-Black), genetic ancestry (African, European or Asian), and bone fragility genetic scores for Europeans only (percentage of BMD lowering alleles carried at 63 common loci and at 18 WNT signaling loci) were separately tested.

RESULTS: In partition models, high impact PA was positively associated with each aBMD bone Z-score (e.g., total hip aBMD: $\beta=0.05$, $P=5.5 \times 10^{-14}$) and TBLH-BMC Z-score ($\beta=0.05$, $P=4.0 \times 10^{-22}$), whereas low impact PA was not associated with each aBMD bone Z-score (e.g., total hip aBMD: $\beta=0.00$, $P=0.878$) and TBLH-BMC Z-score ($\beta=0.01$, $P=0.125$). In isotemporal substitution models, replacing 1 hour per day of low impact PA for high impact PA was associated with an increase in each aBMD bone Z-score (e.g., total hip aBMD: $\beta=0.05$, $P=1.6 \times 10^{-8}$) and TBLH-BMC Z-score ($\beta=0.06$, $P=4.2 \times 10^{-15}$). Conversely, the opposite 1 hour per day substitution was associated with a decrease in each aBMD bone Z-score (e.g., total hip aBMD: $\beta=-0.05$,

$P=1.6 \times 10^{-8}$) and TBLH-BMC Z-score ($\beta=-0.06$, $P=4.2 \times 10^{-15}$). The substitution associations were similar by sex and race, genetic ancestry, the common variant genetic score, and the WNT signaling genetic score (interaction P-values >0.05).

CONCLUSION: Dedicating a significant proportion of daily PA to high impact activities is beneficial to the growing skeleton for all children. Importantly, replacing low impact PA with more high impact PA is beneficial even for European children genetically predisposed to bone fragility.

Sedentary Time and Anthropometric Characteristics Among Hispanic Children in Puerto Rico

Marcos A. Amalbert-Birriel, Lucía del R Martínez-Colón, Marta I. Amaral-Figueroa, Farah A. Ramírez-Marrero, FACSM. University of Puerto Rico, Rio Piedras Campus, San Juan, PR.

Email: marcos.amalbert@upr.edu

(No relationships reported)

Too much sedentary time (ST) is associated with poor overall health among adults. However, the effect of ST on children's health is not clear. **PURPOSE:** To evaluate the association between ST, percent of the day in ST (ST%), sedentary breaks (STB), length of sedentary breaks (LSTB) and anthropometric measurements among Hispanic children in Puerto Rico. **METHODS:** A group of 114 children (54 girls and 60 boys; mean age = 7.0 ± 0.73 years, range = 6 to 8 years) completed measurements of height, weight, skinfolds, and waist circumference. They also wore an accelerometer for 7

days attached to an elastic belt placed on the right hip area. T-tests were conducted to detect gender differences, and Spearman correlations to detect associations between ST, ST%, STB, LSTB, age, and anthropometric variables. **RESULTS:** No gender differences were detected for ST (4.9±1.2 hrs/day girls, 4.9±1.1 hrs/day boys), ST% (41.1±8.2 % girls, 40.5±6.6 % boys), STB (4.7±2.1 breaks/day girls, 5.0±1.8 breaks/day boys), LSTB (65.3±2.4 min/day girls, 63.4±2.1 min/day boys), and most anthropometric measurements (BMI percentile (65.7±29.8 girls, 64.5±28.7 boys), waist circumference (57.5±8.8 cm girls, 57.3±5.9 cm boys), waist to height ratio (0.45 ± 0.08 girls, 0.46 ± 0.03 boys). Percent body fat was higher in girls compared with boys (21.1±5.9 % girls, 16.6±7.2 % boys; $P < 0.01$). No correlation was observed between sedentary related measures (ST, ST%, STB, LSTB), anthropometric and body composition measures. However, age correlated with ST ($\rho = 0.27$, $p < 0.01$), ST% ($\rho = 0.30$, $p < 0.01$), STB ($\rho = 0.29$, $p < 0.01$), LSTB ($\rho = 0.24$, $p < 0.01$), BMI percentile ($\rho = 0.19$, $p = 0.04$), percent body fat ($\rho = 0.33$, $p < 0.01$), and waist circumference ($\rho = 0.40$, $p < 0.01$). **CONCLUSIONS:** Although too much ST is not likely a concern, the observed increase in ST, BMI percentile, percent body fat, and waist circumference with age in this group of young children could represent a future health problem. Interventions must be implemented to help reduce this possible trend. Funded by University of PR-FIPI Institutional Grant.

Longitudinal Changes in Normalized Grip Strength is Associated with Cardiometabolic Health Maintenance and Improvement among Adolescents.

Mark D. Peterson, FACSM¹, Sonja Smeding², Paul Visich³, Paul Gordon, FACSM². ¹University of Michigan, Ann Arbor, MI. ²Baylor University, Waco, TX. ³University of New England, Biddeford, ME.

(No relationships reported)

PURPOSE: There is an association between normalized grip strength (NGS) and prevalent cardiometabolic health among adolescents; and yet, what remains to be determined is the extent to which changes in NGS predict subsequent changes in health status. The purpose of this study was to determine the longitudinal effect of NGS on changes in health status in a cohort (n=368) of adolescents.

METHODS: Cardiometabolic risk variables included elevated fasting glucose, high blood pressure, elevated plasma triglycerides levels, and low HDL-cholesterol. Fully-adjusted, multinomial logistic regression models were used to quantify the odds of experiencing health maintenance (no risk factors identified at either time point), health improvement (presence of ≥ 1 baseline risk factor, and no risk factors at follow-up), or onset of health risk (no risk factor at baseline, and presence of ≥ 1 risk factor at follow-up) over a 2-year period. **RESULTS:** For every 0.05 unit increase in NGS from baseline, there was a 1.35 (95%CI: 1.05-1.74) and 1.33 (95%CI: 1.06-1.73) increased odds for health maintenance and health improvement, respectively, even after adjusting for baseline body fat percentage, baseline grip strength, cardiorespiratory fitness and objectively-measured physical activity. Conversely, improvements in NGS were inversely associated with odds of onset of health risk (OR: 0.74, 95%CI: 0.57-0.95). **CONCLUSIONS:** Longitudinal increases in NGS are associated with health maintenance and health improvements in adolescent boys and girls. On the other hand, declines in NGS could be used as a prognostic indicator of onset cardiometabolic risk and to identify adolescents that would benefit from lifestyle interventions to improve muscular fitness and reduce risk.

Physical Activity Bout Patterns From Childhood Through Adolescence: NHANES 2003-2006

David A. White¹, Erik A. Willis², Kimberly J. Reid¹. ¹The Children's Mercy Hospital, Kansas City, MO. ²National Cancer Institute, Bethesda, MD.

Email: dawwhite@cmh.edu

(No relationships reported)

Moderate-to-vigorous intensity physical activity (MVPA) accumulated in bouts greater than 5 minutes in length are related to beneficial cardiometabolic health outcomes independent of total MVPA in youth. While it has been established that total MVPA decreases as youth age, the associations between age and MVPA bout patterns in youth is unknown. **Purpose:** To identify physical activity (PA) bout patterns by age and sex in 6-18 years old youth. **Methods:** This cross-sectional analysis examined accelerometer data from the National Health and Examination Survey '03-'04 and '05-'06. Participants (n=4069; male=2036, female=2033; mean age 12.5 ± 3.6yrs) were required to wear uniaxial accelerometers set on 1-minute epochs on the right hip for 7 days. Included data had a minimum of 3 days of at least 10 hours of valid wear time. PA patterns were assessed by comparing percent time of total MVPA in sporadic (1-4 minutes), short (5-9 minutes), and medium-to-long (med-long) (≥ 10 minute) bouts of MVPA by age and sex. Multivariable regression analysis was used to determine independent associations of age, sex, race, ethnicity, income, and PA bout patterns. **Results:** Data are presented as percent time. Significant differences by age group were

observed for: sporadic bouts (6-7yrs, 91.2 ± 3.9; 8-9yrs, 92.5 ± 4.1; 10-11yrs, 93.7 ± 4.2; 12-13yrs, 93.7 ± 5.4; 14-15yrs, 93.4 ± 6.3; and 16+yrs, 93.5 ± 8.3; $p < 0.001$), short bouts (6-7yrs, 6.4 ± 2.7; 8-9yrs, 5.5 ± 2.8; 10-11yrs, 4.7 ± 3.1; 12-13yrs, 4.5 ± 3.8; 14-15yrs, 4.6 ± 4.5; and 16+yrs, 4.6 ± 5.8; $p < 0.001$), and med-long bouts (6-7yrs, 2.4 ± 1.8; 8-9yrs, 2.0 ± 2.1; 10-11yrs, 1.6 ± 1.9; 12-13yrs, 1.8 ± 2.6; 14-15yrs, 2.0 ± 3.1; and 16+yrs, 1.9 ± 4.4; $p = 0.002$) of MVPA. Males participated in less sporadic bouts of MVPA (male: 91.7% ± 2.6; female: 94.6% ± 5.6, $p < 0.001$), more short bouts of MVPA (male: 5.8% ± 4.3; female: 4.1% ± 4.1, $p < 0.001$), and more med-long bouts (male: 2.5% ± 3.1; female: 1.4% ± 3.0, $p < 0.001$) of MVPA. Results remained significant after multivariable adjustment for sex, race/ethnicity, income, and age. **Conclusions:** In addition to decreasing total minutes of MVPA, there are also changes in PA bout patterns as youth age. Changes in PA bout patterns by age are moderated by race/ethnicity and sex. Future interventions could focus on changing PA patterns in addition to increasing total minutes of MVPA.

B-11 Thematic Poster - Landing Biomechanics

The Role of the Midtarsal Joint in Drop Landings

Dustin A. Bruening, Mark T. Olsen, A. Wayne Johnson, Sarah T. Ridge. *Brigham Young University, Provo, UT.*

Email: dabruening@byu.edu

(No relationships reported)

Multi-segment foot models have allowed the foot to be studied in greater detail, in particular separating the functions of the ankle andmidtarsal joints. While these models have been used in walking and running, they have been limited in application to other sports movements, such as jumping and landing. **Purpose:** To investigate the role of themidtarsal and ankle joints in energy absorption during drop landings using a multi-segment foot modeling approach, and to compare these results with those obtained from a single segment model. **Methods:** Twelve volunteer female collegiate athletes [age: 20.5±1.4 years, height: 162.1±5.4 cm, weight: 58.2±6.1 kg] performed one legged barefoot drop landings from a height of 40 cm. Hanging from wooden rings, each subject dropped onto two adjacent force platforms, so that the hindfoot and forefoot contacted separate plates. Sufficient trials were performed until 3 accurate landings were achieved. 28 reflective markers, attached to the subjects' dominant leg, were used to create a custom kinetic multi-segment foot model. Ankle andmidtarsal joint angles, powers, and total work were calculated from initial contact through the lowest point of the subject's center of mass, representing the energy absorption phase of the landing. **Results:** Themidtarsal joint was plantarflexed prior to contact and moved through nearly as great a range of motion (90%) as the ankle (24.6 ± 7.3° ankle vs. 21.9 ± 7.5°midtarsal), while performing two-thirds the amount of work done by the ankle (0.63 ± 0.21 J/kg at the ankle vs. 0.42 ± 0.17 J/kg at themidtarsals). The single segment foot overestimated both range of motion (40.4 ± 8.8°) and work done (1.05 ± 0.28 J/kg) by 40%. **Conclusion:** Themidtarsals can play a substantial role in impact energy absorption, which may have implications in injury prevention strategies. Future studies should attempt to separate active (i.e. muscles) and passive (e.g. ligaments, windlass mechanism, etc.) contributions tomidtarsal function.

609 Board #2 May 31 1:00 PM - 3:00 PM
Effects of Achilles Tendon Taping on Joint Energetics in Jumping and Landing

Evan McConnell, Philip Hernandez, Robin Queen, FACSM. *Virginia Tech, Blacksburg, VA.* (Sponsor: Robin Queen, FACSM)

Email: mevan6@vt.edu

(No relationships reported)

Taping of the Achilles tendon is used by athletes to manage pain during recovery. Previous work has shown differences in ankle work but no differences in force

production with various ankle taping techniques during athletic tasks. **PURPOSE:** To examine the effects of an Achilles tendon assistive taping technique and gender on lower extremity joint work, power generation, and power absorption during jumping and landing in healthy recreational athletes. **METHODS:** 29 subjects - 16 males (20.9 ± 2.4 years, 1.79 ± 0.06 m, 79.0 ± 11.9 kg) and 13 females (21.4 ± 3.2 years, 1.66 ± 0.06 m, 66.1 ± 7.6 kg) - participated in the study. Each subject's dominant limb underwent an Achilles tendon assistive taping procedure by a certified athletic trainer. Subjects performed 5 trials of a stop jump task in both a taped and non-taped condition (randomized test order). The first landing and subsequent jump were analyzed with a 10-camera motion analysis system (240Hz). Joint power was determined based on data from 2 embedded force plates (1920 Hz) using inverse dynamics and was integrated to yield joint work. 2x2 ANOVAs were performed ($p < 0.05$) to determine gender and taping condition effects on peak power generation, power absorption, and work at each joint during landing and jumping. **RESULTS:** Subject height ($p < 0.001$) and mass ($p = 0.002$) differed based on gender, but age ($p = 0.633$) did not. No significant interactions and no taping condition main effects existed for power or work during either jumping or landing. A main effect of gender was identified, with females showing decreased peak power generation at each joint during jumping (Table 1). **CONCLUSIONS:** The assistive taping does not alter peak power generation, power absorption or joint work during landing and jumping in healthy subjects, but gender-specific differences in power generation do exist. Future work is needed to determine the effect of this taping technique in injured athletes.

Table 1: Peak Power Generation

		Females		Males		Gender Effect
		Non-Taped	Taped	Non-Taped	Taped	
Ankle	Landing	-12.3 ± 4.6	-12.3 ± 4.5	-13.0 ± 4.6	-11.6 ± 4.8	$p = 0.863$
	Jumping	15.6 ± 5.4	13.4 ± 4.2	18.1 ± 3.8	15.9 ± 4.0	$p = 0.042$
Knee	Landing	-17.3 ± 2.9	-18.6 ± 5.5	-21.0 ± 6.0	-20.0 ± 5.4	$p = 0.077$
	Jumping	11.2 ± 2.9	11.5 ± 3.3	15.2 ± 3.5	14.7 ± 3.4	$p < 0.001$
Hip	Landing	-7.6 ± 5.0	-6.1 ± 3.2	-13.3 ± 6.1	-14.9 ± 6.1	$p = 0.040$
	Jumping	6.3 ± 5.0	4.6 ± 1.9	10.2 ± 8.1	9.6 ± 6.4	$p = 0.009$

Lateral Extrinsic Foot Muscle Size Best Predicts Time To Stability In Single Leg Landing

Julia L. Dunbar, Sarah T. Ridge, Dustin Bruening, Kelsey R. Garner, Dennis L. Eggett, Aaron W. Johnson. *Brigham Young University, Provo, UT.* (Sponsor: Ty Hopkins, FACSM)
(No relationships reported)

A single leg, barefoot landing is a functional movement often executed in athletic events. The inability to quickly stabilize the ankle joint during a landing may contribute to injury risk. **PURPOSE:** To determine whether the size of specific medial and lateral extrinsic foot muscles can be used to predict shorter time to stability in female athletes performing single leg, barefoot landings. **METHODS:** Twenty-one female collegiate gymnasts and cheerleaders (age: 21.2 ± 1.4 years; height: 1.6 ± 0.06 m; weight: 58.1 ± 5.7 kg) completed a dominant single leg, barefoot landing onto a force plate from a height of 28 cm. The time to stability was calculated from the recorded medial to lateral force after landing. The size of the tibialis anterior (TA), tibialis posterior (TP), flexor digitorum longus (FDL), fibularis brevis (FB), and fibularis longus (FL) were measured using ultrasound imaging (12L probe, GE Logiq P6). The TA, TP, and FL were assessed at a distance of 30% from the knee joint-line to the tip of the lateral malleolus. FDL was measured at a distance of 50% from the knee joint-line to the medial malleolus while FB was measured at a distance of 50% from the knee joint-line to the lateral malleolus. Muscle sizes (thickness for the TA and TP and cross sectional area for FDL, FB, and FL) were measured from the ultrasound images ($p > 0.05$). **RESULTS:** A stepwise regression (including height, weight, and muscle size(s)) indicated that the two best predictors of time to stability were the FB and FL ($r^2 = 0.45$, FB $p = 0.002$, FL $p = 0.083$; cross-sectional areas: FB = 3.4 ± 1.2 cm², FL = 4.8 ± 1.1 cm²). **CONCLUSION:** It appears athletes with larger FB and FL had shorter time to stability. These results suggest strengthening of the lateral extrinsic muscles may be a key component in both the prevention and rehabilitation of ankle injuries among gymnasts and other barefoot athletes.

611 Board #4 May 31 1:00 PM - 3:00 PM
Landing Patterns of Collegiate Female Volleyball Players During Practice and Game Competition

Jenny L. Kantor, Steven L. Dischiavi, Thomas J. Hockenjos, Jeffrey B. Taylor. *High Point University, High Point, NC.* (Sponsor: Dr. Kevin R. Ford, FACSM)
 Email: jtaylor@highpoint.edu
(No relationships reported)

Women's volleyball is generally recognized as a high-volume jumping sport. This repetitive jumping and landing can lead to overuse injuries, especially if performed exclusively on a single-leg. While some data is available regarding jumping volume during competition, there have been few reports on jumping load during practice, and minimal characterization of the double- (DL) and single- (SL) leg landing patterns during the sport to help shape training and/or rehabilitation procedures. **PURPOSE:** To quantify and characterize the jump landing patterns that occur during women's collegiate volleyball practice and game competition. **METHODS:** Recordings from two video cameras from four consecutive competitions (three practices, one game) of 14 Division-1 collegiate women's court volleyball players were analyzed for this study. Recordings were viewed by one of two raters who noted the total number of jumps and categorized each landing as a DL landing, or SL landing on the right (SL_R) or left (SL_L) side. Repeated measures ANOVAs identified differences in jumping load, and the ratio of DL to SL, and SL_R to SL_L landings among practices and between practice and game competition ($p < 0.05$). **RESULTS:** On average, there was a significantly higher overall jumping load (practice: 66.7 ± 40.1 jumps (j), game: 41.5 ± 44.6 j; $p = 0.01$), and frequency of DL (practice: 50.5 ± 38.5 j, game: 31.9 ± 38.6 j; $p = 0.03$) and SL (practice: 16.2 ± 12.8 j, game: 9.6 ± 15.8 j; $p = 0.04$) landings during practice than games. However, individual patterns of DL to SL (practice: 0.76 ± 0.13, game: 0.75 ± 0.18; $p = 0.99$) and SL_R to SL_L (practice: 0.35 ± 0.17, game: 0.36 ± 0.39; $p = 0.89$) were consistent across competitive events. There were no significant differences in any of the jumping or landing variables between practices ($p > 0.05$), yet substantial variability of landing patterns was identified between individuals, with the percentage of DL landings ranging from 35.8-96.0% of total landings and SL_R landings ranging from 3.6-97.4% of SL landings. **CONCLUSIONS:** Volleyball players were found to jump significantly more often during practices than games, but DL and SL landing patterns remained consistent. These data may help clinicians and coaches design training and/or rehabilitation procedures to better simulate the landing demands during volleyball competition.

Influence of Hip Extension Strength on Landing Biomechanics In Collegiate Basketball Players

Connor R. Whicker, Jeffrey B. Taylor, Emma F. Zuk, Kevin R. Ford, FACSM, Anh-Dung Nguyen. *High Point University, High Point, NC.* (Sponsor: Kevin Ford, FACSM)
 Email: whickc14@highpoint.edu
(No relationships reported)

Decreased hip strength has been suggested to contribute to landing biomechanics that increase the risk of ACL injuries. However, the relationship between hip strength and landing biomechanics is conflicting. Previous studies are limited to examining the peak torque produced during isometric or isokinetic assessments of hip strength. Understanding how the isokinetic torque production of the hip through a range of motion may help clarify the role of hip strength in landing biomechanics. **PURPOSE:** To examine the influence of hip isokinetic eccentric (ECC) and concentric (CON) work on landing biomechanics in male and female basketball players. **METHODS:** Twenty-three male (N=11, 20.5 ± 1.4 yrs, 189.2 ± 8.0 cm, 90.2 ± 10.4 kg) and female (N=12, 19.9 ± 1.4 yrs, 172.4 ± 6.8 cm, 78.9 ± 13.8 kg) Division 1 basketball players participated. Using an isokinetic dynamometer, 5 repetitions of isokinetic CON and ECC hip extension torque were measured at 60 deg/s, with the work per repetition of the middle 3 repetitions used for analyses. Established 3D motion analysis techniques were used to collect three trials of a drop vertical jump and quantify the left limb's sagittal, frontal, and transverse plane hip and knee joint excursions and peak external joint moments, normalized to body weight and height (BWHT). Separate step-wise, linear regressions determined the extent to which CON and ECC work predicted landing biomechanics in males and females. **RESULTS:** In males, the average ECC and CON work per repetition was 0.98 ± 0.15 J/BWHT and 0.92 ± 0.18 J/BWHT, respectively. In females, the average ECC and CON work per repetition was 0.91 ± 0.25 J/BWHT and 0.94 ± 0.21 J/BWHT, respectively. Greater ECC work predicted less hip adduction moment (0.40 ± 0.29 Nm/BWHT, $R^2 = 0.411$, $P = 0.025$) in females. ECC and CON work was not predictive of any other hip or knee joint excursions or peak moments in males or females (all $P > 0.05$). **CONCLUSIONS:** With the exception of hip adduction moment in females, ECC and CON hip strength was not predictive of landing biomechanics. This suggests that a combination of neuromuscular factors at the hip, such as muscle activation, combine to predict lower extremity biomechanics during dynamic activities. Further work is needed to clarify this relationship in more demanding tasks.

613 Board #6 May 31 1:00 PM - 3:00 PM
The Changes in Impacts and Soft-tissue Responses of Lower Limbs between Active and Unanticipated Landings

Shen Zhang, Weijie Fu, Yu Liu. *Shanghai University of Sport, Shanghai, China.*
 Email: zhangshen0708@163.com
 (No relationships reported)

Muscle activity patterns can be modulated in response to soft-tissue vibrations of lower extremity induced by the magnitude of the peak impact and the high loading rate of vertical ground reaction force during landing to reduce the high injury risk. However, the sudden changed pattern of unexpected landing would potentially influence the impact force (as a input signal) and the soft-tissue vibration (as a response), which may further affect the landing performance or even cause injury.

PURPOSE: To determine the biomechanical differences of impact force and soft-tissue vibration between active landing (AL) and unexpected landing (UL). **METHODS:** Twelve trained male basketball volunteers were requested to land from self-made elevated platform at three heights (30, 45, and 60cm) in two different landing maneuvers (AL & UL). The 3D force plates and accelerometers were used to collect the impact and soft-tissue vibration characteristics. The variables for AL & UL included: 1) impact characteristics: the peak of impact force (BW), maximum loading rate (kN/s) and impact frequency (Hz); 2) soft-tissue vibration: maximum amplitude (g) and damping coefficient (s^{-1}) of soft-tissue vibration of quadriceps & hamstrings. A 2 × 3 (landing style × height) repeated measures analysis of variance was used to examine the differences between conditions. **RESULTS:** For the impact characteristics, the peak of impact force (30cm: 3.90 ± 1.16 vs. 2.17 ± 0.50 ; 45cm: 4.35 ± 1.02 vs. 2.82 ± 0.80; 60cm: 4.73 ± 0.84 vs. 3.60 ± 0.64), maximum loading rate (30cm: 240.3 ± 63.8 vs. 88.4 ± 22.5; 45cm: 273.9 ± 77.3 vs. 157.3 ± 36.0; 60cm: 301.6 ± 73.3 vs. 203.3 ± 46.0), and impact frequency (30cm: 15.6 ± 2.3 vs. 7.96 ± 2.2; 45cm: 23.1 ± 2.2 vs. 8.73 ± 1.7; 60cm: 26.1 ± 2.4 vs. 10.38 ± 1.5) in UL was significantly higher than those in AL ($p < .05$) for all three drop heights, respectively. For soft tissue vibration, UL had a significantly greater maximum amplitudes of vibration of quadriceps (except for 60 cm) and hamstrings ($p < .01$) and lower damping coefficients ($p < .05$) compared with AL. **CONCLUSION:** If the neuromuscular system fails to prepare properly for an unexpected landing impact, increased magnitude of impact forces and soft-tissue vibrations emerged which might be detrimental to the impact-related injury.
 Supported by NSFC grant (81302131).

Effect of Different Sports on Hip and Knee Biomechanics in Adolescent Females During a Jump-Landing

Kelci B. Besand¹, James M. Bothwell², J Craig Garrison², Joseph P. Hannon², Shiho Goto², Adam C. King¹. ¹*Texas Christian University, Fort Worth, TX.* ²*Texas Health Ben Hogan Sports Medicine, Fort Worth, TX.*
 (No relationships reported)

Anterior Cruciate Ligament (ACL) injury is common in adolescent female athletes, with those who participate in soccer (SC) being at the highest risk for primary and secondary ACL injury. However, little is known about the biomechanical differences that may contribute to the variance in injury rate between SC and other sports in adolescent females. Previous research demonstrates that college-age females who participate in SC exhibit greater frontal plane projection angle (FPPA) values than those who participate in basketball (BKB). **PURPOSE:** To assess for differences in hip and knee frontal plane kinematics between adolescent female SC and BKB players. **METHODS:** Cross-sectional study design. Females (N = 30) participating in BKB (Age = 15.33 ± 1.68 yrs; Ht = 167.14 ± 5.91 cm; Mass = 60.49 ± 9.59 kg) or SC (Age = 15.33 ± 1.68 yrs; Ht = 162.86 ± 3.84 cm; Mass = 56.55 ± 5.85 Kg). Participants had International Knee Documentation Committee Subjective Knee Form (IKDC) scores ≥ 95, were healthy at time of testing, and were matched by age and side of dominance (DOM = limb used to kick a ball). During three separate jump-landing tasks, bilateral lower extremity joint angles and moments were assessed at initial contact. Joint displacement (DSP = maximum or minimum - IC) and FPPA (2-dimensional measure of knee valgus) were calculated. Separate independent t-tests were performed to examine differences between groups. **RESULTS:** DOM hip adduction (ADD) DSP was significantly greater in the SC group (9.51 ± 1.3°) compared to the BKB group (4.9 ± 3.1°, $t_{(28)} = -5.2, p < .001$). DOM hip abduction DSP was significantly greater in the BKB group (-3.7 ± 3.2°) compared to the SC group (-1.0 ± 0.9°, $t_{(28)} = -3.1, p = .004$). DOM FPPA negative DSP (knee varus) (BSK = -9.8 ± 8.0°, SC = -5.29 ± 3.9°, $t_{(28)} = -1.96, p = .05$) and non-DOM FPPA negative DSP (BKB = -13.5 ± 4.4°, SC = -6.3 ± 3.0°, $t_{(28)} = -2.7, p = .01$) was significantly greater in the BKB group compared to the SC group. No other significant differences were observed. **CONCLUSIONS:** Greater hip ADD DSP is associated with higher ACL injury risk. Female SC players may be at increased ACL injury risk partially due to higher hip ADD DSP exhibited during

landing as compared to the BKB group. The ability of female BKB players to maintain greater knee varus when compared to SC may also contribute to the variance in ACL injuries in these sports.

615 Board #8 May 31 1:00 PM - 3:00 PM
Landing Biomechanics Influence Circulating Stress Hormone Levels

Barnett S. Frank, Claudio L. Battaglini, FACSM, Troy Blackburn, Steven W. Marshall, Anthony C. Hackney, FACSM, Darin A. Padua. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Claudio Battaglini, FACSM)
 Email: bsfrank@email.unc.edu
 (No relationships reported)

High training load (HTL) exposure and stiff landing biomechanics increase an individual's risk of lower extremity injury during sport and physical activity participation. **Purpose:** To determine the influence of movement profile on systemic stress response to HTL exposure. **Methods:** 40 physically active, healthy, college-aged females were enrolled in this study and were assigned to a low-risk / soft (n=19; age=20.5±1.9 yr, height=1.44±0.44 m, mass= 64.5±7.8 cm) or a high-risk / stiff (n=21; age=20.4±1.3 yr, height=1.63±0.23 m, mass= 64.9±6.1 cm) movement profile group defined by The Landing Error Scoring System. Participants completed five cycles of 5-minute treadmill running at a speed coincident with 110-120% ventilatory threshold and 10 jump-landings from a 30 cm box. Blood samples were collected at baseline and 30 minutes following HTL exposure. Menstrual cycle phase, prior diet and exercise were controlled. Samples were analyzed using commercially available ELISA kits to determine serum cortisol concentrations [C]. A two-way mixed model ANOVA was used to evaluate the effect of movement profile on systemic stress response to HTL exposure. **Results:** No significant movement profile-by-time interactions were observed ($F_{1,38} = 0.157, p > 0.05$). There were significant main effects for group ($F_{1,38} = 10.81, p < 0.05$) and time ($F_{1,38} = 9.64, p < 0.05$), with a high-risk / stiff movement profile being associated with greater overall circulating cortisol, and HTL exposure inducing increases in cortisol in both movement profile groups. Movement profile and time descriptive statistics and effect sizes are presented in table 1. **Conclusions:** A high-risk / stiff movement profile is associated with elevated cortisol, a biomarker of systemic stress. Movement profile may moderate systemic stress levels via a high or low level of biomechanical efficiency and shielding against or amplifying mechanical loads experienced during activities of daily life and physical activity.

Figure 1. - Raw group serum cortisol response to HTL exposure.

Figure 2. - Log-transformed group serum cortisol response to HTL exposure.

Table 1. - Means, standard deviations, 95% confidence intervals, and effect sizes for the main effects of movement profile and half training load exposure on serum cortisol concentrations [C].

Real-time Assessment of the Relationship Between Exercise and Psychological Stress in Overweight Women

Jessica L. Unick¹, Leah Dorfman¹, Katie M. Becofsky², Dale S. Bond¹, Graham Thomas¹, Christie Ward-Ritacco³, Rena R. Wing¹. ¹*The Miriam Hospital and Brown Medical School, Providence, RI.* ²*University of Massachusetts, Amherst, MA.* ³*The University of Rhode Island, Kingston, RI.* (Sponsor: Kelliann Davis, FACSM)

Email: junick@lifespan.org

(No relationships reported)

Although higher physical activity (PA) levels are associated with lower psychological stress, real-time associations between PA and stress have not been adequately examined. It is unclear whether stress more often serves as a barrier to PA, thus reducing the likelihood of exercising when stress is high, or whether PA is used as a coping strategy for reducing stress. **PURPOSE:** This study combined objective PA monitors with real-time psychological stress assessments to examine the pattern of stress prior to and following an exercise bout and to determine whether the magnitude of stress predicted PA engagement. **METHODS:** 52 women with overweight/obesity (BMI: 31.5±4.5 kg/m², age: 48.9±9.0 years) were instructed to respond to 5 semi-random prompts delivered daily via their smartphone over a 14-day period while simultaneously wearing an objective PA monitor (SenseWear armband). Stress ratings at each prompt were reported using a 1-7 Likert scale (ranging from 'not at all' to 'very much so'). Moderate-to-vigorous intensity PA bouts (MVPA; ≥3 METs & ≥ 10 minutes in duration) were identified and examined in relation to stress ratings. **RESULTS:** Compliance to answering the surveys (88.0±9.1%) and wearing the armband was high (13.1±1.9 days; 14.1±1.6 hrs/day). On average, participants engaged in 17.3±16.2 min/day of bout-related MVPA and stress ratings were 2.17±0.03 (mean±SE). There was no association between each participant's total MVPA minutes and average stress over the 14-day period ($r=-0.03$, $p=0.81$). However when examined acutely, stress decreased in the time preceding exercise and continued to decrease following exercise ($p=0.04$). Further, when stress was high during the first prompt of the day (stress≥5; 16% of all cases), participants were significantly less likely to exercise on that day compared to when stress was low (stress<5; $\beta=0.70$, $p=0.004$). **CONCLUSIONS:** When PA and stress were assessed using a unique combination of real-time data collection methods, overweight women did not appear to use PA as a method of coping with stress; rather PA occurred more often when stress was low and on a downward trajectory. These findings suggest that reducing stress may be a useful strategy for promoting PA adoption. Future studies should examine this relationship in other populations, including those with higher stress levels.

618 May 31 1:15 PM - 1:30 PM

Age Moderates the Association Between Short Sleep Duration and Reduced Exercise Frequency

Patrick O'Connor, FACSM. *University of Georgia, Athens, GA.*
Email: poconnor@uga.edu

(No relationships reported)

Chronic short sleep increases the risk of a driving accident, obesity and cardiovascular disease mortality. Whether the frequency of resistance and aerobic exercise is reduced among short sleepers has not been examined across a broad range of ages. **PURPOSE:** To assess relationships between sleep duration and self-reported aerobic or resistance exercise frequency according to age. **METHODS:** 8,479 female and male online game players, aged 13 to 79 years, completed a lifestyle survey. Participants provided demographics (age, gender, education level), typical sleep duration, and typical weekly frequency of aerobic and resistance exercise. Data also were obtained on smoking and caffeinated coffee and tea use. Sleep duration (short [< 7 hours per night] vs. normal [7 to 9 hours per night]) x Age (13-19, 20-29, 30-39, 40-49, 50-59, 60-69, 70-79) ANCOVAs were used to examine relationships. **RESULTS:** Compared to normal sleepers (68% of the sample), short sleepers reported fewer weekly resistance (1.77 vs. 1.99) and aerobic exercise (2.62 vs. 2.92) bouts, effects that interacted with age (RESISTANCE: sleep x age interaction $F=2.243$, $P=.036$; AEROBIC: sleep x age interaction $F=2.142$, $P=.046$). The sleep x age interaction remained significant for both resistance ($F=2.744$, $P=.012$) and aerobic ($F=2.449$, $P=.023$) exercise after including

gender, education level, smoking and caffeinated coffee and tea in the models as covariates. Post-hoc tests showed that compared to normal sleepers, weekly resistance exercise frequency was lower in 40-year old (1.46±1.61 [n=428] vs. 1.75±1.66 [n=752], $t=-2.892$, $df=1,178$, $P=.004$) and 50-year old (1.50±1.57 [n=593] vs. 1.81±1.64 [n=1161], $t=-3.741$, $df=1,752$, $P<.001$) short sleeper groups only. Compared to normal sleepers, weekly aerobic exercise frequency was lower in the 40-year old (2.32±1.83 [n=435] vs. 2.82±1.98 [n=756], $t=-4.282$, $df=1,189$, $P<.001$), 50-year old (2.58±2.06 [n=597] vs. 3.04±1.98 [n=1173], $t=-4.572$, $df=1,160.228$, $P<.001$) and 60-year old (2.81±2.04 [n=455] vs. 3.05±1.99 [n=1017], $t=-2.115$, $df=1,470$, $P=.035$) short sleepers. **CONCLUSION:** Age moderates the association between short sleep duration and self-reported aerobic and resistance exercise in online game players.

619 May 31 1:30 PM - 1:45 PM

Exploring The Link Between Exercise Identity And Intervention Dosage: I-fit (Initiating Feelings Of Individual Transformation)

Eydie N. Kramer, Daheia J. Barr-Anderson, FACSM. *University of Minnesota, Minneapolis, MN.*

Email: krame640@umn.edu

(No relationships reported)

Adolescent overweight and obesity in the United States has increased in past decades, resulting in numerous physiological and psychological consequences. Obesity interventions often aim to increase physical activity (PA). Such interventions may strengthen Exercise Identity (EI). A strong EI has been positively related to long-term PA engagement, as individuals seek to engage in behaviors congruent with the role identity of "exerciser." Greater dosage of PA intervention may progressively increase EI, and enhance future exercise behavior. However, the relationship between PA intervention dosage and EI in an overweight and obese adolescent population is unclear.

PURPOSE: To determine if a PA intervention, when delivered in varying dosages, may strengthen an overweight or obese adolescent's EI.

METHODS: Fifty overweight and obese adolescents (age=14.16 ± 1.88 years, BMI=35.66 ± 7.87 kg/m², BMI percentile=97.5% ± 3.7%) were recruited from a behavior change summer camp, which included a PA intervention component. Age, gender, height, and weight were collected, and BMI was calculated. The participants were categorized into three separate groups, according to length of PA intervention (dosage): 3 week PA dosage, 4-5 week PA dosage, and 6-7 week PA dosage. Participants completed the Anderson Exercise Identity Scale and 3 Day Physical Activity Recall (3DPAR) at pre- and post-intervention. Group comparisons of EI were made using two-way ANOVA. Changes in vigorous physical activity (VPA) within groups were calculated using Log-Rank, Kaplan-Meier, and Wilcoxon. Activities on the 3DPAR were categorized and coded to compare exercise behavior within groups.

RESULTS: Upon comparison, the mean EI in the 6-7 week intervention group significantly differed from other group means and resulted in a significant increase in EI within groups ($p<0.001$). All intervention groups demonstrated significant increases in VPA ($p<0.05$), and complied with National PA Guidelines of 60+ minutes of MVPA daily; VPA performed on at least 3 days/week.

CONCLUSION: Exercise Identity may be increased in overweight and obese adolescents following a physical activity intervention. Greater dosage of physical activity intervention will result in greater benefits to Exercise Identity, and may ultimately enhance long-term exercise behavior.

620 May 31 1:45 PM - 2:00 PM

Physical Activity Beliefs in Middle-aged, Weight-challenged Women with Sedentary Jobs

Mary M. Yoke, FACSM. *Indiana University, Bloomington, IN.*
Email: mmyoke@indiana.edu

(No relationships reported)

Physical inactivity, overweight, and obesity are major public health problems in the United States and in the developed world, leading to increased morbidity and mortality. More information is needed regarding physical activity beliefs, attitudes, and perceived self-control among those who are currently sedentary, weight-challenged, and who are frequently underserved by the health/fitness industry.

Purpose: To elicit physical activity beliefs about feasibility, pleasure, and movement descriptions from middle-aged, weight-challenged women with sedentary jobs.

Method: Open-ended questions were utilized throughout individual 30-minute interviews with 23 female participants (age: $M = 52.0$, $SD = 7.3$; BMI: $M = 34.2$, $SD = 9.79$). The intention of the questions was to obtain in-depth insights into participants' beliefs, attitudes, perceived norms, and physical activity behaviors. Questions were asked regarding physical activity descriptions, preferences, pleasurable, and motivating phrases used by physicians and fitness professionals. After the interview process, participants were divided into those who reported they were completely sedentary (12 non-doers) and those who reported they regularly engaged in physical activity (11 doers).

Results: A content analysis and independent *t*-test revealed that non-doers were significantly less active and had more perceived barriers to physical activity (4.58 + 1.88) than doers (1.27 + 1.49; $p < 0.05$). The most frequently cited perceived barriers were injuries, caregiving responsibilities, time, age, dislike of sweating, and depression. Non-doers were significantly more likely to prefer easy-to-moderate intensities, while doers preferred moderate-to-vigorous intensities. Non-doers were also significantly less likely than doers to report physical activity as pleasurable, and they were more likely to cite needing an exercise buddy. The most frequently cited pleasurable activities in both groups were yoga, movement to music, stretching, and walking.

Conclusions and implications: This study provides useful information for health educators and health/fitness professionals seeking to promote physical activity among middle-aged women with weight challenges.

Body-heart-brain Interaction On Exercise: Effects Of Intensity On Inhibitory Control, Affect, Autonomic Cardiac Function And Brain Oxygenation

Wesley Quirino Alves da Silva¹, Eduardo Bodnariuc Fontes¹, Zayonara Larissa Lima¹, Rodrigo Menezes Forti², Alexandre Hideki Okano¹, Andréa Camaz Deslandes³, Erika Hussey⁴, Nathan Ward⁴, Hassan Mohamed Elsangedy¹. ¹Federal University of Rio Grande do Norte, Natal, Brazil. ²Campinas State University, Campinas, Brazil. ³State University of Rio de Janeiro, Natal, Brazil. ⁴Tufts University, Medford/Somerville, MA.

Email: wesleyquirino@gmail.com

(No relationships reported)

Recent work suggests that inhibitory control influences affective regulation and is an important neurobiological mechanism that contributes to physical activity behavior. However, the effects of exercise intensity in this complex interaction body-heart-brain remain unclear. **PURPOSE:** Investigate the effects of exercise intensity on inhibitory control, affect, autonomic function and prefrontal cortex (PFC) oxygenation. **METHODS:** 37 sedentary young adults were randomly assigned to two experimental conditions (control or exercise). For the exercise condition, a maximum incremental test was performed on a cycle ergometer with continuous measurements of PFC oxygenation, heart rate variability (HRV), inhibitory control (Stroop test), associative and dissociative thoughts (ADT) and affect scale every 2 minutes at each of 8 intensity increments. For the control condition, the same assessments were carried out, but participants sat on a cycle ergometer without active pedaling. We evaluated the effects with a two-way repeated measures ANOVA with *Bonferroni* adjustments to compare the effects and interactions of condition and intensity. Then, *Pearson's correlations* to evaluate the relationship between affect and inhibitory control, ADT, HRV and PFC oxygenation. **RESULTS:** Intensities above the ventilatory threshold (VT) induced poorer inhibitory control ($F=33.64$; $p < 0.001$), more ratings of unpleasantness ($F=200.60$; $p < 0.001$), increased HRV activity ($F=29.96$; $p < 0.001$) and increased oxygenation of the PFC ($F=55.97$; $p < 0.001$). Pleasure perception was correlated with ADT at almost all intensities from 2-VT to VT+2 ($r_s > -0.33$, $p_s < 0.05$). We also found pleasure correlation with HRV lower frequencies analysis ($r = -0.34$; $p < 0.05$) and ratio between low and high frequency ($r = -0.33$; $p < 0.05$), in the last stage of intensity, and to PFC deoxy was found at VT+2 intensity ($r = -0.37$; $p < 0.05$). **CONCLUSION:** Exercise at high intensities reduces inhibitory control and affect (ratings of pleasantness). Displeasure correlates to increases in thoughts associated to exercise, and at high intensities, displeasure is correlated with PFC deoxygenation and sympathetic activity. These findings strengthen the existence of an integrative body-heart-brain system and suggests a role of the exercise intensity in this interaction.

622 May 31 2:15 PM - 2:30 PM

Associations Between Mother'S And Children'S Moderate-to-vigorous Activity And Sedentary Time In The Family Context

MinKyoung Song¹, Nathan F. Dieckmann¹, Sydnee Stoyles¹, Julie C. Lumeng². ¹Oregon Health and Science University, Portland, OR. ²University of Michigan, Ann Arbor, MI.

Email: songm@ohsu.edu

(No relationships reported)

Little is known about association between moderate-to-vigorous physical activity (MVPA) and sedentary time (ST) among mothers and their children in different settings (e.g., home, outside of home, weekday vs. weekend).

PURPOSE: (1) Describe the association of MVPA and ST among mothers and their children, overall and while they are at home together, (2) determine how children's and parents' characteristics, and setting, moderate the association in their respective MVPA and ST.

METHODS: We used Healthy Families baseline data from 55 mothers and their children (aged 3-5 years [$n=25$] and 10-13 years [$n=30$]). MVPA and ST data were collected using accelerometry over a seven day period. Proportion of time in sedentary behavior and MVPA between 08:00 h and 20:00 h was calculated. Mixed-effects models were used to examine the association between mothers' levels of ST and MVPA and those of their children.

RESULTS: There was little variability in levels of ST and MVPA by time of day among mothers or children, overall and while at home together. After controlling for child and parent characteristics, and setting variables, mother-child ST and MVPA levels were positively associated ($P < 0.001$). The association for ST and MVPA were 2.2 times ($\beta = 0.254$ versus $\beta = 0.116$) and 1.7 times ($\beta = 0.365$ versus $\beta = 0.215$) stronger, respectively, when mother and child were at home together (compared to when one or neither were at home). The association did not differ by day of the week.

CONCLUSION: MVPA and ST in mothers and their children are directly associated, and that association differed by changes in setting. These results support the rationale for developing a family-centered interventions that take place in the home to increase PA and decrease ST.

Variables	Models	
	Child's ST	Child's MVPA
Mother's ST/MVPA	0.116 (0.050, 0.182)*	0.215 (0.066, 0.363)*
Mother's ST/MVPA by both at home	0.138 (0.059, 0.217)*	0.150 (0.013, 0.286)*

*adjusting for child's gender, child's age group, mother's BMI, age, education, race/ethnicity, family income to needs ratio, number of electronic devices at home, number of available PA equipment pieces at home, day of the week, both at home or not. * $P < 0.001$

623 May 31 2:30 PM - 2:45 PM

A New Test to Measure Neuromuscular Fatigue During and Immediately After Cycling Exercise: A Reliability Study

Douglas Doyle-Baker, John Temesi, Mary E. Medysky, Robert J. Holash, Guillaume Y. Millet. University of Calgary, Calgary, AB, Canada.

Email: doug.doylebaker@gmail.com

(No relationships reported)

Neuromuscular (NM) fatigue has often been measured in human participants through single-joint isometric exercise tests. However, this task is not representative of whole-body exercise (WBE) such as running, and cycling. Furthermore, most studies assessing NM fatigue from WBE have delayed measurement for 1-4 minutes after task failure, despite the knowledge that the NM system can recover quickly. **PURPOSE:** To demonstrate the reliability of a new cycling ergometer for the measurement of NM fatigue in healthy subjects during and immediately after WBE. **METHODS:** A sample consisting of 12 healthy adult males and females aged 19 to 32 was recruited. Each subject performed a fatiguing protocol on the new cycling ergometer on two separate occasions. This protocol had subjects pedal until task failure at pre-determined power outputs scaled to their body weight that increased after NM assessments performed at three-minute intervals. NM assessments included voluntary and evoked force production of the quadriceps measured through instrumented pedals within the ergometer. Evoked contractions were achieved through electrical nerve stimulation and transcranial magnetic stimulation. Reliability was determined with intraclass correlation coefficients (ICC) and coefficients of variation (CV).

RESULTS: During the two sessions, the new cycling test produced a significant mean percent reduction in maximal voluntary contraction (MVC) force from pre to post test of $36 \pm 12\%$ ($p < .0001$). There was no significant difference in MVC measured on the ergometer between sessions ($p > .05$), with excellent relative (ICC = 0.97 ± 0.06) and absolute reliability (CV = $3.2 \pm 1.6\%$). Evoked twitch force, a measure of peripheral fatigue, was reduced by $46 \pm 14\%$ ($p < .0001$) from pre to post test and showed excellent reliability as well (ICC = 0.97 ± 0.06 ; CV = $5.2 \pm 1.5\%$). There was no significant change ($p > .05$) in percent voluntary activation, a measure of central fatigue, within each session, however there was excellent absolute reliability (CV = $1.3 \pm 0.5\%$; $97 \pm 2\%$ vs. $97 \pm 2\%$ measured at pre). **CONCLUSION:** The results suggest that the new ergometer is a reliable tool for measuring NM fatigue during and immediately after exercise. Ultimately, a greater knowledge and understanding of the etiology of NM fatigue will be gained by measuring it during WBE.

624 May 31 2:45 PM - 3:00 PM

Lap Time Variation Predicts Task Error During Dual-Task Walking In Cognitively Healthy Women

Joaquin U. Gonzales¹, Youngdeok Kim¹, Hyung Suk Yang², Daniel Jensen², Lee Atkins², C. Roger James, FACSM². ¹Texas Tech University, Lubbock, TX. ²Texas Tech University Health Sciences Center, Lubbock, TX. (Sponsor: C. Roger James, FACSM)

Email: joaquin.gonzales@ttu.edu

(No relationships reported)

Variation in lap time (LTV) during a fast pace 400m walk test is a new metric thought to be an early indicator of cognitive decline in older adults. While LTV has been found to associate with executive function, no study has examined the potential for LTV to predict capacity of the brain to divide attention and meet the demand of walking and performing other tasks simultaneously. **PURPOSE:** The purpose of this study was to test the hypothesis that greater LTV would associate with larger dual-task cost during walking. **METHODS:** Fifty-two cognitively healthy (MoCA>25) women across a broad age range (30-80y) performed fast pace walking while balancing a tray (Dual1) or balancing a tray while vocalizing serial subtractions by 7's (Dual2). Task error was quantified by degrees of tray tilt and subtraction error. On a separate day, women completed a fast pace 400m walk test (40m x 10 laps) with time to complete each lap recorded. LTV was defined as standard deviation of residuals estimated from the random effects linear model where each lap time was regressed on a person-specific random intercept and random slope associated with lap. Women were categorized into tertiles based on LTV. Comparisons were made between tertiles using ANCOVA after adjusting for age, years of education, and mean lap time. **RESULTS:** Gait speed ($p=0.57$) or the percent change in gait speed ($p=0.34$) were not significantly different between tertiles for the Dual1 condition, but tilt angle was larger in women with greater LTV (tertiles 1 vs. 3: 1.37 ± 0.12 vs. 1.94 ± 0.11 degrees; $p=0.006$). During the Dual2 condition, women with greater LTV had faster gait speed ($p=0.02$), lower percent change in gait speed (tertiles 1 vs. 3: 20.5 ± 2.8 vs. $9.3\pm 2.6\%$, $p=0.02$), similar subtraction error ($p=0.58$), but larger tilt angle (tertiles 1 vs. 3: 1.24 ± 0.19 vs. 2.09 ± 0.17 degrees, $p=0.007$). **CONCLUSION:** Lap time variation identified women that exhibited greater difficulty balancing an object while walking suggesting that LTV may be sensitive to deficits in the ability to share neural substrate for sensorimotor function. Supported by a Women's Health Research Scholar Grant award from the Laura W. Bush Institute of Women's Health and University Medical Center in Lubbock, TX

Quantifying Physical Activity Performed During Yoga

Bethany M. Forseth, Caitlyn Hauff, Ann Swartz, FACSM. *University of Wisconsin - Milwaukee, Milwaukee, WI.* (Sponsor: Ann Swartz, FACSM)

(No relationships reported)

The intensity of yoga is challenging to assess because the asanas of yoga include aerobic and anaerobic components; both of these components are measured through different methods. **PURPOSE:** The purpose of this project was to explore a method of assessing the physical activity completed during yoga. This study had two objectives: 1) Quantify characteristics of yoga (number of poses, body posture of a pose), and explore the concept of a pose rate (number of poses per minute of the routine), 2) Compare characteristics between different yoga categories to assess if the measures can differentiate between different yoga practices. **METHODS:** A content analysis was used to assess yoga routines; these routines were categorized by their primary purpose into one of the following groups: weight loss, beginner, or meditation. Researchers recorded the following characteristics from each routine: body position of each pose, number of poses, and duration of the yoga routine. An ANOVA was used to compare routine characteristics between yoga categories. **RESULTS:** Fifteen yoga routines were assessed (weight loss: 4, beginner: 5, and meditation: 6). The total number of poses completed ($p = 0.010$), number of total standing poses ($p = 0.001$), and percent of time in standing poses ($p = 0.018$) were significantly different between the three categories, with weight loss having the highest values. Significant differences were also observed in the number of body postures completed in standing with the head up ($p < 0.001$), and 'other' body positions (any body posture not explicitly

listed) ($p = 0.033$). The number of poses and percentage of time spent in the body postures of supine, seated, and standing with the head down were not significantly different between the routine categories. The pose rate was not significantly different between categories. **CONCLUSIONS:** This study demonstrated that assessing certain characteristics of routines may be one way to describe activity performed during yoga. A common method to assess the activity performed during yoga will allow for easy comparisons between studies and provide a basis to better interpret results. Further research should assess if similar results are found between different yoga styles and if the number of poses completed corresponds to larger physiological or metabolic responses.

Practical Issues Relating to a 7 Consecutive Days Wear Protocol Using the activPAL™ in Adolescents

Yan Shi¹, Wendy Yajun Huang², Sinead Sheridan¹, Stephen Heung-sang Wong, FACSM¹. ¹The Chinese University of Hong Kong, Hong Kong, Hong Kong. ²Hong Kong Baptist University, Hong Kong, Hong Kong. (Sponsor: Stephen Heung-sang Wong, FACSM)

Email: shiyan@link.cuhk.edu.hk

(No relationships reported)

The activPAL™ has been increasingly used in field-based studies as a valid measure of posture and activity. Practical issues relating to its use have been raised in adults but limited information is available in adolescents. **PURPOSE:** To examine the practical utility of a 7 consecutive days wear protocol of the activPAL™ in adolescents. **METHODS:** Six secondary schools in Hong Kong were randomly chosen for the study. 368 students (12-18 yrs; 47.6% boys) agreed to wear the activPAL3™ for 7 consecutive days. The device was worn on the midpoint of the anterior aspect of the right thigh using a water-proof Tegaderm adhesive dressing. Participants were asked to log the duration of and reasons for device removal. Semi-structured interviews with two focus group were conducted to further examine practical wearing issues. Each interview (30 mins) included 6 participants, 3 of them had worn the device continuously for 7 days and the remaining 3 participants had self-reported removing the device. 14 questions were asked to seek further information on the reasons for removal and uncomfortable feelings experienced. **RESULTS:** Of the 368 log records of the participants, 8 of them (2.2%) reported that they lost the monitor while wearing it. 184 participants (50%) wore the device for 7 consecutive days without removal while the other 50% reported removal in their logs. In total, 248 accounts of removal were reported and the main reasons included automatic dropping (48%), allergic reaction (34.7%), loss of adhesiveness during water based activities (10.1%) and voluntary removal (4.4%). For automatic dropping, sweating (78.5%) was the most commonly reported reason; and for allergic reaction, 61.6% of unknown allergy, 20.9% of itch, 7.0% of red skin, 5.8% of erythema, 2.3% of pain and 2.3% of blisters were reported. Uncomfortable skin feeling related to wearing the device was commonly reported during the interviews and the majority of them claimed that they would like to wear this monitor again but without adhesive dressing. **CONCLUSIONS:** The primary practical issue related to continuous wearing of the activPAL™ among adolescents was automatic dropping caused by sweating and allergic reaction to the adhesive dressing. The use of adhesive dressing caused uncomfortableness among adolescents and reduced their compliance to wear the device.

Estimates Of Body Composition In Normal Weight And Overweight Adults Using The Leanscreen App

Pat R. Vehrs, FACSM, Elizabeth MacDonald. *Brigham Young University, Provo, UT.*

(No relationships reported)

The LeanScreen™ app (LS) uses photographs taken from the front and side views, touch screen technology and manufacturer algorithms to estimate circumferences of the neck, abdomen, waist, and hips. The LS app then estimates body composition using the Department of Defense (DOD) circumferences regression equation. **PURPOSE:** This study evaluated the validity and reliability of estimates of percent body fat (%BF) in adult men and women using the LS app compared to DEXA as the criterion method. **METHODS:** Height and body mass were measured on 63 males and 58 females between 18 and 50 years of age. The participants were categorized as normal weight ($n=61$) or overweight ($n=60$) based on BMI. A DEXA scan was performed on each subject once. To assess the within-day and between-day reliability of the LS app, an administrator took front- and side-view photographs of each subject twice on the same day and once on a second day. The LS app was used to identify landmarks of the neck, abdomen, waist, and hips on each set of photographs of each subject. The LS app provided an estimate of %BF. Estimates of %BF from the LS app were compared to %BF values obtained from DEXA. **RESULTS:** A mixed model ANOVA indicated that the LS app significantly ($p = 0.0001$) underestimated DEXA %BF by an average of 3.6 %BF. The difference in %BF values between the LS app and DEXA were not influenced by gender or BMI category. Regressing the %BF determined from the LS

app against DEXA resulted in an $R^2 = 0.83$ and a $SEE = 3.4\%BF$. The intercept (2.84 %BF) and slope (1.035) of the regression line confirmed the significant bias. Bland-Altman analysis suggest that the bias of the LS app estimates of %BF increased with increasing body fatness. Use of the LS app to estimate %BF resulted in high intrarater (0.99) reliability within and between days. **CONCLUSIONS:** The results of this study show that the LeanScreen™ app, although highly reliable, significantly underestimated DEXA %BF. We suspect that this is related more to the DOD regression equation rather than the use of photographs and touchscreen technology.

629 May 31 1:45 PM - 2:00 PM

Body Composition and Bone Mineral Density of NCAA Division I Football Players

Tyler A. Bosch¹, Aaron Carbuhn², Philip R. Stanforth³, Jonathan M. Oliver⁴, Kathryn A. Keller¹, Donald R. Dengel, FACSM¹.

¹University of Minnesota, Minneapolis, MN. ²Kansas Athletics Inc., Lawrence, KS. ³University of Texas at Austin, Austin, TX. ⁴Texas Christian University, Fort Worth, TX. (Sponsor: Donald R Dengel, FACSM)
Email: bosch041@umn.edu

(No relationships reported)

Purpose: To examine positional differences in total and regional body composition in Division I collegiate football players using dual X-ray absorptiometry (DXA). Data is from the Consortium of College Athlete Research (C-CAR) group. **Methods:** Height, weight, total and regional fat mass, lean mass and bone mineral density were measured on 467 players in the preseason (June-August). Players were categorized by their offensive or defensive position (offensive linemen [OL] and defensive linemen [DL], linebacker[LB], tight end [TE], running back [RB], wide receiver [WR], defensive back [DB], quarterback [QB], kicker/punter/long snapper [ST]). An ANOVA tested the effect of position on body composition and bone density, and the Tukey honest significant difference test compared the differences between each position. **Results:** Table 1 presents the positional comparisons. If the rows do not share a letter, the positions are significantly different ($p < 0.05$). All positions were classified as overweight or obese based on body mass index [BMI ($>25 \text{ kg/m}^2$)], yet other than OL and DL, all positions had healthy percent body fat (13-20%) and low visceral fat mass ($<500 \text{ g}$). For bone mineral density (BMD), player position had an effect on total and regional (ex. legs) BMD with OL and DL being similar to TE/LB/RB ($p > 0.05$ for all), but higher than WR/DB/QB/ST ($p < 0.05$). **Conclusions:** Position had a significant effect on body composition measures and is likely associated with on-field positional requirements. From a health perspective, while most positions had higher BMIs, the majority had relatively low body fat and visceral fat. However, OL and DL had elevated total and visceral fat which could place them at higher health risk. Compared to other methods, DXA increases the accuracy and reliability of body composition and BMD, thus improving within and between position comparisons.

Table 1: Positional Body Composition Characteristics mean (\pm SD)

	OL (n=83)	DL (n=53)	TE (n=30)	LB (n=58)	RB (n=36)	DB (n=78)	WR (n=75)	QB (n=23)	ST (n=31)

Bone Mineral Density in Aesthetic and Performance Sports in Female Collegiate Athletes

Jessica A. Inogna, Ryan ER Reid, Patrick Delisle-Houde, Charlotte D. Haugan, Ross E. Andersen, FACSM. McGill University, Montreal, QC, Canada. (Sponsor: Ross E. Andersen, FACSM)

(No relationships reported)

Bone mineral density (BMD) in female athletes is influenced by many factors including genetics, menstrual history, calcium and vitamin D levels, hormonal changes, and physical activity. Percussive activity has been shown to lead to increased BMD. Peak BMD is achieved between the ages of 16-20 in females. Females begin participation in both ice hockey and synchronized swimming during crucial bone building years, which may affect peak BMD and therefore risk of osteoporosis later in life. **PURPOSE:** To evaluate BMD in the lower limb between ice hockey and synchronized swimming female collegiate athletes. **METHODS:** 41 female collegiate athletes ($n=22$ hockey players, $n=19$ synchronized swimmers) received a total body and left femur iDXA scan to evaluate total and regional BMD. Average age of the athletes was 20.30 ± 1.77 yrs. Average weight of the athletes was 65.36 ± 8.37 kg (synchronized swimmers: 62.62 ± 8.45 kg, hockey players: 67.73 ± 7.73 , ($F(1,40)=4.09$, $p \leq 0.05$). Analysis of covariance (ANCOVA) was used to compare BMD of the legs, pelvis, femur, femoral neck, femoral shaft, trochanter, and total body while controlling for age and weight. **RESULTS:** Average body fat percentage as measured by iDXA for all athletes was $28.55 \pm 5.97\%$. Hockey players had higher BMD than synchronized swimmers in their legs ($F(1,37) = 17.31$, $p \leq .01$), pelvis ($F(1,37) = 34.63$, $p \leq .01$), femur ($F(1,37) = 15.2$, $p \leq .01$), femoral neck ($F(1,37) = 7.30$, $p \leq .01$), femoral shaft ($F(1,37) = 13.77$, $p \leq .01$), trochanter ($F(1,37) = 25.88$, $p \leq .01$), and total body ($F(1,37) = 17.58$, $p \leq .01$). **CONCLUSIONS:** Female collegiate hockey players have higher weight and age adjusted BMD than female collegiate synchronized swimmers in the lower limb and multiple sites around the femur. A lower BMD puts these female athletes at a greater risk of developing osteoporosis later in life. Exercise scientists should develop alternative land training programs that focus on bone loading exercises for female synchronized swimmers to optimize bone health at a young age.

A National Survey of Impact of Afterschool Physical Activities on U.S. Youth

Xiong Qin, Jinghao Wang, Yan Yang, Weimo Zhu, FACSM. University of Illinois at Urbana-Champaign, Urbana, IL. (Sponsor: Weimo Zhu, FACSM)
Email: xiongg2@illinois.edu

(No relationships reported)

PURPOSE: To address the worldwide childhood obesity epidemic, afterschool physical activities (PA) could play an important role. Yet, little is known about the status and impact of afterschool PA on U.S. youth. This study was to examine the impact through a national survey. **METHODS:** Data from the 2012 National Youth Fitness Survey were used for the study, in which a representative/weighted national sample of 4,647,648 youth, aged 12-15 yr. old (51.30% male) responded to the PA questionnaire and were assessed for their physical fitness, including Plank, Handgrip, Pull-ups, Leg extension, Body mass index (BMI), and Waist circumference. A descriptive statistical summary of the PA participation was created first and, then the relationships between PA participation and PA times, as well as the difference in physical fitness measures between PA participation and no participation groups, were examined. **RESULTS:** The top-5 afterschool PA for boys of this age group are basketball (19.60%), roller blading (14.50), volleyball (12.43), football (11.83), and bike riding (11.68), and for girls are roller blading (11.52), volleyball (11.37), basketball (8.49), dance (7.01), and bike riding (5.98), respectively. Although the correlation is not high, the afterschool PA participation was positively correlated with the number of PA days in the past week ($r = .23$), total time of vigorous PA on a typical day (.15), total time of moderate-vigorous PA (.17), and total time walking (.17). The participation in afterschool PA was found also to have a positive impact on the physical fitness measures. **CONCLUSIONS:** Positive impact of afterschool on promoting youth's overall PA time and improving their physical fitness was confirmed. It is also interesting to find out that activities such roller blading have become popular afterschool PA for U.S. youth. Future school physical education curriculum and afterschool programs should reflect the new interest and trend of this population.

Instant Metabolic Power: Yet too Simplified but with High Potential
 Ralph Beneke, FACSM, Max Niemeyer. *Philipps-University, Marburg, Germany.*
 Email: ralph.beneke@staff.uni-marburg.de
(No relationships reported)

Instant metabolic power (IMP) to assess energy cost (W) in running tasks with variable velocity (v) has come under critique in terms of substantial underestimations. IMP is based on assumptions that W per meter running distance at constant v (Cr) is invariant of v and that acceleration and deceleration can be modelled as constant v uphill and downhill running (CrIMP), respectively. **PURPOSE:** To test the hypotheses that the observed underestimation of W via IMP is caused by a dependence of Cr on v at running speeds at and above the v corresponding to VO_{2max} (vVO_{2max}) and the limited validity of the IMP-model to acceleration and deceleration less than $\sim 4.4 \text{ m/s}^2$ under interval training (IT) conditions. **METHODS:** 9 males (25.6 ± 2.0 yrs, 176.8 ± 4.2 cm, 76.8 ± 4.1 kg) performed an incremental load test on the treadmill, 15 min constant v runs (2.5 m/s) and IT of 30 x 10 s (average $v = vVO_{2max}$) with 20 s breaks on treadmill (TM) and outdoor track (OT), respectively. Total energy costs (W_{TOT}) of all tests were calculated from respiratory gas measurements and net lactate appearance. W assessed via IMP (W_{IMP}) for TM and OT was estimated using CrIMP: 1) as published previously using Cr of running at 2.5 m/s on TM and OT, respectively, and the previously published IMP-model (W_{IMP1}), 2) using a modified CrIMP-model considering also acceleration and decelerations higher than $\sim 4.4 \text{ m/s}^2$ (W_{IMP2}), 3) considering individual dependence of Cr on v at $v > vVO_{2max}$ (W_{IMP3}). **RESULTS:** W_{TOT} of running at 2.5 m/s on TM ($9210 \pm 842 \text{ J/kg}$) and OT ($8926 \pm 1028 \text{ J/kg}$), and IT on OT ($8970 \pm 559 \text{ J/kg}$) were not different but all higher ($p < 0.05$) than W_{TOT} at IT on TM ($7856 \pm 515 \text{ J/kg}$). W_{IMP1} (OT: $6363 \pm 442 \text{ J/kg}$; TM: $5691 \pm 367 \text{ J/kg}$) and W_{IMP2} (OT: $6528 \pm 368 \text{ J/kg}$; TM: $5691 \pm 367 \text{ J/kg}$) were lower ($p < 0.001$) than the corresponding W_{TOT} . W_{IMP3} (OT: $8731 \pm 484 \text{ J/kg}$; TM: $7009 \pm 572 \text{ J/kg}$) matched W_{TOT} on OT but still underestimated ($p < 0.001$) W_{TOT} of TM conditions possibly due to neglecting W of jumping onto and of the TM. **CONCLUSIONS:** Realistic estimates of W_{TOT} via IMP require adjustments for increased Cr at high v and accelerations and decelerations higher than $\sim 4.4 \text{ m/s}^2$.

Muscle-damage Biomarkers, Hydration And Electrolytes Status Associated With Surfing Sessions Of Elite Brazilian Surfers
 Franz H. Burini¹, Rafael Rezende¹, Pedro Rodstein¹, Rodrigo Manda¹, Okesley Teixeira¹, Salete Coelho¹, Paulo Mendes², Roberto C. Burini, FACSM¹. ¹UNESP Medical School, Botucatu, Brazil. ²SURFCo., São Paulo, Brazil. (Sponsor: Roberto C. Burini, FACSM)
 Email: fburini@fmb.unesp.br
(No relationships reported)

Surfing demands multifactorial physical fitness and continuing interaction with environmental variables, such as tide, wind, wave size and swell direction. Surfing athletes should focus on performance and artistic overview of movements, specially when in competition, regarding scoring criterias. Health issues, such as metabolic and biomechanical, associated with nutritional and hydration status may modulate athletes performance and fatigue. **PURPOSE:** The purpose of this study was to describe surfing sessions on a routine training-day of elite professional surfers using Global Positioning System (GPS) data, and analyze hydration and electrolytes status, as also as muscle-damage biomarkers prior, after and 12h after sessions. **METHODS:** 6 professional male surfers (24 ± 1 yrs) were evaluated using a GPS module on a typical day of surf training session (3×90 sessions), for determining distance, average and maximum speed. Blood samples were collected for Hematocrit (Ht), Sodium (Na), Potassium (K), Urea and CAK levels before, after sessions and 12h after resting period. **RESULTS:** Average distance during the session was 9.1 ± 3.5 km, and maximum and average speed were 38.4 ± 0.1 km/h and 4.7 ± 0.4 km/h, respectively. Pre, post and 12h post sessions values for CK were 223.5 ± 49.5 ; 328.6 ± 94.1 and 305.5 ± 4.2 mg/

dL. Urea values were 26.3 ± 2.1 ; 35.6 ± 4.9 and 35.6 ± 2.8 mg/dL. Hydration variables such as Ht, Na and K were 42.1 ± 2.1 , 40.5 ± 2.1 , $40.3 \pm 1.4\%$; 140.5 ± 0.7 , 140.8 ± 2.8 , 140.3 ± 1.4 mEq/L and 4.2 ± 0.1 , 3.9 ± 0.1 , 4.1 ± 0.2 mEq/L. **CONCLUSION:** Surfers athletic performance should be focused on a multifactorial matter. Dietary pattern, hydration and electrolytes issues may influence performance on a short-term base, specially on typical surfing contests, characterized by followed days of competition. This data suggests that athletes have considerable physical demands, and such tools may guide to improvement on health and performance.

B-14 Free Communication/Slide - Walking Biomechanics

Asymmetry in Lower Extremity Biomechanics During Walking & Stair Ambulation Following Total Knee Replacement
 Tyler Standifird¹, Harold E. Cates², Songning Zhang, FACSM³. ¹Utah Valley University, Orem, UT. ²Tennessee Orthopedic Clinic, Knoxville, TN. ³University of Tennessee, Knoxville, TN.
 Email: tyler.standifird@uvu.edu
(No relationships reported)

Total knee replacement (TKR) presents many challenges to patients including difficulty with activities of daily living. It has been shown that following a TKR there is a non-random evolution of joint problems that begins with the contralateral knee joint. An understanding of asymmetry in the joints following TKR may provide additional information as to why this evolution may occur. Previous research has shown that there is no differences of knee joint excursion and ground reaction force between replaced and non-replaced legs during level walking. **Purpose:** To compare asymmetry in the non-replaced and replaced limbs of TKR patients during level walking, stair ascent, and stair descent. It was hypothesized that greater asymmetry would be seen in knee joint biomechanics during the more demanding tasks of stair ambulation. **Methods:** A total of 13 TKA (65.6 yrs, 28.3 BMI & 24.5 months from TKA surgery) participants performed five trials of level walking, stair ascent and stair descent at preferred speeds. A paired samples t-test was used to detect differences in the replaced and non-replaced limb for each condition ($p < 0.05$). **RESULTS:** There were no differences in first or second peak vertical ground reaction force between limbs for any of the walking conditions. There were also no differences between sagittal plane knee joint range of motion (ROM) between limbs for any conditions. The first peak knee extension moment showed asymmetry only during stair ascent. The non-replaced limb had a trend for elevated peak knee extension moment (1.17 Nm/kg) compared to the replaced (0.97 Nm/kg , $p = 0.05$). No differences were seen for peak internal knee abduction moments between the limbs in any condition. **CONCLUSION:** It appears that there is very little asymmetry between the replaced and non-replaced limb following a TKR in this participant group. Only the knee extension moment during stair ascent showed any signs of asymmetry. Similar results have been shown in previous research when considering only level walking. Contrary to our hypothesis the more difficult tasks of stair ascent and descent did not create asymmetry between limbs. This participant group was highly functional as determined by their ability to ascend and descend stairs without the use of a handrail. Future studies should consider how groups with mixed recovery results may fair.

Walking Aid Use And Arthritis: Impact On Time Spent In Active Propulsion In Older Adults
 Eryn Murphy, David W. Keeley, Robert Wood. *New Mexico State University, Las Cruces, NM.* (Sponsor: Joseph Berning, FACSM)
 Email: emurphy2@nmsu.edu
(No relationships reported)

Gait cycle percentage spent in active propulsion is significantly greater in those without a history of falling in the past year than those with a history of falling in the past year. **PURPOSE:** This study examined the impact of walking aid use and diagnosed arthritis on gait cycle percentage spent in active propulsion in fallers and non-fallers. **METHODS:** A total of 250 subjects over the age of 60 years (age; 71.1 ± 7.4 yrs, height; 1418.5 ± 21.2 cm, mass; 57.1 ± 6.3 kg) were recruited from the southwest

United States, completed a brief medical history and gait analysis. Following the collection of these data, subjects were assigned to one of two groups based on having fallen (F; n=90) or having not fallen (NF; n=160) in the past year. Independent t-tests were conducted to explore group differences (walking aid, arthritis; $\alpha = 0.05$) in time spent in active propulsion. For these analyses the F and NF groups were analyzed separately with percentage spent in active propulsion as the dependent variable and both walking aid use and self-reported diagnosis of arthritis were the independent variables. **RESULTS:** For walking aid use, NF not utilizing a walking aid had a significantly higher ($p = 0.033$) gait cycle percentage spent in active propulsion ($56.9\% \pm 2.6$) than NF who use a walking aid ($41.4\% \pm 6.4$). There was also a significant difference ($p = 0.029$) in gait cycle percentage spent in active propulsion for NF without a diagnosis of arthritis ($60.6\% \pm 3.4$) compared to NF with a diagnosis of arthritis ($49.9\% \pm 3.4$). In contrast, there were no differences among the fallers in gait cycle percentage spent in active propulsion based on walking aid use ($48.3\% \pm 2.8$ for no walking aid; $43.1\% \pm 6.4$ for walking aid, $p = 0.46$) or arthritis diagnosis ($52.2\% \pm 3.8$ for no arthritis diagnosis; $43.7\% \pm 3.4$ for arthritis diagnosis, $p = 0.09$). **CONCLUSIONS:** Specific to those with a history of falls, use of a walking aid or history of arthritis does not impact gait cycle percentage spent in active propulsion. However, for individuals with no history of falling in the last year, both use of walking aid and diagnosis of arthritis significantly reduces percent of the gait cycle spent in active propulsion which has been previously shown to differ between people with and without a history of falls.

Increasing Body Weight Alters Lower Limb Muscle Balance And Foot Control

Hechmi Toumi¹, Thomas M. Best, FACSM², Masensen Cherief³, Gaith Larguech³, Marija Mazor³, Eric Lespessailles³. ¹Service de Rhumatologie, Centre hospitalier régional d'Orléans., Orleans University, Orleans, France. ²Department of Orthopedics, Division of Sports Medicine, Miami, FL. ³Orleans University, Orleans, France. (Sponsor: Thomas Best, FACSM)
Email: hechmi.toumi@univ-orleans.fr
(No relationships reported)

Obesity is a well established risk factor for developing osteoarthritis (OA). Population-based studies in particular have consistently shown a link between obesity and knee OA. Yet many factors for diseases and conditions associated with obesity could contribute to OA initiation and/or progression. The present study examined the effects systematically increasing subject weight and the effects on quadriceps femoris muscle function and foot balance stability during walking and squatting. **Methods:** Twenty asymptomatic healthy young adults (Age = 22 ± 2 ; 19 kg/m²) < BMI < 22 kg/m²) were studied. A three-dimensional gait analysis was conducted for all subjects. Plantar pressure distribution (the peak pressure of the eight plantar surface areas) and foot kinematics, surface electromyograms from the lateral and medial gastrocnemii, lateral and medial hamstrings, vastus lateralis (VL), vastus medialis (VM), and rectus femoris (RF) were recorded during squatting and self-selected speed walking. Weight increase (10, 20 and 30% of subject body weight) was achieved by placing a belly bag on the subject's body attached around the hip and to the shoulders. Principal component analysis was used to extract major features of amplitude and temporal pattern variability from the electromyograms of each muscle group (gastrocnemii, quadriceps, hamstrings separately). Analysis of variance models tested for weight load effects and interaction effects for these features ($\alpha = 0.05$). **Results:** Significant weight load effects were found for features that described more prolonged activation of the gastrocnemii and quadriceps muscles during the stance phase of gait ($P < 0.05$). Load increase selectively activated the VL compared to the VM during walking and the first 20 degrees of knee flexion during the squat. Load increase was also associated with increased mid-rear-foot pressure and delay in both the onset of the second wave of flexion at the knee joint and reduced range of motion of the ankle ($P < 0.05$). **Conclusions:** We confirm the effects of increasing body weight on lower extremity muscle activation and foot balance control, both of which may contribute to knee OA development and progression.

638 May 31 1:45 PM - 2:00 PM

Effect Of Excess Weight on Lower-Extremity Vertical Stiffness, Muscle Activation, And Metabolic Cost Of Walking

Victoria A. Gregory, Ronald V. Croce, Timothy J. Quinn, FACSM, Dain P. LaRoche, FACSM. University of New Hampshire, Durham, NH.
Email: vgreg6@gmail.com
(No relationships reported)

PURPOSE: To study the relationship between energy cost of walking (Cw), lower-extremity vertical stiffness (K_{vert}), and muscle activation across various BMIs. **METHODS:** This study compared Cw, K_{vert} , and muscle activation between obese (OB), normal weight (NW), and NW individuals carrying a load (NWL). A sample

of 10 NW (24.2 ± 1.3 kg m⁻²) and 10 OB (33.1 ± 2.0 kg m⁻²) individuals (29.5 ± 11.7 yr, 14 females, 6 males) walked for six minutes on an instrumented treadmill at 1.25 m s⁻¹ while oxygen uptake, muscle activation, and lower-extremity kinetics and kinematics were measured using an indirect calorimeter, electromyography, and a 3D optical motion tracking system, respectively. **RESULTS:** Cw was 24% greater in OB (277.5 ± 45.3 J m⁻¹) compared to NW (211.0 ± 27.0 J m⁻¹, $P = 0.001$), 23% greater in NWL (272.7 ± 35.7 J m⁻¹) compared to NW ($P = 0.002$), but similar between OB and NWL ($P = 0.955$). Mass-specific Cw (Cw_{kg}) was not statistically different between NW (2.99 ± 0.24 J m⁻¹ kg⁻¹) and OB (2.85 ± 0.18 J m⁻¹ kg⁻¹, $P = 0.382$), NW and NWL (2.74 ± 0.24 J m⁻¹ kg⁻¹, $P = 0.071$), or OB and NWL ($P = 0.602$), however a negative correlation ($r = -0.44$, $P = 0.008$) existed between BMI and Cw_{kg} . K_{vert} was higher in OB (32.7 ± 5.2 kN m⁻¹) than NW (23.3 ± 4.7 kN m⁻¹, $P < 0.001$), but NWL (27.5 ± 3.4 kN m⁻¹) was not different from either. K_{vert} per kilogram ($P = 0.081$) and muscle activation ($P > 0.05$) were similar across all conditions. A positive correlation existed between K_{vert} and Cw ($r = 0.55$, $P = 0.001$), but not when expressed per kilogram ($r = 0.22$, $P = 0.120$). Center of mass (COM) vertical displacement was similar between OB (3.3 ± 0.4 cm) and NW (3.5 ± 0.7 cm, $P = 0.875$), OB and NWL (3.9 ± 0.7 cm, $P = 0.076$), and NW and NWL ($P = 0.194$). Angle of attack between the leg and ground was similar between OB (104 ± 6 deg) and NW (106 ± 6 deg, $P = 0.731$) and between NW and NWL (110 ± 3 deg, $P = 0.198$), but 5% lower in OB than NWL ($P = 0.045$). **CONCLUSION:** Cw_{kg} decreased from the NW to NWL condition. K_{vert} was greater at higher BMIs, but per kilogram was lower in NWL than OB likely due to NWL having a greater angle of attack and COM displacement. The linear relationship between K_{vert} and Cw is likely due to the greater muscle force needed to support larger body masses. Contrary to our hypothesis, Cw_{kg} was not different between NW and OB and neither K_{vert} nor muscle activation explained the variability in Cw_{kg} .

639 May 31 2:00 PM - 2:15 PM

Concurrent Validity Of Zeno Compared To Gaitrite With Backward Walking In Healthy Older Adults

Rebecca Lin, Shagun Patel, Coty Thomas, Jane Freund, Srikant Vallabhajosula. Elon University, Elon, NC. (Sponsor: Dr. Stephen Bailey, FACSM)
Email: rlin@elon.edu
(No relationships reported)

Previous research has identified an age-related decline in backward walking performance measured via spatio-temporal parameters using GAITRite walkway. Moreover, it has also been shown that older adults categorized as fallers performed poorly with slower gait compared to non-fallers during backward walking. Zeno and GAITRite are both instrumented walkway systems used to assess spatio-temporal parameters of gait. The Zeno has a wider walkway than the GAITRite but is less portable for similar configurations. The GAITRite has been used extensively for measuring spatio-temporal parameters of backward gait. The Zeno has been less researched. **PURPOSE:** To determine concurrent validity of the Zeno and GAITRite walkways to assess spatio-temporal parameters of backwards walking in healthy older adults. **METHODS:** 30 healthy older adults (19 females, 75.1 ± 6.3 years of age) participated in this study. Participants were 65 or older, could walk 30 feet independently, and were not at risk for falls as determined by American Geriatric Society guidelines. The participants walked backwards at a comfortable pace on both the Zeno walkway ($16' \times 4'$) and GAITRite walkway ($14' \times 2'$). Participants performed one practice walk and five test walks on each walkway. ICC values (2,5) were calculated using GAITRite compared to Zeno measurements for stride length, width, and velocity, step, stance, and swing time, stance and swing percent, single support time, single support percent, velocity, and cadence. A paired sample t-test was used to determine a significant difference between measurements from both the systems. **RESULTS:** The ICC values ranged from 0.665 to 0.971. Backwards walking stride width was significantly greater when walking on GAITRite (16.80 ± 4.74 cm) compared to Zeno (14.98 ± 3.58 cm; $P < 0.001$). **CONCLUSION:** The validity between the GAITRite and Zeno walkway systems showed excellent correlation on most spatial measurements and moderate agreement for some temporal parameters. Differences in stride width could have been due to method of calculation or perception of participants while walking on a narrower walkway. The results indicate clinicians can use Zeno for clinical assessment of backwards gait, keeping in mind the differences in temporal measurements if compared with published GAITRite results for healthy older adults.

640 May 31 2:15 PM - 2:30 PM

Gait Variability Among Breast Cancer Survivors During Forward And Backward Walking

Srikant Vallabhajosula, Emily H. Harrison, Caroline D. Deaterly, Takudzwa A. Madzima. Elon University, Elon, NC. (Sponsor: Dr. Stephen Bailey, FACSM)
Email: svallabhajosula@elon.edu
(No relationships reported)

Increased in gait variability measured using instrumented techniques has been associated with increased risk of falls in persons with Parkinson's disease, decreased

functional performance and increased fall-risk in older adults. Recently research on breast cancer survivors (BCS) has focused on estimating fall-risk in this population attributed to gait performance. However, little is known about gait variability characteristics among BCS. **PURPOSE:** To assess the differences in gait variability among BCS compared to healthy controls during forward, backward, and accelerated forward walking. **METHODS:** 13 postmenopausal BCS (mean age: 58.5±8.5 years) and 8 healthy controls (mean age: 60.8±6.1 years) participated. Participants completed 5 trials each of forward, backward, and accelerated forward walking conditions on a 16x4' Zeno walkway with a lead and follow-up distance of 1m to capture steady-state gait. Coefficient of variation (CV) was calculated as % of standard deviation over mean of 5 trials. CV of stride length, stance time, and stride width were used as dependent variables. A Group (BCS vs healthy controls) X Condition (forward, backward, accelerated forward walking) ANOVA was performed. **RESULTS:** Significant interaction for stance time showed that BCS had greater CV during forward (4.89±0.63%) and accelerated forward (6.49±0.78%) but lesser CV during backward walking (6.28±1.09%) compared to healthy controls (forward: 3.81±0.80%; accelerated forward: 4.23±1.00%; backward: 9.20±1.38%; $P=0.018$). Significant group main effect indicated that BCS (7.09±3.59%) had greater stride length variability compared to healthy controls (3.59±1.32%) across all conditions ($P=0.05$). Significant condition main effect was observed for stride length and stance time CV (both $P=0.02$) but not stride width ($P=0.063$). During forward walking, stride length (by 5%) and stance time (by 3.3%) CV were significantly less compared to backward walking (both $P=0.004$). There were no other significant differences. **CONCLUSION:** Increased stance time variability during backward walking and overall greater stride length variability may be indicative of increased fall-risk among BCS. Future studies need to examine other balance tests in conjunction with these measures to determine the level of fall-risk among BCS.

641 May 31 2:30 PM - 2:45 PM
Upper Body Accelerations During Walking are Altered in Individuals With ACL Reconstruction
 Cortney N. Armitano, Steven Morrison, Daniel M. Russell. *Old Dominion University, Norfolk, VA.* (Sponsor: David P. Swain, FACSM)
 Email: carmi002@odu.edu
 (No relationships reported)

One function of the trunk and neck segments is to act as a filter to dampen gait-related oscillations, so ensuring the head is stabilized. While persons with ACL reconstruction exhibit similar overall spatiotemporal gait features to healthy controls, there has been no direct assessment of whether ACL reconstruction impacts the ability of the upper body to attenuate oscillations while walking. **PURPOSE:** This study was designed to assess and compare the pattern of acceleration from the lower trunk, neck and head regions for individuals with reconstructed ACL compared to healthy controls during walking. **METHODS:** Seventeen participants with unilateral ACL reconstruction and 17 control persons matched for age, height, and weight participated in the study. Participants performed 3 trials of over-ground walking at their preferred pace (distance: 55 m). Acceleration were collected using three triaxial accelerometers attached to the head (occipital), neck (C7), and lower trunk (L3). Measures of amplitude (i.e., RMS, peak frequency power) and signal regularity (i.e., ApEn) of the acceleration data were performed. A within-subject, repeated-measures generalized linear model was used to analyze the data. **RESULTS:** Similarities were seen between both groups with regards to the general acceleration patterns in all three axes with trunk acceleration generally being of greater amplitude (both RMS and peak power) than the head ($p<0.05$). However, the results also revealed that the individuals with ACL reconstruction had significantly greater peak power in the AP and ML directions at higher frequencies (3-10 Hz, $p<0.05$), indicating a reduced ability to attenuate frequency signals. Further, the ACL group had an increase in ApEn values for VT direction head motion ($p<0.05$), indicating a reduced ability to control head motion during gait. **CONCLUSIONS:** Both groups demonstrated a similar pattern of gait-related oscillations across the head, neck and trunk segments. However, adults with a reconstructed ACL demonstrated a reduced capacity to compensate for the higher frequency components of the gait signal, which may have led to a decline in head control. Overall, these findings indicate that previous damage to the ACL is not simply localized to the knee joint, but is widespread, impacting on upper body control as well.

642 May 31 2:45 PM - 3:00 PM
Characterizing Shank Angular Velocity During Gait in Individuals Post-ACLR Using IMUs in Ecological Settings
 Paige E. Lin, Gabriel M. Glasser, Ming-Sheng M. Chan, Susan M. Sigward. *University of Southern California, Los Angeles, CA.*
 Email: paigeeli@usc.edu
 (No relationships reported)

Individuals post ACL reconstruction (ACLR) exhibit decreased knee extensor moments during gait in the absence of visible gait deviations that can last up to 2 years post-

surgery. Inertial measurement unit (IMU) derived shank angular velocities (skAV) can be used to detect knee extensor moment asymmetries during gait in individuals 3 months post-ACLR; providing a clinical tool for identification of altered mechanics. These methods could be expanded to quantify gait mechanics during daily activities if skAV asymmetry can be detected during more ecological gait tasks. **PURPOSE:** To compare skAV asymmetry during ecological gait in individuals 3 months post-ACLR to controls. **METHODS:** 7 individuals (4F, 33 ± 9.6 yrs) 84 ± 20 days post-ACLR without observable gait deficits and 5 healthy controls (4F, 24 ± 2.8 yrs) performed 2-5 bouts of unconstrained walking intermixed with standing and sitting. Sagittal skAV was measured using IMU tri-axial gyroscopes (128Hz) affixed to lateral shanks bilaterally. Peak negative skAV after heel strike was identified (2nd order Butterworth filter; high pass 0.25 Hz; low pass 6 Hz) using a previously validated algorithm. skAV for each limb was averaged for 20-231 continuous steps of gait per walking bout. skAV asymmetry was calculated as the ratio between surgical/non-surgical limbs (ACLR) and dominant/non-dominant limbs (control). Independent t-test was used to compare skAV ratios between groups; $\alpha \leq .05$. **RESULTS:** On average, skAV ratios were 0.89 ± 0.09 and 1.00 ± 0.09 for the ACLR and control groups, respectively ($p=0.024$). **CONCLUSIONS:** Consistent with previous studies, individuals after ACLR demonstrate reduced skAV in the surgical limb during loading response as evidenced by a smaller ratio compared to controls. Differences between groups during natural gait tasks performed with other daily tasks suggest that skAV asymmetries are detectable in less controlled settings. Given the capabilities of IMUs to collect and store large amounts of data, these data support the use of IMUs for assessing the quality of gait mechanics throughout the day. Understanding the extent to which individuals adopt altered loading outside of the laboratory is needed for the development of training interventions aimed at mitigating altered gait mechanics during early rehabilitation following ACLR.

Low Back and Bilateral Posterior Hip Pain in an Adolescent Female
 Jasmin Mosley Gooden, Michael Fong, Marissa S. Vasquez. *Kaiser Permanente, Los Angeles, CA.* (Sponsor: Aaron Rubin, FACSM)
 (No relationships reported)

HISTORY: 14-year-old female presenting with persistent low back pain of insidious onset for 1.5 years. Patient initially managed at outside hospital. Work-up included MRI lumbar that noted possible early lumbosacral facet arthritis. Pain persisted despite oral anti-inflammatory medications, functional modifications, and physical therapy. On presentation to our institution, patient was referred by primary care to rheumatology. Patient's generalized low back pain noted to progress to involve the posterior aspect of both thighs with occasional weakness of her legs, right more than left. Pain worsened with prolonged walking and sitting. No radiating pain, night time or early morning pain, nor pain nor swelling of other joints. Rheumatologist recommended Naprosyn, advanced imaging, and referral to sports medicine.

PHYSICAL EXAMINATION: Normal back exam; lower motor strength; muscle tone; and hip and back range of motion. No muscle atrophy. She had posterior hip tenderness in the Ischia-gluteal region that worsened with resisted hip abduction. Negative FABERE, OBER, and straight leg raise. Negative FADIR for anterior hip pain; maneuver produced tenderness in gluteus region. Femoral stretch equivocal bilaterally. Positive Trendelenberg
DIFFERENTIAL DIAGNOSIS.
 - Spondyloarthropathy
 - Bilateral Isthiofemoral Impingement
 - Bilateral Meralgia Paresthetica

TEST AND RESULTS:

EMG LE (08/10/16): normal

MRI Pelvis with/without contrast (05/08/16):

- No osteonecrosis, joint effusion, synovitis.

- Narrowed ischiofemoral interval bilaterally: 11mm on left, 10mm on right; Quadratus femoral space measured 7mm on left, 9mm on right.

- Quadratus femoris soft tissue edema, Left more than Right

X-ray hips (04/25/16): Normal alignment. No fracture.

Spina Bifida Occulta at L5.

HLA-B27; Cocci IgG/IgM; ESR; CRP; ANA within normal limits

MRI lumbar (04/17/15): facet arthritis

FINAL WORKING DIAGNOSIS: Bilateral Ischiofemoral Impingement.**TREATMENT AND OUTCOMES:**

1. Naprosyn - minimal improvement

2. Physical Therapy (gluteal strengthening). Tolerated home exercise program - improved anterior leg pain, but persistent posterior hip pain.

3. Ultrasound guided corticosteroid Injection to right quadratus femoris and relative rest. If symptoms improve will inject left quadratus femoris in 1-2 weeks post treatment.

647 May 31 1:20 PM - 1:40 PM

A Real Pain in the BehindSpencer Jones. *TriHealth Orthopedics & Sports Institute, Cincinnati, OH.*

Email: spencer_jones@trihealth.com

*(No relationships reported)***History and Presentation:**

22-year-old female presented to sports medicine clinic for acute on chronic coccyx pain. She initially sustained an injury 6 years ago when she slipped on some steps, pain resolved until 4 years ago when she slipped stepping out of a car. The pain at that time was identical to previous, with coccygeal pain when seated or supine for extended periods. X-rays were negative at the time, and her pain resolved with PT and meloxicam. She was lost to follow up for 2 years after that time, until she presented with increased pain again. No new injury, but pain feels similar. She has been unable to exercise including bike riding since the onset of her pain. She reported no ambulatory pain. She denied radicular symptoms, systemic symptoms, or bowel/bladder incontinence. PMH was unremarkable, non-smoker, no significant family history.

Physical Examination: Vitals were revealed and normal. No deformity of the lumbar spine, sacrum, or coccyx. She did have some mild tenderness to palpation at the sacral-coccyx joint, but range of motion was normal. Straight leg raise negative. Distal sacral plexus sensation intact. **Differential Diagnosis:** 1. Coccydynia 2. Sacroiliitis 3. Rectal abscess 4. Pilonidal cyst 5. Soft tissue mass 6. Sacral-coccyx joint dislocation 7. Occult fracture **Testing and Results:** Repeat x-ray was negative for fracture, dislocation. There was some non-specific soft tissue edema around the sacral coccyx junction which is unclear. MRI was obtained which revealed a large expansile midline mass occupying the sacrum and coccyx and extending into the anterior pelvis measuring 7.2 x 9 x 8.5 cm. Tissue sampling would confirm a chordoma. **Final Diagnosis:** Sacral chordoma **Treatment & Outcomes:** 1. NSAIDs and opioids for pain control 2. Neurosurgical consultation 3. This patient's treatment is still ongoing at time of abstract submission. Initial surgical resection was modestly successful although the size of the tumor complicated complete resection Possible complications include chronic surgical site pain, nerve damage, continue chronic coccydynia. Median survival rate for sacral chordoma is approximately 7 years

648 May 31 1:40 PM - 2:00 PM

Rapid Return To Sport After Lumbar Epidural Steroid InjectionLauren Geroski, James Natalie, Stephen Woods. *COPC Sports, Spine & Joint, Westerville, OH.**(No relationships reported)*

HISTORY: A 66-year-old healthy active adult male with acute onset lumbosacral pain with referral into left leg while putting weights down after exercising. Initial primary care evaluation was unremarkable and patient was given Naprosyn, Percocet and an XRay was ordered, showing grade 1 spondylololthesis L2-3. Pain continued and he presented one week later with continued severe pain and new left lateral leg numbness. Oral steroids and physical therapy were initiated and pain continued. Gabapentin was tried with no response. He was seen at 9 weeks and complained of pain with all activities, including sitting. MRI was ordered and he was referred to physiatrist. He was seen one week later with 6/10 severe pain in left low back radiating down the left leg into lateral foot and ankle. Activity remains limited with pain even in the seated position and ADLs affected

PHYSICAL EXAMINATION: Positive straight leg raise, decreased sensation left lower limb in the entire foot and lateral calf, 4/5 strength left ADF

DIFFERENTIAL DIAGNOSIS: Lumbar disc herniation, lumbar radiculopathy, spondylololthesis, lumbar stenosis

TESTS AND RESULTS: MRI Lumbar Spine without Contrast:L4-L5 broad-based left-sided disc herniation extruding inferiorly left paracentral measuring 16 x 14 x 15 mm effacing the thecal sac and displacing the left L5 nerve root

FINAL WORKING DIAGNOSIS: L5-S1 disc herniation with left L5 radiculopathy
TREATMENTS AND OUTCOMES: Symptoms persisted despite oral steroids, NSAIDs, and physical therapy, and lumbar epidural steroid injection was performed. Patient had 98% pain relief with resolution of numbness. Left ankle dorsiflexion strength that improved (5-/5), pain was only 1/10 in left lumbosacral junction. Physical therapy was restarted for 4 weeks to improve core strengthening. At 6 wks, numbness had resolved, strength had normalized, and he was back to normal activities of biking 21 miles and lifting regularly.

649 May 31 2:00 PM - 2:20 PM

Back Injury - CheerleadingMichael A. Stiller, Michelle A. Miller. *The Ohio State University, Columbus, OH.**(No relationships reported)*

HISTORY: A 15-year-old high school cheerleader sustained a back injury while cheering on her school's football team. She was performing a "toe touch" jump and upon landing, she felt a "pop" and a sharp pain posteriorly between her shoulder blades. An hour later, she developed a "pins and needles" sensation from her belly button to her toes bilaterally. The next morning, the numbness had spread to just under the ribcage and she fell when trying to stand upright from bed. She presented to the emergency room later that morning.

PHYSICAL EXAMINATION: Examination revealed that she was afebrile with normal vital signs. There was no tenderness on palpation over the spinous processes or the paraspinal musculature. Her neurologic exam was significant for decreased sensation to light touch at the T8 dermatome and caudally with a proprioception deficit in the great toe bilaterally. Strength was 4/5 throughout the left lower limb. The patellar reflexes were 3/4 and the Achilles were 2/4 bilaterally. She demonstrated a wide-based gait with significant loss of balance.

DIFFERENTIAL DIAGNOSIS:

1. Spondylololysis/spondylololsthesis
2. Vertebral fracture
3. Intervertebral disc herniation
4. Transverse myelitis
5. Psychogenic

TESTS AND RESULTS:

ESR and CRP normal

T-spine MRI:

1. Mild age related change/disc degeneration at T7-8 and T8-9 with a small acute appearing central disc protrusion at T8-9 that abuts the adjacent spinal cord.

2. No findings to indicate transverse myelitis.

FINAL/WORKING DIAGNOSIS: T8-9 intervertebral disc herniation resulting in myelopathy.

TREATMENT AND OUTCOMES:

1. Neurosurgery consult with no surgical intervention taken. Patient admitted for continued monitoring, PT, and OT.
2. Notable lower limb strength improvement seen over the first three days, however, acute inpatient rehabilitation was needed to assure ability for safe ambulation with impaired lower limb sensation.
3. After 12 days of inpatient rehab, lower body sensation was still impaired, but patient demonstrated improved lower limb strength and was ambulating with proper technique multiple times around the unit without assistance.
4. Patient discharged with outpatient therapy and a follow-up with neurosurgery in one month with repeat spine MRI.
5. Patient instructed to not return to cheerleading until follow-up.

Low Back Injury- Soccer

Aynur Demirel, Mehmet Yörübulut, Özlem Ulger Hacettepe University, Ankara, Turkey

aynur.demirel@hacettepe.edu.tr

(sponsor:)

HISTORY: A 17-year-old soccer player has severe back and groin pain applied to our clinic. Two years ago he had transverse process fracture of L5 vertebrae and bone marrow edema in this level. After 8 months, he returned the sport without pain but one month ago problems repeated.

PHYSICAL EXAMINATION: Paravertebral and quadratus lumborum muscle spasm were palpated. Straight leg raise test, sacroiliac mobility tests were negative on both side. Sacroiliac provocation tests were positive at right side. He had pain with trunk extension and rotation. There was no strenght and sensorial deficit. Lumbar lordosis increased.

DIFFERENTIAL DIAGNOSIS

Facet joint syndrome

Fracture of lumbar vertebra (transverse or spinous procces)

Spondylolysis (pars interarticularis defect)

TEST AND RESULTS

Lumbar spine Computed Tomography:

-Chronic fracture at L5 level (pars interarticularis fracture)

Sacroiliac joint T1 and T2 weighted coronal and transverse plane MRI:

-Right sacroiliac joint subchondral lesion (anterosuperior side)

-Left facet joint effusion (L5-S1 intervertebral disc level)

FINAL/WORKING DIAGNOSIS:

Pars interarticularis fracture

TREATMENT AND OUTCOMES

-21 sessions of physiotherapy applied to decrease muscle spasm, gain painless range of motion and functional restoration.

-During therapy, lumbar orthoses was used to stabilization.

-Physiotherapist guided lumbar stabilization exercise applied (4 months follow-up, progression started with positional and went on dynamic and resistive tasks).

-Sport related running, one leg balance and coordination, agility tasks were performed with transversus abdominus muscle contraction.

-After therapy he has painless extension and running.

The Relationship Between Fitness App Use And Physical Activity Behavior Is Mediated By Exercise Identity

Antonio S. Santo¹, Andrew Lepp², Jacob E. Barkley². ¹University of Western States, Portland, OR. ²Kent State University, Kent, OH. (Sponsor: Ellen Glickman, FACSM)

Email: tsanto@uws.edu

(No relationships reported)

There is evidence that cell phone use is associated with greater sedentary behavior and decreased cardiorespiratory fitness. Conversely, certain cell phone functions (e.g., listening to music, mHealth care) may promote healthy behaviors. The use of cell phone based software applications designed to monitor and/or promote exercise behavior (i.e., fitness apps) are a cell phone function which may promote physical activity. However, the relationship between fitness app use and physical activity is not well studied.

PURPOSE: To assess the relationship between physical activity and fitness app use and then to determine if this potential relationship was mediated by measures of exercise identity (i.e., the degree to which someone defines themselves as being an exerciser).

METHODS: A sample of 351 (21.0 ± 2.1 years old, n = 201 females) college students were surveyed for: weekly vigorous, moderate, walking and total physical activity and sedentary behavior via the validated International Physical Activity Questionnaire, exercise identity via the validated Exercise Identity Scale and were asked to report the number of fitness apps they had on their cell phones. Participants were then split into groups of those who use one or more (apps group, dummy coded 1, n = 207) and do not use any (no apps group, dummy coded 0, n = 144) fitness apps.

RESULTS: Correlation analyses revealed that exercise identity was positively associated (r ≥ 0.13, p ≤ 0.02) with all measures of physical activity except walking (r = 0.06, p = 0.31). Exercise identity was inversely associated (r = -0.20, p < 0.001) with sedentary behavior. The app group reported a greater exercise identity (4.61 ± 1.6 app, 3.44 ± 1.8 no app, r = 0.32, p < 0.001) and participated in greater vigorous (2690 ± 2775 MET min per week app, 1651 ± 2344 MET min per week no app, r = 0.19, p < 0.001) and total (6541 ± 4691 MET min per week app, 5122 ± 4381 MET min per week no app, r = 0.15, p = 0.007) physical activity than the no app group. However, when controlling for exercise identity, via partial correlation, physical activity differences between groups were rendered non-significant (r = 0.04, p = 0.50).

CONCLUSIONS: Differences in weekly physical activity between participants who use at least one fitness app on their cell phone versus those with no apps were mediated by exercise identity.

723 **Board #2** May 31 3:15 PM - 5:15 PM

Pokémon Go! Play May Promote Walking And Discourage Sedentary Behavior In College Students

Jacob E. Barkley, Andrew Lepp, Ellen L. Glickman, FACSM. *Kent State University, Kent, OH.* (Sponsor: Ellen Glickman, FACSM)

Email: jbarkle1@kent.edu

(No relationships reported)

Pokémon Go! is a downloadable video game for use on an internet-connected cellular telephone (cell phone). The game encourages the player to traverse real-world locations (e.g., neighborhoods) and tracks the player, via GPS, as they move through these locales. The purpose of the game is to find computerized characters as the player moves through the real-world locations. Because the game requires players to move through real-world locales, it may promote physical activity.

PURPOSE: The purpose of this study was to assess self-reported walking and sedentary behavior in young adults before and after downloading Pokémon Go!.

METHODS: A sample of 238 (19.5 ± 1.7 years old, n = 119 females) college students who had downloaded Pokémon Go! on their cell phone for a minimum of two weeks were surveyed for weekly walking and sedentary behavior via the International Physical Activity Questionnaire. Participants reported their walking and sedentary behavior at three time points: the week immediately preceding their download of

Pokémon Go!, the first week after downloading the game and currently. Differences in self-reported physical activity and sedentary behavior across the three time points were compared via repeated-measures analyses of variance.

RESULTS: There was a significant main effect of time ($f \geq 38.4, p \leq 0.001$) for walking and sedentary behavior. Participants reported greater ($t \geq 7.4, p \leq 0.001$) daily walking during the first week after downloading Pokémon Go! (206 ± 138 min) and currently (191 ± 202 min) versus the week before downloading (105 ± 101 min). There was no difference ($t = 1.1, p = 0.27$) between the first week after downloading and current walking behavior. Participants reported greater ($t \geq 6.5, p \leq 0.001$) daily sedentary behavior during the week before downloading (329 ± 219 min) versus both the first week after downloading (242 ± 181 min) and currently (256 ± 152 min). There was no difference ($t = 1.5, p = 0.15$) between the first week after downloading and current sitting behavior.

CONCLUSIONS: Use of the popular, physically-interactive cell phone game, Pokémon go!, had favorable effects upon self-reported physical activity (96% to 82% increase) and sedentary behavior (26% to 22% decrease). Such games hold promise as technology that may promote physical activity and discourage sedentary activity.

724 Board #3 May 31 3:15 PM - 5:15 PM
Effects of Social Support on Physical Activity Participation in College Freshman: The HERD Study
 Robert Powell, Lauren Bartoldson, Jared Mattingly, Holly Cyphert. *Marshall University, Huntington, WV.*
 Email: powellro@marshall.edu
 (No relationships reported)

Approximately 1 in 6 college aged adults in the United States engage in no leisure time physical activity. Still, a paucity of literature exists regarding what influences physical activity participation in this age group. **PURPOSE:** To determine the effects of social support on physical activity participation in college freshman enrolled in the HERD (Higher Education Reducing Diabetes) Study at Marshall University in Huntington, West Virginia. **METHODS:** The HERD Study is a prospective, randomized study examining the effects of a freshman year, healthy lifestyle intervention on the reduction of student's risk factors for type 2 diabetes and cardiometabolic disease. Freshman students were recruited during the University's Week of Welcome activities throughout campus. Physical activity measures, cardiometabolic health parameters and other demographics were obtained at baseline. Social Support was assessed by the Social Support and Exercise Survey; a 13 item, Likert scale survey that queries about family and friends social support for exercise over the past 3 months. **RESULTS:** To date, 76 freshmen have enrolled into the HERD Study [age = 18.5 ± 2.36 years; female = 60.5% (n = 46); 85.5% Caucasian (n = 65); BMI = 26.5 ± 5.85 kg/m²; VO₂max = 35.4 ± 9.3 ml/kg/min]. Roughly 44% (n = 33) reported engaging in regular exercise, however, of those, only 9.2% meet the recommendations of the aerobic guidelines for American adults and 26.3% meet the resistance training criteria. Those who participate in regular exercise were significantly more likely to report that friends help to: plan activities around their exercise, exercise with them, or ask them about how they (the friend) can adopt more exercise compared to their non-exercising counterparts ($p = .026, p = .037$ and $p = .015$, respectively). Moreover, those who participate in regular exercise were more likely to report that their family makes plans for exercise on recreational outings compared to their non-exercising counterparts ($p = .042$). **CONCLUSION:** Support from both friends and family appears to play a decisive role in the adoption and adherence to regular physical activity in late teenage years. Physical activity interventions should include strategies to promote peer social support in the college setting to enhance physical activity participation in college students.

Academic Success And One-Year Of Intramural Sports Participation By Freshmen Students
 Kerri L. Vasold, Lauren E. Kosowski, James M. Pivarnik, FACSM. *Michigan State University, East Lansing, MI.*
 Email: vasoldke@msu.edu
 (No relationships reported)

Previous research has shown small, positive relationships between academic success and overall recreational sports participation. However, few studies have focused on these relationships within intramural sports participation specifically rather than recreational sports as a whole.

PURPOSE: To investigate differences in cumulative grade point average (GPA) and cumulative credit difference (CD, credits attempted - credits completed) among intramural sports participants and non-participants following their first year of college. **METHODS:** Participants included first time, on campus, freshmen from the FS13 and FS14 semesters. Matched samples (n = 1,796; 898 pairs) were generated based on cohort, high school GPA, race, socioeconomic status, first generation status, and gender. Intramural sports usage was obtained via an online database system (IM Leagues). All other variables were obtained from a university database, including GPA and CD. Means ± SD and percentages were calculated for all variables of interest. Paired sample t-tests were used to assess differences in cumulative GPA and CD between participants and non-participants after first semester and first year time points.

RESULTS: First semester cumulative GPA was significantly higher (p -value < 0.001) for participants (3.25 ± 0.66) than non-participants (3.09 ± 0.80). Likewise, first year cumulative GPA (p -value < 0.001) was also significantly higher for participants (3.25 ± 0.63) than non-participants (3.07 ± 0.78). First semester cumulative CD was significantly lower (p -value = 0.001) for intramural sports participants (5.53 ± 7.00) than non-participants (6.63 ± 7.72). Finally, first year cumulative CD (p -value < 0.001) was also significantly lower for participants (6.09 ± 7.13) than non-participants (7.70 ± 8.20). **CONCLUSIONS:** Results suggest that freshmen students participating in intramural sports during their first year of college achieve higher cumulative first semester and first year GPAs, and have a lower first semester and first year cumulative CD than students who do not participate in intramural sports. Future studies should investigate intramural sports participation and academic variables beyond the first year, and also include retention as an outcome variable.

The Relationship between Physical Activity and Binge Drinking among College Students: A Qualitative Investigation
 Mary K. Dinger¹, Danielle R. Brittain¹, Heidi M. O'Mara¹, Brent M. Peterson², Kelly C. Hall¹, Molly K. Hadley¹, Teresa A. Sharp¹. ¹Colorado School of Public Health at University of Northern Colorado, Greeley, CO. ²Biola University, La Mirada, CA.
 Email: mary.dinger@unco.edu
 (No relationships reported)

An incongruous association between regular participation in physical activity (PA) and binge drinking (BD) among college students (CS) has been reported in the literature. **PURPOSE:** The purpose of this study was to qualitatively investigate the relationship between PA and BD among CS. **METHODS:** CS (18-24 years, non-varsity athletes) who were meeting the national physical activity recommendation (≥ 150 minutes/week of moderate and/or vigorous PA) and reported consuming at least five or more alcoholic beverages in a single sitting within the previous 30 days were recruited to participate in the study. A trained facilitator asked open-ended questions based on the social ecological model during focus groups, separated by sex, to inquire about PA and BD experiences among CS. The sessions were audio-recorded and transcribed verbatim. Transcripts were analyzed by three researchers (first independently, then jointly) to determine emergent themes. **RESULTS:** Participants (n = 58, 19.7 ± 0.2 years, 76% Caucasian) described how PA and BD were related in their everyday lives as full-time students. Several intrapersonal, interpersonal, institutional and community factors were identified. The most frequently occurring theme among females (n = 25) was "calorie conscious." "Damage control: healthy/unhealthy" was the most frequent theme/sub-theme among males (n = 33). **CONCLUSION:** The results indicate there are multiple social ecological levels that influence PA and BD behavior in CS. Although additional research is warranted, results of this study suggest that community level factors greatly influence several intrapersonal and interpersonal level factors described by participants. It is imperative that all social ecological levels are considered when designing interventions to promote PA and reduce BD among CS.

How Is Self-efficacy Related To Components Of Health-related Fitness In Male And Female Undergraduates?
 Sandy T. Nguyen, Paul E. Yeatts, FACSM, Gene L. Farren, FACSM, Tsz Lun Chu, FACSM, Mitch Barton, FACSM, Scott B. Martin, FACSM. *University of North Texas, Denton, TX.*
 (Sponsor: Dr. Scott Martin, FACSM)
 Email: nguyensandyt@gmail.com
 (No relationships reported)

Introduction: As part of Social Cognitive Theory (Bandura, 1986), self-efficacy (SE) represents the extent to which an individual believes a behavior can be successfully completed (Bandura, 1977). Previous research has found evidence that SE is an important factor for promoting exercise adherence and is related to improvements in health-related fitness (HRF; Imayama et al., 2013). However, additional research is needed to investigate how SE is related to each component of HRF (i.e., cardiorespiratory fitness, muscular strength and endurance, and body fatness) across gender.

Purpose: To investigate how SE is related to each component of HRF in male and female college students.

Method: Participants included 399 male and 327 female college students ($M_{age} = 20.57 \pm 3.82$ years) enrolled in a physical health and wellness course. Students completed survey items assessing exercise SE (Resnick & Jenkins, 2000) and a HRF battery (FITNESSGRAM®; Cooper Institute, 2013) assessing cardiorespiratory fitness (Progressive Aerobic Cardiovascular Endurance Run [PACER]), muscular strength and endurance (curl-ups, push-ups, and handgrip strength), and body composition (body fat percentage). Separate correlation analyses were conducted by gender to examine the bivariate relations between SE and each component of HRF.

Results: Among males, SE was weakly correlated with curl-ups ($r = .11, p < .05$) and push-ups ($r = .14, p < .01$), but SE was not significantly correlated with PACER, handgrip strength, or body fat percentage ($p > .05$). Among females, SE was significantly correlated with PACER ($r = .23, p < .001$), push-ups ($r = .33, p < .001$), handgrip ($r = .23, p < .001$), and body fat percentage ($r = .22, p < .001$), but SE was not significantly correlated with curl-ups ($p > .05$).

Conclusion: Overall, SE was weakly related to each component of HRF. Compared to males, females had slightly stronger correlations between SE and each component of HRF. The lack of moderate or strong relationships between SE and HRF may be due to the focus on academic outcomes in undergraduate courses. Thus, fitness class instructors should consider making additional efforts to promote SE among their students. Techniques could include positively reinforcing small improvements in fitness, discussing ways to overcome barriers, or helping students to experience success.

728 Board #7 May 31 3:15 PM - 5:15 PM
Motivational and Self-Perceptions of College Students Who Exercise for Different Reasons

James R. Whitehead, FACSM, Amanda Dufner, Jesse L. Rhoades, Tanis J. Walch. *University of ND, Grand Forks, ND.*
 Email: james.whitehead@email.und.edu
 (No relationships reported)

College students exercise for a variety of reasons, but specific differences in their motivations and perceptions have not been extensively studied. **PURPOSE:** The main purpose was to see if students whose primary reason for exercise is to lose fat (FATCON), gain muscle mass (MUSC), or maintain health (HLTH) had differences in their exercise motivations, social physique anxiety, and body image self-perceptions. A secondary purpose was to explore if the participants' supplement use reflected their exercise priorities. **METHODS:** Data were collected at a university Wellness Center, or from exercise classes. Participants ($N = 216$) completed a packet of four questionnaires: Multidimensional Body Self Relations Questionnaire (MBSRQ), Social Physique Anxiety Scale (SPAS), The Behavioral Regulation of Exercise Questionnaire (BREQ-3), and an ad hoc Dietary Supplement Questionnaire (DSQ). **RESULTS:** MANOVA revealed a significant difference between groups ($F(14, 350) = 4.89, p < .001$). Post hoc tests showed significant differences between groups on six out of seven dependent variable scales. Specifically, MUSC was significantly higher in autonomous motivation than FATCON and HLTH ($p < .001$), but FATCON scores on SPAS, appearance evaluation, body areas satisfaction, overweight preoccupation, and self-weight classification were all less positive than the scores of MUSC and HLTH ($p < .001$ to $p < .005$). Supplement use was low in HLTH (11%), FATCON (15%), but higher in MUSC (49%). In addition, some of the supplements listed by MUSC were of questionable efficacy and safety. **CONCLUSIONS:** The majority of these college student exercisers were autonomously motivated, but those who exercised primarily for fat control had more negative body-related perceptions than those who exercised primarily for health, or for muscle gain reasons. Additionally, the data on supplement use indicates a need for consumer education, especially for those who report they are exercising primarily to gain muscle.

An Analysis Of Physical Activity Knowledge, Motivators, and Self-efficacy In An Undergraduate Wellness Course

Monica M. Maldari¹, Michelle Scribner-MacLean², David J. Rice³. ¹Fitchburg State University, Fitchburg, MA. ²University of Massachusetts Lowell, Lowell, MA. ³Florida Southern College, Lakeland, FL.
 (No relationships reported)

Research suggests that many undergraduates do not achieve the minimum recommended amounts of physical activity (PA). These findings are concerning as habits developed during college are likely to be continued into adulthood. **PURPOSE:** The purpose of this investigation was to identify changes in health-related fitness knowledge (HRFK), PA practices, self-efficacy and motivations for exercise that occurred while participants were enrolled in a conceptually-based, mandatory, health and fitness course. **METHODS:** One hundred and thirty-five students (66 females) enrolled in the course (mean \pm SD; age 19.89 ± 2.3 years; BMI 24.5 ± 5.24 kg/m²) completed a pre-course survey on the first day of classes and a post-course survey during the last week of classes. The survey collected demographic data and information on HRFK, PA practices, motivations, and self-efficacy for exercise. **RESULTS:** Analysis demonstrated that HRFK increased significantly ($p < .001$) during enrollment in the course. Self-efficacy and BMI values were largely unchanged between pre- and post-course values. Results for PA practices noted increases in miles walked ($p > .05$) and flights of stairs climbed ($p < .05$) per day. Significantly more ($p = .002$) male students reported muscle development, whereas significantly more ($p = .046$) female students reported weight management as a motivators for exercise. Motivations shifted slightly post-course with a significant increase ($p = .014$)

in the number of females exercising for muscle development at the end of the course compared to beginning. Responses to Likert scale (1=Strongly Disagree, 5=Strongly Agree) questions on course outcomes revealed that most students "agreed (4)" that as a result of the course they understood physical responses to exercise training ($M = 4.3, SD = .67$), improved understanding of their current fitness levels ($M = 4.0, SD = .69$), and learned tools to design effective, individualized exercise plans ($M = 4.2, SD = .64$). However, most students "neither agreed nor disagreed (3)" that they exercised more at the end of the course compared to the beginning.

CONCLUSION: Enrollment in a conceptually-based, health and fitness course can increase HRFK over the course of the semester, however this increase in knowledge is not associated with concurrent increases in activity levels or self-efficacy.

B-40 Thematic Poster - Distance Running Issues

Wednesday, May 31, 2017, 3:15 PM - 5:15 PM

A 5-year Descriptive Epidemiology and Performance Study of Adolescent Recreational Marathon Runners

Mary A. Kennedy¹, Matthew W. Penney², Dai Sugimoto³, Anna N. Brilliant⁴, Christopher R. Cuna⁴, Pierre A. d'Hemecourt, FACSM⁵. ¹DREAMFAR High School Marathon, Chestnut Hill, MA. ²Advanced Sports Therapy, Wellesley, MA. ³The Micheli Center for Sports Injury Prevention, Waltham, MA. ⁴Boston Children's Hospital Department of Orthopaedic Surgery and Division of Sports Medicine, Boston, MA. ⁵Harvard Medical School, Boston, MA.
 Email: mary@dreamfarhsm.org
 (No relationships reported)

PURPOSE: To descriptively examine injuries, treatments, and performance of adolescent recreational runners who trained for a half or full marathon from 2011-12 to 2015-16. **METHODS:** Musculoskeletal injuries and medical treatments of high school recreational runners who committed to a 30-week half or full marathon training program (mean=3.5 practices/week) were recorded by physical therapists over a 5-year period. The recorded information included number of injured participants, number of injuries, injury sites, diagnosis, and number of treatment sessions. Number of participants who completed a half or a full marathon at the end of the 30-weeks of training was recorded annually for the last 5 years. Obtained information was descriptively analyzed. **RESULTS:** Throughout the 5 training seasons, a total of 448 adolescent runners (age: 16.2 ± 0.9 years; 55% female $N = 247$, 45% male $N = 201$) participated in the 30-week training period. During the training periods, 165 adolescent runners (36.8%) reported 225 musculoskeletal injuries (50.2%). The most common injury site was lower leg (29.9%) followed by knee and ankle/foot as the second and third most commonly injured sites (25% each). Achilles/posterior/peroneal tendonitis was the most common injury diagnosis reported (16.1%) followed by patellofemoral pain (14.7%) and shin splints (14.3%). Overall 87.1% of the injuries required 3 or fewer treatment sessions with a mean of 1.82 treatment sessions per injury. Of the 448 adolescent runners, a total of 441 adolescent runners completed either a half ($N = 62$) or full marathon ($N = 379$). The completion rate was 98.4% in this cohort following the 30-weeks of training. **CONCLUSIONS:** Despite the number of injured runners and reported injuries, most adolescent participants completed a half or full marathon following 30-weeks of training. Also, the injuries do not appear to be severe as evidenced by the low number of treatment sessions required and high percentage of students able to complete the race. Further research detailing volume of training with more precise measures of training time lost to injury is needed to more thoroughly validate these results.

732 Board #2 May 31 3:15 PM - 5:15 PM
Runner's Perceptions And Expectations Of Medical Coverage At Ultramarathons

Jeff S. Lynn, Kim Keeley, Kristen Zaitz, Kelly Holzberger. *Slippery Rock University, Slippery Rock, PA.* (Sponsor: Patricia Pierce, FACSM)
 (No relationships reported)

As the popularity of ultramarathons grows, medical directors and staff could benefit from greater understanding of runners' needs and expectations. **PURPOSE:** The purpose was to describe runners' expectations and perceptions of medical coverage at 100-mile trail races. **METHODS:** A survey was distributed via email to 230

registrants of a 100-mile trail race in the Northeast United States. Questions included expectations of medical coverage at ultramarathons as well as perceptions of coverage at prior races. **RESULTS:** One hundred sixteen runners completed the survey (98 men, 18 women; age=42±8). Ultramarathon experience ranged from 2-50+ races with runners reporting 1-20 years' experience (mean 4.6 years). Ninety-one percent (n=110) of runners reported a medical issue during prior ultramarathons. The most common were chafing (n=81; 70%), blisters (n=66; 57%), muscle cramps (n=64; 55%), blood under toenail (n=54; 47%), and GI distress (n=47; 41%). Of those who received medical care during a race, 45 of 46 were satisfied with the treatment they received. Runners thought that medical aid should be available every 10 miles (n=49; 45%) or 20 miles (n=33; 30%) and should include medical tape (n=89; 81%), sodium (n=88; 80%), Band-Aids (n=88; 80%), anti-chafe products (n=86; 78%), emergency blankets (n=82; 75%), and ice packs (n=78; 71%). Runners reported carrying few medical items with them including sodium (n=65; 57%), anti-chafe lube (n=40; 35%) anti-inflammatories (n=39; 34%), and Band-Aids (n=28; 24%). While only 4% (n=4) of respondents believed that there are no conditions under which medical personnel should stop a runner from continuing, others thought that appropriate reasons include venomous bite (n=90; 84%), seizure (n=82; 73%), head injury (n=80; 71%), altered consciousness (n=70; 63%), irregular heart beat (n=60; 54%), chest pain (n=58; 52%), or blood in urine (n=56; 50%). **CONCLUSIONS:** Based on this small sample, a large percentage of ultramarathoners suffer from non-emergent conditions, but most do not seek medical care during the race. Those who sought treatment tended to be satisfied with the care received. Medical directors should provide supplies to care for skin care but have the expertise to recognize and treat more serious issues that may require the runner to stop.

733 Board #3 May 31 3:15 PM - 5:15 PM

Pre-Race Medical Screening and Educational Intervention Reduces Medical Complications: A SAFER Study in 153208 Runners

Martin Peter Schweltnus, FACSM¹, Karen Schwabe², Sonja Swanevelder³, Esme Jordaan³, Wayne Derman⁴. ¹University of Pretoria, Pretoria, South Africa. ²University of Cape Town, Cape Town, South Africa. ³South African Medical Research Council, Cape Town, South Africa. ⁴Stellenbosch University, Cape Town, South Africa.

(No relationships reported)

We previously reported a high rate of medical complications (1/121 race starters) in a cohort of 65 865 runners participating in 21.1km and 56km races over a 4-year period (2008-2011) (SAFER study 1). **PURPOSE:** To determine if an online pre-race medical screening and educational intervention program reduces medical complications in distance running events. **METHODS:** An online pre-race medical screening (based on the European guidelines for pre-screening of leisure athletes participating in moderate- to high-intensity sports) and an educational intervention program was designed and introduced as part of the race registration process, in the period 2012 to 2015 at the Two Oceans Marathon races (21.1km and 56km). The incidence of medical complications (per 1000 race starters; all and serious life-threatening) during the 4-year post-intervention period (2012-2015: 87 343 race starters) was compared with the pre-intervention period (2008-2011: 65 865 race starters). **RESULTS:** Compared to the pre-intervention (baseline) period, there was a significant reduction in the incidence (per 1000 starters, 95% CI; adjusted for age group, gender and race distance) of all medical complications in all runners by 29% [pre=8.6 (7.9-9.4); post=6.1 (5.6-6.7), p<0.0001], 21.1km runners by 19% [pre=5.1 (4.4-5.9); post=4.1 (3.6-4.8), p=0.0356], and 56km runners by 39% [pre=14.6 (13.1-16.3); post=9.0 (7.9-10.1), p<0.0001]. Serious life-threatening complications were significantly reduced in all runners by 64% [pre=0.6 (0.5-0.9); post=0.2 (0.1-0.4), p=0.0003; adjusted for age group and gender]. **CONCLUSION:** A pre-race medical screening and educational intervention program significantly reduced medical complications and serious life-threatening complications among all runners in community-based mass participation distance running events. The reduction in all medical complications was significant in both the 21.1km and 56km races. Pre-race screening and educational intervention programs could be introduced to reduce medical complications during endurance running events.

Two-peaked Increase of Serum Myosin Heavy Chain-α After Ironman Demonstrates Heart Muscle Cell Death

Jörg Carlsson, Tom Danielsson, Patrick Bergman. *Linnaeus University, Kalmar, Sweden.*

Email: jorg.carlsson@ltkalmar.se

(No relationships reported)

There is an ongoing debate about the significance of cardiac troponin T (cTnT) elevation after strenuous exercise: heart muscle cell death versus physiologic mechanism of release through an intact cell membrane. While cTnT is a small molecule (37 kDa), cardiac specific myosin heavy chain-α (MHC-α) is much larger (224 kDa) and an increase after exercise could hardly be explained by passage

through an intact cardiac cell membrane. **PURPOSE:** To measure MHC-α, and other biomarkers (C-reactive protein (CRP); cTnT, creatine kinase (CK), myoglobin (MG), creatinine (C), and N-terminal pro-hormone of brain natriuretic peptide (NT-proBNP) before and after a full distance Ironman in order to answer the question of heart muscle cell death versus physiologic changes. **METHODS:** In 52 non-elite athletes (14 female, 38 male; age 41.1 ± 9.7, range 24-70 years; all completed the race) biomarkers were measured by standard laboratory methods 7 days before, directly after, and day 1, 4 and 6 after the race. MHC-α was measured with a commercially available ELISA with no cross reactivity with other myosins. **RESULTS:** The course of MHC-α concentration [μg/L] was 1.33 ± 0.53 (before), 2.57 ± 0.78 (directly after), 1.51 ± 0.53 (day 1), 2.74 ± 0.55 (day 4) and 1.83 ± 0.76 (day 6). Other biomarkers showed a one-peaked increase with maximal values either directly after the race or at day 1: cTnT 76 ± 80 ng/L (12-440; reference <15), NT-proBNP 776 ± 684 ng/L (92-4700; ref. < 300), CK 68 ± 55 μkat/L (5-280; ref. < 1.9), MG 2088 ± 2350 μg/L (130-17000; ref. < 72), and creatinine 100 ± 20 μmol/L (74-161; ref. < 100), CRP 49 ± 23 mg/L (15-119; ref. < 5). There was a significant correlation between MHC-α and NT-proBNP (R=0.48; p<0.001) but neither between MHC-α and cTnT (R=0.13; p=0.36) nor MHC-α and myoglobin (R=0.18; p=0.2). **CONCLUSION:** An Ironman leads to remarkable disturbances in biomarkers as e.g. cTnT was in the range of myocardial infarction in 100% of women and 97% of men. This is to our best knowledge the first investigation of MHC-α after strenuous exercise and its two-peaked increase most likely represents first release from the cytosolic pool and later from cell necrosis including the contractile apparatus. However, many questions remain, not at least why MHC-α baseline levels are as high as 1.33 ± 0.53 μg/L.

Are Clinical Symptoms Of Running Overuse Injuries Associated With Thermographic Response? A Proof-of-concept Study.

Jessica S. Siplon¹, Angela S. Gisselman², Steve Tumilty², James M. Smoliga¹. ¹High Point University, High Point, NC. ²University of Otago, Dunedin, New Zealand. (Sponsor: Gerald Zavorsky, FACSM)

Email: jsmoliga@highpoint.edu

(No relationships reported)

Medical infrared thermography (MIT), a non-radiating imaging technology, detects changes in skin temperature. Musculoskeletal injuries result in blood flow changes which may produce patterns of associated changes in skin temperature that can be visually detected by MIT.

PURPOSE: To determine if clinical symptoms of distal lower extremity overuse injuries in runners are associated with visually detectable changes in MIT.

METHODS: 29 competitive distance runners (age 18-25y, running >25 miles per week) enrolled and participated. Once weekly, runners reported to lab for MIT photos of bilateral lower limbs taken with an infrared camera. Prior to MIT, runners acclimatized to lab conditions for 15 minutes and the camera was calibrated to the room temperature and humidity. A modified Oslo Sports Trauma Research Centre (OSTRC) overuse injury questionnaire was used for athlete-reported musculoskeletal symptoms and problems. MIT photos and OSTRC scores were obtained on a weekly basis for 8 weeks. Runners' photos were grouped into those with no reports of any lower extremity problems (Controls: OSTRC = 0, n=5); and those with reports of significant lower extremity problems (Injured: OSTRC >50, n=7). Photos from each group were placed into an online viewer and evaluated by 7 blinded clinicians. For the injured group, a photo from the week of the highest reported OSTRC score was paired with a baseline (OSTRC <25) photo. For the control group, two uninjured photos were paired. The reference photo for each pair was labeled. The order of photos (control vs. injured) was randomized and reviewers were not provided the number of included injured runners. Clinicians visually inspected 12 image pairs and decided whether or not the photo suggested a lower extremity problem existed. Diagnostic accuracy statistics were computed for each evaluator.

RESULTS: The median (interquartile range) for the seven evaluators were: sensitivity=0.43 (0.29), specificity=0.60 (0.2), positive likelihood ratio=1.43 (0.0), negative likelihood ratio=0.71 (0.18).

CONCLUSIONS: Low diagnostic accuracy and considerable inter-rater variability suggests evaluator training of MIT interpretation is necessary to accurately confirm or disconfirm presence of injury based on MIT findings.

736 Board #6 May 31 3:15 PM - 5:15 PM
Hematological Changes in Elite Collegiate Cross Country Runners Residing at Moderate Altitude: A Retrospective Analysis

Kalee L. Morris¹, Jesse A. Goodrich¹, Sourav Poddar², Luke Widstrom², Miguel Rueda¹, William Byrnes¹. ¹University of Colorado Boulder, Boulder, CO. ²University of Colorado Denver, Denver, CO.

(No relationships reported)

PURPOSE: This study assessed selected seasonal hematological changes in elite male and female collegiate cross-country (XC) runners residing at a moderate altitude (1655 m). **METHODS:** Previously collected de-identified data from 29 members of the University of Colorado's XC team (12 males, 17 females) were analyzed for this project. The data was part of the regularly scheduled monitoring of these athletes through the CU Sports Medicine program. This program involves blood samples being taken following a rest day, after an overnight fast, at five time points across the year, (August, October, January, April, and August of the new season). Hematological parameters measured included red blood cell count (RBC), hemoglobin concentration (Hb), hematocrit (Hct), mean corpuscular volume (MCV), red cell distribution width (RDW) and serum ferritin. A linear mixed model was used to assess changes over time, significance set at $p < .05$. For variables that violated the assumptions of the linear mixed model (ferritin), non-parametric analysis was used. **RESULTS:** Males (M) and females (F) had significantly different baseline values for Hct (%) (M: $46.5 \pm .8$ versus F: $43.0 \pm .6$) and Hb (gm/dL) (M: $16.3 \pm .3$ versus F: $14.6 \pm .2$), although they exhibited the same pattern of change across the season. Overall, Hct increased from baseline at the October time point (+5.4%) before returning to near baseline levels for the remainder of the season. Hb had a similar trend, being higher at the October time point (+2.2%, $p = 0.083$) before returning to near baseline levels. MCV (Aug1- $90.4 \pm .6$, Aug2- $92.4 \pm .6$) and RDW (Aug1- $12.7 \pm .1$, Aug2- $12.5 \pm .1$) were the only two variables whose two August time points were significantly different. Serum ferritin (ng/mL) was stable over all five time points for males (average of all time points: 56.5), whereas females demonstrated significantly lower values in January (49.2), (average of all time points excluding January: 56.9). **CONCLUSION:** These results suggest seasonal hematological changes occur in elite collegiate XC runners. These changes could be the result of adaptations associated with alterations in training, nutrition and/or altitude exposure. Future studies should directly assess the contribution of these parameters to the observed changes and determine the impact of these changes on performance.

(No relationships reported)

Cross-country is a popular interscholastic sport with a growing number of participants annually. As most training and competitions take place during summer and fall, the risk of dehydration may be increased. Unlike other fall high school sports, knowledge about hydration and fluid intake have not been reported in cross-country runners. **PURPOSE:** To assess fluid replacement knowledge and sources of hydration in high school cross-country runners. **METHODS:** Runners were recruited from high school cross-country teams in San Diego. Each runner completed a questionnaire that assessed fluid replacement knowledge and sources of hydration. **RESULTS:** Overall, 148 runners (80 girls, 68 boys) participated in the study. Less than a quarter (23%) of runners correctly indicated that thirst is not a timely indicator of when to drink fluids. Most runners correctly indicated that monitoring urine color is an effective way to determine if hydrated (89.9%), dehydration decreases performance in endurance events (92.6%), dehydration increases risk of heat-related illness (95.9%), running in hot or humid conditions affects hydration (96.6%), runners should begin each training session or competitive event well-hydrated (98.6%), fluid replacement during running should prevent dehydration of greater than 2% of body weight (89.9%), and during recovery runners should rehydrate within a 2 hour period after running (93.9%). Girls (96.2%) were more likely to report that monitoring urine color is an effective way to determine hydration level than boys (83.8%) ($p=0.02$). Runners in the 9th grader (83.7%) were less likely than 10th (88.4%), 11th (100.0%), and 12th (96.6%) graders to report that monitoring urine color is an effective method to determine if dehydrated ($p=0.02$). **CONCLUSIONS:** Most high school cross-country runners indicated a high knowledge of fluid intake and sources of hydration. However, improving runners' knowledge to hydrate regardless of thirst appears warranted. The data suggest that boys and younger runners may need increased education on how urine color indicates safe/unsafe hydration levels.

B-41 Thematic Poster - Macronutrient Metabolism in Athletes

Exercise Mode Combined with Essential Amino Acid and Carbohydrate Supplementation Differentially Regulate Skeletal Muscle microRNA

Lee M. Margolis, Holly L. McClung, Nancy E. Murphy, Stefan M. Pasiakos, FACSM. United States Army Research Institute of Environmental Medicine, Natick, MA. (Sponsor: Stefan M Pasiakos, FACSM)

Email: lee.m.margolis.ctr@mail.mil

(No relationships reported)

Skeletal muscle microRNAs (myomiR) have been implicated in modulating intracellular regulation of muscle protein synthesis by negative inhibition of the mTORC1 pathway. The acute effects of endurance exercise mode and recovery essential amino acid and carbohydrate (EAA+CHO) nutrition on myomiR expression are not well defined. **PURPOSE:** Determine the effects of endurance exercise mode, with or without EAA+CHO ingestion on myomiR expression. **METHODS:** Twenty five adults (mean \pm SD; 22 ± 2 y, 82 ± 11 kg, $VO_{2peak} 4.0 \pm 0.5$ L \cdot min⁻¹) performed 90 min of metabolically-matched (2.2 ± 0.1 VO₂ L \cdot min⁻¹) load carriage (LC; performed on a treadmill wearing a vest equal to 30% of individual body mass; load carried 24 ± 3 kg) or cycle ergometry (CE) exercise, during which EAA+CHO (10 g EAA and 46 g CHO) or non-nutritive control (CON) drinks were consumed. Expressions of myomiR were determined using RT-qPCR in muscle samples obtained at rest (PRE), immediately post-exercise (POST) and after 3-hr recovery (REC). **RESULTS:** Relative to PRE, POST and REC expressions of miR-1-3p, miR-206, miR-208a-5 and miR-499 were lower ($P < 0.05$) for LC compared to CE, regardless of dietary treatment. Independent of exercise mode, miR-1-3p and miR-208a-5p expression were lower ($P < 0.05$) after ingesting EAA+CHO compared to CON. Expression of miR-206 was highest for CE+CON than any other treatment (exercise-by-drink, $P < 0.05$). **CONCLUSIONS:** These data show that myomiR expression is differentially regulated by endurance exercise mode and EAA+CHO nutrition. Weight bearing exercise downregulates myomiR expression, whereas myomiR expression appears to be upregulated after non-weight bearing exercise. Consuming EAA+CHO attenuated the increase in myomiR expression with non-weight bearing exercise, yet the suppression of myomiR expression with feeding was more pronounced when EAA+CHO were consumed during weight bearing exercise. These findings suggest that combining weight bearing exercise with protein and carbohydrate supplementation may facilitate muscle anabolic adaptations to exercise by lowering mTORC1 inhibition.

Fructose and Sucrose Ingestion Increase Exogenous Carbohydrate Oxidation Rates During Exercise in Trained Cyclists

Jorn Trommelen¹, Cas J. Fuchs¹, Milou Beelen¹, Kaatje Lenaerts¹, Asker E. Jeukendrup, FACSM², Naomi M. Cermak¹, Luc J.C. van Loon¹. ¹Maastricht University, Maastricht, Netherlands. ²Loughborough University, Loughborough, United Kingdom. (Sponsor: Janice Lee Thompson, FACSM)

Email: jorn.trommelen@maastrichtuniversity.nl

(No relationships reported)

Peak exogenous carbohydrate oxidation rates typically reach ~ 1 g \cdot min⁻¹ during exercise when ample glucose or glucose polymers are ingested. Fructose co-ingestion has been shown to further increase exogenous carbohydrate oxidation rates. **PURPOSE:** To determine the impact of fructose co-ingestion provided either as a monosaccharide or as part of the disaccharide sucrose on exogenous carbohydrate oxidation rates during prolonged exercise in trained cyclists. **METHODS:** Ten trained male cyclists (VO_{2peak} : 65 ± 2 mL \cdot kg⁻¹ BM min⁻¹) cycled on 4 different occasions for 180 min at 50% Wmax and consumed a carbohydrate solution providing 1.8 g \cdot min⁻¹ of glucose (GLU), 1.2 g \cdot min⁻¹ glucose + 0.6 g \cdot kg⁻¹ fructose (GLU+FRU), 0.6 g \cdot min⁻¹ glucose + 1.2 g \cdot min⁻¹ sucrose (GLU+SUC), or water (WAT). Breath samples were collected to determine the ¹³C/¹²C ratio in expired air and combined with indirect calorimetry (VO₂ and VCO₂) to calculate oxidation rates of total fat, total carbohydrate, and exogenous carbohydrates. Repeated measures ANOVA with treatment as within-subject factor was used to determine differences in exogenous carbohydrate oxidation rates between treatments.

RESULTS: Peak exogenous carbohydrate oxidation rates did not differ between GLU+FRU and GLU+SUC (1.40±0.06 vs 1.29±0.07 g·min⁻¹, respectively, $P=1.000$), but were 46±8% higher when compared to GLU (0.96±0.06 g·min⁻¹; $P<0.05$). In line, exogenous carbohydrate oxidation rates during the latter 120 min of exercise were 46±8% higher in GLU+FRU or GLU+SUC compared with GLU (1.19±0.12, 1.13±0.21, and 0.82±0.16 g·min⁻¹, respectively, $P<0.05$).

CONCLUSION: Fructose co-ingestion (0.6 g·min⁻¹) with glucose (1.2 g·min⁻¹) provided either as monosaccharide or as sucrose strongly increases exogenous carbohydrate oxidation rates during prolonged exercise in trained cyclists.

Multiple-transportable Carbohydrate Has Minimal Impact On Long-distance Triathlon Race Performance

David S. Rowlands, FACSM, Stuart Houltham. *Massey University, Wellington, New Zealand.*
 Email: d.s.rowlands@massey.ac.nz

(No relationships reported)

PURPOSE: In the laboratory, the ingestion of multiple-transportable carbohydrates (fructose, glucose) in beverages at high rates (>1.3 g·min⁻¹) enhances exogenous carbohydrate oxidation, fluid absorption, gut comfort, and performance, relative to single carbohydrate equivalents. In competition, however, endurance athletes prefer to ingest carbohydrate in a solid-gel-drink format but whether multiple-transportable carbohydrates in the mixed format also enhance competition performance is unknown. The objective of the study was to determine the effect of multiple- vs. single-transportable carbohydrate on triathlon race performance when ingested in the common format of bars, gels and drinks.

METHODS: A double-blind randomized controlled trial was conducted within two sanctioned half-ironman triathlon races held 3 weeks apart in 74 well-trained male triathletes (18-60 y; >2 y competition experience). Carbohydrate was ingested before (94 g) and during the race from bars (25%), gels (35%) and drink (40%) comprising a 2:1 glucose/maltodextrin:fructose ratio vs isocaloric placebo glucose/maltodextrin only. Ingestion was apportioned by unit-distance covered during the cycle (2.5 g·km⁻¹) and run (7.8 g·km⁻¹) averaging 78.6 g·h⁻¹ (SD 6.6). Post-race 0-10 unit Likert-type scales were completed to assess gut comfort and energy.

RESULTS: The trial returned low dropout rate (9%), high compliance and sensitivity (typical error 2.2%), but the effect of the multiple-transportable carbohydrate on overall performance time (-0.6%, 95%CI -1.8%, 0.7%), swim, bike, and run times, and on nausea, gut comfort and perceived energy was of trivial-small magnitude without statistical significance. Within-subject covariate adjustment for pre-exercise body weight, heat stress, and within-race change in body weight had negligible impact on outcomes.

CONCLUSION: Multiple-transportable carbohydrate ingested in the common bar-gel-drink format provided negligible benefit to long-distance triathlon performance. The experience of the large sample intervention study showed that in-competition clinical trials offer ecological validity, and high throughput rate, compliance, and sensitivity for evaluation of health and performance interventions in athletes. Funding: Nestec Ltd, Switzerland.

Alterations in Exogenous Carbohydrate, Liver and Muscle Glycogen Oxidation with Different Doses of Glucose and Fructose ingestion during Prolonged Cycling

Andy J. King¹, John P. O'Hara¹, Douglas Morrison², Tom Preston², Roderick FGJ King¹. ¹Leeds Beckett University, Leeds, United Kingdom. ²Scottish Universities Environmental Research Centre, Glasgow, United Kingdom.
 Email: a.k.king@leedsbeckett.ac.uk

(No relationships reported)

PURPOSE: To investigate the effect of three CHO doses on fuel selection during exercise, in particular exogenous and endogenous (liver and muscle) CHO oxidation.

METHODS: Eleven trained male cyclists ($\dot{V}O_{2max}$: 60.0 ± 4.3 ml/kg/min) cycled on 4 occasions at 60% $\dot{V}O_{2max}$ for 3 hours after an overnight fast. From 15 min into exercise and every 15 min thereafter, either 80 g·h⁻¹ (LOW), 90 g·h⁻¹ (MED), 100 g·h⁻¹ (HIGH) of GF (all 2:1 ratio) or a placebo (PLA) was ingested in a double-blind randomised order. The formulations contained ¹³C isotope tracers and were designed to span the reported saturation levels for SGLT1 and GLUT5. Total, exogenous, endogenous (muscle and liver) CHO oxidation, and total fat oxidation were computed using indirect calorimetry and isotope ratio mass spectrometry.

RESULTS: Total CHO oxidation was elevated, and total fat oxidation suppressed in all CHO conditions relative to PLA (CHO range 94.0-125.0 g higher, Fat 29.7-34.3 g lower; both ES > 1.05). Exogenous oxidation in the final hour was greatest in HIGH (91.1 g·h⁻¹), a moderate effect to LOW (81.6 g·h⁻¹, ES = 0.64, P = 0.10) and MED (82.9

g·h⁻¹, ES = 0.70, P = 0.39) a moderate increase from the second hour in all conditions (ES = 1.38-2.00, P < 0.014). However, increasing GF dose beyond intestinal saturation increased muscle glycogen utilisation in the final hour (101.6 ± 16.6 g·h⁻¹ in HIGH; 62, -23.5 to 11.1 g·h⁻¹ higher [95% CI] vs. LOW, ES = 0.47, P = 0.61 & 16.1, 0.9 to 31.4 g·h⁻¹ [95% CI] higher vs. MED, ES = 0.68, P = 0.16), and second hour (ES = 0.51 & 0.48, P > 0.05). A small, non-significant reduction was seen in liver glycogen oxidation with HIGH in the last hour compared with LOW (-2.6, -5.6 to 0.4 g·h⁻¹, ES = 0.40) and MED (-2.6, -6.8 to 1.6 g·h⁻¹, ES = 0.42).

CONCLUSIONS: Increasing CHO ingestion beyond previously reported saturation rates produces higher exogenous oxidation, but results in an increased reliance on muscle glycogen. Ingestion of 90 g·h⁻¹ GF can attenuate the rate of muscle glycogen oxidation by the end of 3 hours prolonged exercise, but recommendations should remain in the region of 80 to 90 g·h⁻¹.

Glucose Regulation Following A Short And Long Bout Of High-intensity Functional Training

Brian Kliszczewicz, Robert Buresh, Emily Bechke, Cassie Williamson, Paul Bailey, Yuri Feito, FACSM. *Kennesaw State University, Kennesaw, GA.* (Sponsor: Yuri Feito, FACSM)
 Email: bkkliszcz@kennesaw.edu

(No relationships reported)

Glucose regulation is a fundamental process of metabolic function, and is acutely altered by physical activity. Importantly, exercise intensity and duration have been shown to affect glucose regulation differently. High-Intensity Functional Training (HIFT) is a form of exercise performed using combinations of various modalities and durations. Though HIFT is of a high-intensity nature, it is unknown if different durations of HIFT will influence glucose regulation differently.

PURPOSE: To determine the effect of a Short (< 5 min) and Long (15 min) bout of HIFT on plasma glucose and insulin concentration.

METHODS: Ten apparently healthy males (28.11 ± 5.09 yrs) participated in this study. Two HIFT sessions (SHORT and LONG) were performed in a crossover fashion. The SHORT bout consisted of 30 power clean-and-jerk lifts (61 kg) for time, while the LONG bout was a 15-min circuit of 250 m row, 20 kettle bell swings (24 kg), and 15 dumbbell (16 kg) squat presses performed for 15 min. Blood plasma was collected at four different times points: PRE, POST, 1HR, and 3HR in order to examine glucose (GLU) and insulin (INS) responses.

RESULTS: A repeated measures ANOVA showed no trial dependent difference between the SHORT and LONG bouts of HIFT in GLU (p = 0.109) or INS (p = 0.504). A time effect was observed in both bouts only at the POST time point for both GLU; Short: 83.9 ± 16 mg/dL vs. 110.3 ± 18 mg/dL (p < 0.001), Long: 84.5 ± 11 mg/dL vs. 124.6 ± 19 mg/dL and INS; Short: 7.9 ± 4 mU/L vs. 16.1 ± 7 mU/L, Long: 9.1 ± 7.8 mU/L vs. 13.7 ± 7.3 mU/L (p < 0.05).

CONCLUSIONS: This study demonstrated that the SHORT and LONG bouts of HIFT elicited similar glucose and insulin responses. Duration of the HIFT bouts may not be a determining factor in glucose regulation in healthy individuals. Further research is necessary to better understand the relationship of varying durations of HIFT on glucose regulation.

Metabolic Effects of Acute Blood Flow Restricted Exercise: Glucose & Insulin

Larry A. Osborne¹, Lucas Harrison¹, Ge Chen¹, Samuel Pitcairn¹, Michael Kushnick¹, Norio Hotta². ¹Ohio University, Athens, OH. ²Chubu University, Kasugai, Japan.

(No relationships reported)

Blood flow restricted exercise (BFRE) has gained a lot of attention as of late due to its ability to increase muscle mass and strength during low intensity exercise. BFRE results in ischemia, which has been shown to cause a shift to a greater reliance on glucose metabolism. Although the metabolic effect of traditional exercise is well studied, there is a lack of research on the metabolic effects of BFRE. **PURPOSE:** Investigate the blood glucose and insulin response to a single bout of blood flow restricted exercise 12, 36, and 48 hours after completion. **METHODS:** 8 healthy men (22±2 yrs), of above average $\dot{V}O_{2max}$ (46.2±13.4ml/kg/min), and average body fat percentage (17.4±3.2) performed two separate trials of treadmill walking (CON & BFRE) at 50±5% of their predetermined $\dot{V}O_{2max}$ until 200 kcal were expended. For the BFRE trial, pressure cuffs were applied to the most proximal portion of the thigh and inflated to 200 mmHg. Subjects walked in 10-minute increments, interspersed with 2 minutes of passive recovery where the pressure cuffs were deflated. Blood samples were taken at baseline, immediately after exercise, 12 hours, 36 hours, and 48 hours post exercise bout. All values were reported in standard±mean deviation. A 2x3 Repeated Measures ANOVA, a One-way ANOVA, and a Tukey's HSD post hoc test were utilized to evaluate differences from pre to post. **RESULTS:** Minimal differences were found in the glycemic response post exercise between BFRE and CON (95.6±2.8, 99.9±14.1, 102.6±14.8, 104.6±8.2, and 96.8±4.8) vs (97.0±3.9, 93.1±8.1, 96.2±6.5,

92.8±6.2, 93.7±4.7). However, BFRE resulted in significantly lower insulin levels than CON at immediately, 12, 36, and 60 hours post exercise (18.4±7.3, 12.1±6.9, 12.2±7.8, 11.8±5.8, and 12.7±6.0) vs (17.6±7.9, 18.3±8.4, 16.5±8.7, 15.8±6.9, and 18.5±9.4).

CONCLUSION: In this small sample of apparently healthy above average aerobic fitness and average body fat men, treadmill walking to expend 200 kcals in conjunction with BFRE resulted in significant less insulin needed to elicit the same glycemic response post exercise than CON.

Research was funded in part by Sigma Xi Grant in Aide, Provosts Undergraduate Research Fund, and the College of Health Sciences and Professions Student Research Award.

Body Composition, Substrate Utilization, Thermoregulation, And Performance In Male Runners After 3-week High Fat Diet

Alexander J. Heatherly. *University of North Alabama, Florence, AL*. (Sponsor: Matt Green, FACSM)

Email: aheatherly@una.edu

(No relationships reported)

PURPOSE: This study examined physiological and performance effects of a 3-week high fat, low carbohydrate diet (HFLC) in trained runners.

METHODS: Middle-aged, recreationally competitive ($\text{VO}_2 = 48.5 \pm 4.5$ ml/kg/min) male runners ($n = 8$; 39.5 ± 9.9 y) completed 5 sets of 10 min runs separated by 2 min of rest in a controlled, hot environment (29 °C and 60 % relative humidity). The first 7 min of each stage were run at a sub-marathon pace with the last 3 min of each stage matching the runner's goal pace for 5-km, 10-km, half-marathon, marathon, and sub-marathon race pace (1% grade). Indirect calorimetry variables were collected during each race distance pace. Runners rested for 20 min before a challenging outdoor 5-km time trial (5TT). Runners followed their habitual high carbohydrate (HC) for the first phase of the study followed by 3 weeks of HFLC ($\geq 70\%$ kcals from fat; < 50 g/day carbohydrates).

RESULTS: Pre- and post-exercise ketones increased by ~ 0.5 mmol for HFLC. Sum of 7-site skinfold thickness and body mass decreased ($p < 0.01$) by ~ 13 mm and 2.5 kg for HFLC respectively. Mean RER was lower ($p < 0.01$) by 0.08-0.10 at all paces for HFLC. Mean fat oxidation was predicted to be non-existent at 5-km pace and < 0.3 g/min at all other paces for HC, while ranging from 0.32-0.81 g/min for HFLC. Absolute VO_2 was higher for HFLC or neared statistical significance at all paces slower than 5-km. Rectal temperature was higher in HFLC after the first 10 min bout, but did not differ at any other time point. Total sweat losses and heart rate for each pace did not differ between treatments. Five runners completed their 5TT faster after HFLC, 1 remained unchanged and 2 were slower following HFLC. Mean finishing time was ~ 30 -s faster for HFLC, but there was no statistical difference ($p = 0.25$; HFLC = 23.45 ± 2.25 ; HC = 23.92 ± 2.58 min).

CONCLUSIONS: Transitioning to a HFLC resulted in positive fat oxidation adaptations and may even improve late exercise, high intensity endurance performance for well-trained but recreational runners. Anecdotally, non-responders to HFLC may be identified by lack of cessation in training impairment that is almost always experienced in the first 2 weeks during transition to HFLC. In contrast to the runners with improved times, continued difficulties noted in training logs were only noted in runners with lack of 5TT improvement.

B-42 Thematic Poster - Muscle Activation during Sport and Exercise

Relationship Between Passive Hip Range of Motion And Hip Muscle Activation During Landing

Emma F. Zuk¹, Michelle C. Boling², Kevin R. Ford, FACSM¹, Jeffrey B. Taylor¹, Anh-Dung Nguyen¹. ¹*High Point University, High Point, NC.* ²*University of North Florida, Jacksonville, FL.* (Sponsor: Kevin Ford, FACSM)

Email: zuke13@highpoint.edu

(No relationships reported)

Passive hip range of motion (ROM) is theorized to influence activation of the hip musculature during dynamic activity. A decrease in the activation of the hip musculature may lead to landing biomechanics that increase the risk of knee injuries.

Understanding the relationship between passive hip ROM and hip muscle activation during landing is needed to identify individuals at risk for knee injuries. **PURPOSE:** To examine the relationship between transverse plane hip passive ROM and hip muscle activation during a landing task. **METHODS:** Twenty female Division 1 soccer players (19.2 ± 0.9 yrs, 167.2 ± 5.7 cm, 65.9 ± 6.6 kg) volunteered to participate. Passive hip internal (HIR) and external (HER) ROM of the left limb was measured with participants prone and the knee flexed to 90 degrees using a digital inclinometer by a single examiner ($\text{ICC} > 0.87$). The average of three HIR and HER ROM measures was used for analysis. Surface electromyography (sEMG) was used to assess activation of the gluteus medius (GMED) and gluteus maximus (GMAX) during 3 trials of a drop vertical jump (DVJ) task from a 31cm high box. The average root mean square amplitude (RMS) of the sEMG signal of the GMED and GMAX 150ms following initial contact across three DVJ trials was normalized to the peak RMS amplitude across three maximal voluntary isometric contractions (%MVIC). Pearson's Product Moment Correlations were calculated to determine the relationship between passive hip ROM and muscle activation during the DVJ ($p < 0.05$). **RESULTS:** Greater HIR ROM (39.9 ± 11.1 degrees) was correlated with less GMAX activation during the DVJ task ($\text{RMS} = 0.61 \pm 0.40\%$ MVIC, $R = -0.53$, $P = 0.02$). HIR ROM was not correlated with GMED activation during the DVJ task ($\text{RMS} = 0.24 \pm 0.12\%$ MVIC, $R = -0.38$, $P = 0.10$). HER ROM (30.6 ± 8.1 degrees) was not correlated to GMAX ($R = 0.10$, $P = 0.69$) or GMED activation ($R = 0.21$, $P = 0.37$) during the DVJ task. **CONCLUSIONS:** Greater HIR ROM potentially influences the length-tension relationship of the GMAX, decreasing its ability to effectively activate during dynamic activities and increasing the risk of knee injuries. Ongoing work is needed to examine whether the effects of hip ROM on muscle activation contribute to landing biomechanics known to increase risk of knee injuries.

748 Board #2 May 31 3:15 PM - 5:15 PM

Shoe Cushioning Reduces Impact And Muscle Activation During Landings From Unexpected, But Not Self-initiated, Drops

Weijie Fu, Xi Wang, Yang Yang, Yu Liu. *Shanghai University of Sport, Shanghai, China.*

Email: fuweijie315@163.com

(No relationships reported)

The drop jump, regarded as "an active landing from a self-initiated drop" (self-initiated drop landing, SIDL), is an effective training modality to develop explosive strength. Contrarily, "a landing from an unexpected drop" (unexpected drop landing, UDL), which is mostly unanticipated, has been proposed to generate potentially hazardous alterations to impact absorption. To date, few rigorous scientific studies have been conducted to understand the impact mechanics and muscle activation characteristics of these two landing tasks and the role of shoe properties.

PURPOSE: To investigate the shoe effects on impact biomechanics and muscular responses during drop landings.

METHODS: Twelve male collegiate basketball players performed bipedal landings from self-initiated and unexpected drops (SIDL and UDL) from a 60-cm height wearing highly-cushioned basketball shoes (Bball) and minimally cushioned control shoes (CC). Sagittal plane kinematics, ground reaction forces (GRF), accelerations of the shoe heel-cup, and electromyography (EMG) of the tibialis anterior (TA), lateral gastrocnemius, rectus femoris (RF), vastus lateralis (VL), and biceps femoris (BF) were collected simultaneously.

RESULTS: In SIDL, no significant differences were observed in peak vertical GRF, peak heel acceleration, or normalized EMG amplitude (root mean square, EMG_{RMS}) for all muscles during either the pre- or post-activation phase between the two shoe conditions. In UDL, however, both peak vertical GRF (4.1 ± 0.7 vs. 4.7 ± 0.8 BW, $p < 0.05$) and heel acceleration (29 ± 7 vs. 36 ± 8 g, $p < 0.05$) were lower in Bball compared to CC. Furthermore, the EMG_{RMS} of TA (17 ± 6 vs. $24 \pm 8\%$, $p < 0.05$), RF (21 ± 3 vs. $28 \pm 7\%$, $p < 0.05$), VL (28 ± 5 vs. $35 \pm 4\%$, $p < 0.05$), and BF (9 ± 4 vs. $14 \pm 5\%$, $p < 0.05$) muscles showed a decrease in Bball compared to CC within the 50 ms after contact.

CONCLUSION: These observations suggest that shoe cushioning may make only a limited contribution to reducing landing impact forces provided that neuromuscular adjustments occur properly during landings from self-initiated drops. However, in the situation when relevant muscles are not activated on purpose, as in landings from unexpected drops, wearing a highly-cushioned shoe decreases peak impact and muscle post-activation.

Supported by NSFC grant (81302131).

Muscle Activation Patterns during a Novel Lateral Lunge Jump Reaction TaskMichelle A. Aube, Jeffrey B. Taylor, Audrey E. Westbrook, Anh-Dung Nguyen, Kevin R. Ford, FACSM. *High Point University, High Point, NC.* (Sponsor: Dr. Kevin Ford, FACSM)
Email: aubem14@highpoint.edu

(No relationships reported)

Muscular activation and recruitment patterns of the hamstrings and quadriceps may play an important role in knee joint stabilization with unanticipated reactions during sport.

PURPOSE: To examine lower limb muscle activation during a lateral lunge jump reaction task.

METHODS: Female soccer players participated in the study (n=10, age: 15±1yrs, height: 162.3±4.6cm, mass: 54.5±4.5kg). While wearing standardized cleats, each participant was instrumented with reflective markers for motion analysis. Surface EMG sensors were placed on the semimembranosus (MH), biceps femoris (LH), vastus lateralis (LQ), and vastus medialis (MQ). While standing in a ready position (feet shoulder width apart, knees slightly bent) on force platforms covered with artificial turf, a visual cue of an arrow pointing either left or right was projected on a screen in front of the participant, at which time they were to lunge jump laterally in the correct direction as quick and far as possible. Right directed lunge trials were analyzed. Muscle onset time was defined as greater than SSD above the resting threshold prior to the visual cue. Peak root mean square EMG amplitudes of the left leg were calculated and normalized to maximum amplitude (%) during a cutting task. Reaction time (Rt) was defined as the difference between the visual cue popup and left toe off from the force platform. Paired t-tests (p<0.05) were used to determine differences in muscle onset time and amplitude during the task. Stepwise linear regression was utilized to determine significant predictor variables for Rt.

RESULTS: Rt from visual cue to toe off was 0.99±0.10s. There was a significant difference (p=0.039) between LH (0.40±0.12s) and LQ (0.47±0.11s) onset times with no significant difference (p=0.2) between MH (0.42±0.09s) and MQ (0.48±0.10s) onset times. Differences were not found between peak EMG amplitude (LH: 67.6±24.9%, LQ: 80.9±8.2%, p=0.16; MH: 66.3±24.1%, MQ: 79.2±14.9%, p=0.18). Stepwise linear regression indicated that the single predictor variable of Rt was LQ onset time (R²=0.616, F(1,8)=12.81, p=0.007).

CONCLUSION: Earlier hamstrings activation may provide increased co-activation during an unanticipated reaction requiring a rapid lunge jump. However, quicker quadriceps activation is strongly correlated with improved reaction time performance.

Changes in Lower Extremity Muscle Activation After Different Types of ExerciseLindsay Slater, Joe Hart, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Joe Hart, FACSM)

(No relationships reported)

Muscle activation changes after exercise due to muscular fatigue. Muscular fatigue is often induced using standard exercises such as treadmill incline walking and squats, however exercise that simulates sport including high-speed movements, changes in direction, and decision-making may elicit different muscle activation adaptations.

Purpose: Compare muscle activation patterns before and after two exercise protocols.

Methods: 14 healthy volunteers (10F/4M, 168.3±10.0cm, 66.7±12.5kg, 19.3±0.9 yrs) completed two exercise protocols within 14 days. One exercise protocol (Control) included 30 minutes of incline walking intermixed with brief periods of squat jumps and lateral hops. The second exercise protocol (Sport) included 30 minutes of walking and running intervals intermixed with brief periods of sprinting forcing subjects to respond in random directions. EMG electrodes were placed on the vastus lateralis, vastus medialis, and gluteus medius of the dominant leg using standard EMG placement procedures. Data were recorded while walking at 1.3m/s before and immediately after exercise intervention. Normalized EMG data (MVIC) for 5 strides were reduced to 101 points from heel strike to ipsilateral heel strike to represent 0-100% of the gait cycle. Means and 90% confidence intervals were calculated for each muscle before and after exercise. Areas in which the confidence intervals for EMG activity across the entire gait cycle did not overlap for 3 or more consecutive points were considered statistically significant differences. Cohen's *d* effect sizes and 90% confidence intervals were calculated for portions of gait with significant differences. **Results:** Vastus medialis activation increased during walking gait after both Control (74-78%, *d* = 38.2±9.5) and Sport exercise (73-76%, *d* = 15.0±3.6). Gluteus medius activation only increased after Sport exercise (76-84%, *d* = 7.5±2.0). There were no changes in vastus lateralis after either exercise. **Conclusion:** Both exercise protocols increased vastus medialis activation, however only Sport exercise increased gluteus medius activation, demonstrating that different types of exercise may elicit different EMG activity responses. These differences should be considered when designing exercise protocols for muscle activation testing.

Influence of Force Application Strategies on Muscle Activation and Plantar Pressure during Maximal Ergometer RowingRena Jackson¹, Will Wu¹, Mimi Nakajima¹, Tiffanye Vargas¹, James Becker². ¹*California State University Long Beach, Long Beach, CA.* ²*Montana State University, Bozeman, MT.*

(No relationships reported)

The rowing stroke begins with the feet generation force against the foot stretcher. It has been suggested that force application at the foot stretcher can be a limiting factor to rowing performance, however it is unknown how different strategies of applying force underneath the feet influence muscle activation and force-time profiles.

PURPOSE: To determine how different strategies of applying force underneath the feet influences muscle activation and force-time profiles during maximal ergometer rowing. **METHODS:** Seven collegiate rowers (5-female, 2-male) completed two trials of ten maximal strokes. Trial conditions consisted of instructional cues: "Push through the balls of your feet", "Push through the heels of your feet". EMG of the erector-spinal (ES), lastissimus-dorsi (LD), gluteus-maximum (GM), and rectus-femoris (RF) were bilaterally recorded, sampling at 1500Hz. Pressure distribution under both feet was recorded while using a wireless in-shoe plantar-pressure system sampling at 500Hz. Peak force and impulse were calculated in a custom MATLAB program for the total foot, heel, and forefoot regions, under both conditions. Timing of muscle activation, duration, and integrals (iEMG) of drive activation were calculated for the middle 5 strokes. Paired t tests were used to compare dependent variables between the conditions. **RESULTS:** Six participants produced significantly higher peak forces (517.6±109.8N, *p*<0.012, *d*=1.57) and impulses (359.3±57.2N, *p*<0.007, *d*=1.80) when pushing through the balls than when pushing through the heels. Three participants displayed the opposite pattern. EMG analysis did not reveal significant differences in onset, duration, or integration of muscle activation between conditions.

CONCLUSIONS: Rowers in this study can be separated into two groups based on their ability to produce force and generate impulse: those more effective at pushing through the balls of the feet, at those more effective at pushing through the heels. Future research may want to examine performance, strength, and flexibility parameters to determine whether this difference is a beneficial or detrimental adaptation. If certain strategies are associated with variables that determine successful performance, then coaches may use this information to improve rowing performance.

752 Board #6 May 31 3:15 PM - 5:15 PM

Electromyographic Activation Of Quadriceps In Single And Multi-joint ExercisesJessica F. Perle, Danilo S. Felipe, Tamires F. da Silva, Fabiano F. da Silva, Wonder P. Higinio, Elisângela Silva, Wagner Z. de Freitas, Daniela G.M. Bueno, Dênis B. da Silva, Renato A. de Souza. *IFSULDEMINAS, Muzambinho, Brazil.*

(No relationships reported)

Resistance training (RT) is a form of physical activity that is designed to improve muscular fitness. Considering the need to adequately prescribe RT, a better understanding about the effects of mono and multi-joint exercises is required, mainly using electromyographic (EMG) findings. **PURPOSE:** to compare EMG activation of quadriceps in mono-joint and open kinetic chain versus multi-joint closed kinetic chain exercises. **METHODS:** Ten healthy male (25.3 ± 3.7) and with no previous experience with RT were recruited. This study was conducted as a cross-over design; i.e., the subjects were randomly assigned either to mono-joint (n = 5; seated knee extension machine) or multi-joint (n = 5; back squat at knee joint angle of 90°) for the 1(st) trial and 15 days later the subjects were switched conditions for the 2(nd) trial. Surface electromyography was used to measure muscle activation of the vastus lateralis (VL), vastus medialis (VM) and rectus femoris (RF) using Root Mean Square (RMS) signal normalized by peak during dynamic contraction. A 12-RM test was used in order to promote some standardized load for both experimental situations. For statistical analysis a two-way ANOVA was performed (muscle and treatment effects). **RESULTS:** RF showed a lower (p<0.05) EMG activation than VL and VM in multi-joint exercise (26.81 ± 7.84% versus 33.43 ± 5.49% and 33.27 ± 4.96, respectively). In another way, RF showed a higher (p<0.05) EMG activation than VL and VM in mono-joint exercise (41.17 ± 5.08% versus 37.87 ± 4.94% and 37.12 ± 3.79%). Mono-joint exercise increased ~34% the EMG activation of RF than multi-joint exercise. There are no significant differences between the vastus (p>0.05). **CONCLUSION:** A mono-joint and open kinetic chain exercise promoted higher RF-EMG activation and not altered vastus-EMG activation when compared with a multi-joint and closed kinetic chain exercise. These findings suggest that EMG pattern may be muscle-dependent even within the same muscle group as the quadriceps.

Activation Of Knee Extensor Muscles During Rapid Force Development In Men And Women

Minhyuk Kwon, Jose D. Delgadillo, Jonathon W. Senefeld, Christopher W. Sundberg, Sandra K. Hunter, FACSM. *Marquette University, MILWAUKEE, WI.* (Sponsor: Sandra K. Hunter, FACSM)
 Email: minhyuk.kwon@marquette.edu
 (No relationships reported)

Adequacy of activation during rapid voluntary contractions is limited in young and old adults and can be shown by comparing the voluntary rate of force development (RFD) and electrically evoked RFD. Nonetheless, it is unknown whether the activation of rapid voluntary contractions differs between young men and women.

PURPOSE: The purpose of this study was to compare the maximal RFD of young men and women during electrically evoked isometric contractions and rapid voluntary contractions with the knee extensor muscles across a range of torques.

METHODS: Eight young adults (18-26 years; 4 men, 4 women) consented to sets of single and double pulse (10 ms interval) stimulations of the femoral nerve at maximal intensities followed by rapid voluntary isometric knee extensions at target torques matched to the electrically evoked torques. For the rapid voluntary isometric contractions, subjects were instructed to kick as fast as possible rather than as accurately as possible. Voluntary target torques ranged between 10-40% of maximal voluntary contraction (MVC) and were set to match the electrically evoked torques. Maximal RFD for each trial (voluntary and electrically evoked) was calculated as the peak values of the first derivative of the torque signal.

RESULTS: Torques (between 10-40% MVC) were similar for the electrically evoked and voluntary contractions ($F_{1,6} = 0.54, P = 0.49$) for both the men ($25.0 \pm 0.6\%MVC$ vs. $26.4 \pm 0.7\%MVC$) and women ($26.0 \pm 2.0\%MVC$ vs. $26.5 \pm 2.7\%MVC$). Although torques were similar, RFD from electrically evoked contractions in men ($514.8 \pm 30.4\% MVC \cdot s^{-1}$) and women ($475.1 \pm 78.0\%MVC \cdot s^{-1}$) was 36% greater than the voluntary contractions (men; 330.2 ± 18.8 vs. women; $305.9 \pm 21.2\%MVC \cdot s^{-1}$; $F_{1,6} = 23.1, P = 0.003$). The linear association between relative torque (%MVC) and electrically evoked RFD ($R^2 = 0.85, b = 0.92, P < 0.001$) was larger and steeper than the association with voluntary RFD ($R^2 = 0.72, b = 0.85, P < 0.001$) indicating that the difference in RFD between the electrically evoked and voluntary contractions increased at the higher forces.

CONCLUSIONS: Young men and women had marked reductions in the ability to voluntarily generate isometric knee extension torque rapidly compared with electrically evoked contractions that were independent of the central nervous system. Supported by NIA R01 AG048262 to SKH

Proximal Joint Muscle Activation During Cutting In Chronic Ankle Instability Patients Following a Rehabilitation Intervention

Cody J. Perry¹, S. Jun Son¹, Hyunsoo Kim², Brian Wiseman¹, Dustin Breuning¹, Matthe K. Seeley¹, J. Ty Hopkins, FACSM¹.
¹Brigham Young University, Provo, UT. ²West Chester University, West Chester, PA. (Sponsor: J. Ty Hopkins, FACSM)
 Email: codyjperry6@gmail.com
 (No relationships reported)

Sensorimotor deficits due to ankle sprains often result in altered lower extremity muscle activation during cutting. Interventions focusing on the ankle and hip could enhance muscle activation and subsequent sensorimotor function in patients with chronic ankle instability (CAI).

PURPOSE: To examine the effect of a 6-week ankle and hip intervention program on vastus lateralis (VL), medial hamstring (MH), gluteus medius (GM), and gluteus maximus (GX) activation during cutting in patients with CAI.

METHODS: 15 CAI subjects in a rehab group (23±2 yrs, 178±8 cm, 76±9 kg, 83±7% FAAM ADL, 56±10% FAAM Sports, 3.6±1.1 MAII, 4.7±2.0 ankle sprains) completed a series of 10 ankle and hip strength and proprioceptive exercises (theraband, wobble board, ankle disk, etc.) 3 times/week for 6 weeks under supervision. 14 CAI subjects participated in a control group (22±2 yrs, 177±9 cm, 75±12 kg, 81±9% FAAM ADL, 56±12% FAAM Sports, 3.4±1.2 MAII, 5.9±3.3 sprains). Subjects performed 10 jumps consisting of a max vertical jump plus a side cut. Functional analyses ($\alpha = .05$) were used to detect a group x treatment interaction over time. If 95% CI did not cross the zero, significant differences existed.

RESULTS: Figure 1. The rehab intervention resulted in up to (i) 28% less VL activation at 0-20% of stance, (ii) 31% more MH activation at 43-100% of stance, (iii) 14% less GX activation at 83-100% of stance. No changes were detected in GM activation over time.

CONCLUSIONS: Relative to the control group, reduced proximal joint muscle activation in CAI patients in the rehab group may be due to altered knee and hip positions. A less flexed position of the knee and hip often leads to less knee and hip extensor moments, which potentially could result in reduced VL and GX muscle activation.

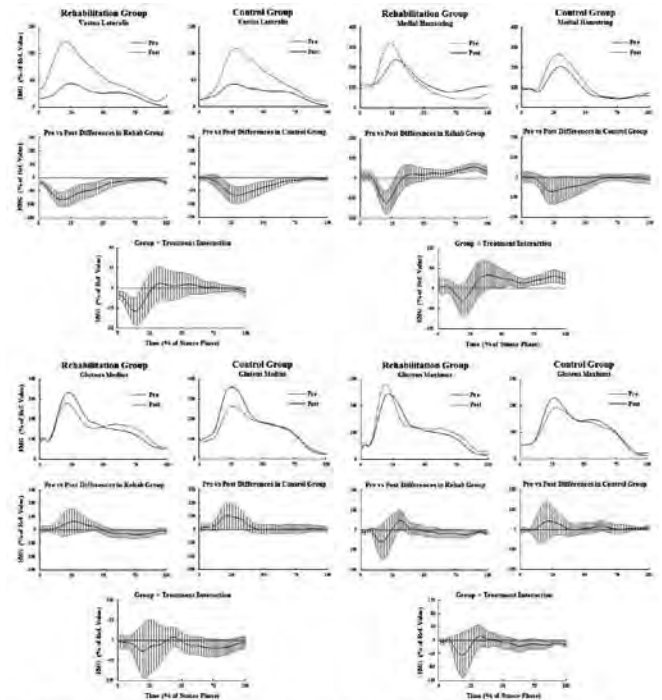

Figure 1. Grand ensembles for proximal joint muscle activation during the stance phase of a cutting task. A group x treatment interaction was defined subtracting "Pre vs Post Differences in Rehab Group" from "Pre vs Post Differences in Control Group". When 95% confidence intervals (shaded area) did not overlap the zero (horizontal red line), significant differences existed.

Energy Expenditure During Treadmill Walking and Running: Accuracy of the 100 Kcal Per Mile Estimate

Brian B. Parr, Andrew G. Hatchett, Lianna R. Epstein, Rachael L. Herring, Harli R. Eggenberger. *University of South Carolina Aiken, Aiken, SC.* (Sponsor: Michael J. Turner, FACSM)
 Email: brianp@usca.edu
 (No relationships reported)

Walking and running are widely used modes of exercise to improve fitness and promote weight loss. The energy expended during walking or running can be measured in a lab or estimated based on speed, grade, and body weight. However, these assessments are not easily completed by the general population, so a crude estimate of energy expenditure (EE) of 100 kcal•mile⁻¹ is commonly used. Although the equations for estimating EE at a given walking or running speed have been validated, the accuracy of the 100 kcal•mile⁻¹ value has not been evaluated.

PURPOSE: The purpose of this study was to determine the accuracy of the 100 kcal•mile⁻¹ estimate across a wide range of walking and running speeds.

METHODS: A sample of 21 subjects (age 23.6±8.8 y) walked or ran one mile at a self-selected speed on a motorized treadmill while VO₂ was measured. The EE was calculated from VO₂ measured after subjects achieved steady-state. The significance of differences in measured EE and the 100 kcal•mile⁻¹ estimate were determined using t-tests.

RESULTS: There were no significant differences between the measured EE and the 100 kcal•mile⁻¹ estimate (108.6±31.5 vs. 100±0 kcal•mile⁻¹, p=0.22) across both running and walking speeds (range: 72.4-187.6 m•min⁻¹). There were also no significant differences between the actual and estimated EE at walking speeds (95.6±12.6 m•min⁻¹; 100.1±23.1 vs. 100±0 kcal•mile⁻¹, p=0.98) or running speeds (158.8±19.4 m•min⁻¹; 115.0±36.2 vs. 100±0 kcal•mile⁻¹, p=0.18). However, the measured EE during running was significantly higher (p=0.03) than during walking.

CONCLUSION: The widely used EE estimate of 100 kcal•mile⁻¹ appears to be accurate across a wide range of walking and running speeds. While the measured EE during running was significantly higher than during walking, neither was significantly different from the 100 kcal•mile⁻¹ estimate. This suggests that this value may be useful for estimating EE for fitness or weight loss purposes in a general population.

The Effect Of Acute Body Mass Reduction On Metabolism And Endurance Running Performance

Elias Zacharogiannis¹, Giorgos Paradisis¹, Stamatis Magos¹, Isidoros Plavoukos¹, Fotini Dagli¹, Theofilos Piliandis¹, Maria Maridaki¹, Angeliki Zacharogianni². ¹National and Kapodistrian University of Athens, Athens, Greece. ²Leeds Beckett University, Leeds, United Kingdom.

Email: elzach@phed.uoa.gr

(No relationships reported)

Reduced body mass and/or relative fat mass is expected to improve endurance running performance, by lowering energy cost of running and allowing the runner to maintain higher mean race velocity using identical %VO₂max. The majority of studies during the last 40 years have been centered mainly on the effect of adding external load on energy cost of walking and running. **PURPOSE:** The purpose of this study was to examine the effect 5 and 10% reduction of inactive body mass on metabolic responses and 3km running performance.

METHODS: Eleven trained (8 male, 3 female) club level runners (mean ± sd body mass, height, %fat, peakVO₂ and vVO₂max, 65.71 ± 12.07 kg, 174.59 ± 8.32 cm, 12.54 ± 3.55%, 56.30 ± 4.57 ml.kg⁻¹.min⁻¹ and 17.1 ± 1.4 km.h⁻¹ respectively) participated in a series of 4 maximal trials 4-6 days apart. During the first trial, the subjects completed an exhaustive incremental peakVO₂ test on the treadmill. On the second visit they completed a 3 km race time trial on the treadmill running with normal body mass (BM). During the last two laboratory visits, the subjects completed two 3km race trials in random order on the treadmill while body mass (a rope through a system of pulleys lifted the runner with the calculated body weight throughout striding phases while not interfering with running technique) was reduced 5 (5%BM) or 10% (10%BM). Repeated Anova was used for the statistical analysis.

RESULTS: Mean (±sd) 3km performance time was lowered (improved) during 5%BM (663.5 ± 76.05 s) and 10%BM (648.9 ± 74.9 s) trials (p<0.05) compared with BM (684.9 ± 74.8 s). The 5 and 10% reduction in body mass induced a mean 3.1 and 5.2% improvement in 3km race performance accordingly. Every kg reduction of inactive body mass improved 1.4% running endurance performance. Mean values of the Rate of perceived exertion, heart rate, VO₂ ml.min⁻¹, RQ, Blood lactate and Volume of expired air were not different between time trials and peak VO₂max test (p>0.05).

CONCLUSIONS: The results of the present study showed that the reduction of 5 and 10% of inactive body mass may improve significantly 3km performance time without noticeable effects on metabolic parameters and are supportive of the notion that one way to maximize further running performance is to reduce inactive body mass.

Comparison Of RPE And Energy Expenditure Between Circuit Weight Training And Treadmill Running

Christi Brewer, Breann Booher, Nathaniel Lawton, Wendy Repovich, FACSM. Eastern Washington University, Cheney, WA. (Sponsor: Wendy Repovich, FACSM)

(No relationships reported)

Due to the fact circuit weight training (CWT) maximizes exercise density by minimizing rest intervals, individuals with limited time to exercise may rely on CWT to meet caloric expenditure recommendations for the prevention of weight gain.

Exercise density may lead to an inaccurate perception of energy expenditure (EE). **PURPOSE:** To compare acute EE indices and RPE between traditional CWT and an equivalent bout of treadmill running (T). **METHODS:** College-aged males (n=9) regularly engaged in running and resistance training volunteered. CWT session was performed first and consisted of 10 resistance training stations performed for 30 sec each at 40%1RM for 20 min. HR (Polar monitor) and EE (Cosmed K4 b2) were monitored continuously, and RPE (0-10) was assessed every fourth station. A 20 min T session occurred 2 days later at the average HR maintained during CWT. A dependent samples t-test was used to determine significant differences between RPE, total EE (TEE, kcal), rate of EE (REE, kcal/min), and relative rate of EE (RREE, kcal/kg/min). Pearson's correlation was used to assess the relationship between EE and RPE. **RESULTS:** The average HR elicited by CWT was 58% HRR, a value within ACSM recommendations for aerobic conditioning. There was no significant association between RPE and EE indices for either CWT or T.

Exercise	RPE (0 – 10 scale)	TEE (kcal)	REE (kcal.min ⁻¹)	RREE (kcal.kg ⁻¹ .min ⁻¹)
CWT	6.0 ± 1.1*	168.19 ± 16.42*	8.49 ± 0.90*	0.10 ± 0.02*
T	4.1 ± 0.6	244.20 ± 44.80	12.21 ± 2.24	0.15 ± 0.02

*p<0.001

CONCLUSIONS: CWT elicited an average HR suitable for aerobic conditioning. At equivalent HRs, CWT resulted in a significantly higher RPE but significantly lower EE. It is imperative for participants engaged in CWT to understand that although CWT results in HR values within an aerobic training zone and feels more strenuous than T, it is not associated with greater acute energy expenditure than steady-state treadmill running.

ACSM May 30 – June 3, 2017

Effect of Wearing Lower-Body Compression Garment Following Downhill Running on Running Economy

Sahiro Mizuno¹, Yoshifumi Tsuchiya², Kazushige Goto¹. ¹Ritsumeikan University, Kusatsu, Japan. ²Atomic Bomb Disease Institute, Nagasaki, Japan. (Sponsor: Robert R. Kraemer, FACSM)

Email: librae.librae@gmail.com

(No relationships reported)

Accumulating evidences suggest that wearing lower-body compression garment (CG) after exercise facilitates recovery of muscular strengths. However, efficacy of wearing CG during post-exercise period on endurance capacity has not been fully determined.

PURPOSE: To examine effect of wearing lower-body CG for 24 h following downhill running on running economy. **METHODS:** Ten male subjects (170.2 ± 4.1 cm, 63.7 ± 4.1 kg, VO₂max; 52.4 ± 6.1 ml/kg/min) completed 2 trials, with either wearing lower-body CG or placebo garment (CON) during 24 h of post-exercise period. At least 3 months period was provided between the two trials. The exercise consisted of 30 min of downhill running (slope: -10%) at 70% of VO₂max. Time course changes in jump height and score of muscle soreness were evaluated before exercise and during post-exercise period. Blood samples were also collected to determine serum creatine kinase (CK) and hsCRP concentrations. Running economy (RE) was assessed at 24 h following exercise under three different running velocities (70%, 80% and 90% of VO₂max). P < 0.05 was considered to be statistically significant. **RESULTS:** Jump height significantly decreased immediately after exercise in both trials, while the CG trials showed significantly higher values at 24 h following exercise compared with the CON trial (P = 0.0008). Although serum CK and hsCRP concentrations significantly elevated during post-exercise period, the responses were similar between trials. For the RE, no significant difference was observed between two trials. However, there was a relatively large inter-individual variation for efficacy of CG on RE (ΔVO₂ range: -7.1% to 12.2%), and we have divided all subjects into two different groups [improved RE (n = 5), decreased RE (n = 5)]. No significant difference between the groups was observed for jump performance or score of muscle soreness at 24 h after the exercise, while improved RE group showed significantly higher serum CK and hsCRP concentrations compared with impaired RE group (P = 0.005 for CK, P = 0.04 for hsCRP). **CONCLUSION:** Wearing lower-body CG during 24 h of post-exercise period did not improve RE. However, relatively large inter-individual variation existed for efficacy of the CG, and wearing CG during post-exercise period might promote recovery of RE under situation with severe muscle damage.

Novel Field Test To Identify Critical Velocity During Non-linear Running: Physiological Profile, Reliability, And Validation

Eric M. Bradley, Bradley W. Wilkins, Brett S. Kirby. Nike Inc, Beaverton, OR. (Sponsor: Larry Kenney, FACSM)

(No relationships reported)

PURPOSE: Athletes and coaches have interest in identifying specific work rates and related physiology discriminating sustainable vs unsustainable exercise intensity. A threshold intensity for running, termed Critical Velocity (CV), is the boundary between stable metabolism and progressively disturbed metabolism (& ensuing fatigue). We aimed to develop a simple short duration field test (Critical Velocity Shuttle Test, CVST), to accurately and reliably identify CV during intermittent non-linear running. Further, we tested the hypothesis that CV during dynamic non-linear running is distinctly different (i.e. lower) than linear running.

METHODS: Young healthy adults performed a custom designed 7 minute shuttle test consisting of intermittent dynamic non-linear sprint running. Each sprint covered 30 feet out and back, with rest time between maximal efforts of 15 secs for the first 3 mins, 10 secs for the next 2 mins and no rest for the final 2 mins. The CVST was performed twice over the course of 2 weeks to examine test reliability (N=6). In addition, two separate validation trials inclusive of 5% above or below shuttle test end velocity (EV; N=8) were conducted where blood lactate was measured every 4 mins until exhaustion. To compare CV during linear and non-linear running, 10 subjects completed 3 'linear' time trial efforts (1.6, 2.4, 5KM) and the CVST.

RESULTS: Average total distance and shuttle test EV were not significantly different between visits (visit 1 = 864±9m and 3.23m/s±0.05 vs visit 2 = 900±13m and 3.21m/s±0.06, respectively). All subjects who ran 5% above shuttle test end velocity fatigued prior to 20 mins and displayed unstable blood lactate, whereas a stable lactate profile was observed for all running 5% below EV. Non-linear running CV obtained from the CVST was significantly lower than linear running CV (Δ -17±2%), highlighting the importance of modality for threshold determination.

CONCLUSIONS: Collectively, the CVST provides a repeatable and accurate estimate of critical work rate for dynamic intermittent non-linear running activity. Accordingly, the CVST could be employed by coaches and athletes to better understand the physiological impact and rate to fatigue of their chosen work rates during competition.

New Running Shoe Reduces the Energetic Cost of Running
 Wouter Hoogkamer¹, Shalaya Kipp¹, Jesse H. Frank¹, Emily Farina², Geng Luo², Rodger Kram¹. ¹University of Colorado, Boulder, Boulder, CO. ²Nike, Inc., Portland, OR. (Sponsor: Ray Browning, FACSM)
 Email: wouter.hoogkamer@colorado.edu
 (No relationships reported)

Running shoe features (low mass, cushioning, midsole bending stiffness) have been shown to individually reduce the energetic cost of running. Recently, energetic cost has been directly linked to time-trial performance.

PURPOSE: To quantify the energetic cost of running in three marathon racing shoes: a prototype and two shoes currently available to runners. **METHODS:** 18 sub-elite runners (sub-31 min 10km at altitude or equivalent; altitude $\dot{V}O_{2max}$: 72.1 ± 3.4 ml O_2 /kg/min) ran six 5 min trials (3 shoes \times 2 replicates) in: a prototype shoe (NP), and two established marathon shoes (NS6) and (AB2), all equilibrated to 250g/shoe (the mass of AB2, size 10) during three separate sessions - 14, 16 and 18 km/hr. The order of the shoe conditions within a session and the session speed order were pseudo-randomized, mirrored and counterbalanced. The NP shoe has a novel, lightweight and highly resilient midsole and a carbon fiber plate that stiffens the shoe in longitudinal bending. We measured submaximal $\dot{V}O_2$ and $\dot{V}CO_2$ during min 3-5 and averaged metabolic rate (W/kg) for the 2 trials in each shoe model. Blood [La] measured after the last trial of each session and RER indicated running energetics were at steady-state (<3.0 mmol/L and <0.91 , respectively). We compared the 3 shoes over 3 speeds using a two-way ANOVA with repeated measures. **RESULTS:** A significant main effect for shoe ($P < 0.0001$) indicated the NP shoes required $4.0 \pm 1.3\%$ (mean \pm SD) less energy than the NS6 and AB2 shoes (NP vs. NS6: $P < 0.0001$; NP vs. AB2: $P < 0.0001$), which had similar metabolic costs (NS6 vs. AB2: $P = 0.34$): NP 16.45 ± 0.89 , NS6 17.16 ± 0.92 and AB2 17.14 ± 0.97 W/kg averaged across 3 speeds. Although the shoe \times speed interaction effect was significant ($P = 0.0005$), post-hoc analyses suggest that relative percent differences between shoes were similar at the 3 running speeds (all $P > 0.56$). **CONCLUSIONS:** The new shoe reduces the cost of running by 4.0% as compared to two other established marathon racing shoes.

Metabolic Cost Of Overground, Motorized Treadmill And Non-motorized Treadmill Running
 Douglas G. Whyte, Paul J. Tofari, Stuart J. Cormack, Robert B. Edwards. Australian Catholic University, Melbourne, Australia.
 Email: doug.whyte@acu.edu.au
 (No relationships reported)

Non-motorized treadmills (NMT) are becoming an increasingly popular tool for both athletic training and laboratory investigations. However, very little is known about how the physiological response to running on a NMT compares with that of running on either a motorized treadmill (MOT) or overground (OVR).

PURPOSE: To compare the metabolic cost of running on a NMT, MOT and OVR. **METHODS:** Fourteen runners ($\dot{V}O_{2max}$, 57 ± 4 mL \cdot kg⁻¹ \cdot min⁻¹; female, n=7) completed three experimental sessions. Each session consisted of 5 \times 6 min bouts of running at progressively higher speeds, separated by 6 min rest. Running speeds ranged from 9-15 km \cdot h⁻¹ for females and 10.5-16.5 km \cdot h⁻¹ for males. Participants completed the NMT (Woodway Curve 3), MOT (HP Cosmos) and OVR sessions in a crossover manner. OVR sessions were performed around an indoor 144 m oval and pacing maintained using evenly spaced timing lights. Pacing during the NMT was achieved by participants matching a line reflecting their current speed with the required speed on a projected display. Oxygen consumption ($\dot{V}O_2$) and heart rate (HR) during the last 2 min of each bout were determined using a portable metabolic cart (K4B2, Cosmed) and compared between conditions using a magnitude based statistical approach.

RESULTS: Each runner successfully completed all of the 6 min running bouts in the MOT and OVR trials. However, only 1 runner (male) completed the entire NMT trial, and only 6 of 14 runners could maintain the penultimate speed on the NMT. There was an *important* difference in the average % $\dot{V}O_{2max}$ used when running on the NMT compared to OVR (mean \pm 90% CI, $22 \pm 2\%$; ES \pm 90% CI, 1.87 ± 0.15) and MOT ($16 \pm 2\%$; ES 1.50 ± 0.15). Similarly, there was an *important* difference in HR when running on the NMT compared to OVR (25 ± 2 beats \cdot min⁻¹, ES 1.35 ± 0.13) and MOT (22 ± 2 beats \cdot min⁻¹; ES 1.23 ± 0.14). While there was an *important* difference in % $\dot{V}O_2$ max between MOT and OVR trials ($5 \pm 1\%$; ES 0.33 ± 0.08) the difference in HR was *trivial* (2 ± 1 beats \cdot min⁻¹; ES 0.10 ± 0.04).

CONCLUSIONS: Steady state submaximal running on a NMT imposes a markedly higher physiological demand than running on either a MOT or OVR. This increased metabolic cost needs to be considered when designing training programs for or interpreting data obtained from a NMT.

Assessing the Relationship Between Body Composition and 50-km Running Performance
 Jonathan Houck, Andy Bosak, Christopher Carver, Austin Smith, Matthew Sokoloski. Liberty University, Lynchburg, VA. (Sponsor: James Schoffstall, FACSM)
 Email: jhouck@liberty.edu
 (No relationships reported)

Interest in ultramarathon participation and research has grown substantially over the past decade, with one of the main focus in research being race performance. Previous studies have focused on body composition in relation to race performance at distances ranging from 5-km to multi-day adventure races. However, no previous studies have assessed body composition and performance measures at the 50-km distance. **PURPOSE:** To investigate the relationship that may exist between body fat percentage (BF%) and body mass index (BMI) with race finishing time and position in ultramarathon runners who competed in a mountainous 50-km race. **METHODS:** Forty-six ultramarathon runners (male = 31, female = 15; BF%: 19.75 ± 5.64 ; BMI: 23.7 ± 2.58) participated in this study and were given a preliminary screening questionnaire on-site during packet pick-up on the day prior to the 50-km race. The participants' height was calculated using a leveled measuring tape. Weight and body composition measurements were taken using a bioelectrical impedance analysis (BIA) system. Finishing times and positions were collected from the race website four days after the event. Pearson correlations were calculated to determine if a correlation existed between overall race finish time/position and BMI and BF%. **RESULTS:** All forty-six participants completed the 50-km race (22967.37 ± 3001.1 seconds). Significant correlations were noted between race finish time and BF% ($r = .548$, $p = 0.00$) and race position and BF% ($r = .532$, $p = 0.00$). There were no significant correlations between overall race finish time and BMI ($r = 0.036$) or race position and BMI ($r = 0.004$). **CONCLUSION:** BF% measurements may be more accurate in loosely predicting potential overall finish time and position as compared to using BMI calculations. The results suggest that a runner with a lower body fat percentage may finish with a faster time and therefore better order of finish as compared to a runner with a higher body fat percentage. Future studies may focus on the potential change in body composition and its impact on race performance in male and/or female ultramarathon runners.

Effects Of Acute Eccentric Exercise On Primary Antibody Responses To Ovalbumin Vaccination In Aged Mice.
 YI SUN, Jeffrey A. Woods, FACSM. UNIVERSITY OF ILLINOIS, URBANA, IL. (Sponsor: Jeffrey Woods, FACSM)
 Email: yisun6@illinois.edu
 (No relationships reported)

Several studies have suggested that acute eccentric exercise can enhance vaccination responses in humans. However, the underlying mechanisms have remained understudied. We have shown that acute eccentric exercise does not improve the antibody responses to ovalbumin (OVA) vaccination in young mice. Thus, we replicated the study in an immunosenescence animal model, where there is reduced vaccine efficacy.

PURPOSE: To determine the effects of acute eccentric exercise on the primary antibody response to vaccination in aged mice. **METHODS:** C57BL/6 male mice, aged 27 months (n=16) were randomized into either eccentric exercise (ECC, n=8) or sedentary (SED, n=8) groups. For the ECC group, mice were exercised at 17m/min at -20% grade for 45 min on a treadmill. SED mice remained in their home cages. All mice were inoculated in the gastrocnemius with 25 μ g of OVA and 200 μ g aluminum hydroxide (a suboptimal dosage based on titration experiments) in 50 μ l sterile saline immediately after the exercise. Blood was collected prior to, and one, two and four weeks after vaccination. ELISA was performed to analyze anti-OVA IgG. At three weeks post exercise, all mice were injected with 100 μ g OVA dissolved in 10 μ l PBS into the dorsal side of the right ear to determine the delayed-type hypersensitivity (DTH) response. The left ear received 10 μ l PBS alone as a control. Ear thickness was measured immediately before, 24 h and 48 h after intradermal injection. The measurements were performed in triplicate, where

researchers were blinded to treatment. Maximum ear swelling occurred at 24 hours post injection. Results were expressed as the difference between the right and left ear thickness.

RESULTS: We found a significant time main effect ($p < 0.001$) indicating a significant increase in anti-OVA IgG at one, two and four weeks relative to pre-immunization. However, there were no significant time x treatment ($p = 0.652$) nor treatment main effects ($p = 0.764$). There was a significant difference between ECC and SED groups in ear DTH at 24h post injection ($p = 0.028$), indicating eccentric exercise increased the DTH response.

CONCLUSION: Acute eccentric exercise immediately before vaccination improved the DTH (i.e. cell-mediated immune), but not the antibody, response to vaccination in aged mice.

(No relationships reported)

PURPOSE: Exercise has been shown to improve immune responses to viral infections and vaccines in several mouse models. However, previous pathogen studies have primarily used infections limited to the respiratory tract. Additionally, previous studies have utilized forced treadmill exercise paradigms, and voluntary wheel running (VWR) has been shown to have differential effects on the immune system in non-infection models. We examined whether VWR could improve morbidity and mortality to a 50% lethal dose of vaccinia virus (VACV), a systemic pathogen commonly used to examine immune responses. Additionally, we examined whether VWR could improve antibody response to a replication-deficient strain of VACV, mimicking a vaccination. **METHODS:** Male C57Bl/6J mice underwent 8 weeks of VWR or remained sedentary, then were infected intranasally with $10^{7.5}$ PFU VACV strain WR. Mice were followed 14 days for mortality, and body weights and food intakes were recorded daily. In a similar manner, mice in the vaccination study ran or were sedentary for 8 weeks, then were given 10^6 PFU of replication-deficient VACV strain MVA intraperitoneally. Blood was collected under anesthesia from the retro-orbital sinus prior to MVA inoculation and at 1, 2, and 4 weeks post-inoculation, and anti-VACV IgG titer was determined by enzyme-linked immunosorbent assay. **RESULTS:** VWR did not improve mortality due to VACV infection ($p = 0.26$), although fewer VWR mice (4/10) died compared to sedentary (SED, 6/10). VWR did not prevent body weight loss due to infection compared to SED ($p = 0.20$), although VWR mice loss slightly less weight (4%) compared to SED through the first 6 days post-infection. Food intake, the reduction of which is a marker of sickness behavior, was significantly reduced in SED post-infection compared to VWR ($p = 0.05$). In the vaccination experiment, VWR mice developed a greater IgG antibody response, although this was not significant ($p = 0.22$). **CONCLUSIONS:** VWR did not protect against mortality to VACV or prevent infection-induced weight loss, and VWR did not enhance antibody responses. However, there were non-significant trends towards VWR-related improvements in these outcomes, and post-infection food intake was improved by VWR. Funded by ACSM Research Endowment Grant to BDP.

Effect of Exercise Training on Inflammatory Markers in Overweight and Obese Boys and Girls

Huimin Yan¹, Terry E. Jones², Morgan M. Pearce², Kristen A. Lattimore², Gabriel S. Dubis², Patricia Brophy², Robert C. Hickner, FACSM³. ¹University of Massachusetts Boston, Boston, MA. ²East Carolina University, Greenville, NC. ³Florida State University, Tallahassee, FL.
Email: huimin.yan@umb.edu
(No relationships reported)

PURPOSE: The aim of the present study was to examine the effect of exercise training on inflammatory markers in overweight and obese pre-pubertal boys and girls. **METHODS:** Forty-six overweight and obese children (age range 9-11 yr old, mean Tanner stage 1.2) volunteered for the study and were randomized to no-exercise control (CON, 6 boys and 7 girls) and exercise training (EX, 14 boys and 19 girls) groups for 16 weeks. Serum monocyte chemoattractant protein-1 (MCP-1), interleukin 6 (IL-6) and tumor necrosis factor (TNF-alpha) were measured as markers of inflammation before and after the intervention.

RESULTS: There was no difference between boys and girls in age (9.1 ± 0.6 and 9.3 ± 0.5 yr) or BMI percentile (94 ± 1 and $97 \pm 1\%$) before the intervention. After the intervention, a significant increase in fitness (time to exhaustion for incremental treadmill test, $p < 0.05$) was observed in the EX (81 ± 13 sec) but not in CON (12 ± 22 sec). There was no effect of exercise training on MCP-1, IL-6 or TNF-alpha; however,

percent changes in these pro-inflammatory markers were significantly decreased in girls, while the percent change values were significantly increased in boys, regardless of intervention group (significant main effect of sex, $p < 0.05$, table 1). There was no correlation between changes in body weight and inflammatory markers.

CONCLUSION: There was a decrease in inflammatory markers over 16 weeks in girls, but not in boys, that is not due to exercise training. These data indicate previous findings that exercise training, in the absence of weight loss, do not affect inflammatory markers may be sex (and perhaps age) specific.

Table 1. Inflammatory markers and changes in body weight in boys and girls before and after the intervention.

Interval Walking Training Reduces T Cell CCR5 in Individuals with Type 2 Diabetes

Jonathan P. Little, FACSM¹, Julianne Barry¹, Soren Nielson², Louise Justesen², Thomas Solomon³, Kristian Karstoft². ¹University of British Columbia Okanagan, Kelowna, BC, Canada. ²University of Copenhagen, Copenhagen, Denmark. ³University of Birmingham, Birmingham, United Kingdom.
Email: jonathan.little@ubc.ca
(No relationships reported)

Recent evidence implicates chemokine (C-C motif) ligand 5 (CCL5, also known as RANTES) and its receptor CCR5 in mediating T cell infiltration into adipose and other tissues, which contributes to chronic low-grade inflammation in obesity and type 2 diabetes (T2D). Exercise may relieve obesity-related inflammation but the effects of interval training on T-cell migration and tissue infiltration in T2D are unknown. **PURPOSE:** To examine the impact of interval walking training (IWT) versus continuous walking training (CWT) on circulating RANTES along with T cell and adipose tissue CCR5 in patients with T2D. **METHODS:** Participants with T2D were randomized to control (n=8), IWT (n=12) or CWT (n=12). Training groups were prescribed five 60-minute sessions per week of free-living training with intensity monitored with an accelerometer and heart rate monitor. Fasting blood samples and subcutaneous abdominal adipose tissue biopsies were obtained before and 6 days after completion of the 16-week intervention period. Plasma RANTES was measured by ELISA. Peripheral blood mononuclear cells (PBMCs) were isolated for subsequent measurement of CD8+ T cell CCR5 surface protein expression using flow cytometry. mRNA expression of RANTES, CCR5 and CD8 were measured in subcutaneous adipose tissue biopsy samples by qPCR. **RESULTS:** Training duration and mean intensity were well-matched between IWT and CWT. A significant group X time interaction ($p < 0.05$) was detected for CD8+ T cell CCR5 surface protein expression, with post-hoc tests revealing a reduction of ~20% after IWT ($p < 0.05$) with no changes seen in CWT or control. Plasma RANTES concentration and adipose tissue mRNA expression of RANTES, CCR5 and CD8 were not altered in IWT, CWT, or control groups following the intervention period (all $p > 0.05$). **CONCLUSIONS:** Sixteen weeks of IWT, previously shown to benefit physical fitness, insulin sensitivity, body composition, and glycemic control in patients with T2D, resulted in lower CD8+ T cell CCR5 protein expression. These findings suggest lower migratory potential for circulating T cells but future research is needed to determine if IWT influences infiltration of T cells into adipose and other tissues. JPL is funded by a CIHR New Investigator Award (MSH-141890)

Increase in Natural Killer Cells with an Activated Phenotype During Recovery from Acute Dynamic ExerciseEmily C. LaVoy, Priti Gupta. *University of Houston, Houston, TX.*

Email: eclavoy@uh.edu

(No relationships reported)

Acute dynamic exercise enhances Natural Killer (NK) cell cytotoxicity against HLA-expressing tumor target cells. This enhanced killing capacity of NK cells occurs during recovery from exercise. A preferential redeployment of NK cells with an activated phenotype has been proposed as one mechanism to explain increased function. However, NK cells frequently co-express activating and inhibitory molecules, complicating interpretation of earlier results that have failed to fully characterize the mobilized cells. **PURPOSE:** To thoroughly investigate changes in NK cell phenotype due to acute dynamic exercise. **METHODS:** 12 physically active adults accustomed to cycling exercise cycled for 30 minutes at 115% of lactate threshold power. Blood collected pre-, post-, and 1h post-exercise was analyzed using 10 parameter flow cytometry to identify NK cell subsets present at each time point. NK cytotoxicity against the HLA-expressing U266 tumor cell line was assessed following a 4h incubation using a flow-based assay. Differences in NK cell cytotoxicity and NK cell subset proportions between the three time points were assessed using maximum likelihood linear mixed models. **RESULTS:** Similar to earlier reports, NK cell cytotoxicity per cell against U266 tumor cells was highest 1h post exercise ($0.36 \pm .08$ 1H Post vs $0.26 \pm .05$ Pre). The proportion of NK cells expressing the activating receptor NKG2C was increased 1h post exercise (5.1 ± 1.6 vs 4.3 ± 1.6 %; $p < 0.05$), as were cells co-expressing NKG2A (2.0 ± 0.5 vs 1.5 ± 0.5 ; $p < 0.05$). The co-expression of CD158a or CD158b (inhibitory KIRs) by the NKG2C+ NK cells did not differ from pre-exercise at 1h post exercise ($p > 0.05$). Finally, NK cells expressing the late differentiation marker CD57 were at their lowest proportion 1h post exercise (31.6 ± 6.7 vs 37.2 ± 6.7 %; $p < 0.05$). **CONCLUSIONS:** Enhanced NK cell cytotoxicity against HLA-expressing tumor target cells 1h following exercise corresponded to changes in NK cell phenotype towards expression of activating receptors (NKG2C), and away from inhibitory receptors (CD158a, CD158b) and markers of late differentiation. These data lend support to the growing idea that acute exercise may be used clinically to enrich the blood of cytotoxic NK cells for immunotherapy.

Maximal Exercise Alters The Inflammatory Phenotype Of Mononuclear Cells And Response To Ex Vivo Lps StimulationAaron Slusher, Amanda B. Mischo, Tiffany M. Zúñiga, Edmund O. Acevedo, FACSM. *Virginia Commonwealth University, Richmond, VA.* (Sponsor: Dr. Edmund O. Acevedo, FACSM)

Email: slusher@vcu.edu

(No relationships reported)

Monocytes express the CD14 receptor involved in LPS ligation to TLR4 and subsequent production of anti-inflammatory (IL-6 and IL-10) and pro-inflammatory (TNF- α) cytokines. However, under pro-inflammatory conditions, there is an increased proportion of monocytes expressing the CD16 receptor, which amplifies TLR4-mediated TNF- α production. **PURPOSE:** We therefore examined the hypothesis that decreased proportions of classical monocytes (CD14+/CD16-) and TLR4 expression following maximal exercise would be accompanied by reduced CD14 expression. Conversely, the mobilization of pro-inflammatory monocytes (CD14+/CD16+) expressing elevated TLR4 would exhibit increased CD14 and CD16 expression. Concomitantly, LPS-stimulated ex vivo production of IL-6 and IL-10 would be attenuated, while TNF- α would be enhanced post exercise. **METHODS:** Human mononuclear cells ($n = 25$) were isolated prior to and following exercise to assess CD14, CD16, and TLR4 expression by flow cytometry. **RESULTS:** Exercise reduced the proportion of classical monocytes and increased pro-inflammatory monocytes. In addition, TLR4 expression decreased to a greater extent on classical compared to pro-inflammatory monocytes. However, while CD14 expression was reduced on all monocytes, CD16 expression tended to increase on pro-inflammatory monocytes. LPS-stimulated production of IL-6 and IL-10 was also significantly decreased, while TNF- α significantly increased. **CONCLUSIONS:** Exercise shifts monocytes towards a pro-inflammatory phenotype, raising additional questions regarding the anti-inflammatory impact of chronic exercise and the mechanisms involved monocyte immune function.

(No relationships reported)

Despite the known benefits of physical activity on physical, cognitive and mental health, there is a trend in many countries to decrease physical activity opportunities for children and adolescents during the school day. **PURPOSE:** To investigate the influence of a school-based intervention with a tripling of physical education (PE) lessons from two (90 min) to six lessons per week (270 min) added to the normal curriculum on scholastic performance in school-aged children. **METHODS:** This study is a part of the CHAMPS study-DK, a quasi-experimental study that began in 2008. The intervention group consisted of six schools and four matched schools served as the control group (mean age at baseline = 8.4 years). Academic performance was extracted from the Danish national test system from 2010 to 2014 (Math and Danish were measured at 3rd and 6th, and 2nd, 4th and 6th grade, respectively). Participants for this investigation include 1,888 students, participating in at least one national test of scholastic performance. Mean of three different domains (Danish: language understanding, decoding, and text comprehension, and Math: algebra, geometry, and basic mathematics skills) were obtained as the test results (from 0-100 points). Mother's educational status was used as an indicator of socioeconomic status (SES). Linear mixed models were applied to test for differences between Groups. **RESULTS:** No significant differences were observed between groups in any of the academic performance tests (control group reference); Danish 2nd grade $\beta = -1.34$ (95% CI -9.90, 7.22), 4th grade $\beta = 0.22$ (95% CI -6.12, 6.56), 6th grade $\beta = 1.03$ (95% CI -5.02, 7.08) and all grades combined $\beta = 0.28$ (95% CI -5.74, 6.31) and Math 3rd grade $\beta = -2.87$ (95% CI -9.65, 3.90) and both grades combined $\beta = -1.28$ (95% CI -8.10, 5.71). Across groups girls performed significantly better in Danish, whereas boys performed better in Math (all $p < 0.05$). **CONCLUSIONS:** No significant differences were observed between intervention and control schools for scholastic performance, which may be interpreted as a positive result, given that a tripling of PE did not result in a cost to scholastic performance. Such findings suggest that increasing physical activity opportunities during the school day does not detract from academic goals, although making the school days longer.

773 May 31 3:30 PM - 3:45 PM

Evaluation of Kaiser Permanente Colorado's Thriving Schools InitiativeCheryl Kelly¹, Timothy K. Behrens, FACSM², Elizabeth Tucker³, Dick Carpenter³, Carmen Luna¹, Julaine Field³.¹Kaiser Permanente Colorado, Denver, CO. ²Northern Arizona University, Flagstaff, CO. ³University of Colorado Colorado Springs, Colorado Springs, CO.

Email: cheryl.kelly@kp.org

(No relationships reported)

Purpose: To evaluate the Kaiser Permanente Thriving Schools Initiative, a program designed to increase physical activity (PA) in Colorado public schools. **Methods:** This cross-site evaluation examined 27 public school districts funded to incorporate PA into the school day, operationalized as classroom PA (CPA), before and after school PA (BAPA), and PA occurring in physical education classes or recess (PERPA). All data were collected during the 2014-15 academic year using an online data management system. CPA were collected by asking randomly selected teachers in each school to report classroom PA during a one-week period, 2-3 times each semester. Programming for BAPA was reported by each district's health coordinator and included day⁻¹ offered, min^{-d⁻¹} offered, and number of students participating. PERPA schedules were collected for each school and entered into an aggregate database containing all PA. Mean minutes of PA^{-d⁻¹} was calculated using the sum of CPA, BAPA, and PERPA

divided by the number of school days. Descriptive and inferential statistics were calculated. **Results:** Most districts (76%) provided $\geq 30 \text{ min} \cdot \text{d}^{-1}$ ($42.9 \pm 27.6 \text{ min} \cdot \text{d}^{-1}$) of PA, though only 36% provided $60 \text{ min} \cdot \text{d}^{-1}$. There were no significant differences in the likelihood of achieving mandated PA minutes based on school characteristics. Most PA minutes were offered in PERPA (66.8%). In fact, schools that reported more minutes in these two types of PA were significantly more likely to achieve mandated PA minutes. Schools with greater percentages of free and reduced lunch eligible students reported significantly fewer min $\cdot \text{d}^{-1}$ spent on PA in classrooms, PE, recess, and in total. Finally, coefficients for PE, recess, and total minutes indicate schools with greater percentages of minority students tend to report a greater number min $\cdot \text{d}^{-1}$ in said activities. **Conclusion:** These findings support increased efforts for PA promotion in public schools, though additional research is needed to identify best practices for implementing school-based PA promotion.

774 May 31 3:45 PM - 4:00 PM

Effectiveness Of A Preschool-Based Exercise Intervention On Physical Activity, Motor Performance, Body-Mass-Index And Blood Pressure: A Cluster-Randomized Controlled Trial

Claudia Hacke¹, Sascha Ketelhut², Ulrike Wendt³, Götz Müller³, Claudia Schlesner³, Kerstin Ketelhut⁴. ¹University Medical Center Hamburg-Eppendorf, Hamburg, Germany. ²Martin-Luther-University Halle-Wittenberg, Halle, Germany. ³University Heart Center Hamburg, Hamburg, Germany. ⁴Medical School Berlin, Berlin, Germany. (Sponsor: Reinhard G. Ketelhut, FACSMM)
Email: c.hacke@uke.de
(No relationships reported)

PURPOSE: Beneficial effects of physical activity interventions on health are well described for adults and adolescents. However, the impact in early childhood is understudied. The present study set out to investigate the effectiveness of an exercise intervention on activity level, motor performance, BMI and peripheral and central blood pressure (BP) in 3-6 years old preschoolers, with emphasis on social background.

METHODS: A 6-months cluster-randomized controlled trial including a 45min/biweekly supervised exercise program was conducted in 3 intervention and 2 control daycare centers in Hamburg, Germany. A total of 135 children (IG=92, CG=43; 4.8±0.8 years) completed the trial with baseline and follow-up data on BMI, activity level (time during leisure-time and in organized sports) and motor performance (z-scores of 4 test items assessing flexibility, coordination, power, speed). Peripheral and central BP were measured with a brachial cuff-based oscillometric device. Maternal education (high vs. low) was used as an indicator for social background. We applied linear mixed models with random intercepts for daycare center to evaluate differences in mean change adjusted for baseline value of the outcome, age, sex and height.

RESULTS: No significant differences in mean change, comparing the intervention to the control group, could be detected on weekly activity level (-24.7 min; 95%CI: -55.9,6.4), motor performance (-0.1; -0.7,0.6), BMI-percentile (1.3; -14.9,17.6), pBP (1.0 mm Hg; -1.9,3.9/1.7 mm Hg; -0.5,4.0) or cBP (1.8 mm Hg; -1.7,5.2/1.8 mm Hg; -0.4,4.1). However, subgroup analyses revealed a stronger intervention effect in children of low vs. high social status in terms of a lower increase in systolic pBP (-3.5 mm Hg; -6.9, -0.1; P=0.045) and cBP (-3.7 mm Hg; -6.5, -0.9; P=0.010), whereas BP change did not differ within the control group.

CONCLUSION: In preschool children, we found no evidence for effectiveness of a 6-months multifaceted exercise program on physical activity, motor performance, BMI or BP. However, the results of this study indicate that children from lower social backgrounds benefit more from early exercise-promoting interventions. Implementation fidelity, intervention period and sample size are key issues that should be addressed in further trials to provide definitive evidence.

775 May 31 4:00 PM - 4:15 PM

Relationship Between School Physical Environment And Sedentary Time Among Children In Puerto Rico

Maria Enid Santiago-Rodriguez¹, Marcos A. Amalbert-Birriel², Farah A. Ramirez-Marrero, FACSMM². ¹University of Illinois at Chicago, Chicago, IL. ²University of Puerto Rico, Rio Piedras Campus, San Juan, PR.
Email: msanti24@uic.edu
(No relationships reported)

Sedentary time increases the risk of obesity and other hypokinetic diseases. The school's physical environment (SPE) can influence during school sedentary time (DSST) in children. The association between SPE and DSST has not been clearly established in this population. **PURPOSE:** To evaluate DSST and the potential influence of SPE in DSST among children in Puerto Rico. **METHODS:** Fifty-four

girls and 48 boys (age=7.9 ± 0.7 yrs, range=7-9 yrs) wore an accelerometer during 7 consecutive week-days over the right hip area. A filter was created to determine DSST for those children who wore the accelerometer during at least 3 weekdays. The SPE was evaluated taking into consideration the physical education class, recess time, and use of facilities that promoted PA. Time in physical education and recess was provided by the school's administration. To determine the use of facilities, a score was generated based on self-reported activities during school, and the time spent in each activity. Correlation analyses were conducted to test the relationship between: 1) physical education class (min/wk) and DSST (hr/wk); 2) recess time (min/wk) and DSST (hr/wk); and 3), use of school facilities (score) and DSST (hr/wk). **RESULTS:** DSST was different by gender (girls: 4.3 ± 0.5 hr/wk, boys: 4.4 ± 0.3 hr/wk; p = 0.01) and type of school (private: 4.3 ± 0.4 hr/wk; public: 4.6 ± 0.2 hr/wk; p = 0.04). No relationship was observed between DSST and time in physical education (r = -0.15, p > 0.05), or use of facilities that promoted PA (p = 0.001, p > 0.05). However, a direct association between DSST and recess time was observed (p = 0.34, p < 0.01). **CONCLUSION:** Although the average DSST was very low in this group of children, more recess time was associated with more DSST. More research is needed to confirm these observations, and the importance of school interventions to discourage sedentary time during recess time. Funded by University of PR-FIPI Institutional Grant.

The Association Between Perceived Athletic Competence And Physical Activity: Implications For Low-income Schoolchildren

Sarah A. Amin, Kenneth Chui, Paula Duquesnay, Catherine M. Wright, Christina D. Economos, FACSMM, Jennifer M. Sackeck, FACSMM. Tufts University, Boston, MA. (Sponsor: Jennifer Sackeck, FACSMM)
Email: s.amin@tufts.edu
(No relationships reported)

PURPOSE: Addressing athletic competence (AC) may shape children's physical activity (PA) behaviors through participation in organized and unorganized PA, but these opportunities may be limited in low-income children. We aimed to assess the association between children's perceived AC and daily moderate-to-vigorous PA (MVPA) and whether socioeconomic status (SES) modifies this relationship.

METHODS: Schoolchildren (n=1157; grades 3-4) were recruited from 24 schools in Massachusetts communities to participate in the Fueling Learning through Exercise study. Demographic data were collected by parent report. Free or reduced price lunch (FRPL) eligibility was used as an indicator of SES. Seven-day accelerometry (Actigraph GT3X+) was used to measure MVPA. Measured height and weight were used to derive weight status category. The AC domain (6 items, scored 1-4) from the Harter Self-Perception Profile for Children was used to assess perceived AC, and categorized by tertiles into low, moderate, and high. The association between AC and MVPA were examined using mixed effects models adjusting for sex, race, grade, FRPL, weight status category, accelerometer wear time, and controlling for school-level clustering.

RESULTS: Of those participants with valid accelerometer wear time of ≥ 3 days and $\geq 10 \text{ hr/day}$ (n=1054, 44% male, 8.7±0.7 years), 81% did not meet the 60-min MVPA recommendation (44.9±20.1 min/day). AC scores differed by sex (high AC=37% male vs. 31% female; p<0.05) and FRPL eligibility (high AC=42% non-FRPL eligible vs. 28% FRPL eligible; p<0.001). A significant interaction between FRPL eligibility and AC was found (p<0.01). Non-FRPL eligible children who reported either moderate AC ($\beta=4.0 \text{ mins/day}$; 95% CI: 1.1, 6.8; p<0.01) or high AC ($\beta=9.4 \text{ mins/day}$; 95% CI: 6.0, 12.9; p<0.001) were more likely to engage in more minutes of MVPA compared to children who reported low AC. This association between AC and MVPA did not exist for FRPL-eligible children (p>0.05).

CONCLUSION: Self-reported AC was positively associated with MVPA, but not for low-income children. These findings suggest that AC may not correlate with greater engagement in PA behaviors among low-income children. Further research is warranted to assess which social and environmental factors affect the association between AC and MVPA.

777 May 31 4:30 PM - 4:45 PM

Effects Of Interrupting Prolonged Sitting With Activity On Appetite Sensations In Elementary School-age Children

Tiwaloluwa A. Ajibewa, Molly P. O'Sullivan, Matthew R. Nagy, Shannon S. Block, Trevor R. Tooley, Rebecca E. Hasson, FACSMM. University of Michigan, Ann Arbor, MI. (Sponsor: Rebecca Hasson, FACSMM)
Email: tajib@umich.edu
(No relationships reported)

BACKGROUND: Short and long term exposure to prolonged sitting is associated with excess food intake and weight gain in children. Interrupting prolonged sitting with low-intensity activity does not alter subjective appetite sensations or food intake

in children. However, it is unclear whether activity performed at a higher intensity will alter appetite sensations in children. **PURPOSE:** The purpose of this study is to examine the acute effects of interrupting prolonged sitting with intermittent activity performed at varying intensities on hunger, satiety, and prospective food consumption (PFC) in elementary school-age children. **METHODS:** Using a randomized crossover design, thirty-nine children (ages 7-11 years; 18 male, 21 female; 33% overweight/obese and 59% non-white), completed four experimental conditions: 8 hours of sitting interrupted with 20, 2-minute low-intensity (L), moderate-intensity (M), or high-intensity (H) activity breaks or 20, 2-minute sedentary (S) screen time breaks. Exercise intensity for the L, M, and H conditions corresponded with 25%, 50%, and 75% of heart rate reserve, respectively. Hunger, satiety, and PFC, were assessed using the Visual Analog Scale at four time points (post-breakfast, pre-lunch, post-lunch, and pre-dinner) throughout each experimental condition. **RESULTS:** Satiety sensations tended to be lower during the L and H conditions compared to the S condition (S: 5.3±0.3, L: 4.8±0.3, M: 5.2±0.39, H: 4.7±0.4, p=0.05). There were no significant differences across conditions for hunger (S: 4.6±0.3, L: 4.6±0.3, M: 4.6±0.3, H: 4.7±0.3, p=0.99) and PFC (S: 4.5±0.3, L: 4.4±0.3, M: 4.5±0.3, H: 4.7±0.3, p=0.63). There were no significant differences between post-breakfast vs. post-lunch scores (p>0.05), and pre-lunch vs. pre-dinner scores (p>0.05). **CONCLUSIONS:** These data suggest interrupting prolonged sitting with moderate-intensity activity may be an effective strategy to increase physical activity energy expenditure without triggering increases in hunger and PFC or reductions in satiety. Future studies should examine the long-term effects of interrupting prolonged sitting with activity on appetite sensations, food intake, and weight outcomes in elementary school-age children.

778 May 31 4:45 PM - 5:00 PM

The Fueling Learning Through Exercise (FLEX) Study: Short-term Findings On Sedentary Time In Lower-income Schoolchildren

Jennifer M. Sacheck, FACSM¹, Catherine Wright¹, Sarah Amin¹, Stephanie Anzman-Frasca², Virginia Chomitz¹, Kenneth Chui¹, Miriam Nelson, FACSM³, Christina Economos¹. ¹Tufts University, Boston, MA. ²University of Buffalo, Buffalo, NY. ³University of New Hampshire, Durham, NH. Email: jennifer.sacheck@tufts.edu (No relationships reported)

PURPOSE: Throughout the elementary school years school-time moderate-to-vigorous physical activity (MVPA) tends to decrease while sedentary time (SED) increases, contributing independent effects on health outcomes. There is insufficient research on how physical activity (PA) programming may impact SED in children. Our objective was to determine whether two innovative school-based PA programs impact school SED in children and if program reach differed by sex, race/ethnicity, and weight status. **METHODS:** Eighteen schools from lower-income Massachusetts school districts were enrolled in the Fueling Learning through Exercise Study (FLEX) and randomized to 100 Mile Club (100MC; walking/running program), Just Move (JM; active classroom breaks), or a Control group. Third- and fourth-grade children (n=883) were recruited and measured at baseline (Fall 2015) and short-term follow-up (Spring 2016) for height/weight and 7-day accelerometry (ActigraphGT3x). Demographic information was obtained by parent questionnaire. PA program effects on SED were examined using mixed-effects models adjusting for child sex, race/ethnicity, free or reduced-price lunch (FRPL) eligibility, weight status, accelerometer wear time, average daily temperature, and controlling for school-level clustering. **RESULTS:** 793 children (8.7 ± 0.7 years, 44% male, 65% non-white, 53% FRPL, 41% overweight/obese) had valid accelerometer wear-time (3 days, 310 hrs/day) at both study visits. At baseline, few children achieved the recommended 30 minutes of school-time MVPA (9%; 18.1 ± 7.9 min) and children were sedentary for 59.7% (233 ± 43 min) of their school day. There was a significant effect of program on SED (p=0.041) with Control and JM increasing in SED (6.2 [95%CI: 2.7, 9.5], p<0.001 and 4.3 [95%CI: 0.9, 7.7] mins/day, p=0.012 respectively) while 100MC did not change (p=0.88). There were no differences in program effects by sex (p=0.58), race/ethnicity (p=0.08), or weight status (p=0.19). **CONCLUSIONS:** Short-term follow-up of program implementation during a two-year PA intervention demonstrates a potential effect of 100MC on mitigating an increase in SED that may occur over the elementary school years. Longer-term findings will demonstrate whether the effects of PA programming on SED are sustained.

779 May 31 5:00 PM - 5:15 PM

Comparison of Moderate-to-Vigorous Physical Activity Between In-school and an Afterschool Program among Urban Underserved Children

Ryan McVann, Marlo P. Dell'Aquila, Madison Burke, Zi Yan, Kevin Finn, Kyle McInnis, FACSM. Merrimack College, North Andover, MA. (No relationships reported)

With the elimination of physical education and recess, the opportunities for children to be physically active in schools has declined. Therefore, afterschool programs have been identified as ideal settings where children (5-14 years) can accumulate a significant portion of their total daily, recommended level of moderate-to-vigorous physical activity (MVPA). **PURPOSE:** The first purpose of this pilot study was to quantify the level of in-school MVPA in underserved elementary school settings. A second purpose of the study was to quantify the level of MVPA achieved through a structured afterschool program that integrates physical activity with a STEM (Science, Technology, Engineering, and Mathematics) learning component. **METHODS:** Participants were 13 children (female n=5, age= 9.36, SD=0.83) enrolled in an afterschool program offered at a YMCA located in an urban community. All participants wore accelerometers to track their MVPA during the school day (6 hours and 15 minutes) and while participating in the structured afterschool program (30 minutes) called *Active Science*. During the program, the participants completed thirty minutes of physical activity followed by a science lesson delivered through the *Active Science* Mobile App. Physical activity levels were monitored for five consecutive days (Monday-Friday) during the in-school and afterschool environments. **RESULTS:** Participants mean in school and afterschool MVPA were M=14.5+2.60, M=16.87+3.6 minutes, respectively. T-test showed a significant difference between these two settings t(12)= 16.29, p<.05. The 6-hour school day contributed to approximately 24% of the recommended daily physical activity, while the 30-minute afterschool program contributed to 28% of the daily-recommended MVPA time. **CONCLUSION:** A guided and well-structured afterschool physical activity program can significantly impact MVPA levels in children. The results of this study are well aligned with national recommendations that endorse innovative strategies to incorporate movement into afterschool programs to improve physical activity levels in children.

B-46 Clinical Case Slide - Foot and Ankle I

Wednesday, May 31, 2017, 3:15 PM - 4:55 PM
Room: 504

Recurrent Medial Heel Pain In An Elite Triathlete: Location, Location, Location.

Jason L. Zaremski, FACSM¹, Dustin Nabhan². ¹University of Florida, Gainesville, FL. ²United States Olympic Committee, Colorado Springs, CO. Email: zaremjl@ortho.ufl.edu (No relationships reported)

Case History We present a 25 year old female elite triathlete with nine months of left medial calcaneal discomfort associated with running. Her symptoms are described as aching in the medial inferior calcaneus. She denies swelling, sensory changes, discoloration, or burning. Previously she was diagnosed at an outside institution with plantar fasciitis as well as impingement of the first branch of the lateral plantar nerve. She was treated with a diagnostic lidocaine injection, as well as a cortisone injection without relief. **Physical examination** The patient was tender to palpation posterior and inferior to the medial malleolus. Tapping at that location created mild pain and sensation of radiation of pain inferiorly but there was no electrical or burning sensation. Range of motion, strength, and light touch of the ankle was normal. There was a negative Tinel's sign at the Fibular Head. A calcaneal squeeze test created medial sided calcaneal pain only. The patient had negative slump and straight leg raise tests. **Differential Diagnosis** Impingement of the First Branch of the Lateral Plantar

Nerve Posterior Tibial Nerve Impingement Stress Reaction/Fracture of Calcaneus Fat Pad Syndrome Plantar Fasciitis **Tests and Results** Previous MRI's of the foot and ankle as well as lumbar spine were negative. A reported electromyographic and nerve conduction study was negative for lumbar radiculopathy but without evaluation of calcaneal nerves. Given the entire clinical picture, we proceeded with a lidocaine challenge with ultrasound guidance at the location at the bifurcation of posterior tibial to calcaneal nerves. She received complete relief of pain within five minutes.

Working Diagnosis Posterior Tibial Nerve Impingement at Level of Bifurcation of Calcaneal Nerves

Treatment & Outcomes Given the positive Lidocaine challenge, the decision was made to proceed with hydro-dissection at the level of posterior tibial nerve bifurcation of medial and lateral calcaneal nerves. In plane short axis hydrodissection technique with 1% plain Lidocaine and Triamcinolone was performed. The patient had complete relief of pain at 5 minutes, 24 hours, 72 hours, and 90 days post procedure. The patient has returned to training without restriction with hopes of competing for a spot on the next Olympic Team.

784 May 31 3:35 PM - 3:55 PM

Foot Pain - Recreational Skier

Kelly L. Roberts Lane, FACSM. *Fix It physical therapy, Mahtomedi, MN.*
Email: kelly@fixitpt.com
(No relationships reported)

HISTORY: 35 yo slipped down her back deck steps 1/25/16. She experienced severe pain and inability to stand on her R foot with immediate swelling and minimal bruising on day 1. She was evaluated at an Orthopedic Clinic, where X-ray showed a talar avulsion fx. She was given a cast boot and instructed to follow-up in 4 wk. She saw me at the physical therapy clinic 7 days post fx with complaints of severe pain and inability to weight-bear on booted R foot. The boot was not fitted correctly with the front piece missing and the air bladder not inflated. The boot fit was corrected and she left for Colorado. She returned 2 wk later with continued severe pain.

PHYSICAL EXAMINATION: Examination 3 wk post talar avulsion fracture revealed severe tenderness with palpation R foot, significant bruising and severe R lower leg, ankle, and foot swelling. Her R foot skin was cool to touch compared to the L and had a mottled appearance. She had painful and severe tightness with R calcaneal and forefoot varus and valgus PROM and R dorsiflexion PROM. She had limited ability to wiggle her toes, but no complaints of numbness or tingling.
DIFFERENTIAL DIAGNOSIS: 1. Additional Fracture 2. Ligament Tear 3. Complex Regional Pain Syndrome **TEST AND RESULTS:** MRI of R ankle/foot 2/23/16: Avulsion fragment along the talar head, No acute ligament injury, impaction of plantar aspect of talus with extensive marrow edema talar head and neck, calcaneus contusion
FINAL WORKING DIAGNOSIS: Complex Regional Pain Syndrome post avulsion/impaction fx of the talar head complicated by the ill-fitting cast boot **TREATMENT AND OUTCOMES:** 1. Discontinuation of boot 8 wk post fx 2. Knee walker for 10 wk 3. Gabapentin 900 mg / day 4. Facilitation of joint movement to improve gross ankle/foot movement and decrease pain response 5. Fracture fully healed 11 wk post fracture 6. Slow return to activity over 6 mo - dance, paddle boarding, Pilates 7. CRPS sx resolved over 9 mo post fx

785 May 31 3:55 PM - 4:15 PM

Tarsal Dysostosis in the Adolescent Athlete

Bhavesh B. Joshi. *Millcreek Community Hospital, Erie, PA.*
(Sponsor: Patrick F Leary, DO FACSM, FACSM)
Email: bhavesh.joshi.bj22@gmail.com
(No relationships reported)

Articular Dysostosis is a rare musculoskeletal condition due to an abnormal bridging of two bones by cartilage, bone, or fibrous tissue. This abnormality changes the intrinsic physiologic motion of those two bones and surrounding structures. The most common site involves the talus, calcaneus, and navicular bones- known as Tarsal Dysostosis or Tarsal Coalition (TC). The condition has been linked to a gene mutation that can affect both feet in fifty percent of cases. TC typically presents in the adolescent patient after beginning athletic activities.

A 12-year old male with no significant medical history presented to the Sports Medicine office complaining of worsening left non-traumatic foot pain for over one years time. The patient had been participating in high school football and sustained an inversion ankle injury. On physical exam tenderness to palpation at the proximal dorsal surface of his left foot was elicited. Osteopathic exam of the foot and ankle was noted for Pes planus with fallen arch and the inability to induce medial arch, Hammer toes, and hallux valgus deformities of the foot. The patient was empirically started on a rehabilitation program consisting of foam rolling exercises of the lower quarter, increase flexibility, ankle and foot intrinsic exercises, ambulation with a non-inflating walking boot. With only minimal clinical improvement, magnetic resonance imaging (MRI) was ordered revealing bony contusions in the talus, calcaneus, and navicular bones. He was referred to Shriners Hospitals for Children and underwent a resection of the left calcaneonavicular coalition. He has since has returned to pain-free athletics after completing rehabilitation and therapy.

Current literature indicates that Tarsal Dysostosis affects up to 1% of the population. It is a diagnosis found primarily in children and young adolescents during the ages of 8-16 when the ossification process of bones initiates. The disease is caused by mutations in the NOG gene. This gene is responsible for the noggin protein, which plays an important role in proper bone and joint development. The diagnosis of tarsal coalition begins with clinical suspicion and key physical exam findings of pain in an adolescent with decreases in foot range of motion, as well as pain into the hind-foot.

786 May 31 4:15 PM - 4:35 PM

Ciprofloxacin Induced Achilles Tendinopathy

Igor Prus¹, Kenneth Bielak, FACSM¹, Rebecca Morgan².
¹University of Tennessee Graduate School of Medicine, Knoxville, TN. ²University of Tennessee, Knoxville, TN.
(Sponsor: Kenneth Bielak, FACSM)
(No relationships reported)

HISTORY: 26 year old college graduate student with past medical history of a kidney stone had painful urination and increased frequency over several days. He was seen by internist at student health center, prescribed Ciprofloxacin for 14 days for acute bacterial prostatitis. Two months later he developed right Achilles tendon pain which had started insidiously upon awakening one morning, with no inciting event except for taking Ciprofloxacin 6 weeks earlier. **PHYSICAL EXAMINATION:** Swelling of the of posterior ankle noted. Tenderness to palpation at the insertion site of a tight Achilles tendon was appreciated. **DIFFERENTIAL DIAGNOSIS:** 1. Ciprofloxacin induced Achilles tendinopathy 2. Idiopathic Achilles tendinopathy 3. Posttraumatic Achilles tendinopathy **TEST AND RESULTS:** 1. Ankle ultrasonography: Thickening and swelling of Achilles tendon. 2. Ankle X-ray: No bony abnormalities. **FINAL WORKING DIAGNOSIS:** Ciprofloxacin Induced Achilles Tendinopathy **TREATMENT AND OUTCOMES:** 1. Walking boot 2. NSAIDs 3. Physical therapy. Patient has recovered after six month of treatment.

787 May 31 4:35 PM - 4:55 PM

Ankle Pain and Swelling - Tennis.

Gabriel Carpio-Bracho, Poonam Thaker, Anthony Rizzo, Brian Donohue. *Presence Resurrection Medical Center, Chicago, IL.*
(No relationships reported)

HISTORY: 19 yo F D3 collegiate tennis player presented to the athletic training room for evaluation of b/l ankle pain on 9/12/2016. Pain began 2 months prior, while at home in Germany, starting in the left ankle, progressing to the right ankle a few weeks later with accompanying swelling, numbness & weakness. Denied any trauma or acute injury. Initial evaluation in Germany consisted of serum blood analysis and joint aspiration without joint fluid analysis. She returned to school & began a course of PT with the athletic training staff, with improvement in the numbness and weakness, but continued to have intermittent ankle pain and swelling. She denied taking any medications or herbal supplements. History of "allergic" reactions to many medications, which vary from blisters on her body to GI upset. At the time of initial presentation ROS neg. **PHYSICAL EXAMINATION:** Ankle: mild non pitting edema b/l. No erythema, ecchymosis, or deformity. Full A/PROM. Pain with passive and active dorsiflexion, plantar flexion, eversion, and inversion b/l. TTP over anterior and inferior aspect of lateral malleoli b/l, Achilles' insertion b/l. Anterior drawer negative b/l. Altered gait due to pain. Normal arches. Toe walk elicited pain, heel walk was painless. Strength 5/5 b/l in ankle and foot. DTR 2+ at Achilles' tendon b/l. Sensation intact b/l in all fields. **DIFFERENTIAL DIAGNOSIS:** 1. Systemic Lupus Erythematosus (SLE) 2. Drug Induced Lupus 3. Rheumatoid Arthritis 4. Seronegative Spondyloarthropathy 5. Lyme Disease 6. Synovitis/Tenosynovitis 7. Stress fracture / Stress reaction 8. Hypercholesterolemic Arthritis **TEST AND RESULTS:** Initial labs: **Chol 202, TG 178, LDL 110, CBC** (WBC = 9.5, Hb = 12.4, **Plt = 473**), CMP wnl. ASO neg, Fe wnl, Uric acid = 3.1, CRP = 5; CCP, Lyme neg. MRI = synovitis & edema around talar joint. Otherwise normal. F/u Labs: **ESR = 26; Anti-histone = 1.3 (weak positive);** CRP, CCP, ANA, dsDNA, Smith Ab, RNP Ab, SSA, SSB, SCL70, myeloperoxidase Ab, Anti-Centromere Ab, Lyme neg **FINAL WORKING DIAGNOSIS:** Early Lupus or drug induced lupus **TREATMENT AND OUTCOMES:** She was prescribed prednisone but preferred nonpharmacologic therapy. Continue PT, repeat labs. F/u in 2 wks: Symptoms improved. Work up ongoing. Continues to have occasional foot and ankle pain without functional limitation. Final diagnosis pending

B-47 Clinical Case Slide - Lumbosacral Spine II

Wednesday, May 31, 2017, 3:15 PM - 5:15 PM
Room: 401

788 **Chair:** Sherrie L. Ballantine-Talmadge. *CU Sports Medicine and Performance Center, Boulder, CO.*

790 **Discussant:** John P. Batson, FACS. *Lowcountry Spine and Sport, Hilton Head Island, SC.*

(No relationships reported)

791 May 31 3:15 PM - 3:35 PM
Loss Of Forward Flexion And Lumbar Back Pain In A 7yo Male.

Danielle M. Magrini. *Children's Hospital of Philadelphia, Philadelphia, PA.*

(No relationships reported)

HISTORY: A 7 year old male comes into the office with low back pain which is worse with activity. Mother states that there is no specific injury or mechanism just progressive pain over the last 2-3 months prior to this visit. He was seen by an OSH where he obtained X-rays and was prescribed physical therapy. Pain began to progress despite PT and now he is unable to bend over and touch his toes. There is no numbness, tingling, or overt weakness in the lower extremity. He does have an occasional radicular pain into the left leg. No recent infections, fever, or change in bowel or bladder habits.

PHYSICAL EXAMINATION: Inspection: stiff gait otherwise reciprocal and non-antalgic; able to walk on toes and heels. No swelling, erythema or superficial skin stigmata in the lower lumbar spine Palpation: midline tenderness to palpation over the L2-L4 vertebrae. Mild paraspinal tenderness left greater than right. ROM: unable to forward flex at the waist; decreased ROM in extension, lateral side bending and rotation. Special tests: + 2 patellar and achilles reflexes; sensation intact throughout. Negative straight leg raise. Unable to bring knees into chest. **DIFFERENTIAL**

DIAGNOSIS:Tumor, ABC, muscle strain, infection

TEST AND RESULTS: Xray of lumbar spine-shows obliteration of the left L3 pedicle, + winking owl sign. MRI L spine- L3 vertebral body severe compression deformity on the left, essentially vertebral plana appearance, bulging/extraneous extension of enhancing tissue involving the left vertebral body, pedicle, and posterior elements extending into paraspinal tissues. Findings may represent Langerhans cell histiocytosis or other neoplasm. CT needle guided biopsy-confirmed LCH Skeletal survey- no other bony involvement **FINAL WORKING DIAGNOSIS:** Bone tumor of L3 pedicle. Possible LCH

TREATMENT AND OUTCOMES: - Symptomatic treatment including-TSLO brace and activity modifications - close monitoring and followup - no chemo or radiation secondary to focal disease.

792 May 31 3:35 PM - 3:55 PM

Back Injury - Mountain Biking

Cory Mitchell, Lauren Simon, FACS. *Loma Linda University, Loma Linda, CA.* (Sponsor: Lauren Simon, FACS)

(No relationships reported)

HISTORY: A 31-year-old recreational mountain biker presented with a one-month history of 5/10 low back pain. During a weekend excursion, he rode off of a 15 foot drop and landed flexed forward at the waist on his bike with his tailbone landing directly on the rear tire. He experienced immediate low back pain without radiation, numbness or tingling in the legs, or loss of bowel and bladder control. He was able to complete his ride and walk to his car. He continued to have low back soreness (2-4/10) particularly when sitting upright in a chair that limited his normal 5x/week exercise routine.

PHYSICAL EXAMINATION: Examination revealed tenderness to palpation off of the midline bilaterally at L3-L4. He was nontender over the sciatic notches with very mild lumbar paraspinal muscle spasm at L2-L4. Forward flexion was 90% of the floor. He exhibited full extension and lateral bend. L1-S1 sensation was intact. Normal squat, heel and toe walk with 5/5 EHL strength bilaterally. He had negative straight leg raises supine and seated. Achilles and Patellar reflexes were 2 and 2+.

DIFFERENTIAL DIAGNOSIS: 1. Lumbar Compression Fracture 2. Lumbar Paraspinal Muscle Sprain 3. Lumbar Disc Injury 4. Lumbar Isthmic Spondylolisthesis

TEST AND RESULTS: Lumbar spine AP and lateral radiographs: -No evidence of acute fracture or dislocation. No significant degenerative changes. -Partial fusion of the anterior aspects of the vertebral bodies of T12 and L1, possibly congenital. Lumbar spine MRI without contrast: -Partial fusion of T12 and L1 vertebral body. -Degenerative disc disease at L4-L5 with central annular tear of the disc.

FINAL WORKING DIAGNOSIS: Central annular tear of the L4-L5 disc

TREATMENT AND OUTCOMES: 1. Rest and activity modification for 7 months. 2. Core strengthening physical therapy program for 8 weeks. 3. Negative radiographs rule out compression fracture with continued symptoms 9 months post injury. 4. Return to 65% capacity mountain biking with new onset low back weakness and radiation of pain into left buttock/testicle. Continued to deny red flag symptoms. 5. MRI revealed an annular tear of the L4-L5 disc. 6. Return to physical therapy for core strengthening program. Pain decreased to only upon awakening after 12 of 16 sessions. Gradual return to activity will be implemented with continued pain free progress with physical therapy.

793 May 31 3:55 PM - 4:15 PM

Back Pain in a Tennis Player

Renu Gautam, George Pujalte, FACS. *Mayo Clinic Florida, Jacksonville, FL.* (Sponsor: George Pujalte, FACS)

Email: gautam.renu@mayo.edu

(No relationships reported)

HISTORY:

A 51-year-old female with a history of rhabdomyosarcoma and breast cancer presented with sudden, sharp, constant, 10/10 pain on the left lower back, radiating to her left hip and thigh. She had numbness and tingling over her left anterior thigh. The pain decreased when supine or standing, but increased with sitting. The pain was worse at night and in the early morning. Methylprednisolone and opioids provided little relief. No history of trauma. She had done light rowing machine workout the previous day. Rest of review of systems negative.

PHYSICAL EXAMINATION:

Back inspection showed no deformities, step offs, nor erythema. Level shoulders and iliac crests. Able to rise from a seated position. Gait was normal; toe and heel-walking, normal. Normal and pain-free lumbar spine range of motion (ROM). Negative straight leg raise test. No tenderness. Full ROM of left hip and knee. Mild left hip flexion weakness. Stinchfield negative. Decreased L2-L3 light touch sensation. Anterior thigh tingling reproduced with palpation inferomedial to left anterior superior iliac spine.

DIFFERENTIAL DIAGNOSIS:

Lumbrosacral plexopathy
Meralgia Paresthetica
Lumbrosacral plexitis
Paraneoplastic syndrome
Lumbar radiculopathy

TEST AND RESULTS:

X-rays: Straightening of normal lumbar lordosis. Lower lumbar facet joint osteoarthritis. Normal lumbar vertebral body heights and intervertebral disc spaces. EMG: Nerve conduction normal. Fibrillation potentials and mildly polyphasic motor unit potentials in the left L2 innervated muscles. MRI: Foraminal/extracanalicular disc extrusion on the left at L2-L3 compressing and superiorly shifting L2 nerve root and dorsal root ganglion with associated left L2 radiculopathy. No pathologic contrast enhancement or metastatic disease.

FINAL WORKING DIAGNOSIS: L2-L3 radiculopathy

TREATMENT AND OUTCOMES:

1. Physical therapy (PT) with mild improvement in symptoms
2. Epidural steroid injection with minimal relief
3. Continued PT; tried acupuncture and chiropractic treatments. Improved strength and decreased pain; continued numbness
4. Gabapentin with minimal improvement
5. Neurosurgery recommended microdiscectomy, patient declined
6. Continued nonsteroidal anti-inflammatory drugs. Advanced tennis skills slowly, introducing serving 10-15/session at mild to moderate level.

794 May 31 4:15 PM - 4:35 PM

Low Back Injury - Football: Complexities of In-Season Decision Making

Luke Widstrom, Sourav Poddar. *CU School of Medicine, Aurora, CO.* (Sponsor: John Hill, FACS)

(No relationships reported)

HISTORY: A 23 year old division I football player presented for recurrent back pain after two separate injuries at practice. He has a prior history of left sided low back pain and spasm which responded well to mobilization treatments. However, during a power lifting session he felt increased pain with radiation down the left leg with extension maneuvers. At a subsequent practice, he rotated to grab a ball and noted significant right sided low back pain.

PHYSICAL EXAMINATION: Full flexion, extension, sidebending, and rotation at waist

Bilateral lumbar paravertebrals are tight and TTP, worse on left. Left SI region TTP.

Spinous processes are non-tender.

Full sensation in bilateral LE L2-S1 dermatomes

5/5 strength in bilateral LE L3-S1 myotomes

2+ patellar and achilles reflexes bilaterally. No clonus.

SLR equivocal left, negative right. Slump test positive left, negative right. Stork test with mild discomfort left, negative right. **DIFFERENTIAL DIAGNOSIS:** 1. Lumbar radiculopathy 2. Lumbar paraspinal strain 3. Spondylolysis 4. Spondylolisthesis 5. Degenerative disc disease

TEST AND RESULTS: XR L-spine, AP/Lat/Flexion/Extension views: Negative **MRI L-spine:** 1. Stress fracture with nondisplaced fracture of anterior pedicle on left and pars interarticularis on right of L4. Early stress injury without fracture at the pedicle and pars interarticularis of L5.

2. Left paracentral protrusion compressing left S1 nerve root at L5-S1.

CT scan L-spine: Bilateral posterior element fractures at L4 vertebral body level, involving right lamina and pars interarticularis and left pedicle. No evidence of spondylolisthesis.

FINAL WORKING DIAGNOSIS: Left L4 pedicle fracture. Right L4 pars fracture. Bilateral L5 pars and pedicle stress reactions. L5-S1 disc protrusion with left S1 nerve root compression.

TREATMENT AND OUTCOMES: 1. L4-L5 and L5-S1 transforaminal epidural steroid injections: Complete resolution of leg pain.

2. Restricted from practice, weight lifting, and extension activities for 4 weeks with LSO brace.

3. Returned to running at 4 weeks, progressed to non-contact drills without pain.

4. Progressed to full contact practice and game play at 8 weeks without pain.

5. Plan for surgical fixation with screws at end of season with 3 to 6 month recovery.

6. If any setbacks, will be withheld from football and plan for earlier surgery.

795 May 31 4:35 PM - 4:55 PM

Back Pain in a High School Soccer Player

Laura M. Nilan, Greg Canty, *Children's Mercy, Kansas City, MO.*

Email: lmnilan@cmh.edu

(No relationships reported)

History: A 16 year-old male soccer player presenting to primary care sports medicine with 2 months of low back pain that was first noticed after a throw-in during a game. The patient has previously been evaluated by a pediatric orthopedic spine surgeon and was noted to have scoliosis and mild kyphosis but no other diagnosis. On further history he recalled intermittent low back pain prior to the injury, but it has become much more consistent since the injury. He has not had any numbness, tingling, weakness or incontinence. Upon further review of systems he has crampy, loose stools daily for over 2 months. Stool studies by his primary care provider have been negative so far. He denies any recent fevers. He has started probiotics and cholestyramine. **Physical Exam:** Well-developed young man in no distress. Spine with a mild thoracolumbar scoliosis, mild kyphosis. Pain with both forward bend and lumbar extension. Stork test revealed mild discomfort. No pain on palpation over the lumbar spine. Negative figure 4. Popliteal angle 120 degrees. No SI joint tenderness. Nonantalgic gait. Normal deep tendon reflexes.

Differential Diagnosis

1. Spondylolysis
2. Disc Herniation
3. Muscle strain
4. Scoliosis
5. Infection
6. Inflammatory bowel disease

Test and Results:

-Spine radiographs show a mild scoliotic curve but no signs of spondylolysis or listhesis

-No clear indications for MRI

-Labs:

CBC-

WBC 7.02 (4.5-11)

HBG 14.8 (13.5-17.5)

Platelet 296 (150-450)

BMP Normal

ESR-33 (0-15)

CRP 2.3 (0-1)

Final Diagnosis

1. Crohn's Disease

Treatment

1. Gastroenterology consultation. He had an extensive work-up including a colonoscopy which showed inflammation of the terminal ileum consistent with Crohn's disease. GI has tried multiple immunomodulators including steroids, vedolizumab, ciprofloxacin, vancomycin and infliximab. He remains difficult to control and is being considered for a fecal transplant.

2. He has continued to participate in soccer

ACSM May 30 – June 3, 2017

796 May 31 4:55 PM - 5:15 PM

Sacral Stress Fracture in a Collegiate Distance Runner

Samuel F. Carlson, Ward McCracken, Suzanne Hecht, FACSM.

University of Minnesota - Twin Cities, Minneapolis, MN.

(Sponsor: Suzanne Hecht, FACSM)

(No relationships reported)

HISTORY: A 20-year-old male NCAA D1 distance runner presented with gradual onset of left low back pain present for two weeks without acute injury. He was running 60 miles per week and had been running seven days a week for an extended period of time. The pain was notably aggravated the week prior to presentation while practicing hurdles. He has no history of stress fractures. He endorsed mild radiation of the pain to the lateral buttock and hip, but not further down the thigh. He experienced no numbness or tingling.

PHYSICAL EXAMINATION: FROM of the lumbar spine, but with painful F/E. Negative SLR and Slump. 5/5 strength throughout LE b/l. Reflexes 2+ b/l. TTP over L SIJ and sacrum. The left sided pain was reproduced with single leg hopping, worse on the left than the right. He had a non-antalgic gait.

DIFFERENTIAL DIAGNOSIS:

1. Lumbago with Radiculopathy
2. Sacroiliac Joint Dysfunction
3. Sacral Stress Injury

TEST AND RESULTS:

XR Lumbar Spine

- negative

MRI of the Lumbar spine and pelvis

- Non-displaced fracture of the left sacrum predominantly at the S1 vertebral level, with subtle extension to the S2 vertebral level

DEXA Hip/Pelvis/Spine

- Z score L1-4 = -1.4

Laboratory Testing

- normal range for all labs including Vitamin D, Calcium, Testosterone Free and Total, BMP, PTH, Ferritin, CBC, LH, FSH, TSH, and free T3 & T4

FINAL/WORKING DIAGNOSES:

- 1) Left grade 4 sacral stress fracture
- 2) Low bone mineral density for an athlete

TREATMENT AND OUTCOMES:

1. Initial treatment – stop high impact activity and running, cross-train, and counselled regarding appropriate calcium intake
2. At 8 weeks, started return to run program under team's ATC
3. At 4 months, returned to regular training, running up to 5 days per week
4. At 5 months, began to have discomfort in the left lower back. Repeat MRI showed resolution of previous fracture, but now showed marrow edema involving the right peripheral aspect of S5, most consistent with stress reaction. This area is asymptomatic to the patient and he has no TTP at either site.
5. Presently, working with formal PT and returned to reduced volume running.

B-48 Clinical Case Slide - Shoulder IV

Wednesday, May 31, 2017, 3:15 PM - 5:15 PM

An Unusual Cause Of Arm Pain - Lacrosse

Brady J. Bowen, Deborah I. Light, Alexander Gozman, Hamish

A. Kerr, FACSM. *Albany Medical Center, Albany, NY.* (Sponsor:

Hamish A. Kerr, FACSM)

Email: bowenb1@mail.amc.edu

(No relationships reported)

HISTORY:

A 17-year-old female presented with 2 days of right arm pain. The day after lacrosse practice, she awoke with a dull ache, swelling and redness starting at the elbow then progressing to the shoulder, worse with movement and improved with elevation.

She denied recent trauma, shortness of breath, cough, paresthesias or arm weakness. There was no recent immobilization or travel, no illness or history of similar symptoms.

Past medical, surgical and birth history were unremarkable. She denied tobacco use or known allergies. She was started on levonogestrel-ethinyl estradiol four months ago. Her Father had a remote post-surgical deep vein thrombosis.

PHYSICAL EXAMINATION:

Vitals: Temp 36.7, BP 112/64, HR 58, RR 16, 99 % O2 on room air
Well-appearing female in no apparent distress. Normal heart sounds. Lungs were clear, abdomen was benign. Pulses were intact and bilaterally symmetric throughout. Good muscle tone and bulk. The right arm was swollen from the elbow to the shoulder with mild erythema and warmth. Moderate tenderness to palpation of the elbow and shoulder, worse on the medial brachium. Elbow and shoulder range of motion was full but painful, limiting provocative maneuvers. Adson's test and costoclavicular compression tests were negative. Reflexes were 2+ throughout.

DIFFERENTIAL DIAGNOSIS:

1. Undisclosed trauma or non-accidental injury
2. Septic or reactive arthritis
3. Cellulitis or bursitis
4. Upper extremity DVT
5. Thoracic outlet syndrome or overuse injury

TESTS AND RESULTS:

- CBC, CMP, PTT, INR unremarkable
- Hypercoagulable work up pending
- Chest x-ray: No cervical rib or acute pathology
- Venous Doppler: Extensive right subclavian and axillary vein DVT
- Venogram: subacute thrombosis of the axillary and subclavian veins likely due to stenosis at the level of the first rib and medial clavicle

FINAL/WORKING DIAGNOSES:

Paget Von Schroetter Syndrome

TREATMENT AND OUTCOME:

1. Initial anticoagulation with Enoxaparin
2. Thrombectomy with heparin and tPA infusion
3. Repeat thrombectomy and balloon venoplasty for residual stenosis
4. Discharged on Apixaban
5. Right thoracic outlet decompression with anterior scalenectomy and balloon venoplasty
6. Hypercoagulable work up was negative
7. Three months oral anticoagulation with Apixaban
8. Held from contact sports for the duration of anticoagulation

801 May 31 3:35 PM - 3:55 PM

Unusual Cause of Periscapular Pain

Kimberly Sikule, John H. Stevenson. *UMass Worcester, Worcester, MA.*

(No relationships reported)

HISTORY: 38 yo female recreational athlete presents with left posterior shoulder pain which has gradual worsened over the past 4 months. Denies any previous trauma, injury to the area. It 8/10 sharp quality pain localized to posterior scapula with radiation to the neck. Denies any numbness, tingling, weakness, instability or crepitus. Symptoms are worse with activity. She tried PT and has modified her activities. On 1/29/2016 she underwent an ultrasound guided injection into the subscapular bursa. On 4/29/2016 she reports symptoms had resolved. On 7/29/2016 she reported her symptoms returned with a feeling of crunching under the shoulder blade. Underwent a second injection into the subscapular bursitis, MRI was obtained and she restarted physical therapy home exercise program.

PHYSICAL EXAMINATION:

GEN: Alert, oriented x 3
EYES: emoi
RESP: normal respiratory effort
SKIN: intact no signs of infection
NEURO: sensation to light touch intact. CN 2-12 intact.
MSK: Neck: full rom to flexion, extension, lateral rotation. Negative spurlings.
Shoulder: Mild periscapular tenderness, crepitus with active abduction. ROM 180 degrees of abduction, forward flexion. 5/5 strength with empty can testing, internal external rotation, negative obriens, Hawkins, neers testing. Myofascial soreness on posterior medial boarder of the scapula. Negative scapular liftoff with scapular stress, pain with scapular compression and active abduction.

DIFFERENTIAL DIAGNOSIS:

- Subscapular Bursitis
- Cervical Paraspinal Muscle Strain
- Cervical Radiculopathy
- Glenohumeral Joint Arthritis
- Labral Tear
- Neoplasm
- Multidirectional Instability
- Parascapular Strain
- RTC Tendonitis

TESTS AND RESULTS:

Musculoskeletal Ultrasound left periscapular region showing no subscapular bursal fluid collection. MRI: medial border of right upper scapula, within intermuscular planes between trapezius, erector spinae, serratus anterior muscles there is a 2.9 x 1.3 x 1.1 cm mass. Lobulated cluster of grapes morphology with interspersed fast and central low T2 signal dots. No surrounding soft tissue edema. 3cm soft tissue mass consistent with a vascular lesion such as soft tissue hemangioma.

FINAL WORKING DIAGNOSIS:

3cm soft tissue hemangioma

TREATMENT AND OUTCOMES

Consult Vascular Surgery
Continue activities as tolerated

802 May 31 3:55 PM - 4:15 PM

A Shot at Expanding Shoulder Pain Differential Diagnosis

Mark McEleney, Andrew Peterson. *University of Iowa, Iowa City, IA.*

(No relationships reported)

History

14 yo male swimmer who was seen on 2/24/16, for evaluation of left upper extremity numbness and weakness of 2 month duration. Symptoms had begun the day after receiving his second of three injections for HPV vaccination series in his left shoulder on December 29, 2015. The patient woke up the following day with tightness in his left shoulder. Intense, sharp pain and weakness of his arm developed inhibiting participate in swim practice the following evening.

The patient had previously been seen by his pediatrician as well as an orthopedist, neurologist, and physical therapist. Parsonage-Turner syndrome was diagnosed clinically. The patient received a six-day course of oral methylprednisolone and underwent physical therapy for shoulder strengthening and range of motion. There was improvement of pain though weakness with shoulder flexion and abduction, decreased tactile sensation over the shoulder, and paresthesias of the fingertips had persisted.

Exam

Decreased tactile sensation over the dorsal hands and fingers. Passive ROM full, active ROM was limited to 90 of forward flexion and abduction. Scapular winging with flexion and abduction. 5/5 strength with resisted internal and external rotation. 4+/5 strength with empty can and Speed's test. Lift off test was positive.

Differential Diagnosis

cervical disk herniation, cervical neural foraminal stenosis, mass lesion compressing the brachial plexus, calcific tendonitis, acute subacromial bursitis, adhesive capsulitis, thoracic outlet syndrome

Tests/Results

NCS/EMG of the left upper extremity (2/24/16)
-mild median neuropathy at the left wrist
Left shoulder MRI without contrast (5/31/16)
-normal

Final Working Diagnosis

Parsonage-Turner syndrome

Treatments and Outcomes

Two rounds of IVIG (135 g) separated by 24 hours were given on 3/7/16 - 3/8/16. Shoulder strength improved significantly and pain resolved completely within one week of treatment. There was slightly diminished muscle bulk of the supraspinatus, deltoid, bicep, tricep, and latissimus dorsi as well as scapular winging with wall push-up and scapular dyskinesia at follow-up exam (3/28/16). Mild (4+/5) weakness with shoulder shrug/protraction/retraction, resisted internal rotation, and supraspinatus testing persisted to visit on 5/31/16.

803 May 31 4:15 PM - 4:35 PM

Shoulder "Droop" In Multi-sport Athlete

Amy Rabatin¹, Daniel Lueders², Cara Prideaux¹. ¹Mayo Clinic, Rochester, MN. ²University of Michigan, Ann Arbor, MI.

(Sponsor: Karen Newcomer, FACSM)

Email: rabatin.amy@mayo.edu

(No relationships reported)

HISTORY: A 16 year old, right handed, multi-sport male athlete presented with right shoulder region asymmetry noted 3 months prior by teammates and athletic trainer. Scapular dyskinesia noted one month prior. No associated pain, paresthesias, sensation changes, or frank weakness. Active range of motion was impaired with overhead activities, but did not adversely affect sports performance. No history of shoulder, arm or neck trauma or injury. Past medical history unremarkable with no recent viral illnesses.

PHYSICAL EXAM: Peripheral pulses intact, normal capillary refill. Gross asymmetry and atrophy in right trapezius and latissimus dorsi muscle bulk with prominence of right scapula inferior angle. Right acromion 2-3 cm inferior to left. Normal activation of serratus and stabilization of scapula with wall push with no frank scapular winging.

Right scapula dyskinesis with slowed elevation and rotation with shoulder abduction and forward flexion. Ten degrees of right glenohumeral internal rotation deficit. 2/5 right shoulder elevation and external rotation strength, otherwise normal. Reflexes and sensation normal. No tenderness to palpation. No pain with Neer's, Hawkins, Scarf, O'Brien's and dynamic labral shear testing. No shoulder apprehension.

DIFFERENTIAL DIAGNOSIS:

1. Brachial plexopathy
2. Focal myopathy or myositis
3. Neuromuscular disease
4. Mononeuritis

TEST AND RESULTS:

Shoulder radiograph:

- Normal

MRI chest:

- Diminutive right trapezius relative to left. Mild increased T2 signal in right trapezius with subtle post contrast enhancement. No abnormality noted in latissimus dorsi.

EMG:

- Electrophysiologic evidence of focal myopathy involving right trapezius, latissimus dorsi and sternocleidomastoid.

Laboratory:

- CK, CRP, and ESR normal

- Connective tissue disease testing negative

- Fascioscapulohumeral Dystrophy testing negative

FINAL/WORKING DIAGNOSIS:

Focal myopathy involving right trapezius and latissimus dorsi, possible FSHD variant

TREATMENT AND OUTCOMES:

1. Physical therapy - scapular stabilization and strengthening of compensatory musculature.
2. Overhead sport evaluation. Neuro-reeducation focused on form and positioning during exercise performance.
3. Educated in safety with weightlifting activities.
4. Participated in football camp and fall football.

804 May 31 4:35 PM - 4:55 PM

Soccer Player with Neck Pain and Upper Extremity Parasthesias

Adam Susmarski¹, Stephanie Giammittorio². ¹University of Pittsburgh Medical Center and US Navy, Pittsburgh, PA.

²University of Pittsburgh Medical Center, Pittsburgh, PA.

(Sponsor: Dr. Bradley C. Nindl PhD, FACSM)

Email: susmarskia@upmc.edu

(No relationships reported)

HISTORY: An 18 year old right hand dominant female Division 1 soccer goalie with no medical history presented in February to clinic with neck pain and right upper extremity parasthesias radiating to her wrist. Initial symptoms began in October after diving for a ball when an opponent fell on to her right shoulder, neck, and head. She was diagnosed with a concussion and was held out of competition for 3 weeks during which she reports resolution of her symptoms. Her symptoms gradually returned and then remained present during activity only after she was cleared to return to play from her concussion.

PHYSICAL EXAMINATION: Full cervical and upper extremity range of motion. No tenderness or swelling in the cervical spine or upper extremities. Upper extremity strength was 5/5, reflexes were 2+/4, and sensation was intact to light touch and pinprick. Speed's, Yergason's, Empty Can, Hawkin's, O'Brien's, Spurling's, cervical facet provocation, Neer's, and Tinel's at the medial elbow were negative. Adson's, Wright's Hyperabduction, Allen's, and Costoclavicular maneuvers reproduced her symptoms.

DIFFERENTIAL DIAGNOSIS:

Brachial Plexopathy

Cervical Radiculopathy

Cervical Discogenic Pain Syndrome

Cervical Fracture

Clavicle Fracture

Mononeuropathy

Shoulder Impingement Syndrome

Spondylolisthesis

Thoracic Outlet Syndrome

Tumor

TEST AND RESULTS: Cervical X-ray (November 2)-No abnormalities

MRI cervical spine without contrast (November 13)-Punctate focus of increased susceptibility in the cervical cord at C1-C2. Recommend MRI with contrast to exclude hemorrhage or vascular malformation

MRI cervical spine with contrast (November 19)-Previously questioned susceptibility at C1-C2 is not seen and most likely represents artifact

EMG/NCS (February 13)-Normal study without evidence of radiculopathy, brachial plexopathy, or mononeuropathy

Right upper extremity ultrasound (February 18)-Vascular compression with reproduction of symptoms in provocative positioning

FINAL WORKING DIAGNOSIS: Vascular Thoracic Outlet Syndrome

TREATMENT AND OUTCOMES: Through a comprehensive rehabilitation program and adjustment in her throwing mechanics she was able to prevent provocation of symptoms without hindering her performance and ultimately was able to continue her college soccer career without symptoms or limitations

805 May 31 4:55 PM - 5:15 PM

Do Not Get Stung By What Is Not A Stinger In Boys Lacrosse Player

Matthew D. Sedgley. *MedStar Sports Medicine, Ellicott City, MD.*

Email: msedgley@mac.com

(No relationships reported)

14 year old male is at the sports medicine outpatient clinic with his mother. She mentions that her son gets "stingers" all the time. The stingers are felt to be appreciated in the bilateral upper arms. The duration is for many months (greater than 6.) Time makes them better and they are worse with motion around the neck or playing lacrosse.

PHYSICAL EXAMINATION: VITAL SIGNS: Pulse is 72 and regular, respirations 18 and regular, blood pressure 122/78. GENERAL: WNWD 14yom in no acute distress. EXTREMITIES: No peripheral edema or varicosities. NEURO: Inspection: no atrophy or bruising Palpation: no tenderness to palpation to the spinous process of the neck DTRs: Negative for Hyperreflexs bilaterally. Cervical range of motion: 1. Right side bending: Within normal limits, painful. 2. Left side bending: Within normal limits. 3. Forward flexion: 45 degrees with pain at the end of range. 4. Extension: Within normal limits. Special Test: + Spurlings:shows Positive with pain down the bilateral arms and occasional tingling and numbness. MSK: Palpation of the upper neck and shoulders is non tender ROM: full range of motion of arms is noted Gait: normal with normal station

Images: MRI C Spine: Cranioclavial angle of 139.
DIFFERENTIAL DX: 1.HERNIATED DISK 2.SPINAL STENOSIS 3.OCCULT FRACTURE OF THE C SPINE 4.TUMOR OF THE SPINAL CORD 5.ABSCCESS OF THE SPINAL CANAL 6.PYSCHOGENIC ETIOLOGY 7.VASCULAR ANOMALY/ THORACIC OUTLET 8.REDUCED CLIVAL ANGLE**FINAL DIAGNOSIS**

ABNORMAL CRANIOCLIVAL ANGLE
Cranioclival angle is the angle at the base of the skull that forms when a line is drawn at the posterior of the axis and the dorsum of the skull base. Normal angles range from 150 to 180 degrees. If the measurement is 150 degrees or less, there may be the concern for ventral spinal cord compression.

Disposition: Patient was referred to Orthopedic spine clinic. Consult performed there determined that there was no evidence of any symptoms at rest or baseline. There was no evidence of cord compression or injury on images. Only recommendations were to avoid contact sports and to follow up if any further symptoms presented. After discussion of the risks (of invasive surgery) and the benefits patient and his parents decided not to pursue further work up and and stop all contact sports including lacrosse.

The Acute Effects Of A Physically Active Games Lesson On Cognition In Primary School Children

Andy J. Daly-Smith¹, Margaret A. Defeyer², Jim McKenna¹, Pamela L. Graham², Melissa A. Fothergill², Scott Lloyd³. ¹Leeds Beckett University, Leeds, United Kingdom. ²Northumbria University, Newcastle, United Kingdom. ³Redcar & Cleveland Borough Council, Redcar, United Kingdom.

Email: a.j.w.smith@leedsbeckett.ac.uk

(No relationships reported)

Evidence regarding the impact of acute physically active bouts on cognition in schools is conflicting. Treatment fidelity of PA bouts is often unconfirmed, while many studies focus on few cognitive outcomes. **PURPOSE:** To investigate effects of a physically active games lesson (PAGL) on cognition in primary school children. **METHODS:**

Six schools (N=123, F=73; 9.9±0.3yrs) were ranked and paired by socio-economic status, with one per pair randomly allocated, by coin toss, to a ~40 min PAGL (n=62) or sedentary class lesson (n=61). One week post-familiarisation, immediately before and 10-mins after each lesson, pupils completed a computerised cognitive battery (COMPASS): simple, easy and hard reaction time (correct response reaction time, RT), Stroop (RT and % correct answers, %C), Digit Vigilance (RT & %C), Tower of London (ToL; thinking time TT, RT & %C), immediate word recall (%C), delayed

word (RT & %C) and picture recall (RT & %C). MVPA was measured in 15-second epochs using accelerometers and Evenson cutpoints. A threshold for the PAGL analysis was ≥ 12 mins MVPA. Two-way ANOVA with repeated measures assessed changes in cognitive outcomes. **RESULTS:** Average MVPA was 12.19 ± 2.55 mins (range 7.00-17.50 mins). Only 36 participants (58%) met the MVPA threshold. Negative effects of time were observed for: simple RT ($p=0.024$); hard RT (RT, $p<0.001$; %C, $p=0.002$); Stroop congruent (%C, $p=0.006$); Digit-vigilance (RT, $p=0.003$); immediate word recall (%C, $p<0.001$); delayed word recall (%C, $p<0.001$) and delayed picture recall (%C, $p<0.001$). Positive effects of time were observed for ToL RT ($p<0.001$). Significant interaction effects favoured the PAGL for ToL thinking RT ($p=0.048$, Partial eta squared = 0.041). **CONCLUSIONS:** We addressed a range of weaknesses affecting previous studies of the acute effects of PA. Low MVPA excluded many pupils from analysis. MVPA during PAGLs may be insufficiently intense or prolonged to influence these cognitive processes. ToL performance may be improved by MVPA total or the cognitive demands of PAGL lessons.

823 Board #2 May 31 2:00 PM - 3:30 PM
The Impact of Daily Physical Education on Perceptual Speed and PACER Laps Over Time

Haley K. Holan, Julian A. Reed, Abigail C. Short. *Furman University, Greenville, SC.* (Sponsor: Anthony Caterisano, FACSM)
 Email: haley.holan@furman.edu
 (No relationships reported)

Developmental research has demonstrated that Perceptual Speed is related to higher cognitive abilities and linked to increases in fitness and physical activity participation. Epidemiological research has also shown that there is an inverse relationship between cardiorespiratory fitness and all-cause mortality. **PURPOSE:** The purpose of the study was to examine the impact of 45 minutes of daily physical education on Perceptual Speed and on fitness performance among youth attending Legacy Charter School. **METHODS:** An analysis of variance (ANOVA) mixed effect linear model was used to evaluate the effectiveness of 45 minutes of daily physical education and Perceptual Speed among youth in grades 2nd-5th attending Legacy Charter, a Title I school in the southeastern US. Gain scores (final post-test assessment in May 2016 - pre-test assessment in September 2014) were calculated and analyzed for significance. The interaction between school and time was estimated for each outcome. Each analysis was stratified by gender and adjusted by age to control for baseline differences by school. A Title I control school who provided physical education once per week was identified and utilized as a comparison. **RESULTS:** Legacy Charter School students observed significant gain increases on: 2 of 4 ($p<0.05$) Perceptual Speed sections, including the Total section, compared to 0 of 4 for the control ($p<0.05$). When stratified by gender, Legacy Charter females observed significant gain score increases on 3 of 4 sections. In particular, significant increases were observed in the Total section (Gain Score= 14.14 ; $F=8.17$; $df=1,162$; $p=0.005$) over time. On the PACER fitness test, Legacy Charter School students observed significant gain score increases (Gain Score= 9.75 ; $F=64.07$; $df=1$; $p=0.000$) over time. Legacy Charter School males and females also demonstrated significant increases in gain scores on the PACER test (Males: Gain Score= 11.59 ; $F=40.58$; $df=1,170$; $p=0.000$) (Females: Gain Score= 8.06 ; $F=27.26$; $df=1,166$; $p=0.000$). **CONCLUSION:** 45 minutes of daily physical education led to increases in Perceptual Speed and fitness performance among Legacy Charter male and female elementary school students over time from 2014 to 2016. Funded by Campbell Young Leaders.

824 Board #3 May 31 2:00 PM - 3:30 PM
Links Between Daily Physical Education, Fluid Intelligence, and Fitness Levels of Underserved Middle School Youth

Abigail C. Short, Julian A. Reed, Haley K. Holan. *Furman University, Greenville, SC.* (Sponsor: Anthony Caterisano, FACSM)
 Email: abi.short@furman.edu
 (No relationships reported)

The investigation of the impacts of regular physical activity on cognition and general intelligence is under studied, however findings from a report from the Institute of Medicine (IOM) suggest positive associations between participation in regular physical activity and youth brain health. Unfortunately, only 8% of American public middle schools provide daily physical education according to the CDC School Health Policies and Program Study. **PURPOSE:** Examine the impact of 45 minutes of daily physical education on fluid intelligence and fitness levels among underserved middle school youth attending Legacy Charter School. **METHODS:** An analysis of variance (ANOVA) mixed effect linear model was used to evaluate the effectiveness of 45 minutes of daily physical education on fluid intelligence and the fitness performance among middle school youth attending Legacy Charter, a Title I school in the southeastern US. Gain scores (post-test assessment in May 2016 - pre-test assessment in September 2015) were calculated, stratified by ethnicity and gender, and analyzed

for significance. The interaction between school and time was estimated for each outcome. Each analysis was adjusted by age to control for baseline differences by school. A control school that did not provide daily physical education was utilized as a comparison. **RESULTS:** Legacy Charter School underserved females improved in fluid intelligence total score (Gain Score= 2.16 ; $F=5.88$; $df=1$; $p=.016$), aerobic capacity (Gain Score= 0.59 ; $F=7.796$; $df=1$; $p=.006$), number of push-ups performed (Gain Score= 2.58 $F=25.065$; $df=1$; $p=.000$), and number of curl ups performed (Gain Score= 5.64 ; $F=37.592$; $df=1$; $p=0.000$) compared to controls. Legacy Charter School underserved males improved in aerobic capacity (Gain Score= 1.94 ; $F=4.316$; $df=1$; $p=.039$), number of push-ups performed (Gain Score= 2.60 ; $F=35.542$; $df=1$; $p=.000$), and number of curl-ups performed (Gain Score= 11.27 ; $F=42.904$; $df=1$; $p=.000$) compared to controls. **CONCLUSION:** These findings suggest that daily physical education can influence the cognitive and fitness performance of underserved middle school youth. Funded by Campbell Young Leaders.

825 Board #4 May 31 2:00 PM - 3:30 PM

Dose Response Effect Of Physical Activity And Behavioral Regulation Measures On The Science Achievement Of At-risk Middle School Girls

Jennifer A. Gatz, Angela M. Kelly. *Stony Brook University, Stony Brook, NY.*
 Email: jennifer.gatz@stonybrook.edu
 (No relationships reported)

PURPOSE: After school programs have played a key role in engaging youth in the learning process by providing opportunities to explore interests, increase health and wellness, set goals, solve problems, and connect with adult role models. The purpose of this study is to measure the effects of an after school program with a fitness and informal health and nutrition science curriculum on cognitive processes and science achievement in previously sedentary middle school girls. **METHODS:** A between subjects study was designed with $n=29$ female adolescents (mean age = $12.03 \pm .73$) engaged in supervised triathlon training, health and nutrition science education in a 20 week intervention. A second group of $n=30$ randomly selected females (mean age = $12.93 \pm .91$) served as the comparison group. To assess changes in science achievement, data were collected pre- and post- intervention. Hierarchical regression analyses examined the linear association of physical activity, aerobic fitness level, cognition and science content knowledge controlling for relevant covariates. **RESULTS:** Science achievement by treatment group was significantly predicted by fitness level $F(5,53) = 6.27, p < .001$; physical activity $F(5,53) = 6.98, p < .001$; aspects of cognition including behavioral regulation $F(5,50) = 5.88, p < .001$; and processing speed $F(5,53) = 6.27, p < .001$. **CONCLUSIONS:** The intervention with informal nutritional science learning and a controlled aerobic fitness component suggested improved cognition and science achievement in previously sedentary middle school girls.

826 Board #5 May 31 2:00 PM - 3:30 PM

The Effect of Different Exercise Modalities on Cognition Among Adolescent Populations

Akash R. Patel, Kenneth D. Hartline, Alexandria Riopelle, Nell B. Pawlenko, Tracy L. Zaslow, Anita Herrera-Hamilton. *Children's Hospital Los Angeles, Los Angeles, CA.*
 Email: akpatel@chla.usc.edu
 (No relationships reported)

PURPOSE: A growing body of literature documents the beneficial effects of aerobic exercise on cognition. One of the most interesting findings dictates that aerobic exercise preferentially benefits executive function, a term for complex cognitive processes including attention, working memory, mental flexibility, reasoning, planning, and inhibition. The purpose of this study was to measure the effect of acute intervals of two different exercise modalities (soccer and running) on cognition and executive function among adolescents between the ages of 11-14 years. **METHODS:** Ninety-eight middle-school students (50 males, 48 females, mean age = 13.09 years) volunteered to participate in this prospective study. Baseline neurocognitive and background data was collected at an initial study point. Two-weeks after the initial study point, subjects were matched by age, math class, and grade. Participants were randomized into one of three study groups involving soccer, running, or no aerobic activity for 30 minutes. Directly after the 30-minute exercise period, all participants were re-administered the neurocognitive battery. **RESULTS:** Subjects in the soccer group had significantly higher average score differences from baseline ($M = +0.588$, $SD = 0.556, p = .01$) on a neuropsychological measure of executive functioning, specifically planning and organization (Rey-Osterrieth Complex Figure) compared to subjects who did not participate in aerobic activity ($M = -1.770$, $SD = 0.573$). There was no significant difference found for this measure between subjects who participated in 30 minutes of running and those who did not engage in aerobic activity. No significant differences found between groups on measures of creativity and divergent thinking, processing speed, perceived stress, self-efficacy, or inhibitory control and cognitive flexibility. **CONCLUSIONS:** The modality of physical activity may

influence subsequent cognitive performance. Specifically, physical activity involving strategy and planning may prime maturing adolescent brains toward enhanced organization. The duration of these cognitive effects are unknown; further investigation is needed.

Low Academically-achieved Students Did Not Get Worse Score from Being Physically-active

Jacky Ka-wai Chan, Stanley Sai-chuen Hui, FACSM. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.*
 Email: jacky.sspe@link.cuhk.edu.hk
 (No relationships reported)

It is not surprised that parents and educators struggled for time resources allocated to low academically-achieved students. Cutting physical activity (PA) time is one of the common practices as PA has been generally thought to produce negative impact on academic performance. Such belief has not yet been verified. **PURPOSE:** To examine the associations between mathematics performance and level of PA engagement in Chinese adolescents.

METHODS: A total of 882 grade 9th Chinese students were randomly recruited in Hong Kong that covered all 18 districts and three school bandings (high, middle, and low). Participants' mathematics performance was assessed at the beginning (T0) and the end (T1) of an academic year using validated and uniformed test papers. Their PA level was measured using self-reported questionnaire (PAQ-A). At both T0 and T1 time points, participants were classified as physically-active, moderate-active, and inactive according to the composite ratings in PAQ-A. They were further categorized into Go-Active, Go-Inactive, and Unchanged-PA groups based on the changes in their PA status throughout the academic year. Longitudinal changes in mathematics scores over the year were compared among the groups using two-way repeated measures ANCOVA, adjusted for family income and revision time.

RESULTS: Significant Time (T0 - T1) x PA-group interaction effect on mathematics ($F=5.22, p=0.02$) was observed. Significant improvement was found in Go-Active participants. When same analysis was split by school-banding, no adverse effect was shown in low-banding students ($F=2.35, p=0.14$) but a significantly positive change in high- and middle-banding students. Shift of PA status from T0 to T1 was a significant predictor of mathematics score change ($p=0.02$). **CONCLUSIONS:** Higher school-banding students gained better mathematics scores from being more active. More importantly, a reduction in PA time among low-achieved adolescents seemed unrelated to academic performance. This study demonstrates that students' academic achievement (i.e. mathematics scores) may not be boosted considerably from cutting their PA time. However, such finding has yet to be examined in other learning areas such as languages and science subjects.

 (No relationships reported)

Working memory capacity (WMC) is a core cognitive process that involves holding and manipulating information to meet task goals. WMC, in conjunction with other cognitive processes, is essential for improving vocational performance, academic achievement and for developing skills to achieve life goals. While evidence indicates the positive influence of structured aerobic exercise on WMC, few studies have examined how sitting time (ST) -alone or in combination with habitual physical activity (PA)- influences WMC. **PURPOSE:** To examine combined associations between self-reported context-specific ST and PA with WMC and academic achievement in a sample of Spanish adults. **METHOD:** Undergraduates (n=371; 21 years \pm 3 yrs, 44% female) from University of Vic-Central University of Catalonia completed a 68-item survey that assessed socio-demographic variables (e.g., age, gender, academic year), min/week of light, moderate and vigorous PA (International Physical Activity Questionnaire), min/day of domain-specific ST (Last 7 days sedentary behavior questionnaire), academic performance (grade point average) and perceived stress (Perceived Stress Scale). WMC was assessed through a multiple complex span task that included: Operation Span, Symmetry Span and Rotation Span. These tasks interleave a processing task with a short list of to-be-remembered items. General linear models - adjusted by PA, ST, gender and stress- assessed combined associations between ST and PA with WMC and academic achievement. **RESULTS:** Performing at least 3 hrs/week of moderate-intensity PA was related to increases in WMC ($p<0.001$). However, PA intensity was not associated with academic performance. >3 hrs seated on a weekend day while performing non-screen leisure activities (e.g., listening to music) was related to reduced WMC after adjusting for

PA intensity ($p=0.012$). Similarly, >3 hrs/weekday spent seated in these sedentary activities and in leisure-forms of screen time were inversely associated with academic performance regardless of PA time and intensity ($p=0.033$; $p=0.048$). **CONCLUSION:** Moderate PA may benefit working memory; however, specific domains of leisure-time sedentary behavior may have an unfavorable influence on working memory and academic performance regardless of time spent in PA.

 Email: davidphillips2@suu.edu
 (No relationships reported)

PURPOSE: To determine the effect of Physical Activity (PA) on three differing types of cognitive processes, within an under-researched segment of the population. **METHODS:** 45 College-Aged Students were recruited from a University in the Southwestern United States. These participants completed three computer-driven tests from a battery of measurements that assess various components of cognitive control (CC)- One Card Learning Test (Attention) Two Back Card Test (Working Memory) Revised Groton Learning Maze Test (Inhibition/ Executive Function). Testing took place after a bout of Sedentary Activity, and two weeks later, after a bout of individualized PA (based on VO₂ max). **RESULTS:** Due to the high intellect/ high fit nature of the participants there was no statistical significance with the One Card learning or Two Card Back Tests (i.e. many reached the test 'ceiling' on the initial attempt). After controlling for sex, age, GPA, BMI and aerobic capacity, there was significant differences between sedentary and PA conditions in both moves (mean difference = 0.136, $p < 0.001$, Cohen's $d = 0.85$) and duration (mean difference = 22179, $p < 0.001$, Cohen's $d = 0.74$) within the Revised Groton Maze Learning Test. The differences between conditions represented a medium-to-large effect. There were no moderating influences on the condition differences.

CONCLUSIONS: This study adds to the existent literature that suggests PA may facilitate increases in CC, dependent on the nature of the cognitive task.

Correlation Of BDNF And Irisin With Aerobic Fitness And Cognition In Graduate Students

David M. Boland¹, Brett A. Dolezal², Alan Garfinkel², Christopher B. Cooper². ¹*U.S. Army-Baylor University, San Antonio, TX.* ²*UCLA, Los Angeles, CA.*
 Email: bolanddpt@gmail.com
 (No relationships reported)

PURPOSE: A positive relationship between exercise and cognition has been observed in the developing brains of school children and the degenerating brains of elderly adults. However, this relationship remains relatively unstudied in the fully functioning brains of young adults. Brain-derived Neurotrophic Factor (BDNF) is known to promote neurogenesis and long-term potentiation within the hippocampus and is believed to mediate the effect of exercise on brain structure and function. A recently discovered myokine, irisin, may upregulate expression of hippocampal BDNF in response to exercise. This study explored the impact of fitness on cognition in graduate students and considered BDNF and irisin as potential mediators of the relationship. **METHODS:** Forty-four apparently healthy graduate student participants (19 women) completed a comprehensive online cognitive assessment (Lumosity™) and an incremental maximal treadmill exercise test immediately followed by blood collection. Aerobic fitness was measured in terms of maximum oxygen uptake (VO₂max) during the exercise test and expressed relative to body mass (mL/kg/min) for data analysis. Plasma concentrations of BDNF and irisin were determined by enzyme-linked immunosorbent assay (ELISA).

RESULTS: Participants were 26.0 (23.0-28.3) years old, with 19.4 (12.1-24.7) % body fat and a VO₂max of 44.8 (38.3-53.5) mL/kg/min; median (IQR). The median score on the cognitive assessment was 63.5 (55.8-74.0) %. The median plasma BDNF concentration was 1.00 (0.28-2.09) ng/mL and irisin was 19.79 (16.98-24.65) ng/mL. Significant correlations between aerobic fitness and performance on the cognitive assessment were not found. An inverse relationship was observed between aerobic fitness and BDNF ($\rho=-0.32, P=0.03$), as well as irisin ($\rho=-0.27, P=0.11$). Irisin was moderately and positively correlated with cognitive assessment score ($\rho=0.33, P=0.03$).

CONCLUSIONS: Irisin may be a valuable peripherally detectable marker of cognitive ability. An inverse relationship between fitness and irisin is inconsistent with the original understanding of irisin's role. The lack of correlation between aerobic fitness and cognitive performance may suggest the presence of a cognitive ceiling, above which the benefits of exercise on cognition significantly taper off.

The Effects of Exercise Intensity on Cognition In Adults Age 18-45
 Said Mekary¹, Meghan Earl¹, Melanie Killen¹, Olivier Dupuy².
¹Acadia University, Wolfville, NS, Canada. ²Université de Poitiers, Poitiers, France.
 Email: said.mekary@acadiau.ca
 (No relationships reported)

Purpose: Growing evidence suggests that moderate intensity continuous training (MICE) appears to improve cognition function. Physical activity to improve cognitive function is thus strongly recommended, however evidence regarding the training intensity is still lacking. The purpose of this randomized study was therefore to assess the effects of a high intensity interval training (HIIT) compared to MICE, representing the same total training load, for improving cognitive functions in healthy adults. **Methods:** Twenty-five participants exercised three times a week for 6 weeks after randomization to the HIIT or MICE training group. Target intensity was 60 % of maximal aerobic power (MAP) in the MICE group and 100% MAP in the HIIT group. A maximal graded test, a cognitive battery of paper tasks and a computerized Stroop task, were performed before and after the six weeks training program. **Results:** After training, MAP increased significantly in both the HIIT and MICE groups (9% and 15 %, $p < 0.01$). The cognitive results from this study showed that after 6 weeks of training HIIT was mainly associated to a greater improvement of overall reaction time in the executive components of the computerized Stroop task (980.43 ± 128.97 ms vs 890.89 ± 109.45 ms, $p < 0.01$). Participants in the HIIT training also improved their test time in the executive component of the Trail test after 6 weeks of training (42.35 ± 14.85 s vs 30.35 ± 4.13 s, $p < 0.01$). **Conclusion:** Exercise intensity was clearly an important factor for improving executive functions in young adults. These findings may have important implications in designing effective training programs to help improve cognition in different populations.

Time-Dependent Effects of Acute Cycling Exercise On Long-Term Emotional Memory and Salivary Alpha-Amylase
 Lauren R. Weiss¹, Andrew C. Venezia², Kenyon U. Aguilar³, Sasa E. Vann⁴, J. Carson Smith, FACSM¹. ¹University of Maryland, College Park, MD. ²University of Scranton, Scranton, PA. ³University of New Mexico, Albuquerque, NM. ⁴Buffalo State College, Buffalo, NY. (Sponsor: J. Carson Smith, FACSM)
 Email: lrweiss@terpmail.umd.edu
 (No relationships reported)

Psychological research has strongly documented the memory-enhancing effects of emotional arousal. Current opinion implicates the central release of stress hormones, specifically norepinephrine, as the neurobiological basis for this enhancement. Experimental induction of arousal has been shown to enhance long-term memory in a time-dependent manner. While extensive research has provided evidence for the memory benefits of exercise training, the effects of an acute bout of exercise on long-term memory are not as well understood. Furthermore, acute exercise of a sufficient intensity and duration stimulates norepinephrine release. This presents an opportunity to investigate the role of acute exercise-induced arousal in the modulation of long-term memory. **PURPOSE:** The purpose of this study was to determine the time-dependent relationship between acute exercise-induced arousal and long-term emotional memory. **METHODS:** Forty healthy young adults (22±4 yrs) were randomly assigned to an exercise-before, exercise-after, or rest group. Participants in the exercise groups completed a high-intensity session of cycling exercise before or after viewing pleasant, neutral, and unpleasant images. Exercise intensity was prescribed using Borg's Ratings of Perceived Exertion (RPE) scale, and participants were instructed to exercise at an intensity of 15 ('Hard'). Salivary α -amylase (sAA), a noninvasive biomarker of noradrenergic activation, was measured as an indicator of arousal. A recognition memory test was administered after a 48-hour delay. Memory data were submitted to a 3×3×2 (Group × Valence × List) mixed ANOVA. The sAA data ($n = 33$) were submitted to a 3×4 (Group × Time) mixed ANOVA. **RESULTS:** No effect of Group or Valence on recognition memory was revealed, however; high-intensity cycling (159 ± 18 bpm) increased sAA in both exercise groups, indicated by a significant Group × Time interaction, $F(6,90) = 6.995$, $p = .001$, $\eta^2 = 0.318$, and confirmed with paired t -tests ($p < .05$). **CONCLUSION:** We demonstrated that an RPE-prescribed 'hard' bout of cycling exercise resulted in increased sAA. Further investigation is needed to draw conclusions about the memory-enhancing potential of acute aerobic exercise. Supported by the University of Maryland Kinesiology Graduate Research Initiative Fund.

Changes In Cortical Neural Arousal As A Result Of Increasing Exercise Intensity
 Nicholas J. Hanson, 49008, Taylor L. Lee, Nicholas Cherup, Timothy Michael, FACSM, Michael Miller. Western Michigan University, Kalamazoo, MI.
 (No relationships reported)

Exercise has been shown to affect central nervous system arousal, which in turn may impact cognitive performance during certain tasks. What is not known is if there is an intensity threshold for these effects to occur. **PURPOSE:** To investigate changes in cortical neural arousal as a result of increasing exercise intensity. **METHODS:** This study included 22 recreational runners (12 women, 10 men) with a mean (SD) age of 25.1 (6.2) years. Subjects were asked to complete three 30 minute runs on a motorized treadmill at prescribed rating of perceived exertion (RPE) levels of 13, 15 and 17. These correspond to the verbal descriptors of "somewhat hard," "hard," and "very hard," respectively. Individuals were blind to the treadmill control panel but allowed to adjust their speed throughout the trials in order to maintain the prescribed RPE. Prior to and immediately after each exercise session, subjects were asked to complete a critical flicker fusion threshold test (CFFT). This test is designed to assess cortical neural arousal via visual stimuli and requires individuals to determine the precise moment in which a low frequency flashing light fuses into a solid light (ascending) and vice versa (descending). Subjects identified the change by pressing a handheld button on a wired remote. The final value was an average of three ascending and descending values. **RESULTS:** No changes occurred from pre (37.5 ± 3.8 Hz) to post (37.4 ± 4.2 Hz) exercise at RPE13 ($p = 0.729$). Similarly, pre (37.1 ± 4.2 Hz) and post (37.7 ± 4.4 Hz) values did not differ at RPE15 ($p = 0.082$). However, there was a significant increase from pre (36.7 ± 3.6 Hz) to post (37.8 ± 4.8 Hz) values after exercise at RPE17 ($p = 0.019$). **CONCLUSIONS:** These results confirm that a specific threshold exists where cortical sensitivity is determined by the intensity level of exercise. These findings may be useful when considering ways in which to enhance cognitive performance during certain tasks that require substantial focus and attention. Increases in cortical arousal as the result of exercise could positively affect cognitive functioning, and could be advantageous for athletic, professional, and military populations.

Habitual Physical Activity Moderates the Negative Influence of Adiposity on Cognitive Control
 Nicholas W. Baumgartner, Anne M. Walk, Caitlyn G. Edwards, Alicia R. Covello, Morgan R. Curran, Ginger E. Reeser, Andrew M. Taylor, Hannah D. Holscher, Naiman A. Khan. University of Illinois, Champaign, IL.
 Email: nbaumg2@illinois.edu
 (No relationships reported)

PURPOSE: To assess the moderating influence of time spent engaging in moderate to vigorous physical activity (MVPA) on the known inverse relationship between adiposity and cognitive control. **METHODS:** Bivariate correlations and hierarchical linear regression analyses were conducted among a sample of adults between 25-45 years ($N = 65$, 39 females). Subjects completed a modified version of the Eriksen Flanker task to assess cognitive control, specifically attentional inhibition. Whole body adiposity (%Fat) was assessed using Dual Energy X-ray Absorptiometry (DXA). Daily percent time spent engaging in MVPA (> 1951 counts per minute) was monitored using an accelerometer (Actigraph GT3X+) worn for at least 4 days (minimum 8 hours/day). **RESULTS:** After adjusting for significant demographic variables (age and IQ), %Fat was a negative predictor of attentional inhibition ($\beta = -0.32$, $P = 0.02$) such that those with higher %Fat exhibited lower inhibitory control, as measured by incongruent Flanker task accuracy. Interestingly, the negative effect of %Fat ($\beta = -0.21$, $P = 0.13$) was mediated after controlling for the influence of %MVPA. Furthermore, hierarchical linear regression analyses revealed an added positive effect of %MVPA on incongruent Flanker task accuracy ($\beta = 0.30$, $P = 0.03$), with those spending a higher percentage of time engaged in MVPA demonstrating higher attentional inhibition. **CONCLUSIONS:** Although previous research has examined the relationship between excess fat mass and cognitive function, the influence of habitual physical activity in moderating this relationship has received comparatively less attention. These results replicate previous work linking excess fat mass to lower cognitive control while extending the body of literature by demonstrating that habitual moderate to vigorous activity mediates this influence while independently and positively predicting cognitive control. These findings have implications for public health policy advocating for greater daily MVPA for cognitive health among adult populations. Funded by the Department of Kinesiology and Community Health at the University of Illinois and the Hass Avocado Board.

835 Board #14 May 31 2:00 PM - 3:30 PM
Training-Induced Modulation of Cerebral Blood Flow and Cognition
 Gilbert F. Acosta, Joel Ramirez, Jose Benavidez, Christine Dy, Stefan Keslacy. *California State University Los Angeles, Los Angeles, CA.*
 Email: Gacost14@calstatela.edu
 (No relationships reported)

Exercise may be a means to ameliorate the progression of cognitive decline in older adults, although the mechanisms underlying exercise-induced neuroprotection are not well understood.

Purpose: (i) To assess cerebral hemodynamics under exercise-induced stress on cognitive function; (ii) To determine the cerebral changes occurring during cognitive tasks; We hypothesized that these effects will be different with training.

Methods: Right-handed college-aged adults (28 sedentary and 24 athletic) performed 10 minutes of light and moderate (20% and 65% max power) constant-load cycling. Right middle cerebral artery (rMCA) blood flow velocity (CBFv) was continuously monitored during exercise and cognitive test using Transcranial Doppler ultrasonography (TCD). Cognition was assessed using the Cogstate brief battery test: Detection (psychomotor function/ processing speed), Identification task (visual attention), One-card learning (Visual learning & memory), One-back task (working memory) and Groton maze (for visuospatial memory) before and immediately after exercise.

Results: Exercise increased CBF during 20% but this was not significant for either group. Exercise at 65% decreased CBF with a significant decrease of -9.6% ($p < .05$) for athletes. It also decreased for sedentary individuals but it was not significant. Cognitive performance improved significantly during the ONB with a significant increase in reaction time (RT). At 20 and 65% for sedentary and only at 65% for athletes. Speed on the Groton Maze test increased following exercise at 65% however this increase was associated with a significant increase in number of errors in the sedentary participants. Athletes demonstrated increased Groton maze speed however no significant change in errors (1.3%). Athletes also demonstrated an increase in RT for the ONB only following exercise at 65%.

Conclusion: Training status may demonstrate adaptations to cerebral blood flow and cognition.

Differences In Brain Structure And Function Among Yoga Experts And Controls
 Neha P. Gothe, Jessica S. Damoiseaux. *Wayne State University, Detroit, MI.*
 Email: nehagothe@wayne.edu
 (No relationships reported)

Yoga is a mind body based physical activity that has demonstrated a variety of physiological and psychosocial benefits. Recent studies have also examined the benefits of this practice on behavioral measures of cognitive function. **PURPOSE:** To determine the effect of yoga practice on brain function and structure by examining: i) differences in brain activation, and ii) differences in grey matter volume of subcortical structures among yoga-experts and controls. **METHODS:** Participants included 13 yoga experts, defined as having more than 3 years of regular yoga practice, and age-sex-matched controls. All participants completed a 6-minute walk test to assess fitness, psychosocial and demographic questionnaires. They were scheduled to complete a 3T MRI scan lasting one hour, during which the Sternberg working memory task was administered. **RESULTS:** The mean age of the participants was 35.8 and 35.7 respectively and the experts on average had 9.3 years of yoga experience. There were no groups differences on demographic measures of income, education, personality, and on estimated VO₂max (6-minute walk) or physical activity assessed using the Godin leisure time exercise questionnaire. Experts showed less activation in the frontal pole area of the prefrontal cortex compared to controls during the encoding phase of the Sternberg task. Reaction time and accuracy on the task did not differ between the two groups. We investigated grey matter volume differences in the hippocampus, thalamus, and caudate nucleus and the left hippocampal volume was found to be greater in yoga experts compared to controls. **CONCLUSION:** Our preliminary results suggest that regular long-term yoga practice affects selective structures and neural networks in the brain. The literature on behavioral studies of yoga appears to corroborate these findings as the frontal pole and hippocampal areas have been implicated in performance on executive function measures. Future studies need to examine intervention effects of yoga and explore the potential of this practice to maintain and improve cognitive health across the lifespan.

Effects of a Combined Aerobic and Cognitive Training Intervention on Cognitive Function in Cancer Survivors
 Brent M. Peterson¹, Cynthia Johnson², Kaylene Case², Daniel Y.K. Shackelford², Jessica M. Brown², Trent L. Lalonde², Reid Hayward². ¹*Biola University, La Mirada, CA.* ²*University of Northern Colorado, Greeley, CO.*
 Email: brent.peterson@biola.edu
 (No relationships reported)

INTRODUCTION: Cancer-related cognitive impairment (CRCI) has been reported to negatively affect upwards of 75% of cancer patients undergoing treatment. Treatment and management of CRCI has proven to be a difficult task due to the fact that it has yet to be fully characterized. Some studies have shown that cognitive training or aerobic exercise may mitigate aspects of CRCI. Yet, it is unclear whether simultaneously combining these two interventions could provide additive or synergistic benefits on cognitive function in cancer survivors. **PURPOSE:** To determine the effects of a quasi-randomized, controlled aerobic and cognitive training intervention on cognitive function in cancer survivors ($N = 28$). **METHODS:** Pre and post physical and cognitive assessments were administered. A 36-session computer-based cognitive, aerobic, and flexibility training intervention was completed. Participants were assigned to one of the following groups: aerobic exercise only (AER), cognitive training only (COG), simultaneous aerobic exercise plus cognitive training (AER+COG), or a control flexibility only group (CON). **RESULTS:** No significant ($p > 0.05$) main effects between groups and variables were observed. Within groups measures revealed that the AER logical memory scaled scores (+33%), delayed recall scaled scores (+27%), block design scaled scores (+19%), and letter-number sequencing scaled scores (+12%) significantly increased ($p < 0.05$, respectively) pre-to-post. The CON group significantly ($p < 0.05$) increased from pre-to-post in controlled oral word association gender, age, and education verbal fluidity subtests (Z-scores). All cognitive scores (AER+COG and COG groups) failed to significantly ($p > 0.05$) increase pre-to-post. **CONCLUSIONS:** Aerobic training alone had the greatest impact on cognitive function. Individually, these methods may be appropriate for addressing CRCI in this population, but combined training of this nature may be too demanding for cancer survivors suffering from CRCI.

Golf Intervention For Veterans Exercise: Can Golf Influence Gait Speed And Cognition In Older Veterans?
 Nicole A. Marcione, Andrea M. Du Bois, George S. Salem, FACSM. *University of Southern California, Los Angeles, CA.*
 (No relationships reported)

Gait speed is an important predictor of successful aging. For example, slow gait speeds are associated with poor health outcomes and decreased dual-task (DT) walking performance is associated with increased fall risk. We hypothesize that golf may improve gait speed, DT gait speed, and cognitive function in older military veterans. **PURPOSE:** The objective of the present study was to examine the influence of a 12-week golf intervention on walking performance and cognitive function in older military veterans. **METHODS:** Gait speed and cognition were measured before and after a 12-week golf intervention (2 x weekly; 90 min per session). Two male participants (74 and 67 years old) completed 5 gait trials walking as fast as possible, 5 dual-task gait trials walking as fast as possible while performing a backwards counting task, and the Dimensional Change Card Sort Test, Flanker Inhibitory Control and Attention Test, List Sorting Working Memory Test, Picture Sequence Memory Test, and Pattern Comparison Processing Speed Test, which make up the Fluid Cognition composite score of the NIH Cognition Toolbox. **RESULTS:** Participants improved gait speed by 5.3% and 15.8% and fast DT gait speed by 29.2% and 26.1%. Fluid Cognition composite scores improved by 11% and 1% and the percent change in DT accuracy were -2.9% and 0%. **CONCLUSION:** Following the 12-week golf intervention, both participants improved their fast gait speed, fast DT gait speed, and fluid cognition function. There was little to no decrease in counting accuracy during the fast DT gait speed. These results demonstrate that the participant's improved gait speeds were not at the expense of maintaining cognitive performance. These preliminary findings suggest that the physical and cognitive demands of golf (navigating the course, walking hilly terrain, bending over, swinging, shifting the center-of-pressure, planning and strategizing) may improve physical and cognitive function in older military veterans. Future expansion of this study will inform the development of golf programs to improve everyday function and quality of life in older adults.

Changes in Cognition and Power Output in Adults Following High-Velocity Circuit Resistance and Treadmill Training

Sean Chowdhari, Kirk Roberson, Melanie Potiaumpai, Kayla Widdowson, Annmarie Jaghab, Catherine Armitage, Katherine McGriff, Kevin A. Jacobs, FACSM, Joseph F. Signorile. *University of Miami, Miami, FL.* (Sponsor: Kevin A Jacobs, FACSM)
Email: kxr181@miami.edu
(No relationships reported)

Previous studies report that increases in aerobic capacity produce improvements in cognition. However, the effects of power training on cognitive domains are not well understood. **PURPOSE:** To compare the effects of high-velocity circuit resistance (CRT), treadmill (TM) training and no exercise (CONT) on cognitive domains and power output in older adults. **METHODS:** Fifteen subjects (2M, 13F; 71.3 ± 2.5 yr) participated in 12-wks of CRT, TM or CONT. Executive function (EF)/attention, EF, episodic memory, working memory, processing speed and overall cognition were measured by the flanker (FL), dimensional card sort (DCS), picture sequence (PS), list sorting (LS), pattern comparison (PC), and composite score (CS), respectively, using the NIH Cognition Battery. The walking response and inhibition test (WRIT) also assessed EF. A global score (GS) was determined by the WRIT. Aerobic power (AP) was determined from a peak oxygen consumption test, and lower body power (MP) by a chair stand. **RESULTS:** A between-groups analysis revealed significant decreases in MP (MD= -269.3, SE= 91.6, p=.04) for TM compared to CONT and a decrease approaching significance compared to CRT (MD= -213.7, SE= 81.9, p=.07). There was a significant main effect for AP (p=.05, n_{2p}=.448) with a trend towards an increase for TM compared to CONT (MD=2.4, SE=1.0, p=.09) and CRT compared to CONT (MD=2.5, SE=1.0, p=.07). No significant interactions were present for cognitive measures. Within-group analyses revealed a significant increase in PC (MD=12.6, SE=4.9, p=.04), a decrease in MP (MD=-205.3, SE=56.9, p=.01), and a trend towards an increase in LS (MD=9.8, SE=4.7, p=.08) and GS (MD=33.1, SE=16.2, p=.07) for TM. For CONT, there was a significant decrease in PC (MD=-12.8, SE=4.9, p=.04) and AP (MD=-2.4, SE=.8, p=.02). Correlation analyses revealed a strong positive association between AP and FL (r=.99, p=.008), MP and GS (r=.97, p=.03), and an inverse correlation between MP and AP (r=-.97, p=.03) and MP and FL (r=-.93, p=.02) for CRT. A strong positive correlation was observed for AP and FL (r=.96, p=.03) for TM, and an inverse correlation between MP and FL (r=-.99, p=.04) for CONT. **CONCLUSION:** TM and CRT resulted in an increase in AP compared to CONT that corresponded to improvements in EF and WRIT performance, however, only TM exhibited significant decreases in MP.

Differences Between Functional Fitness and Cognitive Impairment in Independent Older Adults in the Community

Linda L. Lin, Yen-Ting Shen, Nai-Hsin Yang, Wei-chi Tseng, Tai-you Lin. *National Cheng Kung University, Tainan, Taiwan.*
Email: lin22@mail.ncku.edu.tw
(No relationships reported)

PURPOSE: The purpose of this study is to examine the performance of functional fitness in a community-dwelling elderly population with different levels of cognitive impairment. **METHODS:** 316 community-dwelling older adults aged 60 to 91 years were divided into normal cognitive group (NOR, N=84, 68.5±0.76 yrs), mild cognitive impairment group (MCI, N=124, 71.8±0.62 yrs) and serious cognitive impairment (SCI, N=108, 75.8±0.67 yrs) group using the Saint Louis University Mental Status (SLUMS) examination. The Senior Functional Fitness Test (SFFT) was used to measure upper muscle strength (30-second arm curl), lower muscle strength (30-second chair-to-stand), aerobic endurance (two-minute step), upper (back scratch) and lower flexibility (chair sit-and-reach), agility and dynamic balance (eight-foot up-and-go). **RESULTS:** There was a significant relationship between the SLUMS score and SFFT (p<.05). The NOR subjects scored significantly higher than the SCI subjects in BMI(5%), lower- and upper-body strength (33.1%; 17.4%), max strength (22.5%), upper- and lower-body flexibility (102.1%; 83.1%), cardiovascular endurance (16.2%) and dynamic balance (29.5%) (p<.05). The MCI subjects also had better performance than the SCI group with regard to lower- and upper-body strength (23.9%; 13.7%), cardiovascular endurance (13.8%), upper- and lower-body flexibility (71.3%;34.0%), and dynamic balance (20.5%) (p<.05). Furthermore, there were no significant differences between MCI and NOR group in cardiovascular endurance and muscle strength. **CONCLUSIONS:** The level of cognitive impairment was correlated to the degree of body composition and functional fitness in the group of community-dwelling elderly adults examined in this work, influencing muscle strength, flexibility, cardiovascular endurance and dynamic balance. The MCI period is perhaps the key phase during

which it is still possible for most elderly people to return the normal condition of functional fitness in cardiovascular endurance and muscle strength. Therefore, the any director or interventions aimed at achieving this should be properly developed modified to reflect the elderly subject adult's level of cognitive abilities.

Peak Heart Rate during the 6-Minute Walk Test Predicts Cognitive Performance of Healthy Older Adults

Nicole S. Spink, Erik A. Anderson, Ranier Castillo, Roger A. Chandler, Tori Coleman, Cathy Inouye, Sherri N. Morioka, Michel Ossene, Pavel V. Romanovski, Jennifer J. Sherwood, Joaquin S. Tabera, Shannon L. Webb, Yan Yan Zhou. *California State University, East Bay, Hayward, CA.*
(No relationships reported)

Purpose: Cardiorespiratory fitness positively correlates with cognitive function in healthy older adults (Barnes et al., 2003) and quality of life depends on maintaining cognitive and physical health (Ortman et al., 2014). The submaximal 6-minute walk test (6MWT) is a commonly used clinical assessment of cardiorespiratory fitness in older adults, but the relationship between 6MWT and cognitive performance remains undefined. Here, we tested the relationship between 6MWT and cognitive performance in healthy, ethnically diverse older adults. **Methods:** In this cross-sectional study, 90 participants (69 female, 21 male), ages 60-95 years (75 + 9.5 yrs.; mean + SD), were recruited from the local area. Cognitive performance was measured in the Modified Mini-Mental State Test (3MS), Trailmaking tests A and B, and Animal Naming test. Physical measures included 6MWT active and recovery heart rates, distance walked, anthropometric data, peak hand-grip strength, and surveys including Physical Activity Scale for Elderly (PASE) and Perceived Stress Scale (PSS). Stepwise multiple regression analyses were used to evaluate the contributions of 6MWT performance and physical measures to cognitive performance. **Results:** Mean 3MS scores (92.5 + 7.7) revealed that our population was cognitively healthy. Controlling for demographic covariates, peak heart rate recorded during the 6MWT (6MWT HR_{PEAK}) significantly predicted performance on 3MS (R²=0.462, p<0.001), and Trailmaking A (R²=0.328, p<0.001) and B tests (R²=0.379, p<0.001). Controlling for age and education level, PASE was found to significantly predict Animal Naming test performance (R²=0.309, p<0.001). **Conclusion:** Results suggest that peak exercise intensity, as determined by 6MWT HR_{PEAK}, significantly contributes to executive function and self-reported physical activity levels with verbal fluency.

PURPOSE: Physical activity (PA) are important for maintenance and improvement of cognitive health as well as prevention of non-communicable diseases. We are conducting a 2-year (2015-2017) community-wide campaign to promote PA in Fujisawa city, Kanagawa, Japan. The campaign contains multilevel interventions. As a part of these interventions, community-dwelling elderly groups who commit doing exercise together at least once a week were registered. We analyzed the baseline data and examined the relationship between PA, fitness levels and cognitive function. **METHODS:** Participants were 157 elderly group. Physical activity levels were assessed using a triaxial accelerometer for 1 week. We used steps and duration of moderate-to-vigorous PA as indicators of PA level. In terms of fitness level, one foot standing, grip power, chair stand test and sit & reach test were examined. Cognitive function were assessed by Cognitive Assessment for Dementia iPad version 2 (CADi2) which consists of 10 simple questions and is self-administered. We dichotomized CADi2 score as less than 9 (low) and 9 or 10 (high) and compared physical activity level, physical fitness level between the two groups using unpaired t-test. **RESULTS:** The sample consisted of 104 women (age: 76.0±6.9 yrs, mean±SD) and 53 men (74.4±5.1 yrs). CADi2 score (median (25-75%tile)) was 9 (8-10) in women and 9 (9-10) in men, respectively. Other results were shown in the table. **CONCLUSION:** Fitness level of low-score elderly of cognitive function is tend to lower compared to high-score elderly. Longitudinal observation with intervention is necessary to know further relationships. Supported by Comprehensive Research on Aging and Health Science Research Grants for Dementia R&D from the Japan Agency for Medical Research and Development (AMED).

 (No relationships reported)

Exercise training is gaining attention regarding its role in the prevention and treatment of Alzheimer's disease (AD). **PURPOSE:** The purpose of our meta-analysis was to evaluate: the effect of exercise on cognitive function in individuals at risk for or diagnosed with AD; potential moderators of the cognitive effects of exercise; and whether the cognitive effects of exercise are dependent upon *Frequency, Intensity, Time, and Type (FITT)* of the exercise. **METHODS:** Databases were searched for trials that measured pre- and post-exercise cognitive function in adults at risk for or diagnosed with AD. Analyses followed random-effects assumptions. **RESULTS:** 19 studies with 23 interventions qualified with 1,256 subjects (71.1% women; 28.3% men) that were 77.0±7.5yr and who completed 9.2±4.3yr of school. A majority of the sample was at risk for AD due to mild cognitive impairment (64%), another 1% was at risk due to a parent diagnosed with AD, and 35% had AD. Exercise interventions were performed at vigorous intensity for older adults (3.7±0.6 metabolic equivalents) for 3.4±1.4 d·wk⁻¹, 45.2±17.0 min-session for 18.6±10.0 wk. A majority were aerobic exercise training (AET) interventions (65%) and 35% other types (i.e., concurrent [31%] or resistance exercise training [4%]). Only questionnaires were used to assess cognitive function with the Mini-Mental State Examination most commonly used (61%). Overall, there was a positive, moderate effect of exercise on cognitive function versus control (standardized mean difference [SMD]=0.47, 95% confidence interval [CI]=0.26, 0.72; P=59.6%). The within group analysis revealed exercise improved cognitive function (SMD=0.20, 95% CI=0.11, 0.28; P=0%), whereas cognitive function declined in the control group (SMD=0.18, 95% CI=0.36, 0.00; P=65.1%). Furthermore, AET had a strong, positive effect on cognitive function (SMD=0.66, 95% CI=0.30, 1.02), whereas the other exercise types did not (SMD=0.19, 95% CI=-0.12, 0.49). **CONCLUSIONS:** Our findings suggest that exercise may reverse the decline in cognitive function that occurs among older adults who are at risk for or have AD, with favorable exercise effects that are largely mediated by AET. Future randomized clinical trials that include objective measurements of cognitive function are needed to confirm our novel findings.

Square-stepping exercise (SSE) is a visuospatial working memory task with a cued stepping response; it has demonstrated mobility and cognitive benefits in older adults. **PURPOSE:** To explore whether a SSE program is feasible in long-term care (LTC) and retirement living (RL) facilities in populations with diverse mobility and cognitive abilities. **METHODS:** A cluster-randomized trial was conducted; 4 sites (2 LTC and 2 RL) were randomized to SSE [2x/wk for 12-wks by trained kinesiologists (kings)] or control (CON). Recruitment, attendance, program fidelity, and feedback were monitored throughout the program. **RESULTS:** All residents were invited to participate; in the intervention sites, there were 192 and 144 beds for the LTC and

RL, respectively. Recruitment was via information sessions. Intervention participants (n=30) were 80.5 ± 13.2 yrs old, 77% female, and had 12.2 ± 3.2 years of education. In LTC (n=15) there was an average of 5.5 residents in attendance at each session ranging from 3-9 over 19 sessions. LTC residents attended an average of 45.6% sessions (range: 10.5-79.0%); 6 attended >50% of sessions. In RL (n=15) there was an average of 7.8 residents in attendance at each session ranging from 3-12 over 24 sessions. RL residents attended an average of 21% of sessions (range: 8.3-75%); 8 attended >50% of sessions. To maintain a pragmatic approach, SSE was modified following feedback: sessions were reduced from 60 to 45 min; residents who used gait aids were assisted by kins; and in LTC program, progression was limited. Residents in RL became peer-coaches to assist kins and act as moderators. Anecdotal feedback from kins and residents was positive, with comments about SSE being fun but also a 'good' challenge; both sites have continued the program. **CONCLUSIONS:** Recruitment for this study was considered a success from the perspective of the LTC and RL facilities. Attendance was variable; it is understandable with a variety of mobility and cognitive abilities that achieving perfect attendance is unlikely. It is reasonable, with program modifications and flexibility in program progression, for this to be a feasible program for adults living in LTC and RL facilities to engage physically, cognitively and socially. **FUNDING:** Western Centre for Studies in Family Medicine, Schlegel Villages and Ontario Graduate Scholarship.

It is recognized that visual cognitive abilities is an important characteristic of athletic performance, however, testing, training and determination of factors that influence this ability has been elusive. **PURPOSE:** The purpose of the Nutrition, Vision and Cognition in Sport Study (IONsport) is to determine the factors that explain the large difference in visual cognitive performance and training responses between elite and non-elite athletes. **METHODS:** College age men and women performed 15 visual cognitive training sessions in 10 visits to the laboratory (all 10 visits within 15 days). On the days of training, all food intake was documented along with measures of body composition, sleep patterns, fluid intake and recent exercise. Longer term assessments of these and other factors were measured prior to initiating training. Mean nutritional intakes were calculated for the 10 days of food records. **RESULTS:** Excluding results from the initial training session in which variability was high, participants increased visual cognitive performance by 27.5% (P<0.001) which was not significantly different (P>0.05) between men (32.1%) and women (24.1%). Linear regression was performed using select nutritional candidates (based on literature evidence and using mean 10 day intake) and non-nutritional factors to predict trained visual cognitive performance. Nutritional copper (r²=0.237, p=0.01) and percent body fat (r²=0.11, P=0.027) entered the significant model (P=0.001). Mean visual cognitive performance improvement for copper intakes that were 16-47%, 50-109% and 132-346% of the Dietary Reference Intake (Recommended Dietary Allowances, RDA) were 10.1%, 22.6% and 43.1%, respectively. **CONCLUSION:** These results suggest that dietary copper intake at or below the RDA may impair visual cognitive training performance and more broadly suggest that visual cognitive performance is more than an innate ability.

Different Influences Of Aerobic Exercise Types On Cognitive Control Of Athletes

Junyeon Won. University of Maryland at College Park, College Park, MD. (Sponsor: J. Carson Smith, FACSM)
 Email: andrewon1990@gmail.com
 (No relationships reported)

Acute exercise has been shown to improve executive function, and in particular performance on tasks that measure inhibitory control. However, few studies have compared laboratory-based exercise sessions to more complex modes of exercise, such

as soccer, that involve attention to multiple aspects of the environment and for which performance success depends on the active engagement of executive control processes. **PURPOSE:** To compare the effects of acute treadmill exercise versus futsal (indoor soccer) on performance and electroencephalographic event-related potentials measured during an inhibitory control task. **METHODS:** Twelve experienced soccer players (24.8±2 years) completed three counterbalanced 20-minute sessions of: 1) seated rest; 2) moderate intensity treadmill exercise; and 3) a game of futsal. Once heart rate (HR) returned to within 10% of pre-activity levels, participants completed the Stroop Color Word Conflict Task while reaction time (RT) and P300 event-related potentials were measured. **RESULTS:** HR did not significantly differ during treadmill exercise (122.4±5.4 bpm) compared to futsal (126.7±6.7 bpm). Reaction time during Stroop performance was significantly faster following the futsal game (765±29 ms) compared to seated rest (835±28 ms), but was not significantly different than treadmill exercise (784±22 ms). However, the P300 amplitude at three midline recording sites was significantly greater following futsal ($F_z=5.77±2.87$; $C_z=4.84±1.66$; $P_z=4.25±1.43$ μV) compared to both the treadmill exercise ($F_z=4.96±2.66$; $C_z=4.02±2.58$; $P_z=3.7±1.02$ μV) and seated-rest conditions ($F_z=4.19±1.58$; $C_z=3.12±1.69$; $P_z=3.09±1.42$ μV). **CONCLUSIONS:** These findings suggest that single bouts of indoor soccer among college-aged soccer players, compared to treadmill and seated-rest conditions, may engender the greatest effect on brain networks controlling attention allocation and classification speed during the performance of an inhibitory control task. Future research is needed to determine if cognitively engaging forms of sport-related aerobic exercise may differentially impact executive control processes in less experienced and older adult participants.

The Effects of Repeated, Consecutive High-Intensity Exercise on Cognitive Performance in Well-Trained Team Sports Players

Sarah E. Browne¹, Barry V. O'Neill¹, Phillip G. Bell¹, Ken van Someren¹, Glyn Howatson, FACSM², Crystal F. Haskell-Ramsay². ¹GSK Human Performance Lab, Brentford, United Kingdom. ²Northumbria University, Newcastle-upon-Tyne, United Kingdom.

 (No relationships reported)

Improvements in cognitive performance and mood are generally accepted following moderate intensity exercise; however, the impact of high-intensity exercise is less clear. Given that professional team sports are performed at high or maximal intensity, which can be further compounded during periods of intensified periods of competition, investigations into the effect of such exercise on cognition are needed. **PURPOSE:** To determine the effect of repeated high-intensity exercise on cognitive function, mood and perceptions of both physical and mental energy, and fatigue. **METHODS:** In a counterbalanced crossover design, twenty-four well-trained, sub-elite rugby players (mean ± SD age, height, mass were 20.7 ± 1.9 yrs, 181.7 ± 5.5 cm, 88.2 ± 9.0 kg, respectively) completed a series of repeated sprints (20 x 20 m, three times per day for two consecutive days) or a seated control. Prior to and following each set of sprints or equivalent control duration, a selection of cognitive tests including simple reaction time, four-choice reaction time (FCRT), Corsi blocks and Stroop task (ST) were completed in addition to visual analogue scales assessing mood, energy and fatigue. Repeated-measures ANOVAs were conducted with pairwise comparisons where necessary ($\alpha = 0.05$). **RESULTS:** No changes were observed in any cognitive, mood, energy or fatigue measures after one single high-intensity session. However, compared to the control, ST accuracy was lower in the exercise condition (-0.6%, $P < 0.05$) which was largely due to a sharp decline at bout 3 on day 1 that continued throughout day 2. Additionally, FCRT was slower on day 2 (+2.2%) whilst feelings of alertness (-12%), contentedness (-5%), and physical (-22%) and mental (-24%) energy were reduced and ratings of physical (+22%) and mental (+40%) fatigue increased (all day 2 vs. day 1, $P < 0.05$). No changes were observed in the control condition. **CONCLUSION:** Intensified periods of exercise have detrimental effects on cognitive performance, mood and perceptions of physical and mental energy, and fatigue. The deleterious effects on these parameters could be contributing to increased injury rates during fixture congestion alongside decrements in performance. Player rotation may help alleviate these effects whilst also prompting further research into cognitive recovery strategies.

Injury-Related Reductions in Skilled Visuomotor Learning Revealed by Single Trial Analysis and Response Time Variability

Courtenay Dunn-Lewis¹, Shawn D. Flanagan¹, James A. Onate², Jeff S. Volek², Carl M. Maresh, FACSM², William J. Kraemer, FACSM². ¹University of Pittsburgh, Pittsburgh, PA. ²Ohio State University, Columbus, OH. (Sponsor: William J. Kraemer, Ph.D., FACSM)
 (No relationships reported)

Classical psychometric tests emphasize measures of central tendency as it relates to response times, contact times, and errors. More sophisticated techniques, however, may complement neurophysiological measures of neuroplasticity in response to behavioral interventions or changes in intrinsic state. **PURPOSE:** To determine whether learning on a skilled lower extremity visuomotor task was affected by prior ACL injury. **METHODS:** Eighteen healthy women between 18 and 32 yr participated. Nine women served as controls; nine others had unilateral ACL reconstruction between 6 months and 5 years from the start of the investigation. All participants completed 120 trials of a choice reaction test with a Stroop-like effect and randomly-ordered stimulus presentation order (3 sets of 40 repetitions with 30 sec rest between sets and 1 sec intertrial interval) (The Quick Board, LLC Memphis TN). Response time, contact time, and error count was recorded for each leg during each trial. **RESULTS:** In total, controls performed 525 trials with the dominant leg and 555 trials with the non-dominant leg. ACLs performed 550 trials with the injured leg and 530 trials with the uninjured leg. Average time to set completion, response time, contact time, and error count did not differ by group or leg or measurement (mean or median). ACLs displayed better initial response times but failed to improve to the same extent as controls (6.1% improvement, $y = -1.51x + 1110.2$, $R^2=0.74$ for non-injured; 2.7% improvement, $y = -0.97x + 1004.8$, $R^2=0.62$ for ACL). Greater improvements in response time were generally observed in the (initially worse performing) non-dominant leg. In the less frequently injured (3/9) dominant leg, virtually no improvement (1.4%) in response time was observed in ACLs overall, resulting in a 341.5% relative improvement in controls. The variability of single trial response time increased from the dominant to the non-dominant leg and from the healthy to injured leg. **CONCLUSIONS:** Single trial analysis revealed injury-related deficits in skilled visuomotor learning years after ACL rupture and rehabilitation despite the apparent recovery of the musculoskeletal system. This suggests a central neurological association with musculoskeletal injury that may affect neuroplasticity in the affected and unaffected extremity.

Unique Leg-specific Executive And Motor BOLD Activity With Visually-guided Imagery Following ACL Injury

Shawn D. Flanagan, 15203¹, Courtenay Dunn-Lewis¹, James A. Onate², Jeff S. Volek², Carl M. Maresh, FACSM², William J. Kraemer, FACSM². ¹University of Pittsburgh, Pittsburgh, PA. ²Ohio State University, Columbus, OH. (Sponsor: William J. Kraemer, Ph.D., FACSM)
 (No relationships reported)

Given the change in sensorimotor system activation during limited movements of the injured leg after unilateral ACL rehabilitation, we asked whether the frontostriatal network might be involved during visually-guided action-imagery. **PURPOSE:** To determine whether injured individuals displayed different activity during a proprietary cognitive motor-oriented imagery test. **METHODS:** Healthy women (18-32 yr, n=19) provided written informed consent. Ten served as controls; nine others experienced unilateral ACL rupture, repair, and rehabilitation between 6 months and 5 years from the start of the study. All participants completed a proprietary attention-switching task for 4 trials of 10 repetitions. The test required subjects to react to congruent and incongruent signals prompting them to jump and land with the right or left leg. Subjects wore a camera to record first person perspectives of test performance. Brain images were acquired with a three tesla Siemens Trio MRI with TIM system. Subjects watched the cues and their first person performance while imagining themselves physically reacting/jumping in response to the cues. A three-dimensional magnetization-prepared rapid gradient-echo (MP-RAGE) sequence acquired whole-brain structure. Voxel size was set at 1.0mm³ for structural scans and 3.0mm³ for functional scans. Significant clusters were included if meeting a six-voxel cluster threshold. A false discovery rate (FDR) threshold was set at $q=0.05$. Map clusters were then converted to voxels of interest, and small cluster suppression highlighted the most affected brain regions. **RESULTS:** Occipital activity increased in response to visual cues. BOLD signal increased in the prefrontal cortex, primary somatosensory cortex, and the primary, pre, and supplementary motor areas ($p < 0.01$). Activity was lower in ACLs than controls, particularly when using the injured leg. However,

activity was increased in the right dorsolateral prefrontal cortex in both groups, with more pronounced increases in the injured group; the highest dIPFC activity was observed when participants imagined jumping and landing with their injured leg.
CONCLUSIONS: Prefrontal regions of the brain display heightened activity after ACL individuals, whereas motor regions tend to display decreased activity compared to controls.

850 Board #29 May 31 2:00 PM - 3:30 PM
Cardiovascular Dynamics During The Cold Pressor Test In Recently Concussed College Athletes

Blair D. Johnson, James R. Sackett, Zachary J. Schlader, Barry Willer, John J. Leddy. *University at Buffalo, Buffalo, NY.*
 Email: blairjoh@buffalo.edu
 (No relationships reported)

Concussion patients who are experiencing symptoms appear to have impaired cardiovascular responses during sympathoexcitatory tests such as handgrip exercise and head-up tilting. However, it is not known if impaired cardiovascular responses are present during a cold pressor test (CPT).

PURPOSE: We tested the hypothesis that recently concussed college athletes would have a blunted cardiovascular response during a CPT.

METHODS: Four college athletes (age: 19 ± 1 years, 2 women) who were within 7 days of concussion diagnosis and still reporting symptoms and four healthy controls (age: 27 ± 4 years, all men) underwent a CPT. During the CPT, the participant's right hand was submerged in an ice slurry mixture for 120 seconds. Heart rate (ECG) and blood pressure (photoplethysmography) were continuously measured and averaged at baseline and every 30 seconds during the CPT.

RESULTS: Heart rate was increased at 30 seconds (20 ± 5 bpm, $P = 0.001$) and 60 seconds (26 ± 13 bpm, $P < 0.001$) in the healthy controls but remained unchanged throughout the CPT in the concussed athletes (peak increase at 120 seconds: 10 ± 5 bpm, $P = 0.257$). Mean arterial pressure was elevated throughout the CPT in the healthy controls with a peak increase of 27 ± 6 mmHg at 120 seconds ($P < 0.001$). The peak increase in mean arterial pressure of 9 ± 6 mmHg in the concussed athletes was observed at 120 seconds, but did not reach statistical significance ($P = 0.079$). Systolic blood pressure was elevated at 60 seconds and throughout the remainder of the CPT in healthy controls reaching a peak increase of 28 ± 6 mmHg at 120 seconds ($P < 0.001$). Systolic blood pressure in concussed athletes did not increase at any point of the CPT ($P > 0.196$ for all time points). Diastolic blood pressure in healthy controls was elevated throughout the CPT and reached a peak increase at 120 seconds (21 ± 4 mmHg, $P < 0.001$). In concussed athletes, diastolic blood pressure was elevated only at 120 seconds (7 ± 5 mmHg, $P = 0.014$) of the CPT.

CONCLUSIONS: These preliminary data show that recently concussed athletes have a blunted cardiovascular response to the CPT. These data support evidence indicating that concussed patients who are experiencing symptoms have impaired cardiovascular responses to sympathoexcitatory stimuli.

Effects of Multiple Sports Related Concussions On Neurocognition and Cerebral Vascular Function

Nicholas G. Evanoff¹, Kara L. Marlatt², Bryon A. Mueller¹, Suzanne S. Hecht, FACSM¹, Jeffrey R. Wozniak¹, Kelvin O. Lim¹, Donald R. Dengel, FACSM¹. ¹University of Minnesota, Minneapolis, MN. ²Pennington Biomedical Research Center, Baton Rouge, LA. (Sponsor: Donald R. Dengel, FACSM)
 Email: evan0012@umn.edu
 (No relationships reported)

PURPOSE: To determine the differences in neurocognition (NC) and cerebral vascular reactivity (CVR) between athletes with multiple sports related concussions (mTBI) and matched controls (C).

METHODS: Twelve athletes (22 ± 0.5 y SEM) who reported multiple sports related concussions (≥ 3) and 12 matched [age, sex, body mass index (BMI), and athletic status] healthy concussion free controls (23 ± 0.5 y) were recruited. **Neurocognitive methods** Each participant completed neurocognitive testing (NC) including WASI II, HVLIT R, Grooved Pegboard, DKEFS, Connors' CPT test II, WAIS-IV subsets, and BRIEF. **CVR methods** Participants were fitted with a custom breathing circuit attached to a computer-controlled gas-blending device to evaluate baseline end-tidal carbon dioxide (P_{aCO_2}). To alter brain blood flow a P_{aCO_2} gas challenge, which consisted of two square wave increases of 10 mmHg above baseline P_{aCO_2} and a ramp protocol that decreased P_{aCO_2} to 32 mmHg and then increased linearly to 50 mmHg over a 7 min. period was utilized while P_{aO_2} was maintained at 100 mmHg. Each participant underwent brain imaging using a 3T MRI for concurrent structural and functional (BOLD) imaging. CVR (% BOLD signal change/mmHg CO_2) was computed by using a robust linear least squares fit to the correlation between the two time courses.

RESULTS: As expected mTBI and C were similar in age (22 ± 1 vs. 23 ± 1 y, $P = 0.07$), height (173 ± 3 vs. 174 ± 3 cm, $P = 0.76$), weight (76 ± 6 vs. 80 ± 6 kg, $P = 0.37$) and BMI (24 ± 1 vs. 26 ± 1 kg/m², $P = 0.18$). Baseline P_{aCO_2} (38 ± 1 vs. 36 ± 1 mmHg, $P = 0.44$) was

not significantly different. Whole brain gray matter CVR was also not significantly different in mTBI vs. C groups for the full sequence (0.380 ± 0.014 vs. 0.379 ± 0.014 %BOLD/mmHg, $P = 0.94$), squares waves only (0.380 ± 0.017 vs. 0.390 ± 0.017 , $P = 0.68$) and ramp only (0.377 ± 0.013 vs. 0.375 ± 0.013 , $P = 0.92$). Differences in NC testing (mTBI vs. C) were DKEFS Trail Making-motor speed (11.4 ± 0.3 vs. 12.5 ± 0.3 , $P = 0.02$); DKEFS Color Word Inference inhibition (13.0 ± 0.4 vs. 11.8 ± 0.4 , $P = 0.05$); and Connors' CPT Test II Commission (%) (58.2 ± 2.8 vs. 51.4 ± 2.8 , $P = 0.04$).

CONCLUSIONS: The data from this study suggest that multiple sports related concussions do not have long-term effects on CVR, however NC data showed reduced reaction time and attention.

The Effect of Industrial Hyperthermia on Firefighters' Cognitive Function in Warm Humid Environment

Ali M. Aljaroudi¹, Amit Bhattacharya², Darren S. Kadis³, Amanda L. Strauch¹, Tyler Quinn¹, W. Jon Williams¹. ¹CDC/NIOSH, Pittsburgh, PA. ²University of Cincinnati, Cincinnati, OH. ³Cincinnati Children's Hospital Medical Center, Cincinnati, OH.
 Email: koj3@cdc.gov
 (No relationships reported)

Firefighting is a physically and mentally strenuous job requiring rapid, appropriate decision making in extremely hot environmental conditions. Intact cognitive function is imperative to firefighters' effectiveness and safety. **PURPOSE:** To investigate the effect of industrial hyperthermia [rectal temperature (T_{re}) $\geq 38^\circ\text{C}$] on cognitive performance while wearing a firefighters' encapsulating protective ensemble after exercise in a warm, humid environment. **METHODS:** Eight healthy male subjects (VO_{2max} : 52.83 ± 5.60 mL.kg⁻¹.min⁻¹; Age: 26 ± 4 yrs) performed computer-based cognitive tests (Go/No-Go) before and after exercise under hyperthermic conditions (30°C / 70% relative humidity). Exercise included 40-min treadmill walking at 40 % VO_{2max} or until $T_{re} \approx 39^\circ\text{C}$ while wearing a firefighters' protective ensemble. For the Go/No-Go tests, participants were required to button-press to a target stimulus, and withhold button-presses to a non-target. The test appears as a 2×2 grid with one star in each square. A letter is presented in one square for duration of 500 milliseconds (ms), followed by an inter-stimulus interval of 1500ms. The first test (P-Go) required participants to respond to the target letter P and withhold response to the non-target letter R. The second test (P-No-Go) was a reversal, with R as the target and P as the non-target. Both tests had 160 trials (320 total), and constant ratio of targets to non-targets (80:20). Comparisons were drawn using paired-samples t-test with statistical significance shown at $p < 0.05$. **RESULTS:** Following hyperthermia, participants' reaction time (RT) was reduced in both tests (Go/No-Go) and exhibited a non-significant increase in percentage performance error (PE) compared to normothermic condition. The mean differences found between hyperthermic and normothermic conditions are: T_{re} : $1.46 \pm 0.44^\circ\text{C}$, $p = 0.0001$; P-Go RT: -17.22 ± 18.89 ms, $p = 0.0365$; P-No-Go RT: -36.31 ± 28.11 ms, $p = 0.0081$; and PE: $1.02 \pm 2.20\%$, $p = 0.2333$. **CONCLUSION:** Cognitive function was not altered negatively by hyperthermia. However, the hyperthermia condition resulted in accelerated reaction time which may have been influenced by change in human mood following mentally stressful hyperthermic conditions. Accelerated reaction time may cause a non-significant change in firefighters' performance.

Annual Baseline Drift in Professional Rugby League Players

Lisa Hodgson¹, Peter Walker², Paul Maruff³, David Darby⁴, Conor Gissane⁵. ¹The FA, Burton Upon Trent, United Kingdom. ²Yorkshire and Humberside Deanery, West Yorkshire, United Kingdom. ³CogState, Melbourne, Australia. ⁴University of Melbourne, Melbourne, Australia. ⁵St Mary's University, Twickenham, United Kingdom.
 Email: lisa.hodgson@thefa.com
 (No relationships reported)

Purpose: Annual baseline testing within professional Rugby League has been mandatory since 2004. The question: "Do annual baselines drift over time or as a result of a concussion in rugby league players?" is unanswered. If they do drift, what is the magnitude and in what tasks and is this correlated with associated concussions. This study evaluated if baselines drift over time and if so is this related to concussive injury or accumulating injury.

Design: Retrospective study

Method: Participant players were those who held a professional contract between the 2006-2012 season. It is mandatory to provide an annual baseline test using CogSport and following any diagnosed concussion, with full symptom resolution, a valid return to play test. Concussion test data was provided by CogState Australia from tests performed over 7 seasons.

Results: Over the 7-year period 4762 players suffered 470 concussions (2.65/1000 hours, 95% Confidence Interval 2.4 to 2.9). Reaction time on a choice reaction time task (Identification) slowed with previous concussions (0.017, .001 to .029, $P=0.05$) but not seasons. Accuracy on a working memory task (One Back) decreased with concussion (-0.05 to -0.05, $P=0.001$) and on an episodic memory task (One Card Learning) decreased with previous concussion (-0.041, -0.049 to -0.34, $P=0.001$) and season (-0.006, -0.007 to -0.005, $P=0.001$).

Conclusions: Over seven seasons, item scores within the CogSport test varied as a function of previous concussion and time suggestive of a subtle deterioration in cognitive performance with prior concussions. Individual items within the CogSport test were influenced by differing factors and more detailed examination of the scores and co-factors is warranted.

854 Board #33 May 31 2:00 PM - 3:30 PM
Change in Serum Protein S100B Following a Collegiate American Football Game

Sydney A. Keuler, Abigail E. Harris, Scott W. Ringgenberg, Matthew J. Rogatzki. *University of Wisconsin - Platteville, Platteville, WI.*

Email: sydneykeuler@gmail.com
(No relationships reported)

Protein S-100 Beta (S100B) is a calcium handling protein found in astrocytes. Following traumatic injury to the brain, S100B can be measured in blood serum as an indicator of brain damage severity. **PURPOSE:** To determine if S100B is increased in the serum of football players following a game in which traumatic head injury was not reported yet subconcussive hits were experienced by the players. **METHODS:** S100B was measured in the serum of 15 football players before and after two collegiate varsity football games. Of the 15 players, seven received a large amount of playing time, and eight received no playing time and served as the control group. In addition, the change in serum level of S100B was correlated to the number of total hits (described as impact to the head or body) each player sustained to determine if S100B serum levels rose in correlation with the number of hits each player experienced. **RESULTS:** No concussions or significant head injuries were reported by any of the players or certified athletic training staff, yet S100B (Pre-game 1: $0.051 \mu\text{g}\cdot\text{L}^{-1} \pm 0.056$ vs. Post-game 1: $0.084 \mu\text{g}\cdot\text{L}^{-1} \pm 0.055$, $p=0.019$) (Pre-game 2: $0.088 \mu\text{g}\cdot\text{L}^{-1} \pm 0.071$ vs. Post-game 2: $0.170 \mu\text{g}\cdot\text{L}^{-1} \pm 0.151$, $p=0.028$) increased significantly in those who played. S100B (Pre-game 1: $0.031 \mu\text{g}\cdot\text{L}^{-1} \pm 0.008$ vs. Post-game 1: $0.022 \mu\text{g}\cdot\text{L}^{-1} \pm 0.009$, $p=0.069$) (Pre-game 2: $0.052 \mu\text{g}\cdot\text{L}^{-1} \pm 0.009$ vs. Post-game 2: $0.041 \mu\text{g}\cdot\text{L}^{-1} \pm 0.017$, $p=0.161$) did not increase significantly in those who did not play. Pearson Correlation showed there was a moderate correlation between the change in S100B and the number of hits each player experienced ($R^2=0.419$; $p=0.009$). **CONCLUSION:** Serum S100B concentration does increase in response to subconcussive injury in a manner dependent on the number of hits the athlete withstands. Despite the increase in S100B levels caused by a football game, the increase in S100B was found to be similar to that found in runners, soccer players, or basketball players but greater than that found in swimmers and cyclists. This indicates sustaining subconcussive hits from playing football may cause damage to the brain but be no more damaging than playing other sports resulting in external forces being applied to the brain.

855 Board #34 May 31 2:00 PM - 3:30 PM
Affective Responses During High-intensity Exercise Detect Changes In W'

Mark E. Hartman, 50014¹, Nathan D. Dicks², Panteleimon Ekkekakis, FACSM¹, Thomas W. Kernozek³, Robert W. Pettitt, FACSM⁴. ¹Iowa State University, Ames, IA. ²North Dakota State University, Fargo, ND. ³University of Wisconsin-La Crosse, La Crosse, MN. ⁴Minnesota State University, Mankato, Mankato, MN.

(No relationships reported)

The feeling scale (FS) provides a valid measure of positive or negative feelings (i.e., affect) during dynamic exercise; however, research on constant work rate (CWR) exercise has been confined to lower intensities. Exercise >critical power (CP) is characterized by a time-dependent utilization of the finite work capacity >CP (W'), resulting in predictable time limits to exhaustion (t_{LIM}). Glycogen depletion (GD) evokes declines in W' , independent of changes in CP, resulting in earlier t_{LIM} . **PURPOSE:** To determine if GD evokes a more rapid time-dependent change in affect correlating to physiological responses during exhaustive CWR exercise. **METHODS:** In counterbalanced-order, 15 participants completed CWR exercise at 10% >CP in glycogen loaded (GL) and GD conditions. The FS, pulmonary gas exchange, capillary lactate, and electromyography (EMG) of the vastus lateralis were evaluated. **RESULTS:** A 62.3 ± 22.5 s reduction in t_{LIM} ($p < 0.05$) and a 3.2 ± 1.2 mmol·L⁻¹ reduction of end-exercise blood lactate concentration ($p < 0.01$) was evoked by GD. A greater decline in slope relative to time for the FS was observed for GD (-1.87 ± 1.12) vs. GL (-1.24 ± 0.91) ($p < 0.01$), correlating with earlier t_{LIM} in both the GL ($r = 0.78$)

and GD ($r = 0.76$) conditions. A 13.4% increase in iEMG occurred in the GD trial ($p < 0.05$). Oxygen uptake ($\dot{V}O_{2max}$) kinetics for ~½ of the sample exhibited a continuous primary phase until exhaustion (i.e., extreme domain) whereas a O_2 slow component was observed with the remaining participants (i.e., severe domain). Exercise in the extreme domain evoked 43% greater decline in affective responses ($p < 0.01$) and a 274.6 ± 78.1 s reduction in t_{LIM} ($p < 0.01$) and the gain in $V_E/\dot{V}CO_2$ relative to t_{LIM} was 6.9% greater for those exercising in the extreme domain ($p < 0.001$). **CONCLUSION:** Affective responses during severe and extreme exercise is sensitive to changes in metabolic responses occurring with a compromised W' .

856 Board #35 May 31 2:00 PM - 3:30 PM
Vitamin D and Neuropsychological Skills of Cross Country Skiers at 64° North

Scott P. Jerome, Hannah T. Short, Rebecca L. Gever, Kriya L. Dunlap, Arleigh J. Reynolds. *University of Alaska Fairbanks, Fairbanks, AK.*

Email: scott.jerome@alaska.edu
(No relationships reported)

Vitamin D insufficiency and deficiency are well-documented in populations living north or south of approximately 35° N or S latitude, respectively; these are even more pronounced during winter months. Athletes have been shown to be more susceptible to insufficiency and deficiency than non-athletes. Vitamin D has been linked to mental cognition. Winter-sports athletes residing in the circumpolar north may experience sub-optimal vitamin D levels and depressed cognitive abilities during the competitive season.

PURPOSE: To determine if significant differences of vitamin D concentrations and manual dexterity exist in winter athletes mid- and post-season in the circumpolar North. **METHODS:** Fifteen competitive cross country skiers residing at 64° N were recruited for this study. Blood samples were taken in early February ("mid-season") and in late April ("post-season"). Subjects completed the Purdue Pegboard Test (PPT), an assessment of mental cognition and manual dexterity, at the time of the blood draws. Plasma vitamin D concentration was measured as 25-hydroxyvitamin D [25(OH)D] using an ELISA. Significance was determined by permutation test with 95% confidence interval. **RESULTS:** Subjects exhibited significantly lower mean concentration of plasma 25(OH)D in post-season ($\mu=3.39$ ng/mL, $SD=4.53$) as compared to mid-season ($\mu=5.94$, $SD=3.37$). PPT revealed significantly higher scores in three of four tests in post-season ($\mu=18.00$, $SD=1.31$; $\mu=16.89$, $SD=1.12$; $\mu=46.64$, $SD=3.40$) versus mid-season ($\mu=17.04$, $SD=1.82$; $\mu=15.98$, $SD=1.62$; $\mu=41.69$, $SD=4.37$) with no significant differences in the remaining test. **CONCLUSION:** Post-season mean plasma 25(OH)D concentration was significantly lower than mid-season. This could be explained by significantly reduced intake of vitamin D supplements post-season. PPT scores improved significantly in two of four tests in the post-season suggesting that 25(OH)D may not necessarily be linked to cognitive function measured with PPT. However, mean 25(OH)D concentrations from both mid- and post-season fell below the Institute of Medicine's definition of "deficient" suggesting that subjects' improvement on PPT may have been attributable to another factor or factors such as reduced stress levels.

The Effects of Self-selected Music as a Diverting Activity Between Two Bouts of Fatiguing Isokinetic Leg Extensions

Vanessa M. Rojo, Gloria H. Moon, Jared W. Coburn, FACSM, Lee E. Brown, FACSM, Pablo B. Costa. *Cal State Fullerton, Fullerton, CA.* (Sponsor: Jared W. Coburn, FACSM)

Email: Vanessa.Rojo@csusb.edu
(No relationships reported)

Previous studies have shown music's ability to act as an ergogenic aid. However, there is limited research investigating the effects of music as a diverting activity in fatiguing exercise protocols. **PURPOSE:** To investigate the effects of listening to music as a diverting recovery intervention on peak torque and percent torque decline.

METHODS: Thirty-nine recreationally trained men ($n = 18$; 22.3 ± 2.7 y; 177.6 ± 8.8 cm; 80.7 ± 10.0 kg) and women ($n = 21$; 22.2 ± 1.7 y; 162.2 ± 5.2 cm; 62.6 ± 9.9 kg) performed 4 experimental visits consisting of 2 bouts of 50 maximal isokinetic leg extensions at $180^\circ\cdot\text{s}^{-1}$. Between each bout of maximal exercise, 2 minutes of recovery involving one of the 4 interventions (no music, white noise, self-selected slow tempo music, and self-selected fast tempo music) was completed. Torque values were collected during the pre-intervention and post-intervention maximal isokinetic strength tests. Percent torque decline was calculated for both the first and second set of 50 repetitions.

RESULTS: There were no significant ($p > 0.05$) 3-way interactions for peak torque or percent torque decline. There was a significant 2-way (time \times sex) interaction ($p < 0.05$) for peak torque. The decrease in peak torque from the pre-intervention test to

the post-intervention test was significantly greater for men (pre = 138.1 ± 3.68 Nm; post = 127.4 ± 3.2 Nm) than for women (pre = 84.7 ± 3.4 Nm; post = 80.4 ± 2.9 Nm), regardless of intervention. There was a significant main effect ($p < 0.05$) for percent torque decline, where the torque decline was greater for the post-intervention test (45.8 ± 1.2%) than the pre-intervention test (43.2 ± 1.3%). There were no significant interactions or main effects involving diverting conditions ($p > 0.05$).

CONCLUSIONS: These findings indicate that listening to self-selected music, slow or fast tempo, was not an effective diverting activity.

858 Board #37 May 31 3:30 PM - 5:00 PM How Sociodemographic Characteristics Of Activity Monitor Users Relate To Device Use And Perceived Physical Activity.

Ciaran P. Friel, Joseph T. Ciccolo, Carol E. Garber, FACSM.
Teachers College, Columbia University, New York, NY. (Sponsor: Carol Ewing Garber, FACSM)
Email: cpf2111@tc.columbia.edu
(No relationships reported)

Wearable activity monitors (AM) have been well accepted in some randomized controlled trials and have contributed to an increase in levels of physical activity (PA) in some, but not all participants. The sociodemographic profiles of users may be associated with the length of time (number of months) they wear the device, and how they perceive it impacts their PA behavior.

PURPOSE: To assess whether sociodemographic characteristics of AM users are related to 1) duration of device use, and 2) perceived changes in PA behavior.
METHODS: Current (n=1355) and former (n=590) AM users from across the United States were recruited online and completed a web-based survey. Sociodemographics, health information, and AM use were queried. Moderate to vigorous PA (MVPA) score was calculated using the Godin Leisure Time PA Questionnaire. Respondents also reported how AM use influenced their PA. Descriptive statistics are reported as medians, means ± standard deviations, and frequencies. AM users were categorized based on the median use time: AM use for > 6 months or ≤ 6 months. Age, income and MPVA score were categorized by quartiles. Chi-squared analyses were used to compare groups for all categorical variables.

RESULTS: Respondents were 18-81 years old (33.0 ± 12.2) with 73.1% women. A majority were current AM users (69.7%) and BMI was 26.7 ± 6.6. The number of months of AM use among current users was 10.1 ± 11.6, and 6.8 ± 6.4 among former users. Age ($\chi^2(3)=38.8$), income ($\chi^2(3)=22.0$), MVPA ($\chi^2(3)=22.4$) and relationship status (partnered vs single; $\chi^2(1)=14.7$) were all significantly different across the device-use categories ($p < 0.001$). A majority of current (76%) and former (53.2%) users perceived that the AM contributed to increased PA. Across all respondents, purchasing an AM themselves, as opposed to receiving it as a gift, was associated with a perceived increase in PA after device use ($p < 0.05$).

CONCLUSION: Duration of activity monitor use was associated with the sociodemographic characteristics of users, with a majority perceiving an increase in their physical activity as a result of use. This supports the need for further research to explore how sociodemographic data can be used to tailor interventions to specific populations using technology-based objective monitoring.

859 Board #38 May 31 3:30 PM - 5:00 PM Predictive Indicators of Early Fitness Club Membership Termination in Japan: A Cohort Study

Nobumasa Kikuga¹, Susumu S. Sawada, FACSM², Munehiro Matsushita³, Yuko Gando², Natsumi Watanabe⁴, Yuko Hashimoto⁴, Yoshio Nakata⁵, Robert A. Sloan⁶, Steven N. Blair, FACSM⁷, Noritoshi Fukushima¹, Shigeru Inoue¹. ¹Tokyo Medical University, Tokyo, Japan. ²National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan. ³Waseda University, Saitama, Japan. ⁴Juntendo University, Tokyo, Japan. ⁵University of Tsukuba, Ibaraki, Japan. ⁶Kagoshima University, Kagoshima, Japan. ⁷University of South Carolina, Columbia, SC.
Email: kiku@profitjapan.co.jp
(No relationships reported)

Approximately 40% of fitness club members in Japan have been reported to opt for early termination (within one year) of their membership. Identifying common

indicators among members who choose early termination may allow for the development of prevention strategies. **PURPOSE:** Identifying the characteristics of those who opt for early termination via a cohort study. **METHODS:** Across 17 fitness clubs, members completed a self-report questionnaire at baseline and follow-up.

The survey included the following indicators 1) baseline characteristics; 2) purpose of membership; 3) health status; and 4) psychological factors (perceived benefit of exercise, perceived barriers to exercise, and exercise self-efficacy). Participants were followed to determine whether they terminated their memberships. Odds ratios (OR) and 95% confidence interval (95%CI) for the incidence of early termination adjusted for age and gender were obtained using a logistic regression model. **RESULTS:** There were 1,839 participants (average age 37.9 years, 520 males and 1319 females) were involved in this observational study. During the follow-up period (six months on average), 428 participants early terminated. For every five-year increase in age, the gender-adjusted OR (95% CI) was 0.91 (0.87-0.94) for early termination. Members that joined an fitness club to relieve stress had an adjusted OR of 1.33 (1.06-1.68) for early termination. Additionally, the participants who joined an fitness club to improve their health had an adjusted OR of 0.81 (0.65-1.01) for early termination. The participants who agreed with the statement "recognition of one's ability to others," the benefits of exercise, had a higher adjusted OR for early termination 1.46 (1.11-1.91). Similarly, the participants who agreed with the statement "improve appearance" had a higher adjusted OR for early termination 1.33 (1.03-1.72).

CONCLUSIONS: The predictive indicators for early fitness club termination included young age, perceived exercise benefit for stress reduction, "recognition of one's ability by others" and "improve appearance". Lastly, perceived benefit of health improvement may prevent early termination.

860 Board #39 May 31 3:30 PM - 5:00 PM Presence of Master Plans Supportive of Active Living in U.S. Municipalities

Erin L. Peterson, Susan A. Carlson, Thomas L. Schmid, David R. Brown, FACSM. CDC, Atlanta, GA.
Email: lwt0@cdc.gov
(No relationships reported)

PURPOSE: Community planning documents can play an important role in promoting the design and maintenance of communities to support active living. This study estimates the prevalence (overall and by municipality characteristics) of (1) community wide planning documents and (2) inclusion of objectives within plans supportive of active living.

METHODS: Data from the 2014 National Survey of Community-Based Policy and Environmental Supports for Healthy Eating and Active Living (CBS HEAL) were analyzed. CBS HEAL collects data through a survey of local officials for a nationally representative sample of US municipalities with a population of at least 1000 people (n=2005 representing a 45% response rate). Prevalence of a comprehensive or general Plan, 3 specific plan types (land use, transportation, and bicycle or pedestrian (stand-alone or part of a general Plan)), and 3 objectives (implementing Complete Streets policies, promoting street connectivity, or encouraging mixed-use development) were analyzed using survey weights to create national estimates.

RESULTS: Overall, 64% of US municipalities in our sample had a comprehensive or general plan. Plan is types ranged from 76% for a land use plan to 48% for a bicycle/pedestrian plan and 46% for a transportation plan. 67% of municipalities with plans had an objective for encouraging mixed-use development, 54% for the promotion of street connectivity, and 37% for the implementation of a Complete Streets policy. Across all plan types, municipalities with a larger population, that were urban, located in the West, with a median college graduate education level and a lower poverty prevalence had a higher prevalence of plans than their counterparts. Among municipalities with a plan, similar patterns by municipality characteristics were observed for the presence of objectives with one exception, presence of objectives by poverty level did not differ significantly.

CONCLUSIONS: Helping communities, especially smaller or rural municipalities and those with lower median education levels, address issues related to the adoption and creation of planning documents supportive of active living can be an important step toward creating more walkable communities.

861 Board #40 May 31 3:30 PM - 5:00 PM Exercise Trials In Co-morbid Adults: A Missed Opportunity For Behavior Change?

Ashley B. Sanders, Adam R. Konopka, Jaime L. Laurin, Benjamin F. Miller, Karyn L. Hamilton, FACSM, Heather J. Leach. Colorado State University, Fort Collins, CO. (Sponsor: Karyn Hamilton, FACSM)
(No relationships reported)

PURPOSE: Exercise (EX) trials in adults with co-morbid conditions such as type 2 diabetes offer an opportunity to address behavior changes needed to increase physical activity (PA) and improve long-term health. The aim of this study was to determine whether it was feasible to include a low-dose PA behavior change intervention in

an EX trial. **METHODS:** For the original EX trial, participants were randomized to one of four groups, to test the interactive effects of metformin and post-exercise ingestion of protein versus carbohydrate on mitochondrial protein synthesis, and the blunting effect of metformin on EX response. Participants were ≥ 55 years of age, had fasting glucose values ≥ 100 mg/dl, hemoglobin A1c 5.7-6.4%, two hour postprandial glucose 140-200 mg/dl, or a family history of type 2 diabetes. All participants received supervised EX sessions, three times per week for 12 weeks. For the behavior change intervention, participants were randomized to receive a one-hour PA counselling session, or not, held after completion of the 12 week EX intervention. The session was based on social-cognitive theory, and the primary goal was to increase post-intervention PA maintenance through discussion of PA benefits, PA goal setting, and identifying and overcoming PA barriers. Self-reported PA was measured using the International PA Questionnaire (IPAQ), pre, post and three-months after the EX intervention. **RESULTS:** There was no additional time burden for participants or the principal investigators of the original EX trial. Baseline, post-intervention PA questionnaires, and the counselling session were done while participants were in the laboratory doing their oral glucose tolerance test, and the follow-up PA questionnaire was completed by mail or online. PA questionnaire completion rates were high; 30/31 (96.7%) completed baseline, 100% (N=17) completed post-intervention PA questionnaire and counselling session (if randomized to receive it), and 7/8 (87.5%) have completed the three-month follow up PA questionnaire. **CONCLUSIONS:** Based on the high completion rates and no added time commitment, including behavior change strategies as part of an exercise trial is feasible. This trial is ongoing, and upon completion, effectiveness of the counselling session for increasing PA at three-month follow-up will be examined.

862 Board #41 May 31 3:30 PM - 5:00 PM
Effects Of Removing Electronic Devices From An Athletes' Sleeping Environment On Sleep And Anxiety
 Maddison J. Jones¹, Brian Dawson¹, Peter R. Eastwood¹, Shona Halson², Joanna Miller², Ian C. Dunican¹, Peter Peeling¹. ¹The University of Western Australia, Crawley, Australia. ²Australian Institute of Sport, Bruce, Australia.
 (No relationships reported)

Studies have suggested that the light emitted from electronic devices can impair sleep. However, it is unclear whether removing electronic devices from the sleeping environment in the evening and overnight provides an extended sleep opportunity. **Purpose** To investigate the effects of removing electronic devices in the evening and overnight on measures of sleep and anxiety during a seven-night training camp. **Methods** Twenty-six water-polo athletes (12 males, 14 females, aged 17±1 y) attending a training camp were allocated to either a no-device group (no electronic devices could be used after dinner or overnight; ND) or a control group (unrestricted electronic device use; CON). Athletes in the ND group also completed a modified version of the Nomophobia Questionnaire (Yildirim, 2015), which measured anxiety related to being unable to use electronic devices. Sleep was monitored with wrist actigraphy in both groups. One-way ANOVA calculated between-group differences and repeated measures ANOVA calculated within-group differences across each night. Cohen's *d* effect sizes were calculated for anxiety scores. **Results** Athletes in the ND group went to bed earlier than those in the CON group on the first night of camp (21:40±0:48 h vs. 22:20±0:48 h; $p=0.049$). Athletes in the ND group also spent longer in bed (520±41 min vs. 478±41 min; $p=0.015$) and slept for longer (474±55 min vs. 433±41 min; $p=0.044$) than the CON group on the first night. However, there were no differences between groups for any other nights. Electronic device-related anxiety in the ND group did not significantly change from the first (61±27) to the last night of the camp (49±18), although a moderate effect size for the change in scores over time ($d=0.50$) suggested a trend towards decreased anxiety over time. **Conclusion** Removing electronic devices from athletes overnight resulted in sleep extension on the first night of the training camp. It is possible that the lack of differences between the two groups for the remaining six nights was due to athletes in the ND group seeking other means of delaying bedtime (e.g. by engaging in other activities). Future research is needed to better understand the effects of electronic device use in young adults and athletes, particularly in relation to evening electronic device use habits.

Effects of Sitting and Three Treadmill Desk Speeds on Cognitive Function, Typing Speed and Accuracy
 Rebecca R. Rogers, Alec Hulmes, Kinsey Sessions, Yifan Shen, Conner Siekmann, John K. Petrella, FACSM, Mallory R. Marshall. Samford University, Birmingham, AL.
 Email: rrogers1@samford.edu
 (No relationships reported)

Active workstations have become a common method of combating the prolonged sedentary setting of the workplace and potentially decrease the risk of chronic diseases and health conditions due to inactivity. However, there is no evidence to indicate an optimal treadmill speed to increase physical activity without compromising employee

productivity. **PURPOSE:** The purpose of this study was to determine whether four workstations including sitting, walking on a treadmill at 1.0 mph, 1.3 mph and 1.7 mph affect typing speed, typing accuracy, and cognitive function in college students. Additionally, this study aimed to determine optimal speed for treadmill desk users. **METHODS:** Forty college-age students (n=20 males, n=20 females) were recruited into the study. Participants completed a health history and informed consent. The university Institutional Review Board approved the study. Participants completed one counterbalanced trial with one cognitive test and one typing test at each of the four workstations with a two-minute break between each test and workstation. Each participant sat, walked at 1.0 mph, 1.3 mph and 1.7 mph while performing the Stroop test for cognitive function and a typing test to assess speed and accuracy. The order of the four workstations and order of the tests were randomized. **RESULTS:** No significant differences were found in the Stroop test for the percent correct for normal ($p=0.277$) or interference responses ($p=0.940$) or the average response time for normal ($p=0.909$) or interference response time ($p=0.808$) responses between the workstations. No significant differences in average type speed in words per minute ($p=0.673$), the average error count ($p=0.764$) or the average adjusted speed in words per minute ($p=0.836$) for the typing tests at each workstation. **CONCLUSION:** Cognitive performance, typing speed and accuracy are not affected by sitting or walking on a treadmill desk. Data suggests cognition and typing productivity are not compromised by using a treadmill desk. Results indicate active workstation users are able to choose various walking speeds (1.0 mph, 1.3 mph and 1.7 mph) to minimize the sedentary nature of an occupational setting without concern of impaired workplace performance.

864 Board #43 May 31 3:30 PM - 5:00 PM
Immersive Cycling Environment Yields High Intensity Heart Rate Without High Perceived Effort In Novice Exercisers
 Jinger S. Gottschall¹, Bryce Hastings². ¹The Pennsylvania State University, University Park, PA. ²University of Auckland, Auckland, New Zealand. (Sponsor: Larry Kenney, FACSM)
Reported Relationships: J.S. Gottschall: Ownership Interest (Stocks, Bonds); FITOLOGY, LLC.

Exercise prescription is a multifaceted topic with the singular goal of defining a protocol that maximizes health and adherence. The ACSM guidelines reference previous results that there is an intensity threshold to continually improve fitness and reduce disease risk. The threshold for well-trained individuals is 95-100% max heart rate (HR) whereas the threshold for less-trained individuals is only 70-80% max to achieve the same benefits. Exercising at these intensities can be uncomfortable and unpleasant leading to low compliance. However, past research has demonstrated that engaging distractions such as an instructor, music, or digital images can enhance enjoyment while diminishing rate of perceived exertion (RPE). It is therefore possible that an instructor-guided workout with digital images synchronized to music could be the ideal combination to reach higher intensities with a lower perception of effort. **PURPOSE:** Our aim was to compare an audio (AUD; music only) environment with an immersive (IMM; music + digital images) environment during group fitness cycling classes in both well-trained and less-trained individuals. **METHODS:** To date, 6 elite participants (more than 10 hours PA/wk) and 6 novice (less than 2 hours PA/wk) completed 8 AUD and 8 IMM classes in 8 wks. Both class formats were approximately 40 minutes in duration with parallel strength and speed intervals led by an instructor. We collected HR (% time in 80-100% max zone) during each class and survey data (RPE, satisfaction, enjoyment) immediately after each class. **RESULTS:** For the elite participants, % time in the max zone and RPE were significantly greater during AUD (54 + 8%; 18 + 1) compared to IMM (46 + 9%; 15 + 2; $p < 0.05$). In contrast, for the novice participants, RPE was significantly less during IMM (16 + 2) compared to AUD (18 + 1; $p < 0.05$) while the % time in the max HR zone did not differ between the two conditions (AUD = 62 + 11%; IMM = 64 + 12%; all values mean + sd). Satisfaction ratings were high for both groups and both conditions, but the novice participants rated IMM as more enjoyable than AUD. **CONCLUSION:** Both AUD and IMM group fitness cycling formats are an ideal way to meet the exercise guidelines with high satisfaction. IMM may promote adherence in novice participants compared to AUD as HR intensity did not differ, RPE was less and enjoyment was greater.

USE OF SIT-TO-STAND WORKSTATIONS: IMPACT ON PHYSICAL ACTIVITY
 Shiann Wickham, Catherine Patrick, Larissa Boyd, Melissa Powers University of Central Oklahoma, Edmond, Oklahoma
 Prolonged sitting affects daily total physical activity. Standing in order to break long periods of sitting may be beneficial to an individual's health. **PURPOSE:** The purpose

of this pilot study was to determine whether physical activity would change when using a sit-to-stand workstation in a workplace environment. **METHOD:** Volunteers from the faculty of the University of Central Oklahoma included apparently healthy male and female adults ($N = 11$, $M = 39.09 \pm 10.445$ years). Participants were asked to use sit-to-stand workstations for a minimum of three hours per workday. The International Physical Activity Questionnaire (IPAQ) was used to measure self-reported daily physical activity. **RESULTS:** Dependent t -tests were used to analyze changes in self-reported physical activity over 5 months. Non-significant ($p > .05$), meaningful improvements were seen in METmin/wk for walking ($d = .19$), total physical activity ($d = .14$), moderate activity ($d = .01$), and vigorous activity ($d = .02$). Total minutes of sit time per week ($d = .25$) and average daily minutes sitting ($d = .25$) decreased ($p > .05$). **CONCLUSION:** Sit-to-stand workstations do provide an increase in daily physical activity levels. Although the results were non-significant, they do indicate a small decrease in time spent sitting along with small improvements in walking and total physical activity. Decreasing employee sitting time can increase the amount of physical activity achieved throughout the day. Future research should evaluate the use of sit-to-stand workstations in a larger, more diverse group of employees.

Table 1
Paired t -test Comparisons of Subjectively Measured Physical Activity Before and After 5 Months of Sit-to-Stand Workstation Use

	Pre		Post		t	p
	M (SD)	95% CI	M (SD)	95% CI		
Walking (met-min-wk)	699.00 (537.72)	[337.75, 1060.25] [1309.37, 5356.99] [453.54, 2681.01] [347.88, 2335.76] [1348.25, 2889.94] [192.61, 412.85]	802.78 (626.05)	[382.19, 1223.36]	.50	.63
Total PA (met-min-wk)	3333.18 (908.30)		3764.32 (3491.25)	[1418.87, 6109.77]	-.63	.55
MPA (met-min-wk)	1567.27 (1657.81)		1590.91 (1303.82)	[714.99, 2466.83]	-.05	.96
VPA (met-min-wk)	1341.82 (1479.50)		1370.91 (2379.25)	[227.50, 2969.32]	-.07	.95
Weekly ST (min-wk)	2119.10 (1147.42)		1838.18 (618.48)	[1422.68, 2253.68]	.72	.49
Daily ST (min-d)	302.73 (163.92)		262.60 (88.36)	[203.34, 321.95]	.72	.49

Note. MET = metabolic equivalent; min. = minutes; wk. = week; d = day; PA = physical activity; MPA = moderate physical activity; VPA = vigorous physical activity; ST = sit time; SD = standard deviation; CI = confidence interval.

Bicycling for Exercise Helps Maintain a Youthful Metabolic Cost of Walking in Older Adults

Daniel H. Aslan, Joshua M. Collette, Justus D. Ortega. *Humboldt State University, Arcata, CA.*

(No relationships reported)

Impaired walking performance is a key determinant of morbidity among older adults. A distinctive characteristic of impaired walking performance among older adults is a greater metabolic cost compared to young adults. Specifically, healthy older adults have been shown to have a 15-20% greater metabolic cost of walking compared to young adults. However, a recent study suggests that older adults who routinely run for exercise have a lower metabolic cost of walking compared to older adults who walk for exercise. Yet, it remains unclear if other aerobic exercises such as bicycling elicits similar improvements on walking metabolic cost among older adults. **PURPOSE:** To determine if regular bicycling exercise affects metabolic cost of walking in older adults. To our knowledge, there has been no research looking at metabolic cost of walking in older adults who bicycle for exercise. **METHODS:** 13 young adults (23 ± 2 years), 16 "older walkers" (71 ± 5 years) who walk ≥ 30 min, 3x/week, and 17 "older bicyclists" (68 ± 3 years) who bicycle ≥ 30 min, 3x/week, walked on a level treadmill at four speeds (0.75, 1.25, 1.60, and 1.75 m/s). Using an open circuit expired gas analysis, we measured $\dot{V}O_2$ and $\dot{V}CO_2$ in the last 2 minutes of each 6 minute trial to determine metabolic cost (J/kg/s). We compared metabolic cost in the three groups. **RESULTS:** Across the range of walking speeds, older bicyclists had a 9-17% lower

metabolic cost of walking compared to older walkers (3.24 ± 0.14 vs. 3.80 ± 0.16 J/kg/s, respectively; $p = .006$) and similar metabolic cost of walking compared to young adults ($p = .973$).

CONCLUSIONS: Bicycling exercise mitigates the age-related deterioration of walking metabolic cost, whereas walking for exercise appears to have a minimal effect on improving metabolic cost of walking in older adults. We suspect the greater aerobic intensity of bicycling exercise may maintain muscle mitochondrial efficiency in aging and thus helps explain the lower metabolic cost of walking in older bicyclists versus older walkers.

Exergaming Intervention in Sedentary Middle-Aged Adults Improves Lower Extremity Functional Fitness and Exercise Self-Efficacy

Daniel M. Rosney, Sr, Dmitriy V. Belous, Mingmei Tian, Courtney E. Miller, Katherine T. O'Donnell, Sabrina M. Daniels, Peter J. Horvath. *State University of New York at Buffalo, Buffalo, NY.* (Sponsor: Luc E. Gosselin, FACSM)

Email: dmrosney@buffalo.edu

(No relationships reported)

Interactive video game technology has been extensively utilized in rehabilitative settings. However, few studies have explored the potential benefits of interactive video games as a within-the-home exercise instrument for middle-aged adults who do not have a gym membership or who otherwise cannot regularly make it to their local fitness center. Features of interactive "exergaming" (modeling proper exercise biomechanics, increasing self-monitoring of behavior, encouraging participants to set health-related goals, and rewarding regular use) may help increase self-efficacy (SE), which in turn could promote physical activity and functional fitness (FF).

PURPOSE: To compare FF and SE in relation to exercise tests and self-reported questionnaires in sedentary men and women before and after regularly participating in interactive video game play ($n = 12$, 56 ± 4 yrs, 162.1 ± 10.9 cm, 79.2 ± 19.1 kg, $39.6 \pm 7.7\%$ fat mass).

METHODS: All subjects were initially screened and underwent a battery of FF tests and SE questionnaires. Subsequent observations took place in a monitored laboratory setting where subjects engaged in self-selected, low- to moderate-intensity exergaming involving aerobic, resistance, flexibility, or neuromotor training for 20 min/3d/wk between August 2015 and June 2016. After 8 weeks, FF and SE were retested.

RESULTS: Exercise using interactive video game technology significantly increased 30-second Sit-To-Stand repetitions ($14.2 - 16.8$, $p < 0.05$). Additionally, all participants reported with 100% confidence they would continue to exercise for at least 20 min/3d/wk for up to 8wks post-study if they owned an interactive video game system within their home.

CONCLUSIONS: Exergaming improved lower extremity functional strength and endurance as well as participants' confidence in their ability to continue exercising beyond this study in previously sedentary middle-aged adults. Interactive video game systems should be considered a viable option for convenient, enjoyable, within-the-home exercise programs to assist individuals in meeting ACSM physical activity guidelines.

Association between Increased Activity and Wellbeing under Weight Stable Conditions

Madison M. DeMello¹, Bernardine M. Pinto¹, Steven N. Blair, FACSM¹, Gregory A. Hand, FACSM². ¹University of South Carolina, Columbia, SC. ²West Virginia University, Morgantown, WV.

Email: demello@mailbox.sc.edu

(No relationships reported)

The increasing prevalence of physically inactive adults within the United States continues to be a health burden, as inactivity is linked to several non-communicable diseases. Even modest increases in activity can improve health benefits, even without weight loss. However, little is known about the psychosocial outcomes of exercise in weight stable conditions.

PURPOSE: The purpose of this research is to evaluate the effects of time spent in aerobic activity on self-reported psychosocial outcomes in previously sedentary young adults when weight is maintained.

METHODS: 65 previously sedentary overweight/obese adults (54% male, 31.3 ± 7.3 years), were randomized into a high flux (35 kcal/kg/week) or low flux (17.5 kcal/kg/week) exercise group for a 6-month aerobic intervention. All sessions were on site and consisted of 3-5 sessions per week for approximately 1 hour (dependent on body weight). Additionally, weight maintenance ($\pm 3\%$) was required for the entire 6 months. Exercise trainers monitored heart rate (HR) every 5 minutes to ensure intensity

between 70-75% of maximal HR and all sessions were timed and recorded. To evaluate wellbeing, participants completed assessments relating to mood (POMS) and health status (SF-36) at baseline and at intervention completion.
RESULTS: The average exercise time in the high (n=32) and low (n=33) flux group was 220.0 ± 54.6 minutes and 155.9 ± 28.6 minutes per week, respectively. Quintiles were created based off average time per week of aerobic exercise (±SD) (mean values for least time to most time: 137.3 ± 19.2, 175.6 ± 8.8, 249.4 ± 39.4 minutes). There was a linear trend (p for trend <.05) across quintiles for SF-36 (Role Emotional) subscale for time spent in routine activities due to emotional wellbeing, after adjusting for age and sex. No other significance was seen across the 6-month psychosocial wellbeing assessments.
CONCLUSION: These results indicate that an increase in time spent exercising will allow for less time spent in routine tasks due to emotional wellbeing. No other significance was found within the POMS or SF-36 evaluations. While these results are consistent with previous findings, more research is necessary to determine if exercise duration contributes to spending less time on daily activities in weight stable adults.

 (No relationships reported)

Parents are key for promoting physical activity (PA) in children. Family Gym provides a free, 90 minute weekly opportunity for families with young children (ages 3-8) to be active together. Family Gym is located in a community center in a Boston, MA low-income, minority neighborhood.
PURPOSE: To examine the PA levels of parents and children during Family Gym sessions and to determine the effect of varying lengths of structured activity sessions for parents and children.
METHODS: Twelve children (4.8 ± 1.9 yrs) and their parents (27.2 ± 9.4 yrs) participated in group sessions which included free play followed by staff structured activities that were either short (S) (n = 8, averaging 4.4 ± 1.4 minutes per session) or extended (E) (n = 9, averaging 18.9 ± 3.5 minutes per session) in duration. PA levels of each participant were measured using an Actigraph GT9X accelerometer worn at the waist. Percent of time spent in sedentary behaviors (%sed), and in light (%LPA), and in moderate-to-vigorous (%MVPA) PA were estimated using the Troiano cut points for parents, using Pate cut points for children 3 to 5 yrs, and Puyau cut points for children 6 to 8 yrs. Paired t-tests were used to test for differences in PA levels in S versus E sessions. Independent t-tests were used to compare PA between parents and children.
RESULTS: Parents and children did not differ in %sed (p>.05). Compared to children, parents had significantly more %LPA during the S and E sessions (parents, 69.0 ± 10.5 and 63.3 ± 15.5 vs. children, 33.4 ± 23.1 and 30.1 ± 19.5, respectively; p<.05) and less %MVPA (parents, 16.3 ± 6.8 and 10.8 ± 4.9 vs. children, 56.0 ± 24.2 and 57.6 ± 25.7, respectively; p<.05). Parents had less %MVPA in E versus S sessions (10.8 ± 4.9 vs 16.3 ± 6.8, respectively; p = 0.036) while there was no difference between the E and S sessions for %sed (E, 24.1 ± 14.5 vs. S, 14.2 ± 10.4; p = 0.215) or %LPA (E, 63.3 ± 15.5 vs. S, 69.0 ± 10.5; p = 0.421). There were no differences between E and S sessions for children's %sed, %LPA, and %MVPA.
CONCLUSIONS: Parents are not as active as their children in an open play environment. However, open play appears to be as effective as structured activity for increasing %MVPA in children. Organized but unstructured programming is needed to increase PA in parents in group play settings with their children.

Exergaming Intervention in Sedentary Individuals Improves Attitudes Towards Exercise and General Health
 Courtney E. Miller¹, Katherine T. O'Donnell¹, Daniel M. Rosney¹, Dmitriy V. Belous¹, Mingmei Tan¹, Kelsey Jaynes², Peter J. Horvath¹. ¹University at Buffalo, Buffalo, NY. ²Cornell University, Ithaca, NY. (Sponsor: Luc E. Gosselin, FACSM)
 (No relationships reported)

Interactive video game technology has been utilized in rehabilitative settings. However, research is limited in its possible role as a within-the-home exercise instrument for those who do not have a gym membership, or who otherwise cannot regularly make it to their local fitness center. **PURPOSE:** To compare quality of life and emotional well being before and after eight weeks of exercise using interactive

video game technology in sedentary community members. **METHODS:** 12 Sedentary, middle-aged men and women (56±4 years, 162.0±10.9 cm, 79.2±19.1 kg, % fat mass 39.6±7.7%) exercised under monitored conditions using interactive video game technology at a low to moderate intensity level for 20 minutes a day, three days a week for eight weeks. Participants were allowed to choose which activities they participated in each visit. The SF-36 questionnaire for assessing general health was administered before and after the intervention. Participants took a Subjective Exercise Experience Survey (SEES) with a scale ranging from 1 (not at all), 4 (moderately) to 7 (very much so) after the completion of the study. **RESULTS:** Self-reported SF-36 physical functioning scores approached significance (84.6 before to 90.4 after, p < 0.08) after eight weeks of exercise. Review of the SEES taken after an exergaming session at the end of the study showed that after exergaming subjects felt slightly tired, but not at all drained. They also reported feeling positive and not at all discouraged post exercise. **CONCLUSION:** Virtual gaming platforms may be utilized by sedentary community members in place of regular physical activity. Eight weeks of exergaming might improve physical functioning and have a positive effect on sedentary individuals attitudes toward exercise and general health. Supported by Departmental Funds.

 (No relationships reported)

Exercise plays an important role in health maintenance; however, it is unclear what the best motivation is for maintaining a long-term exercise plan. **PURPOSE:** To examine the effects of intrinsic and extrinsic motivational support programs on physical activity levels in older Japanese subjects.
METHODS: Forty-one older subjects (age, 73.2 ± 7.3 years; body mass index, 26.9 ± 3.2; male, n = 17; female, n = 24) were randomly assigned to an intrinsic motivational support (IMS) or an extrinsic motivational support (EMS) group. Both groups participated in a 12-week exercise program that met once a week. Each 60-min exercise session included warm-up period, dual-task "square-step", and cool-down period. Subjects in the EMS group were given a monetary reward (JPY500=US\$5) every week if they achieved each target values of average daily step counts during 7 days between sessions. Subjects in the IMS group received a program that was designed using a self-determination theory to enhance competence, self-determination, and relatedness. The motivations to exercise were assessed by a questionnaire (BREQ-2) and the amount of physical activity was measured by a three-axis accelerometer before and after the program. BREQ-2 evaluates five types of motivations to exercise (i.e., amotivation, external regulation, introjected regulation, identified regulation, and intrinsic regulation).
RESULTS: Moderate-to-vigorous physical activity (MVPA) was defined as 77.0 ± 28.4 min at baseline and 86.4 ± 37.0 min at post in the IMS group and 72.4 ± 33.3 min at baseline and 96.7 ± 39.0 min at post in the EMS group. No significant time x group interaction was found in the MVPA values. In the IMS group, there was a significant trend (P = 0.08) in the score for intrinsic regulation to exercise (15.0 ± 2.7 points at baseline, 16.0 ± 2.0 points at post). In total subjects, the amount of physical activity was not significantly correlated with any of the five types of intrinsic motivations for exercise.
CONCLUSIONS: These results suggest that the exercise program with intrinsic motivational support and extrinsic motivational support both enhanced physical activity level in study participants and that effectiveness did not differ between the two programs. This research was designed to examine 1-year follow-up test for these legacy effects.

 (No relationships reported)

The complex relationship between eating behaviors and physical activity, and their effects on weight loss, is not well understood.

PURPOSE: To examine the indirect effects of moderate-to-vigorous physical activity (MVPA) on weight loss through changes in eating behaviors (dietary restraint and disinhibition) in response to a behavioral weight loss intervention (BWL).

METHODS: Subjects ($n=221$; 42.8 ± 9.2 years; $BMI=32.7\text{kg}/\text{m}^2\pm 3.6$) with complete data were included in this secondary mediation analysis. The 18-month BWL included prescribed energy intake of 1200-1500kcal/d and MVPA to 300min/wk. Weight, Restraint (flexible (FR), rigid (RR)), Disinhibition (internal (ID), external (ED)) and MVPA were assessed at 0, 6, and 18 months. Restraint and Disinhibition were measured by questionnaire. Objective MVPA was defined as bouts >10 min in duration and >3.0 METs.

RESULTS: Weight decreased [6mo:- $9.07\pm 6.26\text{kg}$; 18mo:- $8.1\pm 8.5\text{kg}$] and MVPA increased [6mo: 673.9 ± 1199.1 MET-min/wk; 18mo: 428.6 ± 101.4 MET-min/wk] ($p<0.001$). RR [6mo: 2.85 ± 1.89 ; 18mo: 2.50 ± 1.94] and FR [6mo: 2.13 ± 1.76 ; 18mo: 1.73 ± 1.73] increased and ID [6mo:- 2.41 ± 3.11 ; 18mo:- 1.74 ± 3.25] and ED [6mo:- 1.05 ± 1.65 ; 18mo:- 0.82 ± 1.59] decreased over time. Change in FR and ID, but not RR or ED, partially mediated the effect of MVPA on weight loss at 6 months. At 18 months, change in FR, RR, and ID, but not ED, partially mediated the effect of MVPA on weight loss.

CONCLUSIONS: The influence of MVPA on weight loss may be partially explained by improvements in eating behaviors. Interventions designed to focus on changing these specific eating behaviors in combination with MVPA may improve weight loss in adults with obesity.

Mediator Analyses: Effect of Eating Behavior Changes on the Association Between Change in PA and Weight Loss		
Mediators:	Baseline to 6 months Indirect Effect (95% CI)	Baseline to 18 Months Indirect Effect (95% CI)

BACKGROUND: Despite having many health programs available, native men on the Colville Indian Reservation do not regularly participate.

PURPOSE: This qualitative study was designed to gain an understanding of how to effectively recruit and retain American Indian men in a Diabetes Prevention Study.

METHODS: Before recruitment, IRB approval was received from Washington State University and the Colville Tribes. Forty participants (31 males, 9 females) volunteered for five focus groups held in Omak, Nespelem, Keller and Inchelium. Verbal permission was given by participants for audio taping the discussion. Each participant completed a survey prior to the focus group to gather additional data related to diet and exercise. No identifying information was collected on the survey or in the focus groups. Questions elicited opinions about nutrition, physical activity (PA) and culture related to participation in a healthy lifestyle program, including perceived obstacles to participation. Participants were also asked whether their emotional state, including stress, trauma, historical trauma and depression may influence their decisions to participate in the program and in making personal health decisions. Dinner was served at each focus group and all received two \$25.00 Walmart gift cards.

RESULTS: Participants identified a lack of quality produce at local grocery stores as a primary reason for poor eating habits. The men reported that they did not like to shop or cook, but thought recipes and video demonstrations would be helpful. Everyone thought inter-community competition would be motivation to increase PA and decrease weight. They recommended using native cultural activities in the program i.e., traditional dancing, hunting, fishing and gathering roots and berries to increase relevance. Obstacles identified included their emotional state, weather and seasons, as well as a lack of facilities and time.

CONCLUSIONS: Changing our intervention based on these suggestions is the next step. A secondary benefit mentioned in the focus groups is using cultural activities to encourage men, which will also keep those activities alive for the youth in the tribe. Colville tribal men do have an interest in their health and would like to participate in our program if we make it culturally-based and at a time that is convenient.

Factors that Associate With Better Exercise Compliance in Mobile App Based Program: The Virtual Trainer Project

Stanley Sai-chuen Hui, FACSM¹, Ron C.W. Kwok², Eric W.C. Tam³. ¹The Chinese University of Hong Kong, Shatin, Hong Kong. ²City University of Hong Kong, Kowloon Tong, Hong Kong. ³Hong Kong Polytechnic University, Hung Hom, Hong Kong.
Email: hui2162@cuhk.edu.hk
(No relationships reported)

Exercise-related mobile apps and wearable movement detection devices have become popular tools for active lifestyle promotion. Behavioral modification theories such as goal setting, stimulus control, incentive scheme, and self-determination theory could be easily integrated into mobile apps program design so as to make these exercise motivational strategies more interesting and appealing. Limited studies have evaluated these strategies for promoting better exercise compliance. **PURPOSE** To evaluate factors that contribute to a better exercise compliance in a mobile-app based exercise promotion program called the Virtual Trainer (VT) project. **METHODS** A VT mobile app that integrated various lifestyle modification theories, such as goal setting (exercise prescription module), know-how (educational materials dissemination), stimulus control (constant exercise reminding messages and health tips), incentive (exercise credit-points accumulated for prize redemption), feedback system (online health & fitness assessment), and self-determination theories (personalized exercise training scheduling), was designed and prescribed to 126 Chinese adults (age=20.98 +/- 5.35 yrs.) for a 8-12 weeks exercise intervention program. Exercise compliance was computed from ratio of completed exercise session that recorded from the VT system against planned exercise session at the beginning. At end of intervention a questionnaire was completed by participants to report ratings that they perceived as useful for encouraging exercise participation. Responses were compared between the high compliance group (100% compliance) and low compliance group (<70% compliance). **RESULTS** High compliance group accounted for 67% of total whereas low compliance group 15%. Mean compliance rate for low compliance group was 44.9%. Regarding VT built-in psychological factors the high compliance group reported significantly higher rating in educational contents ($p<.01$), feedback system ($p<.05$), stimulus control ($p<.05$), whereas other factors were not different between groups. **CONCLUSION** Among various behavioral modification theories the stimulus control, know-how, and feedback system are more effective strategies in promoting exercise compliance when integrated with mobile technology.

Exergaming by Sedentary Middle-Aged Adults Did Not Alter Self-Reported Dietary Intake and Physical Activity

Mingmei Tian, Sean M. Kishel, Katherine T. O'Donnell, Daniel M. Rosney, Peter J. Horvath. State University of New York at Buffalo, BUFFALO, NY. (Sponsor: Luc E. Gosselin, FACSM)
Email: mingmei@buffalo.edu
(No relationships reported)

Self-regulation and self-control is a critical consideration to ensure the cogency of the final result in long-term, exercise-related studies since they act as confounding variables that can impact the outcome. Although researchers inform subjects to maintain unwavering lifestyle habits during an experiment, sedentary older people who barely focused on healthy dietary intake and exercise tend to alter their eating and exercise habits due to health awareness evoked by the research experiment.

PURPOSE: To investigate the change in dietary nutrients and physical activity after sedentary middle-aged adults have participated in regular, consistent exergaming.

METHODS: 12 sedentary, middle-aged men and women (56 ± 3.6 years, 162.0 ± 10.9 cm, 79.2 ± 19.1 kg, % fat mass 39.6 ± 7.7 %) used interactive exercise exergaming under monitored conditions at a low to moderate intensity level with self-selected exercises for 20 minutes a day, 3 days a week for 8 weeks. A three-day diet record was used to assess dietary intake and the Yale Physical Activity Survey (YPAS) to estimate energy expenditure and to document the frequency and intensity of various activities before and after the study for each subject.

RESULTS: No significant differences were found between before and after the exercise intervention for total energy intake or any dietary nutrient. The only variable in the YPAS analysis to change was the standing score which significantly increased after exergaming ($5.00-7.33$, $p<0.05$). However, total energy expenditure per day ($p=0.10$) as well as the activity dimension index ($p=0.12$) did not change.

CONCLUSION: Dietary intake and overall physical activity did not change. This indicates a strong control for confounding variables, which can impact final results besides the exercise due to exergaming. The increase in standing score suggests that participation in exergaming can lead to more awareness for healthier lifestyle habits.

Myplate Enhances Physical Activity Along With Nutritional Knowledge In College Students: A Pilot Study

ALI M. Al nawaiseh, Moath F. Bataineh, Akef M. Taifour. Hashemite University, Zarqa, Jordan. (Sponsor: Matt Green, FACSM)

Email: nawaiseh_a@yahoo.com

(No relationships reported)

Purpose: The objective of this study was to investigate whether MyPlate, used as a nutritional assessment and an educational platform, can improve nutritional knowledge, eating attitudes and physical activity levels compared to food records. **Methods:** One hundred twenty university students (18-22 years old) with a normal Body Mass Index (BMI) were recruited and randomly yet equally assigned into one of three groups after signing an IRB approved informed. The groups were: MyPlate group (MG), food records group (FG), and control group (CG). All participants attended two nutritional seminars and completed a modified and validated general nutrition knowledge questionnaire (GNKQ), Eating attitude test (EAT-26) at the beginning and the end of the 4-week study period. A detailed exercise log was also obtained from each participant for the entire period of study. **Results:** Participants in the MG group showed a significant improvements in their nutritional knowledge ($p < 0.05$), eating attitude ($p < 0.05$) and physical activity ($p < 0.05$) compared with other groups. Vegetable consumption elevated from start to finish in the MG ($p < 0.05$) along with a trend towards elevated wholegrain consumption. Males tended to show a more positive eating behavior compared with females in all groups. No significant differences were observed in eating attitude, and physical activity in FG compared with CG. **Conclusion:** MyPlate appears to be an effective tool to improve physical activity, nutritional knowledge and promote positive eating behaviors and therefore wellness.

Comparison of Mindful and Slow Eating Strategies on Acute Energy IntakeAnna Peluso¹, Kelliann K. Davis, FACSM², Bethany Barone Gibbs², Elizabeth M. Venditti², John M. Jakicic, FACSM². ¹Greensboro College, Greensboro, NC. ²University of Pittsburgh, Pittsburgh, PA. (Sponsor: Kelliann K. Davis, FACSM)

Email: anna.peluso@greensboro.edu

(No relationships reported)

Purpose: Mindfulness and slow eating techniques are commonly recommended to aid in weight loss within behavioral weight management programs; yet, the role of these eating strategies on acute energy intake (EI) and satiety are not clear. The purpose of this study was to investigate the effects of mindful and slow eating strategies on acute EI and satiety. **Methods:** 24 subjects (median BMI: 29.1 (24.3 – 36.7), median age: 24.0 (21.0 – 31.8)) were randomized to one of three eating conditions (EAT, SLOW, or MIND). For the EAT condition, subjects were instructed to eat as they normally would for both test meal sessions. For the SLOW condition, subjects were instructed to eat as they normally would for their first test meal session and to slow their eating for their second test meal session. For the MIND condition, subjects were instructed to eat as they normally would during their first test meal session and were given brief instructions on mindful eating for their second test meal session. For each condition, subjects were provided ad-libitum access to a test meal and EI was calculated based upon food consumed during this period. Subjects rated their level of satiety following each meal. **Results:** There were no significant differences in EI between eating strategy conditions (EAT: 848 (704-1071) kcals, MIND: 673 (485- 846) kcals, SLOW: 756 (611-1076) kcals) ($p = 0.786$). There was a trend toward a decrease in energy intake in the MIND condition (mean change in energy intake: -64.4 ± 178.4 kcals) compared with the EAT (mean change in energy intake: 98.3 ± 169.6 kcals) condition and a prevention of increased intake in the SLOW (mean change in energy intake: 2.6 ± 107.9 kcals) condition ($p = 0.133$). There were no significant differences in ratings of satiety between conditions. **Conclusion:** Neither mindful nor slow eating strategies significantly decreased acute EI or satiety, although a decrease in EI achieved through a brief mindfulness practice and prevention of increased intake through slow eating may be clinically meaningful for weight management. Future studies should aim to investigate the potential benefits of slow eating and mindfulness for weight management.

878 Board #57 May 31 3:30 PM - 5:00 PM

Adherence-related Psycho-perceptual Responses To High-intensity Interval Training In Physically Inactive Middle-aged Adults

Eric Tsz-Chun Poon, Anthony Pui-Wan Chung, Waris Wongpipit, Sinead Sheridan, Stephen Heung-Sang Wong, FACSM. The Chinese University of Hong Kong, Hong Kong, Hong Kong. (No relationships reported)

High-intensity interval training (HIIT) has recently been advocated as a time efficient alternative to traditional continuous exercise for combating physical inactivity related morbidities. Previous studies have demonstrated the physiological health benefits of HIIT, but relatively little is known about the adherence related psycho-perceptual responses to this form of exercise in physically inactive individuals. **PURPOSE:** To compare the adherence-related psycho-perceptual responses after a single session of HIIT versus moderate-intensity continuous exercise (MICE) and vigorous-intensity continuous exercise (VICE) in physically inactive middle-aged adults. **METHODS:** Using a repeated measures randomized cross over design, twelve middle-aged apparently healthy physically inactive males (mean age: 46.8 ± 7.5 years; BMI: 23.4 ± 2.1 kg m⁻²; VO_{2max}: 39.5 ± 5.6 mL kg⁻¹ min⁻¹) undertook three main trials (7-days apart) consisting of: HIIT (10 x 1-min run at 100% VO_{2max} interspersed with 1-min active recovery at 50% VO_{2max}), MICE (40-min run at 65% VO_{2max}) and VICE (20-min run at 80% VO_{2max}). Participants' adherence-related psycho-perceptual responses including: (i) Self-efficacy assessed via a 5-item task-specific questionnaire; (ii) Perceived enjoyment responses measured via the Physical Activity Enjoyment Scale (PACES) and (iii) exercise modality preference were assessed upon completion of the trials. [hg1] One-way repeated measures ANOVA was used to identify within-subject differences. Pairwise comparison was conducted with LSD corrections. **RESULTS:** There was a significant main effect between the trials. Participants displayed significantly lower exercise task self-efficacy scores towards HIIT (42.7 ± 25.3) and VICE (49.2 ± 23.9) than MICE (63.4 ± 18.3 , both $P < 0.01$) based upon pairwise comparison. Additionally, only 17% of participants (2 out of 12) reported a preference to engage in HIIT as opposed to either MICE and VICE. No significant difference was found for perceived enjoyment responses between the trials. **CONCLUSION:** Our finding suggests that HIIT does not promote self-efficacy and may not be an adherable exercise strategy for health promotion in physically inactive middle-aged individuals. Future research examining the long-term adherence to HIIT in this population is warranted.

Social Impact Bonds - Applicability In Preventive Medicine

Roni S. Moran, Daniel S. Moran, FACSM, Gil Fire. Ariel University, Ariel, Israel. (Sponsor: Daniel S. Moran, FACSM) (No relationships reported)

Social impact bonds (SIBs) are a relatively new financial model which suggests the entry of private investors into the public sector, in fields which are under the responsibility of government establishments. The private investor goal is to initiate a social program agreed upon together with the government. The investor will receive payment only according to the program's success in achieving its objectives. The growing rate in obesity and related chronic diseases calls for new creative and innovative solutions. **PURPOSE:** To assess the applicability of SIB in preventive medicine and health promotion programs. **METHODS:** Reviewing of all the available academic and governmental publications on existing SIBs and analyzing the reasons for their success and failure. **RESULTS:** Sixty SIBs were launched between 2010-2016 in 15 countries mainly UK, USA, Australia, and Israel focusing on issues of: education, prisoners' rehabilitation, unemployment, health and family care. Out of 22 projects whose data has been delivered, 21 show a very positive outcome. The first SIB ever launched was to reduce recidivism. The project matured in 2016 was declared a success and returned in full the investors' capital. **CONCLUSIONS:** The SIB is a novel model that has the potential to make a dramatic change in the strategy of funding health promotion programs (e.g., obesity epidemic). The model is applicable in preventive medicine and health promotion programs given that a clear and fair contract is signed between the public authority and the private investor. To note, SIBs can be a primary catalyzer in health promotion programs, but cannot substitute government's responsibility for permanent solutions.

Health Promotion Intervention On Rural Roads In Sweden - A Case Study Of Cycling SafetyRuggero L. Ceci¹, Christopher J. Patten². ¹Swedish Transport Administration, Stockholm, Sweden. ²Swedish National Road and Transport Research Institute, Borlänge, Sweden. (Sponsor: Christopher Dunbar, FACSOM)

Email: ruggero.ceci@trafikverket.se

(No relationships reported)

PURPOSE: In Sweden, as well as in many countries in Scandinavia and in northern Europe, there is a growing trend to allocate the daily exercise routines to cycling and walking in the form of work commuting. This has led to an increase of bikers with light race bikes and garment for race bike training along the roads and streets of major cities like Stockholm and Gothenburg and elsewhere. The health gained from this new trend is of course an important factor to consider and the Swedish authorities, cycling organizations and researchers are actively engaged in the development and evaluation of this health trend. One crucial factor in this development is the safety of the bikers on the public roads with mixed traffic. A cyclist is often overtaken by cars and other vehicles and does not have control over the distance between them and the other vehicles. However, if the cyclist had control over the distance between themselves and the motor vehicle/object, how much space would they give themselves? To investigate how road safety factors such as proximity to vehicles passing the bikers on a rural roads a study was conducted.

METHODS: The experiment was conducted in an indoor athletics arena at Lugnet stadium in Falun where 48 participants were assigned to one of three groups. Group one with a balanced order of the object-proximity variable (n = 24); group two with the object-proximity variable ordered closest first and moving outward from the track (n = 12); and group three with object-proximity variable ordered furthest away first and moving inward towards the track (n = 12). The participants were donned with a bicycle helmet with a GoPro camera, a second camera was attached to the handlebars. Independent variables were object proximity to the bicycle lane (cm) measured from the center of the lane; dependent variables were lateral position in cm to moving objects, cycling speed and heart rate.

RESULTS: The preliminary results suggest that bicycle lane must be at least 140 cm broad to accommodate a 'comfortable' passing distance (for the cyclist). The equivalent passing speeds equates to a car speed of approximately 40 km/h. If the car speeds were higher, the bicycle lane will need to be broader.

CONCLUSIONS: This would suggest that the current minimum bicycle lane breadth (in Sweden) of 70 cm would appear to be woefully under-dimensioned.

Relationship Between Affective Responses And Adherence To High Intensity Interval Training In Obese African-American WomenAlvin L. Morton¹, Kelley Strohacker¹, Michael J. McKenzie, FACSOM², Melicia C. Whitt-Glover, FACSOM³, David L. Mount⁴, Lyndsey M. Hornbuckle¹. ¹University of Tennessee, Knoxville, TN. ²Winston-Salem State University, Winston-Salem, NC. ³Gramercy Research Group, Winston-Salem, NC. ⁴Mind Body Institute Beyond, Winston-Salem, NC. (Sponsor: Melicia C. Whitt-Glover, FACSOM)

Email: amorto16@vols.utk.edu

(No relationships reported)

Introduction: A previous parent study showed significantly better adherence for high intensity interval training (HIIT; 31% dropout) compared to steady state (SS; 73% dropout) in a sample of inactive, obese African-American (AA) women (N=27; age: 30.5±6.8 yrs; 5274±1646 steps/day; BMI: 35.1±5.1 kg/m²). However, the relationship between affective responses and adherence is unclear.

Purpose: To conduct exploratory and descriptive analyses of affective responses over time between SS vs. HIIT conditions, and between study completers vs. non-completers.

Methods: Subjects were randomized into a 16-week treadmill exercise intervention, consisting of 4 weeks of conditioning, then 12 weeks of SS or HIIT training. The intervention consisted of three, 32-min bouts/week. SS bouts consisted of continuous exercise at 60-70% of maximal heart rate (HR_{max}). The time-matched HIIT bouts alternated 3-min lower-intensity intervals (60-70% HR_{max}) with 1-min high-intensity intervals (80-90% of HR_{max}). Core affect was assessed using the Feeling Scale (FS), pre- and post-exercise, as well as after the 8th, 20th, and 32nd minute of exercise. Possible FS scores range from -5 (very bad) to 5 (very good). Mean in-task FS scores are reported for the average of three sessions of week 5 and the last week of participation. Descriptive and frequency analyses are presented over the entire week.

Results: SS completers reported FS values of 5.00±0.00 both at week 5 and week 16. HIIT completers reported mean in-task FS values of 2.88±1.19 at week 5 and 3.82±0.63 at week 16. At week 5, SS and HIIT non-completers reported FS values of and 4.08±0.86 and 2.91±1.77, respectively. During the final week of participation

(8.7±3.3 wks), SS and HIIT non-completers reported FS values of 3.88±1.13 and 3.16±1.18, respectively. Of 221 SS and 586 HIIT bouts completed, 11 (5.0%) and 42 (7.2%) contained ≥ one negative in-task FS score, respectively.

Conclusion: While HIIT subjects consistently reported lower FS values relative to SS subjects, mean values were positive and similar to those observed for SS exercise in prior studies. Further, despite lower FS values, HIIT subjects had less dropout. Thus, it seems that HIIT is feasible in this population. These pilot data suggest the need for further research on contributors to adherence to HIIT in low-active, obese AA women.

882 Board #61 May 31 3:30 PM - 5:00 PM

Effect Of Frequent Daily Walking Bouts On Sedentary Time And Self-perceived Fatigue In Free-living Adults

Nathan DeJong, Corey A. Rynders, Daniel H. Bessesen, Audrey Bergouignan. University of Colorado Denver, Aurora, CO.

Email: nathan.dejong@ucdenver.edu

(No relationships reported)

PURPOSE: Breaking up sedentary time with frequent short bouts of activity has been suggested as a novel strategy to reduce sedentary behaviors, but whether this strategy will be effective at reducing sedentary time in free-living conditions is unknown. In this pilot study, objective measures of physical activity and self-reported measures of fatigue and vigor were compared over 3-days among the following free-living conditions (1) microburst activity (MICRO: 5-min of brisk walking every hour for 9 hours), (2) one 45-min bout of brisk walking (ONE), and (3) a sedentary control condition (SED).

METHODS: Eighteen sedentary overweight adults (12F/6M, mean±SD; age=32.2±6.1 yo, BMI= 30.8±2.5 kg/m²) completed each condition (MICRO, ONE, SED) in a randomized crossover study. The percentage of time spent in sedentary, light-intensity (LPA) and moderate-to-vigorous intensity physical activity (MVPA) were measured by accelerometry (ActiGraph GT3X+). At the end of each day, participants self-reported their level of fatigue and vigor using visual analog scales (VAS).

RESULTS: Both MICRO (7.5±3.3%, p=0.04) and ONE (9.5±3.3%, p<0.0001) increased the percentage of time spent in MVPA during waking hours compared to SED (5.2±2.4%). However, MVPA decreased between the first (10.1±2.5%) and the third day (8.2±2.5%, p=0.02) of ONE, while no changes occurred in MICRO. ONE (79.3 ± 5.9%, p<0.0001), but not MICRO (83.1±5.4%) reduced the percentage of time spent sedentary during waking compared to SED (84.4±5.7%). The fact that LPA was lower with MICRO (10.6±4.1%) than with ONE (12.9±5.4%, p=0.03) suggests a spontaneous displacement from LPA towards sedentary time. Participants reported feeling less "worn out" (34.3±25.9 vs. 42.8±26.1, p=0.04), "bushed" (33.8±25 vs. 41.6±24.1, p=0.05), and had a lower desire to close their eyes (37.3±27.5 vs. 44.1±26.6, p=0.05) and lie down (39.5±28.0 vs. 47.6±27.7, p=0.055) during MICRO compared to ONE conditions.

CONCLUSIONS: Performing a continuous bout of brisk walking per day seems to be more potent at increasing MVPA and reducing time spent sitting, however, the effects may not be long lasting. Small lifestyle changes such as those induced by microbursts of activity may be easier to implement in at-risk populations. Long term studies are needed to confirm this hypothesis.

883 Board #62 May 31 3:30 PM - 5:00 PM

Effects Of Whole 30 Dietary Program On Body Composition And Crossfit PerformanceValden Luis Matos Capistrano Junior¹, Renata Alves Carnauba², Natália Marques², Ana Beatriz Baptistella², Renata Desiree Beserra de Sena¹, Angela Siqueira Furtado Martin¹, Adriana Pereira Sampaio¹, Diego de Castro e Silva Lacerda¹, Valéria Paschoal², Andreia Naves². ¹VC Nutrition Clinic research, Fortaleza, Brazil. ²VP Research Institute, São Paulo, Brazil. Email: valdenjunior@hotmail.com

(No relationships reported)

PURPOSE: To evaluate the influence of Whole30 program on body composition and CrossFit performance in trained individuals.

METHODS: Sixty four subjects (age range: 21-54years) attended to nutrition education class to learn food items and recommended volumes comprising the Whole 30 program (allowed foods: meats, seafood/ fish, eggs, fruit, vegetables and mono and polyunsaturated fats; forbidden foods: sugar, sweeteners, alcohol, flour, oat, quinoa, corn, rice, starch, beans, soy, milk and dairy products) and underwent a 15-day training protocol (4 days/ week). On day 1 and day 15 of the training protocol, performance was measured as the minimum time taken to perform CrossFit workout. The body composition was evaluated by portable ultrasound during the days 1 and 30 of the dietetic program. The collected measures were chest (C), triceps (TR), subscapular (SB), medial axillary (MA), suprailiac (SI), abdomen (AB) and medial thigh (MT), and the fat percentage was automatically calculated by the Body View Software. Samples were tested for normal distribution and groups were compared by either Student's t-test or Wilcoxon Mann Whitney test. The type 1 error was set at p<0.05.

RESULTS: After 30 days of Whole 30 program, there was a significant reduction on the sum of 9 skinfolds (67.76±21.21 vs 53.89±16.32, $p < 0.0001$), total fat (23.24±6.73 vs 19.66±6.37, $p < 0.0001$) and trunk fat (47.07±16.14 vs 36.51±11.91, $p < 0.0001$); and a significant gain of body fat-free mass (76.76±6.73 vs 80.34±6.37, $p < 0.0001$). When subgroup analyses were performed by sex, it was found that the relative loss of body fat (sum of 9 skinfolds, total fat and trunk fat) were similar. Regarding performance, a time reduction to perform the Crossfit workout was observed (14'18" vs 12'33", pre and post dietetic intervention, respectively).

CONCLUSIONS: The Whole 30 dietary program promoted body fat reduction and fat-free mass gain in trained Crossfit individuals. Additionally, after 30 days of dietary program, there was observed improvement in performance by reducing the time taken to perform the CrossFit workout.

Variation In Daily Physical Activity During An Exercise Intervention Period In Older Adult Japanese

Ryuji Takigawa¹, Kazunori Sakamoto², Soichi Ando¹, Naoki Yamazaki¹, Ataru Kobayashi¹, Shinobu Tsurugano¹, Kiyoji Tanaka, FACSM³, Kazunori Ohkawara¹. ¹The University of Electro-Communications, Tokyo, Japan. ²National Institute of Informatics, Tokyo, Japan. ³University of Tsukuba, Ibaraki, Japan.
 Email: t1630076@edu.cc.ucc.ac.jp
 (No relationships reported)

Previous studies have reported that healthy middle-aged adults spend less time on physical activity during the weekend than during the weekday. However, there are few reports about this topic that include older Japanese adults.

PURPOSE: To examine variation in the amount of daily physical activity during an exercise intervention for older Japanese adults. Variations between the sexes were also examined in this study.

METHODS: Forty-one healthy adults (female: $n = 24$; male: $n = 17$; age: 73.2 ± 7.3 years) participated in an exercise intervention (UMIN000020678). The exercise program was conducted once a week for 3 months. Daily physical activity was measured using three-axis accelerometers (OMRON: HJA-750C). Physical activity data were categorized into two types: locomotive or household activity. For each day of the week, we compared locomotive and household activity between male and female participants using one-way ANOVA. Statistical significance was set at $P < 0.05$.

RESULTS: For all participants, physical activity amounts for each day of the week (Monday-Sunday) was $21.7\text{-}23.0$ Mets-h/day. There were no significant ($P < 0.05$) differences among the days of the week. The average total amount of daily physical activity through all 7 days of the week was higher for female subjects (24.2 ± 4.5 Mets-h/day) than for male participants (20.0 ± 3.9 Mets-h/day). The average amount of locomotive activity was higher for male participants (5.42 ± 1.81 Mets-h/day) than for female participants (4.8 ± 2.0 Mets-h/day). However, the average amount of household activity was higher for female participants (19.3 ± 3.7 Mets-h/day) than for male participants (14.6 ± 3.5 Mets-h/day).

CONCLUSIONS: The results suggest that there is no significant variation in daily physical activity amounts in older Japanese adults during our exercise intervention. Furthermore, female participants in this intervention had higher total amounts of daily physical activity because of higher household physical activity amounts, even though male participants had higher locomotor activity.

Effects Of Consecutive And Non-consecutive Days Of Resistance Training On Erythrocytes Responses

Yongtai Raymond Wang¹, Pang Boon Bay¹, Junli Huang¹, Hilary Wei Jian Teo¹, Jorming Goh², Yifan Yang¹. ¹Nanyang Technological University, Singapore, Singapore. ²National University of Singapore, Singapore, Singapore.
 Email: ytraymond@hotmail.com
 (No relationships reported)

Exercise has been shown to alter blood parameters depending on the intensity, duration and type of activity. However, most of the documented changes stem from research using aerobic training with little exploration in resistance training (RT). **PURPOSE:** To determine the effects of 12 w of either 3 consecutive (C) or non-consecutive (NC) d/w of RT on erythrocyte responses. **METHODS:** Thirty healthy and recreationally active men [25 (SD 2) y] were randomly assigned to either C or NC for 12 w. Both groups performed 3 sets x 10 repetitions at pre-determined 10 repetition-maximum of leg press, latissimus pulldown, leg curl, shoulder press and leg extension for each RT session. Blood was sampled in untrained state pre (UT Pre), immediately post 3rd day of RT (UT 0 h), 24 h post 3rd day of RT (UT 24 h) in week 1, and also in trained state pre (T Pre), immediately post 3rd day of RT (T 0 h), 24 h post 3rd day of RT (T 24 h) in week 12. Whole blood was analyzed for red blood cell (RBC) counts, hemoglobin (Hb), hematocrit (Hct), mean cell volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), mean plasma

volume (MPV), and red cell distribution width (RDW). Analysis was conducted using Generalized Estimating Equations. **RESULTS:** Both groups were similar in age, weight [65 (10) kg], height [1.72 (.06) m], BMI [22.2 (2.7) kg/m²], systolic and diastolic blood pressures [114 (5)/69 (8) mm Hg], fasting glucose [4.5 (.3) mmol/L] and physical activity level [2144 (1428) MET-min/w] pre-RT. No interaction was found for all measures ($p = .350\text{-}.944$). There were no group differences except for Hb, MCHC, and RDW ($p = .001\text{-}.022$). Differences were due to the means (SE) of Hb [C: 15.150 (.194) > NC: 14.396 (.267) g/dL], MCHC [C: 35.071 (.217) > NC: 34.060 (.231) g/dL], and RDW [C: 12.553 (.163) < NC: 13.530 (.328) %] being lower in one group than the other at baseline. C and NC showed similar profile across respective time points. Hct, MCV and MCH increased at UT 0 h ($p = <.001\text{-}.033$) but Hct lowered at UT 24 h ($p = .006$) while MCH remained elevated at UT 24 h ($p = .042$) compared to UT pre. RBC and Hb lowered at UT 24 h compared to UT Pre ($p = .002\text{-}.029$). MCV and MPV increased ($p < .001\text{-}.037$) while MCHC lowered ($p = .022$) at T 0 h compared to T Pre. **CONCLUSION:** Both groups demonstrated similar post-RT responses in erythrocytes profile.

No Difference in Body Composition and Strength between Consecutive and Non-consecutive Days of Resistance Training

Yifan Yang¹, Pang Boon Bay¹, Yongtai Raymond Wang¹, Junli Huang¹, Hilary Wei Jian Teo¹, Jorming Goh². ¹Nanyang Technological University, Singapore, Singapore. ²National University of Singapore, Singapore, Singapore.
 Email: yifan.yang@nie.edu.sg
 (No relationships reported)

PURPOSES: Health authorities worldwide recommends 2-3 d/w of resistance training (RT) for health, preferably spread 48-72 h apart. However, it is common among fitness buffs, top athletes and weekend warriors to RT on consecutive days. Yet, effects of recovery period in between RT sessions on many physiological variables are unclear. Therefore, the purpose of this study is to determine the effects of 12 w of either 3 consecutive (C) or non-consecutive (NC) d/w of RT on body composition and strength. **METHODS:** Thirty young, healthy and recreationally active men [25 (SD 2) y] were randomly assigned to either C or NC for 12 w. Both groups performed 3 sets x 10 repetitions at 10 repetition-maximum (RM) of leg press (LP), latissimus pulldown (LAT), leg curl (LC), shoulder press (SP) and leg extension (LE) for each RT session. Body composition using dual-energy X-ray absorptiometry and 10RM for the RT were determined pre- and post-RT. Differences were analyzed using 2x2 mixed design repeated measures ANOVA (with aligned rank transformation for nonnormal data with or without equal variances). **RESULTS:** Both groups were similar in age, weight [65 (10) kg], height [1.72 (.06) m], BMI [22.2 (2.7) kg/m²], systolic and diastolic blood pressures [114 (5)/69 (8) mm Hg], fasting glucose [4.5 (.3) mmol/L] and physical activity level [2144 (1428) MET-min/w] pre-RT. No interaction was found for all measures of body composition and 10RM ($p = .242\text{ to } .999$). There were no group differences ($p = .143\text{ to } .948$) except bone mineral density (BMD), which was higher in C (11.81 kg/m²) than NC (11.08 kg/m², $p = .025$). However, C and NC improved their BMD similarly following RT [+0.19 kg/m²; 95% CI of gain (.11, .28), $p = <.001$]. Both groups also gained weight ($p < .001$; C: 65.7 to 67.0 kg; NC: 63.8 to 65.7 kg) due to lean body ($p < .001$; C: 50.5 to 52.0 kg; NC: 48.6 to 50.6 kg) and bone mass gains ($p = .003$; C: 2.50 to 2.53 kg; NC: 2.30 to 2.32 kg) with an insignificant fat loss ($p = .438$). Body fat % reduced similarly for both groups ($p = 0.029$; C: 18.7 to 18.0%; NC: 19.8 to 18.9%) with no change in fat distribution in the limbs and trunk ($p = .172\text{ to } .898$). Both groups improved 10RM similarly for all exercises ($p < .001$ for all; 55 kg for LP, 22 kg for LAT, 13 kg for LC, 6 kg for SP and 20 kg for LE). **CONCLUSIONS:** Both groups improved body composition and strength similarly post-RT.

A Mobile Application for Improving Gait Characteristics in Community-Dwelling Older Adults

K. Jason Crandall, Dustin Falls, Matthew Shake, Elizabeth Norris, Scott Arnett, Kathryn Dispenette, Rilee Mathews. Western Kentucky University, Bowling Green, KY.
 Email: Jason.Crandall@wku.edu
 (No relationships reported)

PURPOSE: Evaluate the efficacy of a mobile health promotion application (app) to improve gait characteristics related to increased fall risk in older adults. **METHODS:** Community-dwelling older adults ($N=38$; age 72.42 ± 12.58) were recruited and randomly assigned to experimental ($n=20$; app with exercise) or control ($n=18$; app without exercise) condition. Pre/post gait analysis at self-selected (SS) and fast walking speeds was measured using the GAITRite® Electronic Walkway. Gait variables included ambulation time (AT), velocity, cadence, step length and width, base of support, cycle time, single and double support time. Statistical analysis included a

mixed-model ANOVA ($p < .05$). RESULTS: No main effects were found. Significant improvements (group x time) were observed for the experimental group at fast walking speed for AT ($\lambda = .878$, $F(1, 36) = 5.01$, $p = .031$, $ES = .122$); velocity ($\lambda = .886$, $F(1, 36) = 4.61$, $p = .039$, $ES = .114$); and step length ($\lambda = .864$, $F(1, 36) = 5.64$, $p = .023$, $ES = .136$). Significance at SS speed included AT ($\lambda = .892$, $F(1, 36) = 4.37$, $p = .044$, $ES = .108$) single support ($\lambda = .887$, $F(1, 36) = 4.59$, $p = .039$, $ES = .113$); and double support time ($\lambda = .886$, $F(1, 36) = 4.63$, $p = .038$, $ES = .114$). The remaining variables were non-significant. CONCLUSION: The mobile health promotion app can significantly improve AT, velocity, step length and body support time during the gait cycle at varying speeds to potentially reduce the risk of falls in older adults. Nurses' Physical Activity Study: Caring For You So You Can Care For Others

Bhibha M. Das¹, Brianna S. Clemmons¹, Charles D. Kemble¹, Ann M. Schreier¹, Matthew T. Mahar, FACSM². ¹East Carolina University, Greenville, NC. ²San Diego State University, San Diego, CA. (Sponsor: Matthew Mahar, FACSM)
 Email: dasb@ecu.edu
 (No relationships reported)

Nurses face multiple negative stressors and report the greatest stress of all health care workers. The stress can have a negative effect on the health of nurses (e.g., obesity, fatigue, decrease in quality of life and satisfaction with life, and burnout). Stress is common among nurses with negative impacts on a nurse's health as well as the quality of care patients receive. It is important for nurses to implement self-care strategies techniques (e.g., physical activity) to lower feelings of stress.

PURPOSE: To examine the relationship between physical activity levels and measures of health among nurses in eastern NC.

METHODS: Nurses ($n = 62$, 94% females; 85% White; age = 42.2 ± 11.7) were assessed for physical activity via the Fitbit Flex activity tracker over a 7 day period and the International Physical Activity Questionnaire. Nurses reported burnout, stress, and fatigue using self-reported questionnaires. Body mass index was measured by dividing weight (kg) by the participant's squared height (m).

RESULTS: BMI was significantly correlated with moderate-to-vigorous physical activity ($r = -.28$), steps ($r = -.029$), and vigorous intensity physical activity ($r = -.32$). Fatigue was significantly correlated with moderate-to-vigorous physical activity ($r = -.27$). Stress was significantly correlated with steps ($r = -.27$), moderate intensity physical activity ($r = -.25$), and light intensity physical activity ($r = -.40$). Significant associations were also found between quality of life and light intensity physical activity ($r = .40$), moderate intensity physical activity ($r = .30$), and steps ($r = .29$). A relationship was found between high intensity physical activity and burnout ($r = -.23$, $p < .001$) and between steps and compassion fatigue ($r = -.26$, $p < .05$).

CONCLUSIONS: Findings demonstrated that stress, fatigue, and burnout were lowly correlated with physical activity among nurses. Thus, a physical activity intervention among nurses may be needed to fully see the effects of physical activity on nurses' health, and ultimately patient health and safety.

889 Board #68 May 31 3:30 PM - 5:00 PM
Evaluation of a Screening Device that Incorporates the ACSM'S Newly Revised Screening Guidelines

JoAnn M. Eickhoff-Shemek, FACSM¹, Aaron C. Craig².
¹University of South Florida, Tampa, FL. ²TechnoGym, Tampa, FL.
 Email: eickhoff@usf.edu
 (No relationships reported)

Major revisions in the ACSM's screening guidelines will be included in the 10th edition of the ACSM's Guidelines for Exercise Testing and Prescription (GETP). The primary goal of the revised guidelines is to streamline the screening procedures published in the 9th ed. of the GETP by (a) eliminating the assessment of risk factors and stratification of individuals into low, moderate and high risk categories, and (b) possibly reducing the number of individuals needing to obtain medical clearance. A pre-activity screening questionnaire (PASQ) that incorporated the revised guidelines was administered to employees who participated in the 2016 University of South Florida FIT program.

PURPOSE: To evaluate the PASQ by obtaining feedback from FIT participants and the exercise professional who administered the PASQ. **METHODS:** After completing the PASQ, participants were sent an e-mail asking them to complete a survey to determine if the terms and questions in each of the following five sections of the PASQ were clear and understandable: (1) Instructions, (2) Current Physical Activity, (3) Medical Conditions, (4) Signs/Symptoms, and (5) Acknowledgement/Signature. **RESULTS:** Of the 20 participants, 15 (75%) completed the survey including 10 new and five returning FIT participants. All participants indicated "yes" when asked if the terms and questions were clear and understandable in all of the five sections except one participant. This individual indicated that the definitions of moderate and vigorous intensity (in Section 2) were not clear and understandable and commented that there

was not much variance in the activity levels. Regarding level of difficulty to complete the PASQ, 10 indicated "very easy" and five indicated "easy". The professional who administered/interpreted the PASQ indicated the process was easier and more time efficient than the PASQ used for the FIT program in previous years that incorporated the screening guidelines from the 9th ed. of the GETP. Three of the five returning FIT participants also indicated that the PASQ was easier and faster to complete than the previous PASQ. In addition, none of the FIT participants needed to obtain medical clearance compared to previous years in which 25-35% of the participants did. **CONCLUSION:** The PASQ was found to achieve the primary goal of the ACSM's revised guidelines.

Perceived Enjoyment Responses to High-intensity Interval Exercise and Continuous Exercise in Physically Inactive Young Men

Waris Wongpipit, Eric T.C. Poon, Anthony P.W. Chung, Sinead E. Sheridan, Stephen H.S. Wong, FACSM. The Chinese University of Hong Kong, Hong Kong, Hong Kong.
 Email: waris.w@link.cuhk.edu.hk
 (No relationships reported)

Exercise enjoyment is purported to predict future exercise engagement. While the physiological benefits associated with high intensity interval exercise (HIIE) have been well documented, limited information exists regarding individuals' enjoyment of this form of exercise in comparison to traditional continuous exercise modalities, particularly in physically inactive individuals. **PURPOSE:** To quantify rating of perceived enjoyment using the physical activity enjoyment scale (PACES) following HIIE, moderate-intensity continuous exercise, and vigorous-intensity continuous exercise in physically inactive young men. **METHODS:** Twelve physically inactive apparently healthy young men (mean age: 24.33 ± 1.72 years; body mass index: 23.49 ± 4.64 kg m⁻²; VO_{2max} : 44.86 ± 6.55 mL kg⁻¹ min⁻¹) participated in the study. Using a randomized cross over design, participants undertook three running trials consisting of HIIE (10 x 1 min at 100% VO_{2max} interspersed with 10 x 1 min active recovery at 50% VO_{2max}), moderate-intensity continuous exercise (40 min at 65% VO_{2max}) and vigorous intensity continuous exercise (20 min at 80% VO_{2max}). After the completion of all trials, participants were asked to rate their perceived enjoyment using PACES. Statistical analysis was calculated using one-way ANOVA with repeated measures to examine within-subject effect. **RESULTS:** There was no significant difference in perceived enjoyment rating following HIIE (92.42 ± 13.77), moderate-intensity continuous exercise (87.67 ± 15.38), and vigorous intensity continuous exercise (90.58 ± 16.38) ($p = 0.10$). **CONCLUSIONS:** Acute enjoyment responses to HIIE and continuous exercise were similar in physically inactive young adults. Future research is warranted to compare the chronic enjoyment responses to HIIT and continuous exercise in this population.

Food Insecurity and Physical Activity Insecurity among Rural Oregon Families

Katharine B. Gunter, 97331, FACSM, Jennifer Jackson, Emily Tomayko, Deborah H. John. Oregon State University, Corvallis, OR.
 Email: Kathy.Gunter@oregonstate.edu
 (No relationships reported)

Obesity rates are higher among rural compared to urban children in the U.S. for reasons that are incompletely understood. Emerging data suggest a relationship between food insecurity (FI) and physical activity (PA) insufficiency among children in the U.S., both factors that have been associated with obesity. Rates of child FI are known to be higher among rural compared to urban households, but research is mixed regarding rural/urban differences in PA. As such, exploring the relationships between FI, PA insufficiency, and obesity may help us better understand the rural/urban differences in child obesity rates.

PURPOSE: To examine the association between FI risk and family diet and PA behaviors associated with child obesity, among a sample of families residing in rural Oregon.

METHODS: Families ($n = 144$) were recruited through six elementary schools (K-5/6) in low-income, rural, Oregon communities. Families completed surveys including a FI risk screener and the Family Stage of Change Survey (FSOC), a measure of readiness to change family-level diet ($n = 6$ items), sleep ($n = 1$ item) and PA ($n = 5$ items) behaviors shown to predict child obesity. Logistic regression was applied to examine associations between FSOC scores and FI risk.

RESULTS: Among families at risk for FI (40.2%), a higher proportion were non-white (77.8% versus 22.2%; $p = 0.036$) and had lower adult education levels (30.4% versus 11.8% with a high school degree or less; $p = 0.015$) compared to families not at risk for FI. Of the 12 FSOC items, only one significant difference emerged between families at risk and not at risk for FI: families at risk for FI scored lower on an item reflecting their readiness to provide and support opportunities for structured PA ($p < 0.001$).

Logistic regression analyses showed the odds for FI risk were 55% lower among families reporting higher readiness to provide and support structured PA opportunities ($p=0.003$).

CONCLUSIONS: FI risk is associated with rural families' readiness to provide PA and support structured PA opportunities for their children. A better understanding of factors relating to readiness and ability to provide structured PA and its relationship to FI may inform future obesity prevention efforts for at-risk families.

Impact of Visual Feedback on Exercise Intensity and Motivation

Kelsey Reynolds, Dale D. Brown, FACSM, Daniel Dodd, Kelly R. Laurson. *Illinois State University, Normal, IL.*

(No relationships reported)

PURPOSE: Determine if visual feedback motivates college-aged students to maintain a higher exercise intensity during an indoor cycling class and to ascertain the favored type of visual feedback.

METHODS: Thirty participants took part in a within-subject design experiment. Participants were assigned a heart rate monitor and identification number to record and monitor exercise intensity during each class session. Participants completed three cycling classes that were randomly assigned as a no visual feedback (NF), individual feedback (IF), or group feedback condition (GF). A Spielberger Trait Anxiety survey was completed before the first session and the Spielberger State Anxiety survey was completed before every cycling session. For each condition, participants stated if they enjoyed the heart rate feedback received and using the heart rate monitors. At the end of the study, participants specified the visual biofeedback condition they preferred.

RESULTS: The group feedback condition spent a higher percentage of time above 80% of their age-predicted heart rate maximum. Participants spent 17.5% of their time in the 80-90% heart rate zone and 2.8% in the 90-100% zone. No feedback and individual feedback groups spent 13.2% and 15.1% in the 80-90% heart rate zone and 0.9% and 2.7% in the 90-100% zone. A 1-way repeated measures ANOVA indicated a statistically significant difference between the time spent in the 60-70% heart rate zone between the three conditions. The group feedback condition had the highest average heart rate (138.1 bpm), maximal heart rate (174.4 bpm), and heart rate predicted caloric expenditure (293.5 kcal). A positive correlation was found between the group feedback RPE and enjoyment of group feedback ($r=0.55$, $p=0.01$). The RPE of individual feedback was positively correlated with working harder due to wearing a heart rate monitor ($r=0.54$, $p=0.01$) and receiving individual feedback ($r=0.57$, $p=0.01$). Twenty-one (70%) participants preferred group feedback, 4 participants (13.3%) favored the individual feedback, 1 participant (3.3%) chose no feedback, and 4 participants (13.3%) had no preference.

CONCLUSIONS: Participants favored group feedback over individual feedback and no feedback. Visual feedback was associated with higher exercise intensity and greater enjoyment of the exercise session.

Impact Of Sit-to-stand Workstation Use On Physical Fitness: A Pilot Study

Catherine Patrick, Shiann Wickham, Larissa Boyd, Melissa Powers. *University of Central Oklahoma, Edmond, OK.*
Email: cpatrick3@uco.edu

(No relationships reported)

Recent studies indicate sedentary lifestyles have a negative impact on physical fitness. Modifying sedentary daily activities could maintain and improve optimal health. The introduction of sit-to-stand workstations within the workplace provides sedentary employees an opportunity to alternate between sitting and standing positions.

PURPOSE: The purpose of this pilot study was to determine if using a sit-to-stand workstation would improve physical fitness. **METHOD:** Eleven healthy male and female full-time faculty (age = 39.09±10.45 years) volunteered to use a sit-to-stand workstation for a minimum of three hours per workday for one year. Muscular fitness was assessed as hand-grip strength, partial curl-up test, and push-up test. Flexibility was measured using the sit-and-reach test, while estimated $\dot{V}O_{2max}$ was determined through the Queens College Step Test. Balance was evaluated by a timed one-leg stance with eyes closed. **RESULTS:** Six participants completed this one year pilot study. Three participants withdrew from the study due to inconvenience or difficulty using the workstation; one withdrew due to retirement. One additional participant was unable to complete post-testing. Independent samples *t*-tests indicate no difference at baseline in any physical fitness variable between those who completed the study and those who withdrew ($p > .05$). Due to the sample size, no significant differences were observed in physical fitness over the one year period ($p > .05$); however, potential meaningful changes were observed using Cohen's *d* calculations for effect size. Hand-grip strength increased by 3.17 kg ($d = 0.11$, +4.82%), while the number of curl-ups performed

increased by 3.5 ($d = 0.17$, +9.46%). Estimated $\dot{V}O_{2max}$ increased by 1.12 kg/ml/min¹ ($d = 0.31$, +2.57%) and one leg stance with eyes closed increased by 2.62 seconds ($d = 0.15$, +15.20%). **CONCLUSION:** Improvements in strength, balance, and $\dot{V}O_{2max}$ suggest sit-to-stand workstations may have a positive impact on employees' physical fitness. Participants who withdrew due to difficulty of use indicate a need for examining desk selection, instruction of use, and motivational techniques. Further investigation of a larger population should focus on potential physical fitness benefits and functionality for the user of sit-to-stand workstations.

Soccer Training Improves Metabolic and Cardiovascular Health in 50-70-yr olds with pre Type 2 Diabetes

Magni Mohr¹, May-Britt Skoradal¹, Jann Mortensen², Pál Weihe³, Peter Krstrup⁴. ¹University of the Faroe Islands, Tórshavn, Faroe Islands. ²The Faroese National Hospital, Tórshavn, Faroe Islands. ³The Faroese Hospital System, Tórshavn, Faroe Islands. ⁴University of Southern Denmark, Odense, Denmark.

Email: magnim@setur.fo

(No relationships reported)

Type 2 Diabetes Mellitus is a pathological condition, which partly is provoked by an inactive lifestyle. **PURPOSE:** To examine effects of soccer training vs. dietary advice on glucose control, metabolic and cardiovascular health status in patients with pre-T2DM. **METHODS:** Fifty 50-70 yr-old untrained participants (26 women and 24 men; age: 61±1 yrs; height: 171±1 cm, weight: 85.7±2.3 kg; $\dot{V}O_{2max}$: 22.1±0.8 ml·min⁻¹·kg⁻¹; mean arterial pressure (MAP): 103±2 mmHg) suffering from pre-T2DM were randomized into a soccer training (SOC; n=26) and control (CON; n=24) group. Both group received standardized dietary advice during a 16-wk intervention period. Additionally, SOC completed two sessions/wk of soccer training. Training consisted of small-sided games being increased progressively from 30 to 60 min per session during the 16-wk intervention period. Pre and post-intervention, the participants completed a maximal oxygen uptake ($\dot{V}O_{2max}$) bike test, an oral glucose tolerance test (OGTT), a DXA-scan, as well as assessments for blood lipid profile, blood pressure and resting heart rate. **RESULTS:** Post-intervention plasma glucose at rest and at 120 min in the OGTT were lowered ($P<0.05$) in SOC and CON, with a greater effect ($P<0.05$) in SOC compared to CON (-2.3±0.3 vs -1.2±0.4 mmol·L⁻¹). After 16 wks $\dot{V}O_{2max}$ was improved ($P<0.05$) by 4.3±0.5 ml·min⁻¹·kg in SOC, which was more than in CON (-0.6±0.5 ml·min⁻¹·kg). In SOC, body fat content and plasma triglycerides were lowered by -3.4±0.6 kg and -0.31±0.06 mmol·L, respectively, and with changes scores greater ($P<0.05$) compared to CON. Moreover, SOC improved ($P<0.05$) resting heart rate, lean body mass and waist circumference to a greater degree than CON. **CONCLUSIONS:** Soccer training in combination with dietary advice improves glucose control, as well as metabolic and cardiovascular health to a greater degree than dietary advice alone in 50-70 yr old patients with pre-T2DM.

Do University Fitness Classes Meet Acsm'S Daily Activity Recommendations

Jeff Williams, Taylor Ottesen, Zachary Fuller, Mitch Kass, William Mitchell, Ellis Jensen, Steven F. Namanny. *Utah Valley University, Orem, UT.*

Email: namanny@uvu.edu

(No relationships reported)

Purpose: The obesity crisis facing the American population is well documented. The American College of Sports Medicine (ACSM) recommends individuals exercise for 30 minutes five days a week at moderate intensity. College and University activity courses may be one avenue for obtaining such activity. **Methods:** To determine if college activity courses meet this requirement, physical activity was monitored in 78 students during their class activity period. The students were men and women between the ages of 18-35. Actigraph GTX9 accelerometers were used to estimate caloric expenditure as well as time spent in sedentary, light, and moderate intensity zones. **Results:** 3 out of the 8 fitness courses measured provided students with 30 minutes or more of physical activity, meeting ACSM recommendations. **Conclusion:** While college activity courses are a good supplement to an individual's physical activity regimen, many courses should not be considered sufficient to provide all of the daily exercise a student needs.

B-62 Free Communication/Poster - Aging in Skeletal Muscle and Bone

Chronic Systemic Inflammation, Physical Activity and Skeletal Muscle in Elderly

Fawzi Kadi, Andreas Nilsson, Britta Wåhlin-Larsson, Oscar Bergens. *Örebro University, Örebro, Sweden.*
(No relationships reported)

PURPOSE: It is hypothesized that chronic systemic inflammation is influenced by physical activity level and is involved in the age-related decline in muscle function. The impact of physical activity behaviours on the level of C-reactive protein (CRP) and tumour necrosis factor alpha (TNF- α) in elderly women is investigated. The impact of chronic systemic inflammation on muscle mass and the cellular and molecular mechanisms behind the putative inflammation-mediated action on human muscle cells are explored.

METHODS: Total amount of sedentary time, 30-minute periods of sedentary time and breaks in sedentary behaviour and time spent in moderate-to-vigorous physical activity (MVPA) were assessed using accelerometry in a cohort of 89 elderly women. Serum HsCRP and TNF- α were measured. The proliferative and metabolic capacity of human muscle cells obtained from vastus lateralis and exposed to CRP are assessed. **RESULTS:** No variables of sedentary behaviour were significantly associated with the level of CRP or TNF- α . In contrast, time spent in MVPA was inversely associated with the level of CRP, independently of sedentary behaviour and waist circumference, but not TNF- α . Serum CRP levels were inversely associated to skeletal muscle mass. Elevated serum CRP levels were associated to reduced proliferative rate of human muscle cells and changes in the regulation of the size muscle cells.

CONCLUSIONS: Elevation in the inflammatory status in elderly is influenced by the amount of time spent in MVPA and exerts detrimental effects on skeletal muscle mass.

897 Board #76 May 31 3:30 PM - 5:00 PM
Biomarkers of Senescence in Aging Skeletal Muscle

Dongmin Kwak¹, Cory W. Baumann², LaDora V. Thompson¹.
¹Boston University, Boston, MA. ²University of Minnesota, Minneapolis, MN.
(No relationships reported)

PURPOSE: Cells enter into a state of senescence in response to certain stressors, such as aging and age-related diseases. It is proposed that senescent cells drive pathogenesis (e.g., atherosclerosis). Hence, it is possible that senescent cells underlie sarcopenia. Biomarkers of senescence include p53, p21, p16, IL-6, and senescence associated beta-galactosidase (SA β -gal). These biomarkers have been extensively investigated using in vitro cell culture experimentation. The purpose of this study was to explore the role of senescence as a potential driver of age-associated sarcopenia. We hypothesized that biomarkers of senescence will be increased in aging skeletal muscle and it is highly associated with sarcopenia.

METHODS: To identify biomarkers of senescence in aging skeletal muscle, the extensor digitorum longus (EDL) and tibialis anterior (TA) muscles were excised from male C57BL/6 adult (<12 months, N=11) and elderly (>28 months, N=11) mice. The EDL was then used to assess ex vivo whole muscle physiology while the TA was used for histological and biochemistry analyses. Western blotting was performed to determine the expression of p53, p21 and p16, and an ELISA was performed to detect IL-6 content. Senescent cells were determined by SA β -gal staining. **RESULTS:** Muscle wet weight and absolute force production were significantly reduced in the elderly group. Aging resulted in a significant increase in p21 and IL-6, but did not alter p53 or p16 expression. Because the identification of senescent cells by SA β -gal staining was very low the statistical comparison between adult and elderly was not performed.

CONCLUSIONS: Taken together, selective biomarkers of senescence are present in muscles from elderly mice. Because p21 and IL-6 both increased in the elderly muscle, it is possible that these proteins play a role in the development of age-associated sarcopenia.

The Effect of Weighted Vest Use During Caloric Restriction on Bone Health in Obese Older Adults

Jessica L. Kelleher¹, Dan P. Beavers², Rebecca M. Henderson², Jessica Kiel³, Barbara J. Nicklas², Kristen M. Beavers¹. ¹Wake Forest University, Winston-Salem, NC. ²Wake Forest School of Medicine, Winston-Salem, NC. ³Medifast, Inc., Owings Mills, MD. (Sponsor: Peter Brubaker, FACSM)
(No relationships reported)

PURPOSE: To explore the effects of weighted vest use during caloric restriction on bone density and turnover.

METHODS: 37 obese older adults underwent a 5.5 month dietary weight loss intervention (1000-1300kcal/d) with (D+V; n=20) or without (D; n=17) weighted vest use (10+ hrs/d). Bone mineral density (BMD) of the total hip, femoral neck and lumbar spine, and biomarkers of bone turnover (OC, BALP, PINP, CTX) were measured. General linear models, adjusted for baseline values of the outcome and gender, were used to examine intervention effects.

RESULTS: Mean age of participants was 70.1 \pm 3 years, 78% were female, 78% were Caucasian, and baseline BMI was 35.3 \pm 2.9 kg/m². Average weight loss was 11.2 \pm 4.3 kg and 11.0 \pm 5.9 kg in the D+V and D groups ($p=0.94$), and average weighted vest use was 6.7 \pm 2.3 hrs/day. No significant changes in BMD or biomarkers were observed, although trends were noted for total hip BMD and BALP. Loss in total hip BMD was greater in the D group compared with D+V (Δ : -18.7 [29.3, -8.1] mg/cm² versus -6.1 [-15.7, 3.5] mg/cm²; $p=0.08$). BALP increased in the D+V group by 3.8% (Δ : 0.59 [-0.33, 1.50] U/L) and decreased by -4.6% in the D group (Δ : -0.70 [-1.70, 0.31] U/L, $p=0.07$).

CONCLUSIONS: Weighted vest use during weight loss may attenuate loss of hip BMD and increase bone formation.

Age-dependent Genomic Responsiveness Following Stretch-shortening Contraction Training In Rats

Brent A. Baker, James Ensey, Michael L. Kashon, Ja K. Gu. *NIOSH, Morgantown, WV.* (Sponsor: Stephen E. Alway, FACSM)
Email: bwb3@cdc.gov
(No relationships reported)

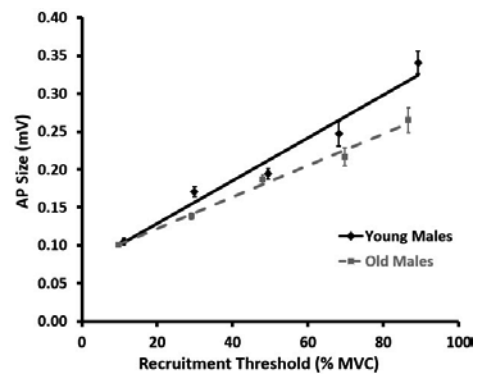

When administered repeatedly, "resistance-type" exercise training may result in adaptation; but, if not properly prescribed, may also result in maladaptation. Maladaptation is characterized by diminished muscle performance and/or muscle mass enhancement. Nevertheless, the genomic response owing to age-dependent adaptation or maladaptation has not been fully established. **PURPOSE:** Our aim was to characterize the genomic responses to adaptation or maladaptation following stretch-shortening contraction (SSC) training with aging. **METHODS:** Dorsiflexor muscles of F344xBN hybrid rats (N=8 per group) were exposed to 1 month of training using a custom-built dynamometer *in vivo*. Transcriptional microarray analysis was conducted in the tibialis anterior 24 hours following the final session. Genes fulfilling the criteria of fold change < -1.1 and > 1.1, $p < 0.05$, and False Discovery Rate $p < 0.05$ were considered significant and analyzed by Ingenuity Pathway Analysis (IPA). **RESULTS:** Concomitant with age-dependent adaptive and maladaptive functional outcomes, transcriptional microarray analysis of muscles from young rats differentially expressed 475 genes following SSC training, while muscles of old rats differentially expressed 1095 genes. Bioinformatic analysis revealed that cellular function and maintenance was a major biological process and tissue development was a major physiological function overrepresented with genes altered by SSC training in young rats, while small molecule biochemistry was a major biological process and organismal development was a major physiological function overrepresented in old rats. Furthermore, in young rats, upstream regulator analysis predicted the activation of CREB1 (z-score 3.144) involved in transcriptional regulation and growth with a parallel inhibition of TSC2 (z-score -2.538) a negative regulator of cell size. In contrast, old rats displayed activation of MAP4K4 (z-score 4.526) involved in apoptotic signaling with concurrent inhibition of PPARC1A (z-score -4.347) that's involved in mitochondrial biogenesis and hypertrophy. **CONCLUSIONS:** The results highlight an altered age-dependent genomic pattern of responsiveness subsequent to SSC training, and emphasizes the molecular features which accompany these disparate outcomes.

Regression Equation To Predict Body Fat In Elderly Women Using Body Circumference Measures
 Eliane Cunha GONCALVES, DRA. *FAcadade Estácio de Vitória, VITORIA - ES, Brazil.*
 Email: elianecgc@hotmail.com
 (No relationships reported)

Purpose: The purpose of this study was to develop and validate an equation to estimate body composition in elderly women above 60 years of age using body circumference measures. **Methods:** The sample consisted of 60 women individuals with an average age of 68.23 ± 5.84 years, 63.97 ± 10.65kg, 1.542 ± 0.52m from the Vitória metropolitan area. The group was split into two subgroups: a regression group (n=50) used to develop the equations and a validation group (n=10) used for cross reference. A multiple linear regression was used to develop the equation. Both equations were compared using the Student's *t* test for paired samples. The reliability of the equations was analyzed by the *Blant and Altman* method. **Results:** The regression group had the following descriptive metrics: age 67.62 ± 5.87 years, body weight 64.27 ± 11.11kg, height 1.53 ± 0.11m; and percent body fat 41.73 ± 5.69%. The validation group had the following descriptive metrics: 71.3 ± 4.8 years, body weight 62.49 ± 8.34kg, 1.55 ± 0.53m; and percent body fat 41.75 ± 4.04%. Body circumferences variables were used to develop equations to predict body fat. Using the stepwise selection criteria, the following equation was developed: % body fat = 0.343 (hip) + 0.289 (waist) - 0.0714 (handle)². Several parameters validated the strength of the equation: R² = 0.997; EPE = 3.29; EPE ≤ 3.5%; and validation of the model based on the partial significance (F) of the subset of variables that showed the strongest effect. **Conclusion:** It is possible to develop an accurate and specific equation to estimate of body fat percent in elderly women using circumference measurements. The more important is that is easy to use by health professionals.

Motor Unit Action Potential Size In Young And Old Males
 Garrett Hester¹, Zachary Pope², Alejandra Barrera-Curiel², Jason DeFreitas². ¹*Kennesaw State University, Kennesaw, GA.* ²*Oklahoma State University, Stillwater, OK.*
 Email: ghester@okstate.edu
 (No relationships reported)

PURPOSE: To examine the effect of aging on action potential size (AP_{size}) of motor units (MUs) across the relative recruitment threshold (rRT). **METHODS:** Nineteen young (YM: age = 21.68 ± 2.31 yrs., BMI = 26.07 ± 4.89 kg·m⁻²) and eighteen older (OM: 63.55 ± 8.02 yrs., BMI = 27.94 ± 4.12 kg·m⁻²) untrained males participated in this study. Upon completion of a familiarization, subjects performed 2 maximal voluntary isometric ramp contractions (MVCs) of the knee extensors using an isokinetic dynamometer while 4 surface electromyography (sEMG) signals were recorded from the vastus lateralis using a 5-pin surface array sensor. The raw sEMG signals were decomposed into their constituent MU action potential trains to determine the rRT and AP_{size}. rRT was defined as the relative force level (%MVC) when the MU began firing, and AP_{size} was considered the maximum peak-to-peak amplitude (mV). Linear regression was used on the pooled and individual data for YM and OM separately to examine the relationship between rRT and AP_{size}. For the pooled data, bin widths of 20% were used for rRT. The means for individual slope coefficients (SLP_c; mV/%MVC) were compared between the YM and OM using independent samples *t*-tests. **RESULTS:** A total of 810 MUs were detected (YM: 389; OM: 421). The regression equations for the pooled data were - YM: $y = 2.82e^{-03}x + 7.18e^{-02}$; R² = 0.965 and OM: $2.09e^{-03}x + 8.01e^{-02}$; R² = 0.991. SLP_c was greater in YM compared to OM (+40.8%; *p* = 0.013). A qualitative, visual inspection of the regression lines for the pooled data (figure below) suggest that AP_{size} for MUs at a higher rRT (i.e., >60%) were most affected in OM. **CONCLUSIONS:** Our findings indicate that aging negatively affects the relationship between rRT and AP_{size}. Specifically, AP_{size} for later-recruited MUs was substantially decreased in OM which may indicate a MU-specific decrease in sarcolemma area and/or excitability due to aging.

IGF-1 Response In Middle-aged And Older Men During Continuous And Intermittent Cycling At Lactate Threshold
 Kenji Narazaki¹, Yukiya Tanoue², Yoichi Hatamoto², Yasuki Higaki², Hiroaki Tanaka². ¹*Fukuoka Institute of Technology, Fukuoka, Japan.* ²*Fukuoka University, Fukuoka, Japan.*
 (No relationships reported)

Insulin-like growth factor-1 (IGF-1) is a trophic factor promoting growth and survival in various types of cells including muscle cells and neurons. In our recent study, young men showed comparable IGF-1 responses in continuous and intermittent exercise at lactate threshold, whereas stress responses were smaller in the intermittent exercise. It is yet unclear if the exercise format affects the IGF-1 response in older individuals. **PURPOSE:** To compare changes in the circulating level of IGF-1 in middle-aged and older men during continuous and intermittent cycling at lactate threshold. **METHODS:** Six men, middle-aged and older (57.8 ± 11.6 years), randomly performed two cycling tests at lactate threshold load (108.8 ± 27.3 W) and a control test with rest on separate days. The cycling tests comprised a 20-min continuous cycling (CC) and an intermittent cycling (IC) consisting of 20 repetitions of 1-min bouts separated by 30-sec rests. The control test was administered with a schedule identical to CC. During each session, blood samples were drawn via peripheral cannulation at rest, at 25, 50, and 100% of cycling time, and 10 min after cycling. A blood concentration of IGF-1 and those of lactate, cortisol, and catecholamines were measured at each time point. Two-way analyses of variance for repeated measures with post-hoc tests, if appropriate, were performed to mainly compare changes between CC and IC. **RESULTS:** Significant interactions were found in all the indices (*p* < .05). Changes in IGF-1 concentration were comparable between CC (102.0 ± 29.3 to 116.0 ± 30.2 ng/ml, *p* < .05) and IC (104.2 ± 33.6 to 112.0 ± 38.6 ng/ml, *p* < .05). In contrast, although concentrations of lactate and norepinephrine increased in both CC and IC (*p* < .05), the effect was greater for CC (*p* < .05). Furthermore, dopamine concentration increased only in CC (*p* < .05) while cortisol concentration decreased in IC (*p* < .05) but not in CC. **CONCLUSIONS:** As previously shown in young men, intermittent cycling at lactate threshold evoked an IGF-1 response comparable to its continuous counterpart in men middle-aged and older, but the two cycling formats induced different stress responses. These results suggest that moderate intermittent exercise has the potential to stimulate the IGF-1 pathway without considerable stress in older individuals. Supported by JSPS 25242065.

Ageing Affects Cell Cycle Regulation In Human Skeletal Muscle Undergoing Atrophy And Regrowth
 Ulrik Frandsen¹, Tatyana Prokhorova¹, Line Jensen¹, Lars G. Hvid¹, Peter Scherling², Per Aagaard¹, Michael Kjaer², Charlotte Suetta³. ¹*Faculty of Health, University of Southern Denmark, Odense, Denmark.* ²*Faculty of Health, University of Copenhagen, Bispebjerg Hospital, Copenhagen, Denmark.* ³*Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.*
 (No relationships reported)

Cellular senescence is an irreversible arrest of cell division, which could influence the regenerative potential of skeletal muscle stem cells (satellite cells) during aging. The molecular mechanism of senescence is complex and involves epigenetic control of the Polycomb repressive complexes, as well as CDKN2A (p16) and TP53 tumor mediated repression of cyclin dependent kinases and G1 cell cycle arrest. **PURPOSE:** To investigate the effect of ageing on satellite cell cycle regulation in human skeletal muscle undergoing atrophy and regrowth induced by short-term immobility and subsequent reloading. **METHODS:** Myofiber atrophy was induced by application

of a knee-brace for a period of 4 days in young (Y, ~20 yrs, n=9) and aged (O, ~70 yrs, n=9) individuals. Muscle regrowth after atrophy was induced by 6 days of re-ambulation supplemented by one session of supervised unilateral resistance training for the disused leg 3 days after brace removal. Muscle biopsies (VL) were collected pre and at 1d, 2d and 4d of immobility and after additional 6 days of re-mobilization (10d). Protein and mRNA expression levels of CDKN2A (p16), CDKN1A (p21), CDKN1B (p27), TP53 and PCNA were determined using real-time RT-PCR and Western blotting, respectively. Satellite cell content was determined by immunohistochemical expression of Pax7. **RESULTS:** Satellite cell content increased in Y at 4d and 10d with no changes in O ($p < 0.05$). p16 mRNA was upregulated at 2d and 4d in O compared to Y and at 10d in Y and O compared to pre ($p < 0.05$). TP53 mRNA was upregulated at 2d in O and at 4d in Y and O compared to pre, while downregulated at 10d in Y and O compared to 4d ($p < 0.05$). p27 mRNA was downregulated in Y and O at 4d and 10d compared to pre ($p < 0.05$). p16 protein increased in O at 1d (7.2-fold) and 2d (3.9-fold) compared to Y and decreased to pre levels in Y and O at 10d ($p < 0.05$). PCNA protein was upregulated in Y (5.5-fold) but blunted in O (1.6-fold) at 10d compared to pre ($p < 0.05$). **CONCLUSION:** p16 and TP53 early (2-4 days) were selectively upregulated during immobility in O compared with Y subjects, suggesting that cellular senescence and SC cycle arrest could be implicated in the defective regenerative response in O compared to Y. Further analysis of epigenetic modifications may provide further explanation for the present findings.

Age-Related Reductions in Muscle Quality Influence the Relative Differences in Strength and Power
 Gena R. Gerstner¹, Hayden K. Giuliani¹, Joseph G. Rosenberg², Eric J. Sobolewski¹, Michael J. Scharville², Jacob A. Mota¹, Eric D. Ryan¹. ¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²Quintiles, Durham, NC. ³Furman University, Greenville, SC. (Sponsor: Abbie Smith-Ryan, FACSM)
 Email: gerstner@email.unc.edu
 (No relationships reported)

Recent studies have demonstrated that age-related changes in the relative differences in isokinetic strength and power may reflect fast twitch fiber alterations. It is possible skeletal muscle ultrasound (US) imaging may reflect these changes. **PURPOSE:** The purpose of this study was to examine the influence of muscle quality on the relative differences in strength and power in younger and older adults. **METHODS:** Twenty young (20.1±1.5 yrs) and 20 older (69.5±3.1 yrs) healthy, recreationally active men performed two plantar flexion maximal voluntary isometric actions (MVCs) and three maximal isokinetic actions on a calibrated isokinetic dynamometer. Panoramic brightness-mode US images of the medial and lateral gastrocnemius were taken to determine subcutaneous fat corrected echo intensity (EI) to represent muscle quality. Isokinetic peak torque (PT), mean power (MP), and peak power (PP) at 0.52 rad·s⁻¹ and 2.09 rad·s⁻¹ were normalized as %MVC. Six separate 2-way mixed factorial analyses of variance were used to evaluate absolute and normalized PT, MP, and PP. Independent samples t-tests were used to compare isometric PT, EI, %decrease in PT and %increase in MP and PP between the younger and older men. Pearson's correlation coefficients were used to examine the relationship between EI and the %decrease in PT, %increase in MP, and %increase in PP. An alpha of $P \leq 0.05$ was used to determine statistical significance. **RESULTS:** The younger men exhibited greater absolute isometric PT, isokinetic PT, MP, and PP at 0.52 rad·s⁻¹ and 2.09 rad·s⁻¹ ($P = 0.001-0.003$). After normalizing to isometric PT, age-related differences were eliminated. The older men exhibited higher EI ($P < 0.001$), greater %decrease in PT (43.6% vs. 38.9%; $P = 0.006$), and lower %increase in MP (167.5% vs. 186.3%; $P = 0.049$) and PP (125.5% vs. 144.5%; $P = 0.006$). Echo intensity was significantly related with the %decrease in PT ($r = 0.605$; $P < 0.001$), %increase in MP ($r = -0.419$; $P = 0.009$), and %increase in PP ($r = -0.605$; $P < 0.001$) from 0.52 rad·s⁻¹ to 2.09 rad·s⁻¹. **CONCLUSIONS:** The absolute age-related reductions in isokinetic strength and power are eliminated with normalization. However, the relative differences from slow to fast velocities may reflect the age-related decreases in fast-twitch fiber and subsequent alterations in muscle quality.

Exercise Reduce The Rate Of mtDNA Deficiency And Mutation In Aged Muscle
 Yu Zhang, Xiang Lin, Jian Zhang, Yang Ren, Li Wen, Yong Zhang. Tianjin University of Sport, Tianjin, China.
 Email: wenli34@hotmail.com
 (No relationships reported)

Calorie restriction and exercise can relieve the oxidative damage in skeletal muscle caused by the aging, but it is still unclear that whether these two factors improved the rate of deficiency and mutation of mtDNA in skeletal muscle by the increase of mitochondrial repair enzyme (OGG1).

Purpose: Study the effect from the calorie restriction and exercise to the mitochondrial repair enzyme OGG1, nuclear-encoded COX I and mitochondria-encoded COX IV, and thus exploit the variation of the rate of mitochondrial deficiency and mutation (RMD) in aging mouse.

Method: Grouping 32 mice in 24 months into 4 groups: control (C), calorie restriction (CR, 60% diet of control group), exercise (E, running in treadmill in the angle of 5, the intensity of 64% VO₂ max for 60 min, the rate of 15m/min and the frequency of 5 days a week for 12 weeks) and calorie restriction combined exercise (CR+E). Decollated the model animal 24 h after the last intervention, and then collected the red muscle (gastrocnemius) and white muscle (rectus femoris) in hind legs.

Results: The rate of mutation and deficiency (ultraviolet spectroscopy and gel-imaging) was significantly lower in E (red: 0.089±0.007, $P < 0.05$; white: 0.091±0.006, $P < 0.01$) and CR+E (red: 0.081±0.004, $p < 0.01$; white: 0.089±0.006, $p < 0.01$) than in C. The level of α -OGG1 (Western-blotting) in CR+E (1.302±0.086) was significantly higher than that in CR (0.859±0.073, $P < 0.05$). The level of β -OGG1 was higher in CR+E (1.302±0.086) than in C (0.816±0.062, $P < 0.01$). In red muscle, the level of COX I (Western-blotting) was significant higher in E (1.02±0.043, $P < 0.01$) and CR+E (0.94±0.091, $P < 0.01$) than in C compare to C (0.790±0.052), the level of COX IV was significant higher in CR+E (0.848±0.152, $P < 0.01$) than in C (0.578±0.051). In white muscle, the level of COX I was significantly lower in E (0.807±0.072) than in C (0.990±0.080, $P < 0.01$), and the level of COX IV was significant lower in CR+E (0.740±0.104, $p < 0.01$) than in C (0.903±0.081).

Conclusion: Exercise and calorie restriction reduce mtDNA deficiency, increase the level of OGG1 in skeletal muscle, increase mitochondrial biogenesis in red muscle, but not in white muscle, thus enhance the ability of aging skeletal muscle to resist the oxidative damage. Does Running And Bone Mineral Density Affect Blood Pressure In Non- And Post-menopausal Women
 Doris J. Morris, Inbar Naor-Maxwell, Anjuly Davis, Christina St. Martin, L. Jerome Brandon, FACSM. Georgia State University, Atlanta, GA.
 (No relationships reported)

The literature is mixed as to the benefits of weight bearing activities such as running on osteogenic responses for non- (N-MEN) and postmenopausal (MEN) women. **PURPOSE:** Therefore, this study was designed to compare bone mineral density (BMD) in N-MEN and MEN women with a running (RUN) history and those who were not runners (N-RUN). **METHODS:** A repeated measures design was employed as 100 Women (30 N-RUN/N-MEN; 12 N-RUN/MEN; 42 RUN/N-MEN; 16 RUN/MEN) were evaluated for differences and relationships between BMD, blood pressure (BP) and body composition. **RESULTS:** Although the MEN women were older (MEN 55.6 yrs. vs N-MEN 36.2 yrs.) the MEN women did not differ for body fat% (MEN 38.5%; N-MEN 34.5%, $p < 0.05$) but did differ for BMD (MEN 1.11 vs N-MEN 1.23). Weight and central adiposity as measured by waist circumference was related to BMD in both RUN ($r = 0.43$; $p < 0.01$) and N-RUN ($r = 0.28$; $p < 0.05$). Age was the only factor that produced a difference ($p < 0.05$) in BMD in the N-MEN and MEN. The RUN/MEN had a trend toward a higher BP than the other groups and this may have contributed to their BMD response not being higher than the N-RUN. **CONCLUSIONS:** Although further study is needed to validate the findings in this study, these data indicate that a history of running does not result in a higher BMD or lower BP in MEN women. This may have been partially because body composition was not different between the groups and therefore the runners were not placing greater stress on the bone response.

Notch Reduces Muscle Injury in Aged Mice Following Downhill Running
 Susan T. Arthur, Brooke Wilson, Joshua Huot, James Jones, Joseph Marino. UNC Charlotte, Charlotte, NC.
 Email: sarthur8@uncc.edu
 (No relationships reported)

PURPOSE: It is known that Notch signaling regulates skeletal muscle repair and is suggested to be inhibited in aged muscle. However, little is known about the effects of Notch on muscle injury following exercise in aged mice. The purpose of this project is to determine the impact of Notch signaling on aged skeletal muscle injury following downhill running (DHR). **METHODS:** C57B/J6 and CBF1 mice (20-25 mo old) served as controls or performed a bout of DHR (~11m/min, -15% grade) until exhaustion. A Notch inhibitor (GSI) or Notch force-activator (FA) reagent were injected into the left gastrocnemius and PBS (control) was injected into right gastrocnemius starting at 24h post exercise. Haemotoxylin and Eosin staining was used to quantify muscle injury. **RESULTS:** In C57B/J6 mice, DHR induced injury in GSI (4D: $P = < 0.001$; 5D: $P = < 0.001$; and 6D: $P = < 0.001$) and PBS-treated (4D: P

= 0.016; 5D: P = 0.004) muscles. Relative to PBS, GSI increased muscle injury two-fold 4D-6D post-exercise (P < 0.001). DHR did not induce significant muscle injury in CBF1 mice (P = 0.12). FA reduced muscle injury compared to PBS (P = 0.04). **CONCLUSIONS:** Notch inhibition appears to increase muscle injury post-exercise, while Notch activation appears to reduce injury. Supported by UNC Charlotte Faculty Research Grant

Adiponectin Is Inversely Associated With Estimated Intramuscular Fat Index In Middle-aged And Elderly Adults

Maya Hioki¹, Nana Kanehira², Teruhiko Koike¹, Akira Saito³, Kiyoshi Shimaoka², Hisataka Sakakibara¹, Yoshiharu Oshida¹, Hiroshi Akima¹. ¹Nagoya University, Nagoya, Japan. ²Tokaigakuen University, Nagoya, Japan. ³Waseda University, Tokorozawa, Japan.
(No relationships reported)

Adiponectin is a fat tissue-derived adipokine, and it has beneficial effects on lipid metabolism, and plays a protective role in the development of metabolic syndrome. Adiponectin is inversely associated with insulin resistance, and low levels of adiponectin are correlated with visceral adipose tissue (VAT). Age-induced intramuscular fat accumulation is implicated in insulin resistance and type 2 diabetes. Therefore we hypothesized that intramuscular fat is also associated with adiponectin. **PURPOSE:** The present study aimed to determine the relationship between adiponectin and estimated intramuscular fat index in middle-aged and elderly adults. **METHODS:** Twenty-two physically active middle-aged and elderly adults (mean age 68.7±4.4 years, mean body mass index 22.2±2.2 kg/m²) participated in this study. We assessed echo intensity as the intramuscular fat content index by using ultrasonography. Echo intensity of the vastus lateralis at the mid-thigh was measured, which was calculated based on the mean of grey scale. Blood samples were collected for the measurement of adiponectin. Waist circumference was measured at the level of the navel as the VAT index. **RESULTS:** Echo intensity was 70.2±6.2 a.u. and adiponectin was 12.4±8.8 µg/mL in the subjects. Adiponectin was inversely correlated with echo intensity (r=-0.43, p<0.05), and waist circumference (r=-0.46, p<0.05). After controlling for waist circumference, there remained a significant inverse association between adiponectin and echo intensity (r=-0.47, p<0.05). **CONCLUSION:** This suggests that adiponectin affects intramuscular fat content; independent of VAT. This study was supported by KAKENHI grant #23650432 and the Descente and Ishimoto Memorial Foundation for the Promotion of Sports Science.

Age-related Changes In Contractile Function Of Mouse Soleus And Edl Muscles

David W. Russ¹, Eric X. Beck², Eric Leach¹, Kevin E. McElhanon², Noah Weisleder². ¹Ohio University, Athens, OH. ²Ohio State University, Columbus, OH.
(No relationships reported)

PURPOSE: Rodent models are often studied to gain insight into aging in human muscle. However, lifespan is not consistent across rodent species or strains, and muscular impairments may not occur at the same relative age (i.e., % survival). We have previously reported ~25% loss of muscle force in rats in early-stage aging, despite smaller (8-15%) declines in muscle mass. It has been suggested that mice, despite shorter lifespans, exhibit less sarcopenia than rats. The goal of the present study was to study the contractile responses of two muscles in aging mice of the same absolute age (24 months), but greater relative age (75% survival, ~ 75 yo in humans), as the rats we have previously studied. **METHODS:** *Ex vivo* contractility was studied in the soleus (SOL) and extensor digitorum longus (EDL) muscles of adult (n=6, 12 mo.) and aged (n=7, 24 mo.) male, C57Bl/6 mice. All muscles underwent force-frequency relation (FFR) testing and fatigue. Force, muscle quality (force/cross-sectional area (CSA)) and contractile properties for twitch and peak tetanic stimulation were determined for each muscle. **RESULTS:** Overall analysis of the FFR revealed a significant main effect of muscle and age x frequency and age x frequency x muscle interactions (all P < 0.001). Muscle mass did not differ with age, although there was a trend toward an effect in SOL (P = 0.062). Age significantly (P = 0.035) reduced twitch force in the EDL, but not the SOL, and maximum tetanic force showed no effect of age in either muscle. Twitch contractile properties did not differ with age or muscle. However tetanic rates of force development and relaxation in the EDL were reduced with age (P = 0.065 & 0.098, respectively), differences which became significant when normalized to force (P = 0.018 & 0.035, respectively). No differences in muscle fatigue were found in either muscle. **CONCLUSIONS:** Relative to aging rats, aging mice exhibit modest changes in muscle mass and force in both the EDL and SOL. Changes in force appear largely determined by changes in mass. Since many studies of human aging indicate that

loss of force exceeds loss of strength, these data suggest that mice may not fully recapitulate all aspects of aging human muscle. Future studies should make efforts to examine muscles other than the EDL and SOL to determine if other muscles more closely model aging human muscle.

Dysregulated Extracellular Matrix Remodeling Of Aged Human Skeletal Muscle Following Damaging Exercise.

Jacob R. Sorensen, Alex Holland, Allen C. Parcell, FACSM, Robert D. Hyldahl. Brigham Young University, Provo, UT.
Email: jross.sorensen@gmail.com
(No relationships reported)

Aged skeletal muscle has a diminished capacity to regenerate following injury. Effective regeneration of skeletal muscle necessitates the widespread remodeling of its extracellular matrix (ECM). Tenascin C is an ECM protein that is markedly increased following skeletal muscle damage, and is critical for effective ECM remodeling and subsequent muscle regeneration. **PURPOSE:** To assess markers of muscle damage and extracellular matrix remodeling in skeletal muscle of old (65+ yrs) and young (18-30 yrs) adults. We hypothesized that tenascin C expression would be dysregulated in older adults following exercise-induced muscle damage. **METHODS:** 10 young (22.7 ± 2.25 yrs) and 8 old (70.9 ± 7.5 yrs) participants completed 300 lengthening contractions (LC) on a biodes dynamometer to induce muscle damage. Soreness and muscle function were measured and muscle biopsies taken pre-exercise and at 3, 24, and 72 hours post-exercise from the vastus lateralis muscle. **RESULTS:** Both age groups performed a similar amount of work during LC (young: 44,718 ± 13,730 vs old: 49,038 ± 10,217 J; p=0.47). Soreness increased in both groups, with no differences between age groups (p=0.1). Additionally, both age groups demonstrated a marked decrease in functional measures following LC, which remained reduced out to 72 hours post-exercise (p<0.05). As expected, young subjects showed significantly higher absolute values in each of the functional measures compared to old at the pre-exercise time point. However, young subjects showed a significantly higher percentage of torque (53.6 ± 5.19 vs 34.5 ± 7%), and power (57.4 ± 23 vs 34.4 ± 19%) loss following LC compared to old subjects. Expression of tenascin C was significantly elevated in both old and young groups 24h following LC (p<0.001). Overall, there was a significant main effect of group, with the older group demonstrating greater tenascin C expression. However, there was no significant timexgroup interaction, indicating that tenascin C responds similarly between young and old muscle following LC. **CONCLUSION:** Elevated expression of Tenascin C may contribute to the reduced capacity of aged muscle to adapt following muscle damage. These data also demonstrate increased functional sensitivity in young muscle compared to old following a damaging bout of lengthening contractions.

IMCL:EMCL and rVO2 Changes following Vitamin D Repletion and Aerobic Training In Aged Individuals

D. Travis Thomas, Maja Redzic, Mingjun Zhao, David M. Schnell, Hideat Abraha, Guoqiang Yu. University of Kentucky, Lexington, KY.
Email: dth225@uky.edu
Reported Relationships: D. Thomas: Consulting Fee; Advisor to Wheat Foods Council.

Extramyocellular (EMCL) and intramyocellular (IMCL) lipid is associated with muscle metabolic dysfunction in aging. We recently reported a positive linear relationship between vitamin D status and IMCL in aged individuals that was independent of body mass and physical activity. The combined effect of vitamin D and exercise on muscle lipid has not been investigated. **PURPOSE:** Compare the magnitude of changes in myocellular lipid stores and local muscle oxygen consumption rate following combined treatment of vitamin D repletion and aerobic training (DAT) compared with vitamin D repletion alone (D), aerobic training alone (AT), and control conditions (Ctl). **METHODS:** Aged subjects (>60 YO) with vitamin D insufficiency (25(OH)D < 32 ng/mL) were randomized to a double blinded, 2X2, four group design. Vitamin D₃ (10,000 IU X 5 days/week) or placebo was provided for 12 weeks with 1 additional week (7 consecutive days) of aerobic training or no training. Gastrocnemius IMCL and EMCL were measured with magnetic resonance spectroscopy and fat segmentation. Hybrid near-infrared and diffuse correlative spectroscopy measured local tissue blood flow, oxygen saturation, and VO₂ during and following (recovery) a gastrocnemius fatiguing protocol. All measurements were completed at week 0 and at end-study. **RESULTS:** Ten males and 9 females completed all measures. Mean age and BMI were 67.2±6 YO and 25.9±4 kg/m², respectively. Mean 25(OH)D concentrations increased significantly in subjects receiving vitamin D (45±16) vs. placebo (10±5)(p<0.05). Although not significant by group, DAT (n=5) experienced a mean reduction in IMCL:EMCL ratio of 33%, compared to a 9% reduction in AT (n=4), 6% reduction in D (n=6) and a gain of 12% in Ctl (n=4). This corresponded to a 26% increase in rVO₂ during full exercise recovery in DAT compared to an 11%, 24%, and 11% reduction in AT, D, and Ctl, respectively.

Abstracts were prepared by the authors and printed as submitted.

CONCLUSIONS: These data suggest a trend that vitamin D, when combined with exercise, may potentiate the metabolic benefits of exercise by affecting muscle lipid deposits and altering tissue-level VO_2 . These data also provide an indication of effective metabolic response to a dietary supplement and exercise intervention. Future work will examine muscle mitochondrial function as a potential target of action of vitamin D + exercise on muscle metabolism.

Relationships of Muscle Quality among Back, Lower and Upper Limbs in Older Individuals
 Akito Yoshiko¹, Takashi Kaji², Hiroki Sugiyama³, Teruhiko Koike¹, Yoshiharu Oshida¹, Hiroshi Akima¹. ¹Nagoya University, Nagoya, Japan. ²Kajinoki Medical Clinic, Gifu, Japan. (Sponsor: Katsumi Asano, FACSM)
 Email: yoshiko@nagoya-u.jp
 (No relationships reported)

The ratio of fat tissue within a skeletal muscle (i.e. intramuscular fat) is accessed as muscle quality. It is well known that muscle quality becomes worse with aging by increasing of intramuscular fat and/or decreasing of muscle tissue. It is shown that intramuscular fat is related to physical dysfunction and insulin resistance. However, this result was given from only a selected region such as quadriceps femoris. It is not well understood that the relationships may also be found the other regions of muscle such as posterior of the thigh, low back or upper limb. **PURPOSE:** The purpose of this study was to assess the relationships of muscle quality among low back, anterior and posterior region of the thigh, and upper limbs in older men and women. **METHODS:** Seven men (age, 74 ± 5 years; height, 161 ± 7 cm; weight, 60 ± 7 kg) and fifteen women (age, 80 ± 8 years; height, 147 ± 5 cm; weight, 48 ± 8 kg) participated in this study. B-mode transverse ultrasonographic images were taken from rectus femoris (RF), biceps femoris (BF), multifidus (MF) and triceps brachii (TB). Echo intensity (EI) as an index of muscle quality was calculated in these muscles. We measured physical performance tests, i.e. isometric knee extension peak torque, functional reach, one-leg stand, 30-sec chair stand, hand grip strength, 5-m normal/maximal walk, and timed up and go, and blood biochemistry. **RESULTS:** There was significantly difference in EI in MF between men and women (men, 48.1 ± 7.3 a.u. vs. women, 59.5 ± 10.3 a.u., $P < 0.05$), but not in the other regions. Significant relationships were confirmed among EIs in RF, BF and TB ($r = 0.46$ to 0.50 , $P < 0.05$), but not in MF and other muscles ($r = 0.23$ to 0.39). Mean EI of upper and lower limbs ($[(EI \text{ in RF}) + (EI \text{ in BF}) + (EI \text{ in TB})] / 3$) as a dependent variable was explained by leptin and insulin as a result of stepwise regression analysis ($R = 0.55$, adjusted $R^2 = 0.45$, $P < 0.01$), and EI in MF as another dependent variable was explained by age and 30-sec chair stand ($R = 0.81$, adjusted $R^2 = 0.61$, $P < 0.01$). **CONCLUSIONS:** These results suggest that the pattern of muscle quality is inconsistency between limbs and trunk. Furthermore, the factor to explain muscle quality may be different depending on the regions of the muscle.

Relationship Between Quadriceps Femoris Echo Intensity And Functional And Morphological Characteristics In Older Men And Women
 Hiroshi Akima¹, Akito Yoshiko¹, Aya Tomita¹, Ryosuke Ando¹, Akira Saito², Madoka Ogawa¹, Shohei Kondo¹, Noriko I. Tanaka¹. ¹Nagoya University, Nagoya, Aichi, Japan. ²Waseda University, Tokorozawa, Saitama, Japan. (Sponsor: Katsumi Asano, FACSM)
 Email: akima@nagoya-u.jp
 (No relationships reported)

The age-related decrease in human skeletal muscle mass; i.e. sarcopenia, has received much attention, but an age-related decrease in muscle quality; i.e. the ratio of adipose tissue to muscle tissue, has received noticeably less. A few studies have shown that muscle quality, as determined by ultrasonographic echo intensity, is negatively associated with functional capacity, but the best parameters by which to predict muscle quality have not yet been established for older individuals. **PURPOSE:** The purpose of this study was to assess the relationships between quadriceps femoris (QF) echo intensity and demographic, functional and morphological characteristics of older men and women.

METHODS: Sixty-four healthy men ($n=27$; age, 72.9 ± 5.0 years; height, 164.1 ± 6.2 cm; weight, 60.6 ± 6.8 kg) and women ($n=37$; age, 71.5 ± 5.3 years; height, 152.8 ± 4.8 cm; weight, 50.8 ± 6.8 kg) aged 62-88 years participated in this study. The echo intensity and muscle thickness of the QF at the mid-thigh were calculated using ultrasonography. Sit-up, supine-up, sit-to-stand, 5-m maximal walk and 6-min walk tests were performed.

RESULTS: As expected, QF muscle thickness in men was significantly larger than women (men, 3.1 ± 0.6 mm; women, 2.7 ± 0.6 mm, $P = 0.01$); however, no significant differences were observed in QF echo intensity between sexes (men, 63.0 ± 8.7 a.u.; women, 69.9 ± 7.4 a.u.). QF echo intensity was significantly correlated with QF

muscle thickness as a result of simple linear regression analysis (men, $r = -0.734$, $P = 0.001$; women, $r = -0.565$, $P = 0.001$). Stepwise multiple regression analysis with QF echo intensity as a dependent variable revealed QF muscle thickness, age and sit-to-stand test in men ($R = 0.875$, adjusted $R^2 = 0.734$), and QF muscle thickness and sit-to-stand test in women ($R = 0.648$, adjusted $R^2 = 0.383$), to be significant independent variables.

CONCLUSIONS: These results suggest that functional ability and greater muscle size are essential factors in the maintenance of muscle quality; however, an age effect was present only in men.

Age-Dependent Responsiveness to Stretch-Shortening Contraction Training and Low Volume Isometric Contraction Training in Rats
 Erik P. Rader, James Ensey, Marshall A. Naimo, Brent A. Baker. National Institute for Occupational Safety and Health, Morgantown, WV. (Sponsor: Stephen E. Alway, FACSM)
 Email: WLZ4@cdc.gov
 (No relationships reported)

A growing body of research has highlighted the benefits of high-intensity exercise. However, concern exists that such high-intensity training, especially in resistance training, is potentially deleterious at advanced age. Recently, we have addressed this issue in part by demonstrating in a rat model of resistance-type training, that training with maximally activated stretch-shortening contractions (SSCs) has no detrimental effect on performance and increases muscle mass at advanced age provided the frequency of training is moderated (i.e. 80 SSCs 2 days per week rather than 3 days per week). A major question remained from this research - whether reducing or altering other parameters when training with high-intensity contractions would also demonstrate similar outcomes at old age. **PURPOSE:** To determine whether decreasing repetition number (i.e. 40 SSCs 3 days per week) and/or changing contraction mode (i.e. 4 isometric contractions (ISOs) 3 days per week and 8 ISOs 2 days per week) induces muscle mass and performance gains in young (3 months old) and old (30 months old) male Fischer Brown Norway hybrid rats. **METHODS:** Dorsiflexor muscles (9-10 per group) were exposed to 1 month of training using a custom-built dynamometer. Dynamic performance was monitored, tibialis anterior muscle mass was normalized to tibia length, and muscle quality determined by dividing performance by normalized muscle mass. ANOVA was used for statistical analysis; significance was set at $p < 0.05$. **RESULTS:** Independent of training protocol, peak force increased by ~20% for young rats while peak force was not significantly altered for old rats. In contrast with performance, muscle mass gains were dependent on the training protocol. For young rats, the normalized muscle mass increase of 18 ± 2% after 40 SSCs 3 days per week training was greater than the increases of 7 ± 2% and 11 ± 1% after 4 ISOs 3 days per week or 8 ISOs 2 days per week training, respectively ($p < 0.05$). For old rats, only 40 SSCs 3 days per week training induced a muscle mass gain, 12 ± 3% ($p < 0.001$), without a decrease in muscle quality relative to values for the other training protocols. **CONCLUSIONS:** These findings demonstrate the extreme adaptability of muscle to various training protocols at a young age and the selectivity at old age especially in regards to muscle mass gain.

B-63 Free Communication/Poster - Altitude/Hypoxia

"BEet On Alps": Ergogenic Effects Of Dietary Nitrate Supplementation During Prolonged Exposure To Hypobaric Hypoxia
 SIMONE PORCELLI¹, Letizia Rasica², Desy Salvadego³, Simona Mrakic-Spota¹, Fabrizio Gelmini², Giangiacomo Beretta², Mauro Marzorati¹. ¹Italian National Research Council, Segrate (MI), Italy. ²Università degli Studi di Milano, Milan, Italy. ³University of Udine, Udine, Italy.
 Email: simone.porcelli@ibfm.cnr.it
 (No relationships reported)

PURPOSE: Several studies have demonstrated that dietary nitrate supplementation reduces O_2 consumption (VO_2) during steady-state exercise and enhances endurance performance in young healthy subjects, both in normoxia and acute hypoxia. No data have been provided during acclimatization to high altitude, a condition that affects exercise tolerance and may change nitric oxide bioavailability. Aim of this study was to investigate the effects of dietary nitrate supplementation on oxygen cost of exercise and exercise tolerance during a prolonged sojourn at high altitude.

METHODS: In a double-blind randomized crossover study, fourteen young (29±4 yr) healthy subjects were supplemented for three days with beetroot juice (2x70mL/day, 8.4 mmol nitrate/day [BEET-IT]) or nitrate-depleted juice (PLA). At the end of each supplementation period, subjects performed on a cycle ergometer one 8 min moderate-intensity constant work rate (MOD) exercise and a high-intensity (HIGH) constant work rate exercise up to exhaustion. Experimental sessions were conducted in a refuge at 3269m a.s.l. after 7 and 14 days of exposure to hypobaric hypoxia.

RESULTS: [Nitrate] and [nitrite] were significantly higher in BEET-IT than in PLA. In MOD, oxygen cost of exercise was significantly reduced in BEET-IT vs. PLA (12.7±1.8 vs. 11.8±1.4 mL·min⁻¹·w⁻¹, p<0.01). In HIGH, VO₂ was significantly lower in BEET-IT than in PLA after 6 min of exercise (2.588±0.424 vs. 2.686±0.438 L·min⁻¹, p<0.01) whereas no difference was observed at exhaustion (2.728±0.450 in BEET-IT and 2.763±0.467 L·min⁻¹ in PLA). Time to exhaustion during high-intensity exercise was significantly improved (9%) by dietary nitrate supplementation. Interestingly, two subjects with the higher aerobic fitness level were “non-responder”.

CONCLUSION: After prolonged exposure to hypobaric hypoxia, nitric oxide metabolism was modified at rest. Dietary nitrate supplementation enhanced exercise efficiency during moderate-intensity exercise and improved high-intensity exercise tolerance. These effects were not evident in two highly trained subjects, suggesting an apparent relationship between aerobic fitness and ergogenic potential of beetroot juice supplementation during prolonged exposure to hypobaric hypoxia.

Effects Of Normobaric Hypoxia And Exercise On Cold-induced Vasodilation, Body Temperature, And Oxygen Saturation

Hayden Gerhart¹, Brittany Followay², Jeremiah Vaughan², Jacob E. Barkley², Ellen L. Glickman, FACSM². ¹Indiana University of Pennsylvania, Indiana, PA. ²Kent State University, Kent, OH. (Sponsor: Ellen L. Glickman, FACSM)
 Email: hdgerhart@gmail.com
 (No relationships reported)

PURPOSE: The purpose of the current study was to investigate the effects of normobaric hypoxia on the thermoregulatory and the cold-induced vasodilation (CIVD) response before and following submaximal exercise. **METHODS:** Ten apparently healthy men (23±3 years) volunteered for two experimental trials during which they were exposed to differing O₂ saturations (13% O₂ and 21% O₂) in an environmental chamber. Trials were counterbalanced and blinded from the participant. Following a 60-min acclimation the experimental trials consisted of two 15-min exposures to 5°C water of the non-dominant hand. The exposures were separated by a 30-min bout of submaximal exercise producing the equivalent of 400 watts (W) of metabolic heat. Mean body temperature (MBT), oxygen saturation (SaO₂), and thermal sensation (TS) were collected during the final 5 min of each stage. CIVD was measured pre- and post-exercise during each of the cold water exposures on the nailbed of the middle finger on the non-dominant hand. **RESULTS:** ANOVA revealed a significant time (baseline, acclimation, CIVDpre, exercise, and CIVDpost) by condition (13% O₂, 21% O₂) interaction for SaO₂ ($F = 38.4, p < 0.001$). Significant differences ($p < 0.001$) between conditions existed at all time-points with the exception of baseline ($p = 1.0$). A main effect of time was observed for amplitude temperature ($F = 20.034, p < 0.001$), which was significantly greater ($p < 0.001$) at CIVDpost compared to CIVDpre (CIVDpost: 1.13°C; CIVDpre: 0.28°C). No significant difference across time or condition exists for MBT or TS. In the 13% O₂ condition, the reduction in SaO₂ during exercise (81.5%) was positively associated ($r = 0.656, p = 0.039$) with amplitude temperature at CIVDpost (0.69°C), which was significantly greater ($p < 0.05$) compared to CIVDpre (0.14°C). **CONCLUSION:** It appears that during rest in normobaric hypoxia, a cold stress test has minimal effect on the CIVD response. During exercise, reduced CIVD amplitude is associated with reduced SaO₂. It appears that a submaximal bout of cycling exercise is not the proper stimulus to acutely induce a CIVD response to the magnitude at which physiological changes ensue.

917 Board #96 May 31 2:00 PM - 3:30 PM
The Effects Of Cold-Water Hand Immersion On Executive Function, Mood, And Memory In Normobaric Hypoxia

Ellen L. Glickman, FACSM¹, Jeremiah Vaughan¹, Brittany Followay¹, Jacob E. Barkley¹, Hayden Gerhart². ¹Kent State University, Kent, OH. ²Indiana University of Pennsylvania, Indiana, PA.
 Email: eglickma@kent.edu
 (No relationships reported)

PURPOSE: The purpose of the present study was to investigate the effects of cold-water hand immersion (CWI) on changes in executive function, mood, and memory during normobaric hypoxia and normoxia. **METHODS:** Ten apparently healthy men (23±3 years) volunteered for this study. The two experimental trials (13% O₂, 21%

O₂) were counterbalanced and blinded from the participant. The non-dominant limb was exposed to 5°C water for 15-min after a passive acclimation to the randomized experimental condition. Executive function (Stroop), total mood disturbance (TMD), and memory (RMCPT) were recorded during the final 8 min. of the following time points: baseline, acclimation, and CWI. **RESULTS:** Condition (13% O₂, 21% O₂) by time (baseline, acclimation, CWI) ANOVA's revealed no significant interaction or main effects of time or condition for any score of executive function ($F \leq 3.12, p \geq 0.069$) or mood ($F \leq 0.773, p \geq 0.477$). A significant time by condition interaction exists for throughput score ($F = 3.19, p = 0.039$), a measure of RMCPT. The score during CWI in the 13% O₂ condition was significantly lower compared to the 21% O₂ condition ($p = 0.05$), as well as when compared to acclimation of the 13% O₂ condition ($p = 0.02$). The worsening TMD trend led to positive associations between skin temperature during CWI and TMD scores at baseline ($r = 0.753, p = 0.012$), acclimation ($r = 0.653, p = 0.041$), and CWI ($r = 0.657, p = 0.039$) in the 13% O₂ condition. In the 21% O₂ condition, TMD at acclimation was significantly associated with skin temperature during CWI ($r = 0.716, p = 0.02$). **CONCLUSION:** Despite no effect on executive function in both normoxia and normobaric hypoxia, it appears CWI impairs measures of memory. Decreased skin temperature observed during CWI correlates to reduced mood throughout all time points in a hypoxic state. Further research is necessary to elucidate mechanisms to improve mood and memory in normobaric hypoxia.

Human Cognitive Function During Acute Hypoxic Exposure

Manabu Shibasaki¹, Shigehiko Ogoh, FACSM², Tadayoshi Miyamoto³, Hiroki Nakata¹. ¹Nara Women's University, Nara, Japan. ²Toyo University, Kawagoe, Japan. ³Morinomiya University of Medical Science, Osaka, Japan. (Sponsor: Shigehiko Ogoh, FACSM)
 (No relationships reported)

The execution or inhibition of decision making is critical for survival in a severe environment. Although cognitive performance (behavioral executive response such as reaction times) appears to be impaired at a given level of high altitude, the effect of hypoxia on cognitive processing including executive and inhibitory responses remains unclear. **PURPOSE:** The aim of present study was to test our hypothesis that not only executive processing but also inhibitory processing may be impaired during acute hypoxic exposure.

METHODS: We investigated two neural activities in motor execution and inhibition processing evaluated by the Go/No-go task with electroencephalographic event-related potentials before and during acute (~30 min) hypoxic condition. As a time control, subjects performed the same sessions in normoxia.

RESULTS: The amplitudes of the Go-P300 (i.e. execution) and No-go-P300 (i.e. inhibition) components were unchanged during normoxic trial. However the amplitudes of the Go- and No-go-P300 components were significantly reduced during acute hypoxic trial ($p < 0.05$), whereas reaction times and error rates were not changed. **CONCLUSIONS:** These results suggest that acute hypoxia impaired human cognitive processing including response execution and inhibition.

Inspiratory Muscle Training and Endurance Performance in Hypoxia

Daniel G. Hursh, Chad C. Wiggins, Shane A. Bielko, Marissa Baranuskas, Timothy D. Mickleborough, FACSM, Joel M. Stager, FACSM, Robert F. Chapman, FACSM. ¹Indiana University, Bloomington, IN. (Sponsor: Robert F. Chapman, FACSM)
 Email: dhursh@iu.edu
 (No relationships reported)

Ventilation is higher at any submaximal workload in hypoxia as compared to normoxia. Whether or not training the respiratory muscles helps to improve exercise performance in hypoxia is unclear. **Purpose:** To determine if improvements in ventilatory strength with chronic inspiratory muscle training (IMT) improves 20km cycling time trial (TT) performance in hypoxia (FIO₂ = 16.1%). **Methods:** Ten highly-trained men were pair-matched based on pre-exercise values of maximal inspiratory pressure (MIP) and randomly placed into either a sham (n = 5, VO₂max = 61.7 ± 4.1 ml·kg⁻¹·min⁻¹) or an IMT (n = 5, VO₂max = 61.5 ± 6.8 ml·kg⁻¹·min⁻¹) group. Subjects completed 6 weeks of flow resistive IMT (80% of MIP) or a sham protocol (30% of MIP), with each session consisting of up to 6 sets of 8 MIP maneuvers performed to failure with descending rest intervals 3 times per week. Pre- and post-training, subjects performed tests of pulmonary function, lung volume, MIP, maximal expiratory pressure (MEP), lung diffusion capacity (DLCO), and a 20km cycling TT in hypoxia (FIO₂ = 16.1%). **Results:** After 6 weeks of IMT or sham, the IMT group significantly improved MIP (145.3 ± 27.9 cmH₂O vs 171.7 ± 38.7 cmH₂O, p < 0.05), while MIP in the sham group remained unchanged. MEP, DLCO, lung volumes, and pulmonary function values remained unchanged in both groups post-training. 20km TT mean

ventilation was higher post-IMT (98.9 ± 15.9 l·min⁻¹ vs 109.3 ± 22.4 l·min⁻¹, $p = 0.055$) and unchanged in sham ($p = 0.65$). 20km TT mean breathing frequency was also higher post-IMT (43.5 ± 6.4 b·min⁻¹ vs 47.8 ± 8.0 b·min⁻¹, $p < 0.01$) and unchanged in sham ($p = 0.46$). 20km TT mean \dot{V}_O_2 was higher post-IMT (45.5 ± 6.4 ml·kg⁻¹·min⁻¹ vs 47.5 ± 7.1 ml·kg⁻¹·min⁻¹, $p = 0.05$) and unchanged in sham ($p = 0.65$). In the IMT group, 20km TT performance time pre-training was $37:46 \pm 4:39$ min:sec and post-training was $37:16 \pm 4:02$ min:sec ($-1.2 \pm 2.2\%$, $p = 0.14$). 20km TT performance time was unchanged in the sham group ($+0.2 \pm 2.1\%$, $p = 0.90$). 20km TT heart rate and SpO_2 were unchanged in both groups post-training. **Conclusion:** In a small cohort, IMT-induced improvements respiratory muscle strength resulted in greater ventilation and oxygen uptake during a 20km time trial in hypoxia. IMT should be explored as a useful strategy for improving the quality of cycle exercise training and/or endurance exercise performance at altitude.

The Effect of Inspiratory Resistance on Exercise Performance in Moderate Normobaric hypoxia

Yongsuk Seo¹, Jeremiah Vaughan², Raymond Roberge¹, Jung-Hyun Kim¹, Ellen L. Glickman, FACSM². ¹Centers for Disease Control and Prevention, Pittsburgh, PA. ²Kent State University, Kent, OH.

(No relationships reported)

Various respirators are used to protect workers against toxic airborne substances and pathogens. However, the use of respirators increases inspiratory resistance known to adversely affect physiological and psychological performance in some workers. **PURPOSE:** To evaluate the effect of inspiratory resistances on physical performance and subjective comfort during exercise in normobaric hypoxia. **METHODS:** Nine healthy men (Age: 25 ± 2 years, Height: 181.4 ± 6.1 , Weight: 92.5 ± 2.6 kg) participated in this study. Subjects breathed through a respiratory mask outfitted with one of four different inspiratory resistors (R) (0, 1.5, 4.5, 7.5 cm H₂O·L⁻¹·sec⁻¹) while exercising in normobaric hypoxia (17% O₂) for 10 minutes each at 50, 100, and 150 Watts followed by incremental exercise to maximal exertion (\dot{V}_{O_2max}). **RESULTS:** At exhaustion, added inspiratory resistance in hypoxia significantly decreased the maximal power output ($0R=272.2 \pm 44.1$, $1.5R=263.9 \pm 41.7$, $4.5R=255.6 \pm 34.9$, and $7.5R=241.7 \pm 50.0$ W, respectively, $p=0.009$), respiration rate ($0R=41.9 \pm 6.5$, $1.5R=39.6 \pm 7.6$, $4.5R=37.2 \pm 6.2$, and $7.5R=35.8 \pm 6.7$ bpm, respectively, $p < 0.009$), and minute ventilation ($0R=106.7 \pm 18.5$, $1.5R=98.4 \pm 13.2$, $4.5R=93.2 \pm 13.2$, and $7.5R=86.7 \pm 12.2$ L/min, respectively, $p=0.002$) while oxygen consumption ($0R=31.8 \pm 4.1$, $1.5R=31.7 \pm 3.4$, $4.5R=30.4 \pm 3.4$, and $7.5R=31.4 \pm 6.4$ ml/kg/min, respectively, $p=0.750$) and heart rate ($0R=174.3 \pm 10.9$, $1.5R=173.9 \pm 11.9$, $4.5R=177.4 \pm 10.1$, and $7.5R=171.9 \pm 14.3$ bpm, respectively, $p=0.265$) were not significantly changed. Breathing comfort ($0R=3.0 \pm 1.8$, $1.5R=2.7 \pm 1.3$, $4.5R=4.2 \pm 1.9$, and $7.5R=4.1 \pm 2.0$, respectively, $p=0.014$) and breathing effort ($0R=3.7 \pm 1.6$, $1.5R=3.9 \pm 1.5$, $4.5R=5.4 \pm 1.2$, and $7.5R=5.1 \pm 1.4$, respectively, $p=0.001$) were significantly increased with additional inspiratory resistance, but rating of perceived exertion (RPE) was not significantly increased ($0R=17.8 \pm 1.7$, $1.5R=18.1 \pm 1.6$, $4.5R=18.2 \pm 0.8$, and $7.5R=18.1 \pm 1.6$, respectively, $p=0.664$). **CONCLUSIONS:** Low-to-moderate inspiratory resistance in normobaric hypoxia did not have a detrimental effect on oxygen consumption and RPE at maximal work rates. However, added inspiratory resistance significantly decreased maximal power output and increased perception of breathing discomfort and breathing effort.

Impact of Inspiratory Resistance on Cognitive Function in Normobaric Hypoxia After Exercise

Jeremiah Vaughan, Brittany Followay, Hayden Gerhart, Ellen L. Glickman, FACSM. Kent State University, Kent, OH. (Sponsor: Ellen L. Glickman, FACSM)

Email: jvaugha9@kent.edu

(No relationships reported)

PURPOSE: To determine the effects of added inspiratory resistance on cycling in normobaric hypoxia on cognitive function. **METHODS:** Nine healthy adult males (mean \pm SD: age = 25 ± 2 yr, height = 1.81 ± 0.06 m, mass = 92.5 ± 2.1 kg, BMI = 28.0 ± 5.3 kg·m⁻², $\dot{V}_O_2 = 46.32 \pm 9.01$ ml·kg⁻¹·min⁻¹) data were analyzed. The protocol consisted of a counterbalanced design involving four visits involving a normoxic (21% O₂) condition with zero added inspiratory resistance (NORM0) and three hypoxic (17% O₂) conditions with 3 levels of added inspiratory resistance (HYPOX0, HYPOX1.5 and HYPOX4.5 cmH₂O) attached to a two-way valve facemask. Data were collected at baseline and during 30 min seated rest in the hypoxia chamber with resistor added. This was followed by three submaximal stages on the cycle ergometer (50, 100, and 150 W) which was then immediately followed by a \dot{V}_O_2max test. After completion of the \dot{V}_O_2max test the participants recovered in the hypoxia chamber for an additional 30 min. Cognitive function was assessed via a computerized cognitive test battery with the participants performing the running memory continuous performance task (RMCPT) and Stroop Color Word Test (SCWT). A 2 factor repeated measures ANOVA were used to evaluate condition (NORM0, HYPOX0, HYPOX1.5,

HYPOX4.5) by time (baseline in normoxia, 30 min of rest, after \dot{V}_O_2max test, and after 30 min recovery in hypoxia) were performed on RMCPT and SCWT with post-hoc significance ($p < 0.05$). **RESULTS:** A main effect of condition ($p = 0.001$): NORM0 = 126 ± 20 ; HYPOX1.5 = 116 ± 23 ; HYPOX4.5 = 115 ± 19) and a main effect of time ($p = 0.031$: base = 117 ± 21 ; rest = 120 ± 19 ; max = 123 ± 16 ; recovery = 124 ± 18) existed on throughput of RMCPT. A main effect of time ($p = 0.001$: base = 62 ± 11 ; rest = 67 ± 11 ; max = 69 ± 9 ; recovery = 70 ± 11) existed on word-color association for SCWT. **CONCLUSION:** No significant interactions between time or condition was demonstrated on cognitive function with added inspiratory resistance in hypoxia after cycling performance. It appears from these data that the respirators do not impair cognitive function during work at the selected levels of resistance in normobaric hypoxia. Further research may be performed on this device to elucidate other markers of cognitive function in more extreme environmental conditions.

The Effects of Added Inspiratory Resistance during Exercise in Hypoxia on Lactate and Hemoglobin

Brittany Followay, Jeremiah Vaughan, Hayden Gerhart, Ellen Glickman, FACSM. Kent State University, Kent, OH. (Sponsor: Ellen Glickman, FACSM)

(No relationships reported)

PURPOSE: To determine the effects of adding different levels of inspiratory resistance to submaximal and maximal exercise performance in normobaric hypoxia on blood lactate (Lac) and hemoglobin (Hb) values. **METHODS:** Nine apparently healthy, male adults (mean \pm SD; age = 25 ± 2 yr, height = 1.81 ± 0.06 m, mass = 92.5 ± 2.1 kg, BMI = 28.0 ± 5.3 kg·m⁻², $\dot{V}_O_2 = 46.32 \pm 9.01$ ml/kg·min⁻²) were analyzed. The participants visited the laboratory on four separate visits in a counterbalanced design. The four conditions consisted of a normoxic (21% O₂) condition with zero added inspiratory resistance (Normox0) and 3 hypoxic (17% O₂) conditions with 3 levels of added resistance (Hypox0, Hypox1.5, and Hypox7.5 cm H₂O) attached to a two-way non re-breathing face-mask. The exercise protocol consisted of data collection at baseline and after 30 min rest in the hypoxia chamber. Three submaximal stages followed on the cycle ergometer with increasing levels of intensity (50, 100, and 150 W) which were then immediately followed by a \dot{V}_O_2max test. After completion of the \dot{V}_O_2max test the participants recovered in the hypoxia chamber for an additional 30 min. Lac and Hb data were collected by a finger prick and analyzed. A 2 factor repeated measures ANOVA was used to evaluate condition (Normox0, Hypox0, Hypox1.5 and Hypox7.5) by time (baseline, 30 min of rest in hypoxia chamber, immediately after the \dot{V}_O_2max test, and during 30 min recovery period) on Lac and Hb. Paired-samples t-test were performed as the post-hoc test ($p < 0.05$) level of significance set a priori. **RESULTS:** A significant interaction was found between condition and time for Lac ($p = 0.014$) and was attenuated during Hypox7.5 condition at recovery compared to the other conditions (Normox0: 6.3 ± 3 mmol; Hypox0: 6.5 ± 3.2 mmol; Hypox1.5: 6.3 ± 3.4 mmol; Hypox7.5: 4.5 ± 3 mmol). Also, a main effect of time for Hb ($p < 0.001$) such that there was a 6.7% increase in Hb at max compared to base and rest, and 5.6% higher Hb at recovery compared to base and rest. **CONCLUSION:** Individuals who wear respirator masks with 7.5 cmH₂O in a hypoxic condition may clear Lac faster (turnover) which might improve recovery time. Future research may focus on Lac, Hb and other hemodynamic variables and the mechanism underlying lactate clearance in varying hypoxic conditions.

The Effect of Acute Simulated Altitude on the Lactate Thresholds of Well-Trained Cyclists

Pitre C. Bourdon¹, Sally A. Clark², Robert J. Aughey³, Tom Stanef⁴, Sarah M. Woolford⁴, Walter Schmidt⁵, Christopher J. Gore, FACSM². ¹ASPIRE Academy, Doha, Qatar. ²Australian Institute of Sport, Canberra, Australia. ³Victoria University, Melbourne, Australia. ⁴South Australian Sports Institute, Adelaide, Australia. ⁵Bayreuth University, Bayreuth, Germany. (Sponsor: Christopher J Gore, FACSM)

(No relationships reported)

PURPOSE: Endurance cyclists often race or train at altitudes ranging from 1,000-3,000 m above sea level. It is well known that peak oxygen consumption ($\dot{V}_{O_{2peak}}$) and mean power output (PO) decrease with increasing altitude. However, factors such as lactate thresholds are also important for endurance performance. Research investigating the response of the lactate thresholds to acute hypoxia is however scarce. The aim of this study was to quantify and titrate the acute effect of simulated altitude on the lactate thresholds of well-trained cyclists. **METHODS:** Ten well-trained, non-altitude acclimatized male cyclists and triathletes completed a graded cycling exercise test in a hypobaric chamber at each of four simulated altitudes (200, 1,200, 2,200, 3,200 m). The test protocol comprised 5 x 5-min submaximal efforts (50, 100, 150, 200 and 250 W), to determine \dot{V}_O_2 , heart rate (HR) and blood lactate concentration ([La]) responses. Following a 10 min

passive rest, a 5-min maximal time-trial (5-minTT) was performed to determine peak physiological and performance responses. Combining these measures allowed a modified 2-in-1 protocol to be applied to calculate the lactate thresholds (LT1, LT2) using customized software (ADAPT).

RESULTS: VO_2 decreased by $5.5 \pm 1.1\%$, $15.9 \pm 1.5\%$ and $26.3 \pm 1.4\%$ at LT1 and by $6.5 \pm 1.2\%$, $13.4 \pm 1.3\%$ and $23.2 \pm 1.8\%$ at LT2 at 1,200, 2,200 and 3,200 m compared with 200 m respectively, $P < 0.05$. Mean PO declined by $5.4 \pm 1.1\%$, $17.7 \pm 1.7\%$ and $30.3 \pm 1.9\%$ for LT1 and by $5.2 \pm 1.3\%$, $13.9 \pm 1.4\%$ and $25.7 \pm 1.8\%$ at LT2 at 1,200, 2,200 and 3,200 m compared with 200 m respectively, $P < 0.05$. HR and $[\text{La}^-]$ at these thresholds remained unchanged. 5-minTT $\text{VO}_{2\text{peak}}$ and PO both followed the same pattern of decline with increasing altitude, $P < 0.05$.

CONCLUSIONS: A dose response effect of acute hypobaric hypoxia on VO_2 and PO was found at both submaximal (LT1 and LT2) and maximal (5-minTT) intensities. No such effects were seen for HR or $[\text{La}^-]$ at any intensity.

Resistance Exercise In Hypoxia Combined With Blood Flow Restriction

Olivier Girard¹, Marin Purnelle², Sarah J. Willis², Grégoire P. Millet². ¹Aspetar Orthopaedic and Sports Medicine Hospital, Doha, Qatar. ²Lausanne University, Lausanne, Switzerland. (Sponsor: Robert F Chapman, FACSM)
Email: oliv.girard@gmail.com
(No relationships reported)

The use of blood flow restriction (BFR) or systemic normobaric hypoxia (NH) during resistance exercise to increase metabolic stress and the subsequent muscular development is increasingly popular. However, the extent to which local and systemic hypoxic conditions in combination influence resistance exercise and accompanying physiological responses remains undetermined.

Purpose: To determine separate and combined effects of BFR and NH during resistance exercise on performance, perceptual cues, as well as muscle activation and oxygenation.

Methods: 14 physical education students were tested for 1 repetition maximum (1-RM) in the *barbell biceps curl* (biceps) and *dumbbell pull over* (triceps). On separate visits, they performed 6 separate randomized trials of 4 sets at 70% 1-RM to failure of each exercise (90-s and 10-min rest between sets and exercises, respectively) in normoxia (FiO_2 20.9%) or NH (FiO_2 12.9%) combined with 3 different levels of vascular occlusion (0%, 45% or 60% of maximal occlusion). Arterial oxygen saturation, heart rate, and perceptual responses were assessed following each set. Muscle activation and oxygenation were monitored *via* surface electromyography (EMG) and near-infrared spectroscopy, respectively.

Results: Compared to set 1, the number of repetitions before muscular failure decreased in sets 2, 3, and 4 for both the *biceps* ($-44 \pm 6\%$, $-59 \pm 7\%$ and $-63 \pm 6\%$, respectively; all $P < 0.001$) and *triceps* ($-39 \pm 10\%$, $-56 \pm 7\%$ and $-62 \pm 7\%$, respectively; all $P < 0.001$), independently of the condition ($P > 0.065$). Arterial oxygen saturation was lower with NH ($P < 0.001$), but not BFR, while heart rate ($P > 0.341$) did not differ between conditions. A significant main effect of time was observed for overall perceived discomfort, difficulty breathing and limb discomfort (all $P < 0.001$), but no difference between conditions (all $P > 0.235$). Overall, markers of metabolic stress (tissue saturation index during exercise and subsequent recovery; all $P > 0.206$) and muscle activation (Root Mean Square value; all $P > 0.626$) remained unaffected by environmental conditions.

Conclusion: Local and systemic hypoxic stimuli, or a combination of both, during resistance exercise to failure did not alter performance, perception of strenuous exercise, nor trends of muscle activation or oxygenation.

Effects of Hypobaric and Normobaric Hypoxia on Mitochondrial Related Gene Expression

Robert J. Shute¹, Roksana B. Zak¹, Brent C. Ruby, FACSM², John C. Quindry, FACSM², Dustin R. Slivka, FACSM¹. ¹University of Nebraska at Omaha, Omaha, NE. ²University of Montana, Missoula, MT. (Sponsor: Dustin Slivka, FACSM)
(No relationships reported)

Environmental stimuli such as temperature and hypoxia can influence cellular signaling in the skeletal muscle. Previously we have reported no changes in gene expression related to mitochondrial development with acute exposure to normobaric hypoxia. However, exposure to hypobaric hypoxia may elicit different physiological responses. **Purpose:** To determine the response of skeletal muscle mitochondrial related gene expression after 4-h exposure to normobaric hypoxia (NH), hypobaric hypoxia (HH) and normobaric normoxia (NN) after exercise. **Methods:** Recreationally trained participants ($n = 15$, age: 24 ± 4 y, height: 178 ± 12 cm, weight: 72.47 ± 13.84 kg, body fat: $14 \pm 7\%$, $\text{VO}_{2\text{max}}$: 3.60 ± 0.83 L \cdot min⁻¹, W_{max} : 274 ± 72 W) each completed three trials of 1-h cycling at 70% of W_{max} . Following exercise, participants sat in an environmentally controlled chamber for a 4-h recovery period in NH (4,420

m), HH (4,420 m), or NN (975 m) environmental conditions. Blood oxygen saturation was measured using pulse oximetry at baseline, 30 min into exercise, immediately after exercise, and 30 min into each hour of recovery. Muscle biopsies were taken from the *vastus lateralis* pre-exercise and after a 4-h exposure period. Samples were analyzed using qRT-PCR to assess gene expression related to mitochondrial development.

Results: Arterial oxygen saturation was lower in HH and NH trials compared to the NN trial ($p < 0.001$) and lower in the HH compared to NH ($p = 0.001$). PGC-1 α , GABPA, ERR α , and NRF1 mRNA were not different between the three conditions or from pre-exercise ($p = 0.804$, 0.650 , 0.956 , 0.563 , respectively). TFAM mRNA increased in NH from pre-exercise to post-exercise ($p = 0.036$) and was higher than NN ($p = 0.011$). **Conclusion:** These data indicate that gene expression related to mitochondrial development is only marginally affected (TFAM) by the type of hypoxic environment after a 4-h treatment despite differences in arterial oxygen saturation. Effects of Hypobaric and Normobaric Hypoxia on Myogenic and Proteolytic Gene Expression in Humans

Caleb Ross¹, Robert Shute¹, Roksana Zak¹, Brent Ruby, FACSM², John Quindry, FACSM², Dustin Slivka, FACSM¹. ¹University of Nebraska at Omaha, Omaha, NE. ²University of Montana, Missoula, MT. (Sponsor: Dr. Dustin Slivka, FACSM)
(No relationships reported)

Muscle mass is reduced during extended exposure to a hypoxic environment. Current research suggests that the physiological response to normobaric and hypobaric hypoxia may be different. It is currently unknown if these previously described differences extend to the skeletal muscle and transcriptional response regulating muscle mass.

PURPOSE: To determine the effects of normobaric and hypobaric hypoxia on myogenic and proteolytic gene expression. **METHODS:** Recreationally trained subjects ($n = 15$; age = 24 ± 4 y; $\text{VO}_{2\text{max}}$ = 3.60 ± 0.83 L \cdot min⁻¹) completed three trials of 60-min cycling at 70% of W_{max} followed by 4-h of recovery at ambient control conditions (975 m), normobaric hypoxia (4,420 m), and hypobaric hypoxia (4,420 m). For each trial, a muscle biopsy was taken from the *vastus lateralis* before exercise and at the end of the 4-h recovery period for analysis of gene expression (RT-qPCR).

RESULTS: There were no differences in the myogenic gene expression of MYOD ($p = 0.713$), MYF-5 (0.053), or MYOG (0.832) between trials. MYF-6 was higher after exercise ($p = 0.002$) regardless of trial. MSTN decreased from pre- to post-exercise ($p < 0.001$) in all conditions and was lower in hypobaric hypoxia compared to control condition ($p = 0.02$) and normobaric condition ($p = 0.037$). There were no differences in the proteolytic gene expression of atrogen-1 with exercise ($p = 0.811$) or between trials ($p = 0.419$). However, FOXO3 ($p = 0.009$) and MuRF-1 ($p < 0.001$) gene expression increased with exercise but were not different between conditions ($p = 0.543$, $p = 0.327$, respectively). **CONCLUSION:** These data indicate that hypoxic recovery from exercise, regardless of whether normobaric or hypobaric, does not affect the expression of genes related to myogenesis and proteolysis with the exception of a modest attenuation of myostatin in hypobaric hypoxia.

Prior Heat or Hypoxic Acclimation Does Not Attenuate the Cytokine Response to Hypoxic Exercise

Ben J. Lee¹, Rob S. James², Charles D. Thake². ¹University of Chichester, Chichester, United Kingdom. ²Coventry University, Coventry, United Kingdom.
Email: b.lee@chi.ac.uk
(No relationships reported)

BACKGROUND: Heat acclimation activates the cellular heat shock response (HSR), inhibiting NF- κ B and reducing heat stress-mediated cytokine production and limiting stress-induced inflammation. Hypoxia-mediated intestinal ischemia activates the NF- κ B pathway and stimulates pro-inflammatory responses linked to acute mountain sickness and pulmonary and cerebral oedema. The upregulation of the HSR via heat acclimation may therefore reduce inflammatory responses following subsequent hypoxic exercise.

PURPOSE: To determine whether prior heat acclimation attenuates the cytokine response following hypoxic exercise. **METHODS:** Plasma TNF- α , IL-6, IL-10 and IL-1ra were determined at rest and following a 60 minute cycling normoxic stress test (NST) and hypoxic stress test (HST1; $\text{F}_2\text{O} = 0.14$, 50% $\text{VO}_{2\text{peak}}$) in 21 men (age 22 ± 5 years; stature 1.76 ± 0.07 m; mass 71.8 ± 7.9 kg; VO_2 peak 51 ± 7 mL \cdot kg⁻¹ \cdot min⁻¹). Participants formed 3 groups and completed 10 x 60 minute acclimation sessions (50% $\text{VO}_{2\text{peak}}$) in control ($n = 7$; 18°C, 35% RH), hypoxic ($n = 7$; $\text{F}_2\text{O} = 0.14$, 18°C, 35% RH), or hot ($n = 7$; 40°C, 25% RH) conditions. A second HST (HST2) was completed 48 hours after the final acclimation session. Cytokine data are presented as mean change in ng \cdot mL⁻¹ with 95% confidence intervals and comparisons made

using mixed ANOVA. **RESULTS:** Following the NST plasma IL-6 (+0.6, 95% CI 0.3 - 0.9 ngmL⁻¹), IL-10 (+1.1, 95% CI -2.8 - 5.0 ngmL⁻¹) and IL-1ra (-16.6, 95% CI -60.5 - 27.2 ngmL⁻¹) exhibited minimal change ($p > 0.05$). TNF- α was unaltered throughout the study. IL-6 (+3.9, 95% CI 2.8 - 4.9 ngmL⁻¹), IL-10 (+26.2, 95% CI 15.0 - 37.3 ngmL⁻¹) and IL-1ra (+1506, 95% CI 746 - 2266 ngmL⁻¹) were elevated following HST1 ($p < 0.01$), with no main effect for acclimation group ($p > 0.05$). A similar trend was observed after acclimation (HST2), with IL-6 (+3.1, 95% CI 2.5 - 3.7 ngmL⁻¹), IL-10 (+23.2, 95% CI 14.0 - 32.5 ngmL⁻¹) and IL-1ra (+1237, 95% CI 721 - 1753 ngmL⁻¹) increased ($p < 0.01$), and no main effect for trial or acclimation group observed ($p > 0.05$). **CONCLUSIONS:** Neither prior heat nor hypoxic acclimation attenuated the systemic cytokine response following acute exercise in hypoxia. Future work investigating the effectiveness of different acclimation modalities on improving inflammatory outcomes to hypoxic stress is recommended.

Validity of the Load Velocity for Power Resistance Training Adjustment at Real Moderate Altitude

Lara Rodríguez-Zamora¹, José Antonio Morales-Artacho², Amador García-Ramos², Pérez-Castilla Alejandro², Paulino Padiá², Belén Feriche². ¹Mid Sweden University, Östersund, Sweden. ²University of Granada, Faculty of Sport Sciences, Granada, Spain.
 Email: lara.rodriguez.zamora@gmail.com
 (No relationships reported)

The relationship between muscle power and hypoxia represents a new way to improve the potential benefits of altitude training, especially in sports involving explosive movements. Monitoring workload through velocity (mean propulsive velocity, MPV), seems appropriate since both the neuromuscular demands and the training effect itself largely depend on the velocity at which loads are lifted. **PURPOSE:** To study whether the MPV could be used to adjust the workload during an oriented resistance training program (RT) at moderate real altitude. **METHODS:** 23 collegiate-men volunteers (23±3 yr) followed 4 weeks RT oriented to optimize muscle power development in either normoxia (N) or intermittent hypoxia (IH, 2320 m living at sea level). The RT (2 sessions/wk, 8 in total) was the same for both groups and the training load (TL) was weekly adjusted to elicit 1m·s⁻¹ of MPV. The TL was controlled by a linear velocity transducer, and the session loss-velocity in % (L) was estimated. Maximal isometric handgrip (Din) and SaO₂ were monitored before and after each session (s). The peak relative power at 1 ms⁻¹ of MPV (P), was determined before and after the RT. Intra (s) and inter (N vs. IH) comparisons were made by using mean comparison tests. **RESULTS:** Similar increases in TL were found between N and IH (P=0.716), with both groups showing significant increases when comparing s1 vs. s8 values (N: 9.84%, P=0.03; IH: 8.18%, P=0.007). Interestingly no significant changes in L were found between groups (N: 5.0 vs. IH: 5.9%, P=0.360). Pr increased significantly only in IH (s1: 50.66±5 vs. s8: 54.12±4.9 W·Kg⁻¹, P=0.002). As expected, lower values of SaO₂ were found in IH when compared with N (P<0.05) with no differences among s (P=0.571). No significant changes were found for Din between groups (N: 50.7 vs. IH: 56.3 Kg, P=0.137) or s (P=0.216). **CONCLUSIONS:** Monitoring the MPV allows to adjust the workload during RT. The lack of differences in L between groups, mobilizing similar TL, with an increase of Pr only in IH, supports the idea that intermittent exposure to moderate real altitude would have a positive effect on strength responses. A possible explanation could be the combination of the reduced air density and the stimulation of physiological factors. Supported by the Ministry of Education, Culture and Sport of Spain. Ref. DEP2015-64350-P, MINECO/FEDER

Effects Of Supplemental Oxygen On Submaximal And Maximal Cycling Performance At Altitude

Kathryn Bell, Andrew W. Subudhi, FACSM. University of Colorado Colorado Springs, Colorado Springs, CO. (Sponsor: Andrew Subudhi, FACSM)
 Email: Kbell12@uccs.edu
 (No relationships reported)

Purpose: Reduced partial pressure of oxygen (PO₂) at altitude reduces maximal oxygen consumption (VO₂). When O₂ is supplemented, maximal exercise performance at altitude has been shown to improve. We questioned whether supplemental O₂ would also increase performance during self-regulated, moderate-intensity exercise performed at 1890m. **Methods:** Twelve (7 male) 26.6±6.7 year-old healthy participants (height, 174.8±9.7cm; weight, 71.4±8.4kg) performed one familiarization trial and two experimental trials (double blind, cross over) while breathing either room air or supplemental O₂ to simulate sea level (FIO₂=0.265). To evaluate submaximal exercise performance, participants cycled an electrically braked ergometer (Velotron Elite) at a self-selected cadence and work rate corresponding to an RPE of 9 (very light) for 5 min and RPE of 13 (somewhat hard) for 10 min. Following a 2 min rest, participants performed an incremental test (25W + 25W/min) to maximal exertion. Watts, VO₂, VE, RER, HR, SpO₂, and RPE were recorded each

min. Differences between trials were evaluated by paired t-tests. Chi-square was used to determine subjects' ability to correctly identify the FIO₂ after each phase of the protocol. **Results:** Supplemental O₂ at 1890m increased SpO₂ during submaximal exercise at RPE 9 and 13 (3±3 and 4±2%, respectively P<0.01); Watts, VO₂, VE, RER, and HR were unaffected. Supplemental O₂ at 1890m increased SpO₂ (5±3%), power output (16±8 Watts), and VO₂ (0.28±0.16 L/min) at maximal intensity (all P<0.02). Subjects were not able to correctly identify the FIO₂ (P range: 0.25 to 1.00). **Conclusion:** Although supplemental O₂ improves maximal exercise performance at 1890m, it had little effect on short-duration, moderate-intensity exercise, such as might be performed during a warm-up for a competitive event.

930 Board #109 May 31 2:00 PM - 3:30 PM
Cerebral and Skeletal Muscle Oxygen Response During Exercise With and Without an Altitude Simulation Mask

Alexander Johnson, Reid Nelson. Concordia University Wisconsin, Mequon, WI.
 (No relationships reported)

Altitude as well as hypoxic chambers cause a greater exercise-induced decrease in both cerebral oxygen response (COR) and skeletal muscle oxygen response (SMOR) when compared to exercise in normoxic conditions. Altitude simulating masks (ASM) such as restrictive breathing devices have promoted their products as respiratory muscle trainers that also expose the body to hypoxic conditions.

PURPOSE: To determine if a significant difference in COR and SMOR measured by near-infrared spectroscopy (NIRS) exists during maximal exercise under normoxic conditions with and without an ASM. **METHODS:** Thirteen healthy individuals (F=3, M=10, 24.2 ± 2.7 yr) completed three separate bicycle ergometer maximal exercise tests. Test 1 consisted of respiratory gas analysis to identify $\dot{V}O_{2max}$ ventilatory threshold 1 (VT1), and the respiratory compensation point (RCP). Tests 2 and 3 were with and without the ASM in a counterbalanced crossover design. Heart rate (HR), blood pressure (BP), pulse oximetry (S_pO₂), and blood lactate (BL) were assessed for all tests. COR was calculated by taking the peak 5-second average of oxygenated hemoglobin (O₂Hb) and subtracting it from the O₂Hb at the end of exercise. SMOR was measured by calculating the difference in tissue saturation index (TSI) at the onset and end of exercise. Dependent t-tests were used to assess differences between ASM and non ASM. Significance was set at $p < 0.05$. **RESULTS:** There were no significant differences in COR (non ASM 6.01 ± 3.54 vs. ASM 3.75 ± 1.92 $\mu\text{M} \cdot \text{L}^{-1} \text{O}_2\text{Hb}$; $p=0.078$) or SMOR (non ASM 17.97 ± 8.08 vs. ASM 19.61 ± 10.92%, TSI; $p=0.462$) during maximal exercise. There was, however, a reduced S_pO₂ during exercise in the ASM condition (ASM 3.1 ± 3.3 vs. non ASM 1.0 ± 2.2%; $p < 0.001$). A significantly higher exercise capacity (non ASM 284.2 ± 74.6 vs. ASM 271.6 ± 65.8 watts, $p=0.007$) and BL (non ASM 11.5 ± 3.7 vs. ASM 9.5 ± 2.3 mM · L⁻¹; $p=0.008$) was observed in the non ASM exercise trial compared to ASM. **CONCLUSIONS:** These results suggest that the use of the ASM during exercise in normoxic conditions did not show a significant difference in COR or SMOR when compared to exercise without the ASM. Although this study did not analyze the respiratory muscle training effect of the ASM, there was no evidence of a cerebral or muscle hypoxic effect during the acute bout of exercise.

931 Board #110 May 31 2:00 PM - 3:30 PM
Influence of Exercise Modality on Hypoxia-Mediated Decrements in Endurance Exercise Performance

Jeremy K. Theisen, Nathan C. Grimm, Simon P. Fredericks, Raj Trikhia, Alissa A. Ackerman, Christopher Bell. Colorado State University, Fort Collins, CO. (Sponsor: Raoul Reiser, FACSM)
 Email: jtheisen@colostate.edu
 (No relationships reported)

Low oxygen environments, such as high altitude, impair endurance exercise performance. The magnitude of performance decrements are highly variable and may in part be explained by the exercise modality and volume of active muscle mass. For example, it is unclear if an exercise modality engaging both the upper and lower body, such as rowing, would be more impaired than a predominantly lower body exercise, such as cycling. **PURPOSE:** To determine the influence of exercise modality on hypoxia-mediated decrements in endurance exercise performance.

METHODS: Endurance trained men and women (n=8; 4 female; age: 30±11 years; maximal oxygen uptake: 3.51±1.01 L/min or 48.1±8.2 ml/kg/min (mean±SE)), participated in a Latin Square experimental design. Four time trials were completed: two on a stationary cycle (4km) and two on a rowing (2km) ergometer, in normoxia (FiO₂=0.210) and simulated high-altitude (hypoxia; FiO₂=0.150). Potential differences were analyzed using two-way analysis of variance with repeated measures.

RESULTS: Hypoxia slowed time trial performance (P>0.001) in both exercise modalities (Cycling: 6.7±0.7 vs. 7.3±1.0; Rowing: 8.0±0.9 vs. 8.5±1.0 min); the proportional magnitude of hypoxia-mediated decrements were not different (P=0.45) between cycling (9.5±4.6%) and rowing (6.3±3.7%).

CONCLUSIONS: Endurance exercise performance is attenuated in hypoxia. Our preliminary data suggest the magnitude of decrements may not be appreciably different between exercise modalities engaging upper and lower body, such as rowing, compared with modalities relying predominantly on lower body, such as cycling.

932 Board #111 May 31 2:00 PM - 3:30 PM
Effect of Acute Simulated Altitude Exposure on Excess Postexercise Oxygen Consumption

James W. Navalta, FACSM, Elizabeth A. Tanner, Debra K. Tacad, Nathaniel G. Bodell. *University of Nevada, Las Vegas, Las Vegas, NV.*
 Email: james.navalta@unlv.edu
 (No relationships reported)

Oxygen consumption (VO_2) that remains elevated above the baseline after exercise termination is known as excess post-exercise oxygen consumption (EPOC). Arrival at altitude decreases maximal oxygen uptake, however studies are mixed with respect to the effect of altitude on resting metabolic rate (RMR). To our knowledge, the EPOC response has not been studied with altitude as an independent variable. **PURPOSE:** To observe the EPOC to constant-load cycle exercise performed under acute simulated altitudes of 3353 m and 6401 m.

METHODS: Subjects ($N = 7$ female, 7 male) reported to the laboratory between 0600 and 0830 hours and RMR was obtained. Constant workload cycle exercise was then performed (10-min at 100 W) while breathing air from an altitude simulator under one of the following conditions: control (CON), 3353 m (MID), 6401 m (HI). Subjects returned to complete the remaining conditions in a counterbalanced order. Upon completion of the exercise bout, participants were reconnected to the metabolic system and rested until a running 5-min average of VO_2 values returned to or below baseline (EPOC duration). Magnitude was determined by summing the net oxygen consumption for each minute during the EPOC period. Data were analyzed using 2 x 3 repeated measures ANOVA.

RESULTS: Since no sex differences were detected, data were collapsed and analyzed using one-way repeated measures ANOVA. There was no difference between condition for RMR (CON=3.9±0.5, MID=3.9±0.3, HI=3.9±0.4 ml/kg/min), or cycle performance variables including average power (CON=98±4, MID=100±4, HI=95±9 W). EPOC duration was significant at each altitude increase (CON=15.2±1.9 vs MID=20.7±1.7 min, $p=0.002$) (MID vs HI=28.1±2.6 min, $p=0.006$). Likewise, EPOC magnitude was significant at each altitude (CON=73.5±9.9 vs MID=99.1±9.3 ml O₂, $p=0.002$) (MID vs HI=139.7±14.3 ml O₂, $p=0.001$).

CONCLUSIONS: Determining the EPOC response to altitude is important because it represents a source of elevated caloric expenditure that must be accounted for given that carbohydrates are preferentially utilized with altitude exposure. This has an influence on recovery from exercise as well as future bouts of work. Thus, individuals who are active at altitude must account for this increased caloric deficit despite a loss of appetite that is common with altitude exposure.

Efficacy of Normobaric Intermittent Hypoxic Training to Improve VO₂peak During Acute Hypobaric Hypoxia Exposure

John H. Sellers, Taylor M. Monaghan, Jessica A. Schnaiter-Brasche, Michelle M. Miller, Mitchel A. Magrini, Bert H. Jacobson, FACSM. *Oklahoma State University, Stillwater, OK.*
 (Sponsor: Bert H. Jacobson, PhD, FACSM)
 Email: john.h.sellers14.mil@mail.mil
 (No relationships reported)

Environmental conditions pose additional threats to the health of soldiers during military operations. Missions conducted at high altitude increase the relative workload for military personnel and unacclimatized warfighters may endure performance decrements.

PURPOSE: To examine the effects of normobaric intermittent hypoxic training (NIHT), when compared to normobaric normoxia (NN) training, on peak aerobic capacity ($\text{VO}_{2\text{peak}}$) in hypobaric hypoxia (HH). **METHODS:** Eleven male Reserve Officers' Training Corps (ROTC) cadets (age 19.55±1.44 y, mass 75.80±8.82 kg, stature 177.45±6.67 cm) completed the 6 week training intervention in either the NIHT (EXP, $n=6$) or NN (CON, $n=5$) conditions. Pre- and post-assessment of $\text{VO}_{2\text{peak}}$ was conducted in an HH setting equivalent to 3033 m. The EXP group also completed a follow-up $\text{VO}_{2\text{peak}}$ assessment after a 1 week detraining period. Mixed ANOVA was performed to analyze differences between the within-subjects factor (time) and between-subjects factor (group). Repeated measures ANOVA were also performed to analyze differences between the pre-, post-, and follow-up results of the EXP group. **RESULTS:** There was no significant interaction of time x group, $F(1,9)=1.17$, $P=0.31$, partial $\eta^2=0.12$, nor significant main effect of group, $F(1,9)=0.03$, $P=0.86$, nor was there a significant main effect of time $F(1,9)=3.35$, $P=0.10$, on time-to-exhaustion (TE) measured in HH. Neither was there a significant interaction of time x group for relative $\text{VO}_{2\text{peak}}$ ($\text{RVO}_{2\text{peak}}$). $F(1,9)=1.64$, $P=0.23$, partial $\eta^2=0.15$. Further, there was no

significant main effect of group for $\text{RVO}_{2\text{peak}}$, $F(1,9)=0.61$, $P=0.45$. However, there was a significant main effect of time for $\text{RVO}_{2\text{peak}}$, $F(1,9)=6.88$, $P=0.03$. Finally, there was no significant difference of $\text{RVO}_{2\text{peak}}$ in the EXP group between pre-, post-, and follow-up assessments in the HH chamber, $F(2,3)=6.53$, $P=0.06$. **CONCLUSION:** NIHT, compared to NN, failed to elicit significantly greater aerobic endurance enhancements in acute HH. However, while statistical significance for TE, $\text{VO}_{2\text{peak}}$, and $\text{RVO}_{2\text{peak}}$ may not have been attained, moderate effect sizes for the aforementioned variables reveal a potential practical significance was achieved via increases of 7.37%, 15.99%, and 14.71% for the EXP group, respectively.

Maximum Oxygen Consumption Returns to Sea Level Values after Two Weeks of Altitude Acclimatization in a Large Multi-Year Study

John E. Davis. *Alma College, Alma, MI.*
 Email: davisj@alma.edu
 (No relationships reported)

While it is generally agreed that maximum oxygen consumption ($\text{VO}_{2\text{max}}$) declines upon acute ascent to altitude, there has been some disagreement about the effects of acclimatization on $\text{VO}_{2\text{max}}$. Some of the disagreement reflects a small sample size and lack of control of physical activity during the stay at altitude. To our knowledge, no studies with a large subject pool that controls for physical activity have looked at $\text{VO}_{2\text{max}}$ after acute exposure, acclimatization and upon return to sea level in the same study. **Purpose:** Therefore, the purpose of this study was to determine the effect of moderate altitude exposure on maximum oxygen consumption acutely, after acclimatization, and upon return to sea level. **Methods:** Over the course of a 6-year period, eighty-eight active subjects (age = 23.3 + 3.5 yrs, weight = 78.5 + 17.5 kg, $\text{VO}_{2\text{max}} = 42.4 + 5.7$ ml/kg/min) completed a graded-exercise test on a cycle ergometer at sea level (SL1), upon acute exposure to 3417 m (ALT1), two weeks following acclimatization at 3417 m (ALT2), and upon return to sea level (SL2). Workloads were increased every two minutes following a two-minute warmup until volitional fatigue. Maximum oxygen consumption was measured using a Parvo TruOne 2400 Metabolic cart. Subject's activity levels were assessed during the 2-week period and were unchanged relative to sea level. **Results:** Maximum oxygen consumption significantly declined ($P<0.05$) from SL1 to ALT 1 (3.48 + .39 l/min vs. 3.04 + .32 l/min). However, by ALT2 $\text{VO}_{2\text{max}}$ was not different from SL1 (3.48 + .39 l/min vs. 3.31 + .51 l/min). Maximum oxygen consumption was slightly, but not significantly higher upon return to sea level (SL2 = 3.65 + .66 l/min). While body weight changes occurred in some subjects, overall there was no difference in average body weight between any of the testing points. **Conclusions:** These data suggest that exposure to acute altitude results in a reduction in maximum oxygen consumption. However, after two weeks of acclimatization maximum oxygen consumption returns to pre-sea level values in a large multi-year study.

Does Arterial Oxyhemoglobin Saturation Influence the Hemoglobin Mass-VO₂Peak Relationship in Endurance Athletes at Moderate Altitude?

Jesse A. Goodrich, Benjamin J. Ryan, William C. Byrnes, FACSM. *University of Colorado Boulder, Boulder, CO.*
 (Sponsor: William C. Byrnes, FACSM)
 (No relationships reported)

Total hemoglobin mass (tHb) is a well-established, key predictor of maximal oxygen uptake ($\text{VO}_{2\text{peak}}$) across aerobic fitness levels. Arterial oxyhemoglobin saturation ($\text{S}_{\text{a}}\text{O}_2$) has the potential to modify this relationship, especially in populations that experience exercise-induced arterial desaturation. **PURPOSE:** To examine how variability in $\text{S}_{\text{a}}\text{O}_2$ at $\text{VO}_{2\text{peak}}$ modifies the relationship between tHb and $\text{VO}_{2\text{peak}}$ at moderate altitude (1625m) in highly trained athletes.

METHODS: 16 male and 17 female competitive, highly trained (>10 hr training per week) cyclists/triathletes took part. On visits one and four tHb was assessed via the optimized carbon monoxide rebreathing method. Visits two and three were identical graded exercise tests (GXT) on a cycle ergometer to determine $\text{VO}_{2\text{peak}}$ and $\text{S}_{\text{a}}\text{O}_2$ at $\text{VO}_{2\text{peak}}$; the workload began at 4 and 3 W kg^{-1} for men and women respectively, rounded down to the nearest 20 W increment, and power increased 20 W every minute until volitional exhaustion. VO_2 was measured using indirect calorimetry and $\text{VO}_{2\text{peak}}$ was calculated as the highest average 30 sec VO_2 . $\text{S}_{\text{a}}\text{O}_2$ was measured at rest and during exercise using forehead pulse oximetry; $\text{S}_{\text{a}}\text{O}_2$ at $\text{VO}_{2\text{peak}}$ was calculated as the average $\text{S}_{\text{a}}\text{O}_2$ during the same 30 sec used to determine $\text{VO}_{2\text{peak}}$. Duplicate measures of tHb were averaged in order to reduce measurement error. In order to control for the effect of body mass on $\text{VO}_{2\text{peak}}$ and tHb, both variables were normalized by body mass prior to analysis.

RESULTS: $\text{VO}_{2\text{peak}}$ was significantly higher for the second GXT (+0.06 ± 0.17 L O₂ min⁻¹, $p = 0.05$) and the difference in $\text{VO}_{2\text{peak}}$ was related to the difference in $\text{S}_{\text{a}}\text{O}_2$ ($r = -0.42$, $p = 0.02$), so results from the second GXT were used. $\text{VO}_{2\text{peak}}$ ranged from

62.5 – 83.0 and 44.5 – 67.3 ml kg⁻¹ min⁻¹ in men and women respectively; tHb ranged from 12.1 – 17.5 and 9.1 – 13.0 g kg⁻¹ and S_aO₂ at VO_{2peak} ranged from 81.7 – 94.0 and 85.7 – 95.0%. tHb explained 32% of the variability in VO_{2peak} (p = 0.02) in men and 42% in women (p = 0.01), but correcting by end exercise S_aO₂ did not improve either relationship.

CONCLUSION: Across a range of highly trained athletes at moderate altitude, correcting tHb by S_aO₂ at VO_{2peak} does not appear to explain additional variability in VO_{2peak}, despite large variability in the levels of observed desaturation.

Cardiopulmonary Responses, Brain And Muscle Oxygenation During Incremental Exercise On Acute Hypoxia And Hyperoxia

Jin Uchimar, Xue Wu, I-Chen Yu, Hidekazu Takemura, Hirohiko Takahashi, Shozo Suzuki. *Sendai University, Shibata, Japan.*

Email: jn-uchimar@sendai-u.ac.jp

(No relationships reported)

Changes in inspired oxygen concentration will affect the peak oxygen uptake compared with normoxia. These underlying mechanisms are not fully understood, but peripheral and central mechanisms have been proposed. **PURPOSE:** Our study focuses on the effect of acute moderate hypoxia and hyperoxia on cardiopulmonary responses, brain and muscle oxygenation during exercise. **METHODS:** Seven healthy male subjects performed on incremental maximal exercise test under normoxia (Norm: 20.9 FIO₂), hypoxia (Hypo: 14.5% FIO₂) and hyperoxia (Hyper: 28.5% FIO₂) conditions. We measured cardiopulmonary measurements (VE, VO₂, HR and Q) and blood gas (PO₂ and PCO₂) on incremental exercise. Near-infrared spectroscopy (NIRS) was also used to monitor concentration (μM) changes of oxy- and deoxyhemoglobin (Δ[O₂Hb], Δ[HbHb]) in left frontal cortex region of the forehead and ipsilateral vastus lateralis muscle. Changes in total Hb and StO₂ were calculated and used as index of change in regional blood volume. Repeated-measures ANOVA were performed across treatments. **RESULTS:** VO_{2peak} decreased in Hypo (38.5±3.1 ml/kg/min, p<0.05) and no difference in Hyper (42.6±3.4 ml/kg/min) compared with Norm (42.2±3.9 ml/kg/min). But blood PO₂ at rest and moderate exercise was low in Hypo (57.7±3.1 and 52.2±5.4 mmHg, p<0.05) and high in Hyper (98.6±8.8 and 105.3±9.3 mmHg, p<0.05) compared with Norm (79.3±12.6 and 84.3±4.7 mmHg). Muscle oxygenation dropped progressively during Hypo, and also changes in muscle oxygenation during Hyper were similar to Norm. Interestingly, Brain oxygenation (Δ[O₂Hb]) was slightly increased and deoxygenation (Δ[HbHb]) was increased during exercise under each three conditions, respectively. Furthermore, changes brain and muscle oxygenation was also greater in Hypo compared with Norm and Hyper (p>0.05). **CONCLUSIONS:** Acute hypoxia decrease oxygen uptake with decreased muscle oxygenation and slightly increased brain oxygenation. But it is unlikely that changes in brain and muscle oxygenation was related with oxygen uptake in hyperoxia, despite a similar difference absolute PO₂ in inspired oxygen and blood from hypoxia and/or hyperoxia to normoxia.

Passive And Active Intermittent Hypoxic Exposure Pre-acclimatization Does Not Alter Heart Rate Variability At Altitude.

Elisabeth M. Board¹, Theocharis Ispoglou², Amanda Seims³, Max Garrard², Ingle Lee⁴. ¹University of Sunderland, Sunderland, SR1 3SD, United Kingdom. ²Leeds Beckett University, Leeds, LS6 3QS, United Kingdom. ³Leeds Beckett University, Leeds, LS1 3HE, United Kingdom. ⁴University of Sunderland, Kingston-upon-Hull, HU6 7RX, United Kingdom.

Email: lisa.board@sunderland.ac.uk

(No relationships reported)

PURPOSE: This study evaluated the impact of passive and active intermittent hypoxic (IH) exposure pre-acclimatization strategies on temporal and spectral power measures of heart rate variability (HRV) in normobaric hypoxia (NH), and natural altitude.

METHODS: Thirty participants (17 male and 13 female, aged 20-62 years), matched by sex, age and maximal aerobic capacity (VO_{2peak}), were randomly allocated to either a control, passive IH or active IH group. Experimental groups completed 10 x 2-h, passive (PIH) or active (AIH), normobaric IH exposures (FIO₂ = 0.124, ~4,011 m) over the 14-day intervention period (weekends excluded). The control group received no IH exposure. During the intervention period, participants completed 20 minutes daily running training, at an individualised intensity equivalent to 80% heart rate reserve (HRR). Training workload was determined by regressing HR and running speed data from individual VO_{2peak} tests in normal ambient conditions (control and PIH groups) or NH (AIH group, FIO₂ = 0.124). AIH participants completed the exercise training sessions under supervision, during scheduled IH exposure sessions, while control and PIH groups completed training unsupervised in normal ambient conditions. Within 48 hours of completing pre-acclimatization, participants travelled by air from the

UK to Nepal, a journey time of approximately 36 hours. Participants then trekked from 2800 m to 5300 m over 14 days. Temporal (RR, SDNN, RMSSD) and spectral power measures (LFnu, HFnu and LFHF ratio) of HRV were recorded, at rest with spontaneous breathing, in normal ambient conditions (FIO₂ = 0.209), NH (FIO₂ = 0.124, ~4011 m) and in hypobaric hypoxia (HH) at 4356 m and 5350 m, during ascent. **RESULTS:** Two-way ANOVA (group x condition) with repeated measures revealed neither significant interactions (P>0.05), nor between-group (P>0.05) nor within-group (P>0.05) differences for temporal or power spectral HRV measures between baseline, pre-IH and post-IH. No significant interactions, between-group or within-group changes were noted between post-IH, 4300 m and 5300 m (P>0.05) natural altitude. **CONCLUSION:** Pre-acclimatization using active and passive intermittent hypoxic exposure did not significantly alter heart rate variability responses during ascent to very high altitude.

Hematological Response to Uncontrolled Use of Altitude Training by Elite Distance Runners

Daniel P. Wilhite¹, Joshua Foss¹, Tyler Noble¹, Daniel Bergland², James Stray-Gundersen, FACSM³, Robert F. Chapman, FACSM¹. ¹Indiana University, Bloomington, IN. ²Volt Sports Lab, Flagstaff, AZ. ³US Ski and Snowboard Association, Park City, UT. (Sponsor: Robert F. Chapman, FACSM)

Email: dpwilhit@indiana.edu

(No relationships reported)

Elite endurance athletes typically use “live high - train low” altitude training to enhance sea level performance. Perhaps the most commonly utilized and expected experimental control in altitude training research concerns iron stores and supplementation. Whether elite athletes and coaches independently follow evidence-based best-practice principles regarding iron status and training at altitude, outside of a controlled research setting, is unknown. **PURPOSE:** To examine logistical decisions elite U.S. distance runners make regarding altitude training and the hematological outcomes that result from those decisions. **METHODS:** Elite U.S. distance runners (n = 58) completed altitude training (living elevation = 2,000 - 2,600m) at their own cost and volition. Total hemoglobin (tHb) mass was measured using CO rebreathing upon arrival and departure from altitude. Questionnaires asked athletes to self-report pre-altitude serum ferritin values, if iron was taken (pill or liquid) at altitude, and workout specifics. **RESULTS:** Of the 40 athletes who knew their serum ferritin level at the start of the camp, those with ferritin < 50 ng·ml⁻¹ (n = 11) demonstrated a ΔtHb of 0.6 ± 2.0% (ns) and those with ferritin > 50 ng·ml⁻¹ (n = 29) significantly increased tHb by 3.7 ± 3.0%. Of those with ferritin levels > 50 ng·ml⁻¹, athletes who lived at altitude < 23 days (n = 9) showed a ΔtHb mass of 1.3 ± 1.7% (ns) and those who lived at altitude for > 27 days (n = 20) significantly increased tHb mass by 3.8 ± 2.6%. Of the total cohort, 49 athletes answered questions regarding iron supplementation. Those who supplemented iron in liquid form (n = 27) significantly increased tHb mass by 4.2 ± 3.4%. Those who did not supplement iron (n = 3) or supplemented in pill form (n = 19) showed a ΔtHb mass of 1.5 ± 0.5% (ns) and 1.4 ± 2.7% (ns). Athletes who answered questions regarding training (n = 47) reported completing 8.5 ± 2.5 “higher intensity workouts,” and 3.6 ± 1.1 of those workouts were done at <1,500m. Only 4 of the 47 athletes completed all higher intensity sessions at <1,500m. **CONCLUSION:** A substantial number of elite U.S. distance runners do not follow what would be considered evidence-based best-practice principles regarding altitude training. Coaches, sport scientists, and clinicians would be prudent to strongly advocate for athletes to follow these principles.

939 Board #118 May 31 2:00 PM - 3:30 PM
No Sex Differences in the Cardiac Response to Acute Normobaric Hypoxia

Wesley K. Lefferts, Matthew C. Babcock, Matthew Tiss, Tom D. Brutsaert, Kevin S. Heffernan. *Syracuse University, Syracuse, NY.* (Sponsor: Patricia Fehling, FACSM)

Email: wleffert@syr.edu

(No relationships reported)

Acute hypoxia reduces arterial oxygen content, thereby increasing cardiac work to maintain oxygen delivery. Hypoxia may be accompanied by impairments in cardiac function which may be subject to sex differences, although this remains inadequately described. **PURPOSE:** Explore sex differences in the cardiac response to acute hypoxia. **METHODS:** Thirty healthy participants (15 men, 22±4 yrs, BMI 25.3±3.0 kg/m²; 15 women, 20±3 yrs, BMI 22.6±1.2 kg/m²) underwent echocardiographic measures with simultaneous 1-Lead electrocardiogram-gating following ~1.5 hour sham condition (20.0% O₂) and normobaric hypoxic (12.5% O₂) exposure on two separate days, in a randomized order. Systolic function (M-mode, tissue Doppler imaging [TDI]) and diastolic function (mitral filling velocities, TDI) were assessed in triplicate. Systolic function was assessed using fractional shortening (FS), ejection fraction (EF) from 2D Teicholz M-mode (parasternal short-axis), and S-wave velocity from tissue Doppler Imaging (TDI, apical 4-chamber). Diastolic function was assessed

using ratios between early (E) and late (A) filling waves assessed from Doppler (E, A) and TDI (E', A'). **RESULTS:** EF, FS, S-velocity (septal) were greater in hypoxia vs sham (p<0.05). Markers of diastolic function (E:A, E':A') were lower in hypoxia vs sham (p<0.05). Men had higher EF vs women across conditions (p<0.05). No significant condition by sex interactions were noted. **CONCLUSION:** Hypoxia resulted in greater systolic function but impaired diastolic function compared to the sham condition. Although men tended to have greater cardiac systolic function vs women there were no sex differences in the cardiac systolic or diastolic response to acute hypoxic exposure. Supported by a Foundation Research Grant from ACSM

Effect Of Additional Overnight Hypoxic Exposure In Combination With Intermittent Hypoxic Training On MART

Marie Oriishi¹, Hayato Ohnuma², Masahiro Hagiwara², Ryo Yamanaka², Toshiyuki Ohya², Kazunori Asaba³, Takashi Kawahara², Yasuhiro Suzuki². ¹Tsukuba University, Ibaraki, Japan. ²Japan Institute of Sports Sciences, Tokyo, Japan. ³Tsuru University, Yamanashi, Japan. (Sponsor: Randy Wilber, FACSM)
 Email: oriko@rowing.jp
 (No relationships reported)

We previously demonstrated that 7 days of intermittent hypoxic training (IHT) improved performance in the maximal anaerobic running test (MART) (ACSM 2015). However, it is unclear whether additional overnight hypoxic exposure in combination with IHT can further enhance MART. **PURPOSE:** The purpose of the present study was to compare the physiological adaptations in well-trained 400m or 800m runners following either 7 days of intermittent hypoxic overnight exposure (IHE), IHT, or a combination of IHE and IHT (IHE+IHT).

METHODS: Thirty-two well-trained university female 400m or 800m runners were assigned to either IHE (n=9), IHT (n=9), IHE+IHT (n=6) or Control (n=8) groups. IHE and IHE+IHT slept in a normobaric hypoxic room (FIO₂=16.4%; 2000m; 10 h/d). IHT and IHE+IHT trained in a normobaric hypoxic room (FIO₂=14.4%; 3000m; 4 h/d). Control, non-IHE hours, and non-IHT hours were spent in ambient normobaric normoxia (60m). Subjects trained for 7 days and performed MART and an incremental maximal running test before and after the 7 days training period. Training consisted of high intensity interval training (5 x 30s maximal effort pedaling) and endurance training (30min incremental running and 30min steady pedaling). VO₂max and the velocity equivalent to 4mmol lactate (V4mM) were measured in the incremental running test.

RESULTS: Maximal power in the MART increased significantly (P<0.05) in IHT (109.5±1.4 vs. 111.7±2.8 ml/kg/min). However, there were no significant changes in IHE, IHE+IHT or Control (IHE: 111.0±4.2 vs. 111.6±4.0, IHE+IHT: 109.4±3.3 vs. 110.2±3.6, Control: 112.1±3.0 vs. 111.5±3.9 ml/kg/min). No significant change in VO₂max in any groups was found. V4mM increased significantly (P<0.05) in IHT and

IHE+IHT (IHT: 248.4±13.7 vs. 255.3±15.6, IHE+IHT: 221.8±16.1 vs. 237.8±9.9 ml/min), whereas there were no significant changes in IHE or Control (IHE: 253.1±24.2 vs. 251.6±22.8, Control: 246.7±16.8 vs. 250.6±21.0 ml/min).

CONCLUSIONS: These results suggest that 7 days of IHT (3000m) enhances maximal anaerobic capacity (MART) in well-trained female middle distance runners, which supports our earlier findings (ACSM 2015). However, there does not appear to be further enhancement of anaerobic running performance with the addition of overnight hypoxic exposure to IHT.

941 Board #120 May 31 2:00 PM - 3:30 PM
Influence Of Altitude Difference On Residents' Physical Function

Xiaoli Liu. University of North Texas, Health Science Center, Fort Worth, TX. (Sponsor: Xiangrong Shi, FACSM)
 Email: Xiaoli.Liu@unthsc.edu
 (No relationships reported)

Purpose: To compare the physical characteristics and function between the residents in different altitude. **Methods:** 441 Tujia-Nationality men (24.6±3.2 yr) from high (H = 1500 M, N = 196) and low (L = 800 M, N = 215) mountain areas in Enshi Tujia and Miao Autonomous Prefecture, Hubei province of China who had the same social-economic status were compared with the physical characteristics and physiological functions. **Results:** Compared with the H group, the L group were taller (167.5 ±5.3 vs 165.0 ±5.2cm, P < 0.001) and had lower waist-to-height ratio (0.51 ±0.04 vs 0.52 ±0.04, P < 0.001), but no significant difference in body weight and circumferences. The L group had higher heart rate (79.5 ±10.8 vs 76.7 ±9.4 bpm, P = 0.034), greater vital capacity (3225 ±677 vs 2839 ±731 ml, P < 0.001), lower systolic pressure (112.0 ±10.4 vs 115.7 ±12.4 mmHg, P = 0.007), and lower diastolic pressure (74.5 ±8.0 vs 79.8 ±11.7 mmHg, P < 0.001). The L group had lower sit-and-reach (6.6 ±7.9 vs 8.5 ±5.3 cm, P = 0.015), but had greater vertical jump (34.2 ±9.0 vs 30.4 ±8.4 cm, P < 0.001), longer time to stand on one foot with eyes closed (31.7 ±31.2 vs 20.5 ±21.4 sec, P < 0.001), more push-up (26±13 vs 23±12, P < 0.031) and shorter reaction time (0.46 ±0.08 vs 0.51 ±0.15 sec, P < 0.001). **Conclusion:** Residents in low mountain area are taller, have lower arterial pressure and better neuromuscular function as compared to their counterparts in high mountain area.

Exposure to high altitude induces hypertension that likely exacerbates arterial hypoxia via pulmonary vasoconstriction and ventilation-perfusion mismatching. Research has shown that inhibition of the renin-angiotensin-aldosterone system (RAAS) via an inhibitor provides an antihypertensive effect at rest during acute exposure to high altitude. Such effects may have benefits for exercise performance given the potential for improved arterial saturation, but has not been studied.

PURPOSE: To assess the effects of the RAAS inhibitor losartan on maximal exercise performance at 5000 m.

METHODS: Eighteen lowlanders were paired-matched for age, ACE gene status, previous altitude exposure and sex, with each of the pair randomly assigned to a group (men:women: losartan 6:3, placebo 6:3; age 40 ± 18 years; height 175 ± 9 cm; body mass 72.4 ± 12.4 kg; BMI 23.7 ± 2.2 kg/m²). A 100 mg once daily dose of either losartan or placebo (starch) was administered in a double-blind manner for 21 days, which included a slow 8-day ascent to 5000 m (Whymper Hut, Chimborazo, Ecuador). At sea-level and within 48 h of arrival at 5000 m, participants (pairs exercised within ~1 h of each other) completed a graded exercise test (GXT) to exhaustion on a supine cycle ergometer (Altcycle, BMRES). Ventilation (VE) and end-tidal gases were measured breath-by-breath (K4b2, Cosmed), and heart rate (HR, ECG), arterial oxygen saturation (SpO₂, pulse oximeter) and beat-to-beat blood pressure (finometer) were measured continuously at rest and during exercise. Data are mean ± SD and group differences at peak power output were analyzed using independent t-tests, with significance set at p<0.05.

RESULTS: At 5000 m, resting measures of SpO₂ between losartan and placebo groups were not significantly different (79 ± 5 vs. 76 ± 6%, p=0.40). Peak power was similarly

reduced relative to sea level ($p < 0.01$) in both groups (down 100 ± 29 vs. 91 ± 28 W, $p = 0.55$), while SaO_2 (70 ± 6 vs. $70 \pm 5\%$, $p = 0.96$), $\text{VO}_{2\text{peak}}$ (31.3 ± 4.6 vs. 34.0 ± 7.2 $\text{mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$, $p = 0.35$), VE (142 ± 38 vs. 146.2 ± 31.2 $\text{L} \cdot \text{min}^{-1}$, $p = 0.81$) and HR (146 ± 21 vs. 149 ± 24 $\text{b} \cdot \text{min}^{-1}$, $p = 0.78$) were similar between groups at peak power, as was the increase in BP from rest to peak power (increased by 31 ± 17 vs. 25 ± 16 mmHg , $p = 0.71$).

CONCLUSION: Losartan (100 mg) taken daily for 21 days had no observable effect on exercise performance at 5000 m.

Ischemic Preconditioning Attenuates Acute Mountain Sickness in Hypobaric Hypoxia during Recreational Mountaineering
 Leslie E. Smith, Shawn M. Keeling, Adam D. Skinner, Pedro A. Padilla, Christina A. Buchanan, Lance C. Dalleck. *Western State Colorado University, Gunnison, CO.*
 Email: leslicerin.smith@western.edu
 (No relationships reported)

Purpose: Acute mountain sickness (AMS) is a syndrome commonly experienced in non-acclimatized mountaineers when ascent is too high and too rapid. Ischemic preconditioning (IPC) is a noninvasive experimental technique that has been shown to protect remote organs from ensuing hypoxic damage. In this study we sought to determine if IPC would 1) mitigate the effects of altitude on arterial O_2 saturation (SpO_2) and 2) attenuate the symptoms of AMS. **Methods:** Ten (6 men and 4 women) physically active individuals (Age: 26.7 ± 5.0 yrs, $\text{VO}_{2\text{max}}$: 45.0 ± 7.1 $\text{mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$) who were acclimated to 2350m were randomized to either a treatment (IPC) or control (CON) group. An IPC protocol consisting of 3x5 min bilateral leg occlusion/reperfusion bouts at 200 mmHg was administered to the IPC group. The CON group was administered a protocol identical in time and frequency, but with an inflation pressure of 40 mmHg. To examine the potential late phase protective effects of IPC on SpO_2 and symptoms of AMS, 36 hours post-IPC or CON, all participants hiked 9km at a standardized pace to an elevation of 3800m. Symptoms of AMS were evaluated by Lake Louise score (LLS). **Results:** It was found that SpO_2 was significantly higher ($p < 0.05$) in the IPC group when compared to the CON group (IPC $89.6 \pm 3.9\%$ vs. CON $86.9 \pm 4.2\%$). A LLQ score of less than 3 is considered mild AMS, whereas a score of 3 or more is considered severe AMS. Incidence of severe AMS was significantly lower ($p < 0.05$) in the IPC (0%) vs. CON (50%) group. Moreover, the IPC group (when compared to CON group) had significantly ($p < 0.05$) lower incidence of dizziness/lightheadedness (IPC=0% vs. CON=50%), fatigue/weakness (IPC=25% vs. CON=66.6%), change in mental status (IPC=0% vs. CON=33.3%) and ataxia (IPC=0% vs. CON=16.6%). **Conclusion:** Our findings suggest that IPC may be a strategy to increase SpO_2 and decrease AMS symptoms at high altitude.

Locomotor-Respiratory Coupling is Maintained in Hypoxia in Trained Distance Runners
 Timothy J. Fulton¹, Hunter L. Paris¹, Abigail SL Stickford², Allison H. Gruber¹, Timothy D. Mickleborough, FACSM¹, Robert F. Chapman, FACSM¹. ¹Indiana University, Bloomington, IN. ²Appalachian State University, Boone, NC. (Sponsor: Robert Chapman, FACSM)
 (No relationships reported)

PURPOSE: To determine if acute exposure to normobaric hypoxia alters locomotor-respiratory coupling (LRC) patterns typically observed in trained runners, and to determine if any changes in LRC influence running economy (RE) and/or perceptions of ventilatory effort.

METHODS: Trained male distance runners ($n=13$) with $\text{VO}_{2\text{max}} = 66.8 \pm 1.1$ $\text{ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ completed two laboratory visits, each in a different inspired gas condition, either normoxia (NORM) or hypoxia (HYP) ($\text{FIO}_2 = 15.8\%$; $\sim 2500\text{m} / 8000\text{ft}$). During each visit, subjects ran for 5 min at each of three constant submaximal speeds of 12.9, 14.3, and 16.1 $\text{km} \cdot \text{hr}^{-1}$ with 4 min standing rest between speeds. Following the third stage, an incremental incline ramp protocol was used to determine $\text{VO}_{2\text{max}}$, RE and LRC measures were taken during the 4th min of each speed (3:00-4:00), while ratings of perceived exertion (RPE) and dyspnea (DYS) were taken during the first 30 seconds of the final minute at each speed (4:00-4:30), and again at the conclusion of the test. The degree of LRC was calculated as the highest number of inspirations or expirations beginning in the same decile of the step divided by the total number of breaths.

RESULTS: Compared with NORM, the degree of LRC was not significantly different at any of the three common submaximal speeds with exposure to HYP, however it was increased at $\text{VO}_{2\text{max}}$ ($43.8 \pm 3.4\%$ vs. $57.1 \pm 3.8\%$; $p < 0.05$). Breathing frequency (breaths min^{-1}) was significantly increased at each submaximal speed in HYP compared to NORM (30.3 ± 1.9 vs. 35.9 ± 2.2 , 34.8 ± 2.0 vs. 39.8 ± 2.2 , 40.4 ± 2.4 vs. 45.2 ± 1.9 ; $p < 0.05$), but was not significantly different at $\text{VO}_{2\text{max}}$. Stride frequency-to-breathing frequency quotients were significantly lower at each submaximal speed in HYP (2.91 ± 0.20 vs. 2.45 ± 0.17 , 2.53 ± 0.17 vs. 2.21 ± 0.14 , 2.22 ± 0.14 vs. 1.95 ± 0.09 ; $p < 0.05$)

due to increases in breathing frequency while maintaining stride frequency. RE and RPE were not significantly different at any speed. DYS was only significantly different between NORM and HYP at 16.1 $\text{km} \cdot \text{hr}^{-1}$ ($p < 0.05$).

CONCLUSIONS: Trained distance runners are able to maintain LRC in hypoxia, even when breathing frequency is increased at any submaximal pace. It is possible that within this unique population, years of training enhance and optimize the ability to make adjustments to LRC in order to minimize metabolic costs.

Acute Hypoxia Exacerbates Central Fatigue but not the Fatigue-related Reduction in Motor Neuron Responsiveness
 Luca Ruggiero, Alexandra F. Yacyshyn, Jane Nettleton, Chris J. McNeil. *The University of British Columbia - Okanagan, Kelowna, BC, Canada.* (Sponsor: Charles L. Rice, FACSM)
 (No relationships reported)

It has been shown recently that acute hypoxia (AH) exacerbates fatigue through both muscular and neural mechanisms. At a supraspinal level, the voluntary drive from the motor cortex during fatiguing efforts was impaired compared to normoxia (NM). However, it is currently unknown whether hypoxia acutely affects motor neuron properties and their contribution to fatigue. **PURPOSE:** To examine motor neuron responsiveness and voluntary activation (VA) during fatiguing contractions in AH and NM. **METHODS:** On separate days, 11 males (31 ± 8 years) completed a 16-minute fatigue protocol composed of submaximal (25% maximal torque; MVC) intermittent (10s contraction, 5s rest) isometric elbow flexions in NM ($\text{F}_{\text{O}_2} = 21\%$) and AH ($\text{F}_{\text{O}_2} = 11\%$). For the last contraction of each minute, participants matched the integrated electromyographic activity (EMG) to that recorded during brief contractions at 25% MVC prior to fatigue; motor neuron responsiveness was measured by delivering cervicomedullary stimulation in the silent period evoked by transcranial magnetic stimulation (TMS) of the motor cortex (100ms inter-stimulus interval). Every 2 minutes, VA was measured by delivery of TMS during contractions at 100, 75 and 50% MVC, separated by 3s. **RESULTS:** Prior to fatigue, arterial saturation and cerebral tissue oxygenation index were significantly lower in AH compared to NM (98 ± 1 vs. $76 \pm 3\%$ and 65 ± 7 vs. $48 \pm 12\%$, respectively; $p < 0.01$). MVC torque was equivalent (76.2 ± 9.5 vs. $80.6 \pm 13.0\text{Nm}$, respectively; $p > 0.05$) but VA was significantly lower in AH compared to NM (90.4 ± 5.0 vs. $93.5 \pm 5.4\%$, respectively; $p < 0.05$). At the end of the fatigue protocol, the reductions of MVC torque and VA (relative to control values) were greater in AH compared to NM (20.5 ± 8.2 vs. $11.6 \pm 9.8\%$ and 14.4 ± 12.3 vs. $4.0 \pm 7.1\%$, respectively; $p < 0.05$). Conversely, the reduction in motor neuron responsiveness (area of the cervicomedullary motor evoked potential normalized to the maximal compound muscle action potential) was not significantly greater during AH compared to NM (47.6 ± 30.8 vs. $31.2 \pm 37.2\%$, $p > 0.05$). **CONCLUSION:** While AH elicited a marked effect in the CNS, such impairment was only confined to the cortical compartment (a greater reduction in VA), without affecting the responsiveness of motor neurons to a fatiguing task.

 (No relationships reported)

Previous studies have reported improved sea level performance and increased haemoglobin mass (Hb_{mass}) following hypoxic doses of varying magnitude. Less research has focused on the periodisation of training during hypoxic exposure which may influence subsequent performance.

PURPOSE: To determine the effect of intensified training and tapering during different doses of Live High Train High (LHTH) altitude on sea level performance and Hb_{mass} in elite runners.

METHODS: Twenty one runners completed one of three LHTH altitude camps following 4 weeks of sea level training; 22 days at 1720 m (MOD22; $n = 7$; $\text{VO}_{2\text{max}} = 71 \pm 4$ $\text{mL} \cdot \text{min} \cdot \text{kg}^{-1}$), 22 days at 2100 m (HI22; $n = 4$; 67 ± 3 $\text{mL} \cdot \text{min} \cdot \text{kg}^{-1}$) or 30 days at 2100 m (HI30; $n = 10$; 70 ± 4 $\text{mL} \cdot \text{min} \cdot \text{kg}^{-1}$). Hb_{mass} was assessed via CO rebreathing immediately pre and post LHTH, and sea level performance was measured in competitive races completed pre and within 2 weeks post. For each training session, Training Load (TL) was calculated using the session RPE method. Training Stress Balance (TSB) was calculated as the ratio between 7 and 28 day exponentially weighted moving averages. Differences between groups were assessed using one-way ANOVA, with the Kruskal-Wallis test used when assumptions were violated (TSB).

RESULTS: Race performance improved by $0.6 \pm 1.5\%$ overall, with similar improvements in HI22 ($0.9 \pm 0.5\%$) and HI30 ($0.9 \pm 0.9\%$); however these were not significantly different to MOD22 ($0.1 \pm 2.3\%$). Performance improvements were achieved by all 4 participants in HI22, 9 of 10 in HI30 and 4 of 7 in MOD22 (4, 7 and 3 lifetime bests respectively). HB_{mass} was increased from baseline in all groups (MOD22 = $4.4 \pm 4.6\%$; HI22 = $6.0 \pm 2.1\%$; HI30 = $4.0 \pm 3.1\%$). Weekly TL during the first 2 weeks of LHTH was similarly increased in all groups compared to preceding sea level training (range $58 \pm 13\%$ to $72 \pm 27\%$). TSB at the start of LHTH in MOD22 (132 ± 21) was significantly higher ($p < 0.03$) than HI22 (94 ± 11) but not HI30 (95 ± 11 ; $p = 0.10$). TL for the final week of LHTH was reduced significantly less ($p \leq 0.03$) from weeks 1 and 2 in MOD22 ($23 \pm 13\%$) than in HI22 ($44 \pm 5\%$) or HI30 ($41 \pm 10\%$).

CONCLUSIONS: Lifetime best sea level performances were achieved following various doses of LHTH. Substantial increases in training load were observed within the first 2 weeks at altitude, and tapering concluding LHTH appeared beneficial for optimal performance.

Performance and Muscle Damage Responses during Repeated Sprint Exercise in Hypoxia among Athletes

Nobukazu Kasai, Chihiro Kojima, Daichi Sumi, Akiho Iketomo, Kazushige Goto. *Ritsumeikan University, Kusatu, Japan.*

(Sponsor: Robert Kraemer, FACSM)

Email: nobunbun100@gmail.com

(No relationships reported)

The influence of repeated sprint exercise in moderate hypoxia on muscle damage and inflammatory responses in athletes has not been fully elucidated. **PURPOSE:** The purpose of the present study was to determine the effects of repeated sprint exercise in moderate hypoxia on performance and muscle damage responses among competitive athletes. **METHODS:** Ten sprinters (height; 175.7 ± 1.9 cm, body weight; 67.3 ± 2.0 kg, BMI; 21.7 ± 0.2 kg/m²) participated in this study. They performed two trials under either hypoxic (HYP, F_{iO_2} : 14.5%, a simulated altitude of 3000m) or normoxic (NOR, F_{iO_2} : 20.9%) conditions. The exercise in each trial consisted of three sets of repeated maximal sprints (5×6 -s sprint) with a 30-s rest period between sprints. All subjects were exposed under hypoxic or normoxic conditions during exercise and 3h of post-exercise period. Time-course changes in percutaneous oxygen saturation (SpO₂), power output during exercise, blood lactate, glucose, serum myoglobin (Mb) and plasma interleukin-6 (IL-6) concentrations, and respiratory variables were evaluated. **RESULTS:** During exercise, a significant interaction was observed for mean power output (trial \times number of sprint, $P < 0.001$). However, no significant difference in total power output over all sprints was observed between the two trials. There were significant interaction (trial \times time, $P < 0.001$) and main effect for trial ($P < 0.001$) for blood lactate concentration. The post-hoc test revealed that blood lactate concentrations immediately after exercise was significantly higher in the HYP than in the NOR ($P < 0.05$). Serum Mb concentration increased significantly after exercise (main effect for time, $P < 0.001$), but no significant interaction ($P = 0.804$) or main effect for trial ($P = 0.268$) was observed. Accumulated VO₂ during exercise was significantly lower in the HYP ($P < 0.001$), whereas average RER values during exercise were significantly higher in the HYP than in the NOR ($P < 0.001$). There was no significant difference between trials for any respiratory variables during post-exercise period.

CONCLUSIONS: Repeated sprint exercise in hypoxia elicited blood lactate elevation compared with the same exercise in normoxia. However, magnitude of exercise-induced muscle damage response (elevation of serum Mb) was not affected.

Factors Predicting Performance during a High Altitude Hike

Allison Brown¹, Nicole Deel¹, John E. Davis¹, Eric Achatz², Michael Miller³, Jeremy Reiting³, Elaine Reno², Luke Yaeger³, Ann Wislowski³, Andrew Subudhi, FACSM³, Robert Roach, FACSM³. ¹Alma College, Alma, MI. ²CU School of Medicine, Aurora, CO. ³Altitude Research Center CU School of Medicine, Aurora, CO. (Sponsor: Andrew Subudhi, FACSM)

Email: brownlac@alma.edu

(No relationships reported)

Civilian and military personnel often endure heavy exercise loads at high altitude. To improve performance at high altitude, it is important to understand what factors predict human performance in that setting. **PURPOSE:** To assess whether a physical fitness test at sea-level can be used to predict exercise performance at high altitude. **METHODS:** Subjects were recruited from mid-Michigan (sea level) and were required to pass a medical screening and achieve a high score on the Army Physical Fitness Test (APFT) in order to participate. The APFT performance trial consisted of a pushup test (maximum number of pushups in 2 min), a sit-up test (maximum number of sit-ups in 2 min), and a timed two-mile run. Ninety-nine subjects completed APFT testing at sea-level before being transported to Breckenridge, Colorado (9,075

ft; 2766 m) to undergo APFT testing immediately upon arrival. On day two in Colorado, subjects wore a 35-pound rucksack during a timed, 3.7-mile uphill hike from 10,627 feet (3239 m) to 12,595 feet (3840 m). Multivariable regression analysis was performed to predict which variable(s) (height, weight, pushup score on APFT, sit-up score on APFT, 2 mile run time at the performance trial and at altitude) were most important in determining hike time. **RESULTS:** One multi-variable linear regression model indicated a significant correlation ($p < .05$) between subjects' weight and two-mile run time at the APFT performance trial at sea level relative to hike time ($r^2 = .33$). These findings indicate that as body weight increases hike time was slower, and that a faster 2-mile run time resulted in a faster hike time. A second multi-variable linear regression analysis indicated a significant relationship between the 2-mile run time, sit-ups, and push-ups at high altitude, and subjects' weight relative to hike time ($r^2 = .52$). **CONCLUSIONS:** Overall, the APFT high-altitude trial was a better predictor of hike performance given that the model accounted for 52% of the variance relative to hike performance. Furthermore, in both the sea level and high-altitude trials, subjects' weight and two-mile run time had the greatest influence on hike performance.

Email: sascha.ketelhut@sport.uni-halle.de

(No relationships reported)

Purpose: As demonstrated earlier, one bout of aerobic exercise has been shown to result in a prolonged lowering of peripheral and central blood pressure (BP) and pulse wave velocity (PWV) in normotensive and hypertensive individuals. Therefore, a study was initiated to evaluate if faster and more intense forms of exercise, such as HIIT, can also bring about similar blood pressure and PWV reductions. Since cardiovascular hyper-reactivity to stress has a higher prognostic value than measurements conducted at rest, the responses during a following cold pressor test (CPT) were studied as well. **Methods:** In 39 healthy men (34±8 years, BMI 24±2 kg/m²) peripheral BP (pBP), central BP (cBP) and PWV were measured non-invasively at rest and at the end of a 2 minute CPT using 24 PWA monitor. Following a HIIT (6 x 1 min., 98% of previously determined maximum workload, 4 min. rest between intervals) pBP, cBP and PWV were measured throughout 60 minutes of rest and thereafter during a CPT. **Results:** Even 45 minutes after HIIT, there was a significant reduction in systolic pBP (127 ± 9 mmHg to 124 ± 10 mmHg; $p = 0.029$), systolic cBP (116 ± 8 mmHg to 112 ± 9 mmHg; $p = 0.003$) and PWV (5.92 ± 0.7 m/sec. to 5.84 ± 0.7 m/sec.; $p = 0.037$) compared with pre-exercise. Furthermore there were significant reductions in diastolic pBP (81 ± 8 mmHg to 79 ± 7 mmHg; $p = 0.031$) compared to pre-exercise as well. Moreover, pBP ($144 \pm 13/96 \pm 12$ mmHg to $137 \pm 12/93 \pm 11$ mmHg), cBP ($130 \pm 13/98 \pm 12$ mmHg to $125 \pm 12/94 \pm 11$ mmHg) and PWV (6.4 ± 0.7 m/sec to 6.2 ± 0.8 m/sec.) during CPT after HIIT were significantly ($p < 0.01$) lower when compared with pre-exercise measurements.

60 minutes after exercise, there were no more significant differences compared with pressures at rest before exercise. In contrast, 60 minutes after HIIT the increases in systolic pBP ($\Delta = 16.2 \pm 10$ mmHg vs. $\Delta = 11.8 \pm 11$ mmHg; $p = 0.019$), systolic cBP ($\Delta = 14.5 \pm 11$ mmHg vs. $\Delta = 9.8 \pm 11$ mmHg; $p = 0.017$) and PWV ($\Delta = 0.47 \pm 0.36$ m/sec. vs. $\Delta = 0.29 \pm 0.42$ m/sec; $p = 0.026$) due to CPT were still significantly lower when compared with measurements during CPT before exercise.

Conclusion: HIIT leads to a reduction in pBP, cBP and PWV, which was still established 45 minutes after completion of the training. Moreover, pressures and PWV during a CPT increased less after HIIT, indicating attenuated hemodynamic response to stress testing after a single HIIT-session.

Arterial Compliance Response To Aerobic Exercise With and Without Blood Flow Restriction In Pre-hypertensive MalesMurat Karabulut¹, Margarita Gonzalez¹, Brittany Esparza¹, Ulku Karabulut¹, Ryan Russell¹, Michael G. Bembem, FACSM².
¹University of Texas Rio Grande Valley, Brownsville, TX.²University of Oklahoma, Norman, OK. (Sponsor: Michael G. Bembem, FACSM)

Email: murat.karabulut@utrgv.edu

(No relationships reported)

PURPOSE: The aim of the study was to assess the effects of acute aerobic exercise with and without blood flow restriction on arterial compliance in pre-hypertensive males.**METHODS:** Ten pre-hypertensive male subjects (age= 23.1±3.2) performed two randomized exercise sessions. Anthropometric measurements, questionnaires, and Bruce protocol were completed at screening. Baseline measurements were obtained each testing day following subjects reaching a normal hydration status. Subjects then ran at 65% VO₂ for a 60 min or 20 min at 40% VO₂ with blood flow restriction (BFR). Arterial elasticity was measured at 0, 10, 20, and 40 minutes and pulse wave velocity (PWV) was measured at 5, 15, 25, and 35 minutes post-exercise.**RESULTS:** There were no significant condition*time interactions or no main effects for condition and time for carotid to radial, carotid to femoral, femoral to distal PWV, small (SAE) or large arterial elasticity (LAE). Significant condition*time interaction (p<.03) and time main effect (p<.01) were found in systolic blood pressure (p<.03). There were also significant condition*time interaction (p<.03) and condition main effect (p<.03, BFR higher) in diastolic blood pressure (p<.03). Significant condition*time interaction (p<.01) and condition (p<.01, 60 min higher) and time main effects (p<.01) were found in heart rate (HR). Significant condition*time interaction (p<.01) and condition (p<.05, BFR higher) and time main effects (p<.01) were found in stroke volume (SV). Significant condition*time interaction (p<.01) and time main effects (p<.02) were found in cardiac output (CO). Significant condition*time interaction (p<.01) and condition (p<.01, 60 min lower) and time main effects (p<.02) were found in systemic vascular resistance (SVR). A significant condition main effect for total vascular impedance (TVI) was detected (p<.05, 60 min lower).**CONCLUSIONS:** Since subjects were in supine position for post-testing, significantly lower SV values could be due to lower venous return and/or sweat-related blood volume loss and lower SVR and TVI could be because of endothelium derived nitric oxide following the 60 min session. The findings also indicate that the 20 min with BFR session may not be intense and/or long enough to cause significant changes in variables tested.

Central Cardiovascular Hemodynamics and Vascular Stiffness during Handgrip Exercise with and without Blood Flow RestrictionEdward T. Kelley¹, Jeffrey D. Miller¹, Lee Stoner², Daniel P. Credeur¹. ¹University of Southern Mississippi, Hattiesburg, MS.²University of North Carolina at Chapel Hill, Chapel Hill, NC.

Email: edward.kelley@usm.edu

(No relationships reported)

Walking, coupled with bilateral blood flow restriction (BFR) in legs, augments the central cardiovascular adjustment to activity (e.g., greater blood pressure, and aortic wave reflection) as compared to walking without BFR. Whether the same occurs in response to unilateral, upper-body exercise performed with BFR is unknown.

PURPOSE: To examine the central cardiovascular hemodynamics and vascular stiffness responses to low- and high-intensity, unilateral handgrip exercise performed with and without BFR. **METHODS:** Eight college-aged males (Age=24±5 yrs; BMI=30±7 kg/m², handgrip max voluntary contraction-MVC=52±8 kg) underwent three 5-minute bouts (counter-balanced, 10 mins rest between) of rhythmic handgrip dynamometry (1-2 sec duty cycle, 20 squeezes/min) performed at a low (40% MVC) and high-intensity (60% MVC) with and without proximal occlusion (80-100mmHg, 50-80% arterial occlusion assessed via radial artery Doppler-ultrasound). Brachial pulse wave analysis and carotid applanation tonometry (heart rate-HR, mean arterial pressure-MAP, augmentation index-AIx, aortic pulse wave velocity-PWV, wave reflection magnitude-RM%) were performed at baseline and at the end of each 5-min bout of handgrip. To provide an index of peripheral vasoconstriction, perfusion of the vastus lateralis (oxy-hemoglobin, via Near-Infrared Spectroscopy) was also examined during these time points. **RESULTS:** HR increased more during high-intensity handgrip, both with and without BFR, as compared to low-intensity with BFR (60% with BFR=+9±7, vs. 60% without BFR=+9±7, vs. 40% with BFR=+4±5 bpm, P<0.001). Central MAP increased during all handgrip bouts, with the greatest change during high-intensity with BFR (+17±4 mmHg, P<0.001), but comparable responses observed between low-intensity with BFR and high-intensity without (low-intensity with BFR=+9±4, P<0.001; vs. high-intensity without BFR=+13±3 mmHg, P<0.001).No change was observed for AIx, RM%, aortic PWV, or microvascular perfusion across all handgrip bouts (P>0.05). **CONCLUSIONS:** These preliminary findings indicate that unilateral, handgrip exercise performed with and without BFR produces an intensity-dependent increase in HR and central MAP, with no change occurring in aortic wave reflection, vascular stiffness or leg vasoconstriction.

Acute Effects of Aerobic Exercise with Blood Flow Restriction on Pulse Wave Velocity

Brittany N. Esparza, Margarita Gonzalez, Patrick Murphy, Danny Dominguez, Murat Karabulut. University of Texas at Rio Grande Valley, Brownsville, TX.

(No relationships reported)

PURPOSE: To investigate the acute effects of a 20-minute walk/run at 40% VO₂ with and without blood flow restriction on pulse wave velocity (PWV). **METHODS:** Seventeen female subjects, between the ages of 18 and 40, signed informed consent and were familiarized with the study protocol, on the same day measurements were assessed: height, weight, body composition, and thigh circumference. Followed by each subject performing the Bruce Protocol on a treadmill. Subjects were asked to come back to the lab hydrated and 8 hours fasted on two different days (separated by at least 48 hours). After reaching hydration, participants were asked to lie down in the supine position for a minimum of 10 minutes and baseline hemodynamics and measurement of PWV using SphygmoCor® CPV Pulse Wave Analyzer. The sites tested were carotid to radial (C-R), carotid to femoral (C-F), and femoral to posterior tibial (F-PT). The randomized testing sessions consisted of two 20-minute walk/run sessions at 40% VO₂ intensity with BFR cuffs inflated (BFR), and the BFR cuffs uninflated (CON). Tightness of the cuffs was set at 55-60 mmHg for BFR, and the cuffs were placed snug enough that they don't move during exercise for the CON session. The final cuff pressures were achieved by starting at 120 mmHg and increasing progressively by 20 mmHg with 10 s rest in between increments. Upon completion of exercise, post exercise PWV was assessed at immediately, 15, 25, and 45 minutes. **RESULTS:** No condition*time interaction or condition and time main effects were observed for C-R and C-F sites (p>0.05). There were no significant condition*time interaction or time main effect for the F-PT site (p>0.05), but a significant condition main effect was detected at the 15 minute mark post exercise following the BFR session (p<.01). **CONCLUSION:** The results suggest that the BFR session resulted in an improved arterial compliance at the F-PT site. This may have been caused by the increased shear stress from blood pooling during the BFR session resulting in a greater release of nitric oxide therefore vasodilation in the lower body. There may be a practical application of using this combination of exercise and settings to help improve cardiovascular health. Since this was an acute study, future training studies should look at the chronic effects on pulse wave velocity using these settings.

Exercise-Induced Blood Flow Patterns Changes Based on Lactate Levels

Robert Pawlak, Brycen J. Ratcliffe, Caleb Harrison, Francisco Morales, Alvaro N. Gurovich, FACSM. Indiana State University, Terre Haute, IN. (Sponsor: Alvaro N Gurovich, FACSM)

Email: rpawlak@sycamores.indstate.edu

(No relationships reported)

Exercise improves cardiovascular health. However, only 45% of the mechanisms for its beneficial effects for cardiovascular diseases are known. Blood flow patterns and endothelial shear stress during exercise may explain part of the remaining unknown cardiovascular protective mechanisms.

PURPOSE: To identify blood flow patterns of the brachial artery at specific lactate levels of 0-2, 2-4, and 4+ mmol/L to help standardize exercise intensities in cardiac rehabilitation.**METHODS:** Fifteen young healthy subjects (Age 18-35) (9 males and 6 females) were recruited to perform two exercise tests on a cycle ergometer in fasting and exercise-free conditions for at least 10 hours prior the tests. The first test was a maximal, graded exercise test. The second one, performed 48-72 hours after the first exercise test, was a 3-workload steady state test at lactate levels of 0-2, 2-4, and 4+ mmol/L determined during the first exercise test. Oxygen consumption (VO₂), blood pressure, blood lactate levels, and ultrasound imaging of the brachial artery (assessing vessel diameter and blood flow direction and velocity) were continuously monitored during both tests. Repeated measurements ANOVA comparing all three intensities for all variables were performed at alpha=0.05.**RESULTS:** There were no significant changes in brachial artery diameter between exercise intensities and baseline conditions (3.70±0.21 mm vs. 3.76±0.20 mm vs. 3.68±0.21 mm vs. 3.75±0.21 mm, baseline vs. 0-2 mmol/L vs. 2-4 mmol/L vs. 4+ mmol/L, respectively). However, both antegrade and retrograde shear rates significantly increased with exercise in an intensity-dependent manner from baseline to 2-4

mmol/L (antegrade shear rate: $178 \pm 18 \text{ s}^{-1}$ vs. $260 \pm 22 \text{ s}^{-1}$ vs. $309 \pm 24 \text{ s}^{-1}$, baseline vs. 0-2 mmol/L vs. 2-4 mmol/L, respectively, $p < 0.01$; retrograde shear rate: $42 \pm 5 \text{ s}^{-1}$ vs. $84 \pm 9 \text{ s}^{-1}$ vs. $102 \pm 10 \text{ s}^{-1}$, baseline vs. 0-2 mmol/L vs. 2-4 mmol/L, respectively, $p < 0.05$). No significant difference was observed between the 2-4 and 4+ mmol/L intensities.

CONCLUSIONS:

The data shows that exercise-induced blood flow patterns are exercise intensity-dependent. However, high intensity exercise (lactate 4+ mmol/L) appears to offer little changes in blood flow patterns in comparison with moderate exercise (lactate 2-4 mmol/L).

Autonomic Modulation After an Acute Bout of Bench Press With and Without Blood Flow Restriction
 Olivia Gilmour, Alaina Glasgow, Erica Marshall, Yu Lun Tai, J. Derek Kingsley. *Kent State University, Kent, OH.* (Sponsor: Ellen L. Glickman, FACSM)
 (No relationships reported)

Traditional resistance exercise may decrease vagal tone up to 30 minutes, which may increase the risk of cardiovascular events. However, the effects of resistance exercise with blood flow restriction (BFR) on autonomic modulation are unclear. **PURPOSE:** To evaluate autonomic modulation after resistance exercise with and without BFR in active men. **METHODS:** Sixteen resistance-trained men volunteered for the study. Autonomic modulation was assessed at rest, 15 (Rec1), and 25 (Rec2) minutes after three different conditions. The low-intensity bench press with BFR (LI-BFR) consisted of 4 sets of 30, 15, 15, and 15 repetitions at 30% 1-repetition maximum (1RM) with 30 second rest between sets. The traditional high-intensity bench press (HI) consisted of 4 sets of 8 repetitions at 70% 1RM with 60 seconds rest between sets, and control (CON) consisted of supine rest. Autonomic modulation was expressed as natural logarithm (Ln), and included total power (LnTP), high-frequency power (LnHF), low-frequency power (LnLF), and sympathovagal balance (LnLF/LnHF ratio). A repeated measures ANOVA was used to evaluate conditions (LI-BFR, HI and CON) across time (Rest, Rec1, and Rec2) on autonomic modulation. **RESULTS:** There was a significant condition by time interaction for LnTP (LI-BFR: Rest: $8.6 \pm 0.9\%$, Rec1: $7.9 \pm 1.0\%$, Rec2: $7.9 \pm 1.2\%$; HI: Rest: $8.6 \pm 1.6\%$, Rec1: $7.7 \pm 0.9\%$, Rec2: $7.3 \pm 1.0\%$; CON: Rest: $8.7 \pm 0.8\%$, Rec1: $8.7 \pm 0.7\%$, Rec2: $8.5 \pm 0.8\%$, $p < 0.05$), LnHF (LI-BFR: Rest: $7.3 \pm 1.1\%$, Rec1: $5.5 \pm 1.2\%$, Rec2: $6.6 \pm 1.5\%$; HI: Rest: $7.4 \pm 1.2\%$, Rec1: $5.9 \pm 1.4\%$, Rec2: $6.5 \pm 1.5\%$; CON: Rest: $7.5 \pm 1.1\%$, Rec1: $7.5 \pm 1.8\%$, Rec2: $7.4 \pm 1.3\%$, $p < 0.05$), and LnLF (LI-BFR: Rest: $7.3 \pm 0.9\%$, Rec1: $5.9 \pm 0.9\%$, Rec2: $6.5 \pm 1.2\%$; HI: Rest: $7.3 \pm 1.1\%$, Rec1: $6.4 \pm 0.8\%$, Rec2: $6.6 \pm 1.2\%$; CON: Rest: $7.1 \pm 1.0\%$, Rec1: $7.1 \pm 1.8\%$, Rec2: $7.1 \pm 1.0\%$, $p < 0.05$) such that they were reduced at Rec1 and Rec2 after LI-BFR and HI compared to Rest and CON. There was a significant ($p < 0.05$) of time effect for LnLF/LnHF ratio (Rest: $1.0 \pm 0.1\%$; Rec1: $1.0 \pm 0.2\%$; Rec2: $1.0 \pm 0.1\%$) such that it was increased at Rec1 and Rec2 compared to Rest. **CONCLUSIONS:** These data suggest that LI-BFR and HI significantly alters autonomic modulation for at least 30 minutes, with no difference between LI-BFR and HI.

Pressor Responses To High And Low-intensity Continuous Or Interval Cycling With/without Blood Flow Restriction.

Bianca Galletti¹, Francisco Batista², Jarbas Domingos-Gomes², Eduardo Freitas¹, Piettra Pereira³, Gilmário Batista³, Hassan Elsangedy⁴, Maria Cirilo-Sousa², Rodrigo Aniceto³. ¹University of Oklahoma, Norman, OK. ²Integrated Colleges of Patos, Patos, Brazil. ³Federal University of Paraíba, João Pessoa, Brazil. ⁴Federal University of Rio Grande do Norte, Natal, Brazil. (Sponsor: Michael Bembem, FACSM)
 Email: biancagalletti@ou.edu
 (No relationships reported)

A single bout of continuous or high-intensity interval cycling has been able to induce post-exercise hypotension (PEH). However, it is not clear if low-intensity continuous cycling with blood flow restriction (CLI-BFR) induces PEH. **PURPOSE:** To compare post-exercise pressure responses between high-intensity interval cycling (HII), continuous low-intensity cycling (CLI), and continuous low-intensity cycling with blood flow restriction (CLI-BFR). **METHODS:** Eleven young obese adults (age=24.63 \pm 5.7 yrs, body mass index=33.42 \pm 2.04 kg/m², body fat percentage=27.7 \pm 3.0 %, and peak oxygen consumption [VO_{2peak}]=26.26 \pm 3.54 mL·kg⁻¹·min⁻¹) participated in a crossover randomized counterbalanced study design. Subjects completed four separate visits, each separate by 4-9 days. Following the first visit, assessing VO_{2peak}, subjects completed three different cycling sessions which included: CLI – continuous cycling at 45% VO_{2peak} for 15 min; HII – high-intensity interval cycling at 90% of VO_{2peak} consisting of 5 sets of 90 second exercise intervals with 90 second active rest periods at 45% VO_{2peak}; and CLI-BFR – continuous low-intensity cycling with BFR at 45% of VO_{2peak} for 15 min. BFR was applied at the proximal portion of the thigh using a

76 mm wide elastic knee wraps based upon the thigh circumference. Systolic (SBP) and diastolic blood pressures (DBP) were assessed at rest, immediately post-exercise, 10 min, 20 min, 30 min, 40 min, 50 min, and 60 min post-exercise. To compare SBP, DBP, and mean arterial pressure (MAP) measurements, a two-way ANOVA with Newman-Keuls post hoc was used. **RESULTS:** The main effect of condition was not significant for any of the pressor responses ($p > 0.05$), however there was a significant main effect for time. When compared to rest there were significant increases immediately post-exercise for SBP, DBP, and MAP ($p < 0.05$), and a significant increase in DBP at 60 min post-exercise ($p < 0.05$). **CONCLUSION:** CLI-BFR, HII, CLI were not capable of inducing PEH in young obese adults up to 60 min post-exercise.

Hemodynamic Response to Resistance Blood Flow Restriction Exercise at Different Degrees of Arterial Occlusion Pressure

Eduardo D. S. Freitas¹, Rodrigo R. Aniceto², Julio C. G. Silva², Patrick S. S. Pfeiffer², Joamira P. Araújo³, Maria S. Cirilo-Sousa², Michael G. Bembem, FACSM¹. ¹University of Oklahoma, Norman, OK. ²Federal University of Paraíba, João Pessoa, Brazil. ³Federal Institute of Ceará, Juazeiro do Norte, Brazil. (Sponsor: Michael G. Bembem, FACSM)
 Email: eduardofreitas@ou.edu
 (No relationships reported)

Although resistance exercise involving the application of an external arterial occlusion pressure (AOP) have been widely discussed in the literature, the hemodynamic response to this type of exercise when performed at different degrees of AOP remains unclear. **PURPOSE:** To investigate the hemodynamic response to resistance exercise performed at different degrees of AOP. **METHODS:** Twelve healthy trained males (2.67 yrs, 73.46 \pm 7.89 kg, 1.81 \pm 0.07 m, and 22.50 \pm 1.66 kg/m²) were randomly assigned to four exercise conditions: CON (no occlusion), AOP-50 (50% of AOP), AOP-75 (75% of AOP), and AOP-100 (100% of AOP) in a within subjects cross-over design. A standard 15 cm wide cuff was placed on the thigh, inflated to the target pressure, and four sets of 10 repetitions of unilateral knee extension at 20% of 1RM were executed with 30 s between sets. Subjects performed the same protocol for the CON condition but without occlusion. There was an interval of 7 days between each trial. Total AOP was set as the amount of pressure needed to fully occlude the auscultatory pulse in the lower limbs. Systolic (SBP) and diastolic blood pressure (DBP), mean arterial pressure (MAP), heart rate (HR), and cardiac product (DP) were assessed at rest, between the second and the third set (during), immediately post-exercise, and every 15 minutes until 60 minutes post-exercise. **RESULTS:** SBP and DP significantly ($p < 0.05$) increased from rest, during and immediately post-exercise for each condition. Significant ($p < 0.05$) elevations from rest were observed in DBP for all experimental conditions during exercise. MAP significantly ($p < 0.05$) increased during exercise from rest for all experimental conditions and for AOP-50, and AOP-100 immediately post-exercise. HR was significantly ($p < 0.05$) increased during exercise only for CON and for all conditions immediately post-exercise. All these parameters returned to baseline 15 minutes post, and remained unchanged up to 1 h post-exercise. **CONCLUSION:** Similar hemodynamic responses were observed for the AOP conditions during, immediately post-exercise, and until 60 minutes post-exercise, regardless of the amount of pressure applied.

Importance of Venous Return for Muscle Metaboreflex-mediated Stroke Volume and Cardiac Output Responses

Masashi Ichinose¹, Tomoko Ichinose², Takeshi Nishiyasu³. ¹Meiji University, Tokyo, Japan. ²Osaka International University, Osaka, Japan. ³University of Tsukuba, Tsukuba, Japan.
 (No relationships reported)

It has been shown in animals that activation of the muscle metaboreflex during dynamic exercise increases cardiac output (CO) via rises in heart rate (HR) with sustained stroke volume (SV). In addition, to maintain CO at higher level, venous return also needs to increase. Indeed, decrease in venous return abolishes the muscle metaboreflex-induced rise in CO. However, importance of venous return for the muscle metaboreflex-mediated SV and CO responses has never been examined in humans. **PURPOSE:** We aimed to investigate the influences of decreases in venous return from exercising limbs on the muscle metaboreflex-mediated SV and CO responses in humans. **METHODS:** We studied 9 healthy male volunteers. After resting measurements, the subjects performed cycling exercise for 8-min at 30% and 60% of VO_{2peak} (EX30 and EX60), respectively. Beginning 3 min after the start of the exercise, inner pressure of the occlusion cuffs placed on the both thighs were increased by 80, 100, 120, 140 and then 160 mmHg in stepwise fashion with 1-min step durations. The purpose of the progressive application of thigh cuff pressure was to reduce venous return from exercising limbs as well as to decrease arterial blood flow (i.e., oxygen supply) to exercising skeletal muscles to activate the

muscle metaboreflex. The thigh cuff pressure was not applied in control conditions. **RESULTS:** During exercise at both intensities, the application of thigh cuff pressure progressively increased HR and mean arterial pressure (at last 1-min during exercise in control vs. thigh cuff pressure conditions in EX30: 97 ± 3 vs. 108 ± 3 , 82 ± 3 vs. 104 ± 2 , EX60: 140 ± 3 vs. 155 ± 3 beats/min, 95 ± 2 vs. 116 ± 2 mmHg, $p < 0.05$) indicating activation of the muscle metaboreflex. Meanwhile, SV decreased gradually (EX30: 108 ± 6 vs. 96 ± 5 , EX60: 119 ± 5 vs. 108 ± 5 ml, $p < 0.05$) reflecting reductions in venous return. Consequently, in despite of the rise in HR, CO was maintained at control level (EX30: 10.4 ± 0.5 vs. 10.3 ± 0.5 , EX60: 16.6 ± 0.6 vs. 16.8 ± 0.8 L/min, $p > 0.05$). **CONCLUSIONS:** Our results demonstrate that the muscle metaboreflex-induced rise in HR cannot increase CO due to decrease in SV when venous return from exercising limbs is reduced. We conclude that the venous return from exercising limbs plays a pivotal role in the muscle metaboreflex-mediated SV and CO responses in humans.

Effects of Inversion Table Postural Positions on Cardiovascular Hemodynamics in Apparently Healthy Young Adults

Robert M. Otto, FACSM, Jessica Machaby, John Petrizzo, Ryan Page, John W. Wygand, FACSM. *Adelphi University, Garden City, NY.*
 Email: otto@adelphi.edu
 (No relationships reported)

Treatment of low back pain by inverting one's body on a tilt table permits unloading of bones, joints and discs of the low back. This traction force through the spine has been theorized to decrease low back pain. Randomized controlled studies to evaluate the efficacy of this practice for low back pain are limited. Although the gravitational traction is short lived, patients with hypertension, glaucoma, or cardiovascular disease are cautioned to avoid the inversion treatment because of excessive elevations in blood pressure, heart rate and intraocular pressure. **PURPOSE:** To evaluate the influence of postural change on cardiovascular hemodynamics, 12 subjects (age 22.6 ± 1.8 yrs, ht 170.4 ± 9.2 cm, body mass 74.0 ± 13.0 kg, 7 ♀) volunteered to participate in 6 assessments in the following positions: seated (S), 45° head up (45HI), horizontal [H], modified Trendelenburg (-30° head down) [T], -60° head down [60HD], and -90° inversion [I]. **METHODS:** Baseline measures of hemodynamic function (cardiac output [Q], stroke volume [SV], heart rate [HR], systemic vascular resistance [SVR] and cardiac index [CI]) were obtained with an impedance cardiography system, and blood pressure [BP] by auscultation in a seated position [S], followed by a 5 minute assessment in each of the 6 aforementioned positions. Reliability was ensured with repeat trials separated by 48 hours. ANOVA with repeated measures ($p < .05$) was applied to the data. **RESULTS:** Total mean BP (mmHg), EDV (mL) & SVR [dyn.s/cm] were $114.6/70.5$, 129.7 & 1164.6 , respectively, with NSD among trials. Q (L/min) of 6.6, 6.9, 6.1, 5.9, 5.8, & 6.2; SV [mL/b] of 87.7, 87.9, 88.1, 86.2, 85.1, & 83.8; HR [b/min] of 75.5, 78.8, 68.6, 65.9, 68.3, & 74.7; SVR [dyn.s/cm] of 1030, 986, 1248, 1280, 1288, & 1212; and CI [L/m²] of 3.5, 3.7, 3.2, 3.1, 3.1, & 3.3 were obtained for S, 45HI, H, T, 60HD, and I, respectively. Although statistical analysis revealed differences among several conditions ($p < .05$), they do not appear clinically significant. **CONCLUSION:** Postural changes induced by acute exposure to tilt table inversion did not provide clinically significant changes in measures of cardiovascular hemodynamics in a healthy population and thus appears relatively safe.

Total and Segmental Body Composition Examination in Collegiate Football Players Using Multifrequency BIA and DXA

Christiana J. Raymond, Tyler A. Bosch, Donald R. Dengel, FACSM. *University of Minnesota, Minneapolis, MN.* (Sponsor: Donald R. Dengel, FACSM)
 (No relationships reported)

PURPOSE: To examine the influence of player position on the agreement between multi-frequency bioelectrical impedance analysis (BIA) and dual x-ray absorptiometry (DXA) when assessing percent body fat (BF%) and total and segmental (arms, legs, trunk) fat mass (FM) and lean mass (LM) in male NCAA Division I collegiate football athletes.

METHODS: Forty-four male collegiate athletes (age=19±1 yrs; height=1.9±1.0 m; weight=106.4±18.9 kg; body mass index=30.1±4.2) participated in this study. Player

positions included: offensive linemen (OL; n=7), tight ends (TE; n=4), wide receivers (WR; n=9), defensive linemen (DL; n=6), defensive backs (DB; n=8), linebackers (LB; n=6), and running backs (RB; n=4). Total and segmental body composition was measured using multi-frequency BIA and compared with values obtained using DXA. Paired t-tests using a Bonferroni-adjusted p-value of 0.007 examined differences between the two methods and Bland-Altman analyses evaluated agreement. ANOVA assessed effect of position on total and segmental differences between methods and Tukey's HSD determined differences between each position.

RESULTS: Compared with DXA multi-frequency BIA significantly underestimated BF% ($3.0 \pm 3.8\%$), total FM (2.5 ± 4.3 kg), leg FM (2.8 ± 2.0 kg), and leg LM (3.6 ± 2.3 kg) (all $p < 0.001$) and significantly overestimated total LM (-6.9 ± 4.5 kg) ($p < 0.001$). Limits of agreement (1.96*SD of the mean difference) were: $\pm 7.39\%$ (BF%), ± 10.45 kg (total FM), ± 3.83 kg (leg FM), ± 2.28 kg (leg LM), and ± 8.89 kg (total LM). No significant differences were found between the two devices for trunk FM (-0.3 ± 3.0 kg; $p = 0.565$) and trunk LM (-1.0 ± 2.4 kg; $p = 0.009$) measures, with limits of agreement ± 5.92 kg for trunk FM and ± 4.71 kg for trunk LM. Player position had a significant effect on the mean difference of all measures, including BF%, total FM and LM, leg FM and LM, and trunk FM and LM (adjusted $p < 0.05$). OL demonstrated the greatest effect on the mean difference of each variable.

CONCLUSIONS: Compared to DXA, multi-frequency BIA does not appear to be a valid way to assess segmental measures of body composition in collegiate football players. BIA may thus be limited by non-traditional body types (e.g. football players) indicating between-player comparisons should be limited. Further research in other athletic populations is warranted.

Body Composition And Bone Mineral Density Of Division I Collegiate Track And Field Athletes

Donald R. Dengel, FACSM¹, Kathryn A. Keller¹, Aaron F. Carbuhn², Philip R. Stanforth³, Jonathan M. Oliver⁴, Tyler A. Bosch¹. ¹University of Minnesota, Minneapolis, MN. ²University of Kansas, Lawrence, KS. ³University of Texas at Austin, Austin, TX. ⁴Texas Christian University, Fort Worth, TX.
 Email: denge001@umn.edu
 (No relationships reported)

PURPOSE: To examine the effect of gender and event on total and regional measures of body composition in male and female NCAA Division I collegiate track and field athletes using dual X-ray absorptiometry (DXA). Data was used from the Consortium of College Athlete Research (C-CAR) group.

METHODS: A total of 590 [male (M)/female (F) = 274/316] athletes had their height, weight, total and regional fat mass (FM), lean mass (LM), and bone mineral density measured (BMD). Athletes were classified into one of seven categories: Jumps (M/F=28/30); Long Distance (LD; M/F=104/110), Middle Distance (MD; M/F=27/24), Multi-Event (ME; M/F=11/9), Pole Vault (PV; M/F=21/27), Sprints (M/F=54/96), and Throws (M/F=29/20). Total and segmental differences between categories and gender were assessed by ANOVA.

RESULTS: Events that were significantly different than each other were the same for M and F (Table). Only M and F throwers were classified as overweight based on BMI (> 25 kg/m²). Except for throwers, mean percent body fat for the other events was low, but healthy (M: 10.3-12.6%, F: 17.5-21.6%) and low visceral fat mass (< 500 g). As expected throwers had significantly ($p < 0.05$) higher total and regional FM and LM than other events (Table). One area of concern is that some events (i.e., LD) had negative z-scores for BMD (range M: -1.5 to 3.5, F: -1.5 to 6.3).

CONCLUSIONS: The data presented here provide normative data for total and regional FM, LM, and BMD in NCAA Division I male and female track and field athletes. Most athletes had relatively low body fat and visceral fat, which is important for the health of collegiate athletes during and after their playing career. However, some athletes had low BMD, which may have health consequences.

Event	Total Mass (kg)		Fat Mass (kg)		Lean Mass (kg)		BMD (g/cm ²)	
	Male	Female	Male	Female	Male	Female	Male	Female
Throws	103.5+ 6.5 ^a	89.5+ 16.0 ^a	21.6+ 10.8 ^a	27.5+ 9.9 ^a	78.0+ 9.2 ^a	58.5+ 8.1 ^a	1.5+ 0.1 ^a	1.4+ 0.1 ^a

A Comparison of Body Composition Methods Across Two Phases of the Menstrual Cycle.

Cherilyn McLester, Courtenay Hicks, Tiffany Esmat, John McLester, FACSM. *Kennesaw State University, Kennesaw, GA.* (Sponsor: John R. McLester, FACSM)

(No relationships reported)

Estimating body fat percent (BF%) is an important fitness assessment for determining health status, monitoring weight loss and improving athletic performance. Women have a unique consideration when assessing BF% due to possible fluid retention, weight gain, and hormonal fluctuations that are happening throughout the menstrual cycle, and it has been questioned as to whether or not menses could negatively impact the accuracy of BF% assessments. **PURPOSE:** To identify whether or not body composition results would be affected by a woman during menses and to investigate the effects of birth control on the accuracy of body composition results. **METHODS:** 40 women (26.1 \pm 7.1 yrs) had their BF% estimated with dual energy x-ray absorptiometry (DXA), air displacement plethysmography (ADP), and 3 different hand-to-foot bioelectrical impedance analyzers (BIA1, BIA2, and BIA3). Participants completed BF% testing during 2 different phases of their menstrual cycle. Visit 1 was on day 1 or 2 of menses and visit 2 was 7 to 14 days later. Visit 2 was estimated to be in the pre-ovulatory phase of the menstrual cycle. Prior to testing participants did not exercise for 12 hours, consume alcohol for 24 hours, or eat or drink for 4 hours with the exception of water. All testing was administered per manufacturer specifications. **RESULTS:** 24 women were not on birth control (non-BC) and 16 were on a form of hormonal birth control (H-BC). The BF% means \pm SE between visits for non-BC were: DXA = 30.6 \pm 1.3 vs. 30.3 \pm 1.4, $p = 0.077$, ADP = 28.8 \pm 1.6 vs. 28.3 \pm 1.6, $p = 0.083$, BIA1 = 26.7 \pm 1.5 vs. 27.1 \pm 1.5, $p = 0.122$, BIA2 = 26.1 \pm 1.5 vs. 26.3 \pm 1.5, $p = 0.498$, BIA3 = 27.0 \pm 1.4 vs. 26.8 \pm 1.5, $p = 0.523$. The BF% means \pm SE between visits for H-BC were: DXA = 30.1 \pm 1.5 vs. 30.2 \pm 1.5, $p = 0.677$, ADP = 29.3 \pm 1.8 vs. 28.8 \pm 1.8, $p = 0.215$, BIA1 = 26.2 \pm 2.0 vs. 26.4 \pm 1.9, $p = 0.508$, BIA2 = 26.3 \pm 1.9 vs. 26.3 \pm 1.7, $p = 0.988$, BIA3 = 26.9 \pm 1.9 vs. 26.9 \pm 1.6, $p = 1.000$. **CONCLUSIONS:** For the H-BC group there were no differences for BF% between visits for all methods indicating that results should not be affected by menstrual cycle phase. However, the non-BC group had mixed results with no differences with the 3 BIAs but p -values near 0.05 for DXA and ADP methods. These data suggest that non-BC women should be tested post menses with certain methods, especially when BF% is being tracked over time.

A-mode and B-mode Ultrasound Measurement of Subcutaneous Fat Thickness: A Cadaver Analysis Validation Study

Dale R. Wagner, Brennan J. Thompson, D Andy Anderson. *Utah State University, Logan, UT.* (Sponsor: Edward Heath, FACSM)
 Email: dale.wagner@usu.edu

(No relationships reported)

With technological advances, there has been a resurgence in the use of ultrasound as a method to measure subcutaneous fat thickness. Despite the increased interest in this methodology, there is a lack of research comparing A-mode and B-mode ultrasound devices. **PURPOSE:** Compare subcutaneous fat thickness measured by a low resolution A-mode ultrasound and a high resolution B-mode ultrasound to the actual fat thickness in dissected cadavers. **METHODS:** Six cadavers (3 male, 3 female), 80.8 \pm 8.9 y at the time of death, were measured. Subcutaneous fat thickness was measured at six sites (chest, abdomen, thigh, triceps, suprailiac, calf) with both ultrasound devices before the cadavers were dissected and site-specific thickness was measured. **RESULTS:** Correlations between both ultrasounds and the dissected measurement exceeded 0.90 at all sites with a few exceptions. At the abdomen, the relationship between the two devices was 0.76, and the B-mode and dissected measurement was also 0.76. The correlation between dissection and A-mode was 0.75 for the suprailiac site, but it was not possible to discern the separation of tissue at this site when using the B-mode device. There were no significant differences ($P > 0.05$) between the devices and the dissected measurement at any of the six sites. The mean difference in fat thickness between A-mode and B-mode was < 0.7 mm at all sites except the calf (1.2 mm). **CONCLUSION:** With the exception of the suprailiac site, which was difficult to measure, both A-mode and B-mode ultrasound are equally capable of providing measurements of subcutaneous fat thickness with an accuracy of < 1 mm at most sites.

Effect of Water Consumption and Moderate Intensity Exercise on Body Composition Measures

Brian Tyo. *Columbus State University, Columbus, GA.*
 Email: briantyo@gmail.com

(No relationships reported)

Although the data are not clear, manufacturers of body composition devices often recommend that users avoid exercise prior to measurement. These measures can potentially be impacted by acute exercise and hydration levels. **Purpose:** To determine the effect of water consumption and moderate intensity exercise on body composition measurements using air displacement plethysmography (ADP) and three bioelectrical impedance devices (T, O5, and O3). **Methods:** Twenty four participants (age = 22.3 \pm 23.9y; height = 166.8 \pm 9.9 cm; mass = 77.4 \pm 17.8 kg) completed the study. Pre-exercise (PreE) body composition was measured following manufacturers' guidelines. Participants then exercised on a treadmill at moderate intensity (~50% of HRR) for 30 minutes on two separate occasions. During one visit, participants were allowed water ad libitum following exercise (W) while no water was allowed during the other session (NW). Body composition was measured immediately post-exercise (PE0), 15 minutes post-exercise (PE15), 30 minutes post-exercise (PE30), 45 minutes post-exercise (PE45) and 60 minutes post-exercise (PE60). Repeated measures ANOVA (2 x 6) were used to determine if water consumption and moderate intensity exercise influenced body composition measures for each device. Where appropriate, pairwise comparisons with Bonferroni adjustment were performed to locate differences among the post-exercise time points. **Results:** All devices showed a significant effect of time ($P < 0.01$) and O5 was the only device to demonstrate a significant interaction of group and time ($P < 0.05$). ADP showed no significant differences among the time points during either condition. PreE was significantly greater than all other time points ($P < 0.01$) for T and O5 and was significantly greater than PE0, PE15, PE30, and PE45 for O3 ($P < 0.01$). **Conclusion:** Moderate intensity exercise can impact body composition to varying degrees. Ingestion of water post exercise does not appear to impact most measurements of body composition. Investigators should consider limitations of the device(s) which could impact the interpretation of data.

Predictive Validity Of The Body Adiposity Index In Obese Adults Using Dual-Energy X-Ray Absorptiometry

Katherine Gonzalez-Ruiz¹, Robinson Ramirez-Vélez², Jorge E. Correa-Bautista², Alejandra Tordecilla-Sanders², Daniel H. Prieto-Benavidez², Luis Andrés Téllez-T². ¹*Grupo de Investigación en Ejercicio Físico y Deporte. Vicerrectoría de Investigación, Universidad Manuela Beltrán, Bogotá, D.C, Colombia.*, ²*Centro de Estudios para la Medición de la Actividad Física «CEMA», Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá, Colombia.*
 Email: katherine.gonzalez@docentes.umb.edu.co

(No relationships reported)

PURPOSE: The body adiposity index (BAI) is a recent anthropometric measure proven to be valid in predicting body fat percentage (BF%) in some populations. However, the results have been inconsistent across populations. The study was designed to verify the validity of BAI in predicting BF% in a sample of obese adults, using dual-energy X-ray absorptiometry (DEXA) as the reference method. **METHODS:** A cross-sectional study was conducted in 48 participants (54% female, mean age 41.0 \pm 7.3 years old). DEXA was used as the "gold standard" to determine BF%. Pearson's correlation coefficient was used to evaluate the association between BAI and BF%, as assessed by DEXA. A paired sample t-test was used to test differences in mean BF% obtained with BAI and DEXA methods. To evaluate the concordance between BF% as measured by DEXA and as estimated by BAI, we used Lin's concordance correlation coefficient and Bland-Altman agreement analysis. **RESULTS:** The correlation between BF% obtained by DEXA and that estimated by BAI was $r = 0.844$, $p < 0.001$. Paired t-test showed a significant mean difference in BF% between methods (BAI = 33.3 \pm 6.2% vs. DEXA 39.0 \pm 6.1; $p < 0.001$). The bias of the BAI was -6.0 ± 3.0 BF% (95% CI = -12.0 to 1.0), indicating that the BAI method significantly underestimated the BF% compared to the reference method. Lin's concordance correlation coefficient was considered stronger ($\rho_c = 0.923$, 95% CI = 0.862 to 0.957). **CONCLUSIONS:** In obese adults BAI presented low agreement with BF% measured by DEXA; therefore, BAI is not recommended for BF% prediction in this Latin American obesity sample studied. A Longitudinal Retrospective Study of Body Composition Trends in Police Recruits

Haley O. Norris¹, Robert W. Boyce, FACSM¹, Elizabeth H. Seldomridge¹, Austin C. Smith¹, Glenn R. Jones², Michele A. Parker¹. ¹University of North Carolina Wilmington, Wilmington, NC. ²Charlotte-Mecklenburg City Government, Wilmington, NC. Email: hon3830@uncw.edu
(No relationships reported)

Mapping body composition patterns of those hired as police officers has implications not only to the health of officers during their careers but also in their ability to perform in emergency situations.

PURPOSE: To evaluate body composition changes that occur in police recruits from 1990 to 2013 with gender comparisons. **METHODS:** During the first week of police recruit training in a large southeastern metropolitan area, physical fitness levels were evaluated in 2,468 recruits. This study's variables of interest are: body mass (kg), lean mass (kg), and % body fat. ANOVA and Bonferroni post hoc procedures were used to evaluate data. **RESULTS:** The initial ANOVA shows significance for males in all three variables at $p < 0.05$. Males tended to increase in body mass and lean mass from 1990 to 2000 (80.6 ± 1.2 kg to 87.3 ± 1.2 kg, $p < 0.05$) (68.9 ± 0.8 kg to 73.4 ± 0.8 kg, $p < 0.05$), respectively. These values remained relatively constant between 2000 and 2013. No discernable pattern was seen in female lean mass nor body mass. Males tended to increase in % body fat from 1994 to 2010 (13.6 ± 5.0 to 16.7 ± 7.2 , $p < 0.05$). Although not significant, female % body fat means increased from 1990 to 2013 (22.9 ± 1.0 to 26.2 ± 1.2). **CONCLUSIONS:** Even though there was an increase in body mass, pre lean mass and % body fat over time in males, these increases were low. In addition, these increases were lower in females.

Creating an Overall Body Composition Index to Predict 1.5-Mile Run Performance among University Students

Wenhao Liu, FACSM, Istvan Kovacs, Ethan E. Hull. *Slippery Rock University, Slippery Rock, PA.*
Email: wenhao.liu@sru.edu
(No relationships reported)

PURPOSE: While body mass index (BMI), body fat percent (%BF), and waist circumference (WC) each can be used as a body composition index (BCI) to establish associations with cardiorespiratory fitness, it is desirable to use an overall BCI to establish the association. This study was intended to create an overall BCI from the above three BCIs and see how the overall BCI could predict 1.5-mile run performance among university students.

METHODS: Three different BCIs (BMI, %BF, WC) and 1.5-mile run were measured for 123 university students (mean age: 20.71 ± 98 ; 70 males and 53 females), and an overall BCI was created by converting the three BCIs into z scores and then adding them together. The overall BCI was used to predict students' 1.5-mile run performance with linear regression. All data analyses were conducted separately for males and females.

RESULTS: For both males and females, the scatterplots showed that 1.5-mile run performance increased when the overall BCI decreased, indicating a linear relationship between the two variables. The regression equation for predicting the 1.5-mile run performance from the overall BCI for males was: predicted 1.5-mile run performance (in seconds) = $704.64 + 33.32$ overall BCI, with the 95% confidence interval for the slope ranging from 24.84 to 41.58. The regression was significant ($p < .001$) as $F(1, 68) = 62.68$. Prediction strength was very strong with $r = .69$ ($p < .001$) and $r^2 = .48$. With respect to females, predicted 1.5-mile run performance (in seconds) = $851 + 27.51$ overall BCI, and the 95% confidence interval for the slope ranged from 12.91 to 42.12. The regression was significant ($p < .001$) as $F(1, 51) = 14.30$. Prediction strength was strong with $r = .47$ ($p < .001$) and $r^2 = .22$.

CONCLUSIONS: The overall BCI can predict students' 1.5-mile run performance very well, accounting for 48% of the variance of 1.5-mile run performance for males and 22% of the variance for females. In addition, based on the regression equations, one unit increase in the overall BCI will result in 33.32 seconds slower for males or 27.51 seconds slower for females, on average, in 1.5-mile run for university students.

967 Board #146 May 31 3:30 PM - 5:00 PM

Accuracy of Commercial Body Composition Scales Versus Clinical Dual-Energy X-ray Absorptiometry and Bioelectrical Impedance Analysis

Erica Sander, Bennett K. Ng, Eric Yu, Bo Fan, En Yong Liu, Leila Kazemi, John A. Shepherd. *UCSF, San Francisco, CA.*
Email: John.Shepherd@ucsf.edu
(No relationships reported)

Background. Body composition (BC) analysis is increasingly available to consumers in the form of wifi-connected bioelectrical impedance analysis (BIA) bathroom scales. However the accuracy of current generation scales to criterion methods is not known.

Purpose. To determine the accuracy and precision of BC measurements using scales for men and women compared to dual-energy X-ray absorptiometry (DXA). In addition, we investigate the use of scales for quantifying resting metabolic rate (RMR).

Methods. We recruited a sample of convenience of healthy adults to undergo a series of BC measurements. Height and weight was assessed using a Seca 284. BC was assessed using whole-body DXA (Horizon A), a clinical tetrapolar multifrequency BIA (InBody770), and 7 bathroom scales: Tanita BF-684W, Weightwatchers WW701Y, Taylor 7226SFC, Withings Smart Body Analyzer WS-50 and Body Cardio WBS04, Fitbit Aria, and QardioBase. Duplicate measures were taken on the scales to evaluate the test-retest precision. RMR was calculated using Nelson RMR equations for DXA and BIA measures, and Harris-Benedict (HB) using weight.

Results. In total, 22 participants were recruited (12 male) with an average age of 29.6 (± 7.3 years), weight of 70.0 (± 13.4 kg) and height of 170.0 (± 10.1 cm). PBF was highly correlated between the 770 and DXA for both men and women ($r = 0.9$) but less correlated between the scales and DXA ($0 < r < 0.65$). However, all BIA devices underestimated PBF by 2 to 11 units. There was poor obesity classification between the scales and DXA as well ($\kappa < 0.2$). RMR was highly correlated between DXA and scales for both men and women ($r = 0.50$ to 0.99). RMR was overestimated by all scales compared to DXA from 21 to 184 kcal but in all cases were improvements over the HB RMR estimate (HB-DXA 260 kcal). The test-retest precisions (% coef of var, standard deviation) for PBF and RMR varied by model for men and women (0.2 to 0.5 %, NA) and (0.2 to 0.6 %, 2 to 9 kcal) respectively. Overall, we found the Tanita to have the best correlation to DXA measures, Taylor and Weight Watchers to have the best precision.

Conclusions. We conclude that the use of bathroom scales may provide a more accurate assessment of RMR than the HB equation, and that the precision is comparable to previously-reported DXA values. However, our results varied substantially by make.

968 Board #147 May 31 3:30 PM - 5:00 PM

Relationships Between Bodpod And Field Assessments Of Body Composition In NAIA Athletes

Kaitlyn L. Kelpel, Andy P. Bennett, Christopher A. Fahs, Lindy M. Rossow. *Lindenwood University - Belleville, Belleville, IL.*
Email: kelpel93@yahoo.com
(No relationships reported)

PURPOSE: The purpose of this study was to examine the relationships between body composition measures derived from air displacement plethysmography (BodPod) and several field methods of body composition in a population of National Association of Intercollegiate Athletics (NAIA) athletes. **METHODS:** Twenty-three NAIA athletes visited the lab for a single visit. Percent body fat and lean mass were assessed in all subjects using the BodPod (BP), handheld bioelectrical impedance analysis (HBIA), standing bioelectrical impedance analysis (SBIA), and skinfolds using the 3-site Jackson and Pollack equation. Body mass index (BMI), upper arm circumference (AC), waist circumference (WC), and hip circumference (HC) were also assessed. Relationships between percent body fat as assessed by BP and all field non-lean mass assessments as well as relationships between BP lean mass and all field non-percent body fat assessments were examined using Spearman's correlation coefficients.

RESULTS: Percent body fat (19.1 ± 8.4 %) as assessed by BP was significantly related to BMI ($29 + 8$ kg/m²; $r = 0.515$; $p = 0.012$), percent body fat calculated from skinfolds ($14 + 7$ %; $r = 0.855$; $p < 0.001$), percent body fat from HBIA ($17.9 + 6.2$ %; $r = 0.855$; $p < 0.001$), percent body fat from SBIA ($14.1 + 3.7$ %; $r = 0.748$; $p < 0.001$), AC ($33 + 4$ cm; $r = 0.563$; $p = 0.005$), WC ($90 + 10$ cm; $r = 0.720$; $p < 0.001$), and HC ($102 + 18$ cm; $r = 0.788$; $p < 0.001$). Lean mass as assessed by BP ($73.3 + 8.7$ kg) was significantly related to BMI ($29 + 8$ kg/m²; $r = 0.483$; $p = 0.020$), lean mass calculated from skinfolds ($76 + 10$ kg; $r = 0.817$; $p < 0.001$), lean mass from HBIA ($72.7 + 8.6$ kg; $r = 0.851$; $p < 0.001$), lean mass from SBIA ($76.5 + 11.7$ kg; $r = 0.802$; $p < 0.001$), AC ($33 + 4$ cm; $r = 0.596$; $p = 0.003$), WC ($90 + 10$ cm; $r = 0.496$; $p = 0.016$), and HC ($102 + 18$ cm; $r = 0.570$; $p = 0.005$). **CONCLUSION:** Skinfolds, HBIA, and SBIA appear to be most related to both percent body fat and lean mass in this population of NAIA athletes. Thus, when testing these athletes in a field setting, these tests could be performed to provide useful body composition information. If it were not possible to perform these tests, BMI, UAC, WC, and HC could also be used although these tests did not correlate as strongly as did skinfolds, HBIA, and SBIA with BP assessments.

969 Board #148 May 31 3:30 PM - 5:00 PM
The Effects of a Periodized Resistance Training Program on Body Composition of ROTC Cadets
 Straughn Marisa¹, John D. Wallop¹, Lauren Adlof¹, Amy Crawley¹, Ludmila Cosio-Lima². ¹University of West Florida, Pensacola, FL. ²University of West Florida, PENSACOLA, FL
 Email: mks29@students.uwf.edu
 (No relationships reported)

BACKGROUND: Similar to the general US population, the rate of cardiovascular disease, sedentary lifestyle, and obesity in military populations is growing. Android obesity, a type of obesity where excess fat accumulates around the thoracic and abdominal cavities, is associated with an increased risk of cardiovascular and metabolic deficiencies. Military populations are confronted with high physiological demands therefore it is crucial for them to be in good physical condition and minimize excess body fat in the thoracic and abdominal areas. **PURPOSE:** This research investigated the effects of a 7-week periodized training program on body composition of ROTC cadets. **METHODS:** Subjects consisted of 23 Army and Air Force ROTC cadets (male=18, female=6), Age (yrs)= 2.26±5.96, Height (cm)=172±8.68, Weight (kg)=72.98±12.91. The intervention group (IG n=14) trained for 1 hour/day, 4 days/week and the control group (CG n=9) participated in traditional military training protocol for 1 hour/day, 3 days/week. **RESULTS:** Findings revealed that both groups demonstrated a significant decrease in overall body fat percentage ($p=0.005$) pre to post training, but only the IG demonstrated a significant training effect evidenced by decreases in the abdominal area ($p=0.009$) and mid-axillary ($p=0.025$). **CONCLUSION:** Although this research demonstrated that periodized resistance training reduces abdominal body fat among ROTC cadets, it is important that future studies address certain limitations (small sample size and length of training period) this study encountered. Due to the health risks associated with android obesity, including increased cardiovascular and metabolic disease risk factors, implementing a periodized training program may be beneficial in diverse military populations.

Validation of a Three-Dimensional Body Scanner for Body Composition Measures
 Michelle M. Harbin. University of Minnesota, Twin Cities, Minneapolis, MN. (Sponsor: Donald R. Dengel, FACSM)
 Email: harb0085@umn.edu
 (No relationships reported)

PURPOSE: The accuracy of a three-dimensional (3D) body scanner in determining body composition was compared against other laboratory methods (i.e., hydrostatic weighing, bioelectrical impedance analysis (BIA)). **METHODS:** A total of 176 (males/females= 83/93) young adults [mean±SD: age= 22.2±2.9 years, body mass index (BMI) =24.5±3.8 kg/m²] were recruited. Subjects had muscle mass estimated from the 3D body scanner, hydrostatic weighing, skinfolds, circumference measurements and BIA. The Jackson and Pollock equation was used to estimate body fat percent (BF%) from the sum of three skinfolds (males: chest, abdomen and thigh; females: triceps, suprailium, and thigh). The Navy circumference-based equation was used to estimate BF% (males: waist, neck, height; females: waist, hip, neck, and height). **RESULTS:** Males and females were not significantly different in age ($p=0.192$). As expected, females had lower body mass ($p<0.001$), BMI ($p=0.016$) and height ($p<0.001$). A repeated measures ANOVA indicated significant ($p<0.001$) differences among the methods. Bonferonni post-hoc indicated that BF% from the 3D body scanner (17.6±7.7%) was significantly less than BF% from hydrostatic weighing (22.1±8.7%, $p<0.001$), skinfolds (19.8±9.6%, $p<0.001$), BIA (19.0±8.6%, $p<0.001$), and circumferences (21.3±9.5%, $p<0.001$). The main effects of sex and method were significant ($p<0.001$) with a non-significant interaction ($p=0.060$). Among males, BF% from the 3D scanner (10.6±4.0%) was significantly less than BF% from hydrostatic weight (16.0±6.0%, $p<0.001$), BIA (11.9±3.9%, $p=0.002$), skinfolds (11.8±5.1%, $p=0.03$), and circumferences (13.8±4.4%, $p<0.001$). Among females, BF% from the 3D scanner (23.9±4.0%) was significantly less than BF% from hydrostatic weight (27.6±6.9%, $p<0.001$), BIA (25.2±6.5%, $p=0.003$), skinfolds (26.8±6.6%, $p<0.001$), and circumference measures (28.4±9.3%, $p<0.001$). BF% from the 3D scanner was highly correlated with BF% from hydrostatic weight ($r=0.82$, $p<0.001$), BIA ($r=0.89$, $p<0.001$), skinfolds ($r=0.85$, $p<0.001$), and circumferences ($r=0.85$, $p<0.001$). **CONCLUSIONS:** The 3D body scanner consistently underestimated BF% despite being highly correlated with other established methods. Further research is needed to validate 3D scanning as a reliable method for measuring body composition.

 (No relationships reported)

PURPOSE: Body composition (BC) is a frequently assessed component of health-related fitness. Recently, a portable joint diameter-based body composition assessment system, sold by Integrative Body Composition Assessment (IBC) has become commercially available for estimating BC. This method involves measuring both right and left wrist diameters using calipers, waist circumference, height and weight. These measurements are entered into the IBC software together with age and gender and the average amount of both cardiorespiratory and resistance training exercise the subject has done on average per week for the past six months. However, little is known how IBC BC estimates compare to the dual-energy X-ray absorptiometry (DXA) estimate of body composition in college aged students. The purpose of this study was to determine the accuracy of the IBC as a way to estimate BC.

METHODS: Participants percent body fat (%fat) was estimated using IBC and dual-energy X-ray absorptiometry (DXA), which served as the criterion estimate. Subjects were 162 (75 males, 87 females) physically active college students [age 21 (3) yrs. height 1.73 (0.1) m, body mass 76.09 (15.74) kg. and BMI 25.4 (4.1) kg/m²]. **RESULTS:** The validity of the IBC %fat estimate was based on a comparison to the criterion value from the DXA by calculating the mean, SD, coefficient of determination (r²), and standard error of estimate (SEE) from linear regression analysis. To assess the average deviation of individual scores from the line of identity, total error (TE) was calculated for each IBC estimate. Paired t-tests determined paired-wise differences between measurements with significance set at $p<0.05$. The mean %fat was significantly lower for the IBC [23.0 (9.3) %] estimate than the DXA [25.9 (11.5) %] estimate ($p<0.001$). The r² value was 0.669; SEE was 6.6 %fat; and total error (TE) was 7.2 %fat. When separated by sex, the IBC %fat estimate was still significantly lower for both male [-1.6 (5.9) %fat, r^2 0.456, SEE=5.8 %fat, TE=6.16 %fat] and female [-4.0 (6.9) %fat, r^2 0.462, SEE=6.9 %fat, TE=7.9 %fat] participants. **CONCLUSIONS:** In this study the IBC did not provide a valid estimate of body composition and underestimated %fat compared to the DXA estimate. Based on this preliminary analysis, this method cannot be recommended for estimating BC in college aged students.

Changes in Anthropometric and Physiological Characteristics of Male Collegiate Rugby Union Players throughout a Season
 Edward K. Smith, David Q. Thomas, FACSM, Daniel J. Dodd, Dale D. Brown, FACSM, Kelly R. Laurson, Tyler R. Langosch, Jonathan C. Grimwood, Nathan P. Fillers. Illinois State University, Normal, IL.
 (No relationships reported)

Rugby Union is a physically demanding sport requiring a variety of anthropometric and physiological characteristics to maximize performance. Factors such as muscular power, speed, agility, maximal aerobic power, mobility, and body composition all factor into player performance. **PURPOSE:** To determine changes in body composition, height, speed, muscular power, maximal aerobic power, mobility, and agility of collegiate rugby union players throughout a competitive season. **METHODS:** Participants included 29 (20.32 ± 1.49yrs) men from a collegiate rugby club. Muscular power (vertical jump), speed (10m and 20m sprint), agility (L-drill), mobility (FMS active straight leg raise and shoulder mobility) maximal aerobic power (VO_{2 peak} via 20m multi-stage shuttle run SR), height, body mass, fat mass (ADP), fat-free mass (ADP), and body fat levels (ADP and sum of 7 skinfolds (SKBF%)) were assessed during the pre-season (PRE) and mid-season (MID). Training and match loads were estimated for each player by multiplying each player's rating of perceived exertion (RPE: 6-20) by the amount of training/playing time. **RESULTS:** PRE and MID variables were compared using a Paired-Samples T-Test with an alpha level of $p < .05$. The mean PRE SKBF% of 16.57 ± 6.29 was significantly higher than the mean MID SKBF% of 13.77 ± 7.61 ($t(28) = 2.472$, $p = .02$). The mean PRE 10m sprint time was 1.81 ± .12s and was significantly faster than the MID mean 10m sprint time 1.94 ± .11s ($t(19) = -4.782$, $p < .001$). The mean PRE 20m sprint time 3.15 ± .16s was significantly faster than the mean MID 20m sprint time of 3.3 ± 1.8s ($t(20) = -4.155$, $p < .001$). The mean PRE VO_{2 peak} was 44.65 ± 5.43ml.kg⁻¹.min⁻¹ and was significantly lower than the mean MID VO_{2 peak} of 46.97 ± 6.43ml.kg⁻¹.min⁻¹ ($t(19) = -2.26$, $p = .036$). **CONCLUSION:** Maximal aerobic power increased from PRE to MID while the estimated body fat levels decreased from PRE to MID. Improvements in both

variables are likely due to conditioning during training and increased activity levels of participating in sport. Speed may have decreased from PRE to MID due to fatigue from the first-half of the season with accumulating training and match loads.

in FP across ranked BC groups. Furthermore, these differences were not consistent across BC method and not consistent across sex groups. Practitioners using BC data to predict FP should be aware of these inconsistencies.

Effect Of Hydration Status On Body Composition Assessment Using Dual Energy X-ray Absorptiometry And Ultrasound

Paul T. Cutrufello, Michael J. Landram. *The University of Scranton, Scranton, PA.* (Sponsor: Curt Dixon, FACSM)
 Email: paul.cutrufello@scranton.edu
 (No relationships reported)

The accurate measurement of percent body fat (%BF) is very important in the determination of a wrestler's minimum wrestling weight under the National Collegiate Athletic Association Wrestling Weight Management Program. Skinfold measurements (SF), air displacement plethysmography (ADP), and hydrostatic weighting remain as the only three approved methods. Dual energy x-ray absorptiometry (DXA) is considered a criterion method while type-A ultrasound (US) serves as a less expensive, field alternative; however, a dearth of literature has examined the influence of hydration status on DXA and US determined %BF. **PURPOSE:** To determine the effect of hydration status on fat mass, lean body mass, and %BF using SF, ADP, US, and DXA. **METHODS:** Sixteen college-aged men (20.8 ± 1.6 yrs) participated in this study. Participants reported to the lab on two separate occasions in either a euhydrated state (Usg < 1.020) or a hypohydrated state (Usg > 1.020) using a randomized crossover design. Usg was assessed in order to verify hydration status and %BF was determined using SF, ADP, DXA, and US methods. **RESULTS:** Usg and body mass (BM) measurements were significantly different between the euhydrated (Usg=1.014 ± 0.006; BM=79.1 ± 14.3kg) and hypohydrated (Usg=1.026 ± 0.004; BM=78.4±14.2) assessments (Usg: p<0.001; BM: p=0.006). However, hydration status had no significant effect on %BF observed in the euhydrated or hypohydrated states (p=0.730) although significant differences were observed between the different assessment methods (SF=10.3±1.3%; ADP=13.0±1.9%; US=13.2±1.3%; DXA=19.5±1.8%; p<0.001). Pairwise comparisons identified significant differences between all methods (p<0.001-p=0.018) except for the comparison between ADP and US (p=1.000). %BF measured by DXA was significantly greater than all of the other methods (2.8-9.2%; p<0.004). **CONCLUSION:** Hydration status did not have an effect on %BF measurements when using SF, ADP, US, or DXA. The significant differences among these four methods remain a concern. The difference between two approved methods (SF and ADP) suggests that a wrestler may lose additional weight when using ADP, thus potentially allowing for certification at a lower weight class.

Skinfolds Thickness And Body Surface Area Evaluated With Anthropometry And Its Relationship With Body Fat

Roberto Gabriel Gonzalez-Mendoza¹, Juan R Lopez y Taylor¹, Alejandro Gaytan-Gonzalez¹, Juan Antonio Jimenez-Alvarado¹, Marisol Villegas-Balcazar¹, Edna E Jauregui-Ulloa¹, Francisco Torres-Naranjo². ¹Universidad de Guadalajara, Guadalajara, Mexico. ²Centro de Investigacion Osea y de Composicion Corporal, Guadalajara, Mexico.
 Email: robertoggm@hotmail.com
 (No relationships reported)

In 1921 Matiegka proposed a strategy for estimating adipose tissue mass by calculating the half of average of some skinfolds thickness and multiplying it by body surface area (BSA), but this strategy has not been evaluated with modern body composition methods.

PURPOSE: To describe the utility of the product of skinfold thickness measured by anthropometry and BSA in relation with body fat (% and mass) in varsity athletes. **METHODS:** 10 skinfold thicknesses were assessed in 97 varsity athletes (50 males [age 21.5 ± 2.0 y, weight 72.0 ± 10.9 kg, height 175.7 ± 6.7 cm, BMI 23.3 ± 3.0 kg/m²], 47 females [20.8 ± 1.9 y, 60.1 ± 10.2 kg, 164.7 ± 7.3 cm, 22.1 ± 2.9 kg/m²]). Body fat mass and percentage was assessed by DXA whole body scanning. Body surface area was calculated with two anthropometric equations (DuBois, Biering), additionally Behnke's body building factor was calculated. We performed the Pearson correlation test for body fat mass and body fat percentage with each skinfold thickness, the sum of 10 skinfolds (10SKF), the sum of 8 skinfolds (8SKF) and the product of multiplying 10SKF or 8SKF with either a) DuBois BSA, b) Biering BSA, c) Behnke's factor. **RESULTS:** There was a higher correlation with body fat mass than with body fat percentage when the skinfolds were multiplied by BSA, this correlation was higher in males than females. In males, triceps skinfold thickness had a high correlation with body fat percentage and axilla with body mass. **CONCLUSIONS:** The product of 10SKF (or 8SKF) multiplied by BSA had high correlation coefficients with body fat mass. We propose using the sum of skinfolds (both 10 and 8) and multiplying it by BSA as an adiposity indicator in varsity athletes. There is still need to test if this strategy is useful for monitoring changes in body fat.

Fitness Performance Across Ranked Body Composition Groups Assessed by Different Methods

Gabriel A. Benavidez, Peter D. Hart, 59501. *Montana State University - Northern, Havre, MT.*
 Email: gabe.benavidez72@gmail.com
 (No relationships reported)

PURPOSE: Body composition (BC) is a valuable indicator of performance both across and within certain sporting events. However, the specific relationship between BC and fitness performance (FP) is less understood. Therefore, the purpose of this study was to examine the relationship between BC and FP in a population of college students. An additional purpose was to determine if identified relationships were consistent across different BC methods. **METHODS:** A total of N=131 college students were used in this study. After signing IRB approved consent forms, subjects participated in a series of fitness tests conducted by trained research assistants. BC was assessed using five different methods: 1) body mass index (BMI), 2) percent body fat (PBF) by skinfold technique (SF), 3) PBF by circumference method (CM), 4) PBF by handheld bioelectric impedance (HH), and 5) waist circumference (WC). Fitness test outcome measures included 1) maximal oxygen consumption (VO2max) from the Queens College Step Test, 2) 1-repetition maximum bench press (BP) scores, 3) maximum repetition push-up (PU) scores, and 4) sit-and-reach (SR) flexibility scores. Subjects were categorized into one of three tertile groups where larger tertiles represented greater BC values. Analysis of variance (ANOVA) was used to examine mean FP differences across BC tertiles. Follow-up contrasts were performed to test for linear and quadratic trends. Significance was set to p<.05 for all tests. **RESULTS:** Male VO2max scores showed a significant indirect linear trend in all five BC methods. Male BP scores showed a significant direct linear trend in BMI and WC only. Male PU scores showed a significant indirect linear trend in all BC methods except BMI. And male SR scores showed no significant differences or trends in any BC method. Female VO2max scores showed a significant indirect linear trend in all BC methods except WC. Female PU scores showed only a significant negative quadratic trend in SF, CM, and HH. Finally, female BP and SR scores showed no significant differences or trends in any BC method. **CONCLUSIONS:** Results from this study show clear differences

Association Between Physical Activity, Total Cholesterol, Fasting Blood Glucose, And Body Fat Among Hispanic Males

Ulku Karabulut, Juan Paredes, Danny Dominguez, Margarita Gonzalez, Paloma Mendoza, Murat Karabulut. *University of Texas Rio Grande Valley, Brownsville, TX.*
 Email: ulku.karabulut@utrgv.edu
 (No relationships reported)

PURPOSE: To examine the correlation between physical activity (PA) level, total cholesterol (TC), high-density lipoprotein (HDL), and fasted blood glucose (FBG) among college-aged Hispanic males.

WEDNESDAY, MAY 31, 2017

METHODS: Thirty-five (35) Hispanic males (age = 23.2 ± 2.8) volunteered to participate in the study. Each subject read and signed the consent form prior to any measurement to take place. PA level objectively measured via Actigraph accelerometers. Each subject wore an accelerometer for 7 consecutive days - 5 weekdays and 2 weekend days. At the end of 7 days, the subjects returned to the lab fasted for at least eight hours and gave blood sample to measure TC, HDL, and BG. The ratio of TC to HDL and non-HDL were also calculated. Air-displacement plethysmography was used to determine percent body fat (BF)

RESULTS: Very vigorous PA was positively correlated with levels of HDL ($r=0.557$, $p<0.01$) and negatively correlated with TC-HDL Ratio ($r=0.453$, $p<0.01$). A positive correlation was found between minute length of sedentary bouts and levels of glucose ($r=0.459$, $p<0.01$). There was also a strong negative correlation occurred between max length of breaks in sedentary time with non-HDL ($r=-0.439$, $p<0.01$).

CONCLUSIONS: The results indicate that the intensity of exercise matters for obtaining higher levels of HDL cholesterol and a lower TC-HDL ratio. The findings also suggest that longer durations of sedentary state correlated with an increased FBG and breaks from prolonged sedentary bouts may decrease the risk of developing non-HDL cholesterol related health problems in college-aged Hispanic males. Future studies should be performed to determine the minimum amount of vigorous exercise and length of breaks in sedentary time to improve variables tested in this study.

Validity and Reliability of a Consumer Bioelectrical Impedance Analysis Scale

Dulce H. Gomez, Kelly M. Hood, Jennifer Kirk-Sorrow, Kendrick Uong, John Farmer, IV, Matthew Lee, James R. Bagley, Marialice Kern, FACSM. *San Francisco State University, San Francisco, CA.* (Sponsor: Marialice Kern, FACSM)
Email: dgomez5@mail.sfsu.edu
(No relationships reported)

PURPOSE: Bioelectrical impedance analysis (BIA) scales have gained popularity in monitoring fitness progress at home, yet their accuracy is unknown. We assessed the validity and reliability of body fat percentage (BF%) measurements from a consumer bioelectrical analysis (cBIA) scale compared to the "gold standard" of hydrostatic weighing (HW). **METHODS:** Forty-three [male (n=22); female (n=21)] healthy volunteers [age: 27.9±5.6y; height: 170.0±8.6cm; mass: 69.0±13.7kg; body mass index (BMI) range: 16.8-33.1] arrived at the laboratory 3h fasted after 12h without exercise and underwent measures of residual lung volume (for HW calculations), hydration status, and BF% via cBIA scale ('Lean' and 'Regular' modes) and HW. We assessed cBIA scale validity using Bland-Altman Plots (identifying Mean Biases±Limits of Agreement) and reliability using intraclass correlation coefficients (ICC). **RESULTS:** With HW as the validity criterion, mean BF% was 22.3±6.1% for all participants (range: 5.3-35.8%; male mean: 20.8±6.4%; female mean: 23.9±5.5%). Compared to HW, the cBIA scale in 'Lean' mode underestimated BF% by -5.3±9.1% for all participants (males: -7.9±6.9%; females: -2.6±8.0%) ($p\leq0.05$). In 'Regular' mode, the cBIA scale agreed with HW for all participants (BF% -0.8±9.3%; $p=0.27$) and females (BF% 0.4±10.8%; $p=0.73$); however, there was a significant difference for males (BF% -2.0±7.1%; $p\leq0.05$). The cBIA was reliable when comparing day-to-day ('Lean' mode: 0.5±1.0%, ICC:0.99; 'Regular' mode: 0.4±1.0%, ICC:0.99) and week-to-week ('Lean' mode: -0.4±1.4%, ICC:0.98; 'Regular' mode: -0.2±1.5%, ICC:0.97) BF% for all participants. **CONCLUSIONS:** Compared to HW, the cBIA underestimated BF% in 'Lean' mode, and this discrepancy was more pronounced in males. However, the cBIA scale agreed with HW when analyzing BF% in 'Regular' mode for all participants and females, signifying the "mode" chosen on consumer BIA devices greatly impacts validity. The cBIA was reliable when comparing day-to-day and week-to-week BF% measures for all participants, suggesting this can be a reliable at-home BF% analysis scale.

978 Board #157 May 31 3:30 PM - 5:00 PM
Interrater Reliability For Dxa And Bia Analysis For Measuring Total And Regional Lean Mass

Taylor Boyett, Trisha A. VanDusseldorp, Garrett M. Hester, Yuri Feito, FACSM, Gerald T. Mangine. *Kennesaw State University, Kennesaw, GA.*
(No relationships reported)

Dual-energy X-ray absorptiometry (DXA) and bioelectrical impedance analysis (BIA) are capable of assessing total and regional body composition using different technologies. DXA is considered more reliable than BIA to evaluate body composition, while BIA is a more cost-efficient and portable option. The agreement between these measures has not been determined in Rugby athletes. **PURPOSE:** To assess the interrater reliability between two devices that are capable of assessing total and regional lean mass in rugby athletes. **METHODS:** Body composition was measured in sixteen male rugby players (21.1 ± 1.6 years; 88.3 ± 14.2 kg; 1.78 ± 0.06 m) prior to the onset of their competitive season. Total body estimates of percent fat (%FAT),

fat mass (FM), and lean mass (LM) were determined by DXA (Lunar iDXA) and BIA (InBody 770). Regional LM estimates were also determined for the arms and legs from both devices. To assess the agreement between DXA and BIA on these measures, intraclass correlation coefficients (ICC), 95% limits of agreement (95% LOA), and coefficients of variation (CV%) were calculated. **RESULTS:** The agreement between DXA and BIA for total body estimates of %FAT (ICC_{2,1} = 0.81, 95% LOA = 0.91 - 1.34%, CV% = 10.5%), FM (ICC_{2,1} = 0.48, LOA = 0.63 - 0.92 kg, CV% = 10.1%) and LM (ICC_{2,1} = 0.67, LOA = 0.92 - 1.00, CV% = 2.3%) was variable, while regional values for lean arm mass (ICC_{3,1} = 0.91, 95% LOA = 0.93 - 1.06%, CV% = 3.3%) and lean leg mass (ICC_{3,1} = 0.89, 95% LOA = 1.05 - 1.15%, CV% = 2.4%) agreement was consistent. **CONCLUSION:** These data suggest that the interrater reliability between DXA and BIA is high when estimating total and regional lean mass, but not for estimating fat mass or body fat percentage. Although limited by the cross-sectional nature of the study design, our findings suggest it may be possible to use these devices interchangeably for tracking total and regional lean mass.

979 Board #158 May 31 3:30 PM - 5:00 PM
Effects Of Undulating Periodization On Physical Fitness And Body Composition In Women Practitioners Of Hydrogymnastics

Daniela G.M. Bueno, Marcelo M. Nascimento, Wonder H. Passoni, Stéfani A.M. dos Reis, Renato A. de Souza, Elisângela Silva, Wagner Z. de Freitas, Dênis B. da Silva. *IFSULDEMINAS, Muzambinho, Brazil.*
(No relationships reported)

Recently, new ways of manipulating the different training variables have been discussed in the aquatic environment. However, little attention has been considered in use of periodization theory training. **PURPOSE:** To compare the effect of two types of [daily (DUP) versus weekly (WUP)] undulating periodization on body composition, functional strength and flexibility in women practitioners of hydrogymnastics.

METHODS: 24 women practitioners of hydrogymnastics (age: 56.8 ± 2.4 years) were allocated in DUP (n=12) and WUP (n=12) groups. Both training protocols were periodized integrating a hydrogymnastics program composed by 39 sessions, 3 times per week, alternating in low or high intensity [Borg Rating of Perceived Exertion (RPE)], or per daily (DUP) or per week (WUP). Before and after the experimental protocol the individuals completed four items from the Senior Fitness Test (SFT) and body composition analysis. The SFT task were: Chair Stand test, which assessed lower body muscle strength and endurance; Arm Curl, which assessed arm muscle strength endurance, specifically of the biceps; Chair Sit-and-Reach a test of lower body flexibility; and the Back Scratch Test, which assessed upper body flexibility, particularly of the shoulders. Body composition was performed using the In-Body (720) equipment. Data were analyzed using two-way ANOVA (group and time with a significance level of 5%). **RESULTS:** DUP and WUP treatment produced similar increase ($p<0.05$) of scores related to Arm Curl (~18%) and Chair Stand (~17%) tests; maintenance of Chair Sit-and-Reach scores. Differences between the groups ($p<0.05$; ~25%) were showed only in Back Scratch test with a higher score in DUP group. **CONCLUSION:** Both daily and weekly undulating periodization were able to increase or maintain the physical fitness status and reduce fat mass in women practitioners of hydrogymnastics. Also, it seems that upper body flexibility may be influenced more by DUP than WUP.

Relationship of Fat-Free Mass and Fat Mass to Body Weight in College Male Athletes Players

Richard M. Schumacher. *Truman State University, Kirksville, MO.*
Email: richieschu@live.com
(No relationships reported)

Body mass differs widely across the sports spectrum. While some sports are dominated by large athletes, other sports participants benefit from a small size or weight class restrictions. Perhaps the most frequent measurement of body composition has been %fat with less frequent emphasis on the major components of body composition, fat-free mass (FFM) and fat mass (FM). FFM is the functional component as it is closely associated with maximal voluntary strength, while FM plays an important role in energy balance. With the ever increasing emphasis on control and manipulation of these components in modern sports, perhaps there should be greater focus on the relationship between FFM and FM. **PURPOSE:** To determine the relationship of FFM and FM to height and body mass across the wide range of size typically observed in college athletes. **METHODS:** Two hundred and sixty-seven NCAA D-II male athletes (age = 20.2 ± 1.2 y, height = 180.6 ± 7.9 cm, body mass = 87.3 ± 16.9 kg) volunteered to serve as subjects. Body composition was assessed using dual-energy x-ray absorptiometry (DEXA). This allowed compartmentalization and regional estimates of lean (bone, muscle, etc.) and fat tissue from which FFM and FM are determined. **RESULTS:** The relationship between height and body mass are curvilinear and moderately correlated ($r=0.61$). FFM and FM were significantly related to height

($r = 0.69$ and 0.35 , respectively) and body mass ($r = 0.92$ and 0.91 , respectively), with the relationships being more curvilinear in the latter. FM accounted for 60% of the variance in body mass, while FFM accounted for only 40%. The relationship between FFM and FM was significant ($r = 0.62$) and curvilinear, showing a greater accumulation of FM at higher body masses. **CONCLUSIONS:** FFM and FM increase linearly with height, but showed a curvilinear relationship with body mass suggesting that this population of male athletes may be approaching a theoretical limit of FFM accumulation. In contrast, the accumulation of FM follows a linear pattern with height but increases exponentially with body mass. The curvilinear relationship between body weight and height is not typical and appears to be related to a relative increase in body weight with fat accumulation beyond 180 cm height and 110 kg body weight. Depending on the sport, accumulation of FM may become a hindrance to performance.

981 Board #160 May 31 3:30 PM - 5:00 PM
Relationship Of Fat-free Mass And Fat Mass To Body Weight In College Female Athletes

Taylor Burlis¹, Heather Hughes¹, William F. Brechue, FACSM², Jerry L. Mayhew¹, Jana L. Arabas¹, Amanda Starks¹. ¹Truman State University, Kirksville, MO. ²A. T. Still University, Kirksville, MO.
 Email: tmb8425@truman.edu
 (No relationships reported)

Body mass differs widely across the sports spectrum in female athletes. While some sports are dominated by large athletes, other sports participants benefit from a smaller size and/or are limited by weight class. The most traditional measure of body composition has been %fat with less frequent emphasis on the major components of body composition: fat-free mass (FFM) and fat mass (FM). FFM is the functional component since as it is closely associated with maximal voluntary strength, while FM plays an important role in energy balance. With the ever increasing emphasis on control and manipulation of these components in modern sports, closer observation should be given to the relationship between FFM and FM accumulation. **PURPOSE:** To determine the relationship of FFM and FM to height and body mass across a wide-range of size typically observed in college female athletes. **METHODS:** One hundred and thirty-two NCAA Division-II female athletes (age = 19.9 ± 1.2 y, height = 169.1 ± 7.9 cm, body mass = 67.8 ± 12.2 kg) volunteered to participate. Body composition was assessed using dual-energy x-ray absorptiometry (DEXA) to assess regional estimates of lean (bone, muscle, etc.) and fat tissue which allowed determination FFM and FM. **RESULTS:** Height was linearly correlated with body mass ($r=0.58$). FFM and FM were significantly related to height ($r = 0.63$ and 0.40 , respectively) and body mass ($r = 0.91$ and 0.93 , respectively), with the relationships being linear in all four cases. FFM accumulated at approximately 0.35 kg/cm height and 0.50 kg/kg body mass; accounting for 91% of the variance in body mass, while FM accounted for only 9%. The greatest accumulation of FFM was at a height of 169 cm (0.402 kg/cm height) and body mass of 105 kg (0.663 kg/kg). The relationship between FFM and FM was significant ($r = 0.71$) and curvilinear. Accumulation of FM per kg of FFM increased at FFM > 55 kg. **CONCLUSIONS:** In female athletes, body mass appears to be the significant determinant of FFM accumulation. The accumulation of FM is determined by FFM, while the rate of accumulation of FM increases significantly at a threshold of 55 kg FFM.

The Importance Of Body Composition In The National Hockey League Testing Combine

Nathan Chiarlitti, Patrick Delisle-Houde, Ryan E. Reid, Ross E. Andersen, FACSM. McGill University, Montreal, QC, Canada.
 (Sponsor: Ross E. Andersen, FACSM)
 Email: nathan.chiarlitti@mail.mcgill.ca
 (No relationships reported)

The National Hockey League (NHL) combine was designed to assess draft-eligible players based on speed, power, strength, and physical size. Body composition (anthropometric measures and skin fold values) are recorded for all players, with the belief that it may play a role in physical performance. **PURPOSE:** To examine the role of body composition in the battery of physical tests and to compare differences in combine results based on position.

METHODS: Over two seasons, thirty-seven elite male Canadian university hockey players (age = 22.86 ± 1.55 years, weight = 87.21 ± 6.52 kg, height = 181.69 ± 6.19 cm, body fat percentage = $16.06 \pm 3.93\%$) participated in the study at the beginning of their hockey seasons. All participants underwent physical testing (as outlined in the 2016 NHL combine) and a day after testing, one total body dual energy x-ray absorptiometry (iDXA) scan to measure body composition. **RESULTS:** Pearson product correlations were used to explore the relationship among anthropometric measures (body fat percentage, visceral fat (kg), height, weight, leg lean mass per kg, upper lean mass per kg, and wingspan) with NHL fitness tests (bench press, maximum pull ups, grip strength, long jump, and Wingate anaerobic test). Multiple linear regression was used to explore the association among regional body

composition and NHL combine tests. Upper body lean mass/kg ($R^2 = .417$) explained the most variance in the bench press while height ($R^2 = .566$) explained the most variance in the long jump. Between positions, defensemen displayed greater right grip strength compared to forwards ($p < 0.05$). All other comparisons were non-significant. **CONCLUSIONS:** There are numerous factors that may influence performance on combine-specific physical tests. Body composition and anthropometric measures both seem to influence combine-specific tests, which may help sport scientists better tailor training programs to optimize performance in elite hockey players.

Reference Standards for Lean Mass Measures using GE Dual Energy Xray Absorptiometry

Mary T. Imboden¹, Ann M. Swartz, FACSM², Matthew P. Harber, FACSM¹, Leonard A. Kaminsky, FACSM¹. ¹Ball State University, Muncie, IN. ²University of Wisconsin-Milwaukee, Milwaukee, WI. (Sponsor: Matthew Harber, FACSM)
 Email: mstuttle2@bsu.edu
 (No relationships reported)

Body composition (BC) assessments focus predominantly on fat mass, however lean mass (LM) measurements also provide useful information on clinical and nutritional status. LM measurements have been shown to be predictive of health outcomes, including sarcopenia, which has been associated with frailty and reduced quality of life. Dual energy x-ray absorptiometry (DXA) is an established technique used to assess BC, including total and regional LM. Reference values for LM derived from DXA are necessary for interpretation and detection of LM deficits and its associated health issues. Recently reference values for LM measures specific to Hologic DXA systems were developed, however it is known that BC, including LM measures differ by DXA manufacturer. There currently are no LM reference values available for GE-Healthcare DXA systems. **PURPOSE:** To develop reference values by age and sex for LM measures using with GE-Healthcare DXA systems.

METHODS: A de-identified sample, considered exempt from IRB review, was obtained from Ball State University's Clinical Exercise Physiology Laboratory and University of Wisconsin-Milwaukee's Physical Activity & Health Research Laboratory. DXA scans of 2,076 women and 1,251 men were completed using a GE Lunar Prodigy or iDXA. Variables of interest included total LM and appendicular lean mass index (ALMI; leg lean mass + arm lean mass (kg) / height (m²)). Percentiles (%ile) were calculated and a factorial ANOVA was used to assess differences for each variable between age groups and sex, as well as the interaction between age and sex. **RESULTS:** Men had higher mean total LM and ALMI than women ($p < 0.01$), across all age groups. Total LM and ALMI decreased over the 5 decades in men and women ($p < 0.01$). The 50th %ile for total LM of men and women aged 20-29 years decreased from 63.9 and 42.5 kg to 54.2 and 39.1 kg for ages 70-79 years, respectively. The rate of decline in total LM during a 5 decade period was approximately 3% and 2% for men and women per decade, respectively.

CONCLUSIONS: These age and sex-specific LM reference values are the first developed specifically for use with GE-Healthcare DXA systems. These reference values provide for a more accurate interpretation of DXA-derived LM measurements providing an initial resource to aid in the early detection and assessment of LM deficits.

How Much Weight Have Senior Kinesiology Students Gained?

Alexis A. Neugebauer, Hyun-Sung An, Jung-Min Lee.
 University of Nebraska at Omaha, Omaha, NE.
 Email: aneugebauer@unomaha.edu
 (No relationships reported)

Several research studies have examined the belief of freshman 15 myth as it is well known that an amount of weight gained during a student's first year at college in the United States and Canada. However, mixed results have been found that freshmen gain as much as 15 pounds, whereas other suggests minimal weight gain. There is still limited information available to systematically examine the weight gained in Kinesiology/Exercise Science major senior college students. **PURPOSE:** The present study was to examine the senior college student's body weight compared to the ideal body weight. **METHODS:** Two hundred and thirty-two exercise science major students were participated in the study (age = 21.6 ± 72 yrs; Height = 170.8 ± 12.2 cm; weight = 77.8 ± 14.8 kg; Body mass index = 26.8 ± 5.0 kg-m²; Body Fat% = $19.2 \pm 8.2\%$; ideal body weight = 69.8 ± 14.2 kg) and the ideal body weight was calculated based on using the body fat % obtained by the bio-electrical impedance device. Descriptive for all variables were calculated and Pearson product-moment correlations were calculated to test the association between the actual weight and the ideal body weight. Dependent t-tests were performed to examine the statistically significant difference between the actual weight and the ideal body weight and also examine the ideal body weight differences between the male and female students. **RESULTS:** The difference between the actual weight and the ideal weight was 5.88 kg for male

students and 10.79 kg for female students. A strong correlation was observed between the actual weight and the ideal body weight, $r=.832$ ($p < 0.01$) and $r=.829$ ($p < 0.01$) for male and female students, respectively. The dependent t-test indicated that there are significant differences between the actual body weight and the ideal body weight for both male ($t(133)=9.1$, $p < 0.01$) and female ($t(97)=14.49$, $p < 0.01$). **CONCLUSIONS:** This finding demonstrates that even exercise science major students were heavier than their ideal body weight and female students are heavier than male students. Future researchers should focus on the mechanisms of college student's weight gain to initiate the college level interventions to prevent unhealthy weight gain.

Influence Of Body Fat Percentage And Sex On Mechanical Efficiency Of Rock Climbing

Charli D. Aguilar. *University of Nevada Las Vegas, Las Vegas, NV*. (Sponsor: James Navalta PhD., FACSM)
(No relationships reported)

PURPOSE: The purpose of this study was to determine if there is a relationship between mechanical efficiency (ME) and body fat percentage (BF%) in rock climbers. The secondary aspect was to determine if there is a difference in ME between male and female rock climbers. Years of experience and frequency of climbing was analyzed to correct for variability.

METHODS: 10 experienced rock climbers (7 males, 3 females) mean age of 25 ± 5.8 years volunteered to participate in the study. Each participant climbed up a 30 ft. indoor vertical rock climbing wall at a self-selected pace. VO_2 was analyzed at rest and during the climb using a portable COSMED device. BF% was measured using bioelectrical impedance (BIA) and years of climbing and climbing frequency was self-reported. Participants were separated in two groups based on whether they fell above or below the median BF%. Males and female participants were also analyzed by group. Correlation and independent t-tests were ran using Microsoft Excel 2016.

RESULTS: A negative correlation ($r = -0.37$) was found between ME and body fat percentage. No significant difference in ME was seen between groups ($p = 0.086$). No significance was found between ME and years or frequency of climbing. There was no significant difference in ME between males and females although the difference in BF% was significant ($p = 0.00698$).

CONCLUSIONS: Individuals with higher BF% tend to have lower ME but this difference is not significant. Previous studies have shown that training state has the largest effects ME. Therefore, self-reported years of experience and frequency of climbing may not be an accurate estimator for training status.

Validity of Whole and Regional Body Composition Testing Devices

Alexa Suida¹, Peter J. Chomentowski, III¹, Amanda J. Salacinski², Craig Broeder, FACSM³. ¹*Northern Illinois University, DeKalb, IL*. ²*University of Massachusetts Lowell, Lowell, MA*. ³*Exercising Nutritionall, LLC, Lisle, IL*. (Sponsor: Dr. Craig Broeder, FACSM)
(No relationships reported)

Obesity has been established as a risk factor for multiple diseases and is an increasing problem throughout the world. Advances in technology have enabled health professionals to use many devices to diagnose individuals as healthy, overweight, or obese. However, there are discrepancies between the validity of the devices.

PURPOSE: The purpose of this study is to validate InBody 520 and InBody S10 against the Hologic dual-energy X-ray absorptiometry (DXA) system. **METHODS:** 50 male and female subjects performed body composition testing on an InBody 520, InBody S10, and a Hologic DXA, followed by repeat measurements on the InBody 520 and S10. **RESULTS:** JMP Statistical Discovery Software Version 12.2.0 (Cary, NC) was used to run a matched pairs T-test and one-way analysis of variance (ANOVA) statistical analysis on all data collected. The significance level was set as $p < .05$ with a confidence interval of 95%. Subjects were (31 males, 19 females) mean weight was 87.8 ± 19.6kg (male) and 63.9 ± 10.7 kg (female), mean height was 178.7 ± 6.6cm (male) and 161.9 ± 7.1cm (female), mean age was 23.1 ± 2.7 years (male) and 22.9 ± 2.0 years (female). Body fat percentage was significantly greater for the DXA (28.9 ± 8.2) when compared to the InBody 520 (20.4 ± 9.6), $p < .001$, and significantly greater when compared to the the InBody S10 (21.8 ± 9.8), $p = .001$. Lean body mass was significantly less for the DXA (54.7 ± 14.4) when compared to InBody 520 (62.2 ± 15.1), $p = .036$, but not significant when compared to the InBody S10 (61.0 ± 15.6), $p = .096$. Body fat mass was significantly greater for the DXA (22.3 ± 9.4) compared to the InBody 520 (16.5 ± 10.6), $p = .0156$, but not significant when compared to the InBody S10 (17.9 ± 10.9), $p = .091$. **CONCLUSION:** The overall conclusion of this project is significant differences existed when measuring body composition variables between the DXA and the InBody devices. The InBody devices however, were not significantly different to each other when measuring body fat mass, lean body mass, and percent body fat, but again, they were significantly different when compared to the DXA.

987 Board #166 May 31 3:30 PM - 5:00 PM
Changes in Body Composition among Female College Basketball Players Pre and Post-Preseason Training

Bailey Parton, Taylor Tramel, Chatori Major, Tianna Knuckles, Ja'Da Brayboy, Aubrienne Rote. *UNC Asheville, Asheville, NC*.
(No relationships reported)

PURPOSE: To examine changes in area-specific lean mass and body fat among female, division I college basketball players before and after preseason training. **METHODS:** Body composition was measured before and after preseason training using a dual-energy x-ray absorptiometry (iDXA) scan. Total and area-specific (arms, trunk, legs, android, and gynoid) lean mass and body fat were analyzed. Preseason training lasted 1 month and consisted of 8 hours per week of a combination of weight training, high-intensity interval sprint training, and skill workouts. Paired-sample t-tests were used to examine change pre- and post-intervention. Pearson correlations were conducted to examine potential associations among variables.

RESULTS: Female athletes (N=11) completed this study. Total body mass significantly increased ($p = .001$) after preseason training from 152.8 to 155.6 lbs. Total and area-specific fat mass did not significantly change after preseason training. Total lean mass significantly increased ($p = .004$) from 109.6 to 112.0 lbs. However, for area-specific lean mass, only lean mass in the trunk ($p = .01$) and in the android region ($p = .013$) significantly increased from 51.2 to 52.3 lbs. and from 6.8 to 6.9 lbs., respectively. Individual lean mass responses to training varied widely. Specifically, changes in total lean mass ranged from +.02 to +7.9 lbs. Changes in total fat mass also varied widely between individuals, ranging from a loss of 2.2 lbs. to a gain of 3.5 lbs. Change in total lean mass was not significantly correlated with baseline total lean mass, age, year in school, or position played. Change in total body fat was negatively correlated ($r = -.82$, $p = .001$) but not significantly correlated with age, year in school, or position played. One athlete experienced an ACL tear midway through the season. Although her data was not included in pre-post analysis, her iDXA scan indicated a loss of 11.3 lbs. in lean mass, with the majority of this reduction seen in the legs (-6.4 lbs.).

CONCLUSIONS: Because there were significant increases in total body mass and lean mass but not body fat, it is important to directly measure body composition to examine effects of training. In addition, these data demonstrate that athletes' responses to training can vary widely thus highlighting the potential use of individualized training programs.

988 Board #167 May 31 3:30 PM - 5:00 PM
Relationships Between Body Composition And Sports Performance In Collegiate Baseball

Zachary W. Bell¹, Dr. Michael Lane¹, Mark T. Byrd², Tyler Hurley¹, Kaylee Isfort¹. ¹*Eastern Kentucky University, Richmond, KY*. ²*University of Kentucky, Lexington, KY*.
Email: zachary.bell135@icloud.com
(No relationships reported)

Purpose: Baseball requires a multifaceted list of skills and athletic abilities in order to be successful. This varies even further depending on the player's role within the team, such as pitchers and hitters. There is currently little data seen within the realm of baseball depicting the relationships between athlete body composition and their performance.

Methods: Athletes from a NCAA division I collegiate baseball team were recruited for this study (n=28). The athletes were measured for height, weight, and body composition. Body composition was measured utilizing air displacement (Cosmed, USA). The players were broken into two categories; allocated by their role as a pitcher in the team or as a batter. Pitchers were noted for their earned run average (ERA) and batters for their batting average (BA). Statistics were accessed from season performance data.

Results: The pitchers within this squad had a mean body weight of 186 ± 12.3 lbs., (Mean±STD) a mean BF% of 17.3 ± 4.6, and a mean ERA of 7.31 ± 4.9. The batters had a mean body weight of 194 ± 23.7 lbs., a mean BF% of 16.4 ± 8.2, and a mean BA of .270 ± 0.1. Correlations between body fat percentages and BA were non-significant, and so were correlations between body fat percentages and ERA.

Conclusions: From these results, no significant difference appeared to show how body fat percentage along with total body weight would play a major role in determining the overall ability of the pitchers or the batters. This research shows that variety of body weight and body compositions can be successful when playing baseball since no clear trend was identified. Further research should be conducted with baseball with comparisons at the professional level.

989 Board #168 May 31 3:30 PM - 5:00 PM
Comparing Body Composition Changes Between Skinfold and Air Plethysmography in Division II Men's Basketball Players

Dylan S. North, Nathan R. Paquet, Jeremy L. Knous, Adam M. Coughlin, Rachel L. Darr. *Saginaw Valley State University, University Center, MI.*

(No relationships reported)

Body composition can be used as an indicator of health in the general population and athletes alike. Men's college basketball players are encouraged to make healthy (body composition, aerobic and anaerobic markers, etc.) changes between Post-season and Pre-season, often overseen with a strength and conditioning staff intervention. The ability to measure percent fat, and track those changes during an athlete's career, including the off-season, is a vital measurement for strength and conditioning coaches.

PURPOSE: To compare changes in body density (BD), body fat percentage (BF%) and fat-free mass (FFM) obtained from skinfolds (SKF) using calipers and BodPod values in men's basketball players from Post-season to Pre-season during an off-season college-level strength and conditioning intervention.

METHODS: Certified Strength and Conditioning (CSCS) staff supervised the off-season (April to October) training intervention. SKF were performed by a single, experienced technician on 7 Division II men's basketball players (21.0 ± 0.6 yrs, 1.91 ± 0.11 m, 94.9 ± 17.2 kg) following ACSM Guidelines. BD via SKF was calculated via Jackson-Pollock seven-site formula. For SKF, the BD to BF% conversion utilized either BF% = (4.86/Db) - 4.39 or BF% = (4.95/Db) - 4.50, based on age, sex, and ethnicity. BodPod was performed in accordance with manufacturer's directions. A dependent, t-test was used to determine differences in BD, BF%, and FFM obtained from SKF and BodPod.

RESULTS: Changes in BD did not differ between the two groups (SKF 0.002 ± 0.002 kg/L, BodPod 0.004 ± 0.007 kg/L). The change in BF% did not differ significantly between skinfold and BodPod (SKF 1.2 ± 1.2%, BodPod 2.4 ± 2.2%). Changes in FFM did not differ significantly between the two assessment methods (SKF 1.1 ± 0.9 kg, BodPod 1.4 ± 0.6 kg). Body weight did not change significantly in the off-season (April 94.9 ± 17.1 kg, Oct 94.2 ± 14.5 kg).

CONCLUSION: The changes in body composition were accounted for equally by SKF and BodPod. While SKF and BodPod values may vary in the actual measurement of BD, BF% and FFM, the absolute change in BD, BF%, and FFM from Post-season to Pre-season was assessed equally by both modes of testing. Regardless of the body composition assessment tool, its variation can be presumed accurate as long as the same mode of testing was used at both time points.

990 Board #169 May 31 3:30 PM - 5:00 PM
Differences in Total Body Fat and Body Fat Percentage Between Performance and Aesthetic Collegiate Athletes

Daniel C. Flegg, Jessica A. Insogna, Ryan E.R Reid, Patrick Delisle-Houde, Ross E. Andersen, FACSM. *McGill University, Montreal, QC, Canada.* (Sponsor: Ross E. Andersen, FACSM)
 Email: daniel.flegg@mail.mcgill.ca

(No relationships reported)

Aesthetic sport athletes may believe that they can achieve a higher score if their body conforms to an ideally perceived body image. These athletes may follow extreme diets that can lead to a low body fat percentage, fluctuations in weight, and eating disorders in order to achieve their desirable body image. Although, performance sports do not score points from judges, these athletes may be very lean in response to their training demands. **Purpose:** To compare absolute and relative total fat, android fat, gynoid fat, between synchronized swimming (aesthetic sport) to hockey (performance sport) in female collegiate athletes. **Methods:** 41 female collegiate athletes ($n=22$ hockey players, $n=19$ synchronized swimmers) completed a total body iDXA scan to evaluate total and regional body fat percentage. The average age of the athletes was 20.30 ± 1.77 yrs. The average weight of the athletes was 65.36 ± 8.37 kg where synchronized swimmers weighed 62.62 ± 8.45 kg and hockey players weighed 67.73 ± 7.73kg, ($F(1,40)=4.09, p<0.05$). ANOVA was used to compare between sport differences in total body fat and body fat percentage as well as in the android and gynoid regions. **Results:** Synchronized swimmers had higher total body fat percentages (30.64 ± 6.76% vs 26.74 ± 4.63%, $F(1, 39) = 4.756, p=0.035$), higher android percent fat (27.83 ± 9.91% vs 22.4 ± 7.09% $F(1,39) = 4.156 p=0.048$) and gynoid percent fat (35.18 ± 6.96% vs 30.50 ± 4.86% $F(1,39) = 6.372 p=0.016$) than hockey players. Moreover, there was no significant differences in total body fat (18.79 ± 5.87kg vs 17.57 ± 4.64kg) $F(1,39) = 0.550 p=0.463$, android fat (1.14 ± 0.53kg vs 0.97 ± 0.46kg) $F(1,39) = 1.280 p=0.265$ and gynoid fat (3.68 ± 1.18kg vs 3.51 ± 0.82kg) $F(1,39) = 0.301 p=0.586$ between the two groups. **Conclusion:** Previous literature suggests that synchronized swimmers (aesthetic sports) have lower body fat percentage in order to achieve a higher score from judges. However, our results indicate that collegiate hockey players (performance sports) have lower body fat in all the tested regions.

Factors such as body image perception, training, and diet during the competitive season should be further investigated in order to better tailor health and training programs for female student athletes.

991 Board #170 May 31 3:30 PM - 5:00 PM
Effect of Body Composition and Mass Adjustments on Workload Estimation in NCAA Division I Football Players

Bryce V. Murphy, Donald R. Dengel, FACSM, Eric A. Klein, Dustin J. Perry, Chad M. Pearson, Tyler A. Bosch. *University of Minnesota, Minneapolis, MN.* (Sponsor: Donald R Dengel, FACSM)

Email: murp1142@umn.edu

(No relationships reported)

PURPOSE: Global Positioning Systems (GPS) and accelerometer integrated wearable technology (IWT) is often used to quantify an athlete's work output. Differences in body composition may impact an athlete's workload. This study examined the relationship between IWT determined total workload (TWL) and body composition measurements between 9 football positions. **METHODS:** TWL was measured in 78 NCAA Division I football athletes [9 Safeties (S), 6 Cornerbacks (CB), 12 Wide Receivers (WR), 5 Running Backs (RB), 5 Quarterbacks (QB), 6 Tight Ends (TE), 13 Linebackers (LB), 13 Defensive Linemen (DL), and 9 Offensive Linemen (OL)] using IWT during summer training sessions (June-July). Body fat percentage (BF%) and total upper body – lean lower mass ratio (TULLR) were determined using dual X-ray absorptiometry. Average TWL for the measured period was multiplied by BF%, BMI, and TULLR to obtain relative values for each player. An ANOVA was used to test the effect of position on each workload variable. When position had a significant effect, a Tukey test determined positional differences. **RESULTS:** Position had an effect on TWL ($p<0.001$) with S having a higher TWL than OL. When TWL was adjusted for BF% OL had significantly ($p<0.025$) higher TWL than all positions. There were no differences in TWL by position when adjusted for BMI ($p=0.174$) or TULLR ($p=0.107$). Table 1 presents the positional comparisons for each measure of TWL. **CONCLUSION:** Data from this study suggests that adjustments of TWL influences the interpretation of positional differences. Given that TWL is estimated based on changes in acceleration, the amount, and composition, of the athlete's mass is critical to understanding the actual work being performed. Based on the observed variance in physiological response to similar TWL, future studies should examine relative player loads based on body mass and composition.

Table 1: Total Workload and Relative Adjustments mean (±SD)

	S n = 9	CB n = 6	WR n = 12	RB n = 5	QB n = 5	TE n = 6	LB n = 13	DL n = 13	OL n = 9
Total (AU) Workload	242.9 ^a (41.0)	230.5 ^{ab} (29.7)	234.4 ^{ab} (28.1)	239.6 ^{ab} (11.1)	225.7 ^{ab} (33.3)	208.1 ^{ab} (22.8)	224.3 ^{ab} (47.4)	209.3 ^{ab} (32.0)	187.4 ^b (27.6)
BF% (AU)	3392.5 ^b (760.0)	3177.9 ^b (739.2)	3628.4 ^b (482.8)	3453.4 ^b (676.2)	3475.0 ^b (332.7)	3762.8 ^b (861.7)	4016.8 ^b (997.4)	4637.9 ^b (1255.4)	5941.7 ^a (1241.3)

Changes in Division I Collegiate Ice Hockey Player Anthropometrics and Fitness Over 36 Years

Jane A. Groetsch¹, Ashley N. Triplett¹, Amy C. Ebbing², Matthew R. Green¹, Christopher P. Connolly³, David P. Carrier¹, James M. Pivarnik, FACSM¹. ¹Michigan State University, East Lansing, MI. ²Ohio Dominican University, Columbus, OH. ³Washington State University, Pullman, WA.

Email: groetsc1@msu.edu

(No relationships reported)

Over the past several decades, fitness training has become integral to collegiate ice hockey, with the objective being to improve on-ice performance. However, the change in anthropometric and fitness profiles of collegiate ice hockey players has not been addressed. In addition, it is unknown whether these characteristics differ in athletes who later play in the National Hockey League (NHL) compared to those who do not. **PURPOSE:** The purposes of this study were to describe anthropometric (height, weight, %fat) and aerobic fitness (VO_{2max}) characteristics of collegiate ice hockey players over 36 years, and to evaluate whether these characteristics differ from those athletes who later play professionally in the NHL. **METHODS:** Physiologic and anthropometric profiles were obtained through preseason fitness testing of all players from a NCAA Division I men's ice hockey team from 1980 through 2015. Athletes (N=56) who later played at least one year in the NHL were also compared to non-NHL

athletes (N=220). Descriptive statistics (means, standard deviations) were calculated for non-NHL team players, as well as NHL players. Changes over time in variables of interest for each year's team were evaluated via regression analysis using linear and polynomial models. Characteristics of average non-NHL characteristics and future NHL players were compared via analysis of variance. **RESULTS:** Regression analysis revealed that a cubic model best predicted changes in mean height ($R^2=0.65$) and weight ($R^2=0.77$), while a quadratic model best fit change in %fat by year ($R^2=0.30$). Non-NHL averages were slightly, yet significantly ($P<0.01$) greater for %fat (12.4±3.5 % vs. 11.2±3.3 %), but there was no difference in height (181.8±6.2 cm vs 182.5±4.8 cm), weight (84.6±7.7 kg vs 85.0±5.7 kg), and VO_{2max} (58.0±4.6 ml·kg⁻¹·min⁻¹ vs 58.6±5.0 ml·kg⁻¹·min⁻¹) between non-NHL and future NHL players, respectively. **CONCLUSION:** While average player heights and weights fluctuated over time, increased emphasis on fitness training did not appear to affect athletes' relative aerobic fitness levels.

993 Board #172 May 31 3:30 PM - 5:00 PM
Anthropometric Evolution Of Professional Basketball Positions: A 20-year Retrospective View Of NBA Players
 Christopher W. Bach, Jack W. Ransone, FACSM. *University of Nebraska - Lincoln, Lincoln, NE.*
 Email: chriswbach@gmail.com
 (No relationships reported)

Coaches and management should constantly monitor long-term development of both current and prospective athletes in order to ensure proper fit into their system. Longitudinal analysis of player development and changing physical requirements of specific player positions can help to further evaluate player characteristics and allow for more effective comparison within their organization. **PURPOSE:** To identify whether the anthropometric characteristics of professional basketball positions have changed over the past 20 years (1997-2016). **METHODS:** Anthropometric assessments (height, weight, body fat, wingspan, and wingspan:height ratio) were taken by staff from multiple NBA settings (combines, individual team tryouts, etc.) over the course of 20 NBA seasons (1997-2016) and pooled together in order to evaluate changes in anthropometric characteristics of each the following positions: point guard (PG), shooting guard (SG), small forward (SF), power forward (PF), and center (C). All players included in the analysis were either current NBA players or prospective NBA players selectively chosen by the NBA and its respective organizations. Multilevel modelling was used to explore trends in anthropometric variation over time using linear regression analysis. **RESULTS:** With the exception of PG (2.626 cm), average height decreased for all positions over the course of 20 years (SG: -1.072 cm; SF: -0.335 cm; PF: -0.625 cm; C: -1.646 cm). Weight decreased for the PF position over time (-2.549kg), while all other positions reported increases in average weight (PG: 1.085 kg, SG: 1.301 kg, SF: 0.368 kg; C: 0.017 kg). Wingspan increased for all positions (PG: 2.306 cm; SG: 2.322 cm; SF: 2.581 cm; PF: 1.991 cm) with the exception of C (-0.655 cm). Improved body composition was observed with body fat percentage decreasing for all positions (PF: -2.55%; SG: -1.45%; SF: -1.45%; C: -2.48%; C: -0.72%). PG showed minimal change in wingspan:height ratio (-0.02%), while all other positions reported a slight increase in this ratio (SG: 1.80%; SF: 1.40%; PF: 1.20%; C: 0.60%). **CONCLUSION:** Findings demonstrate the long-term evolution of professional basketball players has resulted in minimal changes in height and weight, while all positions appear to have become longer and leaner over the past 20 years.

Validation Of Air-displacement Plethysmography And Bioimpedance With Dxa In Measuring Body Fat Among Chinese Athletes
 Bei Wang, Chen Wang, Bin Hou, Xue Ren, Yongmei Wang, Jinglong Ye, Dao Wang, Fenglei Qian. *SHRISS, Shanghai, China.*
 Email: 33453189@qq.com
 (No relationships reported)

Estimates of body composition are used to assess nutritional status and training effect in athletes. However, most equations that predict relative body fat were derived from predominantly white samples, and ethnic difference may cause discrepancies in body composition assessment. Moreover, musculoskeletal development in athletes may affect the density of the fat-free mass, which is the primary factor limiting the accuracy of body composition estimates from body density. **PURPOSE:** To validate air-displacement plethysmography and bioelectrical impedance in body fat estimates in Chinese professional athletes. **METHODS:** Body composition was measured by BOD POD and by Inbody 720 (BIA). Dual-energy X-ray absorptiometry (DXA) was used as the criterion measurement. Comparisons were made among three different BMI groups, LOW (BMI<18.5), NOR (BMI 18.5-24.99), and HIGH (BMI 25+). **RESULTS:** A heterogeneous group of 111 professional athletes were randomly recruited from Shanghai, including 63 males and 48 females. An almost perfect

correlation of body fat percentage (%BF) estimated from BOD POD and DXA was found in all three BMI groups (ICC=0.841 for LOW, 0.909 for NOR, and 0.937 for HIGH, respectively), and the same happened for BIA and DXA (ICC=0.818 for LOW, 0.900 for NOR, and 0.909 for HIGH, respectively). The paired-samples t tests also showed significant correlation between BOD POD, BIA and DXA estimates in all three BMI groups ($p<0.001$). Estimated %BF from BOD POD was significantly lower than that from DXA in all three groups ($p<0.001$). Estimated %BF from BIA was significantly lower than that from DXA ($p<0.001$) in HIGH but not significantly different in LOW ($p=0.946$) and NOR ($p=0.681$) groups. Bland-Altman plots showed that BIA tends to overestimate %BF in thinner subjects and underestimated %BF in heavier participants. **CONCLUSION:** Both BOD POD and BIA appear to measure %BF in Chinese athletes reliably; however, findings suggest that BOD POD seems to underestimate %BF compared to DXA, and BIA estimates is valid in low to normal BMI subjects but it may deviate from DXA estimates in high BMI group. Consequently, modifications should be given to the embedded equations in BOD POD and BIA devices when measuring %BF in Chinese athletes.

Association Among Arm Circumference, Anthropometric Variables And Sedentary Time In Children
 Sergio R. Vieira, João Pedro da Silva Junior, Luis Carlos de Oliveira, Rafael Benito Mancini, Timoteo Leandro de Araujo, Victor Matsudo. *CELAFISCS, SÃO CAETANO DO SUL, Brazil.*
 (No relationships reported)

PURPOSE: to verify the association of arm circumference and anthropometric variables. **METHODS:** this study is part to the Mixed-Longitudinal Project of Growth, Development, and Physical Fitness from Ilhabela. A convenient sample of 89 children of both sexes, aged 9-11 years-old, was taken from two public schools of Ilhabela. Anthropometric variables included body weight (kg), body height (cm), body mass index (BMI; kg/m²), arm (AC) and waist (AW) circumference (cm), and adiposity (AT; mm), measured by the mean of seven skinfolds (biceps, triceps, subscapular, supra-iliac, medial axillar, abdominal, an calf. Sedentary time was determined objectively by Actigraph GT3X+ accelerometer (ActiGraph, Pensacola, USA). Children wore the accelerometers for seven consecutive days. The cut-off criteria for sedentary time in the accelerometer was ≤25 counts/15 seconds, according to Evenson, et al., 2008. A Spearman-rho correlation was determine, and a significant level of $p\leq.05$ was taken. **RESULTS:** **CONCLUSIONS:** A significant but weak association was found between arm circumference and sedentary time. However, arm circumference was strongly associated to all anthropometric variables. Then, it seems that arm circumference may be an important obesity predictor in children from 9 to 11 years-old.

Variables	r	IC95%	p
Body Weight (kg)	0.83	0.75-0.88	<0.0001
Body Height (cm)	0.54	0.37-0.67	<0.0001
BMI (kg/m ²)	0.93	0.90-0.96	<0.0001
Waist Circumf (cm)	0.63	0.75-0.88	<0.0001

Effect of Periodized Training on Sarcopenic Obesity and Physical Function in Prostate Cancer Survivors
Jacqueline L. Kiwata, Tanya B. Dorff, E. Todd Schroeder, FACSM, Christina M. Dieli-Conwright. *University of Southern California, Los Angeles, CA.*
Email: kiwata@usc.edu
(No relationships reported)

For prostate cancer survivors (PCS) on androgen deprivation therapy (ADT), the loss of skeletal muscle and increase in adiposity, together called sarcopenic obesity, is a common adverse effect. Sarcopenia is also associated with decreases in strength and mobility. No studies to date have concomitantly improved sarcopenic obesity and physical function in PCS on ADT. This study attempts to improve on existing interventions by employing periodization to optimize physiological and performance adaptations. **PURPOSE:** This ongoing pilot trial investigates the effects of 12 weeks of periodized resistance training on sarcopenic obesity and physical function in PCS on ADT. **METHODS:** Eighteen PCS (65.6 ± 8.8 yr) on current or previous ADT were recruited from the USC Norris Comprehensive Cancer Center and randomized to periodized resistance training (PRT; n=9) or an attention control stretching program (CS; n=9). Outcomes were assessed at baseline and after the 12-wk intervention. Body composition was measured through dual-x-ray absorptiometry, estimated 1 RM strength was tested on leg press and seated row, and mobility was assessed through timed up and go. Appendicular skeletal muscle index (ASMI), a common index of sarcopenia, was calculated from body composition. PRT performed a supervised total-body resistance exercise and stretching program 3 times a week. CS performed home-based stretching 3 times a week. Baseline group differences were tested with univariate ANOVA, while differences in all outcomes were tested with 2 (group) x 2 (time) ANOVA.

RESULTS: No significant differences in characteristics or outcomes were found between groups at baseline ($P > 0.05$). Post-intervention, significant increases were observed in PRT compared to CS for appendicular skeletal mass (0.8 ± 4 kg; $P = 0.04$), ASMI ($0.3 \pm .1$ kg/m²; $P = 0.041$), leg press (126.6 ± 31.7 kg; $P = .004$) and seated row (23.0 ± 3.5 kg; $P < .001$). A nonsignificant decrease in body fat (%) was observed in PRT compared to CS ($1.3 \pm .7$ %; $P = .067$; $d = 0.89$). No differences were found in mobility. **CONCLUSIONS:**

In PCS on ADT, a 12-wk periodized resistance training program improved skeletal muscle mass and strength. Future work is warranted to determine if adiposity can be attenuated and improvements sustained beyond the 12-wk intervention. Supported by an NSCAF doctoral grant.

Efficacy Of An Adaptive Clinical Exercise Program For Cancer Survivors During And After Treatment
Ryan J. Marker, Catherine M. Jankowski, FACSM, W. Thomas Purcell, John C. Peters. *University of Colorado Anschutz Medical Campus, Aurora, CO.* (Sponsor: Catherine M. Jankowski, FACSM)
Email: ryan.marker@ucdenver.edu
(No relationships reported)

Exercise programs for cancer survivors improve endurance, strength, and quality of life. Survivors exercising during cancer treatment tend to show smaller improvements, or performance maintenance, compared to those who have completed treatment.

Adapting exercise to the day-to-day status of survivors during and after treatment is recommended and may improve program efficacy. **PURPOSE:** To investigate a three month adaptive clinical exercise program for cancer survivors during and after treatment. **METHODS:** Cancer survivors undergoing treatment (chemotherapy and/or radiation) at enrollment or within six months of completing treatment were included. No cancer types were excluded. Estimated VO₂peak, grip strength, the Piper Fatigue Scale (PFS), and the Beck Depression Inventory (BDI) were assessed at baseline and program completion. The number of exercise sessions completed was recorded. Age, sex, and body mass index (BMI) at baseline were compared between treatment groups (undergoing treatment and completed treatment). ANOVAs (Exercise [within-participant] x Treatment [between-participant]) were performed for each performance measure in all participants and separately for breast cancer survivors. **RESULTS:** Participants undergoing treatment (N=58) did not significantly differ from those who had completed treatment (N=61) in age (57±12 years; Mean±SD), sex (71% women), or BMI (26.4±5.6 kg/m²). The number of exercise sessions completed was not different between groups (18±5 out of a possible 24, $p > 0.05$). The main effect of Exercise was significant for all measures ($p < 0.01$), with improvements seen from

baseline to program completion (estimated VO₂peak: 3.1 ± 4 ml/min/kg, grip strength: 1 ± 3 kg, PFS: -1 ± 2 , BDI: -3 ± 6), while the main effect of Treatment and Treatment-Exercise interactions were not significant ($p > 0.05$). These results were replicated when only breast cancer survivors were analyzed (N=48, 24 undergoing treatment). **CONCLUSIONS:** Cardiorespiratory fitness, strength, fatigue, and depressive symptoms improved significantly with exercise, regardless of treatment status. These results suggest that cancer survivors currently undergoing treatment can experience benefits equal to those of survivors who have completed treatment through an adaptive exercise program.

(No relationships reported)

PURPOSE: To evaluate the effectiveness of a peer-led multimodal intervention for increasing exercise participation in patients with localized prostate cancer.

METHODS: A randomized controlled trial with 463 prostate cancer patients 10.8 months post-curative therapy, enrolled from September 2011 until November 2012, from Queensland, Australia were randomized into a peer-led multimodal intervention (INT) (n=232) targeting exercise and unmet supportive care needs or usual care (UC) (n=231). The intervention included self-management materials, exercise equipment, and monthly telephone-based group peer-support for 6 months. Patients were assessed for compliance with exercise guidelines for cancer survivors, psychological distress, and quality of life (QoL) at baseline, 3, 6 and 12 months. **RESULTS:** 81.6% completed the final assessment at 12 months. Patients in INT engaged in significantly more resistance exercise than UC at 3 months (19.4 [95% CI 6.52 to 32.28] min/wk, $p = 0.003$) and 6 months (14.6 [95% CI 1.69 to 27.58] min/wk, $p = 0.027$). There was no difference between groups for aerobic-based activity at any time point nor for resistance exercise time at 12-month follow-up. At 3 months 40.3% of UC were inactive compared to 29.3% of INT ($X^2 = 6.12$, $p = .013$), while 7.8% of UC were sufficiently active compared to 18.0% for INT ($X^2 = 8.89$, $p = .003$). INT had significantly higher Assessment of Quality of Life (AQoL)-8D Relationships subscale scores at 3-month follow-up (.03 [95% CI .00 to .06], $p = .038$) compared with UC, with no change in psychological distress. **CONCLUSION:** The intervention was effective in increasing patients' resistance exercise participation in the short- to medium-term, however, this behaviour change was not accompanied by overall improvements in QoL or psychological distress. Further investigation is required to increase effectiveness and maintain long-term adherence.

PURPOSE: The purpose of this study is to identify the effects of 12-week exercise program on physical and psychological health outcome in older prostate cancer patients with androgen deprivation therapy (ADT). **METHODS:** Nineteen prostate cancer patients (mean age 75.26 ± 6.9) receiving ADT at least 3 months were randomized into an exercise program comprising supervised (once a week) and home-based (more than 3 days/week) exercise session ($n = 11$) or usual care ($n = 8$) for 12 weeks. The exercise program was composed of stretching, resistance, and walking based aerobic training. Thigh circumference, level of physical activity, muscle strength, functional fitness, quality of life, and fatigue were assessed at baseline and after 12-week intervention. Data were analyzed using repeated measures ANOVA. **RESULTS:** The exercise group showed improvements in thigh circumference (exercise group (EG) 1.2 vs. usual care group (UCG) -0.5 cm, $p = .013$), level of physical activity using

accelerometer (daily steps: EG 2,247.1 vs. UCG -1,204.3 steps/day, $p=.027$; moderate to vigorous physical activity: EG 85.6 vs. UCG -12 min/day, $p=.008$), muscle strength using hand grip dynamometer (grip strength: EG 2.1 vs. UCG -0.3 kg, $p=.034$; knee extensor: EG 44.2 vs. UCG 6.1 Nm/kg, $p=.004$; knee flexor: EG 18.8 vs. UCG -21.3 Nm/kg, $p<.001$), and functional fitness (chair stand: EG 9.2 vs. UCG 5.1 count/sec, $p<.001$; up and go: EG -1.5 vs. UCG 0.3sec, $p=.003$; 2-min step: EG 67.7 vs. UCG -14.2count/sec, $p<.001$) compared with usual care group. Exercise group also improved quality of life using Functional Assessment of Cancer Therapy-Prostate (EG 21.2 vs. UCG -22.1 points, $p<.001$) and reduced fatigue using Functional Assessment of Chronic Illness Therapy-Fatigue (EG 18.6 vs. UCG 1.9 points, $p=.004$). There were no adverse events during the testing or exercise intervention period. **Conclusion:** Twelve-week exercise program not only significantly improved physical and psychological health but also increased level of physical activity in older prostate cancer patients with ADT. Supported by the Korean society of sports medicine.

Functional Capacity Of Gastrointestinal Cancer Patients - A Pre-therapy Comparison To Breast Cancer Patients And Healthy Women

Lutz Vogt¹, Katrin Stücher¹, Claus Bolling², Axel Dignass², Winfried Banzer, FACS¹. ¹J.W.Goethe-University, Frankfurt/Main, Germany. ²Agaplesion Markus Hospital, Frankfurt/Main, Germany. (Sponsor: Winfried Banzer, FACS¹)
 (No relationships reported)

PURPOSE: Many studies of cancer patients report that frailty, cachexia and decreased physical function during chemotherapy (CT) predict a higher mortality risk. Although a high prevalence of these symptoms in gastrointestinal (GI) cancer patients is known, there is almost no data on functional status and body composition in this population. The aim of the study is to assess and compare the pre-therapy motor performance of advanced GI cancer patients in contrast to breast cancer patients and healthy controls. **METHODS:** In a 3-arm cross-sectional study female patients with advanced cancer (UICC ≥ III) (GI: n=17; 70.1±3.1 yrs; BMI 23.6±5.3 kg/m²; breast: n=17; 66.9±2.3 yrs; BMI 23.6±3.8 kg/m²) before first-line CT and 17 healthy age-matched women (69.4±1.4 yrs; BMI 24.2±3.3 kg/m²) are examined. Body composition was obtained from bioelectrical impedance analysis. The amount of daily physical activity (steps; MVPA/min-wk⁻¹) was calculated from accelerometer (Actigraph) readings. A capacitive force platform (Zebris) was used for gait speed recordings during free level walking. Maximal isometric voluntary contraction force (MIVF) of the quadriceps muscle was assessed by a strain gauge force transducer (ASYS). **RESULTS:** ANOVA with post-hoc test and Bonferroni correction show significant differences in outcome measures of GI cancer patients compared to breast cancer patients and healthy women. GI cancer patients show lower values in phase angle (4.5±0.8°; 5.3±0.5°; $p<.01$) and isometric strength (5.5±2.2; 9.1±3.3; 8.4±1.8 N/kg; $p<.01$). Steps per day (3125±2396; 8703±4104 stp, $p<.001$), moderate to vigorous activity (7.3±11.9; 36.9±28.5 MVPA/min-wk⁻¹; $p=.001$) and gait speed (3.5±1.1; 4.9±0.6 km/h; $p<.001$) are decreased compared to healthy women. **CONCLUSIONS:** Patients with advanced GI cancers demonstrate sufficient deficits in functional status and motor performance before CT compared to advanced breast cancer patients and healthy women. Gait speed, phase angle and force are below cut-off values for low prognosis of survival and may reflect a diminished tolerance of CT. Measures to improve muscle status, physical function and its effects on treatment is warranted in patients with advanced GI cancers.

Feasibility of Exercise for Improving Inflammation in Advance Stage Prostate Cancer Patients

Calvin Lloyd Cole, PhD., Ian Kleckner, PhD., Sarah Kerns, PhD., MPH, Matthew Asare, PhD., Po-Ju Lin, PhD., Charles Kamen, PhD., Michelle Janelins, PhD., MPH, Karen Mustian, PhD., University of Rochester, Rochester, NY. (Sponsor: Leslie J. Brandon, PhD, FACS¹)
 Email: Calvin_Cole@urmc.rochester.edu
 (No relationships reported)

BACKGROUND: Cancer cachexia is a burdensome side effect in prostate cancer patients, with advanced stage (ADV) patients having the highest risk. Chronic activation of immune response as a result of cancer and its treatments is a key stimulator of the chronic pro-inflammatory response hypothesized to result in cachexia in prostate cancer patients. Exercise reduces inflammation in cancer patients; however, it is unclear if exercise is feasible and effective at reducing inflammation among ADV prostate cancer patients with a high risk of cachexia. **PURPOSE:** This study aimed to assess the feasibility of ADV prostate cancer patients completing an exercise intervention and the efficacy of the intervention for reducing inflammation in these men compared to early stage (ERL) patients. **METHODS:** A secondary data analysis was performed on a two-arm randomized clinical trial examining the influence of a 6-week home-based aerobic and resistance exercise program. Participants included 57 sedentary prostate cancer patients aged

67 ± 8.1 years, who were receiving hormone therapy and/or radiation therapy. Each participant was randomly assigned to usual care (UC) or usual care plus exercise (UCE). ERL and ADV cancer was defined based on NCCN guidelines. Mean steps/day, minutes of resistance training/day and serum protein levels of IL-6, IL-1b, IFN_γ, IL-10, IL-8, and TNFR1 were measured at baseline and post-intervention. **RESULTS:** Attrition was minimal, with no significant difference between ERL and ADV patients (5 total withdrawals). No adverse events (AEs) were attributed to exercise and there were no significant differences between ERL and ADV patients in number of AEs. Results also showed no significant difference in the number of steps walked or minutes of resistance exercise between ERL and ADV patients in the exercise arm. (Steps Walked: ERL = 6859 ± 899; ADV = 8939 ± 1359; $p>0.05$); Minutes of Resistance Training per Session ERL = 13 ± 4 (3 days/week); ADV = 19 ± 13 (3 days/week); $p>0.05$). Changes in levels of IL-1b, IFN_γ, IL-10, IL-8, and TNFR1 were similar among ERL and ADV (all $p>0.05$), however changes in IL-6 did significantly differ between groups ($p<0.05$). **CONCLUSIONS:** Findings suggest exercise is feasible and safe, and may have positive effects on chronic inflammation in ADV prostate cancer patients. Effects Of Exercise Training On Physiological And Psychological Measurements Of Cancer-related Fatigue

Trista L. Olson¹, Jessica M. Brown², Kevin D. Dames³, Jeremy D. Smith², Reid Hayward². ¹St. Cloud State University, St. Cloud, MN. ²University of Northern Colorado, Greeley, CO. ³SUNY Cortland, Cortland, NY.
 Email: tloilson@stcloudstate.edu
 (No relationships reported)

While there is extensive evidence connecting exercise to a reduction in psychological fatigue, the effect of exercise on objectively measured muscular fatigue has yet to be studied in cancer patients. Evaluating how exercise modulates physiological and psychological fatigue dimensions either similarly, or independently, could aid in our understanding of how exercise reduces cancer-related fatigue. **PURPOSE:** To evaluate the effect of exercise on self-reported psychological fatigue measures and objectively measured muscular fatigue in cancer survivors. **METHODS:** A total of 21 cancer survivors (62 ± 14 years of age) were asked to complete both physiological and psychological measures of fatigue prior to, at midpoint, and following a 24-week exercise intervention. Participants completed the revised Piper Fatigue Scale (PFS), a subjective and psychological measure of fatigue. The PFS produces a total score (PFST) and four subscale scores: behavioral/severity (PFSB), affective (PFSA), sensory (PFSS), and cognitive/mood (PFSC). For the measurement of objective, physical fatigue, a handgrip fatigue index (HFI) was determined for each participant by repetitively squeezing a handgrip dynamometer 15 times with maximal force for each repetition. Participants also completed 15 maximal force knee extensions at a joint angular velocity of 60 deg·s⁻¹ and a quadriceps fatigue index (QFI) was computed. Following testing, participants completed 24 weeks of supervised exercise training. **RESULTS:** Significant main effects were found for PFST and all four subscales ($p<.05$). Results indicate significant decreases in PFST (-30%; $p=.001$), PFSB (-32%; $p=.015$), PFSA (-33%; $p=.001$), PFSS (-32%; $p=.001$), and PFSC (-25%; $p=.004$) following 12 weeks of the exercise intervention. Testing following 24 weeks of the intervention resulted in significant decreases in PFST (-30%; $p=.031$), PFSA (-32%; $p=.023$), and PFSS (-31%; $p=.016$). **CONCLUSION:** Improvements in psychological fatigue did not mirror the changes in physiological fatigue, indicating that exercise may be a more powerful modulator of emotional fatigue as opposed to muscular fatigue. Clinicians may find utilizing subjective evaluations of cancer-related fatigue more assistive and informative when prescribing exercise interventions in the cancer population.

Validity of The Six-Minute Walk Test For Predicting VO_{2peak} in Cancer Survivors

Alexandra Schumacher, Daniel Shackelford, Deandra Elcock, Jessica Brown, Reid Hayward. University of Northern Colorado, Greeley, CO.
 (No relationships reported)

Exercise improves cardiovascular function in cancer survivors (CS) suffering from treatment-related toxicities, such as decreased peak oxygen consumption (VO_{2peak}). Establishing valid assessment protocols that determine VO_{2peak} are essential for developing individualized exercise prescriptions for cancer rehabilitation programs. The University of Northern Colorado Cancer Rehabilitation Institute (UNCCRI) has developed a valid cancer-specific VO_{2peak} treadmill protocol to address this need. The six-minute walk test (6MWT) is an exercise assessment used in many populations with chronic disease to predict VO_{2peak} but it is not clear whether this test accurately assesses VO_{2peak} in CS. The 6MWT is simple, inexpensive, and representative of daily living

activities. **PURPOSE:** To assess the validity of predicted VO_{2peak} from the 6MWT compared to the UNCCRI treadmill protocol in CS. **METHODS:** 128 CS completed a UNCCRI treadmill protocol and a 6MWT one week apart in randomized order to obtain VO_{2peak} (mL/kg/min). VO_{2peak} values from the UNCCRI treadmill protocol were compared against four common 6MWT VO_{2peak} prediction equations. **RESULTS:** All four 6MWT prediction equations significantly ($p < 0.001$) underestimated VO_{2peak} . Equations 1, 2, 3 and 4 yielded VO_{2peak} values of 18.9 ± 3.0 , 14.2 ± 4.6 , 8.3 ± 3.8 , and 16.4 ± 2.3 , respectively, while the UNCCRI treadmill yielded a much higher VO_{2peak} of 24.7 ± 7.4 . A positive strong correlation occurred between the UNCCRI treadmill protocol and 6MWT prediction equation 1 ($r = 0.83$). A moderately strong correlation occurred between the UNCCRI treadmill protocol and 6MWT equation 3 ($r = 0.70$). Maximum heart rates were significantly higher ($p < 0.001$) during the UNCCRI treadmill protocol compared to the 6MWT (150 ± 21 bpm vs. 109 ± 21 bpm), respectively. **CONCLUSION:** These findings suggest that the 6MWT is not a valid test for predicting VO_{2peak} in CS due to its underestimation of all four equations. The UNCCRI treadmill protocol is much more accurate for assessing VO_{2peak} in CS in order to correctly prescribe an individualized exercise rehabilitation program.

Relationship between Survivorship Time and Physical Activity Level in Puerto Rican Breast Cancer Survivors
 Marta I. Amaral-Figueroa, Jennifer Morales-Cruz, Roberto Velez-Diaz. *University of Puerto Rico, San Juan, Puerto Rico.*
 Email: marta.amaral1@upr.edu
 (No relationships reported)

Cancer is one of the major public health problems in Puerto Rico, especially breast cancer. There is evidence that suggests that engaging in physical activity (PA) during and after cancer treatment improved fatigue, body composition, cardiorespiratory fitness, psychological state, and quality of life. Thus, it is important to assess PA level in breast cancer survivors.

PURPOSE: To assess: 1) the level of PA in a group of breast cancer survivors women; and 2) the relationship of survivorship time and PA level. **METHODS:** 21 breast cancer survivors participated. PA was assessed: 1) using the International Physical Activity Questionnaire - Long Version (IPAQ-L), and 2) pedometer that the participants wore for a week (OMRON-HJ320).

RESULTS: The participants average age was 54 years, height 62.2 ± 2.5 inches, weight 148.1 ± 22.6 pounds, estimated basal metabolic rate 1607.2 ± 132.9 calories. The average survivorship time was 4.24 ± 3.9 years, distributed as follows: 0-11 months, $n=4$; 1-2 years, $n=5$; 3-5 years, $n=4$ and >5 years, $n=8$. The average scores of the IPAQ-L were: Work 393.9 ± 927.4 METS-mins/week, Transportation 976.6 ± 1068.1 METS-mins/week, Home Chores $2,369.7 \pm 3,111.2$ METS-mins/week, Recreational activities $752.6 \pm 1,184.4$ METS-mins/week, Sitting time Week 201.4 ± 176.8 minutes, Sitting time Week End 157.1 ± 151.6 minutes. The average daily steps was $4,870.8 \pm 2,612.5$. A Spearman Correlation analysis did not showed significant relationship between survivorship time and physical activity level.

CONCLUSIONS: There were no significant relationship between survivorship time and physical activity. The participants did not meet the recommendation of 10,000 steps/day. The results from the IPAQ-L showed that the participants engaged in moderate physical activity in some of the domains of the questionnaire such as transportation, home chores and recreational activities.

Feasibility Of Supervised Aerobic Interval Exercise Training Following Treatment For Breast Cancer
 Savanna Rowe¹, Amy A. Kirkham², Kelcey A. Bland¹, Cheri L. Van Patten³, Alis Bonsignore⁴, Don C. McKenzie¹, Karen A. Gelmon³, Kristin L. Campbell¹. ¹University of British Columbia, Vancouver, BC, Canada. ²University of Alberta, Edmonton, AB, Canada. ³British Columbia Cancer Agency, Vancouver, BC, Canada. ⁴University of Toronto, Toronto, ON, Canada.
 (No relationships reported)

Aerobic interval training (AIT) can be more effective in improving cardiorespiratory fitness, and muscle oxidative capacity than moderate continuous training (MCT) in a variety of healthy and clinical populations. Due to physical deconditioning associated with breast cancer treatment, AIT is of interest in this population. However, the feasibility and safety of AIT among breast cancer patients is unknown.

PURPOSE: To assess the feasibility and occurrence of major adverse events (MAE) with AIT among breast cancer patients immediately post completion of adjuvant chemotherapy and radiation.

METHODS: Women with early stage breast cancer were enrolled in the Nutrition and Exercise During Adjuvant Treatment trial within the first half of chemotherapy. MCT aerobic exercise was prescribed 3x/week during chemotherapy and radiation (20-30 min at 50-75% Heart Rate Reserve (HRR)). Upon treatment completion, eligible participants were prescribed AIT (4 sets of 4 min at 75-85% VO_{2R}/HRR and 4 min at 40-65% VO_{2R}/HRR) at least 1x/week, with the choice of either MCT or

AIT for remaining sessions. AIT eligibility included an absence of angina, dyspnea, uncontrolled hypertension, asthma or current prescription for heart medications. The ACSM's metabolic equation for treadmill walking was used to prescribe interval speed/grade, while HRR was used for intervals performed on a cycle ergometer or elliptical trainer.

RESULTS: 57 women (age 51 ± 11) entered the post-treatment phase of the study, of which 44 (75%) were eligible for AIT. 36 (82%) participants performed at least one AIT session. 66% of the total sessions performed were AIT workouts, indicating a potential preference for AIT vs. MCT. Those performing AIT attended significantly more sessions overall relative to those who were not performing AIT (18 ± 6 vs 13 ± 8 , $p = 0.01$). Adherence to AIT intensity was achieved in 68% of all sessions, with no difference between those performed on the treadmill, bike/elliptical, nor relative to MCT sessions. The most common barrier to AIT intensity adherence was the prescription being too difficult (75%). No MAE occurred.

CONCLUSIONS: AIT after treatment completion for breast cancer appears to be feasible, potentially preferable to MCT, and may result in greater attendance than MCT alone.

Effect of Combined Aerobic and Resistance Exercise on Remnant Cholesterol in Breast Cancer Survivors
 Kyuwan Lee, Nathalie Sami, Christina M. Dieli-Conwright. *University of Southern California, Los Angeles, CA.*
 Email: kyuwanle@usc.edu
 (No relationships reported)

PURPOSE: An increased risk of cardiovascular disease (CVD) and mortality is apparent in breast cancer survivors (BCS). Remnant cholesterol, defined as a product of partially catabolized chylomicrons and very-low-density lipoprotein, is a recently identified novel blood marker for increased CVD risk. In fact, the risk for CVD is two-fold greater in patients with high remnant cholesterol possibly due to higher density of remnant cholesterol per particle than LDL-C. The combination of aerobic and resistance exercise has been recommended to reduce cholesterol levels and risk of CVD in BCS, but it is unclear as to whether combined exercise improves remnant cholesterol level. This study sought to examine the effects of a 16-week progressive aerobic and resistance exercise intervention on remnant cholesterol in BCS.

METHODS: Thirty sedentary BCS diagnosed with Stage I-III breast cancer who completed cancer-related treatment within 6 months prior to enrollment were randomized to the Control (CON; $n=15$) or the Exercise (EX; $n=15$) group. The EX group underwent supervised aerobic and resistance exercise sessions 3 times a week for 16 weeks set at a moderate-vigorous intensity. The CON group was asked to maintain their current level of activity. Remnant cholesterol was calculated as total cholesterol-HDL-LDL. Paired t-test and two-way repeated measures ANOVA were used to examine the effects of exercise training on remnant cholesterol.

RESULTS: Prior to the intervention, the EX and CON did not differ by age (52.7 ± 7.9 yr), body mass index (33.9 ± 6.4 kg/m²), waist circumference (99.8 ± 4.2 cm), total cholesterol (196.4 ± 37.5 mg/dL), LDL-C (101.9 ± 31.2 mg/dL), HDL (42.7 ± 5.7 mg/dL), and remnant cholesterol (51.7 ± 28.8 mg/dL). Following the 16-week intervention, mean remnant cholesterol levels were significantly reduced (45.2 ± 13.8 to 9.9 ± 2.5 mg/dL; 78% mean decrease) in the EX group compared to CON group ($P = 0.02$; group x time interaction). There were no significant changes in remnant cholesterol levels in the CON group ($P > 0.05$).

CONCLUSIONS: A 16-week supervised progressive aerobic and resistance exercise intervention is an effective approach to reduce remnant cholesterol in BCS. Participation in combined exercise during cancer survivorship should be considered to reduce the risk for CVD mortality in BCS.

Breast Cancer- And Metabolic-related Predictors Of Vo2peak Amongst Active Post-menopausal Women
 Amy A. Kirkham¹, Kristin L. Campbell², Don C. McKenzie². ¹University of Alberta, Edmonton, AB, Canada. ²University of British Columbia, Vancouver, BC, Canada.
 Email: amy.kirkham@ubc.ca
 (No relationships reported)

Peak oxygen consumption (VO_{2peak}) is reported to be lower amongst breast cancer patients both during and after adjuvant treatment relative to healthy sedentary controls. It is not known whether this is attributable to direct effects of treatment or indirect effects on whole body metabolism and exercise behaviour. **PURPOSE:** To identify metabolic and breast cancer-related predictors of relative VO_{2peak} amongst active post-menopausal women. **METHODS:** 10 subjects were selectively recruited to each of three groups: 1) breast cancer patients 3 weeks post chemotherapy (BC1); 2) breast cancer patients 1-3 years post chemotherapy and radiation (BC2); 3) healthy controls (CON). All women were 45-60 years, self-reported as post-menopausal and performing ≥ 90 min/week of moderate intensity aerobic exercise. Gas analysis measurements were made during rest, a maximal incremental treadmill test, and steady state exercise

(60% VO2R). Univariate linear regressions were performed with adjustment for age and BMI. RESULTS: Group was a significant predictor ($p=0.01$), resulting in β coefficients of -7.5 and -2.5 mL/kg/min for BC1 and BC2 relative to CON. In BC1 and BC2 combined, receipt of non-anthracycline but not anthracycline-containing chemotherapy protocols relative to CON was predictive of a lower VO2peak ($\beta=-8.8$, $p<0.01$). The amount of moderate intensity exercise self-reported in the past month (hours/week) ($\beta=1.5$, $p=0.03$), and surrogates of cardiovascular function, including O2 pulse (ml/beat) during steady state exercise ($\beta=1.7$, $p<0.01$), and five-minute heart rate recovery (bpm) ($\beta=0.3$, $p=0.03$) were also significant predictors. Receipt of fluorouracil chemotherapy or trastuzumab treatments, resting heart rate, resting VO2, substrate utilization (RER) at rest and for moderate intensity exercise, time since last menstruation, and occurrence of chemotherapy-induced menopause were not significant predictors. CONCLUSION: Among post-menopausal women, receipt of chemotherapy for breast cancer, in particular non-anthracycline-containing protocols and more recent completion, are associated with lower VO2peak, but resting and exercise metabolic parameters are not. Better recent exercise behaviour and cardiovascular function are associated with higher VO2peak.

The Effects of Exercise Program on Quality Of Life and Fatigue Level During Autologous Hematopoietic Stem Cell Transplantation
 Vesile Yildiz Kabak, Yasin Ekinci, Songul Atasavun Uysal, Tulin Duger. *HACETTEPE UNIVERSITY, ANKARA, Turkey.*
 Email: vesile_yldz@hotmail.com
 (No relationships reported)

PURPOSE: The purpose of the study was to investigate the effects of exercise program on quality of life (qoL) and fatigue among the patients who undergo autologous hematopoietic stem cell transplantation (AHSCT).
METHODS: Twenty two patients with different diagnosis (9 multiple myeloma, 10 lymphoma, 3 other cancer type) participated in this study. The mean age was 47 ± 13 years. All patients underwent AHSCT. The exercise program started before this procedure and continued until discharge day (mean 15 days). The program included breathing, range of motion, and resistive exercises focusing large muscle groups and brisk walking duration 5-10 minutes in corridor. The Borg Rating of Perceived Exertion was used to estimate the intensity of the program to light to moderate intensity exercise prescription was based on a rating of "somewhat hard" (10-13). The fatigue was evaluated with Fatigue Impact Scale. The European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30) was used to assess qol.
RESULTS: The mean score of Fatigue Impact Scale was 32 ± 32 points before the procedure and 23 ± 17 points at discharge day, but there was not statistical significant difference. Global health status, functional scale and symptom scale scores which are the sub-tests of the EORTC QLQ-C30 were 47 ± 31 , 65 ± 18 , 31 ± 18 points before the treatment and 41 ± 25 , 69 ± 18 , 31 ± 17 points at the discharge day. There were not statistical significant differences between two time points in qoL scores.
CONCLUSIONS: As a result of our study exercise program was effective in reducing fatigue levels and raising qol in AHSCT patients, however the results were not statistically significant. It was thought because of the clinical status of the patients is not recover completely at the discharge day and two week is not enough to show the effects of the exercise program, we could not demonstrate effectiveness of the exercise program statistically.

Metabolic Differences Between A Bout Of Eccentric, Concentric And Traditional Resistance Exercise
 Stephen M. Fischer, Jon Stavres, John McDaniel. *Kent State University, Kent, OH.*
 (No relationships reported)

Eccentric, concentric and traditional resistance exercises that incorporate both eccentric and concentric phases are often used to improve musculoskeletal fitness. Although there is evidence that indicates concentric contractions are metabolically more costly than eccentric contractions, the extent to which this translates to whole body metabolism during an entire resistance workout is less clear. **PURPOSE:** To determine the extent to which metabolic variables such as VO2(ml/kg/min), RER, and HR as well as blood glucose and lactate vary between resistance workouts comprised of only eccentric, concentric or traditional bouts. **METHODS:** N=12 men and women

completed a traditional (TRAD), concentric (CONC), and eccentric (ECC) full-body resistance workout at 65% of a pre-determined 1 repetition max with each condition matched for work. The traditional condition required 3 sets of 10 repetitions on each exercise (6 total). 3 sets of 20 repetitions were required for the eccentric and concentric conditions. During each condition, the subject was fitted to a metabolic cart and the aforementioned metabolic variables were recorded through indirect calorimetry and heart rate monitor. Blood glucose and blood lactate were taken using the ACCU-CHEK glucose monitor and Lactate Plus at five different stages (Pre, Post Leg Curl, Post Ex., 30 min Post, and 60 min Post). **RESULTS:** Both the TRAD (9.26 ± 1.83 ml/kg/min) and CONC (10.03 ± 1.63 ml/kg/min) conditions resulted in significantly ($p < 0.001$, and $p < 0.001$ respectively) greater VO2 values when compared to the ECC condition (6.67 ± 1.25 ml/kg/min). TRAD ($1.03 \pm .04$) and CONC ($1.00 \pm .03$) conditions also resulted in significantly (both $p < 0.001$) greater RER compared to the ECC ($0.88 \pm .09$) with the TRAD condition being significantly ($p = 0.045$) greater than the CONC condition. Accumulation of lactate from Pre to Post Exercise was also significantly (both $p < 0.001$) greater in the TRAD (6.17 ± 2.68 mmol) and CONC (5.73 ± 3.29 mmol) compared to the ECC (1.10 ± 1.60 mmol). **CONCLUSIONS:** Results indicate a much greater metabolic demand from concentric and traditional contractions compared to eccentric contractions on a whole body level.

The Influence of a Single Bout of High-Intensity Interval Exercise on Postprandial Lipemia and Glycemia
 James Rowe, Stephen Decker. *Stephen F. Austin State University, Nacogdoches, TX.*
 (No relationships reported)

PURPOSE: Examine the effects of high-intensity interval exercise (HIIE) on postprandial (PP) triglyceride (TG), glucose, and insulin concentrations following a mixed meal (MM). **METHODS:** Physically active men ($n=10$; age= 22.2 ± 2.1 yrs; body mass = 82.7 ± 13.2 kg; body fat% = 13.3 ± 3.1) completed two trials in random order: 1) Rest and 2) A single bout of high-intensity interval exercise (HIIE). Both trials were performed at 0800 hours. HIIE consisted of performing eight (15-second) maximal effort sprints on a stationary bicycle. Each sprint was followed with approximately 3 minutes of passive cycling with no resistance. Rest consisted of sitting quietly for 30 minutes. Approximately 30 minutes following the completion of each trial, a fasting (12hr) blood sample was collected followed by the consumption of the MM providing 7.5 ± 1.2 kcal/kgBM (body mass) with a macronutrient composition of 35% carbohydrate (CHO), 5% protein, and 60% fat. The MM was blended with whole milk, ice cream, and whipping cream. Blood was collected again at 0.5, 1, 2, and 3 hours post-MM and analyzed for TG, insulin, and glucose concentration. Postprandial responses were quantified via the incremental area under the curve (AUC) using the trapezoidal method. Significant differences ($p < .05$) between trials were determined using a one-way, repeated measures ANOVA and Bonferroni post hoc test. **RESULTS:** The duration of the HIIE was 24 minutes (not including a 5-minute warm up). HIIE expended 90.1 ± 11.8 kcal. HIIE significantly reduced the glucose AUC₁ (Rest: 9.9 ± 43.1 mg·dl⁻¹·3hr⁻¹; HIIE: -39.9 ± 37.0 mg·dl⁻¹·3hr⁻¹; $p=.010$) and insulin AUC₁ (Rest: 36.2 ± 25.4 μIU·ml⁻¹·3hr⁻¹; HIIE: 5.9 ± 30.7 μIU·ml⁻¹·3hr⁻¹; $p=.035$) with no significant effect on TG AUC, (Rest: 57.2 ± 52.8 mg·dl⁻¹·3hr⁻¹; HIIE: 78.7 ± 46.5 mg·dl⁻¹·3hr⁻¹; $p=.20$). **CONCLUSION:** HIIE blunted the postprandial glucose and insulin response to high-fat mixed meal in young physically active men. The lack of change in the TG concentration might be explained by the lower energy expenditure of the HIIE due to its short duration. Future investigations should evaluate the applicability of HIIE within an at-risk populations (i.e. obesity, diabetes). This study was supported by the Stephen F. Austin State University Research Pilot Study Grant and the Texas ACSM Student Research Development Grant.

Effects of Acclimatization to High Altitude on Exogenous Carbohydrate Oxidation During Steady-State Exercise
 Andrew J. Young, FACSM, Claire E. Berryman, Allyson N. Derosier, Robert W. Kenefick, FACSM, Marques A. Wilson, Stefan M. Pasiakos, FACSM. *US Army Research Institute of Environmental Medicine, Natick, MA.*
 Email: andrew.j.young.ctr@mail.mil
 (No relationships reported)

In a previously reported study, oxidation of exogenous glucose consumed before and during exercise was the same in acute hypoxia as normoxia, despite higher endogenous carbohydrate (CHO) oxidation. However, how altitude acclimatization affects exogenous carbohydrate oxidation is unknown. **PURPOSE:** To determine how altitude acclimatization affects exogenous CHO oxidation during exercise. **METHODS:** Male sea level (SL) residents ($n = 17$, mean \pm SD, age, 23.4 ± 5.6 y; body mass, 81.9 ± 13.9

kg; VO_{2peak} 4.17 ± 0.65 L/min at SL and 2.77 ± 0.46 at HA) performed metabolically-matched 80-min exercise bouts (~ 1.7 L/min, $\sim 55\%$ of HA VO_{2peak}) at SL, within 6 h of arrival at 4,300 m (acute HA) and after 21-day residence at 4300 m. Immediately before and every 20 min during exercise, volunteers consumed either a CHO beverage ($n = 9$, 45 g fructose/L + 55 g glucose/L; 0.8 fructose/glucose ratio, CHO ingestion rate = 1.8 g/min) or a flavor-matched, non-nutritive placebo beverage (PLA, $n = 8$). Total, endogenous and exogenous CHO oxidation rates were determined during the last 40 min of exercise by indirect calorimetry and $U-^{13}C$ -glucose. Exogenous CHO oxidation efficiency was the ratio (expressed as %) of exogenous CHO oxidation rate to the CHO ingestion rate. **RESULTS:** Exogenous CHO oxidation rate of volunteers consuming PLA was zero during all trials. For volunteers consuming CHO, exogenous CHO oxidation rate (g/min) during exercise was lower ($P < 0.05$) at acute HA (0.39 ± 0.22) than at SL (0.75 ± 0.16). After altitude acclimatization, oxidation rate (0.62 ± 0.18) was higher ($P < 0.05$) than with acute HA, and not different from SL. Efficiency of CHO oxidation (%) followed the same pattern (SL = 41 > acute HA = 22 < chronic HA = 34), but efficiency did not reach SL values after acclimatization. For those consuming CHO, endogenous CHO oxidation rate at acute HA (1.35 ± 0.48) tended to be but was not significantly higher than at SL (1.05 ± 0.53). After altitude acclimatization, endogenous CHO oxidation rate (0.67 ± 0.45) was lower ($P < .05$) than either SL or acute HA. **CONCLUSION:** Acute hypoxia impairs exogenous CHO oxidation, but adaptations with altitude acclimatization alleviate that impairment, and contribute to a reduction in endogenous CHO oxidation. Supported by U.S. Army Medical Research and Materiel Command; authors' views not official U.S. Army or DoD policy.

Pre-exercise Carbohydrate Ingestion and Transient Hypoglycemia During Exercise: Effects of Fasting vs. Feeding

Saki Kondo¹, Kumpei Tanisawa¹, Katsuhiko Suzuki¹, Shin Terada², Mitsuru Higuchi, FACSM¹. ¹Waseda University, Saitama, Japan. ²The University of Tokyo, Tokyo, Japan.
 Email: sakico117@gmail.com
 (No relationships reported)

Previous studies demonstrated that carbohydrate feeding 30-45 min before exercise results in transient hypoglycemia shortly after onset of exercise in some but not all subjects. However, it remains unclear whether the transient hypoglycemia after pre-exercise carbohydrate intake is more likely to occur under fed or fasted condition. **PURPOSE:** The purpose of this study was thus to directly compare the effects of fasting vs. feeding on plasma glucose kinetics following pre-exercise carbohydrate ingestion and to elucidate the contributing factors of the transient hypoglycemia in each condition. **METHODS:** Sixteen subjects performed 60-min cycle ergometer exercises at 75% VO_{2max} in overnight fasted and fed (3 h after breakfast) states in random order. In both conditions, they consumed 500 ml of a beverage containing 150 g of glucose 30 min before the start of exercise. Plasma glucose and serum insulin levels are determined before and during the exercise. **RESULTS:** In the fasted state, plasma glucose levels dropped transiently below 4.0 mmol/l in 5 subjects, who showed substantially higher serum insulin level at the onset of exercise, while plasma glucose levels remained above this level in the other subjects. On the other hands, 7 subjects developed transient hypoglycemia in the fed state and their VO_{2max} (3285 ± 286.6 L/min) was significantly higher than that in the other subjects who did not demonstrate a decline in plasma glucose (2915 ± 262.7 L/min). **CONCLUSIONS:** Subjects with higher aerobic fitness and enhanced insulin secretory capacity seem to be more prone to transient hypoglycemia following pre-exercise carbohydrate ingestion under fed and fasted conditions, respectively.

Pentraxin 3 And Glucose Responses To Acute High-intensity Interval Exercise Vs. Continuous Moderate-intensity Exercise

Katelyn M. Dodge¹, Michael Whitehurst, FACSM¹, Aaron L. Slusher², Brandon G. Fico¹, Arun Maharaj¹, James T. Mock¹, Chun-Jung Huang, FACSM¹. ¹Florida Atlantic University, Boca Raton, FL. ²Virginia Commonwealth University, Richmond, VA. (Sponsor: Chun-Jung Huang, FACSM)
 (No relationships reported)

PURPOSE: Pentraxin 3 (PTX3) is an anti-inflammatory/cardioprotective protein and responds promptly to down-regulate pro-inflammatory mediators. It may potentially play a role in the regulation of glucose metabolism. Therefore, this study investigated the relationship between plasma PTX3 and glucose responses following both acute high intensity-interval exercise (HIIE) and continuous moderate-intensity exercise (CMIE). **METHODS:** Nine healthy males were recruited to participate in HIIE and CMIE on a cycle ergometer. HIIE consisted of 10 repeated 60 second of cycling at 90% max watts (W_{max}) separated by 2 minutes of cycling without resistance, while CMIE was 28 minutes of cycling at 60% W_{max} . Blood samples were collected prior to, during (4 min, 10 min, 16 min, 22 min), immediately post, and 30 and 60 minutes

into recovery following exercise. A linear mixed model for repeated measures was conducted to control for total work output (kilojoules). **RESULTS:** A significant increase in PTX3 across time was found in both acute HIIE and CMIE ($p = 0.030$), whereas no change was observed in glucose response ($p = 0.108$). Although no difference was shown in carbohydrate (CHO) oxidation between both exercise protocols, fat oxidation and total energy expenditure were greater during acute CMIE ($p = 0.001$, $p < 0.001$, respectively). Furthermore, the percent change in PTX3 from baseline to immediately following acute HIIE was negatively correlated with fat oxidation ($r = -0.769$; $p = 0.015$), while the relationship with CHO oxidation approached significance ($r = 0.608$; $p = 0.082$). **CONCLUSION:** Our results indicate that acute HIIE could be a practical model to understand the potential role of PTX3 in the regulation of energy metabolism during exercise.

Effects of Varying Physical Activity Level on Glucose Tolerance Testing

Gabrielle A. Volk, Michael A. Deal, Adam J. Meisler, Jenna M. Karrow, Alex P. Good, Kevin D. Ballard, Kyle L. Timmerman. Miami University, Oxford, OH. (Sponsor: Helaine Alessio, FACSM)
 Email: volkga@miamioh.edu
 (No relationships reported)

The oral glucose tolerance test (OGTT) is a commonly used method for the diagnosis of insulin resistance. Currently the only level of control prior to an OGTT is an 8-10 hour fast. Physical activity is known to influence glucose uptake kinetics. Thus, our **PURPOSE** was to determine if varying the level of physical activity, the day prior to an OGTT, influenced the blood glucose and insulin responses to an OGTT. We hypothesized that higher levels of physical activity the day prior to an OGTT would result in attenuated blood glucose and insulin responses to an OGTT. **METHODS:** Ten healthy adults (6 m/4 f; age = 21.5 ± 0.3 y; BMI = 24 ± 5 kg·m⁻²) participated in three OGTT trials the morning after performing 50%, 100%, or 150% of their habitual physical activity in randomized order. Habitual physical activity as average steps/day ($12,318 \pm 1310$ steps·day⁻¹) was determined using 7-day pedometer. Pedometers were worn for 24 hrs prior to each OGTT trial and used to confirm steps·day⁻¹ for the 50%, 100%, and 150% conditions. Trials were separated by at least one week and subjects were asked to follow a similar diet the day prior to each OGTT trial. For each OGTT trial, plasma glucose and insulin were measured after an overnight fast and at 30 min intervals for two hours following ingestion of the glucose beverage (1-gm glucose·kg⁻¹ body mass). Area under the curve (AUC) for glucose and insulin for each OGTT was calculated using the trapezoidal method. Between trial differences for these variables were analyzed using a general linear model with repeated measures. Significance was set to $p < 0.05$. **RESULTS:** Subjects successfully achieved the desired percentage of habitual steps prior to each trial: 52±1%, 98±2%, and 146±3%. Fasting plasma glucose (50%: 95 ± 2 mg·dl⁻¹; 100%: 91 ± 2 mg·dl⁻¹; 150%: 91 ± 2 mg·dl⁻¹); glucose AUC (50%: $12,932 \pm 769$ mg·min·dl⁻¹; 100%: $13,239 \pm 1,008$ mg·min·dl⁻¹; 150%: $13,016 \pm 471$ mg·min·dl⁻¹), and insulin AUC (50%: $5,562 \pm 1810$ μU·min·ml⁻¹; 100%: 5181 ± 1839 μU·min·ml⁻¹; 150%: 4735 ± 1776 μU·min·ml⁻¹) did not differ between trials. **CONCLUSIONS:** Our data suggests that varying the physical activity level (from 50 to 150% of habitual activity) the day prior to an oral glucose tolerance test does not influence the blood glucose or insulin responses to this commonly utilized diagnostic test.

1015 Board #194 May 31 2:00 PM - 3:30 PM
Prior Acute Resistance Exercise Enhances Postprandial Fat Oxidation in Response to a High-Fructose Meal

Christopher Melby, Andrea Wysong, Jeffrey Bourquin, Jessie Wilburn. Colorado State University, Fort Collins, CO.
 (No relationships reported)

A fructose-rich, mixed-macronutrient meal rapidly increases carbohydrate oxidation and decreases fat oxidation during the post-prandial period. An acute strenuous bout of weight-lifting exercise has been shown to elevate fat oxidation for many hours following cessation of exercise. **Purpose:** To determine whether or not a single resistance exercise bout performed approximately 15 hours before consumption of a high-fructose, mixed-meal could attenuate the meal-induced shift from fat oxidation to CHO oxidation. **Methods:** Seven apparently healthy men who were recreational weight lifters (Mean ± SEM; age = 27 ± 2 years, BMI = 24.2 ± 0.3 kg/m²) completed three separate two-day conditions in a random order: (1) EX-COMP: a full-body superset weightlifting workout (12 different exercises x 4 sets x 10 reps) with the provision of additional kilocalories to compensate for the energy expended during exercise on day 1, followed by the consumption of a high-fructose, mixed-macronutrient test meal (kcal = 600 ± 8 kcal; 0.75 g fructose/kg body weight) the next morning (day 2) and the determination VO_2 , VCO_2 , and respiratory exchange ratio (RER) for determination of fat and carbohydrate oxidation during a six-hour post-prandial period; (2) EX-NoCOMP: same as EX-COMP condition but without energy

intake compensation for the exercise on day 1; and (3) CON: no exercise control. **Results:** Post-prandial RER was significantly lower in the EX-NoCOMP (0.789±0.01) condition compared to CON (0.809±0.01) ($p=0.005$). Fat oxidation was significantly higher in EX-NoCOMP (0.094±0.009 g/min) compared to CON (0.084±0.009 g/min) ($p=0.001$). CHO oxidation was significantly lower in the EX-NoCOMP (0.09±0.012 g/min) compared to CON (0.108±0.011 g/min) ($p=0.037$). For the EX-COMP condition, postprandial RER (0.787±0.009), fat oxidation (0.095±0.008 g/min) and CHO oxidation (0.091±0.011 g/min) were almost identical to EX-NoCOMP, but these values compared to CON did not quite reach statistical significance. **Conclusion:** A single acute bout of high intensity resistance exercise completed 15 hours prior to a high-fructose, mixed-macronutrient meal results in greater post-prandial fat oxidation than does lack of exercise followed by the same meal.

Differential in Aerobic Capacity Among Collegiate Distance Runners Consuming a Low Carbohydrate Diet

Marissa N. Baranaukas¹, Brian Miller², Jordan T. Olson², Michelle Boltz², Laura Richardson², Matthew Juravich², Ronald Otterstetter, FACSM². ¹Indiana University, Bloomington, IN. ²The University of Akron, Akron, OH.
 Email: marbaran@indiana.edu
 (No relationships reported)

Although current sports nutrition recommendations advocate for a high carbohydrate (CHO) intake among endurance athletes, recent research has suggested that training with low CHO availability may augment adaptations to aerobic training. When adopted during the competitive season, when training intensity and the demand for glycogen replenishment is high, low CHO diets may be detrimental to training adaptations by preventing adequate recovery between concurrent high-intensity endurance sessions. **PURPOSE:** To observe the dietary habits of collegiate distance runners and to investigate the effects of habitual CHO intake on aerobic performance (PostVO_{2max}) during a competitive season. **METHODS:** During an 8-week trial period, 12 collegiate track athletes (males, n=8; females, n=4) recorded their self-selected dietary intake via 24-hr recall. Analysis of CHO intake was conducted by a registered dietitian using NutriCalc software. Pre (PreVO_{2max}) and post season aerobic capacity assessments were performed. A one-way ANCOVA with two covariates controlling for PreVO_{2max} and CHO intake compared the variance in PreVO_{2max} and PostVO_{2max} by sex. **RESULTS:** The average CHO intake was 4.11 ± 1.03 g/kg with only one female athlete meeting dietary recommendations, consuming > 6 g/kg. Male distance runners had a lower CHO intake than females (3.64±0.77g/kg; 5.03±0.91g/kg). After adjusting for PreVO_{2max} and CHO, the male improvement in PostVO_{2max} was 12.62 ml/kg/min (95% CI 2.12-23.12, $p=0.02$) greater than the effect observed in females. There were no differences in weight and body composition changes by sex throughout the season ($p=0.48$; $p=0.86$). CHO accounted for 18% of the variance in PostVO_{2max}. **CONCLUSIONS:** Collegiate distance runners were able to make improvements in their aerobic capacity during a competitive season while consuming a low CHO diet, with a predominant effect in male athletes. Therefore, it may not be detrimental for endurance athletes to consume low CHO diets while undergoing training at high intensities from an aerobic adaptation standpoint.

The Physiological Effects of 12-Weeks of Ketogenic Dieting While Cross-Training

Paul A. Roberson¹, Wesley C. Kephart¹, Coree Pledge¹, Petey W. Mumford¹, Kevin W. Huggins¹, Jeffrey S. Martin¹, Kaelin C. Young¹, Ryan P. Lowery², Jacob M. Wilson², Michael D. Roberts¹. ¹Auburn University, Auburn, AL. ²Applied Sports Performance Institute, Tampa, FL.
 (No relationships reported)

PURPOSE: Recent literature has suggested impaired strength and anaerobic performance outcomes with ketogenic dieting. Herein, we sought to determine the metabolic and performance effects of 12 weeks of ketogenic dieting while cross-training in cross-trained individuals. **METHODS:** Volunteers were divided into a control group (CTL; n=9) and a ketogenic group (KD; n=9). Pre and post-testing involved body composition assessment via dual x-ray absorptiometry (DEXA), vastus lateralis (VL) thickness using ultrasound, resting energy expenditure (REE), phlebotomy to determine serum health biomarkers, an aerobic capacity evaluation, one repetition maximum (1RM) testing, and 400-m sprint time assessments. All subjects were instructed to follow a cross-training routine for 12 weeks. The KD group was given dietary guidelines to follow for 12 weeks, while the CTL group continued their normal diet. Blood ketone bodies were measured weekly to ensure nutritional ketosis was reached by the KD but not CTL. **RESULTS:** KD blood ketone levels were significantly higher than the CTL at each week following intervention ($p<0.05$) except week 9 ($p=0.09$). DEXA fat mass declined in the KD (-3.47 ± 1.06 kg) compared to CTL (-0.06 ± 0.45 kg) ($p<0.01$).

DEXA lean mass and visceral fat mass changes were not different between groups ($p=0.99$ and $p=0.23$, respectively). At rest, respiratory quotient delta scores were not different between CTL (-0.012 ± 0.027) and KD (-0.067 ± 0.020) ($p=0.19$). REE was not altered between groups ($p=0.24$). No between-group differences in delta scores were observed for fasting glucose ($p=0.31$), HDL-C ($p=0.49$) or triglycerides ($p=0.19$), although LDL-C trended with increases in the KD (+33.8 ± 14.3 mg/dL) but not CTL group (+0.2 ± 8.0 mg/dL) ($p=0.052$). Neither VL nor total mid-thigh thickness delta scores were different between groups ($p=0.46$ and $p=0.14$, respectively). There were no between-group differences in delta scores for 1RM Squat ($p=0.15$), 1RM overhead press ($p=0.37$), 400-m sprint times ($p=0.90$) or VO_{2max} ($p=0.57$). **CONCLUSIONS:** Ketogenic dieting improves body composition without negatively impacting muscle mass and/or aerobic, anaerobic or strength performance in recreational cross-trained subjects.

 (No relationships reported)

BACKGROUND: Regular exercise has been shown to diminish the risk of certain cancers. DMBA, (7, 12-dimethylbenz(a)-anthracene) is a complete carcinogen that is used to induce tumors in mice. It has yet to be established whether DMBA has an effect on voluntary wheel running (WR) in mice, and whether these effects may be exacerbated via consumption of a high fat high sugar (HFHS) diet. **PURPOSE:** Determine if DMBA treatment altered voluntary WR in female SENCAR mice, and whether a HFHS diet exacerbated treatment effects on voluntary WR. **METHODS:** Offspring of SENCAR breeder pairs were weaned at 3 weeks (wks) of age onto either an ad lib fed HFHS (20% protein, 45% fat/24% sucrose + 10% fructose water) or a diet restricted (DR) (12% kcal restriction, 20% protein, 10% fat, 57% cornstarch) diet. Animals were double-housed and randomly assigned to either a DMBA (n=40) treatment with HFHS (n=20) and DR (n=20) diets; or a control (CNTL) (n=18) treatment with HFHS (n=10) and DR (n=8) diets. At 4 wks of age, two plastic running wheels were mounted inside standard rat cages, and connected to a computer to record WR duration and distance. At 7-9 wks of age, mice were gavaged with DMBA dissolved in corn oil (20 µg/mouse/day) or with corn oil vehicle only (CNTL) for 5 days/wk for 6 weeks. A two-way ANOVA was employed to determine the effect of DMBA on activity with factors of treatment and diet for wks 9-20. **RESULTS:** Compared to CNTL, DMBA significantly decreased distance (7.41 ± 0.45 vs. 11.08 ± 0.68 km/day; $p=0.0002$), and duration (175.19 ± 8.24 vs. 261.23 ± 12.36 min; $p<0.0001$). No significant difference in speed was noted (40.31 ± 1.37 vs. 40.34 ± 2.05 m/min; $p=0.77$). HFHS diet compared to DR diet significantly decreased distance (5.84 ± 0.60 vs. 11.08 ± 0.55 km/day; $p<0.0001$), duration (168.41 ± 10.9 vs. 233.14 ± 10.1 min; $p<0.0001$), and speed (33.04 ± 1.81 vs. 47.12 ± 1.67 m/min; $p<0.0001$). No significant interactions were observed between treatment and diet groups. **CONCLUSIONS:** DMBA and HFHS diet decrease WR distance and duration, while only the HFHS diet decreased WR speed. Although DMBA and HFHS independently decreased WR, a lack of interaction suggest that they are not additive or synergistic. **ACKNOWLEDGMENTS:** Project was funded by the US Army through the Department of Defense projects W81XWH-13-1-0278 (Fuchs-Young) and W81XWH-13-1-0279 (Lightfoot).

(No relationships reported)

The efficacy of compression garment (CG) application in exercise performance and recovery remains controversial, as limited information exists on the physiological mechanisms of CG action, specifically its effect on vessel morphological and systemic hemodynamic responses.

PURPOSE: To investigate the effect of thigh-length compression tights (CG) on leg vessel morphological and systemic hemodynamic responses in healthy participants.

METHODS: Leg vessel caliber in thirty-two participants (16 males and 16 females) was measured, using 0.25T MRI, at four leg positions; calf, knee, lower-thigh and mid-thigh, in both a supine and upright position. Exerted pressure (EP) from three CGs (Low: G1; Medium: G2; High: G3) were measured at the four leg positions on the right leg during standing. Systemic hemodynamic variables including cardiac output (CO), stroke volume (SV), heart rate (HR), systolic blood pressure (SBP), diastolic blood pressure (DPB) and systemic vascular resistance (SVR) were monitored using non-invasive Doppler ultrasound, in a supine and upright position.

RESULTS: The average EP from G1, G2 and G3 were 2.2 ± 1.3 , 12.2 ± 3.7 and 26.7 ± 8.1 mmHg, respectively. The EP at the calf was higher than in the other leg positions ($P < 0.001$). CO, SV, HR, DBP and SVR were lower in the upright than supine position ($P < 0.001$). Wearing G3 elicited higher CO than wearing G2 ($P < 0.005$) but not G1 ($P > 0.05$). SV was higher in G3 compared to G1 and G2 ($P < 0.05$). Deep vein and great saphenous vein (GSV) calibers were larger at all leg positions in the upright than supine position ($P < 0.001$). Furthermore, G3 elicited smaller superficial vessels caliber than G1 and G2, but the largest deep vessels caliber at calf level ($P < 0.001$) only. The G3 also elicited the smallest GSV caliber followed by G2 and G1 respectively, at knee level ($P < 0.001$). The G1 elicited the largest but similar GSV caliber, among G2 and G3, at lower-thigh and mid-thigh level ($P < 0.005$).

CONCLUSIONS: Leg vessel morphological and systemic hemodynamic responses to compression garment application were greatest in compression garments with a higher exerted pressure and were most pronounced at the calf level.

(No relationships reported)

Spinning (SP) is a very popular indoor stationary cycling advertised as an efficient exercise to foster cardiovascular fitness and weight loss. However, its absolute and relative cardiovascular intensity has been poorly described.

PURPOSE: To evaluate the cardiovascular strain during regular SP classes performed by women.

METHODS: We evaluated 23 women (36.9 ± 11.3 yrs; BMI 24.0 ± 4.1 kg/m²), from 5 fitness centers randomly selected in Brasília-Brazil. Cardiovascular strain was evaluated by the absolute and relative time spent in different effort intensities and by the heart rate (HR) in different moments during SP classes. HR was registered with a RS800 Polar monitor. Each volunteer was monitored in 3 classes to obtain the mean HR of each moment. Effort intensity was classified in 4 HR zones based on percentage of predicted Maximal HR (MHR=220-age): very heavy ($\geq 94\%$); heavy (77-93%); moderate (64-76%) and light (<64%). HR was analyzed in 4 moments: initial (in) (5min average-HRin), highest HR (HRpk), class ending (5min average-HRe1) and after cool down (HRe2). Data was non-normal (Shapiro-Wilk) and presented as median (min-max) values. HR comparisons used Friedman/Dunns post-hoc test at 5% level of significance.

RESULTS: HRpk 167 (127-186)bpm was greater than HRin: 90 (60-122)bpm, HRe1: 135 (111-150)bpm and HRe2: 113 (89-137)bpm ($p < 0.05$). The HRe1 was greater than HRin ($p < 0.05$), but similar to HRe2, which was similar to HRin ($p > 0.05$). Absolute

and relative increase of HR to HRpk was 74 (34-111)bpm, 80.9 (36.6-185.0)%, respectively. The HRe1 reduced 26 (13-57)bpm or 19 (11.4 - 44.2)% from HRpk. HRe2 was similar to HRin ($p > 0.05$). Absolute and relative time in each HR zone are shown in Table_1.

HR Zone	Absolute (min:sec)		Relative (%)	
	Median	Extremes	Median	Extremes
Light	7:06	2:05 - 19:07	15.3	5.0 - 43.1
Moderate	11:00	3:08 - 37:36	23.6	6.4 - 64.2
Heavy	25:00	8:00 - 35:00	50.2	1.5 - 79.3
Very heavy	0:02	0:00 - 13:08	0.1	0.0 - 27.5

CONCLUSIONS: We observed high cardiovascular strain. SP classes were performed usually on heavy or very heavy intensity (50.3%), which deserves safety considerations. The cool down period was effective in reestablishing HR to its initial pattern since HRin and HRe2 were similar.

Cardiorespiratory Responses to a 20-minute Shallow Water Tabata Style Workout: A Gender Comparison

Mitchell G. Fisher, Leonardo J. D'Acquisto, Karen Roemer, Debra D'Acquisto, Jerusalem Tesfaye. Central Washington University, Ellensburg, WA.
Email: fishermi@cwu.edu
(No relationships reported)

PURPOSE: To compare physiological responses to a 20-min high intensity, Tabata-style shallow water exercise workout (TS-SWE) between healthy males (M, n=9, 24±1 y) and females (F, n=9, 26±6 y). **METHODS:** Participants first performed an incremental SWE test to exhaustion while metabolic (indirect calorimetry), heart rate (HR, telemetry) and blood lactate (Bla) responses were monitored. On a second visit, metabolic, HR, rating of perceived exertion (RPE, Borg scale 6-20), and Bla were measured while participants performed TS-SWE. TS-SWE consisted of 4, 4-min bouts with each bout alternating between 20s "all-out" exercise followed by 10s rest. Each bout was separated by 1 min rest (total of 32 "all-out" 20s efforts). For both visits, participants were immersed to axillary level at a water temp. of 83 F. **RESULTS:** M had a greater peak VO₂ and Bla (3.6 ± 0.4 vs 2.7 ± 0.3 l·min⁻¹; 10.9 ± 1.3 vs 8.1 ± 1.7 millimolar (mM); $p < 0.05$) while peak HR was similar (185 ± 7 (M) vs 181 ± 7 bpm (F) ($p > 0.05$)). For the overall TS-SWE workout, %VO₂ peak for M and F was 72.9 ± 4.7 and 72.4 ± 6.5 , respectively, while %HR peak was 83.9 ± 4.9 (M) and 86.3 ± 2.2 (F), ($P > 0.05$). RPE for the overall workout was ~18-19 (very, very hard) for both M and F. %VO₂ peak for M and F was similar for each bout and increased from ~70% (Bout 1), 74% (Bout 2), to 77% (Bout 3) with the greatest metabolic load achieved during Bout 4 (~85%) ($P < 0.05$, main effect bout). %HR peak was also similar between M and F for each bout: ~82% (Bout 1), 85% (Bout 2), 88% (Bout 3) and ~94% for Bout 4 ($P < 0.05$, main effect bout). Bla (mM) was similar between M and F for bout 1 (6.3 ± 1.8 vs 5.2 ± 1.6 , respectively ($p > 0.05$)), however, males accumulated a greater Bla in bouts 2 (9.0 ± 2.0 vs 6.0 ± 1.0), 3 (9.3 ± 2.3 vs 5.9 ± 0.9) and 4 (11.1 ± 2.2 vs 9.2 ± 1.7) ($P < 0.05$). **CONCLUSION:** TS-SWE elicited cardiometabolic and psychophysical responses for both males and females that are classified as vigorous to near-maximal to maximal intensity according to the American College of Sports Medicine. Furthermore, the presence of a cardiometabolic "end-spurt", as reflected in a substantially greater %VO₂, %HR peak, and blood lactate response during bout 4, suggests that a pacing strategy may have been employed despite a-priori instructions to exercise "all-out" throughout the workout.

Long-term Effects Of Exercise On Cardiovascular Disease Risk Profile Following Weight Loss In Overweight Women

Lyndsey Hornbuckle¹, Barbara A. Gower², Stephen J. Carter², Gary R. Hunter, FACSM². ¹University of Tennessee, Knoxville, Knoxville, TN. ²University of Alabama at Birmingham, Birmingham, AL. (Sponsor: Gary R. Hunter, FACSM)
(No relationships reported)

Despite the widely recognized benefits of weight loss, minimal research has examined the longitudinal effects of exercise training on cardiovascular disease (CVD) risk factors after weight loss. **PURPOSE:** To evaluate the long-term influence of exercise training on CVD risk factors after weight loss in previously overweight women.

METHODS: A randomized weight loss trial was conducted in 64 premenopausal women (BMI 28.3 ± 1.2 kg/m²; age 33.7 ± 6.4 yrs). Participants were assigned to either aerobic training (AT: continuous treadmill exercise at 67-80% of maximum heart rate), resistance training (RT: 10 total body exercises at 65-80% of 1-RM), or control (C: no exercise). All groups consumed a standardized diet until achieving

BMI <25kg/m². Exercise groups trained 3x/wk during the weight loss period and were encouraged to exercise 2x/wk for one yr following the initial weight loss. Body weight, % body fat, abdominal fat, resting blood pressure (BP), insulin sensitivity, total cholesterol (TC), high-density lipoprotein (HDL) cholesterol, and triglycerides (TG) were measured. Two-way repeated measures ANOVA was used to analyze dependent variables at baseline, post-intervention, 1 yr post intervention, and 3 yrs post intervention. Post hoc paired sample t-tests were used to examine changes from baseline to 3 yrs post intervention. Significance was accepted at $p \leq 0.05$. **RESULTS:** Mean weight loss for all subjects was 11.92 kg. Significant group x time interactions were found for body weight, % body fat, systolic BP, TG, HDL, and TC:HDL ratio, with no significant interactions for any other variable. Three yrs after weight loss, body weight (74.9.4±5.7 to 71.1±9.6 kg), body fat (39.7±3.9 to 35.9±6.2%), systolic BP (120.0±13.0 to 111.4±8.0 mmHg), HDL (42.0±13.4 to 55.1±11.9 mg/dL), and TC:HDL ratio (4.2±1.6 to 3.3±1.2 mg/dL) were significantly improved from baseline in AT. TG (87.5±32.2 to 74.3±27.0 mg/dL), HDL (41.2±8.9 to 49.4±13.4 mg/dL), and TC:HDL ratio (3.9±0.8 to 3.5±0.8 mg/dL) significantly improved from baseline in RT. C had no differences. **CONCLUSIONS:** Three yrs after initial weight loss, several CVD risk factors were more favorable in women who exercise trained compared to non-exercisers. Further longitudinal research examining the effects of exercise on the maintenance of improved CVD risk factors is warranted.

Cardiovascular Risk Profiles Of World Masters Games Participants

Mark DeBeliso, FACSM¹, Joe Walsh², Tim Heazlewood², Trish Sevens³, Kent J. Adams, FACSM³, Mike Climstein, FACSM⁴.
¹Southern Utah University, Cedar City, UT. ²Charles Darwin University, Darwin, Australia. ³California State University Monterey Bay, Seaside, CA. ⁴University of Sydney, Sydney, Austria.
 (No relationships reported)

Increasing evidence indicates adherence to exercise throughout life is concurrent with improved health. World masters games (WMG) have more participants than any other international sporting competition and is under investigated, particularly with regard to indices of cardiovascular disease (CVD) risk. **Purpose:** This study investigated selected CVD risk factors in WMG participants. **Methods:** This was a cross-sectional, observational study which utilized a web-based questionnaire to survey cardiovascular risk factors of WMG participants. The survey consisted of three sections: basic demographics, medical history and physiological parameters which included body mass index (BMI), waist circumference (WC), resting blood pressure (BP) and lipids (total cholesterol (TC), high density lipoprotein (HDL) and low density lipoprotein (LDL)). **Results:** A total of 1,435 participants (567 female & 868 male), aged 27-91 years participated in the study. Key findings included significant differences between genders where females were significantly lower in BMI (5.3%, $p < 0.001$), WC (10.6%, $p < 0.01$), resting SBP (5.8%, $p < 0.01$), resting DBP (8.4%, $p < 0.01$), significantly higher in HDLs (15.2%, $p < 0.001$) and significantly lower in both the TC:HDL ratio (12.6%, $p < 0.001$) and LDL:HDL ratio (19.0%, $p < 0.001$). Significant differences ($p < 0.001$) were also identified when comparing WMG lipid results to the Australian general population (AGP). WMG demonstrated healthier TC (4.47±1.11 mmol/L), HDLs (1.75±0.79 mmol/L), and LDLs (2.92±0.96 mmol/L) when compared to AGP parameters (TC: 5.07 mmol/L, HDL: 1.34 mmol/L, LDL: 3.13 mmol/L). **Conclusions:** WMG participants demonstrated improved values in a number of CVD risk factors when compared to the general population with female WMG participants presenting healthier CVD risk factors when compared to males. Hence, within the parameters of this study, masters athletes exhibit evidence of superior health when compared to the general population within Australia.

Progressive, High Intensity Endurance Exercise Training Significantly Increases Maximal Cardiac Power Output In Middle Aged, Previously Sedentary Adults

Dean Palmer, Sheryl Livingston, Erin Howden, Mitchel Samels, FACSM, Braden Everding, FACSM, Tom Sarma. IEEM, Dallas, TX. (Sponsor: Dr. Benjamin Levine, FACSM)
 (No relationships reported)

High intensity, endurance exercise increases maximal cardiac power output (CPO) in young, healthy adults. It is less clear whether such gains are realized among sedentary adults who begin such a program during middle-age. **PURPOSE:** To determine whether a progressive, high-intensity endurance exercise program will increase CPO in healthy, middle-aged adults. **METHODS:** We studied 51 middle-aged adults (22 males; 52.7 ± 5.1 yrs). 23 (10 males) were randomized to a non-aerobic exercise group (Control). The remaining 28 (12 males) were assigned to an endurance training group (Exercise), all of whom completed a 24 month exercise training program. This progressive regimen was gradually expanded from 3*30min moderate intensity
