Purpose: As nitric oxide (NO) is both an important vasodilator and considered antiatherogenic, inhibiting nitric oxide synthase (NOS), to assess the role and bioavailability of NO, is commonplace. However, the physiologic window of effect in the human vasculature for the often used NOS inhibitor, L-NMMA, has not been well characterized and hence, this form of NOS inhibition is typically employed last in experimental protocols or on a separate day. Therefore, this study sought to quantify the duration of the measurable physiologic effects of L-NMMA in the peripheral vasculature. **Methods:** The passive leg movement (PLM) assessment of vascular function, which has been documented to be predominantly NO mediated, was performed in 7 young male subjects under baseline conditions, immediately following L-NMMA infusion (0.24 mg/dl/min) into the common femoral artery and then again at 45-60 and 90-105 minutes post infusion. The leg blood flow (LBF) response to PLM, assessed with Doppler ultrasound and expressed as the change from baseline to peak (Δ LBF_{peak}) and area under the curve (AUC), was utilized to assess the effect of L-NMMA on NO-mediated vascular function over the course of the experiment. **Results:** Immediately after the L-NMMA infusion, Δ LBF_{peak} and LBF AUC were significantly attenuated by 38% and 69%, respectively. However, within 45-60 minutes following the L-NMMA infusion neither PLM-induced Δ LBF_{peak} nor LBF AUC were significantly different from baseline and this was still the case at 90-105 minutes post infusion. **Conclusions:** These findings reveal that the potent reduction in NO bioavailability afforded by NOS inhibition with L-NMMA has a window of effect of less than 45-60 minutes in the human vasculature. These data can be used to guide experimental design using this pharmacological approach.

F-10 Thematic Poster - Don't be a Cry Baby: Research in Pregnancy, Child Birth, and Early Life

Longitudinal Trends for Pregnancy Physical Activity as Assessed through Objective and Self-Report Methods

Taylor E. Heppner, Christopher P. Connolly, Robert D. Catena. *Washington State University, Pullman, WA.*

(No relationships reported)

Previous investigations have suggested an overall decrease in physical activity (PA) as pregnancy progresses. Longitudinal investigations of these trends are scarce and have primarily utilized self-report assessments, rather than objective methods. **PURPOSE:** To 1) longitudinally examine month-specific trends in PA during pregnancy and to 2) compare self-report and objective methods of assessing month-specific PA. **METHODS:** Pregnant women (N=23) were recruited to participate in a longitudinal investigation examining anthropometric change, dynamic balance, and PA levels throughout gestation. The assessment of PA occurred each month of pregnancy via two methods: 1) wearing a validated pedometer for seven days and 2) taking an online survey. Following each monthly visit to our laboratory for testing, participants were provided with the pedometer and wearing instructions. Pedometer data included number of steps and amount of time (minutes) each participant was active each day. For analytic purposes, data for a minimum of three week days and one weekend day (converted to steps/day) was used to represent participant activity each month. The monthly online survey queried participants on typical moderate and vigorous-intensity physical activity (MVPA) per day (converted to minutes/week). Month-to-month contrasts and trend analyses were conducted for both pedometer steps/day and minutes/week of MVPA. **RESULTS:** Participants had a mean age 28.7 years at recruitment, with 55.2% being first-time mothers. Mean pedometer-recorded steps/day during pregnancy was 5,491 \pm 2,086 and mean self-reported minutes/week of MVPA was 106.8 \pm 150.6. Mean steps/day significantly differed month-to-month as pregnancy progressed ($F(7, 56)=4.79$, $p<0.001$), with a reduced overall trend. Specifically, steps/

day recorded for pregnancy months five and eight were significantly lower ($p<0.05$) than month four. Our findings reveal a reduced overall trend for MVPA minutes/week as pregnancy progressed, but no significant differences were found month-to-month ($F(7, 56)=1.37$, $p=0.236$). **CONCLUSION:** Pregnant women become less active in the later months of pregnancy according to both objective and self-report methods. Clear variability exists between objective and self-reported PA among pregnant women.

Wrist-Worn Accelerometry Usage in Primiparous Early Postpartum Women

Ali E. Wolpern, 84112, Kyle J. Sherwin, 84112, Whitney D. Moss, Ingrid E. Nygaard, Marlene J. Egger, Timothy A. Brusseau, Janet M. Shaw, FACSM. *University of Utah, Salt Lake City, UT.* (Sponsor: Janet M. Shaw, FACSM)
 Email: ali.wolpern@utah.edu

(No relationships reported)

The early postpartum period (6 weeks) presents major lifestyle change to new parents. Is wearing a wrist-worn accelerometer acceptable to first-time mothers in early postpartum? **PURPOSE:** To describe wrist-worn accelerometry usage in primiparous, early postpartum women.

METHODS: We analyzed wear characteristics, including mean (\pm SD) days of wear and the mean minutes (\pm SD) of wear/day, of women enrolled in the first year of the Motherhood And Pelvic Health Study and determined the proportion of women who met the wear time standards of large published surveillance studies. We asked women to wear a tri-axial accelerometer continuously on the non-dominant wrist (1440 minutes=24 hours) over two specific 7-day periods, 12 to 25 days (T1) and 33 to 46 days (T2) postpartum. Study staff delivered accelerometers to women and verbally reinforced the protocol. We used the Choi et al. (2011) algorithm to determine wear/non-wear time. We assigned 0 days and 0 minutes of wear to women who wore the device outside of prescribed time periods. We excluded from analysis women that we were unable to contact before T1/T2 and those who had device failure.

RESULTS: For T1, 201 were eligible; 17 could not be contacted and 6 had device failures, leaving 178 women for analysis. For T2, 161 were eligible; 10 could not be contacted and 5 had device failures, leaving 146 women for analysis. At T1, most women (N=166, 93.3%) wore the device for 7 days (mean=6.8 \pm 1.0 days) with an average wear time of 1348.0 \pm 135.8 minutes/day. A slightly lower proportion of women (N=126, 86.3%) wore the device for 7 days (mean = 6.7 \pm .88 days) at T2 with an average wear time of 1311.3 \pm 148.0 minutes/day. Two women at T2 and 1 woman at T1 did not wear the device during the prescribed time intervals. Nineteen women at T1 and 17 at T2 averaged 1440 minutes per day (perfect wear). At T1, 96.1% (N=171) and at T2, 93.2% (N=136) of women met the NHANES wear standards. At T1, 90.4% (N=161) and at T2, 82.2% (N=120) of women met the Whitehall II Study wear standards.

CONCLUSION: Despite the challenges inherent in conducting research about physical activity in newly postpartum women, our results indicate that adherence to wrist-worn accelerometry in this population is high.

Physical Activity Monitor Accuracy Among Pregnant Women During Overground Walking

Christopher P. Connolly¹, Jordana B. Dahmen¹, Alexander H. K. Montoyo². ¹Washington State University, Pullman, WA. ²Alma College, Alma, MI.

Email: c.connolly@wsu.edu

(No relationships reported)

Various physical activity monitors have demonstrated respectable step-count accuracy when worn by pregnant women during treadmill walking, particularly at faster speeds. However, it is unclear if this accuracy extends to overground walking, a far more common free-living modality. **PURPOSE:** This study examined the step-count accuracy of five commonly-used physical activity monitors among pregnant women during overground walking at self-paced speeds. **METHODS:** Twenty-nine pregnant women (19 second trimester, 10 third trimester) completed six overground walking trials while wearing three consumer-grade activity monitors (FB, OM, NL) and two research-grade activity monitors (AG, SW). All walking trials consisted of 100 steps, as measured by a hand-tally counter, which served as our criterion measure. Participants were instructed to walk the first three trials at a "normal pace" and the final three trials at a "brisk pace". Steps recorded during each trial were recorded or downloaded for each device in order to calculate mean absolute percentage error (MAPE) ([|criterion measure - monitor measure| / criterion measure] x 100). One-way ANOVAs were performed to determine whether MAPE differed between monitors and also whether pregnancy trimester affected monitor accuracy. Pairwise comparisons with Bonferroni adjustments were performed to explore specific differences between monitors. **RESULTS:** Significant differences were found between monitor MAPE

for normal-pace walking trials ($F(4, 140)=8.66, p<0.001$) and also brisk-pace trials ($F(4, 140)=30.07, p<0.001$). For normal-pace trials, MAPE for the SW (2.67%), NL (4.61%), and OM (4.82%) was significantly lower/better ($p<0.05$) than that for the AG (12.34%) and FB (13.66%). For brisk-pace trials, MAPE for the SW (2.01%) was significantly lower ($p<0.05$) than that for the NL (4.95%), AG (10.64%), and FB (24.61%), but not the OM (2.74%). Trimester was not found to significantly affect accuracy of any monitor at either normal or brisk paces.

CONCLUSIONS: The research-grade SW monitor is highly accurate for overground walking during pregnancy. The OM and NL, while not research-grade, are also accurate tools for overground walking and represent a cost-effective alternative for the consumer or for future pregnancy walking intervention trials.

 (No relationships reported)

Reduced Physical activity (PA) levels have been associations with female-specific life events including pregnancy. Studies in adult women suggest that decreases in PA may persist after childbirth. However, there is little understanding of post-birth PA trends in adolescent females.

Purpose: To examine changes in PA after childbirth in adolescents.
Methods: The Pittsburgh Girls Study collected time-stamped step count data for 7 days, annually from 2010-2013 with a validated monitor, in a local population representative sample of 1045 adolescent females in Pittsburgh, PA (baseline age: 14-17 years). This analysis examines PA in the 95 participants with ≥ 3 days of valid step data who gave birth for the first time between 2009 and 2013. Change in average total steps/day over the 4 years was determined with mixed models (using a step down approach). All models were adjusting for, age cohort, winter wear time (y/n), weekend wear time (y/n), and average daily wear time (minutes/day). The effects of age at pregnancy and race/ethnicity [Non-Hispanic African American (NHAA)/ All Others] were also examined.

Results: At baseline, girls that gave birth during the study period were more likely to identify as NHAA, have lower socio-economic status (all $p<0.001$), and were slightly older (mean [sd] age 16 [.98] vs. 15.4 [1.1] years) than girls who did not give birth. The mean (sd) age at pregnancy was 17 (1.3) years. The final model included the *a priori* covariates and race/ethnicity. Adjusted mean (sd) step counts/day were 7260(577) in the year before pregnancy. The adjusted mean (sd) change in step counts/day from the year before to the year after pregnancy was -2065 (735); $p=0.004$. Overall, 61% of the girls recorded < 5000 mean steps/day in the year after pregnancy versus 41% in the year before pregnancy. There was a non-significant upward trend in mean step counts in subsequent post-pregnancy years. For comparison, girls not experiencing a pregnancy had little change in step counts over the 4 year follow-up (adjusted mean [sd] change: -152 [140], $p=0.05$).

Conclusions: There was a significant drop in PA levels post-pregnancy in this cohort. More than half of these girls could be considered *sedentary* post-pregnancy (<5000 steps/day). Based on this cohort, efforts to improve post-pregnancy PA levels are warranted in adolescent mothers.

The Pregnancy Physical Activity Questionnaire (PPAQ) is a commonly used tool to assess pregnant women's current physical activity levels. However, few studies have evaluated the level of agreement between the PPAQ and physical activity measurement devices during free living conditions at multiple time points throughout pregnancy.

PURPOSE: The purpose of this study was to compare the PPAQ and device based physical activity assessment across phases of pregnancy and postpartum.
METHODS: Physical activity behaviors of 38 women were quantified by the PPAQ and accelerometers worn at the right hip and ankle, at approximately 21 and 32 weeks of pregnancy, and 12 weeks postpartum. Women were evaluated at least eight hours

per day for at least five days of a week. Percent time spent in light, moderate, and vigorous physical activity were compared between the PPAQ and accelerometers using a two-way repeated measures analysis of variance (ANOVA).

RESULTS: Percent of total physical activity time spent in light and moderate activity levels was similar between hip (93.1, 5.7%, respectively) and ankle (89.4, 5.7%, respectively) accelerometers, compared to 47.8, 40.3%, respectively, for the PPAQ ($P<0.01$). Specifically, the PPAQ results indicated significantly less time in light physical activity and more time in moderate activity. In addition, the hip and ankle accelerometers and the PPAQ showed significantly different percent of total physical activity time spent in vigorous activity (1.0, 4.7, 11.8%, respectively, $P<0.01$).

CONCLUSIONS: In free living conditions, accelerometer placement at hip and ankle resulted in similar percent wear time among physical activity intensities, regardless of pregnancy time point. In contrast, greater moderate and vigorous physical activity was recorded via PPAQ survey. These results are similar to those found with nonpregnant adults (Troiano et al., 2008). Researchers should use caution when utilizing and comparing the results of these two physical activity measurement modalities during pregnancy and the postpartum period.

Mother's Smoking Status during Pregnancy on Child's Motor Development: A Propensity Score Analysis

Zezhao Chen, Yan Yang, Zhou tao Pei, Hao Jiang, Weimo Zhu, FACSM. University of Illinois at Urbana Champaign, Urbana, IL.
 Email: ZCHEN106@ILLINOIS.EDU
 (No relationships reported)

PURPOSE: To determinate the impact of a mother's smoking status during pregnancy on a child's motor development using a propensity score (PS) analysis, a statistical method for evaluating treatment effects when using nonexperimental or observational data.

METHODS: Five NHANES National Youth Fitness Survey 2012 data sets, "Demographic Variables," "Physical Functioning," "Early Childhood," in which mother's smoking status during pregnancy was asked, "Physical Activity," and "Test of Gross Motor Development (TGMD-2)" were merged. By matching 10 variables, including "Sex of the child," "At least one adult aged 60 years or older living in the participant's household," "the household reference person's sex," "Weight at birth, pounds," "Your child was overweight," "Crawl, walk, run, play limitations," "Impairment requiring special equipment," "Receive Special Ed or Early Intervention," "Days physically activity least 60 min," and "Hours watch TV or video past 30 days," a regression model was employed for the PS analysis (with inverse probability weighting adjustment and greedy algorithms with 1:1 matching; the covariate adjustment were used to estimate the effect of "Did biological mother smoke at any time while she was pregnant" on a child's gross motor development). The full sample weights were used for the analysis. **RESULTS:** The negative impacts of a mother smoking while pregnant on their child's motor development, with and without the PS analysis, are summarized below:

	Total		Loco Motor		Objective control	
	No-PS	PS	No-PS	PS	No-PS	PS
Smoked	91.18 ±14.30	91.18 ±14.30	26.09 ± 11.28	26.09± 11.28	18.33 ±7.89	18.33± 7.89
Didn't-Smoke	96.06 ±14.57	99.27 ±12.32	28.62± 10.26	29.06± 8.81	21.64 ±8.42	22.51± 7.81
Difference	4.88	8.09	2.53	2.96	3.31	4.18
t-value	-1.85	-2.65	-1.23	-1.25	-2.27	-2.16
p-value	0.07	0.01	0.22	0.21	0.02	0.03
ES	0.34	0.60	0.23	0.29	0.40	0.53

CONCLUSION: By applying the PS analysis, the negative impact of mothers smoking status during pregnancy on children's gross motor development was further confirmed.

Early Pregnancy Leisure Time Physical Activity and Circulating MicroRNAs
 Sylvia E. Badon¹, Alyson J. Littman¹, KC Gary Chan¹, Michelle A. Williams², Daniel A. Enquobahrie¹. ¹University of Washington, Seattle, WA. ²Harvard T.H. Chan School of Public Health, Boston, MA.
 Email: sbadon@uw.edu
 (No relationships reported)

Leisure time physical activity (LTPA) during pregnancy is associated with pregnancy complications and fetal outcomes. Epigenetic mechanisms potentially play key roles in these associations. Few studies have investigated epigenetic biomarkers in relation to LTPA.

Purpose: To determine if maternal LTPA in early pregnancy is associated with candidate circulating microRNAs (miRNAs), epigenetic biomarkers with post-transcription regulatory roles.

Methods: This was a cross-sectional study conducted among participants (N=74) of the Omega study, a pregnancy cohort study. Participants self-reported LTPA duration (hours/week) and energy expenditure (MET-hours/week) during an interview in early pregnancy (16 weeks gestation, on average). LTPA was considered both as a continuous variable and categorized according to current American College of Sports Medicine recommendations for physical activity (not active, active<150 minutes/week, active≥150 minutes/week). Levels of circulating microRNAs (miR-126-3p, 146b-5p, miR-155-5p, miR-21-3p, miR-210-3p, miR-222-3p, miR-223-3p, miR-517-5p, miR-518a-3p, miR-29a-3p), selected based on their role in pathophysiological pathways (e.g. inflammation, oxidative stress, and placental function) related to pregnancy complications and outcomes, were measured using qRT-PCR. Linear regression adjusted for maternal age and gestational age at blood draw was used to determine beta estimates and 95% confidence intervals.

Results: Each additional hour or MET-hour/week of LTPA was not associated with levels of circulating miRNAs (all P>0.05). Compared to women who were not active, women who were active but did not meet recommendations had higher levels of circulating miR-517-5p (β=0.24; 95% CI: 0.06, 1.0; P=0.05). Compared to women who were active below recommended levels, meeting or exceeding recommendations was associated with higher levels of circulating miR-517-5p (β=3.7; 95% CI: 0.99, 14; P=0.05). Early pregnancy LTPA was not associated with levels of other circulating miRNAs.

Conclusion: Maternal LTPA in early pregnancy may be associated with circulating levels of miR-517-5p, a placenta-specific miRNA related to placental growth, development, and function.

2901 Board #8 June 2 1:00 PM - 3:00 PM
Step-Count Accuracy of Physical Activity Monitors During Pregnancy in Free-Living Conditions
 Jordana B. Dahmen¹, Christopher P. Connolly¹, Alexander H. K. Montoye². ¹Washington State University, Pullman, WA. ²Alma College, Alma, MI. (Sponsor: James M. Pivarnik, FACSM)
 (No relationships reported)

Previous studies have assessed the validity and reliability of physical activity monitors worn by pregnant women under laboratory conditions. However, physical activity monitors have not been assessed under free-living conditions in pregnant women.

PURPOSE: 1) Determine the step-count accuracy of four commercially-available physical activity monitors worn by pregnant women under free-living conditions and 2) examine the effect of pregnancy trimester on monitor accuracy. **METHODS:** Participants were pregnant women (n=28) in their second or third trimesters who were 18-40 years of age and free of contraindications to exercise during pregnancy. Participants wore three consumer-grade activity monitors (FB, OM, NL) and two research-grade activity monitors (AG, SW) for three days of free-living activity during all waking hours. Steps recorded over the three days for the FB, OM, NL, and AG were compared to SW recorded steps (the criterion measure) in order to calculate percentage of actual steps taken ([measured steps / actual steps] x 100). Paired-samples t-tests were performed to determine differences in accuracy between monitors and one-way ANOVAs were utilized to determine whether pregnancy trimester affected monitor accuracy. **RESULTS:** The analytical sample consisted of 18 women in their second trimester and 10 women in their third trimester with an overall mean gestational age of 23.9 ± 8.19 weeks and a mean daily step-count of 9354.3 ± 3363.9 steps (as determined by SW). Steps taken per day did not significantly differ between second and third trimester women (F(1, 26)=0.69, p=0.42). The FB and NL were most accurate with mean percentage of actual steps taken recorded at 69.9% and 69.5% respectively. The AG (t(27)=-3.13, p<0.01) and OM (t(27)=-6.27, p<0.001) performed significantly worse with 62.7% and 52.1% of actual steps. Trimester did not significantly affect monitor accuracy. **CONCLUSION:** Compared to the criterion, all other monitors underestimated actual steps taken, with the FB and NL demonstrating smaller underestimations than the AG and OM in a free-living environment. Accuracy of these monitors appears to be worse during pregnancy free-living conditions compared to results of studies performed in controlled laboratory conditions.

Voluntary Drinking Cessation Is Associated With Recovery Of Plasma Osmolality But Not Of Thirst Perception, Usg, Or Body Mass
 Catalina Capitan-Jimenez, Luis Fernando Aragon-Vargas, FACSM. University of Costa Rica, San Jose, Costa Rica. (Sponsor: Luis Fernando Aragon-Vargas, FACSM)
 Email: ktaucr@gmail.com
 (No relationships reported)

Post-exercise rehydration has been widely studied, with special emphasis on retention of ingested fluid; little research has been done on why we drink more or less. **Purpose:** To identify if voluntary drinking cessation coincides with a return to pre-exercise physiological values. **Methods:** 9 males consented to participate. They exercised intermittently (30 min bicycle-30 min treadmill, at 70-80% HRmax) in the heat (WBGT= 28.1±0.7°C), to a dehydration of 3.6±0.3% body mass (BM). Upon exercise termination, participants were instructed to drink as long and as much as they needed while monitoring water intake. When intake was less than 100mL in 15 min, that was considered the point of voluntary drinking cessation. Urine color (U_{color}), specific gravity (USG), and osmolality (U_{osm}), plasma osmolality (P_{osm}), fullness, and thirst perception (TP) were measured pre- and post-exercise, and post-rehydration. Matched pairs analyses were performed to compare pre-exercise and post-rehydration. **Results:** At the point of drinking cessation, participants had recovered 58.7±12% (1445-2427mL, min-max) of body mass loss.

Variable	Pre-exer (mean±SD)	Post- rehy (mean±SD)	t	p
P _{osm}	289.5±2.3	287.3±5.4	-1.11	0.300
U _{osm}	870.7±2.3	763.7±193.9	-1.49	0.175
Thirst	36.2±19.1	25.0±18.2	-2.32	0.049
BM	83.0±12.6	81.8±12.0	-3.99	0.004
USG	1.022±0.004	1.029±0.004	5.82	0.0004
U _{color}	3.4±0.7	6.3±1.1	6.83	0.0001
Fullness	3.1±0.9	2.1±1.1	-1.80	0.1080

Conclusion: the results suggest that voluntary drinking cessation coincided with a return to pre-exercise values of P_{osm}, U_{osm}, and fullness, even though rehydration was under 60%. Nevertheless, body weight, thirst perception, urine color and USG had not returned to pre-exercise values at the same point

Dehydration Impairs Exercise Performance Independent of Thirst Perception: A Blinded Study
 J.D. Adams, Yasuki Sekuguchi, Adam Seal, Hyun-Gyu Suh, Cameron Sprong, Lisa Jansen, Stavros A. Kavouras, FACSM. University of Arkansas, Fayetteville, AR. (Sponsor: Stavros A. Kavouras, FACSM)
 Email: jxa014@uark.edu
 (No relationships reported)

Hypohydration >2% body mass loss impairs endurance exercise performance, but the majority of previous studies are confounded by the lack of subject blinding. Previous blinding hydration studies have used intravenous infusion methods which bypass the oropharyngeal receptors and gastrointestinal tract which seems to play an important role on thirst, thermoregulation, and performance. **PURPOSE:** The purpose of this study was to examine the effect of hypohydration on exercise performance in a blinded manner using intra-gastric water delivery to manipulate hydration status, while thirst was matched between trials. **METHODS:** Seven male cyclists (weight: 71±8 kg, body fat: 14±6%, VO_{2peak}: 59.4±6 ml/kg/min) exercised for 2 hours on a cycle ergometer at 55% VO_{2peak} in a hot-dry environment (35 °C, 30% rh), with a nasogastric (NG) tube under euhydrated (EUH) and hypohydrated (HYP) conditions. In both trials, thirst was matched by drinking 25 mL every 5 min (300 mL/h). In the EUH sweat losses fully were replaced via the NG tube (calculated from the familiarization visit). Following the 2 hours of steady state, the cyclists completed a 5-kilometer cycling time trial at 4% grade. **RESULTS:** Following 2 hours of steady state cycling, post-exercise body mass loss for EUH trial was -0.1% compared to the HYP trial which was -2.2%. Thirst (28±11 vs. 42±12 mm) and stomach fullness (41±8 vs. 38±8 mm) did not

differ between EUH and HYP trials ($P>0.05$). Cyclists completed the 5km time trial faster in the EUH trial compared to the HYP trial (777 ± 47 vs. 822 ± 55 sec, $P<0.05$), while producing higher power output (295 ± 29 vs. 270 ± 26 W, $P<0.05$). During the 5 km time trial, core temperature was higher in the HYP trial (39.2 ± 0.3 °C) compared to the EUH trial (38.8 ± 0.2 °C; $P>0.05$). **CONCLUSIONS:** These data indicated that hypohydration decreased cycling performance and impaired thermoregulation in the absence of thirst, while the subjects were unaware of their hydration status.

 (No relationships reported)

It has been suggested that thirst can influence exercise performance independently of hydration.

PURPOSE: Therefore, the purpose of this study was to examine the effect of thirst on exercise performance during cycling exercise in the heat in dehydrated subjects. **METHODS:** Six male cyclists (weight: 71 ± 8 kg, body fat: $14\pm 6\%$, VO_{2peak} : 59.4 ± 6 ml/kg/min) exercised for 2 hours on a cycle ergometer at 55% VO_{2peak} , in a hot-dry environment (35 °C, 30% rh), while wearing a nasogastric tube. Two experimental trials were performed: a) Dehydration without thirst (DEH-NT) which participants drank 25 mL every 5 min (300 mL/h) with no infusion in nasogastric tube, and b) Dehydration with thirst (DEH-T) which participants were infused with 25 mL every 5 min via nasogastric tube but without drinking. Following the 2 hours of steady state, the cyclists completed a 5-kilometer cycling time trial at 4% grade. During the study, cyclists were unaware of the trial that were participating, the amount of water infused via the nasogastric tube and could not get any feedback regarding their cycling performance or their heart rate. **RESULTS:** Following 2 hours of steady state cycling, post-exercise body mass loss for the DEH-NT trial was $-2.2\pm 0.4\%$ compared to the DEH-T trial which was $-2.8\pm 0.3\%$. Thirst (42 ± 12 mm vs. 61 ± 15 mm; $P=0.007$) and stomach fullness (35 ± 8 mm vs. 54 ± 10 mm; $P=0.007$) were both significantly different between DEH-NT and DEH-T trials. Finishing time in the 5-km time trial was faster in the DEH-NT trial (784 ± 35 s) compared to the DEH-T trial (795 ± 47 s), however, two out of six participants in the DEH-T trial felt exhausted and could not even start the 5 K, time trial following 2 hours of steady state cycling. **CONCLUSION:** The data suggested that thirst had detrimental effect on cycling performance independent of hydration.

Effects of Dose Timing on Fluid Retention during Sodium-Aided Hyperhydration Protocols
 David Morris¹, Shelby Greene¹, Elizaveta Roslanova². ¹University of Texas, Odessa, TX. ²University of Texas, odessa, TX.
 Email: morris_da@utpb.edu
 (No relationships reported)

Co-consumption of sodium and water has been shown to be superior in promoting hyperhydration compared to consumption of an equal amount of water alone. Most sodium-aided hyperhydration studies have provided subjects with a bolus of fluid followed by a urine collection period. However the effect of providing equal amounts of fluid in a single vs. multiple doses over time on fluid retention has not been systematically studied. **PURPOSE:** To compare the effects of different dosing strategies on urine excretion levels following the consumption of consistent amounts of sodium and water. **METHODS:** Urine excretion was measured during three separate 2-hr hyperhydration protocols in 10 well hydrated male subjects (23 ± 3 yr, 176.1 ± 10.1 cm, 82.2 ± 19.4 kg) who were free from known renal, digestive, and cardiovascular disease. Each protocol began with a complete bladder void and assessment of urine specific gravity (USG). Subjects then consumed 20 mL $H_2O \cdot kg^{-1}$ and 110 mg $NaCl \cdot kg^{-1}$ in three different dosing strategies: the entire dose was consumed at the beginning of the period (1X), $\frac{1}{2}$ of the dose was consumed at the beginning and $\frac{1}{2}$ consumed after 60 min (2X), and $\frac{1}{3}$ of the dose was consumed at the beginning and $\frac{1}{3}$ was consumed after 45 and 90 min (3X). Protocols were administered in a randomized, crossover fashion. Total urine excretions (TUE) during the 2 hr collection periods were expressed as a percent of the H_2O consumed. USG and TUE were compared using repeated-measures ANOVA and Sidak *post hoc* analyses. **RESULTS:** USGs were 1.006 ± 0.004 (1X), 1.007 ± 0.003 (2X), and 1.008 ± 0.005 (3X) ($P=0.20-0.78$) indicating that subjects were well and similarly hydrated for each trial. TUE expressed as a percentage of H_2O consumed were $76\pm 15\%$ (1X), $68\pm 12\%$ (2X) and $55\pm 15\%$ (3X). No significant difference in TUE was detected between 1X and 2X ($P=0.25$) but significant differences were observed between 1X and 3X ($P=0.02$) and 2X and 3X ($P=0.01$). **CONCLUSION:** The data suggest that

hyperhydration is better achieved when water and sodium are consumed in three equal doses over 90 min when compared to consuming an equal amount of a sodium and water dose in a single bolus or in two equal doses over a 60 min period.

2907 Board #5 June 2 1:00 PM - 3:00 PM
Time-course Of Diuresis During Sodium-aided Hyperhydration Protocols With And Without Caffeine
 Elizaveta Roslanova, David M. Morris. University of Texas, Odessa, TX. (Sponsor: Alan Utter, FACSM)
 Email: lisa-roslanova@hotmail.com
 (No relationships reported)

When used alone, both caffeine and sodium-aided hyperhydration (SAH) can be ergogenic. Caffeine, when used in conjunction with SAH, promotes diuresis, but hyperhydration is still achieved, albeit at lower levels. Caffeine has been shown to be ergogenic when taken as little as 5 min, or as much as 6 hr prior to the start of exercise. Thus, determining the temporal aspects of caffeine induced diuresis when used in conjunction with SAH may lead to superior pre-exercise nutritional strategies. **PURPOSE:** To investigate the time-course of caffeine-induced diuresis during a 90 min SAH protocol. **METHODS:** Subjects were 15 males (21 ± 2 yr, 176 ± 6 cm, 80.2 ± 10.1 kg) free from known renal, digestive, and cardiovascular disease. Each underwent 2 hyperhydration strategies in a randomized, double-blind fashion. Both protocols began with a complete bladder void and measurement of urine specific gravity (USG) followed immediately by ingestion of a bolus of 20 mL $H_2O \cdot kg^{-1}$ combined with either 110 mg $NaCl \cdot kg^{-1}$ (Na) or 5 mg caffeine $\cdot kg^{-1}$ + 110 mg $NaCl \cdot kg^{-1}$ (CafNa). Subjects then rested quietly for 90 min, performing a measured bladder void every 15 min. Urine excretions were expressed as a percentage of the total fluid consumed during each of the hyperhydration protocols. USG and total urine excreted (TUE) during the trials were compared using paired t-tests. Urine excretion (UE) for each of the 15 min collection periods for the two conditions were compared using a two-way repeated measures ANOVA with Sidak *post hoc* analyses. Levels of significance were set *a priori* at $P<0.05$. **RESULTS:** USGs were 1.007 ± 0.003 (Na) and 1.005 ± 0.004 (NaCaf) ($P=0.34$). TUE were $62.7\pm 13.2\%$ (Na) and $78.7\pm 12.5\%$ (NaCaf) ($P=0.001$). UE for the Na and NaCaf for each collection period were $13.1\pm 7.5\%$, $21.9\pm 12.9\%$ (15 min, $P=0.001$), $11.7\pm 3.3\%$, $13.8\pm 3.8\%$ (30 min, $P=.30$), $13.2\pm 2.8\%$, $15.3\pm 2.4\%$ (45 min, $P=0.32$), $12.2\pm 4.1\%$, $13.7\pm 5.1\%$ (60 min, $P=0.46$), $8.4\pm 6.3\%$, $8.9\pm 4\%$ (75 min, $P=0.80$) and $4.7\pm 3.6\%$, $4.4\pm 2.8\%$ (90 min $P=0.87$). **CONCLUSIONS:** Results indicated that both protocols resulted in hyperhydration. TUE was significantly higher in NaCaf compared to Na; however, increased diuresis in NaCaf occurred only during the initial 15 min following consumption of the treatments.

The Effect of Tackling Form on Head Accelerations Experienced by Youth Football Players
 Eric Schussler¹, Richard Jagacinski², John Buford³, Ajit Chaudhari, FACSM², Susan White², James Onate². ¹Old Dominion University, Norfolk, VA. ²The Ohio State University, Columbus, OH.
 Email: schussler.eric@gmail.com
 (No relationships reported)

A head-up tackling style has been recommended to decrease head contact experienced during tackling. Specific performance metrics have been set to describe and instruct this tackling style including: extended neck position, vertical trunk, head across the front of the target, short steps, and low center of gravity. However, limited information exists regarding the effectiveness of the components of this tackling style on the head accelerations experienced by youth tacklers. **PURPOSE:** Determine the effect of components of a head up, tackling style on head accelerations. **METHODS:** Youth football players ages 9-13 (11.8 ± 0.8 age, 2.5 ± 2 years of experience) were fitted with the xPatch monitoring system (X2 Biosystems, Seattle WA) and tackled a weighted dummy in a laboratory setting. Out of 470 tackles the xPatch system recorded 231 tackles with a peak head acceleration over 6g. Motion data during these tackles were analyzed for cervical angle, trunk angle, pelvic height, step length, and head

and pelvic velocity. Correlational analyses were performed between each movement variable and peak linear acceleration (PLA), peak rotational acceleration (PRA) and Head Impact Criterion over 15ms (HIC15) measures from the xPatch. **RESULTS:** Significant correlations were found between: shoulder extension and PLA ($r=-.141$, $r^2=.020$, $p=.033$), trunk angle and PLA ($r=-.224$, $r^2=.050$, $p=.001$), trunk angle and PRA ($r=.202$, $r^2=.040$, $p=.002$), trunk angle and HIC15 ($r=.156$, $r^2=.023$, $p=.018$), step length and PLA ($r=.138$, $r^2=.019$, $p=.037$) and step length and HIC15 ($r=.131$, $r^2=.018$, $p=.048$). **CONCLUSIONS:** Despite significant correlations between measures of head acceleration and shoulder extension, trunk angle and step length the linear relationship between these values appears clinically negligible. The low strength of these relationships indicate these performance variables may not be responsible for the amount of head acceleration in low speed tackles. Additional analysis on this data should be completed to identify non-linear relationships and identify the interdependence of these variables. Measurements of live tackles during games and identification of other biomechanical parameters best correlated with head acceleration should also be determined, which could lead to more specific and effective tackling instruction.

Isometric Cervical Muscle Strength Does Not Affect Head Impact Kinematics in High School Boys' Lacrosse
 Patricia Kelshaw¹, Nelson Cortes¹, Amanda Caswell¹, Andrew Lincoln², Shane Caswell¹. ¹George Mason University, Manassas, VA. ²MedStar Sports Medicine, Baltimore, MD.
 Email: scaswell@gmu.edu
 (No relationships reported)

Male high school lacrosse has the second highest incidence of concussion in high school sports. Limited research has identified modifiable risk factors that may reduce head impact kinematics. Cervical muscle strength is a proposed modifiable risk factor for head impact kinematics.

PURPOSE: To assess the effects of isometric cervical muscle strength (ICMS) on head impact kinematics in high school boys' lacrosse. **METHODS:** Thirteen male high school varsity lacrosse players volunteered for this study (age = 16.5 ± 1.3 years, height = 1.76 ± 0.1 m, mass = 69.9 ± 10.6 kg). ICMS was measured for forward flexion, extension, and bilateral flexion. Data were collected for neck circumference, head circumference, and neck length. Participants' helmets were instrumented with an accelerometer for an entire season of game play. Video of all game play was captured and time synchronized with accelerometer data. All ICMS measures were normalized to the participants' body mass. Normalized ICMS tertiles were calculated and compared to impact kinematic data using a MANOVA. The relationship of neck anthropometric data and ICMS was investigated using a Pearson's correlation. An alpha level 0.05 was used for all analyses.

RESULTS: 12 games with 367 confirmed impacts (linear acceleration = 54 ± 36 g, rotational velocity = 1362 ± 1258 °/s) were recorded during the 2015 season. Neck circumference showed a positive moderate to strong relationship with ICMS in extension ($r=.63$, $p=.02$). No significant difference existed between ICMS tertiles for linear acceleration and rotational velocity ($p>0.05$).

CONCLUSIONS: Our findings contradict previous research that identified ICMS as a modifiable risk factor for mitigating head impact kinematics. Results suggest that cervical muscle strengthening programs for the reduction of head impact kinematics are not indicated at this time. However, our sample size was small and cervical muscle strengthening may have other potential benefits. Therefore, cervical muscle strengthening programs and potentially modifiable risk factors for reducing head impact kinematics should be further investigated. Supported by the US Lacrosse Sports Science and Safety Committee.

Head Impact Density A Better Estimator Of Concussion Than Threshold
 Steven P. Broglio, FACSM¹, Andrew Lapointe¹, Kathryn O'Connor¹, Michael McCrea². ¹University of Michigan, Ann Arbor, MI. ²Medical College of Wisconsin, Milwaukee, WI.
 (No relationships reported)

PURPOSE: Researchers have sought to identify a single or set of biomechanical variables that can accurately identify a concussive impact *in vivo*. The majority of this work has focused on the final impact prior to injury, failing to account for the influence of prior head impacts over time. This investigation sought to evaluate the relationship between both number and magnitude of head impacts over time in relation to concussion risk. **METHODS:** As part of an ongoing investigation of head impact mechanics, concussions in 29 high school football athletes (16.2 ± 0.9 years, 180.4 ± 5.9 cm, 83.5 ± 12.5 kg, and 0.8 ± 1.2 prior concussions) were captured between 2007 and 2014. Matched control athletes ($n=29$, 16.2 ± 0.7 years, 179.9 ± 9.0 cm, 94.0 ± 12.1 kg, and 0.4 ± 1.2 prior concussions) were selected based on similar final impact linear and rotational acceleration and the prior number of impacts in the season. Impact

magnitude occurring in the 24 hours prior to injury was evaluated using multivariate analyses of variance between groups. Impact counts were evaluated using visual inspection for the 24 hours prior to injury and independent samples *t*-tests in the final three hours. **RESULTS:** In the 24 hours prior to injury, there was no difference between groups in impact number, nor were there differences in cumulative linear or rotational acceleration magnitudes ($p>0.05$). Impact Density (ie impact magnitude divided by time from previous impact) was significantly greater for linear ($p=0.01$) and rotational ($p=0.04$) acceleration among the concussed athletes. **CONCLUSION:** This investigation is the first to account for both impact magnitude and time from previous impact in a concussion estimation model. The findings suggest that concussion tolerance may not be solely dependent on impact magnitude, but also influenced by time. That is, each impact may lower the concussion threshold, but the biological drive to return to homeostasis allows for recovery given enough time before the next impact. This investigation was funded by *The National Institutes of Health: National Institute of Neurological Disorders and Stroke* (1R15NS081691-01)

Concussion History And Kinematics Of Dynamic Balance In Division I Athletes: A Pilot Study
 Moira K. Pryhoda, Jenna Powell, Hammam Belgasem, Connor Landusky, Kevin B. Shelburne, Ann-Charlotte Granholm-Bentley, Bradley S. Davidson. *University of Denver, Denver, CO.*
 Email: moira.pryhoda@du.edu
 (No relationships reported)

A concussion is one of the most complex injuries in sports and can have potentially catastrophic results if not treated correctly. The central nervous system (CNS) integrates visual, proprioceptive, and vestibular sensory information to maintain balance during all movements. Ample clinical evidence exists that a concussion disrupts normal function of the CNS and results in postural instability. However, the long-term effects of concussion on balance control, particularly during dynamic functional movements, are not clear. **PURPOSE:** To determine the effects of concussion history on the kinematics of athletes performing dynamic balance tasks on dynamic balance on athletes. **METHODS:** Division I athletes without ($n=5$; 20.0 ± 1.0 yrs) and with a history of concussion ($n=5$; 19.4 ± 0.9 yrs 1.5 ± 1.2 yrs post injury) performed dynamic balance tasks including gait, gait while stepping over an obstacle, get up and go (GUG), and GUG with a dual task. Speed was recorded for each task, and straightness of trajectory was calculated for normal gait and stepping over an obstacle as a root mean square (RMS) of the mediolateral deviation of the pelvis trajectory from a straight line. Cohen's *d* effect sizes between groups were bootstrapped given the small sample size. Effect sizes greater than 0.8 were considered large, 0.5-0.8 moderate, and less than 0.5 as no effect. **RESULTS:** Athletes with history of concussion performed the dual task GUG 1.7 m/s slower than the control (large effect size: $d=0.90$). In addition, those with history of concussion performed normal gait with an RMS deviation of 30.9 cm compared to 25.1 cm in control (mod effect size: $d=0.66$) when instructed to maintain a straight trajectory. No effect of concussion history occurred for normal gait speed, speed of stepping over an obstacle, speed of GUG without dual task, or mediolateral deviation when stepping over an obstacle. **CONCLUSIONS:** Deficits in dynamic balance control during functional movements in Division I athletes were evident even as long as 1.5 years following concussion event. These data are part of a large prospective investigation (current enrollment: $n=207$), and athletes who sustain a concussion over the course of the study will be re-evaluated at regular intervals to observe changes in postural control during recovery.

The Relationship Between Post-Concussion Neurocognitive Performance and Postural Control
 Katelyn Grimes¹, Emily Lasko¹, Megan E. Mormile¹, Brian J. Szekeley¹, Barry A. Munkasy¹, Douglas W. Powell², Nicholas G. Murray¹. ¹Georgia Southern University, Statesboro, GA. ²University of Memphis, Memphis, TN.
 (No relationships reported)

Executive function (EF) is characterized as an individual's ability to control complex cognition during non-routine tasks. While EF is comprised of several cognitive domains, the ability to maintain task goals and decision making, and to direct attention, known as working memory, is one of the critical components. If a task has sufficient cognitive load to tax working memory, individual's compromise speed for accuracy, known as speed accuracy trade-off (SAT). However, the effect of concussion on SAT, and the ability to perform a physical task has not been well studied. **PURPOSE:** To identify the relationship between neurocognitive and postural control deficits post-concussion. **METHODS:** 15 NCAA Division I athletes (11 male, 4 female; 20.5 ± 1.1 yrs) with diagnosed concussions underwent computerized neurocognitive testing, and a postural control assessment battery within 24-48 hrs of injury. The postural control assessment consisted of 3 trials of eyes open (EO) and eyes closed (EC) quiet standing for 30 sec and the Wii Fit Soccer Heading Game (WFS). The WFS requires

participants to shift their weight in the appropriate medial-lateral direction to hit targets and avoid obstacles. As such, the WFS provides a sport relevant task while simultaneously exerting a cognitive load. Raw Center of Pressure (CoP) was collected using a force platform (1000Hz). From the raw CoP data 95% Confidence Ellipse (CE), along with Peak Excursion Velocity (PEV), and Sample Entropy (SampEn) in anteroposterior (AP) and mediolateral (ML) directions were calculated. **RESULTS:** The results of a Pearson's Product Correlation, indicate a negative relationship between verbal memory (VBMC) and EO PEV ML ($r=-0.611$, $p=.016$), and 95% Confidence Ellipse (CE) ($r = -0.555$, $p= 0.016$). There was a positive relationship ($r = 0.778$, $p= 0.001$) between impulse control and EO PEV AP. During WFS there was a positive relationship between PEV ML and VBMC ($r= 0.532$, $p= 0.041$), and visual motor speed ($r = 0.532$, $p= 0.041$) and CE ($r = 0.531$, $p= 0.042$). Finally, a negative relationship was observed found during the WFS between SampEn ML and Total Symptom Score ($r= -0.582$, $p= 0.023$). **CONCLUSIONS:** The results of the study suggest that participants did have a SAT, sacrificing postural stability for enhanced memory processing while attempting to accomplish an unfamiliar task.

Gender Specific Differences In Knee Kinematics Between Participants With And Without A Concussion History

Andrew P. Lapointe, Luis Nolasco, Aniela Sosnowski, Eva Andrews, Douglas N. Martini, Deanna H. Gates, Steven P. Broglio, FACSM. *University Of Michigan, Ann Arbor, MI.*
 Email: alapo@umich.edu
 (No relationships reported)

PURPOSE: To evaluate differences in knee kinematics during the impact phase between young adult participants with and without a concussion history.
METHODS: 10 controls (6 males, 4 females) and 9 concussed (4 males, 5 females) between the ages of 18 and 26, capable of completing a jump cut motion. All participants were former high school athletes and right foot dominant. Concussed subjects were tested on average 3.3 years post-injury ($SD=0.65$ years). Measures of knee rotation were taken in the X, Y and Z orientation during single limb support of a cutting maneuver. All values are presented as the mean and standard error of the mean.
RESULTS: An initial analysis of variance showed a significant group by gender interaction in peak right knee abduction/adduction [$F=82.0$, $p<.01$] and peak internal/external rotation [$F=17.9$, $p<.01$] between control and concussed groups. Accordingly, post-hoc tests were performed, adjusting for all pairwise comparisons using a Bonferroni correction. The aforementioned post-hoc tests revealed that males and females with a concussion history were differentially affected; with concussed males showing increased peak abduction (Controls: 9.7 ± 0.5 degrees, Concussed: 3.2 ± 0.3 degrees) and females showing increased peak adduction (Controls: 5.6 ± 0.3 degrees, Concussed: 7.2 ± 0.5 degrees). Concussed males showed an increase in peak internal rotation (Controls: 3.1 ± 0.3 degrees, Concussed: 5.5 ± 0.3 degrees) whereas concussed females showed a slight increase in peak external rotation of the knee (Controls: 7.3 ± 0.4 degrees, Concussed: 6.4 ± 0.5 degrees).
CONCLUSION: Our findings, showing small but significant gender specific changes between groups, advise future researchers to use prudence when generalizing post-concussive kinematics across genders as they may not be equally affected. This may have implications for injury risk, however further work is needed, especially in the understudied female population. Collectively, these findings cautiously provide a possible biomechanical underpinning to support recent reports that individuals are at a much higher risk of lower body injuries post-concussion.

Assessments Of Standing Balance In Division I Athletes With History Of Concussion: A Pilot Study

Jenna J. Powell, Moira K. Pryhoda, Hammam Belgasem, William Sanders, Kevin B. Shelburne, Ann-Charlotte Granholm-Bentley, Bradley S. Davidson. *University of Denver, Denver, CO.*
 Email: Jennajpowell@outlook.com
 (No relationships reported)

Concussion, an especially common injury in athletes, can result in notable balance dysfunction arising from disturbance of the somatosensory and vestibular neural networks. Although standing balance is known to be deficient in acute concussion, the rate at which postural control is recovered after symptoms have subsided is not well studied. Center of pressure (COP) can be utilized to quantify balance dysfunction arising from these neural impairments. Current NCAA concussion assessment includes the Balance Error Scoring System (BESS), which is arguably less sensitive than COP variations to detect long term effects.

PURPOSE: To assess measures of standing balance in athletes with recent history of concussion and non-concussed athlete controls.

METHODS: Division I athletes without ($n=5$; 19.4 ± 0.8 yrs) and with a history of concussion ($n=5$; 20.0 ± 1.0 yrs; 1.5 ± 1.3 yrs post injury) performed the BESS tasks while standing on 2 force platforms. COP was recorded during the 4 bipedal BESS

conditions: eyes open versus closed, and hard surface versus memory foam. Average COP velocity and 95% confidence ellipse area were calculated. Trials were also scored per BESS clinical criteria. Cohen's d effect sizes between groups were bootstrapped given the small sample size.

RESULTS: COP velocity was 1.3 mm/s higher (moderate effect size: $d=0.62$) in the concussion group than controls during eyes closed, hard surface, while BESS score was 10 for all athletes in both conditions. The remaining variables indicated no deficits in the concussion group.

CONCLUSIONS: Differences between concussed and control groups in the eyes closed condition may suggest continuing low-grade vestibular impairment detectable when visual feedback is removed, even after clinical symptoms have resolved. Past work indicates changes in COP velocity are related to vestibular dysfunction. In addition, these data allude to a higher sensitivity of COP measures than clinical BESS scoring when assessing balance deficits, particularly these deficits are subtle. These data are part of a large prospective investigation (current enrollment: $n=207$), and athletes who sustain a concussion over the course of the study will be re-evaluated at regular intervals to observe changes in postural control during recovery.

Postural and Gaze Stability Deficits Following Concussion

Nicholas G. Murray¹, Brian Szekely¹, Megan E. Mormile¹, Peter Chrysosferidis¹, Katelyn Grimes¹, Barry A. Munkasy¹, Douglas Powell². ¹*Georgia Southern University, Statesboro, GA.* ²*University of Memphis, Memphis, TN.*
 Email: nmurray@georgiasouthern.edu
 (No relationships reported)

Postural instability and visual system dysfunction are two of the highest reported signs immediately following a sport-related concussion. However, little research has examined both systems simultaneously using sensitive measurements techniques following concussion in the same sample. **PURPOSE:** To investigate and compare postural and gaze stability between a control group of healthy non-injured athletes (NORM) and a group of athletes with concussions (CONC) 24-48 hours post-injury. **METHODS:** 18 post-concussed NCAA Division I athletes (20 ± 1.3 years of age) and 18 matched athletes (19 ± 0.9 years of age) completed two trials of a sport-like antisaccade postural control task, the WiiFit Soccer Heading Game (WFS). During play, all participants were instructed to minimize gaze deviations away from a central fixed area, while simultaneously swaying in a medial-lateral direction to direct an on screen avatar to meet the demands of the game. Monocular raw ocular point of gaze coordinates (240Hz, Argus Science) and raw center of pressure (1000Hz, AMTI) data were collected simultaneously and further analyzed using a custom algorithm. Independent t-tests analyzed gaze Resultant Distance (RD), Prosaccade Errors (PE), Peak Horizontal Velocity (HV), and Vertical Horizontal Velocity (VV) along with center of pressure Root Mean Square (RMS) and Peak Velocity (PV) in the anteroposterior (AP) and mediolateral (ML) directions between groups. **RESULTS:** CONC had a significantly greater RD (CONC= 6.98 ± 0.5 pixels, NORM= 5.2 ± 0.3 pixels; $p=.013$), PE (CONC= 7.11 ± 1.2 errors, NORM= 2.5 ± 0.7 errors; $p=.040$), HV (CONC= 2075 ± 415.4 pixels/s, NORM= 1078 ± 135.6 pixels/s; $p=.018$), and VV (CONC= 2128 ± 481 pixels/s, NORM= 979 ± 144.6 pixels/s; $p=.044$) when compared to NORM. No significant differences were observed for RMS in the AP ($p=.838$) and ML ($p=.543$) directions and PV in the AP ($p=.288$) and ML ($p=.115$) directions between groups. **CONCLUSION:** These results suggest that CONC gaze travelled a greater distance and had less control of gaze in the horizontal and vertical directions during play of the WFS. Conversely, no postural deficits were present during play of the WFS. This could indicate that gaze instability is present even in the absence of postural instability following concussion when comparing CONC to NORM.

(No relationships reported)

Healthy, sedentary aging is associated with marked increased risk for developing (systolic) hypertension, which is partially driven by changes in arterial stiffness. In contrast, lifelong exercise training mitigates the effects of aging on arterial stiffness. **Purpose:** We compared the effects a prolonged, intensive supervised exercise training intervention to two-years of sedentary aging on arterial function and ambulatory BP. **Methods:** Sixty one healthy subjects (52.4±5.1 years, 46% male) were randomized to either non-exercise control (Con; n=27) or aerobic exercise training (ExT; n=34). A comprehensive assessment of arterial function including aortic PWV and indices derived from the central BP waveform, plus resting hemodynamics were performed at baseline (Pre), 10 months (Mid) and two-years (Post). Ambulatory blood pressure was measured at Pre and Post. **Results:** There was excellent adherence to the training intervention (89±9%) resulting in a 21% increase in VO₂max, with no change in Con. Ambulatory systolic BP was significantly increased, while ambulatory and resting HR were significantly reduced in the ExT group (Table 1). In contrast to our hypothesis, large artery function (AIx75, time to reflected wave, aortic PWV) was not improved following exercise training. **Conclusion:** Despite improved exercise capacity and excellent training adherence, large artery function was not improved in the ExT group. Consequently, ambulatory systolic BP was significantly increased, partially due to the lack of change in stiffness and the increased stroke volume associated with training.

Safety, Detection and Hemodynamic Effects of Acute Xenon Inhalation: Implications for Athletic Doping Practices

Justin S. Lawley¹, Gatterer Hannes², Erin J. Howden¹, Satyam Sarma¹, Michinari Hieda¹, Christopher Hearon Jr.¹, Max Hendrix³, Thomas Piper⁴, Mario Thevis⁴, Benjamin D. Levine, FACSM¹. ¹*Institute for Exercise and Environmental Medicine, Dallas, TX.* ²*University Innsbruck, Innsbruck, Austria.* ³*University of Texas Southwestern Medical Center, Dallas, TX.* ⁴*German Sport University Cologne, Cologne, Germany.*
(No relationships reported)

PURPOSE: Xenon is an inhalation anesthetic, which has the potential to increase plasma erythropoietin, red cell mass and thus endurance performance. This study aimed to describe the sedative effects, detection rates and cardiovascular responses of an open circuit breathing system to deliver increasing concentrations of Xenon. **METHODS:** On three occasions, participants breathed increasing concentrations of xenon (Xenon, 30% for 20 min; Xenon, 50% for 5 min; Xenon, 70% for 2 min and oxygen, 21% with balance Nitrogen) in a non-blinded design. Xenon inhalation has been completed in 6 (30%), 5 (50%) and 4 (70%) subjects to date. The level of sedation was monitored by a board certified anesthesiologist (Richmond Agitation and Sedation Scale (RASS)). Over 48 hours post administration, Xenon was measured in blood and urine by gas chromatography-mass spectrometry. All reported beat-by-beat hemodynamics were measured continuously by photoplethysmography (Nexfin; BMEYE, Netherlands) for 10 minutes prior to and throughout xenon administration. **RESULTS:** Xenon caused variable levels of sedation and restlessness between subjects (e.g. 50% xenon RAAS, -2, briefly awakens to voice to +2 frequent nonpurposeful movements), with the greatest symptoms occurring at 50 and 70%. Xenon was detected, albeit in trace amounts, up to 6 hours post xenon inhalation in blood (e.g. 30% 6 hours post, 2.2±2.7 nmol/mL) and urine (e.g. 30% 1.5±0.82 nmol/mL) in all subjects. Over the first minute, xenon cause a substantial reduction in total peripheral resistance (Δ2.7±0.49,mmHg·L·min), which caused a reflex increase in cardiac output (Δ2.7±0.54, L·min). By the end of xenon inhalation, hypertension was observed after all three dosages (MAP: 30%, Δ7±11; 50% Δ12±2; 70%, Δ19±5 mmHg). **CONCLUSIONS:** We show that three different conceivable dosages of xenon inhalation cause a level of sedation incompatible with self-operation of breathing apparatus and a persistent hypertensive state. Dispute begin acute (<5 mins), high dosages (50 and 70%) of xenon caused near anesthesia and thus could present a life threatening condition in the absence of an anesthesiologist. Xenon can be reliability detected in blood and urine up to 6 hours post dosing. These studies were supported in part by funding from the Partnership for Clean Competition Research Collaborative.

Prevalence Of Vo2max Low Response Across Nine Aerobic Exercise Interventions

Leanna M. Ross¹, Timothy S. Church, FACSM², Steven N. Blair, FACSM¹, J. Larry Durstine, FACSM¹, James M. Hagberg, FACSM³, Corby K. Martin⁴, Tuomo Rankinen, FACSM⁴, Robert Ross, FACSM⁵, Claude Bouchard, FACSM⁴, Mark A. Sarzynski, FACSM¹. ¹*University of South Carolina, Columbia, SC.* ²*ACAP Health, Dallas, TX.* ³*University of Maryland, College Park, MD.* ⁴*Pennington Biomedical Research Center, Baton Rouge, LA.* ⁵*Queen's University, Kingston, ON, Canada.*
(No relationships reported)

There is considerable inter-individual variation in the ability to improve VO_{2max} in response to regular exercise. Thus, identifying individuals who do not experience clinically significant gains in cardiorespiratory fitness with aerobic training (i.e., VO_{2max} low response) is of interest. **PURPOSE:** To assess the prevalence of VO_{2max} low response across nine large aerobic exercise interventions. **METHODS:** The prevalence of VO_{2max} low response was examined in 1,432 previously sedentary adults (461 males, 971 females) who completed one of nine exercise programs from five exercise training studies: DREW (n=361), E-MECHANIC (n=117), Energy Flux (n=65), GERS (n=171), and HERITAGE (n=715). The training programs ranged from doses of 4-35 kcal·kg⁻¹·week⁻¹ (KKW); intensities of 50-85% VO_{2max}; and durations of 20-24 weeks. Baseline and post-training VO_{2max} was assessed via maximal exercise testing. VO_{2max} low response was defined in both absolute (gain <120 ml/min from baseline value) and relative (gain < 5% of study-specific baseline average VO_{2max}) terms based on technical error and coefficient of variation values derived from three repeatability studies in HERITAGE. **RESULTS:** All studies showed significant mean increases in VO_{2max} with training. Using the above definitions, 32.6% (absolute) and 21.3% (relative) of the total sample

was considered low responsive for $\text{VO}_{2\text{max}}$. The distribution of low response across the individual exercise programs is shown in Table 1. Prevalence of low response ranged from 7.4% (HERITAGE) to 84% (DREW 4 KKW).

CONCLUSION: Our study found a high prevalence of $\text{VO}_{2\text{max}}$ low response across five diverse exercise training studies, which differed based on how low response was defined. These results underscore the need for further investigation to refine the identification of $\text{VO}_{2\text{max}}$ low response to enhance future exercise program development.

Skeletal Muscle Mitochondrial and Whole-Body Metabolic Performance After An Ultra Endurance Mountain Bike Race

Adam R. Konopka, William M. Castor, Jaime L. Laurin, Christopher A. Wolff, Karyn L. Hamilton, FACSM, Benjamin F. Miller, FACSM. *Colorado State University, Fort Collins, CO.* (Sponsor: Karyn Hamilton, FACSM)

(No relationships reported)

At the annual Colorado Trail Race (CTR), participants cycled for up to 24 hours per day to complete 70,000 feet of elevation gain over 500 miles between the altitudes of 5,500 to 13,200 feet. **PURPOSE:** To characterize skeletal muscle mitochondrial and whole-body metabolic performance after prolonged stress (exercise, sleep deprivation, hypoxia). **METHODS:** One race participant (43yr male; $\text{VO}_{2\text{Max}}$, 58 ml/kg/min; BMI, 21 kg/m²) was studied before and after completing >360 miles of the CTR and a normal activity period (control) separated by 45 days. Each visit the participant arrived fasted overnight for a skeletal muscle biopsy followed by an oral glucose (75g) tolerance test (OGTT). High-resolution respirometry was performed on permeabilized skeletal muscle fibers using 3 different substrate-uncoupler-inhibitor-titration (SUIT) protocols. SUIT1 examined maximal fatty acid-supported respiration with sequential addition of complex I- and complex II-linked carbohydrate substrates and FCCP to determine substrate-specific coupled oxidative phosphorylation (OXPHOS) and uncoupled electron transport system (ETS) capacity. SUIT2 was designed to investigate carbohydrate-supported respiration without fat supply during maximal OXPHOS and ETS capacity. SUIT3 used an ADP titration to determine mitochondrial ADP sensitivity followed by maximal OXPHOS and ETS flux. **RESULTS:** In each SUIT protocol, ETS capacity was >200 pmol/s/mg tissue which are amongst the highest values published for human muscle. Despite the high ETS capacity, carbohydrate linked OXPHOS and ETS capacity (SUIT2) was severely decreased after the CTR. However, the decrease in respiration appeared to be attenuated during fatty acid-linked respiration (SUIT1). Conversely, ADP sensitivity was increased after the CTR and was accompanied by a lower glucose and insulin area under the curve during the OGTT. **CONCLUSIONS:** This study provides a comprehensive characterization of skeletal muscle mitochondrial respiration after an ultra endurance event. The highly trained participant presented with preeminent mitochondrial capacity but was unable to maintain maximal mitochondrial respiration when faced with the extreme stress of an ultra endurance mountain bike race.

(No relationships reported)

Clinical biomarkers of general health status may indicate health impacts of overtraining in athletes attempting to optimize performance using long-term tracking tools.

PURPOSE: To test the hypothesis that biomarkers of cardiovascular, liver, kidney and hematological function reflect athlete health and performance over the course of a collegiate soccer season.

METHODS: 20 NCAA Division I male soccer players (mean±SD; height, 181±6cm; body mass, 77.9±6.2kg; BF%, 11.9±2.4%; $\text{VO}_{2\text{max}}$, 52.9±6.1 mL·kg⁻¹·min⁻¹) provided blood samples for a test panel of 53 biomarkers at 5 time points: before preseason (PS), week 1 (W1), week 4 (W4), week 8 (W8), and week 12 (W12). Significant changes were assessed via repeated measures ANOVA and post hoc testing ($p \leq 0.05$).

RESULTS: Markers of potential organ damage markers aspartate amino transferase (AST) (U·L⁻¹) and creatinine (mg·dL⁻¹) were elevated at W1 (AST, creatinine; 29±11, 1.11±0.13), W8 (31±11, 1.11±0.11), and W12 (28±11, 1.15±0.13) vs. PS (18±4, 1.02±0.13, all $p < 0.05$). Alanine amino transferase (ALT) (U·L⁻¹) levels were also significantly higher at W8 (24±8) and W12 (24±9) vs. PS (18±5, both $p < 0.05$). Hematocrit (%) measures were significantly reduced at W1 (45.5±2.3, $p = 0.015$) vs.

PS (47.2±2.8); W4 (46.4±2.6) and W12 (46.4±3.1) values suggest that values returned to PS levels ($p > 0.05$) later in season. Additional markers of anemia, mean corpuscular volume, mean corpuscular hemoglobin concentration, red cell distribution width were reduced at W12 vs. all time points (all $p < 0.007$). We observed reductions in cardiovascular/metabolic health markers (mg·dL⁻¹) LDL, LDL:HDL (no unit), non-HDL, direct LDL, and Apolipoprotein B at W1 (77±20, 3.2±0.5, 106±24, 96±25, and 71±17) than at PS (87±22, 2.8±0.5, 93±22, 81±22, and 64±15, all $p < 0.017$). HDL (mg·dL⁻¹) was significantly greater at W4 (56±10), W8 (55±10), and W12 (58±11) than at PS (50±8, all $p < 0.05$). Total cholesterol (mg·dL⁻¹) was significantly elevated at W8 (163±28, $p = 0.012$) and W12 (168±31, $p = 0.007$) vs. W1 (145±26).

CONCLUSIONS: Our panel detected a decrease in HCT beginning at W1, but improved cardiovascular/metabolic health throughout the season. Ongoing analysis aims to optimize this general health panel for practical use by correlational analysis to performance data.

Stretching Combined With Tens Or Self-massage Has Differential Effects On Ankle Flexibility

Robyn A. Capobianco, Awad M. Almklass, Roger M. Enoka. *University of Colorado Boulder, Boulder, CO.*

Email: roca8157@colorado.edu

(No relationships reported)

Many studies evaluating the effect of stretching conclude that gains in flexibility are primarily due to improved stretch tolerance (discomfort). Under this rationale, use of pain reduction therapies while stretching should provide greater improvements in flexibility than stretching alone. Transcutaneous electrical nerve stimulation (TENS) is a modality commonly used to mitigate pain. Self-massage with a foam roller, which may modulate the mechanical properties of connective tissues, has been shown to improve flexibility.

Purpose: To compare the influence of TENS and self-massage on ankle joint flexibility and force capacity of the plantar flexor muscles after a stretching intervention.

Methods: 20 healthy young adults (10M, 10F, mean (SD) age 25 (3) y) underwent 3 sessions of ankle plantar flexor stretching: stretching alone (SS), stretching with concurrent application of TENS (TS), and stretching after self-massage using yoga therapy balls (BS). Each visit was separated by one week. All subjects performed SS at the first visit; the remaining 2 visits were counterbalanced. At every visit, subjects performed isometric maximum voluntary contractions (MVCs) for the plantar flexors before and after the intervention. Stretching involved three 30-s standing calf stretches, separated by 30-s rest. TENS was applied at a comfortable current without muscle contraction for 1-min prior to, and for the duration of stretching. Massage with yoga balls was performed for 60-s immediately prior to each of the 3 stretches. Ankle dorsiflexion range of motion (ROM) was assessed before, immediately after, and at 1, 5, 10, and 15 min after the intervention.

Results: All 3 interventions significantly increased ankle dorsiflexion ROM (all $p = 0.00$). The mean (SD) change in ROM was 13 (9)%, 9 (7)%, and 25 (17)% for SS, TS, and BS, respectively. The mean (SD) change in ankle torque was -1(13)%, -3 (10)%, and 16 (11)% for SS, TS, and BS, respectively. In contrast to TENS (TS), the use of yoga therapy balls significantly increased ROM and MVC torque (both $p = 0.00$, effect size 0.40, 0.58 for ROM, torque).

Conclusion: The addition of TENS to a stretch intervention did not improve ankle joint range of motion or alter MVC force. In contrast, self-massage with yoga therapy balls prior to stretching significantly improved range of motion and MVC force.

Lower Limb POWER Training to Enhance Locomotor and Muscular Function Poststroke

Jennifer L. Hunnicutt, Stacey E. Aaron, Aaron E. Embry, Chris M. Gregory, FACSM. *Medical University of South Carolina, Charleston, SC.* (Sponsor: Chris Gregory, FACSM)

Email: hunnicuj@musc.edu

(No relationships reported)

Training to improve muscle power generation has functional benefits beyond strength training in an aging population. Individuals following stroke show pronounced deficits in muscle power generation as well as function (i.e. gait speed), though data on specific adaptations following muscle power training are not available. **PURPOSE:** The purpose of this analysis was to determine the effects of the Poststroke Optimization of Walking Using Explosive Resistance (POWER) training on the paretic limb's contribution to walking. **METHODS:** Twenty individuals (13 male; 51 yrs; 36 mos poststroke) with chronic poststroke hemiparesis participated in this study. Subjects completed 24 training sessions that included a series of progressive, intensive leg press and jump training exercises, sit-to-stands, step-ups, and calf raises. Subjects also performed progressive overground fast walking to emphasize task-specific lower extremity power generation. Kinetic data was collected via a split-belt instrumented treadmill during three walking trials at self-selected (SSWS) and fastest comfortable walking speeds (FCWS). Using the anterior-posterior ground reaction forces (A-P

GRFs), the percentage of total propulsion generated by the paretic limb was calculated by dividing the propulsive impulse of the paretic leg by the sum of the paretic and nonparetic propulsive impulses. Other outcomes included overground SSWS and FCWS, maximum voluntary isometric contractions (MVIC), and peak isotonic power of the knee extensors. Subjects underwent pre-testing, post-testing, and 12-week follow-up testing. One-way repeated measures ANOVAs were used to determine main effects of time. **RESULTS:** Significant effects for time were observed for SSWS ($p<0.01$), FCWS ($p=0.01$), and nonparetic knee extensor MVIC ($p=0.05$) and power ($p<0.01$). Although peak A-P GRFs of the paretic limb significantly increased following training ($p=0.01$), no changes were observed in paretic propulsion. **CONCLUSION:** Subjects improved gait speed, but those improvements were not accompanied by enhanced symmetry following POWER training. Future data will look into other potential underlying kinetic and kinematic mechanisms contributing to the significant and clinically meaningful improvements in gait speed (>0.16 m/s) observed in this cohort.

2925 June 2 2:45 PM - 3:00 PM

Acute Effects of Speed-Dependent Interval Training Versus Continuous Training on Post-Stroke Locomotor Function

Stacey E. Aaron, Chris M. Gregory, FACSM. *Medical University of South Carolina, Charleston, SC.* (Sponsor: Chris Gregory, FACSM)

Email: aarons@musc.edu

(No relationships reported)

The benefits of interval training (IT) compared to continuous training (CT) have been shown on a variety of functional and health-related outcomes. To date, the feasibility of IT has been demonstrated in individuals following stroke, though investigations of its effectiveness are still lacking. **Purpose:** To compare acute changes in locomotor function following single bouts of continuous (CT) and interval (IT) treadmill training, matched for total work, in ambulatory individuals with chronic stroke. **Methods:** Participants completed 20 minute sessions of CT and IT treadmill exercise separated by a minimum of 48 hours. Overground self-selected walking speed (SSWS) was used for CT while IT involved a 1:1 ratio (1 min slow : 1 min fast walking) with the goal of fast walking at 150% of SSWS and slow walking at 50% of SSWS. If subjects could not achieve 150% SSWS then speed was reduced and slow walking speed was adjusted to ensure matched-work between conditions. Overground SSWS was assessed prior to, immediately following as well as 20, 40 and 60min post-training. Subjects also walked at self-selected speed on a split-belt, instrumented treadmill to collect ground-reaction force data at the same time points. **Results:** Six subjects completed both sessions. Average CT treadmill speed was 0.92 m/s; average IT speeds were 0.57 m/s (slow) and 1.26 m/s (fast). Immediate post-training increases in SSWS were realized following CT (+6%) but not IT (-2%). SSWS following CT remained 6% faster than pre-training SSWS over time. In contrast, IT showed a delayed increase in speed with 7% improvement in SSWS at 20min, 11% at 40min, and 6% at 60min. Improvements in peak paretic propulsive (Pp) force were realized immediately post-training for the CT condition (+10.3 N; +21%) and persisted over time (20min +24%, 40m +23%, 60m +19%). IT improved peak Pp force immediately post-training (+6.9 N; +14%) and remained elevated post-training (20m +18%, 40m +16%, 60m +11%). **Conclusion:** These preliminary results suggest single bouts of IT and CT treadmill walking appear to elicit acute increases in SSWS as well as propulsive forces in individuals following stroke. The potentially greater relative improvements following IT suggest its potential effectiveness over CT if changing walking function is the goal. Funding source NIH COBRE Stroke Study P20-GM109040

Exercise Training Improves Ventilatory Efficiency in Patients With Small Abdominal Aortic Aneurysm: A Randomized Controlled Study

Ricardo M. Lima¹, Baruch Vainselboim², Rucha Ganatra², Ronald Dalman³, Khin Chan², Jonathan Myers, FACSM².

¹University of Brasilia, Brasilia, Brazil. ²VA Palo Alto Healthcare System and Stanford University, Palo Alto, CA.

³Stanford University, Stanford, CA. (Sponsor: Jonathan Myers, FACSM)

(No relationships reported)

PURPOSE: To investigate the effects of exercise training on ventilatory efficiency and other physiological responses to submaximal exercise in subjects with small abdominal aortic aneurysm (AAA).

METHODS: Sixty five patients (72.3±7.0 yr) were randomized to exercise training (n=33) or usual care groups (n=32). Exercise subjects participated in a training program for 3 months. Cardiopulmonary exercise testing was performed before and after the study period and peak $\dot{V}O_2$, the ventilatory threshold (VT), the oxygen uptake efficiency slope (OUES) and the $\dot{V}_E/\dot{V}O_2$ slope were identified. Baseline work rates at VT were matched to examine cardiopulmonary responses before and after training. ANOVA was used to assess time by group interactions.

RESULTS: Significant interactions indicating improvements in the exercise group were observed for time ($p<0.01$), $\dot{V}O_2$ ($p<0.01$), and work rate ($p<0.01$) at the VT. At peak effort, significant interactions were noted for time ($p<0.01$) and work rate ($p<0.01$), while borderline significance was noted for absolute ($p=0.07$) and relative ($p=0.04$) $\dot{V}O_2$. Significant interactions were observed for the OUES both when using all exercise test data (Exercise: 2.03 to 2.16, and Usual care: 2.10 to 1.98; p for interaction =0.04) and when calculated up to the VT (Exercise: 2.07 to 2.23, and Usual care: 2.13 to 1.95; p for interaction <0.01). For the $\dot{V}_E/\dot{V}O_2$ slope, significance was only noted when calculated up to the VT (Exercise: 30.4 to 29.5, and Usual care: 29.2 to 30.3; p for interaction=0.04). After training, heart rate (104.5 to 97.3 bpm), \dot{V}_E (34.2 to 32.0 L/min), $\dot{V}CO_2$ (1013.6 to 910.6 ml/min) and respiratory exchange ratio (0.85 to 0.82) were significantly attenuated for the same baseline workrate in the exercise group (all $p<0.01$), but no changes were observed in the usual care group.

CONCLUSIONS: Exercise training improves ventilatory efficiency in patients with small AAA. In addition, exercised patients exhibited less demanding cardiorespiratory responses to submaximal effort, with potential clinical significance for activities of daily living.

2928 June 2 1:15 PM - 1:30 PM

Associations Between Perceptual and Ventilatory Responses to Exercise: Effect of Sympathetic Blockade

Braden L. Mitchell, Kade Davison, Gaynor Parfitt, Simon Spedding, Roger G. Eston. *University of South Australia, Adelaide, Australia.*

Email: braden.mitchell@mymail.unisa.edu.au

(No relationships reported)

Previous studies have shown that the first and second lactate threshold are associated with a rating of perceived exertion (RPE) of 11 and 14 on the Borg 6-20 RPE scale. However, it remains unclear how the RPE is associated with the ventilatory breakpoints and whether this relationship is altered by sympathetic blockade.

Purpose: To determine the association between the RPE and ventilatory breakpoints, and whether the relationship is altered by acute sympathetic blockade. **Methods:** The oxygen uptake ($\dot{V}O_2$) at the ventilatory threshold (VT) and respiratory compensation point (RCP) were determined from a graded exercise test in eleven healthy participants (6 male, 26±5 y) under a β_2 receptor antagonist and placebo. Treadmill speed increased by 2 km·h⁻¹ every two minutes until exhaustion. The $\dot{V}O_2$ was measured continuously and RPE recorded in the final 10s of each min. Linear regression modelled the RPE: $\dot{V}O_2$ relationship and predicted the RPE associated with VT and RCP. The $\dot{V}O_2$ associated with RPE 13 and 15 were also predicted and expressed relative to the VT and $\dot{V}O_{2peak}$. Paired samples t-tests assessed differences between conditions.

Results: The $\dot{V}O_2$ at VT and peak exercise were significantly lower under β -blockade (32±3 vs 30±3 and 52±5 vs 49±7 mL·kg⁻¹·min⁻¹, $p<0.05$), while the $\dot{V}O_2$ at RCP

remained unchanged. The RPE associated with VT and RCP were 13 ± 1 and 17 ± 1 , respectively, and not significantly different during β -blockade (13 ± 1 and 18 ± 0.6 respectively; $p > 0.05$). The VO_2 associated with RPE 13 was significantly lower under β -blockade compared to control (28 ± 6 vs 32 ± 6 mL \cdot kg $^{-1}$ \cdot min $^{-1}$; $p < 0.05$). However, when expressed relative to VT (94 ± 15 and $99 \pm 14\%$) and $\text{VO}_{2\text{peak}}$ (58 ± 8 and $62 \pm 10\%$) differences were no longer significant (all $p > 0.05$). For RPE 15, associated VO_2 was significantly lower during β -blockade (35 ± 6 vs 39 ± 6 mL \cdot kg $^{-1}$ \cdot min $^{-1}$; $p < 0.05$), but no longer significant when expressed relative to VT (116 ± 13 and $120 \pm 13\%$; $p > 0.05$) and $\text{VO}_{2\text{peak}}$ (72 ± 6 and $75 \pm 8\%$; $p > 0.05$). **Conclusion:** Despite changes in the VT and $\text{VO}_{2\text{peak}}$ with β -blockade, the RPE associated with VT and RCP remain constant. Further, the exercise intensity associated with RPE 13 and 15 appear to scale in accordance with changes in VT and $\text{VO}_{2\text{peak}}$.

2929 June 2 1:30 PM - 1:45 PM

Cardiorespiratory Fitness Versus Physical Activity as Predictors of All-Cause Mortality in Men

Taryn Davidson¹, Baruch Vainshelboim², Peter Kokkinos, FACSM³, Jonathan Myers³, Robert Ross, FACSM¹. ¹Queen's University, Kingston, ON, Canada. ²Veterans Affairs Palo Alto Health Care System and Stanford University, Palo Alto, CA. ³Veterans Affairs Medical Center and Georgetown University School of Medicine, Washington, DC. (Sponsor: Robert Ross, FACSM)
Email: taryn.davidson@queensu.ca
(No relationships reported)

A limited number of studies have examined the interaction between cardiorespiratory fitness (CRF), physical activity (PA) and all cause-mortality.

PURPOSE: To assess the independent and combined associations of PA, CRF and all-cause mortality in 11,610 male veterans aged 20 to 89 (mean \pm SD, 58.5 ± 11.2 years) who were referred for exercise testing at the Veterans Affairs Medical Center in Washington, DC, or Palo Alto, CA.

METHODS: CRF was assessed by a maximal exercise treadmill test and PA was measured by self-reported questionnaire obtained at the time of the exercise test. There were 2876 deaths during a mean (\pm SD) follow-up of 9.8 (5.9) years. Cox proportional hazard models were used to assess the independent associations between CRF, PA and mortality. To further explore the interaction between PA and CRF with mortality, we dichotomized the cohort into fit and unfit groups, defined by a CRF threshold of 7 METS. Within the fit and unfit groups, active individuals (meeting 150 minutes of moderate or higher intensity PA per week) and inactive individuals (not meeting 150 minutes of moderate or higher intensity PA per week) were matched, 1:1, for CRF, age and BMI. Hazard ratios [HRs] compared inactive subjects (reference) with active subjects. All analyses were adjusted for age, BMI, smoking status, family history of risk factors, medication use, history of stroke, and presence or absence of hypertension, diabetes, hypercholesterolemia, or cardiovascular disease.

RESULTS: CRF was inversely associated with mortality after adjusting for clinical variables (HR: 0.88; 95% confidence interval [CI]: 0.87 – 0.89), and remained a strong predictor of mortality after further adjusting for PA; the risk reduction per 1-MET increase in CRF was 15% (HR: 0.85; CI: 0.83 – 0.87). PA was a significant predictor of mortality after controlling for clinical variables (HR: 0.83; CI: 0.75 – 0.93), however the association was eliminated after further adjusting for CRF (HR: 0.98; CI: 0.88 – 1.10). Further, within both the fit (HR: 0.91; CI: 0.74 – 1.11) and unfit groups (HR: 0.98; CI: 0.83 – 1.15), meeting the PA guidelines (Active) was not significantly associated with mortality compared to the reference group (Inactive).

CONCLUSION: In adult male, US veterans, CRF is associated with mortality risk independent of PA, whereas the reverse is not true.

2930 June 2 1:45 PM - 2:00 PM

Can A Prediction Formula Accurately Predict Cardiorespiratory Fitness In Fibromyalgia Patients?

Pierre Boulay, Lucie Bouvrette LeBlanc, Daniel Tessier, Warner Mampuya, Pierre Arsenaault, Nathaly Gaudreault. *Sherbrooke University, Sherbrooke, QC, Canada.*
Email: pierre.boulay@usherbrooke.ca
(No relationships reported)

Cardiorespiratory fitness (CRF) is often estimated using prediction formulas when clinicians do not have access to a metabolic cart. Unfortunately, using prediction formulas could potentially over or under estimate the CRF of patients with a chronic disease. Improving the accuracy of CRF in fibromyalgia (FM) patients is important considering that it has been reported that they have a lower CRF when compared to match controlled healthy participants. **PURPOSE:** To assess if a commonly used formula is accurate to predict CRF ($\text{VO}_{2\text{peak}}$ or METs) in women living with FM. **METHODS:** Twelve FM women (age: 50.5 ± 7.9 years; weight: 69.3 ± 16.0 kg; BMI: 26.4 ± 7.1) were submitted twice to a maximal exercise test (BSU/Bruce ramp), with a 24 hours' interval, until participants achieved volitional exhaustion. Gas exchange (Ergogard, Medisoft) and ECG (Quinton) was continuously monitored throughout

the test. $\text{VO}_{2\text{peak}}$ was considered as the highest O_2 uptake averaged over a 30 second period during the test and the highest value obtained between the first test (T1) and second (T2). Predicted $\text{VO}_{2\text{peak}}$ was determined by the formula integrated in the Quinton ECG system and the highest value between T1 and T2. The Metabolic equivalent of task (METs) was determined by using $\text{VO}_{2\text{peak}}$ values divided by 3.5 ml O_2 \cdot kg $^{-1}$ \cdot min $^{-1}$. **RESULTS:** No significant differences were found between both $\text{VO}_{2\text{peak}}$ (T1; 25.5 ± 5.3 vs. T2; 26.5 ± 5.3 ml O_2 \cdot kg $^{-1}$ \cdot min $^{-1}$, $p > 0.05$) tests. However, measured $\text{VO}_{2\text{peak}}$ (27.2 ± 5.6 ml O_2 \cdot kg $^{-1}$ \cdot min $^{-1}$) was significantly lower than predicted $\text{VO}_{2\text{peak}}$ (32.4 ± 5.6 ml O_2 \cdot kg $^{-1}$ \cdot min $^{-1}$, $p < 0.05$). In fact, the prediction formula overestimated the CRF by 1.5 ± 1.1 METs or 19.1%. When participants were divided by the severity of their disease, CRF was overestimated by 1.2 ± 0.8 METs in the mild ($n=5$) and by 1.6 ± 1.3 METs in the moderately-to-severely ($n=7$) affected FM participants, but did not attain statistical difference between groups. **CONCLUSION:** Our results show that system based prediction formula commonly used in the clinical setting overestimate cardiorespiratory fitness in women with fibromyalgia and should be used with precaution.

The Immediate Antihypertensive Effects of Aerobic Exercise: A Meta-Analysis

Lauren ML Corso¹, Hayley V. MacDonald², Blair T. Johnson¹, Jill Livingston¹, Alyssa Jones¹, Linda S. Pescatello, FACSM¹. ¹University of Connecticut, Storrs, CT. ²The University of Alabama, Tuscaloosa, AL. (Sponsor: Dr. Linda S. Pescatello, FACSM)
Email: lauren.lamberti@uconn.edu
(No relationships reported)

Acute aerobic exercise (AE) produces immediate but transient blood pressure (BP) reductions that persist for up to 24 hr, termed *postexercise hypotension* (PEH). PEH is strongly correlated with the BP response to AE training. Surprisingly, 33 meta-analyses exist on the BP response to AE training, but none on PEH. **PURPOSE:** To perform a meta-analysis to determine the effectiveness of PEH as antihypertensive lifestyle therapy among adults with hypertension. **METHODS:** Databases were searched for controlled PEH trials that included: adults (>19 yr) with hypertension (systolic BP [SBP]/diastolic BP [DBP] ≥ 140 and/or ≥ 90 mmHg and/or on BP medication), and BP measured pre- and post-acute AE and control. Study quality was determined using a modified Downs and Black checklist. Analyses incorporated random-effects assumptions. **RESULTS:** Ten studies and 17 interventions qualified. Subjects ($N=260$) were middle-aged (41.8 ± 4.2 yr), overweight (28.9 ± 2.3 kg \cdot m $^{-2}$) adults (24% women, 76% men) with hypertension (SBP/DBP= $140.6 \pm 9.2/89.2 \pm 4.4$ mmHg). The AE bout was performed at moderate intensity (5.4 ± 1.3 metabolic equivalents [METs], $\sim 55\%$ maximal oxygen consumption) for 38.0 ± 8.7 minutes, typically on a cycle ergometer (61.9%, $k=13$). Awake ambulatory BP consisted of 3.1 ± 0.6 measurements/hr at 18.2 ± 4.9 minute intervals over 11.7 ± 4.7 hr. Overall, PEH occurred over the awake hr (SBP/DBP: d , [95% CI]= -0.76 [$-1.03, -0.49$]/ -0.33 [$-0.50, -0.17$]; $-5.42/-2.12$ mmHg), but effect sizes lacked homogeneity (P [95% CI]= 85.0% [77.4%, 90.1%]/67.9% [46.9%, 80.6%]). PEH was of greater magnitude following higher than lower intensity (>6 - <9 METs, $-11.4/-5.6$ versus 4 METs, $-1.6/-0.5$ mmHg, $p=0.04$, respectively), independent of resting BP. For DBP only, PEH was of greater magnitude among trials of lower than higher study quality (-4.0 versus -0.4 mmHg, $p=0.03$). **CONCLUSIONS:** On average, the magnitude of PEH was equal to the magnitude of the BP reductions that are reported after AE training (~ 5 - 7 mmHg). Furthermore, PEH was of greater magnitude among trials of higher intensity (SBP, ~ 11 mmHg) and lower quality (DBP, ~ 4 mmHg). Of note, the antihypertensive benefits of PEH occurred during the awake hr when BP is typically at its highest levels. Future trials are warranted to confirm the effectiveness of PEH as antihypertensive therapy.

2932 June 2 2:15 PM - 2:30 PM

Effect of Differential Exercise Intensities on Interleukin-22 in Metabolic Syndrome

Joyce S. Ramos¹, Lance C. Dalleck, FACSM², Gregore I. Mielke¹, Shelley E. Keating¹, Michael McGuckin¹, Lydia S. Murray¹, Sumaira Hasnain¹, Robert G. Fasset¹, Jeff S. Coombes, FACSM¹. ¹The University of Queensland, Brisbane, Australia. ²Western State Colorado University, Gunnison, CO. (Sponsor: Wendy Brown, FACSM)
Email: mary.ramos@uq.net.au
(No relationships reported)

Elevated serum interleukin-22 (IL-22) concentration is independently associated with the incidence of type 2 diabetes and coronary artery disease. Individuals with metabolic syndrome (MetS) are at increased risk of developing both conditions. Paradoxically, evidence also exists demonstrating that IL-22 may have a role in the alleviation of MetS.

PURPOSE: We investigated the impact of moderate-intensity continuous training (MICT) and different volumes of high-intensity interval training (HIIT) on IL-22.

METHODS: This was a sub-study of the 'Exercise in prevention of Metabolic Syndrome' (EX-MET) multi-center randomized trial, based on data collected at the Brisbane site. Thirty-nine MetS individuals were randomized to one of three 16-wk interventions: i) MICT (n=10, 30min at 60-70%HRpeak, 5x/wk); ii) 4HIIT (n=13, 4x4min at 85-95%HRpeak, interspersed with 3min of recovery at 50-70%HRpeak, 3x/wk); or iii) 1HIIT (n=16, 1x4min at 85-95%HRpeak, 3x/wk). Serum IL-22 concentration was measured following a 12-hr fast via enzyme linked immunosorbent assays, before/after the intervention. MetS severity, cardiorespiratory fitness (CRF), insulin resistance (IR), and visceral adipose tissue (VAT) were also measured via MetS z-score, HOMA-IR, dual-energy x-ray absorptiometry, and indirect calorimetry, respectively.

RESULTS: The median (IQR) IL-22 percent changes from pre- to post-intervention in the MICT, 4HIIT, and 1HIIT groups were -17% (-43.0%; 31.3%), +16.5% (-18.9%; 154.9%), and +15.9% (-28.7%; 46.1%) respectively. Although there was no significant between-group difference in IL-22 change, there was a medium-to-large group x time interaction effect on this cytokine [$F(2,35)=2.08$, $p=0.14$, $\eta^2=0.14$]. There were similar reductions in MetS severity (MICT, -0.5±1.8; 4HIIT, -0.5±0.9; 1HIIT, -1.3±1.8), IR (MICT, -2.1±2.7; 4HIIT, -0.8±1.4; 1HIIT, -1.0±2.0), and VAT (MICT, -47.2±152.6g; 4HIIT, -68.2±106.0g; 1HIIT, -44.9±102.7g) following all interventions. 4HIIT (+5.7±4.7ml/kg/min) significantly improved CRF more than MICT (+2.7±1.9ml/kg/min) and 1HIIT (+2.9±2.2ml/kg/min).

CONCLUSION: Although there was no significant between-group difference in IL-22 change, the study suggests that different exercise intensities may have different effects on IL-22 in MetS individuals.

2933 June 2 2:30 PM - 2:45 PM

Effects Of Aerobic & Resistance Training On Cardiorespiratory Fitness In People Living with HIV. A Meta-analysis

Camilo G.A. Pérez Chaparro¹, Philipp A. Zech¹, Stephan Heinzl², Frank Mayer¹, Bernd Wolfarth³, Michael Rapp¹, Andreas Heißel¹. ¹University of Potsdam, Potsdam, Germany. ²Freie Universität Berlin, Berlin, Germany. ³Humboldt Universität, Berlin, Germany.
Email: perezcha@uni-potsdam.de
(No relationships reported)

The life expectancy of people living with HIV (PLWH) is increasing due to advancements in anti-retroviral drug therapy. For this reason, PLWH are increasingly facing age-related comorbidities. Higher cardiorespiratory fitness is associated with lower risks for cardiovascular and metabolic diseases. Prior meta-analyses have focused on the effect of exercise in PLWH investigating VO_{2max} in a small amount of available studies. This meta-analysis represents a large number of included studies and will be the first investigating the 6-Minute Walk Distance additionally.

PURPOSE

To assess the effects of aerobic exercise alone or in combination with resistance training on cardiorespiratory fitness (Maximal Oxygen Consumption (VO_{2max}) and performance in the 6-minute walk test (6MWT) in PLWH.

METHODS

Two authors (CPC and PAZ) independently performed a systematic literature search for relevant articles in six web-based databases. Only randomized controlled trials (RCTs) were included. The Physiotherapy Evidence Database-Scale (PEDro-scale) was used to rate the quality level of the studies and to assess the risk of bias. A meta-analysis was performed and standardized mean differences (SMDs) were calculated for each outcome and assessed for heterogeneity.

RESULTS

A total of 335 articles were found. After screening, a total of 14 articles were selected with three more articles added after cross referencing, leading to a total of 17 included studies (n=617 subjects after intervention). Only 8 of the selected studies had a PEDro-

Score ≥ 6 after quality assessment. 13 studies assessed VO_{2max} and 4 studies 6MWT. The random-effect model was used. Exercise significantly improved VO_{2max} (SMD = 0.61 ml·kg⁻¹·min⁻¹, 95% CI: 0.35-0.88, $z = 4.47$, $p < 0.001$). After exercise intervention, 6MWT distance also increased significantly (SMD = 0.59 meters, 95% CI: 0.08-1.11, $z = 2.25$ ($p = 0.02$)). Heterogeneity of VO_{2max} and 6MWT between included studies was $I^2 = 50\%$ and $I^2 = 63\%$, respectively.

CONCLUSION:

Performing aerobic exercise alone or in combination with resistance training can lead to significant improvements in outcomes of cardiorespiratory fitness (VO_{2max} and 6MWT) in PLWH and could therefore be a protective factor for PLWH dealing with multiple comorbidities.

2934 June 2 2:45 PM - 3:00 PM

Role Of Physical Activity In Closing The Life Expectancy Gap of People With Mental Illness

Simon Rosenbaum¹, Anita Hobson-Powell², Kade Davison³, Catherine Elliot⁴, Philip B. Ward⁵. ¹Exercise & Sports Science Australia & UNSW, Sydney, Australia. ²Exercise & Sports Science Australia, Queensland, Australia. ³Exercise & Sports Science Australia & University of South Australia, Adelaide, Australia. ⁴Sport and Exercise Science New Zealand & Lincoln University, Canterbury, New Zealand. ⁵UNSW, Sydney, Australia.
Email: s.rosenbaum@unsw.edu.au
(No relationships reported)

PURPOSE: People experiencing mental illness are at high risk of poor lifestyle factors such as physical inactivity, which contributes to a 15 to 25-year gap in life expectancy. To develop an international consensus statement on behalf of Exercise & Sports Science Australia (ESSA), the American College of Sports Medicine (ACSM) and Sport and Exercise Science New Zealand (SESNZ) on the role of exercise interventions as a key component of a global strategy towards achieving a 50% reduction in the life expectancy gap of people experiencing mental illness by 2032.

METHODS: The statement was sent to all signatory organizations for review and endorsement. **RESULTS:** Three factors were identified including i) culture change with psychiatric facilities to allow for the integration of exercise practitioners within routine care, ii) advocating for appropriate infrastructure for the provision of exercise interventions regardless of treatment setting, age, diagnosis or physical health status, and iii) prioritizing training of exercise practitioners to ensure adequate mental health literacy and competency to work within psychiatric facilities. Similarly, training of mental health professionals regarding the role of exercise practitioners within mental health must be addressed. **CONCLUSIONS:** The organisations that endorse this consensus statement commit to promoting the role of exercise interventions as a key component of a global strategy towards achieving a 50% reduction in the life expectancy gap of people experiencing mental illness by 2032. We believe that enhanced training of our members, working with our medical, other allied health and health policy partners to facilitate culture change within mental health services and advocating for the provision of required infrastructure are the cornerstones of achieving this goal.

F-15 Free Communication/Slide - Perception of Effort, Pain and Fatigue

Resistance Exercise Performed With The Same Load In Self-selected And Imposed Intensities Promote Different Affective And Perceptual Responses

Sergio G. da Silva¹, Erick D. Garcia¹, Sandro S. Ferreira¹, Vinicius F. Andrade¹, Lucio Follador¹, Ragami C. Alves¹, Fredric L. Goss, FACSM². ¹Universidade Federal do Parana, Curitiba, Brazil. ²University of Pittsburgh, Pittsburgh, PA.
Email: sergiogregorio@ufpr.br
(No relationships reported)

PURPOSE: to compare the perceptual and affective responses to self-selected and imposed load resistance exercise performed with the same load. **METHODS:** 15 young male college students with at least 6 months experience in resistance training (age: 24.5 ± 3.4 yrs; height: 176.3 ± 5.8 cm; body mass: 79.0 ± 10.3 kg) participated in the study. All subjects completed three exercise sessions: 1. familiarization and 1RM test; 2. self-selected exercise intensity, & 3. imposed exercise intensity. All exercises (chest press, leg extension, lat pulldown, & leg curl) were performed using machines. Each experimental exercise session consisted of 3 sets of 10 repetitions for each of the 4 exercises with 1 min of rest between sets and 2 min of rest between exercises. In the self-selected exercise session, participants were instructed to choose a load in which they could perform three sets. The participants were able to adjust the load at the end of each set. In the second exercise session, the same load was used, but without the individuals' knowledge. Subjects were informed that the investigators selected the load. Affect (Feeling Scale) and Ratings of Perceived Exertion (RPE) - OMNI-RES were assessed after each exercise. **RESULTS:** RPE was similar in 3 of the 4 exercises, but Affect was lower ($p < 0.05$) in all of the exercises in the imposed intensity exercise

sessions. **CONCLUSION:** Self-selected intensity results in a more favorable affective response to resistance exercise than imposed intensity in college men with at least 6 months of resistance training experience.

2937 June 2 1:15 PM - 1:30 PM

Influence Of Physical Activity And Sedentary Behavior On Anticipation-related Pain Sensitivity In Gulf War Veterans With Chronic Muscle Pain

Jacob Lindheimer¹, Aaron Stegner², Stephanie VanRiper², Laura Ellingson³. ¹US Department of Veterans Affairs, East Orange, NJ. ²University of Wisconsin, Madison, WI. ³Iowa State University, Ames, IA. (Sponsor: Dane Cook, FACSM)
Email: jacob.lindheimer@va.gov
(No relationships reported)

Exercise can alter pain sensitivity among Gulf War Veterans with chronic muscle pain (CMP). Anticipation of a painful experience can influence perceptual and neural responses to non-painful thermal stimuli among Fibromyalgia patients and this may extend to other patient groups with CMP. However, the association between physical activity or sedentary behavior and anticipation-related pain sensitivity has not been adequately studied. **PURPOSE:** To determine if (i) anticipation of pain influenced perceptual and neural responses to thermal stimuli among Veterans with CMP and (ii) anticipation-related pain sensitivity was associated with physical activity or sedentary behavior. **METHODS:** Gulf War Veterans with ($n=29$; 46 ± 6.5 years) and without ($n=29$; 45 ± 6.7 years) CMP were randomly assigned to conditions in which they were told that they would receive a painful or non-painful heat stimulus. Following one week of physical activity monitoring (ActiGraph GT3X), functional MRI responses to a 20-second warm stimulus (40C) applied to the left palm were measured on a 3T MRI scanner (GE MR750). Participants were then asked to provide ratings of pain intensity and unpleasantness following thermal stimulus administration. **RESULTS:** Factorial ANOVA with group and condition as between-subjects factors revealed significantly higher pain intensity ($p=.003$; $d=.85$) and unpleasantness ($p=.006$; $d=0.76$) ratings in the pain anticipation condition. A main effect for group and condition by group interaction was not found. Analyses of fMRI responses showed significantly different lateral postcentral gyrus activation in the pain anticipation condition. Linear regression analyses on Veterans in the pain anticipation condition showed that physical activity (e.g., moderate-vigorous physical activity) and sedentary behavior (e.g., average sedentary bouts of 30 or 60 minutes) did not significantly predict perception of pain intensity or unpleasantness. **CONCLUSION:** Pain anticipation influences perceptual and neural responses to non-painful stimuli among Gulf War Veterans with or without CMP; however, physical activity or sedentary behavior may not be related to anticipation-related pain sensitivity in this population. Supported by Dept. of Veterans Affairs grant: 561-00436

2938 June 2 1:30 PM - 1:45 PM

Playing With A Friend Or Parent, Versus Playing Alone, Moderates Associations Between Hr And Rpe.

Mallory S. Kobak¹, Andrew Lepp², Jacob E. Barkley², Michael J. Rebold³. ¹The University of Akron, Akron, OH. ²Kent State University, Kent, OH. ³Hiram College, Hiram, OH. (Sponsor: Ellen L Glickman, FACSM)
Email: msk27@zips.uakron.edu
(No relationships reported)

Previously, our group have shown that interacting with peers and/or parents, relative to playing alone, increases physical activity behavior in children without altering perceived exertion. It is possible that the enriching nature of interacting with peers and parents distracts children from how intense their physical activity is thus disrupting their ability to accurately perceive exertion. **PURPOSE:** To determine if, relative to a condition where a child plays alone, playing with a friend or parent moderates the association between an objective, physiologic measure of intensity (i.e., heart rate) and ratings of perceived exertion (RPE) in children. We hypothesized that the association between heart rate and RPE will weaken from the alone condition to both the parent and friend conditions. **METHODS:** Twenty children (8.3 ± 1.3 years old, $n = 10$ girls) participated in three simulated recess conditions (alone, friend, parent) on separate days. During each of the conditions, children had 30 minutes of free access to an outdoor playground (e.g., slides, crawl tubes, etc.) and a chair with a table of sedentary activity options (e.g., books, toys, coloring sheets, etc.) situated within the playground property. Only a single participant and their friend or parent (during the friend and parent conditions) were present during each condition. Average heart rate was recorded during each condition via a telemetry monitor and self-reported RPE was obtained via the children's OMNI walk/run scale. **RESULTS:** Pearson's correlation analyses revealed that the association between heart rate and RPE was strongest when children were playing alone ($r = 0.34$). This association was 10% and 62% greater than when children were playing with their friend ($r = 0.31$) and parent ($r = 0.21$), respectively. **CONCLUSION:** Playing with a parent and, to a lesser extent, with a friend present moderates the association between heart rate and RPE relative to a condition when

children were playing alone. It is possible that when children played with a parent or friend it was more difficult to perceive effort because they were distracted by their exercise partner. That distraction may come in the form of greater enjoyment of or motivation for participating in physical activity.

2939 June 2 1:45 PM - 2:00 PM

Altered Breathing Pattern Responses to Exercise in Veterans with Fatiguing Illness

Michael J. Falvo¹, Jacob Lindheimer¹, Jacquelyn Klein¹, Duncan Ndirangu¹, Yang Chen¹, Michael Condon¹, Dane Cook, FACSM². ¹VA NJ Health Care System, East Orange, NJ. ²University of Wisconsin-Madison, Madison, WI. (Sponsor: Dane Cook, FACSM)
Email: Michael.Falvo@va.gov
(No relationships reported)

Gulf War Veterans with fatiguing illness often perceive exercise as more effortful in comparison to controls despite similar exercise capacity. Breathing pattern responses may contribute to this perception, but have not been thoroughly examined in this group of Veterans. **PURPOSE:** To evaluate breathing patterns during a maximal cardiopulmonary exercise test (CPX) between deployed Veterans with fatiguing illness and controls. **METHODS:** CPX was performed on a cycle ergometer in 17 deployed Veterans (mean \pm SD; 49.6 ± 6.2 years) with clinical fatigue (Fatigue Severity Scale [FSS]: 54.7 ± 6.1) and 14 non-fatigued controls (53.5 ± 5.8 years; FSS: 18.2 ± 7.9). Ventilatory parameters were obtained breath-by-breath throughout exercise and compared at relative intensities (20, 40, 60, 80 and 100% of peak oxygen consumption [$\dot{V}O_{2j}$]). Primary variables of interest included both tidal volume (VT) and respiratory frequency (RF) at increasing exercise intensities and were compared between- and within-groups using repeated measures ANOVA. **RESULTS:** Demographics (Veterans vs. controls: 30.3 ± 4.4 kg/m² vs. 30.7 ± 4.7 kg/m²), baseline physical activity levels (108.3 ± 45.9 vs. 154 ± 52.6 min-wk⁻¹), and peak $\dot{V}O_2$ (22.5 ± 4.7 vs. 20.9 ± 5.9 ml/kg/min) were similar between groups. A significant main effect for exercise intensity was observed for both VT and RF ($p < 0.05$), but only VT demonstrated a significant group-by-time interaction ($p < 0.05$). Veterans with fatiguing illness had significantly higher VT at each exercise intensity level ($p < 0.01$) in comparison to controls, but RF was similar across all intensities. Bivariate associations were observed between VT at each exercise intensity with FSS ($r = 0.39$, $p < 0.01$) and a measure of physical health-related functioning (physical composite score; $r = -0.35$ to -0.45 , $p < 0.01$), but not for RF ($p > 0.05$). **CONCLUSIONS:** Despite similar peak exercise capacity, Veterans with fatiguing illness adopt a unique breathing pattern characterized by high tidal volumes throughout exercise. Higher exercise tidal volumes may encroach on vital capacity and contribute to perceptions of fatigue and effort. Additional studies are needed to confirm a neurophysiological basis of exercise discomfort in this group of Veterans, but evaluating breathing patterns during exercise may afford unique insight.

2940 June 2 2:00 PM - 2:15 PM

The Influence Of A Sit-stand Desk On Sleepiness, Physical Discomfort, Physical Fatigue And Mental Fatigue

Robert J. Kowalsky, Sophy J. Perdomo, Jeffery R. Balzer, Christopher E. Kline, Bethany Barone Gibbs. University of Pittsburgh, Pittsburgh, PA. (Sponsor: John M. Jakicic, FACSM)
Email: rjk70@pitt.edu
(No relationships reported)

Sleepiness, pain and fatigue significantly impact the productivity of office workers, and prolonged sitting may negatively impact these feelings during deskwork. Using a sit-stand desk could benefit these measures, but it is not clear. **PURPOSE:** To examine whether using a sit-stand desk to alternate posture could improve ratings of sleepiness, mental fatigue, physical fatigue and physical discomfort. **METHODS:** 25 inactive adults (age: 42 ± 12 yr; BMI: 31.9 ± 5.0 kg/m²) participated in a randomized cross-over study of two simulated 8-hr workdays (with a lunchbreak) while performing continuous sitting (SIT) or alternating sit-stand postures every 30 min (SIT-STAND). Ratings of sleepiness were measured by the 9-pt Karolinska Sleepiness Scale each hr while at the desk. A validated questionnaire measured the overall presence of physical discomfort, degree of physical discomfort (averaged across 10 body locations) and degree of physical and mental fatigue every 2 hr by 100-pt visual analog scales. Outcomes were checked for skewness and log transformed. Generalized linear mixed models, controlling for baseline values, evaluated differences across condition and time. **RESULTS:** Sleepiness increased across the day ($p < 0.001$) and was lower in SIT-STAND vs. SIT ($p = 0.036$). Mental fatigue was similar across time ($p = 0.095$) and conditions ($p = 0.068$). Comparing SIT-STAND to SIT, the presence of any physical discomfort was less frequently reported ($p = 0.006$) and degree of physical discomfort was lower ($p < 0.001$). The presence or degree of physical discomfort did not differ over time ($p = 0.378$ and $p = 0.089$, respectively). Physical fatigue was similar across the day ($p = 0.050$) and conditions ($p = 0.712$). (See table 1)

CONCLUSION: Using a sit-stand desk during daily work activity resulted in better ratings of sleepiness and physical discomfort compared to sitting all workday. These measures are important for presenteeism of office workers and should be explored over a longer duration.

2941 June 2 2:15 PM - 2:30 PM

Perceptions At Moderate Work Intensity In Temperate And Hot Conditions In Trained And Untrained Individuals

Aitor Coca, Tyler Quinn, Yongsuk Seo, Tianzhou Wu, Amanda Strauch, Raymond Roberge, Jun-Hyun Kim. *NIOSH/NPPTL, Pittsburgh, PA.*

Email: esq6@cdc.gov

(No relationships reported)

Ratings of perceived exertion (RPE) and thermal comfort (TC) scales are used to assess exercise intensity, subjects' exertion and heat perception. For the safety of workers in the heat, it has been proposed that increased fitness levels may have a protective effect and could be associated with benefits to work in the heat, but it remains unclear if trained individuals perceive exertion and heat differently than untrained individuals at moderate work intensities. **PURPOSE:** This study compares RPE and TC in trained (TR) versus untrained (UT) individuals at a cycling intensity of 75% $\text{VO}_{2\text{max}}$ in the heat.

METHODS: Twelve young healthy males were categorized into two groups, TR (n=6, age=26.3±5.9 years, BMI=23.6±2.0kg/m², aerobic exercise minutes=265±114.5minutes/week) and UT (n=6, age=23.0±2.7 years, BMI=25.6±1.1kg/m², aerobic exercise minutes=55±72.0 minutes/week) based on their self-reported exercise behaviors. Each individual completed a graded exercise test on a cycle ergometer to maximal exertion in a neutral (NORM; 25°C, 50% relative humidity) or hot (HYPER; 40°C, 50% relative humidity) environment. During the HYPER condition, participants also wore a heating garment with 45°C circulating water until their rectal temperature (Tre) increased by 0.5°C from baseline.

RESULTS: At the start of exercise or at 75% $\text{VO}_{2\text{max}}$, neither HR nor Tre showed significant differences between TR and UT in either condition. RPE and TC did not differ between TR and UT in either condition at 75% $\text{VO}_{2\text{max}}$ - NORM: TR: RPE: 14.1±1.8, UT: 15.0±2.2, p=0.458; TC: 0.8±0.7, UT: 1.6±1.1, p=0.141; HYPER: TR: RPE: 13.6±0.5, UT: 12.6±2.3, p=0.369; TC: 1.8±0.4, UT: 1.6±0.5, p=0.649. RPE did not show differences between NORM and HYPER at 75% $\text{VO}_{2\text{max}}$ in TR (p=0.557) nor UT (p=0.152).

CONCLUSIONS: Trained individuals perceive exertion and heat similarly to untrained individuals at 75% $\text{VO}_{2\text{max}}$ in normal or hot conditions. This conclusion has implications for workers safety and the risk for heat injuries in hyperthermia across individuals of varying fitness levels.

2942 June 2 2:30 PM - 2:45 PM

Comparison of Mood Response Through Five Weeks of a High Intensity Functional Training Competition

Allyson G. Box¹, Gerald Mangine¹, Linda Lager¹, Brian Kliszczewicz¹, Steven J. Petruzzello², Yuri Feito, FACSM¹. ¹Kennesaw State University, Kennesaw, GA. ²University of Illinois Urbana-Champaign, Urbana, IL. (Sponsor: Yuri Feito, FACSM)

(No relationships reported)

Mood is known to be affected by exercise, as well as the predictability of an event. By design, high-intensity functional training (HIFT) incorporates a wide variety of exercise modalities. Further, competitive HIFT events generally incorporate a unique and unpredictable combination of fitness challenges that may elicit varying mood responses. **Purpose:** Examine mood prior to and following 5 unique, competitive HIFT events during a worldwide fitness competition. **Methods:** Physically active adults (N=11; 34.9 ± 5.1 years, 77.9 ± 15.1 kg, 166.1 ± 10.6 cm) with HIFT experience (≥6 months) completed a baseline (BL) Profile of Mood States (POMS) questionnaire the week prior to the HIFT competition. During each week of the 5-wk competition, the competitors completed a unique HIFT fitness challenge. For each challenge, the POMS was completed prior to (PRE), immediately post (IP), 30-min post- (30P), and 60-min post-exercise (60P). The POMS yields measures of tension, depression, anger, confusion, fatigue (FAT), and vigor (VIG). Additionally, Total Mood Disturbance (TMD; sum of other 5 subscales minus VIG) and Energy Index (EI; VIG - FAT) were also calculated and analyzed. **Results:** Repeated measures analysis of variance revealed no differences between BL and PRE values across weeks. Week (1-5) x Time (PRE, IP, 30P, 60P) interactions were observed for EI (P=0.025) and FAT (P=0.002). Compared to Week 5, EI was higher (increased VIG and/or decreased FAT) in Week 3 at 30P (Wk3: 12.3 ± 3.6; Wk5: 4.0 ± 5.4, P=0.003), and higher than Wk1 (P=0.005) and Wk3 (P=0.005) at 60P (Wk1: 14.8 ± 8.7; Wk3: 11.6 ± 4.0; Wk5: 6.0 ± 5.4). Compared to Wk3, FAT was significantly greater at Wk1 (P=0.005), Wk4 (P=0.001), and Wk5 (P=0.008) at IP (Wk1: 10.3 ± 4.0; Wk3: 4.4 ± 5.2; Wk4: 9.1 ± 5.9; Wk5: 10.4 ± 7.3). No other significant interactions were observed between weeks. **Conclusion:**

The unique design of the HIFT competition did not seem to impact pre-exercise mood, but the different workouts resulted in differing mood responses, particularly for vigor and fatigue.

Establishing Thresholds for Visual Discrimination of Intrinsic and Novel Coordination Patterns

Shaochen Huang, Qin Zhu. *University of Wyoming, Laramie, WY.*

Email: shuang5@uwyo.edu

(No relationships reported)

Human movements are characterized with different coordination patterns. The ability to visually discriminate the coordination pattern is important for people to recognize the other's movement and plan for the response. Two coordination patterns are known to be intrinsic for humans: in-phase (0°) and anti-phase (180°). They can be perceived and produced easily without practice. Any coordination pattern between 0° and 180° has to be learned through significant amount of practice. Neurological diseases or traumatic brain injury may result in decreased ability to perceive and produce the intrinsic coordination patterns, as well as to learn novel coordination patterns.

PURPOSE: To establish threshold for healthy controls to visually discriminate the intrinsic and novel coordination patterns. **METHODS:** A total of 15 healthy adults aged from 20-40s were recruited (23.47 ± 3.87). They were tested on the ability to visually discriminate three coordination patterns: 0°, 90°, and 180°. A computer display of a target pattern was shown, followed by displays of a pair of patterns, in which one was the target pattern and the other was the distracting pattern. Participants had to press a key to indicate whether the first or second of the pair was the target pattern. Logistic curve fitting was performed to calculate the individual threshold for discriminating each target coordination pattern. **RESULTS:** A one-way repeated measure ANOVA was performed to examine the difference of mean thresholds among three coordination patterns. A significant difference was shown ($F_{2,28} = 54.88$, p<.001). The threshold for discriminating 90° was the greatest with the largest variability (25.64° ± 12.39°). Although thresholds for discriminating the two intrinsic coordination patterns were smaller, discriminating 180° (4.97° ± 3.79°) was more challenged and variable than discriminating 0° (0.56° ± 1.00°). **CONCLUSION:** For health controls, visually discriminating intrinsic coordination patterns is easier and more consistent than discriminating novel coordination patterns. Establishing the normal thresholds for visual discrimination of intrinsic and novel coordination patterns helped to develop visual-motor coordination tests to screen the neurological diseases or traumatic brain injury.

The Level Of Physical Activity Post-myocardial Infarction Predicts Future Mortality

Mats Börjesson¹, Amanda Ek², Kristina Hambraeus³, Lena Kallings², Örjan Ekblom². ¹Sahlgrenska University Hospital, GOTHENBURG, Sweden. ²Swedish School of Sport and Exercise, STOCKHOLM, Sweden. ³Falu Hospital, FALUN, Sweden.

Reported Relationships: M. Börjesson: Consulting Fee; NovoNordisk, AstraZeneca.

There is little knowledge of the association between physical activity (PA) level and the mortality risk post myocardial infarction (MI). Smaller studies have indicated, that individuals who remain active or increase their level of PA after MI have a lower risk of death. However, in order to confirm this and adjust for confounders larger studies are needed. **PURPOSE:** Explore any association between PA level after MI and all-cause mortality during follow-up in a large MI-cohort.

METHODS: A national cohort study including all patients <75 years of age, with a diagnosis of MI between 1991-2014 (Swedish MI register SWEDEHEART). From the register self-reported PA, 6-10 weeks post MI, (i.e. number of sessions during the past seven days with moderate and/or vigorous PA lasting ≥30 minutes) was obtained. The answers were grouped into 0-1 sessions (inactive), 2-4 sessions (moderately active) and 5-7 sessions (highly active). Associations were first assessed unadjusted, stratified by potential confounders (sex, age, smoking status, ejection fraction, ST-

elevation and quality of life). Thereafter, a multiple logistic regression was performed to control for possible confounders. **RESULTS:** Complete data was obtained from 37 655 individuals (median 63 years, 74 % men). A total of 2512 deaths occurred during a mean of 4.1 years of follow-up. The mortality rate was 17.0 cases/1000 person-years. Moderate activity (n= 10 601) and high activity (n=18 545), was associated with a lower risk of all-cause mortality at follow-up (OR 0.356 95 % CI 0.320-0.396 and OR 0.334, 95 % CI 0.305-0.366), compared to being physically inactive (n=8519). The OR's remained largely unchanged when stratifying for age, sex, non-ST elevation MI/ST-elevation MI and ejection fraction. However, active smokers had a lower OR, for subsequent death, as had patients with a low EQ5D. The associations persisted in the multiple logistic regression, after adjustment for the possible confounders above. **CONCLUSIONS:** A higher level of physical activity 6 -10 weeks after myocardial infarction, is associated with a lower risk of all-cause mortality at follow-up. These results suggest that physical activity assessment is important post-MI, not least as an important predictor of subsequent mortality.

Effect Of Cardiorespiratory Fitness On Blood Glucose Trajectory With Aging: A Cohort Study Of Japanese Men

Haruki Momma¹, Susumu S. Sawada, FACSM², Kazunori Shimada³, Yuko Gando², Motohiko Miyachi², Chihiro Kinugawa⁴, Takashi Okamoto⁴, Koji Tsukamoto⁴, Cong Huang¹, Ryoichi Nagatomi¹. ¹Tohoku University, Sendai, Japan. ²National Institutes of Biomedical Innovation, health and Nutrition, Tokyo, Japan. ³Juntendo University Graduate School of Medicine, Tokyo, Japan. ⁴Tokyo Gas Health Promotion Center, Tokyo, Japan.
Email: h-momma@med.tohoku.ac.jp
(No relationships reported)

There has only been one study examining the effect of cardiorespiratory fitness (CRF) on blood glucose with aging among Americans. Whether CRF also has a similar effect on aging-associated change in blood glucose among Japanese with lower prevalence of obesity as compared with Americans. **PURPOSE:** To investigate whether the aging-related increase of glucose in Japanese men with higher CRF is smaller than that of those with lower CRF. **METHODS:** We studied 6,153 Japanese men (age: 20-60 y) free of diabetes, cardiovascular disease and stroke in 1986. The participants completed annual health examinations including fasting blood glucose until 2009. CRF was measured by a submaximal exercise test between 1979 and 1986. Participants were divided into quartiles (Q1, Q2, Q3, and Q4) for CRF based on the cumulative mean of CRF during the period. Time-invariant covariates included BMI, smoking status, drinking habit, desk work, family history of diabetes, and frequency of measurements of blood glucose, and time-variant covariates included systolic blood pressure and fasting blood triglyceride. The trajectories of glucose with aging were analyzed using linear mixed models. **RESULTS:** Fasting glucose increased at a linear rate with aging. Glucose increased at a yearly rate of 0.49 mg/dL (95% confidence interval: 0.48-0.50). After adjustment for covariates, the aging-related glucose increase in men with Q4 of CRF (0.42 [0.40-0.44] mg/dL per year) was smaller than that in men with Q1 (0.55 mg/dL [0.50-0.60] per year), Q2 (0.51 mg/dL [0.46-0.56] per year), Q3 (0.48 mg/dL [0.42-0.53] per year), respectively. **CONCLUSIONS:** Higher levels of CRF is inversely associated with the increase in blood glucose with aging among Japanese healthy men.

2947 June 2 1:30 PM - 1:45 PM

Associations Of Sarcopenia And Low Muscular Strength With All-cause Mortality Among Us Older Adults

Ran Li¹, Jin Xia², Xi Zhang², Jianjun Guo¹, Yiqing Song². ¹China Institute of Sport Science, Beijing, China. ²Richard M. Fairbanks School of Public Health, Indiana University, Indianapolis, IN.
Email: liran@ciss.cn
(No relationships reported)

Sarcopenia is defined as aging-related loss of muscle mass and knee extension strength serves as a marker of lower extremity muscular strength in populations. Sarcopenia and low muscular strength (LMS) may be important but understudied risk factors for aging-related morbidity and mortality in the older and elderly populations. **PURPOSE:** We aimed to prospectively examine individual or joint associations of sarcopenia and LMS with all-cause mortality in a nationally representative sample of US older adults in the National Health and Nutrition Examination Survey (NHANES). **METHODS:** Data sources included the NHANES 1999-2002 with public-use 2011 linked mortality files, which comprised 4,449 participants aged 50 years and older with complete data on body composition by dual-energy x-ray absorptiometry and isokinetic knee extensor strength measurement. Sarcopenia was defined by two definitions proposed by the National Institutes of Health Sarcopenia Project according to appendicular lean mass

(ALM) and ALM divided by BMI (ALM/BMI). LMS was defined as the lowest 25% of measurements of knee extensor strength. Weighted multivariable logistic regression models were adjusted for age, sex, race, BMI, smoking, alcohol use, education, leisure time physical activity, sedentary time, and comorbidities. **RESULTS:** The weighted prevalence of sarcopenia was 23.1% defined by ALM and 17.0% defined by ALM/BMI; the weighted prevalence of low muscular strength was 19.4%. In the multivariate-adjusted models, sarcopenia was significantly associated with increased risk of all-cause mortality for ALM/BMI definition (OR: 1.44; 95% confidence interval [CI], 1.06-1.97) but not for ALM definition (OR: 1.37; 95% CI, 0.90-2.09) while LMS was strongly associated with all-cause mortality (OR: 2.32; 95% CI, 1.70-3.18). In the joint analyses, a significantly increased all-cause mortality was observed only among participants with LMS and non-sarcopenia (OR range: 2.03-2.50) and those with LMS and sarcopenia (OR range: 2.15-2.56) while those without sarcopenia and LMS were the reference group. **CONCLUSIONS:** Low knee extensor strength indicative of low muscular strength was independently and significantly associated with an increased risk of all-cause mortality among US older adults regardless of the presence or absence of sarcopenia.

2948 June 2 1:45 PM - 2:00 PM

Muscle Weakness Increases the Risk of Incident Diabetes in Older Mexican Americans

Brenda M. Vincent¹, Ryan P. McGrath², Soham Al Snih³, Kyriakos S. Markides³, Mark D. Peterson, FACSM². ¹VA Ann Arbor Health System, Ann Arbor, MI. ²University of Michigan Medical School, Ann Arbor, MI. ³University of Texas Medical Branch, Galveston, TX.
Email: brenda.vincent@va.gov
(No relationships reported)

A natural decline of muscle strength occurs during the aging process; however, preserving muscle strength may reduce the risk of many preventable diseases such as diabetes, especially in higher risk populations. **PURPOSE:** The purpose of this study was to examine the sex-specific association between muscle weakness and incident diabetes in older Mexican Americans. **METHODS:** A subsample of 1,903 Mexican Americans aged at least 65 years at baseline was followed for 13 years. Muscle strength was assessed with a hand-held dynamometer and was normalized to body weight (normalized grip strength (NGS)). Male and female participants were categorized as weak if their NGS was ≤ 0.46 and ≤ 0.30 , respectively. Diabetes status and age of diabetes diagnosis was self-reported by participants. Sex-stratified Cox proportional hazard regression models were used to determine the association between muscle weakness and incident diabetes when using age as an entry variable and after adjusting for marital status, employment status, and education. A sensitivity analysis was performed to account for influential outliers in the outcome variable (time to incident diabetes) and the model was re-run. If a >10% change in the hazard ratios was identified, the results of the model that underwent the sensitivity analysis would be presented. **RESULTS:** The hazard ratio for incident diabetes was 1.16 (95% confidence intervals (CI): 1.12-1.20; $p < 0.001$) in weak vs. strong males and 1.24 (CI: 1.21-1.27; $p < 0.001$) in weak vs. strong females, after adjusting for marital status, employment status and education. **CONCLUSIONS:** Muscle weakness was robustly associated with an increased risk of incident diabetes in older Mexican American males and females. Health professionals should encourage physical activities and healthy behaviors that preserve or improve muscle strength, thereby reducing the risk of incident diabetes in older Mexican Americans. NGS may also be used to assess and monitor muscle weakness in older populations, especially because it is inexpensive and non-invasive.

Examining The "Weekend Warrior" And Mortality Using Accelerometer-assessed Physical Activity In NHANES

Eric J. Shiroma¹, I-Min Lee, FACSM², Mitchell A. Schepps¹, Masamitsu Kamada², Osorio Meirelles¹, Tamara B. Harris¹. ¹National Institute on Aging (NIH), Bethesda, MD. ²Brigham & Women's Hospital / Harvard Medical School, Boston, MA.
(Sponsor: I-Min Lee, FACSM)
Email: eric.shiroma@nih.gov
(No relationships reported)

PURPOSE: It remains unclear if those who participate in physical activity on only a few days a week, "weekend warriors", have similar health benefits to those who perform activity more often over the week. Accelerometers provide a real time, objective measure of physical activity that may allow for further exploration of activity and health through pattern analysis, such as examining activity frequency. The aim of this study is to use accelerometer-assessed physical activity to compare the mortality risk among "weekend warriors" to more regularly active adults, in a large population-based study. **METHODS:** Study participants were from the National Health and Nutrition Examination Survey (NHANES), a population-based study with mortality follow-up through 2011. Participants were required to be at least 20 years

old and have worn the accelerometer for 6 or 7 days ($n = 4206$). Weekly moderate-to-vigorous physical activity (MVPA) was categorized based on the US Federal Physical Activity Guidelines: 1) <75 minutes; 2) 75-150 minutes; 3) ≥ 150 minutes per week (recommended). Of those in the ≥ 150 minutes group, participants who performed $\geq 50\%$ of their weekly activity on only 1 or 2 days were classified as "weekend warriors", and the rest as "regularly active". To compare mortality rates based on physical activity category, we calculated hazard ratios (95% confidence intervals) using Cox survival analysis and adjusting for relevant covariates. **RESULTS:** Over an average of 79.4 (SD = 18.6) months of follow-up, there were 419 deaths. Participants with some activity, but insufficient to meet the guidelines (75-150 minutes per week MVPA), had a 61% reduction (HR = 0.39 (95% CI: 0.26, 0.58)) in mortality risk compared to those with <75 minutes per week. Participants meeting the guidelines had a similar mortality risk reduction, $\sim 50\%$, compared to those with the least activity, whether "weekend warriors" (HR = 0.50 (0.32, 0.81)) or regularly active participants (HR = 0.48 (0.28, 0.81)). **CONCLUSIONS:** Active participants and those with some activity, but insufficient to meet the guidelines, both had reduced mortality risk during follow-up compared to the least active participants. "Weekend warriors" were observed to have comparable magnitude of risk reduction as regularly active participants.

The Epidemiology of Health and Morbidity Amongst Former Rugby Union Players

Madeleine A.M. Davies¹, Andrew Judge¹, Antonella Delmestri¹, Simon Kemp², Keith A. Stokes³, Julia L. Newton¹, Nigel K. Arden¹. ¹University of Oxford, Oxford, United Kingdom. ²Rugby Football Union, Twickenham, United Kingdom. ³University of Bath, Bath, United Kingdom.
Email: madeleine.davies@lmh.ox.ac.uk
(No relationships reported)

Despite over 7 million participants in rugby union ('rugby') globally, the effect of rugby on health, in terms of increasing or decreasing the prevalence of long-term morbidity amongst players, has not yet been established. Where sport may be associated with decreased morbidity, participation can be recommended as improving specific health outcomes. Where former players are seen to demonstrate health deficits, potential targets for population interventions may become evident. **PURPOSE:** To determine the prevalence of self-reported physician-diagnosed morbidity amongst former elite rugby players, and compare this with an age and gender-standardised representative national population comparison. **METHODS:** A cross-sectional questionnaire study was used. The English Longitudinal Study of Ageing (ELSA), a nationally representative study of English adults, was used as a control population. Age and gender matched standardised morbidity ratios (SMR) were calculated against the ELSA reference population. A post-hoc sensitivity analysis examined morbidity differences between the complete cohort of former players and ELSA participants. **RESULTS:** Amongst gender-matched rugby ($n=259$) and ELSA ($n=5186$) participants aged 50 and over, diabetes was significantly lower amongst former players (SMR 0.28, CI 0.11 to 0.66), whereas osteoporosis (SMR 2.69, CI 1.35 to 5.38) and osteoarthritis (SMR 4.00) were significantly increased amongst former players. In unadjusted, complete cohort sensitivity analyses, hypertension and heart problems were also decreased compared with ELSA. **CONCLUSIONS:** Morbidity differs amongst former elite rugby players and the general population. The magnitude of musculoskeletal morbidity in this population may warrant proactive osteoarthritis education and management in this at-risk population.

2951 June 2 2:30 PM - 2:45 PM

Longitudinal Associations Of Adiposity And Grip Strength With Physical Activity Assessed With Wrist-worn Accelerometers In 84,779 Adults: The Uk Biobank Study

Youngwon Kim, Tom White, Stephen J. Sharp, Katrien Wijndaele, Soren Brage. University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom.
Email: Youngwon.Kim@mrc-epid.cam.ac.uk
(No relationships reported)

PURPOSE: To determine the longitudinal associations of body mass index (BMI), waist circumference (WC) and grip strength (GS) with objectively measured physical activity (PA) in adults. **METHODS:** This study utilized data from the UK Biobank study, an ongoing prospective cohort of over half a million UK adults aged 40-69yrs at recruitment (2006 to 2010). Each participant underwent baseline measurements of BMI (kg/m²), WC (cm) and GS (kg). GS was measured using a hand dynamometer. Values from the two hands were averaged. Between 2013 and 2015, a sub-sample of over 100,000 participants each wore a tri-axial accelerometer on the dominant wrist for 7 days. Measurements taken at baseline were not repeated during the follow-up accelerometer protocol. Mean acceleration levels were calculated, and moderate-to-vigorous PA

(MVPA) was estimated as time when acceleration was above 125mg. BMI, WC and GS were standardized, and PA outcomes were log-transformed. **RESULTS:** A total of 84,812 participants (46,947 women) with ≥ 72 hours of wear and no missing covariates were included in the analysis. The median follow-up was 5.7 years (interquartile range: 4.9-6.5). Using multiple linear regression adjusted for GS and various potential confounders (demographic, lifestyle, disease status, seasonality), every 1 standard deviation increase in BMI and WC was associated with 0.071 (95% confidence interval [CI]: -0.073, -0.069) and 0.070 (95% CI: -0.073, -0.068) lower log of mean acceleration at follow-up, respectively, in women: in men, BMI (b: -0.066; CI: -0.069, -0.063) and WC (b: -0.076; CI: -0.079, -0.073). Positive associations were found between baseline GS and follow-up acceleration levels after adjusting for confounders and BMI, in women (b: 0.013; CI: 0.010, 0.01) and men (b: 0.004; CI: 0.001, 0.007). Marginal means (adjusted for confounders) of follow-up acceleration were lower in individuals with higher adiposity levels and/or lower GS at baseline. Similar results were observed with MVPA as an outcome.

CONCLUSIONS: BMI, WC and GS at baseline predicted objectively measured PA at follow-up. Findings of our study provide compelling justification for interventions and policies to focus on improving body composition and muscle strength to increase or prevent decline in PA at the population level.

2952 June 2 2:45 PM - 3:00 PM

Energy Expenditure From Light And Moderate-Vigorous Intensity Physical Activity And All-cause Mortality

Pedro F. Saint-Maurice¹, Steven C. Moore¹, Sarah Keadle², Charles E. Matthews, FACSM¹. ¹National Cancer Institute, Rockville, MD. ²California Polytechnic State University, San Luis Obispo, CA. (Sponsor: Charles E. Matthews, FACSM)
Email: pedro.saintmaurice@nih.gov
(No relationships reported)

PURPOSE: It has been suggested that light intensity activity may have health benefits however, it is still uncertain whether 1 MET-hr of light intensity activity confers similar benefit as 1 MET-hr of moderate-to-vigorous (MV) activity. This study examined the mortality benefits of light and MV intensity activity, while accounting for the volume of activity. **METHODS:** Accelerometer (ActiGraph 7164) records were extracted from the NHANES 2003-2006 adult database ($n=6355$). Participants were followed prospectively for mortality through 2011 via the National Death Index. Volume of light and MV activity was determined by classifying monitored time into light (100-759 cts/m) and MV (760+ cts/m) intensity activity and by estimating energy expenditure (MET-hrs/d) within each intensity category. Cox proportional hazard models were used to estimate hazard ratios and 95% confidence intervals (HR [95% CI]) for mortality associated with 1 MET-hr/d increase in light or MV activity adjusted for age, sex, ethnicity, education, smoking, alcohol, health status (diabetes, cancer, heart disease, stroke, mobility), BMI, with and without mutual adjustment for light and MV activity. To account for non-linear mortality associations we examined both exposures among low- ($n=2588$) and highly-active adults ($n=2251$). **RESULTS:** There was complete data on 4839 adults (≥ 40 yrs) followed over a period of 6.5 yrs. There were 572 deaths registered among the low-active group and 128 deaths in the highly-active group. Initial models in the low-active group without mutual adjustment revealed significant associations for light (HR=0.85 [0.80, 0.90]) and MV activity (HR=0.70 [0.64, 0.77]). After mutual adjustment for each activity intensity, among low-active adults, a 1 MET-hr/d increase in light activity was associated with 9% lower mortality (HR=0.91 [0.86, 0.97]; $p = 0.002$), while a 1 MET-hr/d increase in MV activity was associated with 26% lower mortality (HR=0.74 [0.67, 0.81]; $p < 0.001$). There were no significant reductions in mortality risk among the high-active group ($p > 0.05$). **CONCLUSIONS:** The findings support the idea that greater amounts of light activity are associated with lower mortality among less active individuals after considering MV energy expenditure. However, for a given MET-hr of activity, MV may provide more benefit.

F-30 Thematic Poster - Altitude/Hypoxia/Supplementation

Co-ingestion Of Glucose And Fructose During Exercise On Acute Exposure To Altitude

Nicola C. Arjomandkhalil¹, John P. O'Hara², Roderick F. G. J. King². ¹Leeds Trinity University, Leeds, United Kingdom. ²Leeds Beckett University, Leeds, United Kingdom.
Email: n.arjomandkhalil@leedstrinity.ac.uk

(No relationships reported)

The reduction in partial pressure of oxygen (O_2) leading to reduced O_2 delivery to tissues at altitude has the potential to alter substrate utilization during exercise. Experiments at sea level suggest performance benefits from consuming multiple transportable carbohydrates, the impact of this at altitude is not known. **PURPOSE:** To investigate how carbohydrate (CHO) (glucose and fructose) ingestion effects fuel utilization during exercise at 2500m and the impact of this on performance. **METHODS:** Ingestion of 1.2 g·min⁻¹ glucose plus 0.8 g·min⁻¹ fructose was compared to 1.2 g·min⁻¹ glucose and a placebo during 120 minutes running at 70% $\dot{V}O_{2max}$ performed by eight males in a normobaric hypoxic chamber set at 2500m altitude. Exogenous and endogenous oxidation was quantified using ¹³C stable mass isotope tracing techniques. Performance was measured in a 5 km TT. **RESULTS:** CHO ingestion shifted fuel use to predominantly CHO (79.51 ± 7.11, 79.45 ± 1.88 and 56.66 ± 20.18% in glucose plus fructose, glucose alone and placebo, respectively) compared with placebo where fat (20.49 ± 7.11, 20.55 ± 11.88 and 43.34 ± 20.18% in glucose plus fructose, glucose alone and placebo, respectively) was the dominant fuel. Co-ingestion of glucose and fructose led to significantly ($p < 0.001$; ES= 3.82) greater peak exogenous CHO oxidation rates compared to glucose alone (1.51 ± 0.14 g·min⁻¹ and 0.96 ± 0.07 g·min⁻¹, respectively) and this resulted in a significantly ($p = 0.007$; ES= 1.01) lower contribution from endogenous CHO oxidation (49.15 ± 8.85% and 59.65 ± 1.80%, respectively). Co-ingestion of glucose and fructose did not improve performance in the 5 km TT (25:37 ± 03:01 minutes) compared to glucose alone (25:13 ± 02:53 minutes). However, time to complete the 5 km TT was significantly ($p = 0.002$; ES= 0.47) faster in the glucose only trial compared to placebo (26:33 ± 2:59 minutes). **CONCLUSION:** CHO ingestion reduced the reliance on fat oxidation compared to placebo and the co-ingestion of glucose and fructose increased exogenous and spared endogenous CHO oxidation over glucose alone. However, the co-ingestion of glucose and fructose did not provide an ergogenic benefit at 2500m.

No Impact of Carbohydrate Supplementation and Altitude Acclimatization on Aerobic Exercise Performance

Robert W. Kenefick, FACSM, Adam J. Luippold, Karleigh E. Bradbury, Andrew J. Young, FACSM, Allyson N. Derosier, Marques A. Wilson, Claire E. Berryman, Stefan M. Pasiakos, FACSM. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*

Email: Robert.W.Kenefick.civ@mail.mil

(No relationships reported)

Ergogenic benefits of carbohydrate (CHO) supplementation during exercise at high altitude (HA) appear to vary depending on acclimatization status. However, longitudinal evaluation of potential performance benefits of CHO in the same volunteers, prior to- and following acclimatization to HA have not been reported. **PURPOSE:** To determine the impact of a CHO beverage consumed during steady-state exercise, on subsequent time trial (TT) performance (2 mi. run), of lowlanders immediately after they arrived at high altitude (A-HA) and after 22 days (C-HA) of acclimatization at 4,300 m. **METHODS:** Seventeen unacclimatized men (mean ± SD; age, 23.4 ± 5.6 y; body mass, 81.9 ± 13.9 kg; SL $\dot{V}O_{2peak}$ 4.2 ± 0.7 L/min, HA $\dot{V}O_{2peak}$ 2.8 ± 0.5 L/min) performed 80-min of treadmill walking (~55% of HA $\dot{V}O_{2peak}$) at sea level (SL), A-HA and C-HA. Before, and every 20 min during exercise they consumed either a CHO beverage (n = 9; 45 g fructose/L + 55 g glucose/L, 1.8 g CHO/min) or a flavor-matched placebo (PLA, n = 8). Immediately following walking/supplementation, a 2 mi., self-paced TT was performed. **RESULTS:** There were no differences ($P > 0.05$) in TT duration between CHO and PLA at SL (17.1 ± 2.8 vs. 18.8 ± 4.2 min), A-HA (27.9 ± 5.0 vs. 27.3 ± 7.0 min) or C-HA (23.9 ± 4.0 vs. 24.2 ± 4.7 min), respectively. Acute and chronic HA exposure did significantly alter TT

performance such that A-HA duration > SL and C-HA, and C-HA duration was > SL ($P < 0.05$). There were also no differences ($P > 0.05$) at SL, A-HA and C-HA between CHO and PLA in exercise intensity (% SL $\dot{V}O_{2peak}$) and pacing at 0.5 mi. increments during the TTs. **CONCLUSIONS:** CHO supplementation did not provide any benefit to TT performance when volunteers were unacclimatized or acclimatized to HA. Chronic HA exposure/acclimatization did improve performance compared to that after acute HA exposure, but performance remained worse than at SL. Authors' views not official U.S. Army or DoD policy.

Effect Of Sodium Bicarbonate Ingestion During 6-, 8-, 12-hour Hypobaric Hypoxic Acclimatization on Cycling Performance

Nazareth Khodiguiian¹, Jens Johansson², Andrew Cornwell¹, Svenja Wassmann¹, Jacob D. Jelmini¹, Eddie Leon¹. ¹California State University, Los Angeles, Los Angeles, CA. ²Mercy Medical Center, Roseburg, OR.

(No relationships reported)

Numerous studies investigate the ergogenic effects of normobaric and hypobaric hypoxic acclimatization on endurance performance in normobaria. Likewise, numerous studies assessed the ergogenic effect of sodium bicarbonate ingestion on performance. Diuresis of bicarbonate ions induced by altitude exposure may reduce the extracellular buffering of H^+ , compromising the performance at high altitude. Purpose of this study was to investigate the effect of Sodium Bicarbonate ingestion during hypobaric hypoxic acclimatization on cycling performance in hypobaria. Eight, eight, and twelve subjects were exposed to hypobaric hypoxia (525mmHg) for 6, 8, and 12 hours, respectively. Sodium bicarbonate supplementation took place at 4.5 and 1.5 hours (200 mg·kg⁻¹ and 250 mg·kg⁻¹ of body mass, respectively) before performance test (525 mmHg). Subjects were tested in 4 conditions: Normobaric placebo (NBPbo); Normobaric Bicarbonate (NBBC); Hypobaric Placebo (HBPbo); and Hypobaric Bicarbonate (HBBC). Time trials consisted of performing 360 revolutions of pedals as fast as possible against a resistance equal to 5% of body weight. Blood samples were collected from a venous catheter before the exposure, 15 min before the exercise, and 3-5 minutes after the exercise. Urinary bicarbonate excretion was measured during the exposure. There were no differences in performance time, serum bicarbonate and lactate concentrations, as well as total urinary bicarbonate excretion between the 6-, 8-, and 12-hour acclimatization. Therefore the data were pooled and analyzed together. Serum bicarbonate concentration was significantly lower (26.4±2.8 vs 24.1±2.5 P=.000) and urinary bicarbonate excretion was significantly higher (613±460.1 vs 322±264.9, p=.003) in HBPbo than in NBPbo at the end of acclimatization. Bicarbonate supplementation significantly improved cycling performance (2.0±4.21%) in hypobaric hypoxia, while the improvement was not significant in normobaria. It was concluded that sodium bicarbonate supplementation during short-duration acclimatization improves high intensity cycling performance.

Effect Of Dietary Nitrate Supplementation On Step Test Performance At Sea Level And Altitude

Devon Dobrosielski, Chris Goss, Adam Farley, Kyle Moran. *Towson University, Towson, MD.*

Email: ddobrosielski@towson.edu

(No relationships reported)

Nitrate-rich beetroot juice improves exercise performance in untrained and moderately trained individuals at sea level through increased production of nitric oxide (NO). Beetroot supplementation may be more effective during exercise in a hypoxic environment, where NO production is reduced, due to low O_2 tensions and muscle pH. However, results from studies that have examined the effects of nitrate supplementation on exercise performance at altitude have been equivocal. **PURPOSE:** To examine the effect of beetroot-juice ingestion on step test performance at sea level and altitude. **METHODS:** Undergraduate students enrolled in a 10-day study abroad to Peru that included a two-day hike on the Inca trail. Prior to traveling, all students performed a Queens College step test at sea level. Students stepped at a predetermined cadence for 3 minutes, after which recovery heart rate was recorded and entered into a standardized regression equation to estimate $\dot{V}O_{2max}$. The test was repeated at sea level, 90 minutes after ingesting a 70 mL shot of beetroot juice (6.45 mmol nitrate concentration). The step test was completed twice more at an altitude of 3500 meters; both with and without beetroot juice ingestion. All tests were separated by at least 24 hours. **RESULTS:** Twelve students (age 21 ± 1.7 years; M:6, F:6) completed all aspects of the study. The estimated $\dot{V}O_{2max}$ at sea level without and following nitrate supplementation was 45.2 ± 9.3 ml/kg/min and 46.8 ± 9.1 ml/kg/min, respectively. The estimated $\dot{V}O_{2max}$ at 3500 meters increased from 45.2 ± 9.8 ml/kg/min to 47.7 ± 12.3 ml/kg/min following nitrate ingestion. However, one-way repeated measures ANOVA revealed no differences in mean estimated $\dot{V}O_{2max}$ across conditions, $F(3,33) = 1.31, p = 0.29$. **CONCLUSION:** We found no apparent effect of altitude or nitrate

supplementation on step test performance in a group of college students. The duration of the exercise bout, as well as the dosage and timing of nitrate supplementation may explain our inability to observe an ergogenic effect.

3001 Board #5 June 2 3:15 PM - 5:15 PM
"Beet On Alps": Effect of Dietary Nitrate Supplementation on Skeletal Muscle Oxidative Capacity during Prolonged Exposure to Hypobaric Hypoxia
 Desy Salvadego¹, Mauro Marzorati², Letizia Rasica³, Simone Porcelli². ¹University of Udine, Udine, Italy. ²National Research Council, Milano, Italy. ³Università degli Studi di Milano, Milano, Italy.
 (No relationships reported)

PURPOSE: Skeletal muscle oxidative function is influenced by inspired O₂ fraction. Previous studies in acute hypoxia have shown that dietary nitrate supplementation is able to attenuate or prevent the hypoxia-induced decrement of performance. No data have been provided during prolonged exposure to hypobaric hypoxia, a condition that affects both skeletal muscle oxidative metabolism and nitric oxide bioavailability. Aim of this study was to investigate the effects of a dietary nitrate supplementation on *gastrocnemius* muscle oxidative capacity during a prolonged exposure to high altitude. **METHODS:** At altitude (3,269m a.s.l., Casati Refuge, Italy), fourteen healthy young (29±4 yr) subjects were supplemented for three days with beetroot juice (2x70mL/day, 8.4 mmol nitrate/day [BEET-IT]) or nitrate-depleted juice (PLA) following a double-blind randomized cross-over design. As an index of *gastrocnemius* muscle oxidative capacity, the recovery rate of muscle oxygen consumption (mV̇O₂) was measured by near-infrared spectroscopy using repeated, transient arterial occlusions following a brief bout of plantar-flexion exercise. Experiments were carried out after 7-14 days of hypoxic exposure, at the end of both supplementation periods, and in normoxia. **RESULTS:** In normoxia, the time constant of mV̇O₂ (13.2±4.9 s) was comparable to that observed in healthy active subjects. At altitude, the time constant of mV̇O₂ was significantly (p=0.01) faster in BEET-IT (9.3±3.4) vs. PLA (16.7±5.8). Plasma [nitrate] and [nitrite] were significantly higher in BEET-IT than in PLA. **CONCLUSIONS:** During prolonged exposure to hypobaric hypoxia, a three-day dietary nitrate supplementation accelerated the recovery kinetics of mV̇O₂, suggesting an improvement of muscle oxidative capacity. Future studies will have to investigate if these results are related to an increased mitochondrial efficiency and/or to a better microvascular perfusion after nitrate supplementation in hypoxia.

Limb Muscle and Frontal Lobe Oxygenation Saturation during Exercise at Altitude Following Acute Nitrate Loading
 David M. Fothergill, Haley Dodson, Allison R. Loiselle. *Naval Submarine Medical Research Laboratory, Groton, CT.*
 Email: david.m.fothergill.civ@mail.mil
 (No relationships reported)

BACKGROUND: It has been theorized that the ergogenic efficacy of nitrate (NO₃⁻) supplementation on aerobic performance may be best observed during exercise performed at altitude where the O₂ independent NO₃⁻-nitrite (NO₂⁻)-nitric oxide (NO) pathway may become an increasingly important source of NO bioavailability that could potentially favorably influence tissue blood flow and tissue oxygen saturation levels.

PURPOSE: To determine if acute NO₃⁻ supplementation impacts limb muscle oxygen saturation (SmO₂) and brain frontal lobe oxygen saturation (SbO₂) during exercise under hypobaric hypoxia.

METHODS: Recreationally active individuals (11 males, 1 female; mean ± SD age = 38.1 ± 12.6 yr., sea level maximal oxygen uptake (VO₂max) = 41.7 ± 5.7 ml/kg/min) conducted 2 exercise trials (nitrate loading (N), and placebo (P)) while exposed to a simulated altitude of 3,048 m in a hypobaric chamber. Each trial consisted of 15 min of steady state cycle exercise at 45% of their maximum sea level workload, followed by an incremental exercise test to exhaustion. 110 minutes before starting the steady state exercise in the N and P trials, subjects drank 500 ml of water containing either 20.4 mg/kg of NaNO₃ or the equivalent molar concentration of NaCl respectively, in a double-blind randomized, placebo-controlled cross-over fashion. Oxygen saturation of the vastus lateralis and frontal lobe of the brain were measured using near-infrared spectroscopy and were expressed as changes from their respective sea level rest conditions prior to analysis.

RESULTS: SmO₂ decreased linearly with increasing workload (p<0.00001) but did not differ between the N and P trials during the steady state submaximal exercise or at any workload during the VO₂ max exercise. SbO₂ also did not differ between the N and P trials during exercise at altitude. There was however a significant two-way interaction between workload and supplement condition for oxyhemoglobin concentration (ΔHbO₂) of the frontal lobe during the VO₂max test (F_{4,40} = 4.37, p<0.01) that was due to a lower frontal lobe ΔHbO₂ in the N trial compared to the P trial that occurred only at the maximal workload (p<0.05).

CONCLUSIONS: Acute NaNO₃ supplementation does not alter SmO₂ or SbO₂ during steady state or maximal exercise at altitude, but may lower frontal lobe ΔHbO₂ only at maximal exercise.

F-31 Thematic Poster - Nutritional Status of Athletes II

Friday, June 2, 2017, 3:15 PM - 5:15 PM
 Room: 101

3003 **Chair:** Kelly L. Pritchett. *Central Washington University, Ellensburg, WA.*

3004 Board #1 June 2 3:15 PM - 5:15 PM Comparison Of High And Low 25(OH)-Vitamin D Concentrations On Recovery From Resistance Exercise In Men

Leonardo P. Oliveira¹, Sandro Bartolomei¹, Eliahu Sadres¹, David Church¹, Elliott Arroyo¹, Joseph A. Gordon, III¹, Alyssa N. Varanoske¹, Ran Wang¹, Kyle S. Beyer¹, Jeffrey R. Stout, FACSM¹, John A. Rathmacher², Jay R. Hoffman, FACSM¹. ¹University of Central Florida, Orlando, FL. ²Metabolic Technologies, Inc., Aimes, IA. (Sponsor: Jay Hoffman, FACSM)
 Email: loliveira@bsd.uchicago.edu
 (No relationships reported)

BACKGROUND: Vitamin D status (VITD) has been related to impaired skeletal muscle function, and may be associated with recovery after muscle injury. Limited data exists on the relationship between VITD concentrations, muscle damage and inflammatory markers from an acute bout of exercise.

PURPOSE: Examine the effect of VITD concentrations on acute physiological responses and recovery indices from resistance exercise. **METHODS:** 15 resistance trained men (24±4 y) with at least 2 years of resistance training experience volunteered to participate in this study. Participants were grouped into a low 25(OH)-VITD (LVD; 26.7±1.7 ng·ml⁻¹; n=7) or high 25(OH)-VITD (HVD; 37.2±7.2 ng·ml⁻¹; n=8) group based upon baseline (BL) 25(OH)-VITD concentrations. Participants performed 8 sets of 10-12 repetitions at 70% of the maximal strength of the squat exercise, with 75 s of rest between sets. Performance [counter movement jump (CMJP), endocrine (testosterone [T] and cortisol [C]), inflammatory (IL-6 and C-reactive protein [CRP]), and muscle damage (creatinine kinase [CK] and myoglobin [MB]) assessments were performed at BL, 30-min, 24-h, 48-h and 72-h post-exercise. Data was analyzed using a repeated measures ANOVA. To complement this procedure, magnitude based inferences were used to provide additional interpretation of the differences that VITD concentrations may have had on the recovery response. **RESULTS:** No significant interactions were noted between LVD and HVD in CMJP (p=0.26), C (p=0.97), T (p=0.21), CRP (p=0.30), IL-6 (p=0.58) or CK (p=0.16) responses to the exercise protocol. However, a significant interaction was observed in MB (p=0.05) responses. Although post-hoc analyses failed to see any significant differences between the groups at any time point, inferential analysis indicated that MB concentrations was "likely" higher at 30-min for LVD (87.2±57.4 ng·ml⁻¹) than HVD (51.3±21.9 ng·ml⁻¹). CRP levels were "likely" lower at 24-h (549±373 mg·L⁻¹ vs. 1344±1654 mg·L⁻¹) and 48-h (565±386 mg·L⁻¹ vs. 1079±1077 mg·L⁻¹) for HVD. Inferences for all other comparisons were unclear. **CONCLUSIONS:** Results indicated that HVD provides a degree of resiliency towards acute muscle damage and enhances recovery of high velocity resistance exercise compared to LVD. Further research using greater sample size appears warranted.

3005 Board #2 June 2 3:15 PM - 5:15 PM Exploring the Relationship between Soluble Fiber Intake and Bone Mineral Density in Athletes

Anneliese M. Kuemmerle¹, Jody L. Herman¹, Emily N. Werner, FACSM¹, Jacqui Van Grouw¹, Rachel C. Kelley², Francesco Alessio¹, Michael L. Bruneau, 19102¹, Stella L. Volpe, 19102, FACSM¹. ¹Drexel University, Philadelphia, PA. ²University of Florida, Gainesville, FL. (Sponsor: Stella Lucia Volpe, FACSM)
 Email: amk464@drexel.edu
 (No relationships reported)

Short chain fatty acids (SCFAs) produced by bacterial fermentation of soluble fiber in the gut enhance mineral absorption. SCFAs reduce luminal pH, affect signal pathways, alter epigenetic regulation, and foster the proliferation of immune-modulating gut bacteria, suggesting a positive correlation between soluble fiber intake and bone mineral density (BMD). **PURPOSE:** To evaluate the relationship between soluble fiber intake and total body BMD in athletes 18 years of age and older. **METHODS:**

Thirty-one participants (16 females, 15 males) who volunteered for a cross-sectional study underwent dual energy X-ray absorptiometry (DXA) scans and completed self-administered Block Food Frequency Questionnaires (FFQ). **RESULTS:** Participants' mean age was 35.7±10.9 years, and mean body mass index (BMI) was 25.32±3.77 kg/m². Participants consumed an average of 1960.3±644.2 kilocalories/day. Mean daily soluble fiber intake was 7.1±2.3 grams/day. Average total body BMD was 1.28±0.12 g/cm². There was no significant correlation between soluble fiber intake and BMD ($r=-0.188$, $p=0.312$). No significant correlation was found between soluble fiber intake and BMD for women ($r=0.057$, $p=0.835$) or men ($r=-0.477$, $p=0.073$). A multiple linear regression was calculated to predict BMD based on soluble fiber intake controlling for intakes of calcium, vitamin D, and protein. No significant regression equations were found for the total sample ($p=0.357$), women ($p=0.617$), or men ($p=0.177$). **CONCLUSIONS:** Soluble fiber intake was not correlated with BMD in this sample of athletes. Directions for future research include recruiting a larger sample and exploring the possibility of a synergistic relationship between soluble fiber and intake of minerals. These represent data from an unfunded research project

3006 Board #3 June 2 3:15 PM - 5:15 PM
Validation Of A Two-item Food Security Screening Tool For Male, Collegiate Athletes

David H. Holben, Kacie Poll, Melinda Valliant, Hyun-Woo (David) Joung, *University of Mississippi, University, MS.*
 (Sponsor: Mark Loftin, FACSM)
 (No relationships reported)

Food insecurity (FI), lacking access to food for an active healthy life, is associated with poor nutrition and health outcomes. Collegiate athletes may have experienced FI during childhood (CH) or high school (HS) and may also experience it at college (COL), which may negatively impact food acquisition and habits. A brief CH food security status (FSS) screening tool was previously validated by Hager et al. (2010) in low-income families with children.

PURPOSE: To develop a brief FSS screening tool and to examine its sensitivity (SENS) and specificity (SPEC) in a sample of NCAA Division 1 male, collegiate athletes ≥18 years of age (y). **METHODS:** A cross-sectional survey of NCAA athletes from a Southeastern Conference (SEC) university was approved by the Institutional Review Board and conducted during August-September, 2016. The questionnaire included the USDA food security survey module and a 2-item measure to assess CH, HS, and COL FSS. USDA and Hager et al. methods were used to calculate FSS and SENS/SPEC, respectively. **RESULTS:** Participating athletes (n=93) were 19.7±1.4 y and primarily white, football players [race: white (n=45, 48.4%); black (n=38, 40.9%); other (n=10, 10.9%)] [sport: football (n=65, 69.9%); baseball (n=20, 21.4%); cross country/track (n=5, 5.4%); golf (n=3, 3.2%)]. The CH 2-item measure was highly SENS (92.9%) and SPEC (91.1%) for HS FSS, as was the HS 2-item method (SENS 92.9%, SPEC 94.9%). The COL 2-item measure was highly SENS (100%) and SPEC (88.9%) for COL FSS. **CONCLUSION:** A 2-item FSS can be used to screen for FI in male collegiate athletes. Further research to validate its use in a larger sample that includes females is warranted, as is research to assess the relation of FI to eating behaviors in athletes.

3007 Board #4 June 2 3:15 PM - 5:15 PM
The Relationship Between In-Race Nutrition and Finish Time for Ironman Triathletes

Lauren Sutton, Elaina Biechler, Stephanie Harpenau, *Loras College, Dubuque, IA.* (Sponsor: Vincent Paolone, FACSM)
 Email: lauren.sutton@loras.edu
 (No relationships reported)

PURPOSE: The purpose of the present investigation was to determine the predictive power of triathletes' in-race nutrition plans during an Ironman triathlon on overall finish time. Aspects of the in-race nutrition plans considered were calories consumed per hour while biking, total caffeine consumed while biking, and total fluids consumed on the bike portion of the Ironman race. **METHODS:** Ironman triathletes (N= 152) were surveyed to determine their in-race nutrition plan at Ironman Wisconsin and the Ironman World Championships. A regression analysis was utilized to determine the predictive power of calories, fluid and caffeine consumed on the bike on overall Ironman finish time. **RESULTS:** Average Ironman finish time (N= 152) was 12:41:12 (+/-2:04:43), average calories consumed per hour on the bike was 268.83 (+/- 131.71). Average fluid consumed during the biking portion of the race was 3559.52 mLs (+/- 1802.52). Average caffeine consumed during the biking portion of the race was 89.16 mg (+/- 143.84). The amount of calories consumed per hour on the bike and in-race caffeine consumption was significantly ($p < .05$) correlated with Ironman finish time ($r = -.355$, $r = -.191$, respectively), while fluid intake was not significantly ($p > .05$) correlated with Ironman performance ($r = -.054$). Calories and caffeine consumption while biking were used to create a multiple regression equation. The overall regression model was statistically significant $F(2, 137) = 12.845$, $p < .05$. The regression equation revealed that 15.8% of the variance in Ironman race time can be significantly ($p < .05$) attributed to calories and caffeine consumption during the bike portion of the

race. **CONCLUSIONS:** Total fluid consumed on the bike portion of the Ironman was not correlated to overall finish time; however, calories per hour and total caffeine consumed on the bike both were negatively correlated with overall finish time. This suggests that greater calorie and caffeine consumption on the bike can contribute to decreased overall finish time, and hence an improvement in performance.

3008 Board #5 June 2 3:15 PM - 5:15 PM
Weight Cutting And Professional Mixed-martial Artists: How Do They Cut Weight And Who Is Advising Them?

Michelle K. Alencar, David Bautista, John Sassone, Dustin Durke, Leilani Madrigal, Alison Ede. *CSU-Long Beach, Long Beach, CA.*
 Email: michelle.alencar@csulb.edu
 (No relationships reported)

PURPOSE: Although mixed martial arts (MMA) has been around for decades, current peer-reviewed literature is limited to individual sports (such as boxing, judo, and wrestling) that compose mixed martial arts (MMA). Within other combat sports, weight cutting practices have included methods of extreme dehydration or food restriction; however data is lacking in professional MMA athletes. Thus, the purpose of this study was to survey professional MMA athletes about their current and past weight cutting methods as well as to investigate who is advising them nutrition and strength and conditioning.

METHODS: N=55 male professional mixed martial artists (18-40 yrs) were recruited from every weight class in the states of California and New Mexico. Participants were administered a questionnaire that had been reviewed by a registered dietitian, a certified strength and conditioning specialist, and an exercise physiologist. Data presented as percentage of frequency of responses calculated using IBM Analytics, SPSS v24.

RESULTS: The top 3 methods MMA fighters use in cutting weight were food restriction (87.3%), increased training (70.9%) and the Sauna (69.1%). Most MMA fighters do not utilize a professional nutritionist/dietitian for advice during either the weight cut (74.5%) or off-season (75.4%). In fact, only 7.3% reported they regularly used a professional nutritionist/dietitian when cutting weight. Fighters are receiving nutrition advice primarily from teammates (78.2%), while only 23.6% are getting any advice, on or off-season from a professional nutritionist.

CONCLUSIONS: Professional mixed martial artists report cutting weight for a fight using methods that can be considered dangerous and impair performance. Many reported receiving no professional advice on or off-season from a licensed nutritionist or dietitian.

3009 Board #6 June 2 3:15 PM - 5:15 PM
Nutrition Goals Prioritized By Elite Endurance Runners Undergoing A Nutrition Education Intervention

Michelle Barrack¹, Michael Fredericson, FACSM², Tenforde S. Adam³, Emily Kraus², Brian Kim⁴, Sonal Singh⁴, Andrea Kussman⁴, Kristen Gravani², Yasi Ansari⁴, Beth Miller⁴, Aurelia Nattiv, FACSM⁴. ¹California State University, Long Beach, Long Beach, CA. ²Stanford University, Palo Alto, CA. ³Spaulding Rehabilitation Hospital, Cambridge, MA. ⁴University of California Los Angeles, Los Angeles, CA. (Sponsor: Aurelia Nattiv, FACSM)
 Email: michelle.barrack@csulb.edu
 (No relationships reported)

Few studies have evaluated goals selected by endurance runners and their sports dietitian to address nutritional deficits.

PURPOSE: To outline nutrition goal(s) chosen during a nutrition education session among a sample of NCAA Division I male and female endurance runners enrolled in a nutrition education intervention focused on optimizing intake of energy, bone building nutrients, and reducing the risk of bone stress injury.

METHODS: Fifty-nine collegiate distance runners from two institutions met with a sports dietitian for a 15-30 minute counseling session to address current food intake, exercise training, anthropometric measures and nutrition goals. Runners, with guidance from the sports dietitian, chose 1-3 goals from seven preselected goal options including adding ≥1 snacks/day; adding a meal/day; increasing intake of energy dense foods; increasing intake of carbohydrate rich foods; adding or modify a pre/post workout snack; increasing intake of calcium, vitamin D; eating more frequently. Chi-square analyses evaluated group differences.

RESULTS: The most common goals included 1) adding ≥1 snacks/day (45.8% of runners) and 2) adding or modifying a pre/post workout snack (40.7% of runners). Runners' least common goal was to eat more frequently (8.5% of runners). Female compared to male runners were more likely to choose the goal of adding a meal/day (18.5% vs. 3.1%, $p=0.05$), whereas more runners with low BMI (< 18.5 kg/m²) compared to ≥18.5 kg/m² chose goal of increasing intake of energy dense foods (50.0% vs. 12.7%, $p=0.05$). Runners characterized with "moderate" vs. "low" or "high" risk for the Female Athlete Triad (or comparable Male Triad) were more likely

to choose the goal of increasing intake of carbohydrate-rich foods (30.8% vs. 3.7% and 0%, respectively, $p=0.02$). A larger proportion of runners with “high” vs. “moderate” or “low” risk selected the goal of adding a meal/day (40.0% vs. 11.5% vs. 3.7%, $p=0.05$).

CONCLUSIONS: While the most common goal runners selected focused on adding ≥ 1 snacks/day, those classified with “high” risk for the Triad or low BMI prioritized adding a meal/day or increasing the energy density of foods consumed. These findings may aid runners and their sport dietitian in selecting goals for optimizing nutrient intake, which may benefit health and performance.

3010 Board #7 June 2 3:15 PM - 5:15 PM
Influence of a Nutrition Recovery Station Following Exercise on Acute Dietary Intake.
 Ben Desbrow, 4222¹, Katelyn Barnes¹, Gregory Cox², Caroline Young¹, Chris Irwin¹. ¹Griffith University, Gold Coast, Australia. ²Australian Institute of Sport, Gold Coast, Australia. (Sponsor: Professor Louise Burke, FACSM)
 Email: b.desbrow@griffith.edu.au
Reported Relationships: B. Desbrow: Royalty; Human Kinetics - Caffeine for Sports Performance Book.

PURPOSE: Immediate post-exercise access to fluid/food via a recovery station is a common feature of mass participation sporting events. Yet little evidence exists examining their impact on improving recovery or influencing subsequent dietary intake. This study aimed to determine if access to food/fluid during a post-exercise recovery period significantly alters dietary and fluid intakes over a 24hr period.
METHODS: 127 (79 males) healthy participants (mean±SD, age=22.5±3.5y, body mass (BM)=73±13kg) completed two self-paced morning 10km runs separated by 1 week. Immediately following the first run, participants were randomly assigned to enter a “recovery station” (*ad libitum* water, sports drink and fruit) for 30min or leave without access to the recovery area. All participants completed the alternate recovery option the following week. Participants recorded nude BM before and after exercise and measured Urine Specific Gravity (U_{SG}) before running and the following morning. Additionally, participants recorded all food and fluid consumed for both run days via a food diary and photographs which were analysed by a qualified dietitian. Paired-samples *t*-tests assessed differences in hydration and dietary outcome variables (Recovery vs No Recovery).
RESULTS: No difference in pre-exercise U_{SG} or BM change during exercise were observed between intervention groups ($p>0.05$). Attending the recovery zone resulted in a greater total daily fluid intake (Recovery=3.37±1.46L, No Recovery=3.16±1.32L, $p=0.009$) but had no influence on daily total energy (Recovery=10.15±4.2MJ, No Recovery=10.15±3.9MJ), carbohydrate (Recovery=276±131g, No Recovery=264±128g) or protein (Recovery=118±61g, No Recovery=122±54g) ($p>0.05$) intakes. Next day morning U_{SG} values were not different between groups (Recovery=1.018±0.007, No Recovery=1.019±0.009, $p>0.05$).
CONCLUSIONS: Attending a recovery station immediately following a 10km run has little impact on 24h exercise day dietary intake or rehydration in recreational runners.

F-32 Thematic Poster - Physical Activity and Mental Health

Promoting Mental Among Urban Adolescents Through Physical Activity: Open-trial of Leaders@Play 2.0
 Eduardo E. Bustamante¹, Tara G. Mehta¹, Angela L. Walden¹, Hannah Munson¹, Aneisha Dunmore¹, Grace Cua¹, Stacy L. Frazier². ¹University of Illinois at Chicago, Chicago, IL. ²Florida International University, Miami, FL.
 Email: ebusta2@uic.edu
 (No relationships reported)

PURPOSE: Early adolescence is characterized by decreasing parental monitoring and increasing peer pressure to engage in risky behaviors that may initiate a trajectory toward poor school outcomes, association with deviant peers and stressful life events. High-quality physical activity programs can promote mental and physical health of urban youth by providing refuge from neighborhood violence and opportunities for social skills development and positive peer relations. **METHODS:** Middle school

youth across 5 Chicago Park District parks participated in an open trial of Leaders @ Play 2.0, a 1-2 hour biweekly component of a 6-week Summer Camp. Leaders @ Play was developed via university-community partnership, co-facilitated by park staff and mental health staff, and designed to teach and reinforce life skills (i.e., effective communication, emotion regulation, and problem solving) through physically active games and relaxation activities. The Strengths and Difficulties Questionnaire (SDQ) was completed by parents at baseline and post-test. The SDQ reports a prosocial scale, total problems scale, and 4 subscales (emotional problems, conduct problems, peer problems, and hyperactivity / inattention). Descriptive statistics were analyzed for all participants at baseline and paired *t*-tests and within-group effect sizes (Cohen’s *d*) were calculated for participants providing both baseline and post-test data. **RESULTS:** Youth (N=38) were 31% Hispanic; 26% African American; 55% low-income, 57% male, and M=13.2 years-old. Effect sizes demonstrated a moderate effect on prosocial behavior ($t[1,14]=2.02, p=.063; d=0.70$) and a small effect on total problems ($t[1,14]=2.00, p=.066; d=-0.43$). Among subscales, emotional problems improved significantly ($t[1,14]=2.66, p<.05; d=-.70$), a small non-significant effect size was evident for conduct problems ($t[1,14]=1.19, p=.253; d=-.31$), while peer problems ($t[1,14]=-0.37, p=.719; d=0.07$) and hyperactivity / inattention ($t[1,14]=7.91, p=.442; d=-0.16$) were unaffected. **CONCLUSIONS:** Findings provide preliminary support for the potential of physical activity programs that systematically challenge and reinforce social skills to improve prosocial behaviors and decrease emotional problems amongst adolescents in urban settings.

3013 Board #2 June 2 3:15 PM - 5:15 PM
Is There A Shift In The Ideal Body In The Adolescents?
 Christine Sundgot-Borgen¹, Kethe Engen¹, Elin Kollé¹, Jorunn Sundgot-Borgen, FACSM¹, Monica Klungland Torstveit², Solfrid Bratland-Sanda³. ¹Norwegian School of Sport Sciences, Oslo, Norway. ²University of Agder, Kristiansand, Norway. ³University College of Southeast Norway, Bø Telemark, Norway. (Sponsor: Jim Skinner, FACSM)
 Email: c.s.borgen@nih.no
 (No relationships reported)

PURPOSE: A healthy body image is important for adolescents. It serves as a predictor of good quality of life and should be given focus when working to improve health in adolescents. Unfortunately, previous studies have reported that a high prevalence of male and female adolescents are dissatisfied with their bodies, and especially females have high drive for thinness. However, a muscular and lean body is presented as the new ideal body in the social media. Therefore, it is expected that this might affect the ideal body in the adolescents. The purpose is therefore to investigate how male and female adolescents report that a muscular and lean body is important, if there are differences between what male and females report, and whether this drive for muscularity and leanness is more prevalent than drive for thinness among male and female high-school students.
METHODS: We used baseline data from an ongoing RCT aiming to enhance positive body image among high-school students in Oslo and Akershus County. A total of 1703 students aged 16-17 years (n=630 males, BMI=21.7 kg/m² (2,8), and n=1073 females, BMI=21.4 kg/m² (2,9)) were included. The Drive for Leanness Scale (DLS) and the Internalization; Thin/Low Body Fat subscale (of SATAQ-4) were used to assess prevalence of students with high scores on the Drive for leanness and Thin/Low Body Fat subscale. Pearson Chi-Square analyses were used to examine group differences. A *p*-value <0.05 was considered significant.
RESULTS: A significantly higher prevalence of female students (39%) compared to males (18%) had high scores on the Drive for leanness scale ($p<0.001$). A significantly higher prevalence of females (17%) compared to male students (13%) had high score on the Thin/Low Body Fat subscale ($p<0.05$). When comparing physically active male and females with non-active male and females, no significant difference was observed between groups on the Thin/Low Body Fat subscale.
CONCLUSIONS: Our results show that a drive toward a muscular and lean body is more common among both male and female students as compared to the drive for thinness. This might indicate a shift in the ideal body especially for the female adolescents.

Subjective and Physiological Predictors of Anxiety at Rest and During a Working Memory Task
 Brooks P. Leitner, Abigail Hsiung, Courtney Duckworth, Tiffany Lago, Christian Grillon, Monique Ernst, Robert Brychta, Kong Chen. National Institutes of Health, Bethesda, MD.
 Email: brooksleitner@gmail.com
 (No relationships reported)

Purpose: Prior research has suggested that an acute bout of moderate exercise is associated with reduced state anxiety in healthy adults and patients with anxiety disorders. However, it is unclear if low-intensity exercise would have the same or

reduced impact on state anxiety as compared to moderate. Our aim was to combine subjective ratings of exertion and physiological measures to ascertain if low and moderate acute exercise influences anxiety at rest and during a working memory (WM) task.

Methods: In an ongoing study, 21 healthy adults (9 female, age: 26.5±1.25 yrs, VO2Max: 35.3±10.8 mL/kg/min.) performed three exercise sessions on a cycle ergometer: one maximal exercise test and two subsequent randomized 30-minute exercise sessions at moderate and low (60-70% and 10-20% heart rate reserve, respectively) intensities separated by approximately 1 week. Ratings of perceived exertion (RPE) were obtained every 5 minutes during each submaximal exercise session. 30 minutes after exercise, subjects performed a WM task (n-back) under standardized threat of electric shock and safe conditions. Anxiety was assessed subjectively by ratings on a scale from 1-10 before the task and after each of four runs of the n-back (3 difficulty loads: 0-back, 1-back, 3-back). Paired Ttests were used to test the difference in state anxiety following submaximal exercise and linear mixed effects tests were used to assess the influence of RPE these findings.

Results: Anxiety scores post-exercise were lower following moderate exercise during the 3-back while under threat of shock only after the first run (5.5±2.3 vs. 4.1±2.4, p=0.03). TTests did not show anxiety scores to differ at any other time points nor conditions (p's>0.05). RPE scores during moderate and low intensity exercises were negatively associated with anxiety 30-min post-exercise (before the n-back, B= -0.38±0.17, p=0.04), during the 3-back while under threat of shock (B= -0.51±0.17, p<0.01), and during the 3-back safe condition (B= -0.32±0.12, p=0.02).

Conclusion: Moderate exercise led to lower state anxiety than low intensity exercise during the highest difficulty WM task, yet these effects were short lasting. Higher RPE during exercise, up to 60-70% HRR, predicted lower anxiety at rest and during a cognitively challenging WM task under both anxiogenic and normal conditions.

3015 Board #4 June 2 3:15 PM - 5:15 PM

Longitudinal Influence Of Prolonged And Short Bouts Of Sedentary Time On Mental Wellbeing

Laura D. Ellingson¹, Jacob D. Meyer², Robin P. Shook³, Steven N. Blair, FACSM⁴. ¹Iowa State University, Ames, IA. ²University of Wisconsin- Madison, Madison, WI. ³Children's Mercy Hospital, Kansas City, MO. ⁴University of South Carolina, Columbia, SC.

Email: ellingsl@iastate.edu

(No relationships reported)

Excessive sedentary time is related to poor mental wellbeing. However, the differential influence of sedentary time accumulated in prolonged versus short bouts on factors related to mental wellbeing is unknown. **PURPOSE:** To examine the longitudinal influence of sedentary bout length on mood, stress, and sleep over one year.

METHODS: Two hundred and seventy healthy adults (48% women; age 27.8 ± 3.7) completed the Profile of Mood States (POMS) and the Perceived Stress Scale (PSS), and wore a Sensewear Armband to objectively measure sedentary time, physical activity, and sleep duration and efficiency at baseline and one year later. Prolonged and short bouts of sedentary time were operationalized to those greater and less than 30 minutes in duration. Fixed effects regression analyses were performed with baseline minutes and changes in prolonged and short bouts of sedentary time and minutes of moderate and vigorous physical activity (MVPA) as predictors of changes in mood disturbance, stress, and sleep duration and efficiency over one year as outcomes.

RESULTS: For mood, the overall model was significant (p=0.04) with changes in prolonged (p=0.004) and short bouts (p=0.006) of sedentary time positively predicting changes in mood disturbance. For stress, the overall model trended towards significance (p=0.06) with only changes in prolonged bouts of sedentary time as a positive predictor (p=0.003). For sleep duration, the overall model was significant (p<0.0001) with changes in prolonged and short bouts of sedentary time as inverse predictors and change in MVPA as a positive predictor (all p<0.0001).

For sleep efficiency, the overall model was significant (p<0.03) with changes in both prolonged (p=0.017) and short bouts of sedentary time (p=0.008) as inverse predictors.

CONCLUSIONS: Changes in both prolonged and shorter bouts of sedentary time are predictive of future mood, stress, and sleep in healthy young adults adding to the evidence that sedentary time has negative, long-term consequences for wellbeing, regardless of how it is accumulated. Interestingly, in this sample of healthy adults, baseline levels of sedentary time and MVPA were not predictive of changes in mental wellbeing-related outcomes. Interventions targeting sedentary time may not need to target specific bout lengths to realize benefits.

Acute Moderate Exercise Improves Working Memory Efficiency In Humans

Abigail Hsiung, Tiffany Lago, Brooks Leitner, Kong Chen, Christian Grillon, Monique Ernst. *National Institutes of Health, Bethesda, MD.*

Email: abigail.hsiung@nih.gov

(No relationships reported)

Background: Despite evidence indicating that a single bout of exercise can reduce state anxiety and improve cognitive function, (for review Chang et al. 2015, Ensari et al. 2015) few studies have examined the impact of acute exercise on the relationship between anxiety and cognition. The current study explores the modulatory effects of exercise on anxiety and working memory (WM) performance. Moderate exercise, compared to light exercise, was expected to improve WM performance, while decreasing self-reported anxiety and physiological measures (anxiety-potentiated startle) of anxiety.

Methods: Healthy adults (N = 21) of varied physical fitness levels underwent three exercise sessions on a cycle ergometer: one maximal exercise test to assess maximal heart rate (HR) and two subsequent randomized 30-minute exercise sessions at moderate (60-70% HR reserve (HRR)) and low (10-20% HRR) intensities. After exercise, subjects performed a WM task (n-back) under threat of unpredictable electric shock and safe conditions. Anxiety was probed using the acoustic startle reflex and retrospective subjective measures. WM performance (accuracy and reaction time), subjective anxiety, and startle variables were analyzed using 3-way ANOVAs, with Condition (threat, safety), Load (0-back, 1-back, 3-back), and Exercise (light, moderate) as within-subject factors.

Results: Participants reported higher subjective feelings of anxiety and had a greater startle response in the threat compared to the safe condition. Moderate intensity exercise resulted in a faster reaction time at a trend level time (F(1,19) = 3.34, p = 0.08) without compromising accuracy. This was most notable during the 3-back WM level (F(2,18) = 3.69, p = 0.05) during both safe and threat contexts. There was no effect of exercise level on subjective anxiety or anxiety-potentiated startle.

Conclusion: Acute moderate exercise improves cognitive efficiency (shorter reaction times) without compromising accuracy but does not reduce elevated state anxiety. This might be due to an increase in arousal that affects reaction time but not the distribution of working memory resources between cognitive function and anxiety. If this pattern strengthens with the full sample (N=36), we will (1) move to a patient population, and (2) apply this protocol to a neuroimaging study.

3017 Board #6 June 2 3:15 PM - 5:15 PM
Use of a Sit-Stand Desk Reduces Wake Time During the Subsequent Night's Sleep

Christopher E. Kline, Robert J. Kowalsky, Sophy J. Perdomo, Bethany Barone Gibbs. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: John M. Jakicic, FACSM)

Email: chriskline@pitt.edu

Reported Relationships: C.E. Kline: Contracted Research - Including Principle Investigator; HumanScale.

Acute bouts of leisure-time physical activity commonly improve sleep on the subsequent night. However, the impact of sedentary behavior on sleep is unclear. Further, whether breaking up sedentary time during the workday improves the following night's sleep is unknown. **Purpose:** To examine whether breaking up prolonged sedentary time by standing during the workday leads to better sleep the following night in comparison to a sedentary workday. **Methods:** 25 inactive adults with untreated pre- or stage 1 hypertension (16 males, 42±12 yr, body mass index: 31.9±5.0 kg/m²) participated in a randomized crossover trial consisting of two simulated 8-h workdays: one with continuous sitting (SIT) and one with alternating periods of sitting and standing every 30 min (SIT-STAND). Sleep was assessed on the night following each simulated workday. Participants completed a diary to indicate sleep onset latency (SOL), number of awakenings, wakefulness after sleep onset (WASO), and depth and quality of sleep. Participants also wore an accelerometer on the non-dominant wrist (Philips Actiwatch Spectrum) to objectively assess sleep (bedtime, out-of-bed time, total sleep time, SOL, WASO). Paired t-tests and effect size calculations were used to evaluate differences in sleep following the two conditions.

Results: Diary-based WASO was significantly lower following SIT-STAND compared to SIT (13.9±30.1 min vs. 23.2±38.6 min; P=.03, d=0.47). Self-reported SOL, awakenings, sleep depth, and sleep quality were not significantly between conditions, though SIT-STAND led to small-sized reduction in SOL and awakenings (d=0.33 and d=0.29, respectively). There was a small-sized reduction in actigraphic WASO following SIT-STAND compared to SIT (30.2±12.7 min vs. 37.7±25.0 min; d=0.39), though this difference was not statistically significant (P=.09). Actigraphic estimates of bedtime, out-of-bed time, total sleep time, and SOL did not differ between conditions (P>.61, d<0.11). **Conclusion:** Alternating sitting and standing during the workday leads to small improvements in sleep on the night following the simulated workday, particularly in reduced wake time. Whether this effect on sleep remains or is enhanced with long-term reduction in workplace sedentary behavior deserves further exploration.

3018 Board #7 June 2 3:15 PM - 5:15 PM
Physical Activity As A Mediator Of Intervention Effects On Depression And Perceived Stress Among Latinas
 Andrea S. Mendoza-Vasconez¹, Shira Dunsiger², Britta Larsen³, Bess H. Marcus³. ¹UC San Diego/San Diego State University, San Diego, CA. ²Brown University, Providence, RI. ³UC San Diego, San Diego, CA.
 Email: asm015@ucsd.edu
 (No relationships reported)

Physical activity (PA) may reduce depression and stress. While Latinas have unique risk factors and buffers for depression and stress, there is limited research regarding the effects of PA on these outcomes within this population.

PURPOSE: The aim of this study is to investigate the potential mediating role of PA in the effects of a culturally and linguistically tailored PA intervention for Latinas on depression scores and perceived stress.

METHODS: Data are from a sample of 266 Latina women who participated in the Seamos Saludables intervention. Two product of coefficient mediation models were used to assess whether increases in Moderate to Vigorous PA (MVPA, as measured by the 7-day Physical Activity Recall) mediated the effect of the intervention on depression scores and perceived stress (measured by the Center for Epidemiologic Studies Short Depression Scale and the Perceived Stress Scale, respectively).

RESULTS: The Seamos Saludables PA intervention, which was successful in helping participants increase their PA, had no direct effect on change in depression scores, nor on change in perceived stress. Nevertheless, among completers, a significant indirect effect on depression scores ($ab=-0.44$; $CI=-0.87, -0.02$) and perceived stress ($ab=-0.98$; $CI=-1.75, -0.22$) was observed through PA. The intervention significantly increased MVPA at 12 months ($B=57.96$, $p<0.001$), and MVPA significantly reduced depression scores ($B=-0.008$, $p=0.018$) and perceived stress ($B=-0.02$, $p<0.001$), controlling for baseline depression and stress, respectively, and baseline MVPA.

CONCLUSION:

Even though there was no direct effect of the PA intervention on depression scores and perceived stress, higher levels of MVPA among participants were associated with reduced depression scores and perceived stress. Given that depression and stress are associated with negative mental and physical health outcomes, these findings represent a promising approach to improving health among Latinas.

Psychological Antecedents and Consequences of Maximal Fitness Testing Among Firefighters
 Katie L. Andrews, Brian P. Carson, Stephen Gallagher, Matthew P. Herring. *University of Limerick, Limerick, Ireland.*
 Email: katie.andrews@ul.ie
 (No relationships reported)

Little is known about psychological correlates of maximal aerobic and strength performance or psychological responses to maximal fitness testing among firefighters, a high-stress occupational group frequently exposed to psychological and physical stressors.

PURPOSE: To examine the psychological correlates of and acute responses to maximal fitness testing among firefighters. **METHODS:** Twenty-seven male firefighters, aged 31-53 years (42.3 ± 6.8), currently working in Ireland completed measures of positive and negative affect (PANAS), mood (POMS), and state anxiety (STAI-Y1) before and 10-min after maximal fitness testing, including an isometric mid-thigh pull test followed by a maximal treadmill test. Multiple regression adjusted for age quantified associations between psychological variables and maximal aerobic capacity and full body force. Paired t-tests and standardized mean differences (SMD) quantified change in psychological outcomes in response to maximal aerobic and strength tests. **RESULTS:** Mean VO_{2max} was 42.6 ± 7.3 mL·min⁻¹·kg⁻¹. Mean full body force was 2782.3 ± 507.6 N. A significant inverse association was found between age and VO_{2max} ($r=-0.42$, $p\leq 0.03$). No outcomes were significantly associated with VO_{2max} (β : -0.14 to 0.25 ; all $p>0.17$) or maximal full body force (β : -0.24 to 0.35 ; all $p>0.07$). Though statistically nonsignificant, the direction of correlations with both VO_{2max} and maximal strength was consistent (i.e., positive or negative for both) for positive affect, feelings of energy, and state anxiety. Feelings of tension ($p\leq 0.01$) and anger ($p\leq 0.04$) were significantly improved, and feelings of confusion ($p\leq 0.07$) and energy ($p\leq 0.09$) were nominally improved. Exercise effects ranged from small-to-moderate for positive (SMD=0.15) and negative affect (SMD=0.27), feelings of depression (SMD=0.25), energy (SMD=0.31), confusion (SMD=0.36), anger (SMD=0.43), and tension (SMD=0.55), total mood disturbance (SMD=0.24), and state anxiety (SMD=0.27).

CONCLUSIONS: Mood, affect, and state anxiety did not significantly predict maximal aerobic capacity or strength among firefighters. Differential associations with aerobic capacity and strength were suggested. Acute maximal aerobic and strength testing resulted in small-to-moderate improvements in psychological outcomes.

Assessment Of Cardiovascular Fitness In Wheelchair Rugby Athletes: Validation Of The 8-loop Field Test
 Kristian O. Nielsen¹, William J. Bond, IV¹, Peter Henriksen², Tina Junge², Ulrik Frandsen¹, Per Aagaard¹. ¹University of Southern Denmark, Odense, Denmark. ²University College Lillebaelt, Odense, Denmark.
 Email: kristian.a.o.n@gmail.com
 (No relationships reported)

In wheelchair Rugby (WCR), the existence of large differences in disability level complicates utilizing traditional uniform test procedures among different WCR athletes. To date, no field tests measuring VO_{2peak} directly exist for the sport of wheelchair rugby. Thus, a strong need exist to establish valid and standardized, yet individually adjustable testing procedures to evaluate cardiovascular function and physiological mobility capacity in WCR.

PURPOSE: The present study aimed to develop an incremental field test ('8-loop') for WCR athletes, regardless of classification and disability, that involved continuous recording of progressive and maximum cardiovascular data, using an on-court standardized wheelchair exercise protocol. **METHODS:** Ten National Team male WCR athletes (31.2 years) were tested, comprising 7 athletes with tetraplegia, 1 with cerebral palsy, 1 with Charcot-Marie-Tooth Type 2 disease and 1 with lower limb amputations. All WCR classes were represented. An incremental 8-loop field test was performed to voluntary exhaustion to determine VO_{2peak} . The indoor test track consisted of a standardized 8-form (total length 226.2 m). During the test, progressive increases in lap velocity were indicated by sound signals to the athletes until failure to complete a lap within the intended lap time. Test validity was evaluated by direct measurements (Oxycon Mobile) of VO_2 and RER during all laps performed. Furthermore, heart-rate (HR) progression was recorded throughout the test, and blood lactate concentration ([La], earlobe) was measured 2 minutes after test completion. **RESULTS:** During the 8-loop test, a VO_{2peak} of 2014.4 ml/min \pm 987.9 (mean \pm SD), RER 1.11 ± 0.15 , HR_{peak} 143.8 BPM \pm 26.4 and [La] of 4.1 mmol/L \pm 1.7 were measured. VO_{2peak} ($r^2=0.83$, $p<0.01$) and HR_{peak} ($r^2=0.78$, $p<0.01$) were strongly correlated to the number of stages (Laps) completed in the 8-loop test. **CONCLUSION:** Strong linear relationships were observed between the 8-loop test outcome (number of stages/laps completed) and the physiological variables obtained (VO_{2peak} , HR), which suggest that a high validity exist for this field test, when applied in elite wheelchair rugby athletes. Test-retest reliability of the 8-loop test should be evaluated in future studies.

Physical Fitness And Cardiovascular Risk In People With Intellectual Disabilities
 Diana Alexandra Camargo, Sr.¹, Marco Aurelio Rodriguez Mora². ¹Santo Tomas University; National University, Bogotá, Colombia. ²Santo Tomas University, Bogotá, Colombia.
 Email: diana.camargo@usantotomas.edu.co
 (No relationships reported)

PURPOSE: To determine the relationship between physical condition and indirect indicators of cardiovascular risk students with intellectual disability Gustavo Restrepo College. **METHODS:** This is an observational study - analytical cross section. The study makes an assessment of the anthropometric profile and physical qualities, using battery Brockport Physical Fitness for children under 18; for over 18 years, the same tests were used but with rates for their age. A sample of 175 students were evaluated, of whom 96 were men and 79 women. For statistical analysis SPSS was used, using normality tests Kolmogorov-Smirnov and Pearson correlation. **RESULTS:** The results in body composition showed higher for the population over 18 years compared with under 18 values; variables related to physical abilities had higher results in over 18 years. For variables that obtained normality in the population under 18 years, the Pearson correlation was applied, with confidence levels of 95%, where it was observed that the anthropometric variables saved a correlation positive correlation between them, which you are setting a higher cardiovascular risk ($R = 0.85$, $p 0.01$). As for the correlation between anthropometric variables and variables of physical fitness as VO_{2max} , and force variables, this correlation is negative ($R = -0.365$ $p 0.01$), showing that students evaluated with anthropometric overweight and obesity has values less physical condition. In the population over 18 years is a negative correlation between

muscle strength and body composition variables and cardiovascular risk ($R = -0.60$, $p = 0.01$) was observed, and aerobic power equally between these variables ($R = -0.428$, $p = 0.01$). **CONCLUSION:** Although anthropometric measurements in children under 18 are generally below the limits of risk for cardiovascular disease, these results are close to those limits, which leads to argue that they need a specific prevention program. In itself a relationship between risk variables and qualities as strength and aerobic capacity is observed, so it is necessary to create programs that encourage the practice of physical activity in this population.

3023 Board #3 June 2 3:15 PM - 5:15 PM

Relationship between Muscular Strength and Functional Balance in People Post-Stroke

Mayumi Wagatsuma, Taehoon Kim, Brenda Jeng, Cynthia Rhode, Hallie Bui, Keely Ahrold, Teri Todd, Taeyou Jung. *California State University, Northridge, Northridge, CA.*
(No relationships reported)

Impaired balance and weak muscle strength are common deficits associated with stroke. These deficits increase the risk of fall among people post-stroke. The relationship between muscular strength and balance was previously reported to be weak. However, the conclusion was made based on clinical balance assessments instead of biomechanical data. Limited research examined the relationship between balance and strength in people post-stroke. **PURPOSE:** To investigate the relationship between muscular strength and functional balance in people post-stroke. **METHODS:** A total of 20 people post-stroke completed balance and strength assessments over two separate visits. A computerized dynamic posturography system (NeuroCom International, Clackamas, OR, 2010) was used to perform four balance tests including limits of stability test (LOS), sit to stand test (STS), walk across test (WA), and step up and over test (SUO). In addition, participants completed isometric muscle strength tests of the trunk, hip, knee, and ankle. Peak torque was measured with a computerized dynamometer (Biodex Medical Systems Inc, Shirley, NY, 2012). Pearson's correlation test was used for statistical analysis. **RESULTS:** There was a strong correlation between max excursion (LOS test) and muscle strengths of knee flexor/extensor on the affected side (r values ranged between 0.721 and 0.793, $p < 0.04$). A strong correlation was also found between step width (WA test) and muscular strengths of trunk extensor, knee flexor, ankle plantar-flexor, hip flexor and extensor on the unaffected side (r values ranged between 0.797 and 0.902, $p < 0.01$). STS and SUO did not show any significant correlation with muscle strength. **CONCLUSIONS:** Our findings suggest that strengthening of the knee flexor/extensor may help people post-stroke to shift the weight to maximum range without losing balance. Also, our results indicate that the strength of the core and lower extremities muscles is strongly associated with gait stability.

3024 Board #4 June 2 3:15 PM - 5:15 PM

Feasibility And Effectiveness Of High Intensity Exercise Training For High-Functioning Children With Autism Spectrum Disorder

Karl F. Kozlowski, Clancy M. Seymour, James P. Donnelly, Marcus L. Thomeer, Christopher Lopata. *Canisius College, Buffalo, NY.* (Sponsor: Frank J. Cerny, FACSM)
Email: kozlow13@canisius.edu
(No relationships reported)

PURPOSE: This study assessed the feasibility and effectiveness of a high intensity exercise program for high-functioning children with autism spectrum disorder (HFASD). **METHODS:** Thirty children with HFASD (M age: 10.1 ± 1.6 yrs) engaged in a 1-hour exercise session, 4 d/wk for 5 weeks. Each session included an instruction period, warm-up, workout, related game, and cool-down. Child satisfaction surveys (7-point Likert scale) assessed perceived enjoyment of the session/program, difficulty of the activity(ies), level of staff support, physical benefits, etc. Staff satisfaction surveys assessed staff's enjoyment of running the session(s), clarity of the lessons, and utility of the manual and training. Fidelity of implementation (accuracy) was assessed in 67% of all sessions by staff not involved in exercise delivery. Biometric (i.e., height, weight, waist circumference, BMI) and physical performance data (i.e., strength, flexibility, cardiovascular fitness, power) were also collected. The intensity of physical activity during the sessions was assessed using accelerometers during the first and final week on parallel activities. Paired t -tests were used to assess pre to post program differences. **RESULTS:** Child satisfaction ratings indicated that when compared to other fitness/sport programs that they had participated in, this experience was very satisfying (M : 6.3), and that the overall feeling about the program was very positive (M : 6.4). The staff ($N=7$) also rated the program very positively (M : 7.0). Results indicated that the program was implemented with a high level of accuracy (93.7%). Pre-posttest comparisons yielded statistically significant improvements in sit-ups in 60 seconds ($M \Delta = 3.0$, $p = 0.017$), air squats in 60 seconds ($M \Delta = 6.9$, $p = 0.001$), and standing long jump ($M \Delta = 4.7$, $p < 0.001$). Additionally, the rounds completed on parallel workouts

improved significantly ($M \Delta = 1.4$, $p = 0.011$), as did the time spent in moderate-to-vigorous intensity activities ($M \Delta = 4.9$, $p = 0.033$). There were no significant changes in biometric measures.

CONCLUSION: The high intensity exercise program was feasible (high levels of fidelity and child and staff satisfaction) and resulted in a number of significant improvements in the physical performance of children with HFASD.

3025 Board #5 June 2 3:15 PM - 5:15 PM

Assessment of Arm Crank and Wheelchair Treadmill Ergometry in Wheelchair Basketball Players

Ruediger Reer¹, Ann-Kathrin Otto¹, Jan Schroeder¹, Serge P. von Duvillard, FACSM², Klaus-Michael Braumann¹. ¹University of Hamburg, Hamburg, Germany. ²University of Salzburg, Salzburg, Austria.
Email: ruediger.reer@uni-hamburg.de
(No relationships reported)

Assessing training program in competitive wheelchair basketball players is essential for successful competition and performance. **PURPOSE:** The aim of this study was to compare arm to treadmill wheelchair ergometry and to determine various metabolic and respiratory thresholds to provide athletes with optimal training prescription and training program. **METHODS:** Five male and 3 female wheelchair basketball players (age: 29.3 ± 2.9 yrs; BW: 68.0 ± 14.3 kg; Ht: 164.5 ± 20.6 cm) of the first German division participated in this study. Participants were tested twice, once via arm ergometry and again via wheelchair treadmill in randomized order. Measured threshold variables were: blood lactate concentration (LA mmol.l⁻¹), heart rate in beats per minute (HR bpm), power output in Watts (PO), energy expenditure (EE, Kcals), oxygen uptake ($\dot{V}O_2$ ml.kg⁻¹.min⁻¹) and maximal performance expressed in percent (%). The data were calculated for differences via non-parametric statistical analysis, correlation and statistical significance (r ; $P < 0.05$). The data was assessed according to two different concepts previously reported by Dickhuth and by Mader. **RESULTS:** When considering Dickhuth concept, our results yielded significant differences for LA ($P < 0.025$), EE ($P < 0.012$), $\dot{V}O_2$ ($P < 0.012$) and maximal performance ($P < 0.036$). According to Mader concept, we found significant differences for HR ($P < 0.012$), EE ($P < 0.012$), $\dot{V}O_2$ ($P < 0.012$) and maximal performance ($P < 0.02$). When utilizing Dickhuth concept, results yielded significant correlation for EE ($r = 0.81$; $P < 0.015$) only; while Mader concept revealed significant correlation for HR ($r = 0.76$; $P < 0.031$), EE ($r = 0.81$; $P < 0.015$) and maximal performance ($r = 0.81$; $P < 0.015$). **CONCLUSION:** Our results revealed that measures generated from arm ergometry vs. wheelchair treadmill are not useful to monitor training prescription. The large and expected significant differences in $\dot{V}O_2$ uptake alone between arm and treadmill tests lacked usefulness of the tests. We therefore recommend using treadmill test for wheelchair basketball players as it better mirrors demands of wheelchair basketball competition.

3026 Board #6 June 2 3:15 PM - 5:15 PM

Is the Metabolic Cost of Running Different for Athletes with Unilateral Versus Bilateral Transtibial Amputations?

Owen N. Beck¹, Alena M. Grabowski². ¹University of Colorado, Boulder, CO. ²Eastern Colorado Healthcare System, Denver, CO.
Email: owen.beck@colorado.edu
(No relationships reported)

Running-specific prostheses (RSPs) enable athletes with transtibial amputations to run. Yet, it is unknown if distance running performance is different between athletes with unilateral vs. bilateral amputations. **PURPOSE:** Metabolic cost affects distance running performance. Thus, we sought to compare the metabolic cost of running for athletes with unilateral and bilateral transtibial amputations using RSPs. **METHODS:** 10 athletes with unilateral and 5 athletes with bilateral transtibial amputations each completed 15, 5-minute trials on a treadmill (≤ 6 trials per day) at 2.5 or 3.0 m/s, with at least 5 minutes rest preceding each trial. Participants used a different RSP configuration for each trial. RSP configurations consisted of a randomly assigned: prosthetic model (A, B, C) stiffness category (recommended ± 1), and height (recommended ± 2 cm). We instructed participants to fast for at least 3 hours prior to testing. We measured and averaged the rates of oxygen consumption ($\dot{V}O_2$) using open-circuit expired gas analysis during the final 2 minutes of each trial. We normalized $\dot{V}O_2$ by participant mass, which included running gear, for each RSP condition. We then divided $\dot{V}O_2$ by velocity to calculate the metabolic cost of transport (CoT) in ml O₂/kg/km. We independently compared the lowest (best) and highest (worst) CoTs from athletes with unilateral and bilateral amputations using two-tailed t -tests. Significance was set at $\alpha = 0.05$. **RESULTS:** The lowest and highest CoTs for athletes with unilateral amputations were 200.1 ± 14.0 and 238.4 ± 16.5 ml O₂/kg/km (mean \pm SD), respectively. The lowest and highest CoTs for athletes with bilateral amputations were 186.2 ± 12.3 and 226.9 ± 22.7 ml O₂/kg/km (mean \pm SD), respectively. The lowest ($p = 0.085$) and highest ($p = 0.282$) CoTs were similar for both cohorts. For context, Olympic qualifying, sub-elite, and recreational non-amputee runners elicit CoTs of

181.9 ± 9.1, 187.5 ± 9.7, and 190.5 ± 13.6 ml O₂/kg/km (mean ± SD), respectively.
CONCLUSION The metabolic cost of running is similar for athletes with unilateral and bilateral transfemoral amputations, indicating that distance running performance may be the same for both groups.
 This project was supported by the BADER Consortium, a DoD CDMRP cooperative agreement (W81XWH-11-2-0222).

3027 Board #7 June 2 3:15 PM - 5:15 PM

Physiological Responses To A Simulated Half-marathon Road-race In Elite Wheelchair Racing Athletes

Jp Barfield¹, Thomas Edwards², Joseph W. Beals², Grace M. Niemi², Elizabeth Broad³, Robert W. Motl⁴, Michael De Lisio⁵, Laura Newsome¹, Nicholas A. Burd², Lara A. Pilutti². ¹Radford University, Radford, VA. ²University of Illinois at Urbana-Champaign, Urbana, IL. ³U.S. Paralympics, Colorado Springs, CO. ⁴University of Alabama-Birmingham, Birmingham, AL. ⁵University of Ottawa, Ottawa, ON. (Sponsor: Henry Williford, FACSM)
 Email: abarfield@radford.edu
 (No relationships reported)

Technology has traditionally limited research on wheelchair racing (WCR) to simulated training studies based on heart rate and speed. Practical technology is now available to examine actual physiological responses in real-time. **PURPOSE:** The purpose of this study was to characterize physiological responses across a 25-km time trial in WCR athletes with paraplegic spinal cord injury. **METHODS:** Eight internationally-elite WCR athletes (27.5±4.0 yrs, 162.5±18.6 cm, 53.5±10.9 kg, 21.5±6.7 yrs post injury) completed a maximal exercise test and 25-km time trial separated by three to five days. Energy expenditure and related variables were measured continuously during the time trial with a portable metabolic unit (COSMED K4b2, Chicago, Illinois) with field conditions of 21°C, 39.6% humidity, and wind at 22.4 km*hr⁻¹. Blood samples were collected before and immediately after the cessation of the trial to determine blood glucose and lactate concentrations. Core temperature was measured using an ingestible sensor thermistor. **RESULTS:** Six participants completed the 25-km race course (50:42±5:10 minutes) and provided usable data (Table 1). Mean VO₂ and HR were 73% and 92% of peak values, respectively. There was a significant increase in blood lactate concentration from 0.8±0.2 at baseline to 3.9±1.8 mmol/L after the race (P=0.001). Blood glucose concentrations did not differ from pre- (83.2±1.8 mg/dL) to post-race (91.0±6.6 mg/dL)(P=0.30). Core temperature increased from 37.2±0.3 to 38.7±1.2°C immediately after exercise (P=0.007). **DISCUSSION:** We demonstrate the physiologic response to competitive conditions in elite WCR athletes. Similar to elite able-bodied endurance athletes, WCR athletes sustained a high exercise intensity predominantly through carbohydrate metabolism. Our findings enable more accurate estimates of energy expenditure and have implications for the design of effective training strategies.

Table 1. Acute Physiological Responses (M±SD)

Variable	Rest	25-km Time Trial	Trial Range
VO ₂ (ml*kg ⁻¹ *min ⁻¹)	5.0±1.2	32.8±4.6	31–37
HR (bpm)	72.2±11.3	172.7±11.4	161–184
VE (L*min ⁻¹)	9.3±1.4	86.9±20.1	65–124
Calorie Expenditure (kcal*min ⁻¹)	1.2±0.2	8.4±2.1	6–9
RER	0.80±0.04	0.98±0.03	.93–1.02
CHO Utilization (%)	30.1±18.7	84.9±8.3	73–92
FAT Utilization (%)	58.9±12.0	13.6±7.0	6–24

Reliability & Validity Of Aquatic Deep Water Peak VO2 Testing For Individuals With Spinal Cord Injury

William H. Scott¹, Anna Ogonowska-Slodownik², Peter H. Gorman¹, Robert Slodownik², Paula R. Geigle¹. ¹University of Maryland School of Medicine, Baltimore, MD. ²Franz Josef Pisudski University of Physical Education, Warsaw, Poland.
 Email: WilliamScott@umm.edu
 (No relationships reported)

PURPOSE: To understand the reliability of peak VO₂ testing for individuals with spinal cord injury (SCI) in deep water and on land arm cycle ergometer; and to determine the relationship between these two testing conditions. **METHODS:** Nineteen participants (15 men, 4 women) with SCI enrolled in a pilot study to assess peak VO₂ using a Cosmed metabolic cart and tubing connection unit (Aquatrain): (1) in supported vigorous deep water exercise (aquatic), and (2) on land arm cycle ergometer. Participants randomized into either aquatic or arm cycle ergometer

measurements, separated by 48 hours both conditions. Seventeen individuals (13 men and 4 women) completed both testing conditions and two others completed only arm ergometer sessions.

RESULTS: Peak oxygen consumption correlated clinically and statistically significantly for both conditions, aquatic (n=17, r=0.93, p<0.001) and arm cycle ergometry (n=19, r=0.95, p<0.001); and a Pearson correlation between aquatic and arm cycle peak VO₂ existed (n=17, r=0.70, p<0.002). We hypothesized a priori lower extremity motor score (LEMS), age, gender, and weight could potentially impact peak VO₂ outcomes. For these participants only LEMS influenced supported deep water peak VO₂, n=14, B=0.66, p<0.008, and arm cycle ergometer peak VO₂, n=16, B=0.54, p<0.025.

CONCLUSIONS: Determining peak VO₂ for individuals with SCI is highly reproducible for arm cycle ergometry and in supported deep water with the metabolic cart Aquatrainer connection. Additionally, supported deep water peak VO₂ testing is reliable (R=0.93) and valid (r=0.70) compared to arm cycle ergometry (gold standard). Clinically it is important to assess peak VO₂ after an aquatic intervention using the same conditions as the treatment conditions, and both supported deep water and arm cycle ergometer provide reliable and valid peak VO₂ outcomes.

F-34 Thematic Poster - Sports Injuries: Friend or Foe?

Epidemiology Of Sudden Death In American Youth Sports

Brad D. Endres, Rebecca L. Stearns, Robert A. Huggins, Douglas J. Casa, FACSM. Korey Stringer Institute, Storrs, CT.
 (No relationships reported)

Little epidemiological data on the incidence of injury and sudden death in American youth sport exists. **Purpose:** Describe the epidemiology of sudden death (SD) in organized American youth sport. **Methods:** SD surveillance was conducted from 8/1/2011 to 10/27/2016 via LexisNexis and other publicly available news or media reports. A certified athletic trainer reviewed each case to confirm the official cause of SD and/or offer a speculated cause of SD if official cause was unknown. Cases of SD that occurred in youth athletes 17 years of age and younger in organized sports were included. Cases of athletes at the high school level or higher were excluded. Details of the athlete (age, gender, level of play), event (sport, event type, activity), and death (date of incident, date of death, location of death, official and speculated cause of death) were examined. **Results:** From 2007-2015, 45 SDs (average = 5 deaths/yr) were reported in American youth sports. The age range of SD was from 8-17 years old. The mean age of SD was 13 ± 2 years old. The overall incidence rate was 0.23 deaths/100,000 participants. The deadliest year was 2015 with 11 cases. When broken down into three-year segments, 6 SDs occurred from 2007-2009, 16 from 2010-2012, and 23 from 2013-2015. From 2007-2015, males experienced a greater number of SD compared to females (n=36, 80% of all deaths). Basketball had the highest number of SDs from 2007-2015, with a total of 16 occurrences. The most frequent cause of SD was cardiac-related (n=34, 76% of all deaths). Furthermore, 15 of the 16 basketball deaths (94%) were cardiac related. **Conclusions:** From 2007-2015 45 youth athletes died while playing organized sport, with an increasing number of SDs in more recent years. Males experienced a greater number of SDs than females. The sport and condition with the greatest SDs were basketball and cardiac-related SDs, respectively. With an overall incidence of 0.23 SDs/100,000 participants, these rates are on par with reported high school SD rates from 2007-2014 school years as reported by the National Center for Catastrophic Sport Injury Research (average=0.24/100,000). This study sets a precedent for further examination into youth sport SD and supports the need for mandated health and safety guidelines in this population.

Epidemiology Of Sports-related Concussion In Japanese High School AthletesFumiko TSUKUDA, Female¹, Kousuke TAKEUCHI², Shinobu TANAKA², Takeshi KOMATSU², Masao KANAMORI¹.¹Ritsumeikan University, Kusatsu, SHIGA, Japan. ²Biwako Seikei Sport College, Otsu, SHIGA, Japan.

Email: gr0277si@ed.ritsumei.ac.jp

(No relationships reported)

As a result of epidemiological articles on sports-related concussion (SRC) in Japan, few articles were published. Incidence rate of sports-related concussion among high school student athletes in Japan has not been researched. **PURPOSE:** To describe epidemiology of SRC in Japanese high school Athletes. **METHODS:** SRC data from the medical check among 18-19 years old students in total 368 athletes were analyzed. Data are collected from history of concussion, neurological symptoms (SCAT2), Balance Error Scoring System (BESS) by the assessment of concussion held in Zurich (McCrory P et al. 2012). Incidence are obtained to estimate the experience rate of three person-years among the subjects. Cases of concussion are ascertained by certificated Japanese athletic trainer and sports doctors. Symptoms comparisons were made using two-way ANOVA with repeated measures. **RESULTS:** Experience rate of concussion during high school three years were 2.72 percent of ascertain cases, and 4.08 percent of total cases (ascertain and uncertain). Incident rates of ascertained cases were estimated to be 0.013 person-year, rates of total cases be 0.020. Injury rate per 1000 Athletic-Exposures were 0.42 with Men's basketball, 0.22 with Men's soccer. The rates of concussion in basketball were higher than Americans (Daneshvar DH, 2011 and Giza CC, 2013). The rates in soccer were lower. Headache, Pressure in head, Dizziness were statistically increased the number from the result of SCAT2. Higher Incidence among sports are observed in Men's basketball and Men's Soccer. There were not significant different from annual practice time between concussion (CC) and non-concussion (NCC) cases, basketball CC: 1364.0 hours/year. NCC: 1155.8 hours/year. Balance Error Scoring System at baseline were CC: 27.34, NCC: 27.38. Limitations: We could not evaluate the rate of Rugby, American-football and Judo because of a few players.

CONCLUSIONS: Incident rates of concussion of Japanese high school students were estimated to be 0.013 person-year at least. Injury rate per 1000 Athletic-Exposures were 0.42 with Men's basketball, 0.22 with Men's soccer.

Developmental Stage And Age At Time Of First Concussion Influences Subsequent Concussion RiskJulianne D. Schmidt¹, Katherine Rizzone², Nicole L. Hoffman¹, Michelle L. Weber¹, Jeffrey Bazarian². ¹University of Georgia, Athens, GA. ²University of Rochester, Rochester, NY.

Email: schmidtj@uga.edu

(No relationships reported)

Sustaining a single concussion increases the risk of sustaining a subsequent concussion. Individuals that sustain their first concussion during childhood may be at greater risk for sustaining multiple concussions throughout their lifetime, due to a longer window of vulnerability. **PURPOSE:** To determine whether developmental stage and age at first concussion influence risk of subsequent concussion. **METHODS:** A total of 23,582 collegiate athletes from 26 universities and military cadets from 3 military academies completed a concussion history questionnaire (15,232 males, 8,335 females, 15 missing; age: 19.9±1.4 years, mass: 77.4±17.2 kg, height: 177.3±10.4 cm). Participants were asked to self-report the number of concussions and age at time of each injury. Participants with concussion histories (n=3,819) were categorized as having sustained their first concussion during childhood (<10 yo) or adolescence (≥10 yo & ≤18 yo) based on World Health Organization criteria. We then determined the number of subsequent concussions sustained prior to age 18. We used a Poisson regression to model developmental stage predicting risk of subsequent concussion. A second model was developed to determine whether age at first concussion predicted subsequent concussion risk ($\alpha = 0.05$). **RESULTS:** Of the 3,819 participants with a previous concussion, 251 (6.6%) sustained their first concussion during childhood and 3,568 (93.4%) during adolescence. Participants that sustained their first concussion during childhood had 81% higher risk of sustaining subsequent concussions (RR=1.81, 95% CI: 1.49, 2.21) compared to those that sustained their first concussion during adolescence. Subsequent concussion risk decreased by 10% for each additional year of age at the time of first concussion (RR=0.90, 95% CI: 0.88, 0.92). **CONCLUSION:** Sustaining a concussion at a young age seems to lengthen the window of vulnerability to sustaining subsequent concussions, resulting in higher risk of sustaining multiple concussions in a lifetime. Sustaining multiple concussions may cause prolonged recovery, early medical disqualification from sport, and late life cognitive impairments. Concussion prevention strategies are of particular need at the youth level to prevent children from sustaining their first concussion at a young age.

Sex Differences In Head Injuries Among Collegiate Soccer Players: NCAA ISS, 2004-2009Avinash Chandran, Mary Barron, Beverly Westerman, Loretta DiPietro, FACSM. *The Milken Institute School of Public Health, Washington, DC.* (Sponsor: Loretta DiPietro, FACSM)

Email: avinashc@gwmail.gwu.edu

(No relationships reported)

Some of the highest rates of head injuries and concussion among all contact/collision sports are observed in soccer; yet, the multifactorial determinants of head injuries among players remain relatively undefined. **PURPOSE:** To examine sex-differences in the rate and the severity (lost days of participation, resultant concussions) of head injuries among collegiate soccer players between 2004 and 2009, while controlling for several covariables previously linked to injury occurrence. **METHODS:** Data from the National Collegiate Athletic Association Injury Surveillance System (NCAA-ISS) were used to calculate injury incidence density (ID) per 1000 athletic exposures (AE). The rate ratio (RR), along with the 95% Wald confidence interval (CI), compared ID among female, relative to male soccer players. Multivariable logistic regression and multivariable negative binomial regression modeling then tested the relation between sex and head injury incidence and severity while controlling for contact, setting, and competition level. **RESULTS:** Between 2004 and 2009, the sex-specific rate of soccer-related head injuries was 0.87 per 1000 AEs in women and 0.71 per 1000 AEs in men (RR = 1.23, 95% CI = [1.08, 1.41]). The rate of head injuries due to player-to-player contact was comparable between women and men (RR=0.95, 95% CI=[0.81, 1.11]); however, the rate of injury due to contact with apparatus was nearly 2 ½ -fold higher (RR=2.46, 95% CI = [1.76, 3.44]) and the rate due to contact with a playing surface was over two-fold higher (RR=2.29, 95% CI = [1.34, 3.91]) in women than in men. We also observed a significant joint effect between sex and contact in our regression models, with a particularly notable antagonistic interaction observed while modeling head injuries. **CONCLUSION:** Among female players, head contact with a ball, a goal post, or the playing surface may be especially deleterious compared with head contact with another player.

3034 Board #5 June 2 3:15 PM - 5:15 PM

National Hockey League Players' Concussion And Lower-Body Injury Risk Across the 2012-2015 SeasonsKathryn L. O'Connor, Tanu Bhargava, Andrew L. Lapointe, Steven P. Broglio, FACSM. *University of Michigan, Ann Arbor, MI.* (Sponsor: Steven P. Broglio, FACSM)

Email: kloconn@umich.edu

(No relationships reported)

Recent literature has indicated that concussion increases musculoskeletal injury risk. Various studies have demonstrated post-concussion changes in gait and posture, but few studies focus on orthopedic trauma. **PURPOSE:** Investigate the association between concussion and lower-body injury risk in the NHL players during 2012-2015 seasons. **METHODS:** Season statistics and injuries were compiled from hockey-reference.com. All head injuries were reviewed, using public news reports, to determine evidence for concussive injury. Over the four seasons 3505 athlete seasons (2012: n = 839, 2013: n = 886, 2014: n = 882, 2015: n = 898) were compiled with 2048 unique NHL players. Each injury was classified as illness, lower-body, upper-body, concussion, undisclosed, or other. Primary analyses examined the first and second injuries. Odds ratios and 95% CI were calculated for the likelihood of concussion after a lower-body injury and the likelihood of lower-body injury after concussion. Upper-body injuries were not examined as they could be concussive injuries per the NHL reporting guidelines. **RESULTS:** Players had an average age: 26.8 years (SD=4.6), height: 185.7 cm (SD=5.3), weight: 91.7 kg (SD=6.8), and games played: 45.3 (SD = 27.7). The majority of the players were forwards 65% (n = 2286). Across four seasons, 48% (n = 1673) of all athletes had at least one injury or illness with an average of 9.4 (SD = 12.8) games lost per season. There were 141 recorded concussions (4.1%) and 900 lower body injuries (26%) from 2012-2015. Players whose first injury was to the lower-body had 3 times (95% CI: 1.48-6.24) the odds of subsequent concussion within the same season compared to those without lower-body injury. Furthermore, players whose first injury was a concussion had 2.25 (95% CI: 1.28-3.96) times the odds of a lower body injury within the same season.

CONCLUSIONS: Athletes with concussion have greater subsequent lower-body risk when compared to athletes with no injury or illness. However, it may be that certain athletes are generally more injury prone than others given the bidirectional association between concussion and lower-body injury. Future studies should investigate individual characteristics to determine specific injury risk and identify at-risk athletes.

3035 Board #6 June 2 3:15 PM - 5:15 PM
Prediction of Injury among Elite Dancers: Three Years of Prospective Surveillance
 Marijeanne Liederbach¹, Evangelos Pappas², Leigh Schanfein¹, Beth Glace³. ¹*NYU Langone Medical Center Hospital for Joint Diseases, New York, NY.* ²*University of Sydney, Sydney, Australia.* ³*Lenox Hill Hospital Northwell Health, New York, NY.* (Sponsor: Mal McHugh, FACSM)
 (No relationships reported)

Injuries in dance are commonplace and distressing in terms of human and financial impact. It is the hope of dance medicine healthcare professionals and educators to detect risk for injury prospectively, often through screening efforts. It is known that screening has been very useful for rapport building, improving health literacy and facilitating entryways to local healthcare systems. However screening, as we have been conducting it, has still not proven to be predictive of injury despite implementation of preventative interventions such as pre-season conditioning programs. **PURPOSE:** To test the predictive validity of four patient reported outcome measures (PRO) in addition to an array of motor control designed clinical performance-based outcome measures (CPBO) collected during preseason screening in predicting subsequent season time loss injury. **METHODS:** 241 elite classical dancers (21.5±5.0 years; 69 men, 172 women) who received regular onsite care consented to participate in PRO and CPBO-based preseason screenings and ongoing, healthcare practitioner documented injury surveillance. The PRO's utilized in this study were the Discomfort Rating Scale (DRS); the World Health Organization Functional Scale (WHO); the Profile of Mood States total score (POMS) and the Eating Attitudes Test-26 (EAT). Data were analyzed with a multivariate logistic regression model for the outcome variables "injured in subsequent season" and "number of therapy visits in subsequent season". **RESULTS:** All PRO variables were associated with the primary outcome variables (p=0.003, R²=0.492, R²=0.242, adjusted R²=0.205). **CONCLUSION:** Injury prevention screening for dancers should include PRO scores to predict those at greatest risk for time loss injury.

3036 Board #7 June 2 3:15 PM - 5:15 PM
Injury in D III Volleyball Players is Associated with Preseason Jump and Hop Measures
 Jason Brumitt¹, Alma Mattocks², Phil Lentz³, Jeremy Loew⁴. ¹*George Fox University, Newberg, OR.* ²*Spalding University, Louisville, KY.* ³*Pacific University, Forest Grove, OR.* ⁴*Lewis and Clark College, Portland, OR.* (Sponsor: Mitchell J Rauh, FACSM)
 Email: jbrumitt@georgefox.edu
 (No relationships reported)

Purpose: Collegiate volleyball (VB) players are at risk for sports injuries. Reported time-loss injury rates for female Division III (D III) collegiate VB players range from 4.0 to 5.4 injuries per 1000 athletic exposures (AEs). Identifying risk factors in this population may help coaches to reduce injury rates via targeted training programs. The purpose of this prospective cohort study was to determine the ability of 2 functional performance tests (FPTs) [the standing long jump (SLJ) and/or the single-leg hop (SLH) for distance] to identify female D III VB players who may be at an increased risk for a non-contact time-loss lower quadrant (LQ = low back and lower extremities) injury. **Methods:** 68 female VB players (18.9 ± 1.0 years old) from 5 D III teams performed 3 trials of each FPT in the preseason. Off-season training habits were also collected. Mean SLJ and SLH distances (normalized to height) were used for study analysis. Injury rates were calculated per 1000 AEs for initial and subsequent injuries. Crude and adjusted odds ratios (OR) were calculated to identify the risk association between preseason FPT measures and LQ injury. **Results:** The mean SLJ distance was 0.82 ± .09 and the mean SLH distances were 0.68 ± 0.09 (R) and 0.68 ± 0.11 (L). Fourteen initial time-loss injuries [thigh/knee region = 5; foot/ankle region = 9] and 2 subsequent time-loss injuries (foot/ankle = 2) occurred during the study. The initial time-loss injury rate was 3.0 (95% CI: 1.7-5.0) per 1000 AEs and the subsequent injury rate was 5.6 (95% CI: 0.9-18.4) per 1000 AEs. Individual test performance did not discriminate risk; however, a limb symmetry index (LSI) > 10% was associated with an increased risk of LQ injury (OR = 3.8; 95% CI: 1.0, 13.5). Suboptimal FPT scores and an LSI > 10% was associated with an increased risk of LQ injury (OR = 21.2; 95% CI: 2.1, 210) and foot/ankle (FA) injury (OR = 14.3; 95% CI: 2.0, 102.9). Adjusted OR were calculated for the aforementioned categories adjusting for off-season weightlifting reports: 1) LSI > 10% (AOR 5.5; 95% CI: 1.3, 22.3); 2) suboptimal FPT scores and LQ injury (AOR 25.7; 95% CI: 2.2, 299); 3) suboptimal FPT scores and FA injury (AOR 16.3; 95% CI: 1.9, 139). **Conclusions:** Suboptimal performance on a battery of FPTs may be useful as a screening tool to identify female D III VB players at risk for a non-contact time-loss LQ injury.

 (No relationships reported)

INTRODUCTION: The Momentum 94.7 Cycle Challenge is an annual recreational long distance cycling event in South Africa. Medical support at such an event is imperative, with little known regarding the risk of acute traumatic injuries and acute medical illness. **PURPOSE:** To describe the incidence and patterns of acute injury and medical illness and difference between sexes during a mass community cycling race. **METHODS:** A descriptive study of the 2014 Momentum 94.7 Cycle Challenge, documenting the incidence of acute traumatic injuries and acute non-traumatic medical illness in 23055 race starters (males=17520, females=5236, not specified=299) during the 94.7km distance. **RESULTS:** An incidence (per 1000 starters) of 38.69 (females=38.39, males=36.52) for all medical illness; with an incidence of 11.88 (females=16.42, males=10.73) for adverse medical events and of 1.3 (females=2.67, males=0.86) for serious adverse events, were reported. The incidence of non-traumatic medical complaints was 32.48 (females=31.32, males=33.39) and of traumatic injuries was 3.99 (females=7.07, males=3.14). Females had a higher risk of sustaining traumatic injuries (p<0.001), central nervous system (p=0.0062) and eye complaints (p=0.0107). The musculoskeletal system had the most complaints, 80.7%. Males 10-16yrs (p=0.0013) and females 23-39yrs (p=0.0336) and >50yrs (p=0.0002), had a higher risk for traumatic injuries. **CONCLUSIONS:** A reported ratio of 1:26 (females=1:26, males=1:28) of all starters developed medical complaints; with 1:84 cyclists (females=1:61, males=1:93) that developed adverse events and did not finish the race; and 1:769 participants (females=1:374, males=1:1163) developing serious adverse events that required hospitalisation. The majority of admissions for traumatic injuries were followed by cardiovascular complaints. A wide spectrum of medical complaints can be expected during mass recreational sport events, with a higher risk for females to sustain traumatic injuries, and encounter central nervous system and eye complaints. The majority of disorders involved the musculoskeletal system. Information regarding the pattern and type of medical encounters can prove useful during planning and management of similar future events.

Effects Of Three-stages Training Program On Balance And Functional Fitness For Community-dwelling Old-old Japanese
 Hiroshi Kohno¹, Hidenori Asai². ¹*TOYO University, Asaka-shi, Saitama, Japan.* ²*Ehime University, Matsuyama, Ehime, Japan.*
 Email: kohno@toyo.jp
 (No relationships reported)

PURPOSE: To examine effectiveness of three-stages physical training program on balance ability and ADL-related functional fitness for community-dwelling Japanese old-old females. **METHODS:** After giving written informed consent, the subjects, unable to stand on one leg more than 20 seconds with eyes open, were divided into the 3 times/week group (HFG; 13 females, 80.0±2.3 yrs, BMI 23.0±1.8) and the 1time/week group (LFG; 10 females, 81.3±3.6 yrs, BMI 21.4±1.3). The program was composed of three stages for 16 weeks. First, they learned about managing skill for their physical soreness and were asked to standing on one-leg with eyes open for one minutes, 3 times a day both each leg at class and at home. Second, they learned to strengthen their core and lower legs muscle using an elastic band. The last stage was to learn three minutes arm and legs combined exercise program with music. ADL-related functional fitness(sitting & standing time, zigzag walking time), one-leg standing time with eyes open, knee extension strength, fear of falling score were obtained. Balance ability was measured

by the area covering and total length of the center of gravity sway (COP). Each measurement items were assessed before and after the intervention period. Student's T-test and two-way repeated measures ANOVA were used to test the effectiveness. **RESULTS:** The class participation were 83±5% and 71±8% respectively. Sitting & standing time (HFG: 18.4±5.6 to 16.2±5.4 sec., LFG: 17.4±3.9 to 17.4±3.6sec., F=3.205, P=0.088), zigzag walking time (HFG: 19.6±3.0 to 17.0±3.3sec., LFG: 17.1±4.2 to 16.8±2.9sec., F=12.18, P=0.002), one-leg standing time with eyes open (HFG: 6.1±3.1 to 13.3±4.4 sec., LFG: 5.9±2.3 to 6.1±1.8sec., F=26.44, P=0.000), knee extension strength (HFG: 181.5±39.6 to 208.5±41.5 N, LFG: 192.0±15.5 to 196.5±14.5 N, F=4.775, P=0.040), and balance ability (area covering of COP; HFG: 15.3±5.8 to 10.6±7.1 cm², LFG: 14.6±4.1 to 17.2±8.9 cm², F=7.064, P=0.015, total length of COP; HFG: 148.3±31.9 to 100.7±27.4 cm., LFG: 141.0±30.2 to 135.7±37.2 cm, F=12.183, P=0.002) also improved significantly in HFG. Fear of falling score was not change in both groups. **CONCLUSIONS:** Three-stage physical training program was effective on balance ability and functional fitness for Japanese old-old females.

Both MBSR and Aerobic Exercise Training can Affect Physical Activity Behavior in Sedentary Individuals

Jacob Meyer, Elisa Torres, Maggie Grabow, Aleksandra Zgierska, Christopher Coe, Bruce Barrett. *University of Wisconsin - Madison, Madison, WI.* (Sponsor: Dane Cook, FACSM)
Email: jdmeyer3@wisc.edu
(No relationships reported)

Mindfulness-Based Stress Reduction (MBSR) and aerobic exercise training (AET) have emerged as robust programs to improve health and wellbeing. Physical activity may be enhanced to a similar degree by MBSR and AET, although their relative effects on physical activity have not been objectively assessed.

PURPOSE: To compare the effects of 8-weeks of MBSR and AET on objectively measured physical activity.

METHODS: Participants underwent 7-days of physical activity monitoring (Actigraph GT3X) at baseline prior to randomization, and again following completion of 8-weeks of training in MBSR or AET, or neither (no-treatment control group). Actigraph-based average daily minutes of sedentary, light, moderate, vigorous and moderate-to-vigorous (MVPA) activities were calculated. Weekly time spent in MVPA lasting longer than 10 minutes (MVPA Bouts) was calculated to assess physical activity engagement sufficient to meet national recommendations. Groups were compared via pairwise comparisons of changes in MVPA and MVPA Bouts from pre-randomization (August) to post-intervention (November).

RESULTS: Sufficient data for analysis (≥ 3 week and ≥ 1 weekend day, >10 hours/day) were obtained from 49 participants (18 MBSR, 14 AET, 17 control) out of 66 who enrolled. Reflecting a seasonal decline (Aug to Nov), daily MVPA decreased in all groups: control by 17.9 ± 25.7 min/day, MBSR by 5.7 ± 7.5 min/day, and AET by 7.4 ± 14.3 min/day, without statistically significant differences among the groups (all $p > 0.05$). MVPA Bouts decreased 77.3 ± 106.6 min/week in the control and 15.5 ± 37.0 min/week in the MBSR group, with a nonsignificant difference favoring MBSR ($p = 0.080$); AET increased MVPA Bouts by 5.7 ± 64.1 min/week, significantly different from control ($p = 0.029$) but not MBSR ($p = 0.564$).

CONCLUSIONS: This pilot study showed that while exercise training leads to more minutes of MVPA sufficient to meet physical activity guidelines compared to a no-treatment control, MBSR training may mitigate seasonal decline with similar effects to exercise training on daily MVPA and MVPA in 10+ min bouts. As these findings indicate that MBSR training has beneficial effects on MVPA, future research is needed to determine if MBSR improves wellbeing through changes in physical activity.

Effects of High-intensity Interval Training and Moderate-intensity Continuous Training on Sleep in Sedentary Obese Adults

Kirbie E. Huwa¹, Brandon J. Sawyer¹, Matthew P. Buman, FACSM², Glenn A. Gaesser, FACSM². ¹Point Loma Nazarene University, San Diego, CA. ²Arizona State University, Phoenix, AZ.
Email: kirbiehuwa331@pointloma.edu
(No relationships reported)

Regular moderate-intensity physical activity has been shown to improve sleep duration and quality in individuals with mild to moderate sleep complaints. It is not known whether more vigorous exercise may have similar, more pronounced, or even detrimental effects on sleep. **PURPOSE:** To examine the effects of high-intensity interval training vs. moderate-intensity continuous training on objectively- and subjectively-measured sleep parameters. **METHODS:** Fifteen volunteers (35.1 ± 8.1 y; BMI = 36.0 ± 5.0 kg/m²) completed 8 weeks (3 d/wk) of either high-intensity interval training (HIIT (n=8): 10, 1-min intervals at 90-95% of heart rate max (HR_{max}))

or moderate-intensity continuous training (MICT (n=7): 30 min at 70-75% of HR_{max}) on cycle ergometers. Subjects wore accelerometers (Actigraph GT3x+) on the non-dominant wrist during sleep periods for seven consecutive days at baseline, week 5, and week 8. Measures of total sleep time (TST, min), sleep onset latency (SOL, min), and sleep efficiency (SE, %) were derived. Participants also completed the Pittsburgh Sleep Quality Index (PSQI) at baseline and after training. **RESULTS:** For Actigraph-measured sleep, SOL was marginally improved in HIIT (-1.92 ± 3.9 min) compared to MICT (+4.92 ± 8.15 min, $p = 0.08$, $d = 0.61$). SE was also marginally improved in HIIT (+2.5 ± 5.2%) compared to MICT (-3.8 ± 4.6, $p = 0.06$, $d = 0.65$). No changes were observed for TST. For PSQI-measured sleep, MICT showed favorable improvements compared to HIIT for sleep latency ($p=0.09$, $d = 0.51$), sleep duration ($p=0.06$, $d = 0.57$), sleep efficiency ($p=0.07$, $d = 0.55$), and the global score ($p=0.03$, $d = 0.67$), but no differences were observed for sleep quality, disturbances, medication use, or daytime dysfunction. **CONCLUSION:** This study is the first to compare HIIT vs. MICT on sleep using both actigraphy and subjective measures. Our results suggest that in comparison to moderate-intensity continuous training, high-intensity interval training may lead to the perception of poorer sleep quality. Conversely, objectively measured sleep quality may respond more favorably to HIIT than MICT.

(No relationships reported)

PURPOSE: Positive (PoA) and negative affect (NeA) independently contribute to psychological and physical health. Observational studies have shown that active adults have greater daily PoA than less active individuals, whereas there is inconsistent evidence for NeA. We report results of a randomized controlled trial on the effects of 24 weeks of aerobic training on daily PoA and NeA.

METHODS: Sixty-three high stress family caregivers of persons with dementia were randomized into a waitlist control group (n = 33) or a 24-week aerobic training intervention group (n = 30). Treatment group participants gradually increased weekly moderate-to-vigorous activity to 150 minutes per week by the 8th week in the study. Prior to randomization and again in the 24th week, participants completed 6 online ecological momentary assessments per day for 7 days. A visual analog scale of 0 to 100 was used to assess PoA and NeA. Based on the circumplex theory of emotion, we further divided PoA and NeA along their dimensions, valence and activation, leading to four types: Positive Deactivated (PDA), Positive Activated (PAA), Negative Deactivated (NDA), Negative Activated (NAA).

RESULTS: Mixed models revealed that change over time (Δ) between exercise and control group caregivers was significantly different for PoA, NeA, and the four subcomponents (all p 's < .001). Exercisers significantly increased daily PoA ($\beta_{\Delta} = 6.18$, SE = 0.64, CI = 4.93, 7.42) and decreased NeA ($\beta_{\Delta} = -4.74$, SE = 0.62, CI = -5.96, -3.54, $p < .001$) compared to baseline, whereas the control group increased in both PoA and NeA (PoA: $\beta_{\Delta} = 1.74$, SE = 0.56, CI = 0.63, 2.84, $p = .002$; NeA: $\beta_{\Delta} = 2.35$, SE = 0.55, CI = 1.28, 3.42, $p < .001$). These effects were consistent for PDA, PAA, NDA, NAA, with one exception: PAA did not increase significantly in waitlist control participants ($p = .31$).

CONCLUSIONS: All caregivers increased in daily PoA after 6 months, however, those who exercised increased significantly more. On the other hand, there was a significant distinction in the pattern for daily NeA: exercisers decreased and control participants increased. These findings have implications for understanding the role of fitness training on daily affective states, especially in family caregivers of persons with a progressive disorder.

Health In Pregnancy and Postpartum (HIPP): Targeting Gestational Weight Gain and Postpartum Weight Loss

Sara Wilcox, FACSM, Jihong Liu, Gabrielle Turner-McGrievy, Judith Burgis, Cheryl Addy, Ellen Wingard, Brandi Blackmon, Alicia A. Dahl, Lara Schneider. *University of South Carolina, Columbia, SC.*
Email: swilcox@sc.edu
(No relationships reported)

Interventions to prevent excessive weight gain and promote postpartum weight loss have modest results, particularly in overweight and obese women.

PURPOSE: To describe the rationale and design of the HIPP trial; discuss recruitment strategies, challenges, and yield to date; and present baseline demographic and physical activity (PA) data.

METHODS: HIPP is a randomized controlled trial enrolling women from SC who are <16 wks gestation, overweight or obese, white or African American, 18 to 44 yrs old, without exercise contraindications. Participants are randomized to a behavioral lifestyle intervention or usual care (target N=400) and assessed at baseline, 32 wks gestation, and 6- and 12-mos postpartum. Outcomes include gestational weight gain (primary) and PA (secondary) measured with the Sensewear Armband. The behavioral lifestyle intervention, grounded in Social Cognitive Theory, consists of two individual counseling sessions (early pregnancy and postpartum), weekly or biweekly pregnancy counseling calls, biweekly postpartum counseling calls, 10 pregnancy and 16 postpartum podcasts, and an optional private Facebook group (to 6-mos postpartum). The usual care group receives monthly mailings and a matched number of podcasts on non-weight related topics.

RESULTS: To date, 95 participants have enrolled, representing 16% of women who completed a screening form and were initially eligible. Eight (16%) have withdrawn, two due to medical ineligibility. Barriers to enrollment include failure to reach women for telephone screening, ineligibility, and no shows to baseline visits. These challenges led to increasing recruitment sites and replacing group intervention sessions with individual telephone counseling. At baseline, participants were 10.0 ± 2.1 wks gestation, 30.2 ± 5.6 yrs old, 44% nulliparous, 34% African American, 60% college graduates, and 48% obese. Baseline armband average wear-time was 23.5 ± 0.3 hrs/d. Participants accumulated 36 ± 22 total mins/d of MVPA and 5399 ± 2303 steps/d. 32-wk data show trends favoring the intervention group (40 vs. 26 mins/d MVPA, 5078 vs. 4620 steps/d).

CONCLUSION: HIPP is an innovative study that addresses gaps in the literature. Recruitment posed challenges necessitating study modifications. Primary outcome results are expected in 2019.

Effects of a Long-Term Physical Activity Program on Activity Patterns in Mobility Impaired Older Adults

Amal A. Wanigatunga¹, Robert S. Axtell, FACSM², Roger A. Fielding³, Nancy W. Glynn⁴, Abby C. King, FACSM⁵, Mary M. McDermott⁶, Catrine Tudor-Locke, FACSM⁷, Marco Pahor¹, Todd Manini, FACSM¹. ¹University of Florida, Gainesville, FL. ²Southern Connecticut State University, New Haven, CT. ³Tufts University, Boston, MA. ⁴University of Pittsburgh, Pittsburgh, PA. ⁵Stanford University, Stanford, CA. ⁶Northwestern University, Evanston, IL. ⁷University of Massachusetts Amherst, Amherst, MA. (Sponsor: Todd M. Manini, FACSM)
Email: asiri@ufl.edu

(No relationships reported)

Purpose: To examine the effect of a long-term structured physical activity intervention on accelerometer-derived metrics of activity composition changes in older adults at high risk for mobility disability.

Methods: Participants were randomized to either a physical activity (PA) or health education (HE) program. The PA intervention included a walking regimen with strength, flexibility, and balance training. The HE program featured health-related discussions and a brief upper body stretching routine. Participants (n = 1,341) wore a hip-worn accelerometer for ≥ 10 h/day for ≥ 3 days at baseline and again at 6, 12 and 24 months post-randomization. Total physical activity (TPA)—defined as movements registering 100+ counts/min—was segmented into the following intensities: low light (LLPA; 100-759 counts/min), high light (HLLPA; 760-1,040 counts/min), low moderate (LMPA; 1,041-2,019 counts/min), and high moderate and greater (HMPA; 2,020+ counts/min) physical activity. Patterns of activity were characterized as bouts (defined as the consecutive minutes within an intensity).

Results: Both groups decreased TPA (-10.5 ± 1.0 minutes/day annually), but the PA intervention attenuated this effect (PA vs HE: $+6.4 \pm 2.1$ minutes/day, $p < 0.001$). This attenuation shifted TPA composition by increasing daily time in HLLPA (1+ bouts: 0.8 ± 0.3 ; 5+ bouts: 0.2 ± 0.04 ; 10+ bouts: 0.1 ± 0.02 minutes), LMPA (1+ bouts: 2.7 ± 0.4 ; 2+ bouts: 2.4 ± 0.3 ; 5+ bouts: 2.0 ± 0.2 ; 10+ bouts: 1.1 ± 0.1 minutes), and HMPA (1+ bouts: 2.8 ± 0.4 ; 2+ bouts: 2.5 ± 0.3 ; 5+ bouts: 2.1 ± 0.3 ; 10+ bouts: 1.7 ± 0.2 minutes). All findings were statistically significant at $p < 0.01$.

Discussion: The PA intervention increased physical activity by shifting the composition of activity toward higher intensity activity in longer duration bouts. However, a long-term structured physical activity intervention did not completely eliminate overall declines in total daily activity experienced by mobility impaired older adults.

3046 June 2 4:45 PM - 5:00 PM

Effects of Supervised and Unsupervised Physical Activity Programs for Weight Loss

Seth A. Creasy¹, Renee J. Rogers², Kelliann K. Davis, FACSM², Bethany Barone Gibbs², Erin E. Kershaw², Sara J. Kovacs², Meghan R. Maher², Robert J. Kowalsky², Matthew O'Dell², Katherine A. (Sponsor: John M. Jakicic, FACSM)
Email: seth.creasy@ucdenver.edu

(No relationships reported)

Both supervised and unsupervised physical activity programs have been included within a standard behavioral weight loss intervention (SBWI). However, few studies have directly compared supervised and unsupervised physical activity within the context of a SBWI.

PURPOSE: This study examined changes in moderate-to-vigorous physical activity (MVPA), fitness, and weight in response to a supervised physical activity program prescribed in minutes per week (SUP-PA), an unsupervised physical activity program prescribed in minutes per week (UNSUP-PA), and an unsupervised physical activity program prescribed in steps per day (STEP) during a SBWI.

METHODS: Adults (N=52, age: 43.5 ± 10.1 years, BMI: 31.5 ± 3.5 kg·m⁻²) participated in a SBWI and were randomized to STEP (n=18), UNSUP-PA (n=17), and SUP-PA (n=17). Subjects were prescribed a calorie-restricted diet (1200-1800 kcal·day⁻¹) and to progressively increase physical activity (SUP-PA and UNSUP-PA: 150 min·week⁻¹; STEP: 10,000 total steps·day⁻¹ with 2,500 brisk steps·day⁻¹). All three groups attended weekly in-person group intervention sessions for 12 weeks. SUP-PA also attended supervised activity sessions, whereas UNSUP-PA and STEP engaged in unsupervised physical activity.

RESULTS: MVPA in bouts of ≥ 10 minutes significantly increased over the 12-week intervention by 11.5 ± 31.2 min·day⁻¹ in STEP, 16.1 ± 25.8 min·day⁻¹ in UNSUP-PA, and 21.6 ± 24.9 min·day⁻¹ in SUP-PA ($p < 0.001$) with no differences between groups ($p = 0.94$) or group by time interaction ($p = 0.81$). Weight significantly decreased ($p < 0.001$) with no significant difference between groups (STEP: -5.3 ± 3.6 kg, UNSUP-PA: -5.1 ± 3.3 kg, SUP-PA: -3.8 ± 3.0 kg) ($p = 0.81$). Fitness increased significantly greater in both SUP-PA (3.8 ± 1.6 ml·kg⁻¹·min⁻¹; 0.22 ± 0.23 L·min⁻¹) and UNSUP-PA (3.8 ± 3.2 ml·kg⁻¹·min⁻¹; 0.17 ± 0.24 L·min⁻¹) compared to STEP (1.3 ± 2.4 ml·kg⁻¹·min⁻¹; -0.04 ± 0.19 L·min⁻¹) ($p < 0.05$).

CONCLUSIONS: Unsupervised physical activity prescribed in min·week⁻¹ or steps·day⁻¹ may elicit a similar increase in MVPA and reduction in weight compared to supervised physical activity within a SBWI. However, physical activity prescribed in steps·day⁻¹ may elicit less favorable changes in fitness. Whether results are consistent across a longer intervention period warrants further investigation.

Iso-caloric Two-intensity Intermittent Exercise Blunts Detection, Leptin Response, And Dietary Compensation In Obese Women

Katarina T. Borer¹, Elizabeth C. Wuorinen². ¹University of Michigan, Ann Arbor, MI. ²Northern Michigan University, Marquette, MI.

Email: katarina@umich.edu

(No relationships reported)

PURPOSE: Whether obesity can influence appetite, hormonal responses to, and compensation for exercise energy expenditure (EEE) is uncertain. We tested the hypotheses that: (1) EEE suppresses appetite but increases post-exercise food intake independently of obesity, and (2) the effect may be mediated by energy-sensing hormones leptin and insulin.

METHODS: The 57-y old lean (BMI 23.4 kg/m²) and obese (BMI 33.6 kg/m²) women remained sedentary (SED) or did iso-caloric high- or a low-intensity, intermittent exercise (HIE 80%, LIIE 40% of VO₂max, respectively) one h after the morning (0700 h) and mid-day (1300 h) weight-maintenance meals. After the evening 1900 h

meal, an ad-libitum snack (2100 h) assessed compensation for EEE. A visual analog scale evaluated the appetite. Plasma glucose, FFAs, insulin and leptin were measured at 30 to 60-min intervals.

RESULTS: Meal intake (1350 vs 1473 Kcal) and mean EEE at two intensities during morning and mid-day postprandial periods (PPs) (1821 and 2202 Kcal) were similar in lean and obese women, respectively, as was EE during SED day (758 and 818 Kcal). This resulted in 529 and 380 Kcal positive energy balance on SED days and a 471 and 729 Kcal negative energy balance on exercise days in lean and obese women, respectively. Lean women ate an additional 256, and obese women 261 Kcal, of ad-libitum snack in SED trials. On LIIE and HIIE days, lean women increased snack intake by 24.6 and 37.9 %, respectively, but failed to compensate for 32 and 25% of exercise energy deficit. Corresponding increases of snack intake by obese women to LIIE and HIIE was 6 and 15%, and the compensation for EEE failed by 62 and 58%, respectively. Hunger was similarly suppressed during mid-day, but not morning, LIIE and HIIE in lean, but not the obese subjects, while obesity did not affect PP fullness. In LIIE and HIIE trials at mid-day, but not morning, exercise, a rise in FFAs was greater in lean than in the obese. In lean, but not the obese women, exercise suppressed PP insulin responses and led to a 5%, 12-h-sustained decline in plasma leptin.

CONCLUSIONS: EEE at intensities differing by a factor of two, suppresses hunger after the mid-day meal, PP insulin after morning and mid-day meals and leptin over a 12-h period in lean, but not the obese women. Obesity blunts detection, hormonal responses, and dietary compensation to EEE.

Effects Of Steady-state And High-intensity Exercise On Compensatory Eating Behavior

Emily J. Sauers, Jonathan P. Klein, Chad A. Witmer, Gavin L. Moir, Shala E. Davis. *East Stroudsburg University, East Stroudsburg, PA.* (Sponsor: Shala Davis, FACSM)
Email: esauers@esu.edu
(No relationships reported)

Obesity is a worldwide epidemic despite volumes of information while overwhelming evidence exists suggesting exercise and calorie restriction helps manage weight. Studies have shown significant differences in weight loss between high-intensity interval training and moderate continuous training potentially due to compensatory eating behaviors. **PURPOSE:** The aim of this study is to observe the differences in eating behaviors following high intensity intervals (HI) and continuous steady state (SS) running. **METHODS:** Nine lean (BMI=23.90±2.15 kg/m²) exercise trained college-aged (23.56±3.78 years) males (n=3) and females (n=6) participated in this study. Preliminary assessment included informed consent, medical history, body composition, and VO_{2max} (ParvoMedics, Sandy, UT). Subjects were randomized to one of three trials: control, HI, or SS. Subjects arrived fasted to the lab between 6:00-8:00 am. Subjects were given a 20oz sports drink and rested for 30 minutes prior to exercise. During the HI exercise, subjects exercised on a treadmill at 1:1 work:recovery ratio alternating one minute at 90% VO_{2max} and one minute at 50% VO_{2max}. Subjects completed 16 intervals during the SS exercise, subjects ran on a treadmill at 70% VO_{2max} for 33 minutes. Subjects sat quietly for 32 minutes during the control trial. Food logs were collect 24 hours before and after exercise bouts. Data was analyzed using a two-way repeated measures ANOVA (IBM SPSS, Armonk, NY). Significance was set at p=0.05. All data are presented as mean±SE. **RESULTS:** Caloric expenditure was higher during exercise than control (CON: 77.42±3.48kcal, HI: 321.06±24.16kcal, SS: 345.04±24.28kcal, p<0.001) but not different between HI and SS (p=0.49). Caloric intake was not different between trials (CON: 1557.11±172.48kcal, HI: 1849.78±149.80kcal, SS: 1683.11±142.73kcal, p=0.23). Carbohydrate intake was not different between trials (CON: 186.22±25.03g, HI: 224.89±24.28g, SS: 201.44±22.98g, p=0.41). Fat intake was not different between trials (CON: 55.44±8.31g, HI: 72.50±9.05g, SS: 63.44±4.66g, p=0.16). Protein intake was not different between trials (CON: 78.33±28.36g, HI: 69.33±10.18g, SS: 70.00±13.96g, p=0.64). **CONCLUSION:** Subjects diet did not differ in total energy or macronutrient intake after HI and SS exercise.

Aerobic Exercise Training Increases Dietary Restraint and Reduces Hunger and Energy Intake in Overweight/ Obese Adults

Tanya M. Halliday, Kristina T. Legget, Allison K. Hild, Jason R. Tregellas, Edward L. Melanson, FACSM, Marc A. Corrier. *University of Colorado Anschutz Medical Campus, Aurora, CO.*
Email: tanyamhalliday@gmail.com
(No relationships reported)

Exercise is associated with changes in energy intake, but findings are conflicting and mechanisms underpinning responses are unclear.

PURPOSE: To determine how aerobic exercise (AEx) training influences appetite, food-related behaviors, and energy intake.

METHODS: Previously sedentary, overweight/obese (OB/OW) adults (6F, 2M; 33±4 yr; BMI: 30.8±3 kg/m²) completed a 12-week supervised AEx program (5x/wk, energy expenditure ~400 kcal/session). At baseline (PRE) and post-intervention (POST), participants consumed a test breakfast meal (25% of daily energy requirements). Hunger and satiety were evaluated every 30 minutes for 3 hours using visual analog scales. Dietary restraint and disinhibition were assessed via Three-Factor Eating Inventory questionnaire. Subsequently, *ad libitum* energy intake was measured for 3-days under free-living conditions using participant selected meals provided by our metabolic kitchen. PRE-POST differences were assessed using paired sample t-tests. **RESULTS:** Body mass (91.9±19.8 vs. 90.4±20.5 kg, mean±SD) and composition (36±8 vs. 35±6 % fat mass) did not change (p=0.115 and p=0.515, respectively). Fasting hunger was significantly reduced (81±11 vs. 66±20, p=0.048). In response to the test meal, there was a trend for a reduction in hunger area under the curve (AUC) (7228±1459 vs. 6088±2244 pg/mL, p=0.066) but no change in Satiety AUC (7556±2808 vs. 8451±2617, p=0.452). Dietary restraint increased (9.9±2 v. 13.5±5, p=0.045), but disinhibition was unchanged (7.3±3 v. 6.9±3, p=0.476). 3-day *ad libitum* energy intake tended to decrease (2624±1222 vs. 2307±1161 kcal, p=0.089).

CONCLUSIONS: AEx training resulted in reduced *ad libitum* energy intake in OB/OW adults. This was due to decreased hunger cues and increased food-related cognitive restraint. However, because body mass did not change, it is possible that compensatory alterations in free-living energy expenditure and/or habitual energy intake occurred. Larger trials including measures of gut peptides and neuroimaging will be necessary to fully elucidate the bio-behavioral mechanisms responsible for predicting changes in appetite, energy-intake, and body weight regulation in response to AEx training.

Effect Of Employment Status On Physical Activity And Sedentary Behavior Long-term Post-bariatric Surgery

Ryan ER Reid¹, Tamara E. Carver¹, Tyler GR Reid², Katerina Jirasek¹, Kathleen M. Andersen¹, Nicholas V. Christou¹, Ross E. Andersen, FACSM¹. ¹*McGill University, Montreal, QC, Canada.* ²*Stanford University, Stanford, CA.* (Sponsor: Ross E Andersen, FACSM)
Email: ryan.reid@mail.mcgill.ca
(No relationships reported)

Chronic sedentarism and weight re-gain are both serious concerns following bariatric surgery. Pre-surgery, employment rates are lower compared to the normal weight population. Participation in daily activity is affected by multiple factors such as age, sex, high socioeconomic status and white collar occupations, which are also inversely associated with obesity severity. **PURPOSE:** To explore the influence of employment status on the daytime sedentary and physical activity habits of bariatric patients long-term post-surgery. **METHODS:** 59 adults aged 51.19 ± 8.91 years, weighing 95.24 ± 25.0 kg with a BMI of 34.64 ± 10.11 kg/m² having undergone bariatric surgery 9.98 ± 3.09 years earlier participated in this study. Participants were asked to wear an ActivPal™ tri-axial accelerometer attached to their mid-thigh for seven consecutive days, 24 hours/day. All participants wore the device for ≥ 4 days and ≥ 22 hours/day. Self-reported nighttime sleeping facilitated distinguishing this from day sitting time. Patients were collapsed into two groups: employed (N = 21), or unemployed (N = 38). Sedentary time and steps were divided by total day time monitored and expressed as steps/hr and percent of day spent in sedentary behavior. ANCOVA was performed comparing the two groups on their steps/hr and percent sedentary time controlling for age, sex, BMI, and percent weight regained post-surgery. **RESULTS:** Employment status did not influence steps/hr for Week ($F(1, 54) = 2.78, p = .10$) or Weekend ($F(1, 54) = 2.97, p = .091$). Moreover, employment status did not influence percent sedentary time for Week ($F(1, 54) = .36, p = .550$) or Weekend days ($F(1, 54) = 1.29, p = .260$). **CONCLUSION:** Employment status does not appear to affect the percentage of the day spent in sedentary behaviors or physical activity among patients long-term post-bariatric surgery. Future research should focus on tailoring both exercise and lifestyle programs to meet the needs of employed and unemployed patients.

3052 June 2 4:15 PM - 4:30 PM

Diet plus Varying Doses of Physical Activity on Weight Loss: The Heart Health Study

Renee J. Rogers, Meghan R. McGuire, John M. Jakicic, FACSM. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: John M. Jakicic, FACSM)
Email: r.j.rogers@pitt.edu

Reported Relationships: R.J. Rogers: Contracted Research - Including Principle Investigator; Weight Watchers International, Inc..

PURPOSE: This study examined whether adding physical activity recommended for public health (150 min/wk) or weight control (250 min/wk) to a diet enhanced weight loss or selective cardiometabolic risk factors in obesity across 12 months.

METHODS: Participants (N=383; Age=44.7±8.2 years, BMI=32.4±3.8 kg/m²) were randomized to a reduced calorie diet (DIET, N=127), diet plus a moderate dose of physical activity (MOD-EX, N=129), or diet plus a high dose of physical activity (HIGH-EX, N=127). All groups received weekly in-person intervention sessions for months 1-6, with combined in-person and telephonic sessions for months 7-12. Diet was prescribed at 1200-1800 kcal/day. MOD-EX was prescribed physical activity that progressed to 150 min/wk with HIGH-EX progressed to 250 min/wk. Physical activity, weight, waist circumference, and resting blood pressure were assessed at 0 and 12 months.

RESULTS: Retention at 12 months was 86.6% in DIET, 80.6% in MOD-EX, and 83.5% in HIGH-EX. Physical activity at 0 and 12 months was 65.4±73.8 and 88.2±104.3 min/wk in DIET; 68.7±93.8 and 179.1±125.3 min/wk in MOD-EX; and 71.5±84.4 and 228.8±148.3 min/wk in HIGH-EX (Group X Time p<0.001). Weight decreased at 12 months (DIET: -9.9±8.3 kg, MOD-EX: -10.8±8.2 kg, HIGH-EX: -9.5±7.3 kg) (p<0.001), with no difference between groups. There were also significant and similar changes across groups in waist circumference at 12 months (DIET: -8.8±8.1 cm, MOD-EX: -10.4±8.8 cm, HIGH-EX: -9.3±7.4 cm) (p<0.001). Resting systolic and diastolic blood pressure decreased significantly (p<0.001) by 4.3±10.1 mmHg and 2.6±6.6 mmHg, respectively; however, there was no difference between groups.

CONCLUSIONS: MOD-EX and HIGH-EX engaged in physical activity that was consistent with the prescribed doses of physical activity; however, this did not improve weight loss, waist circumference or resting blood pressure compared to DIET at 12 months. It is likely that compensation in energy balance occurred in response to physical activity that limited additional weight loss or changes in selective cardiometabolic risk factors. Additional research is warranted to understand the physiological and behavior compensation that may occur in response to these interventions in adults with obesity.

Metabolic Flexibility Among Women In Response To A Single High Fat Meal.

Alyssa Olenick, Regis Pearson, Nuha Shaker, Rachel Tinius, Maire Blankenship, Evie Oregon, Don Hoover, Jill Maples. *Western Kentucky University, Bowling Green, KY.* (Sponsor: Dr. James Green, FACSM)

(No relationships reported)

Metabolic flexibility is the ability to adjust substrate oxidation according to nutrient availability. For example, one that fails to increase fat metabolism in response to a high fat meal would be characterized as metabolically inflexible. This metabolic inflexibility may lead to weight gain and the development of metabolic disease. Previous studies have shown that obese women are metabolically inflexible in response to short-term high fat diets compared to lean women. However, the acute response to a single high fat meal has not been described. **PURPOSE:** To determine if obese women are metabolically inflexible in response to a single high-fat meal, compared to lean. **METHODS:** Baseline (T1), fasting glucose, resting energy expenditure (REE), lipid and carbohydrate oxidation (estimated using indirect calorimetry), were assessed for lean (n= 4; Age=26.5±4.43 yrs; BMI=23.6±1.7) and obese (n= 2; Age=35.5±2.1 yrs; BMI=34.7±7.6) Caucasian women. Participants then consumed a high fat shake (975 kcal, 62% fat). Additional REE, lipid and carbohydrate oxidation measurements were taken at 120 (T2) and 240 (T3) minutes post shake. **RESULTS:** There were no significant differences in age between groups. T1 REE was significantly higher (p<0.05) among obese (1930.2±179.3 kcal) women compared to lean (1607.7±120.0 kcal) women. There was a significant time effect on lipid and carbohydrate oxidation (p<0.05) and a significant BMI effect (p<0.05) on lipid oxidation. Lipid oxidation increased among both groups, but was significantly higher among obese (T1=0.12±0.01, T2=0.14±0.01, T3=0.13±0.01) women compared to lean (T1=0.08±0.01, T2=0.11±0.01, T3=0.10±0.01) at all three time points. Although not significant, there was a trend for the lean women to increase lipid oxidation to a greater extent from T1 to T2 (lean 38.3±13.8% increase vs. obese 16.7±0.0% increase; p=0.11). **CONCLUSIONS:** Current preliminary data suggest that lipid oxidation is higher among obese women compared to lean after consuming a single high fat meal. The obese women appear to respond similarly in terms of metabolic flexibility, compared to lean women. A single high fat meal may not be enough of a stimulus to elicit the metabolic inflexibility previously reported among obese women in response to a high fat diet. Supported for by WKU Graduate School Research Grant

F-37 Clinical Case Slide - Pulmonary

Friday, June 2, 2017, 3:15 PM - 5:15 PM

Room: 507

Episodes Of Near-syncope In A Runner

Darrika D. Van¹, Thomas G. Allison², Michael S. Emery³.
¹Indiana University Health, Indianapolis, IN. ²Mayo Clinic, Rochester, MN. ³Indiana University School of Medicine, Indianapolis, IN.

Email: dvan@iuhealth.org

(No relationships reported)

History: A 14-year-old female cross-country & track athlete presents with complaints of near syncope towards the end of exercise. Her symptoms do not occur during training only during competitive events in particular when attempting to catch an opponent near the end of a race. She is also a swimmer and has never experienced symptoms with competitive swimming. These episodes have been accompanied by lightheadedness and dizziness and she would "stumble" across the finish line. They have not resulted in bodily injury and she recovers quickly. She has no other past medical history or medications. The family history is noncontributory.

Physical Examination:

Height 5'3". Weight 98 pounds. BMI 17.4

Blood Pressure 101/56; heart rate 97 bpm

Well-developed young female who appears mildly anxious

Normal lung auscultation

Cardiovascular exam with regular rate and rhythm; no murmurs/gallops/rubs

Differential Diagnosis:

1. Primary cardiac arrhythmia
2. Cardiovascular structural abnormality
3. Vasovagal response
4. Postural orthostatic tachycardia syndrome
5. Anxiety

Tests and Results:

ECG: Normal ECG with sinus rhythm at 83bpm.

Echocardiogram: All chambers normal size and function with no valvular abnormalities.

Baseline Spirometry: Normal

Cardiopulmonary Stress Test with reproduction of symptoms on the treadmill:

Peak VO₂ 45.3 mL/Kg/min (100% predicted)

Peak O₂ pulse 9 mL/beat (97% predicted)

Max HR 212 bpm (103% predicted)

Stress ECG: sinus rhythm throughout without ischemic changes

Immediate recovery BP 124/60 (peak BP not obtained due to symptoms)

Peak respiratory rate 77 (53 at AT)

Tidal volume at peak 899 mL/breath (resting 612 mL/breath; AT 821 mL/breath)

Breathing reserve at peak 32%

VE/VCO₂ at AT 26

Vt/FVC at peak 29% (27% at AT)

Final Working Diagnosis: Dysfunctional breathing with patterned disorder breathing

Treatment/Outcomes:

1. Reassurance of no primary cardiovascular abnormality
2. Lifestyle modification including liberalizing salt and fluid intake
3. Encouragement to work on breathing mechanics with her coaches and/or referral to speech pathology

3059 June 2 3:35 PM - 3:55 PM

Chronic Dyspnea - RunningJack Nickless, Anthony Romeo. *Midwest Orthopaedics at Rush, Chicago, IL.**(No relationships reported)*

HISTORY: 63 year-old male presented to clinic with complaint of continued severe shortness of breath status-post left total shoulder arthroplasty. Surgery was performed under general anesthesia with interscalene nerve block for regional anesthesia. Previously, patient had been running 3 miles per day and golfing regularly without issues. Immediately after the surgery, he began to notice a significant decrease in his functional status due to SOB. He now has difficulty walking up one flight of stairs, cutting the grass, or golfing more than 9 holes because of the SOB he experiences with activity. Denies fevers, chills, cough, hemoptysis, chest pain, palpitations, and calf pain. He is otherwise very happy with the improvements in pain, ROM, and overall functionality of his left shoulder s/p left TSA.

PHYSICAL EXAMINATION: VS: BP 132/76, P 66, Temp 36.7 C, Resp 18, SpO2 96%; Gen: Awake, alert, cooperative, NAD; Lungs: No increased work of breathing, good air exchange, CTAB, No rales or wheezing; CV: RRR, +S1S2, no S3 or S4, no murmurs noted; Neuro: AOX3, sensation to light touch intact throughout LUE, no focal deficits; Skin: Surgical incisions clean, dry, and intact

DIFFERENTIAL DIAGNOSIS: 1. Atelectasis 2. Pulmonary Embolism 3. Underlying pulmonary condition (COPD vs. pulmonary fibrosis vs. lung carcinoma) 4. Congestive heart failure 5. Diaphragmatic paralysis from phrenic nerve injury

TEST AND RESULTS: CTA Chest: significant pleural effusion, negative for PE; CXR: elevated left hemi-diaphragm

FINAL WORKING DIAGNOSIS: Left diaphragmatic paralysis secondary to phrenic nerve injury associated with interscalene block

TREATMENT AND OUTCOMES:

1. Patient initially on Aspirin and encouraged to ambulate for DVT prophylaxis 2. Provided with an incentive spirometer to prevent post-op atelectasis 3. Extensive outpatient Cardiology and Pulmonology evaluations without findings of underlying medical condition to explain symptoms 4. Suspected phrenic nerve injury associated with pre-operative interscalene block 5. Pulmonary rehabilitation performed with minimal improvement symptoms 6. We have discussed the possibility of further pulmonary rehabilitation vs. neurosurgical consultation for possibility of phrenic nerve decompression with possible nerve graft

3060 June 2 3:55 PM - 4:15 PM

Thirteen-year-old Female Football Player With Shortness Of BreathMark R. Johnson. *SIU SOM, Springfield, IL.**(No relationships reported)***HISTORY:**

Patient is a 13 yo otherwise healthy female who complains of Shortness of Breath (SOB) and chest discomfort. Patient is a football player (tackle) in a community football program. SOB is described as a chest tightness in the mid chest starting 10 minutes into running. She denies throat tightens and reports expiratory wheezing. She has an associated cough. Rest and relaxation relieve symptoms. Albuterol helps with symptoms. Patient has had trauma to her chest while playing football.

PMH: Had tonsillectomy adenoidectomy otherwise noncontributory

FMH/Social: No significant

PHYSICAL EXAMINATION:

Vitals Wt 89kg(99%), Ht 157cm(40%), BMI 36(99%)

117/73, 78, 16, 99%

General: Stocky well developed female with significant muscular development

HEENT: Unremarkable

Chest: Tender to palpation costosternal articulations, no bruising, no pectus

Lungs: Clear to auscultation, symmetric, no retractions

Heart: RRR no murmur, normal pulses, normal capillary refill

Abdomen: Soft NT ND no mass, no HSM

Neuro: Non-focal

DIFFERENTIAL DIAGNOSIS:

EIB, Extra-thoracic Airflow Obstruction, relative deconditioning, obesity-associated dyspnea, Pulmonary Hypertension, Chest Wall Injury, Costochondritis/Tietze

TEST AND RESULTS:

CXR/Bilateral Ribs: Unremarkable

RAST Environmental Panel: No significant reactions

CPET: VO2 3492(135%), VO2/kg 39.7, VeVO2 22AT 32Max, ETCO2 40/36, Flow Limitation at significant levels starting halfway through testing and approached nearly all the expiratory phase. In last 30 seconds developed stridor, strap muscle use that responded to coaching for on abdominal breathing and concentration on exhalation.

FINAL WORKING DIAGNOSIS:

Physiologic flow limitation resulting in extra-thoracic airflow obstruction

TREATMENT AND OUTCOMES:

1. Weight reduction with goal of BMI 30-32 (approximately 10-15kg)
2. If symptoms persist after weight reduction will consider speech therapy referral
3. Full activity as tolerated without limitation

3061 June 2 4:15 PM - 4:35 PM

Right Upper Quadrant Pain In a Soccer PlayerJason T. Losee. *Evergreen Sports Medicine Fellowship, Augusta, ME.* (Sponsor: James Dunlap M.D., FACSM)

Email: thomaslosee@msn.com

(No relationships reported)

Abdominal injuries are rare in sports. However, unrecognized, they can be serious and even life threatening. A 16-year-old F. soccer player presented with worsening RUQ abdominal pain after being struck in the abdomen by a soccer ball. Two days prior she had been kicked by a goalie in the abdomen, although she did not experience much pain with that incident. In the ED the patient denied chest pain or pressure, cough, congestion, shortness of breath, vomiting, diarrhea, constipation, black or bloody stools. PMH: allergic rhinitis. PSH: none. Allergies: NKDA. Meds: Flonase. **PHYSICAL EXAMINATION:** Temp 98.4 deg, HR 85, BP 116/60, SaO₂ 100% on room air. Well-developed and well-nourished. Alert and oriented to person, place and time. Head normocephalic and atraumatic. Pupils equal, round, reactive to light and accommodation. Sclera anicteric. No conjunctiva injection. Extraocular movements intact. Trachea midline. Lungs clear to auscultation with normal breath sounds bilaterally. Abdomen soft with tenderness in the RUQ and voluntary guarding. No rigidity, rebound, abrasions, Grey-Turner sign, or Cullen's sign. No masses or hepatosplenomegaly. No CVA tenderness. No focal or neurological deficits.

DIFFERENTIAL DIAGNOSIS:

1. Rib contusion/fracture
2. Liver contusion/laceration
3. Bowel perforation
4. Traumatic pancreatitis
5. Pancreatic laceration/pseudocyst
6. Retroperitoneal hematoma
7. Rectus sheath hematoma
8. Pulmonary contusion
9. Splenic contusion/laceration.
10. Kidney hematoma/laceration

TESTS AND RESULTS:

WBC count of 14.6, Hgb and hematocrit of 13.7 and 41. Urine preg. negative, BUN and Cr 21 and 1.03, alk phos 109, ALT 304, AST 346, Total Bilirubin 0.6, Lipase 76, CRP <0.29, lactic acid 0.9, monospot neg, UA positive for trace ketones.

CT abdomen and pelvis with contrast:

- Three hepatic contusions without laceration or hemoperitoneum

FINAL/WORKING DIAGNOSIS:

Liver contusions

TREATMENT AND OUTCOMES:

1. Liver enzymes and WBCs trended to normal.
2. Cleared for light stationary biking at one month.
3. Patient has not been cleared for full sport participation. She will avoid contact sports participation for three months from the time of injury. May consider a repeat CT scan at that time to verify resolution of the contusions.

3062 June 2 4:35 PM - 4:55 PM

Splenic Injury - FootballJennifer Kim. *Kaiser Fontana, Fontana, CA.* (Sponsor: Robert Sallis, FACSM)

Email: jennyskimmd@gmail.com

(No relationships reported)

HISTORY: A 21-year-old football wide receiver sustained a hit to his left ribs by an opposing player's helmet during the last quarter of a mid-season game. After being tackled, the athlete was able to get up and walk off the field.

EXAMINATION: Athlete was assessed on the sidelines shortly after injury and found to have localized tenderness along the lower left ribs. He reported mild nausea but no dizziness or shortness of breath. Pain was made worse by twisting movements of the torso and deep inspiration. He was given a bag of ice to place on his ribs. At the end of the game his exam and symptoms had not changed. A few hours later he noticed the pain was worse with supine position. Pain did not improve with Tylenol. Late in the evening, the intensity of pain did not subside and began to radiate to his left shoulder.

DIFFERENTIAL DIAGNOSIS:

1. Rib contusion
2. Lower rib fracture(s)
3. Splenic injury

TEST AND RESULTS:

On the advice of his trainer, the athlete went to ED that night. X-rays of the ribs were negative for fracture. No further studies were done. He was diagnosed with rib contusion and discharged home with pain medication. The following morning, his pain had worsened and he developed emesis with attempts to eat. Again on the advice of his trainer he returned to Urgent Care. The examining physician noted abdominal bloating and left upper quadrant tenderness. He was then sent to the ED where a CBC drawn was notable for anemia. Ultrasound and CT abdomen confirmed diagnosis of splenic laceration.

FINAL/WORKING DIAGNOSIS:

Splenic laceration, grade IV

TREATMENT AND OUTCOMES:

1. After reviewing the CT scan, it was determined that immediate surgical intervention was not needed
2. Athlete was admitted to ICU where serial Hb/Hct was monitored for the next 48 hours. Hct stabilized and athlete remained hemodynamically stable
3. Athlete was discharged from hospital with restrictions on return to play until 3 months post injury. He is feeling well but unable to return to football before the end of this season.

3063 June 2 4:55 PM - 5:15 PM

Blunt Abdominal Trauma at Pre-season Scrimmage

Brian J. Schutzbach¹, Mark Lavallee, FACSM². ¹Greenville Health System, Greenville, SC. ²Wellspan Health, York, PA. (Sponsor: Mark Lavallee M.D., FACSM)
Email: brian.j.schutzbach@gmail.com

(No relationships reported)

History: 17 year old male wide receiver came to the sideline with severe 7/10 sharp, stabbing, mid abdominal pain at a high school scrimmage after he had caught a pass and was tackled. He was unaware if a body part or a helmet struck him in the abdomen. Another teammate came over and said he was sandwiched by two players. He denied any radiation of his pain. He noted associated difficulty breathing and numbness in his fingers bilaterally. He also pitches for baseball team with aspirations of playing college baseball. **Physical Examination:** Sideline examination of abdomen showed a soft, non-distended, thin abdomen with normal bowel sounds and maximal tenderness in the left upper quadrant. He also displayed guarding. Patient was mentating well but was tachypneic with normal lung sounds. His skin was cool in the distal extremities. After 5 mins of rehydration and monitoring, he was evaluated again with similar findings of 7/10 abdominal pain. The abdominal exam was repeated and no significant improvements were noted. The decision was made him to transfer him to the local emergency department by EMS for imaging of his abdomen and closer monitoring. **Differential Diagnosis:** 1. Diaphragmatic Spasm 2. Rectus Sheath Hematoma 3. Splenic Laceration 4. Rib Fracture 5. Kidney Laceration 6. Liver Contusion 7. Anxiety with Tachypnea causing Hypocarbica **Tests and Results:** CT Abdomen and Pelvis with IV Contrast shows an extensive irregular mid splenic fracture at the level of the hilum measuring from 3.5 to 5.5 cm. There is hypodense intraperitoneal fluid extending across the upper abdomen and down both flanks into the cul-de-sac. Left renal upper pole laceration with contained intracapsular hematoma. **Final/Working Diagnosis:** Grade IV Splenic Laceration **Treatment and Outcomes:** 1. Transferred to Level 1 trauma center for embolization of splenic artery 2. Monitored vitals, hemoglobins and pain control s/p embolization 3. Surgical team performed splenectomy due to persistent sever pain and presence of hemoperitonenum despite stable hemoglobins. 4. Discharged home without complications and did not return to play football again. 5. Patient was able to return to throwing activities for baseball at 8 weeks after initial injury.

Weakness In Shoulder After A Football Collision

Timothy Gill, Kevin Duprey. *Crozer-Keystone Health System, Springfield, PA.* (Sponsor: Thomas Kaminski, FACSM)
(No relationships reported)

HISTORY: 16 year old male football player presented to the office with left shoulder weakness 5 days after he was clipped and landed on his left shoulder. At time of injury, he experienced a dull 6/10 ache in the lateral shoulder, but was able to continue playing for the last few minutes of the game. The following morning, he developed difficulty moving his arm, including reaching across his body and tying his shoes. His shoulder pain was gradually improved at the time of the visit, but weakness persisted.

PHYSICAL EXAMINATION: He has full painless active cervical ROM, Spurling's Negative. Left shoulder exam reveals a diminished painless ROM with forward flexion to 20 degrees and abduction to 20 degrees. He has external rotation to 70 degrees and internal rotation to T10 bilaterally. He has 4/5 strength with internal rotation, 5/5 with external rotation, 3/5 with abduction and forward flexion. He has mild tenderness to palpation over the anterior shoulder. He has no tenderness over the SC, AC, or the supraspinatus. He has a negative scarf test and resisted adduction. He has a drop arm with lowering from abduction.

DIFFERENTIAL DIAGNOSIS: Supraspinatus tear; Labral Tear; Axillary nerve palsy, shoulder dislocation, Cervical radiculopathy, Cervical disc herniation, Humerus fracture.

TEST AND RESULTS: X-ray of the shoulder revealed no evidence of fracture, dislocation or other abnormality. MRI of the shoulder revealed marrow contusion of the greater tuberosity, mild subchondral subdeltoid bursitis and no rotator cuff or labral tear appreciated.

FINAL WORKING DIAGNOSIS: Transient axillary nerve palsy with osseous contusion of humerus.

TREATMENT AND OUTCOMES: Over the following two weeks, he regained full strength and motion. Axillary nerve palsy, commonly associated with shoulder dislocations, is rare following a simple fall to the ground.

3068 June 2 3:35 PM - 3:55 PM

A New Frontier for the Medial Clavicle

Sam Hwu¹, Garry W.K. Ho, FACSM¹, Keith W. Lawhorn². ¹*Sports Medicine Fellowship Program, Virginia Commonwealth University - Fairfax Family Practice, Fairfax, VA.* ²*OrthoVirginia, Fairfax, VA.*
Email: sam.hwu@gmail.com
(No relationships reported)

History: A 63 year-old male presented with a 2-week history of left upper extremity pain after being hit by a car on his left side while riding his bicycle. He sustained fractured ribs, an extraarticular fracture-dislocation of the left medial clavicle, a minimally displaced oblique fractured left scapular body, and a displaced, comminuted fractured left distal radius for which he underwent ORIF. While hospitalized, he was informed there were no surgical options to treat his left clavicle fracture-dislocation. **Physical Examination:** Examination revealed a male with his left arm in a sling. He had a prominent anterior sternoclavicular joint and deformity of his medial clavicle. His range of motion was limited due to pain and guarding. He had 2+ radial pulses, intact sensation to light touch, and no obvious motor dysfunction of his upper extremities.

Differential Diagnosis: 1. Anterior sternoclavicular joint dislocation 2. Medial clavicular fracture-dislocation

Tests and Results: Left shoulder CT scan: 1. Comminuted, anteriorly angulated fracture of the medial aspect of the left clavicle with severe shortening and subluxation of sternoclavicular joint. 2. Minimally displaced oblique fracture through scapular body. Multiple anterior and posterior ribs. No pneumothorax.

Final Diagnosis: 1. Medial clavicular fracture with significant shortening and fracture-dislocation of sternoclavicular joint. 2. Minimally displaced scapular body fracture. 3. Anterior and posterior rib fractures.

Treatment and Outcomes: He underwent an ORIF of his medial clavicle fracture-dislocation using a 7-hole 15-mm hook plate. The plate was placed under the inferior border of the medial head of the clavicle and superior to the first rib to push the lateral clavicle fragment posteriorly to reduce the fracture. Screws were placed in the hook plate to stabilize the fracture and maintain the clavicle out to length as much as possible. The arm was ranged with mild motion of the hook plate under the sternum and the fracture stable. His scapular and rib fractures were treated nonoperatively. A hook plate is designed for fixation of a lateral clavicle fracture, but its use in medial clavicle fractures has not been well established. We offer this case as an example of a successful outcome using this novel operative approach.

3069 June 2 3:55 PM - 4:15 PM

Shoulder Injury - Ground Level Fall

Kevin M. Mullins, Brian A. Davis, FACSM. *University of California, Davis, Sacramento, CA.*
Email: kevmullins@ucdavis.edu

*(No relationships reported)***HISTORY:**

A 60-year-old woman sustained a right shoulder injury after falling from a chair onto an outstretched arm 2 years ago. She immediately had severe right lateral shoulder pain, worse with abduction. Outside facility workup included normal x-rays, C Spine MRI with a small annular posterior disc bulge at C6-7, Shoulder MRI with mild increased T2 signals at insertional sites of supraspinatus and long head biceps tendons. NCS of median/ulnar nerves were normal and needle EMG of deltoid, infraspinatus, serratus anterior and rhomboid major also normal. She was treated with a subacromial corticosteroid injection and therapy with minimal improvement, and is now presenting with unresolved chronic symptoms impacting her ADLs.

PHYSICAL EXAMINATION:

On inspection decreased muscle bulk in right trapezius on shoulder shrug and scapular retraction. No tenderness to palpation. Passive range of motion full in all planes, and notable for right scapular hike with abduction greater than 60 degrees and loss of adduction control of scapula, as it rides into anterior/superior supraclavicular region. Active shoulder abduction limited to 54 degrees when standing due to weakness, but able to obtain full 170 degrees when supine. Strength of right trapezius is 4/5, remaining muscles 5/5 with scapula stabilized. Sensation intact to light touch and shoulder impingement maneuvers are negative.

TEST AND RESULTS:

Our repeat NCS done personally was significant for an abnormal right spinal accessory nerve CMAP to the trapezius with significantly decreased amplitude and onset latency comparable to the left side. Needle EMG was evident for normal right deltoid, infraspinatus, serratus anterior, rhomboid major but markedly abnormal right upper and middle trapezius findings with increased insertional activity, fibrillation potentials, positive sharp waves, polyphasic MUAPs and reduced recruitment.

FINAL WORKING DIAGNOSIS:

Right incomplete spinal accessory neuropathy - mostly affecting upper fibers.

TREATMENT AND OUTCOMES:

1. Collaboration with sports medicine orthotist for molding of a customized scapular stabilizer/restraining brace.
2. Physical Therapy Rx for shoulder girdle complex strengthening and range of motion exercises.
3. Patient with significant improvement in pain, range of motion, and general function with brace.

3070 June 2 4:15 PM - 4:35 PM

Shoulder Pain in a Professional Contemporary Ballet Dancer

Brennan Boettcher, Jonathan Finnoff, FACSM. *Mayo Clinic, Rochester, MN.* (Sponsor: Jonathan Finnoff, FACSM)
Email: boettcher.brennan@mayo.edu

*(No relationships reported)***History:**

A 22 year-old male professional ballet dancer presented with a 1 year history of non-radiating, posterior right shoulder pain. The pain severity was between a 0-8/10, and was aggravated when lifting other dancers. He denied any instability, clicking or catching, weakness, or numbness or tingling.

One year ago, while dancing, he fell on his right shoulder/neck. By report, a c-spine MRI revealed a cervical disc herniation (unknown level). He was treated successfully with physical therapy, but his pain gradually recurred.

Physical Examination:

Fit appearing 22 year-old male in no distress.

At rest, the right shoulder was elevated and protracted. There was subtle scapular dyskinesia with a delay in right scapular movement and prominent right medial scapular border.

He was tender over the supraspinatus and infraspinatus muscles.

Cervical and shoulder motion were full and symmetric.

Special tests revealed a (-) Spurling's, and mild peri-scapular pain with position one of O'Brien's, empty can and Hawkin's impingement tests.

Neurovascular exam was normal.

Differential Diagnosis:

Rotator cuff tendinopathy/tear

Labral tear

Scapular dyskinesia

Peri-scapular myofascial pain

Subacromial bursitis

Cervical radiculopathy

Glenohumeral instability

Tests and results:

Complete diagnostic shoulder ultrasound revealed supraspinatus, infraspinatus, and teres minor hyperechogenicity and loss of the normal muscular architecture with atrophy,

consistent with fibrofatty infiltration from his prior C5 or C6 radiculopathy.

Subacromial bursa was hypertrophic, consistent with subacromial bursopathy.

Final/Working diagnosis:

Scapular dyskinesia, likely secondary to right C5 or C6 chronic radiculopathy with denervation changes to the supraspinatus, infraspinatus, and teres minor.

Subacromial bursopathy

Treatment and Outcome:

The patient was given a rehabilitation program for scapular stabilizers, rotator cuff, postural positioning, stretching anterior shoulders, and trial of Kinesio tape.

The patient returned to ballet, was advised to use caution with lifts.

He was given the option of returning in 4-8 weeks for an ultrasound guided subacromial corticosteroid injection if there was no improvement with rehabilitation.

Return to Kipping After Shoulder Injury: Introducing a Novel Unloading Rehabilitation Technique

Kevin Messey¹, Sarah Mahasin², David Bazzo¹, Kenneth Vitale¹.

¹University of California San Diego, San Diego, CA. ²King Saud University, Riyadh, Saudi Arabia.

(No relationships reported)

HISTORY: 42-yo F CrossFitter with insidious L shoulder pain x 3 mth, worse on ER localizing to posterior shoulder. Notably worse on kipping, at bottom & top of kip. Mild pain after workout, night pain if sleeps on left. No h/o dislocation. No paresthesias or weakness. No recent trauma but frequently loads shoulder with ballistic exercises & Olympic lifts. Trains for CrossFit 1.5hr x 6 d/wk. Tried PT 6 visits, still could not kip, snatch, pull-up. Currently training for competition in 1 month.

PHYSICAL EXAM:

Forward head posture, L trunk rotation, L shoulder elevation, L scapula anterior tilt. Tender periscapular muscles & bicipital groove. ROM Ext: 0, Flex: 180, ER @ 90: 90, IR @ 90: 60; increased pain with ABD + ER. Rotator cuff strength intact. No instability. Positive Speed's, Hawkins. Positive Crank, O'Brien's. AC joint testing negative. Cervical spine exam normal other than C7 abrasion from barbell loading.

Normal neurovascular exam. **DIFFERENTIAL DIAGNOSIS:** 1. Rotator cuff tear 2. Labral tear 3. Bicipital tenosynovitis 4. Post-traumatic loose body, osteoarthritis 5. Adhesive capsulitis

TEST & RESULTS: X-ray: mineralization at medial surgical neck, possible IGHL injury. MR arthrogram: anterosuperior labral tear from 12 to 3 o'clock; extensive chondral delamination anterior glenoid, focal high-grade chondral loss central glenoid; intra-articular bodies in posterior recess; supraspinatus/infraspinatus tendinosis. **FINAL/WORKING DIAGNOSIS:** 1. Type 1 SLAP tear 2. Supraspinatus/infraspinatus tendinosis 3. Glenoid osteoarthritis 4. Intra-articular bodies 5. Radiological evidence of remote IGHL avulsion

TREATMENT & OUTCOMES: 1. Rest, activity modification, naproxen prn. 2. PT, ART, cupping; still unable to kip or snatch. 3. Athletic Training Services for biomechanical analysis, rehabilitation & injury prevention strategies. Treatments included PNF throwers program, pec minor release, swing stretch, plank T rotation, plank board slide. 4. Re-introduction of kips utilizing Keiser device and harness unloading at 114lbs resulted in pain-free kipping with preserved technique. Progressions included further unloading at reduced assistances of 110, 100, 90, 80, 70, 50 lbs in a 6x6 set. At ≤70 lbs. could reproduce typical rhythm of kipping. 5. Returned to sport at 1 mth and able to compete in CrossFit competition.

3072 June 2 4:55 PM - 5:15 PM

An Atypical Cause of Shoulder Pain in a Male Ballet Dancer

Mark Bender, David Leffers, Sean Spence. *University of South Florida, Tampa, FL.*

Email: markbender@health.usf.edu

(No relationships reported)

HISTORY: A 17 year old male, with a history of Type 1 Diabetes presented to our clinic with a complaint of left shoulder pain after an injury that he sustained while participating in ballet practice. He reports that his partner lost her balance during a lift which caused him to overcompensate and shift positions quickly. During this maneuver he felt a sudden, sharp pain in his left shoulder and discontinued practicing. Following this incident he was unable to elevate his arm although he did not complain of any numbness or paresthesia's.

PHYSICAL EXAMINATION: Upon exam, there was no evidence of swelling or ecchymosis around the neck/anterior deltoid and he was neurovascularly intact. He had increased pain with deep inspiration but no shortness of breath or additional respiratory abnormalities. Forward flexion and abduction of the arm were limited to approximately 45° due to pain. Passive range of motion was diminished to 90° with inability to reach end range due to pain. There was no pain to palpation along the clavicle or AC joint; however palpation of the first rib at the base of the neck elicited significant pain.

DIFFERENTIAL DIAGNOSIS:

First rib stress fracture
Rotator cuff tear
Cervical sprain

TEST AND RESULTS: A left sided rib series was performed which demonstrated an incomplete fracture of the first rib. No significant displacement was seen although slight elevation of the distal clavicle was noted which appeared to be chronic.

FINAL WORKING DIAGNOSIS: Stress fracture of the first rib

TREATMENT AND OUTCOMES:

Refrain from participating in ballet practice for 4-6 weeks with gradual return to dance
Arm immobilization with a sling
Vitamin D/Calcium supplementation
Repeat isolated rib radiographs at 2 and 6 weeks
Patient was re-evaluated at 2 and 6 weeks post-injury. At 2 weeks the patient was instructed to participate in graded physical therapy but due to insurance issues he was unable to start until 6 weeks post-injury.
At 6 weeks, he displayed full shoulder elevation and abduction and there was no significant pain to palpation over the first rib. He endorsed some mild discomfort over the trapezius and scalene muscles and his shoulder strength was graded 4/5.
Repeat plain films demonstrated proper rib alignment and some early bridging callus formation. He was instructed to follow-up in 1 month and to begin physical therapy

Anxiety Level Moderates the Acute Impact of Light and Moderate Intensity Aerobic Exercise on Working Memory

Olga G. Berwid¹, Sarah C. O'Neill², Nacima Chen², ¹York College, City University of New York, Jamaica, NY. ²The City College of New York, New York, NY.

Email: olga.g.berwid@gmail.com

(No relationships reported)

PURPOSE: Accruing evidence suggests that there is an improvement in working memory immediately after a single bout of moderate-intensity aerobic exercise with smaller and more variable effect sizes in healthy young adults than in other groups (Ludyga et al., 2016). Individual differences in the impact of exercise on cognition mediated by a variety of different factors may account for some of this variability. The aim of the current study was to determine whether the impact of both light- and moderate-intensity aerobic exercise on verbal and nonverbal working memory differs in individuals who report higher versus lower levels of trait anxiety.

METHODS: 125 young adults were administered Operation Span (O-SPAN) and Symmetry Span (S-SPAN) tasks twice; once after spending approximately 40 minutes completing questionnaires including the State-Trait Anxiety Inventory (STAI-T); and once after 40 minutes of either moderate-intensity (>60% of age-predicted maximum HR) or light-intensity (<55% of age-predicted maximum HR) aerobic exercise. Session order was counterbalanced across participants and participants were randomly assigned to exercise intensity. A median split on the STAI-T was used to separate participants into lower and higher anxiety groups. The impact of exercise and anxiety on WM was examined in 2 (Intensity) x 2 (Anxiety Level) x 2 (Session) mixed-factorial analyses of variance.

RESULTS: For S-SPAN performance, there was a significant Anxiety x Session interaction ($F = 4.04$; $p = .047$; partial eta-squared = .032) indicating that those reporting higher levels of trait anxiety may benefit slightly more from exercise than those with lower levels of anxiety. For O-SPAN performance, there was a significant 3-way Intensity x Anxiety Level x Session interaction ($F = 6.27$; $p = .014$; partial eta-squared = .05) revealing differing patterns of moderate- and low-intensity exercise for the higher and lower anxiety groups. There were no other significant effects.

CONCLUSIONS: The data suggest that light- and moderate-intensity aerobic exercise may exert different impacts on working memory in individuals reporting lower versus higher levels of trait anxiety; however, effect sizes are small.

Physical Fitness, Physiological and Sleep Responses to Stress in Women

Abigail J. Leonard, Meir Magal, FACSM, Daniel Henderson, Christina Huber, Lyndsay Wolfe, Andrea Tobar, Shannon K. Crowley. North Carolina Wesleyan College, Rocky Mount, NC.
Email: al206393@my.ncwc.edu

(No relationships reported)

PURPOSE: Stress-related psychiatric disorders (such as depression) are twice as common in women as in men and have been linked to aberrations in physiological and psychological stress responding. Being physically fit may be protective against the development of adverse symptoms related to stress, however, to date, there has been limited investigation of the relationship between physical fitness and behavioral and physiological responses to stress which considers the profound influence of the ovarian cycle on physiological and behavioral stress responding. This study aims to investigate the relationship between physical fitness and physiological and behavioral (sleep disturbances) responses to stress in women during the follicular phase of the menstrual cycle (when ovarian hormones are low and stable). **METHODS:** Following a two-tiered screening process, 10 healthy women (18-45y) who were medication-free and had regular menstrual cycles were enrolled. Participants completed: (1) enrollment visit, (including mood and sleep assessment and assessment of cardiorespiratory fitness via maximal oxygen consumption during exercise); (2) one-week sleep monitoring period (objective and subjective measures of sleep-wake behavior); and (3) psychosocial stressor protocol for the collection of hemodynamic [blood pressure (SBP, DBP) and heart rate (HR)] and hormonal stress responses. Psychosocial stress testing sessions occurred during the follicular phase of the menstrual cycle to control for hormone fluctuations which can influence the physiological response to stress.

RESULTS: Though not significant at this time, preliminary results from this ongoing study show that higher levels of physical fitness may be associated with lower sleep reactivity to stress ($r = -.43$, $p = 0.17$) and reduced wake after sleep onset (WASO; $r = -.58$, $p = .07$). Consequently, increased WASO was significantly associated with increased SBP and DBP reactivity to an acute psychosocial stressor (r 's = .78, .65; p 's = .01, .05 respectively). **CONCLUSIONS:** If confirmed in our larger sample results suggest that, in women, physical fitness may be protective against the physiological response to stress, perhaps via reduction in stress-related sleep disturbances.

3098 Board #3 June 2 2:00 PM - 3:30 PM

Physical Fitness, Hemodynamic and Affective Responses to Psychosocial Stress in Women

Christina Huber, Meir Magal, FACSM, Daniel Henderson, Abigail Leonard, Lyndsay Wolfe, Andrea Tobar, Shannon K. Crowley. North Carolina Wesleyan College, Rocky Mount, NC.
Email: ch215189@my.ncwc.edu

(No relationships reported)

PURPOSE: Studies suggest that adaptations resulting from regular physical exercise training might positively impact physiological adaptations to psychological stressors. A reduced physiologic sensitivity to psychosocial stressors may be one mechanism by which physical fitness may serve to buffer the deleterious effects of chronic stress. However, to date, there has been limited study of the relationship between physical fitness and physiological and affective stress responding in women which considers the profound influence of the ovarian cycle on physiological and affective responses to stress. This study aims to investigate the relationship between physical fitness and physiological and affective responses to stress in women, while considering ovarian cycle phase effects on the stress response. **METHODS:** Following a two-tiered screening process, 10 healthy women (18-45y) who were medication-free and had regular menstrual cycles were enrolled. Participants completed an enrollment visit, (including perceived stress assessment and assessment of cardiorespiratory fitness via maximal oxygen consumption during exercise); and a psychosocial stressor protocol for the collection of hemodynamic [blood pressure (SBP, DBP) and heart rate (HR)], affective, and hormonal stress responses. Psychosocial stress testing sessions occurred during the follicular phase of the menstrual cycle to control for hormone fluctuations which can influence the physiological response to stress. **RESULTS:** Preliminary results from this ongoing study show a trend for higher levels of physical fitness to be associated with lower SBP ($r = -.58$, $p = 0.08$) and DBP ($r = -.56$, $p = 0.09$) reactivity to stress. Interestingly, higher physical fitness was significantly associated with a more negative affective response to the psychosocial stressor tasks (speech: $r = .70$, $p = .02$, math: $r = .71$, $p = .02$). **CONCLUSIONS:** If confirmed in our larger sample, results suggest a possible dissociation of the physiological and psychological stress responses associated with physical fitness in women during the follicular phase of the menstrual cycle.

Factors Underlying The Contribution Of Psychological Stress To The Induction of Exercise-Related Menstrual Disturbances

Clara V. Etter, Mary Jane DeSouza, FACSM, Jay L. Lieberman, Nancy I. Williams, FACSM. *The Pennsylvania State University, State College, PA.* (Sponsor: Nancy I. Williams, FACSM)
 Email: cve5047@psu.edu

(No relationships reported)

PURPOSE: Our previous findings have shown a significant relationship between the severity of exercise-related menstrual disturbance and an increase in perceived stress. In this analysis, we examined underlying factors that contribute to changes in psychological stress with the induction of exercise-related menstrual disturbances in a 3-month exercise and caloric restriction intervention in sedentary, regularly menstruating women (n=36). **METHODS:** Women (age 18-24 yrs, BMI 18-28 kg/m²) were randomized to either an exercise only group or one of four groups designed to induce an energy deficit through varying combinations of caloric restriction and exercise over 3 menstrual cycles preceded by a Baseline cycle. The intervention included exercise (5 d/wk, 50-85% VO₂max, 20-75 min) and controlled diet. Menstrual function and reproductive hormones were characterized using daily urinary estrone-1-glucuronide (E1G), pregnanediol glucuronide (PdG), luteinizing hormone, and menstrual calendars. Depressive symptoms were assessed with the Beck Depression Inventory (BDI). Presence of eating disorders was assessed using the Eating Disorder Inventory (EDI). Psychological stress was determined with the Perceived Stress Scale. Other factors investigated were anthropometrics, fitness, age, and reproductive factors. **RESULTS:** The intervention caused moderate weight loss (-2.59 ± 0.35 kg), increases in fitness, declines in body fat and declines in E1G and PdG (p < 0.006). Perceived stress increased significantly across the intervention (p < 0.001). Changes in perceived stress were associated with baseline luteal phase PdG AUC (r = 0.387, p = 0.024), change in body weight (p = 0.017, R = 0.401), change in fat free mass (p = .020, r = .391), and the change in BMI (r = 0.419, p = 0.012) such that higher baseline PdG concentrations and greater reductions in BMI and body weight were associated with lower increases in perceived stress. Baseline scores of BDI and EDI were not significantly related. Age, fitness, body composition, luteal phase length, and follicular phase E1G were also not significantly predictive of PSS. **CONCLUSION:** Stress sensitivity as defined by changes in perceived stress and related menstrual disorders may depend on baseline ovarian status and changes intervention induced changes in anthropometrics.

The Effects of an Acute Bout of Yoga on Anxiety Symptoms in Response to a Carbon Dioxide Inhalation Task in Women

Ipek Ensari¹, Steven J. Petruzzello, FACSM², Robert W. Motl³.
¹Columbia University Medical Center, New York, NY. ²University of Illinois at Urbana-Champaign, Urbana, IL. ³University of Alabama at Birmingham, Birmingham, AL. (Sponsor: Steven J. Petruzzello, FACSM)

Email: ie2145@cumc.columbia.edu

(No relationships reported)

Purpose: Yoga as a physical exercise might be a feasible approach for anxiolysis, yet this has not been systematically investigated in well-designed studies that include an anxiety producing challenge. Such research is particularly salient for women, who are significantly more affected by clinical and subclinical anxiety symptoms than men. This study compared the effect of a single bout of vinyasa-style yoga versus a stretching control condition for improving anxiety symptoms induced by a 5-min, 7.5% CO₂-inhalation protocol in women with self-reported high anxiety sensitivity.

Methods: Eighteen women (mean age=22, SD=5) with self-reported elevated anxiety sensitivity completed 2 experimental conditions (40 min of guided yoga or a light stretching protocol) in a randomized, counterbalanced order. Participants completed the CO₂-inhalation task before, immediately after and 1 hour after the experimental conditions and completed measures of state anxiety and panic before and after each inhalation task. Respiratory measures of tidal volume, ventilation and respiratory rate were collected during each of the inhalation tasks.

Results: Based on the results of the repeated measures ANOVA, there was no evidence for a differential pattern of change in self-reported anxiety or respiratory outcomes in response to the CO₂-inhalation task between the 2 conditions (F(2,16)=1.06; $\eta_p^2=.07$; P>.05). There was a significant main effect of CO₂-inhalation task (i.e., from pre- to post-inhalation) on the self-reported panic and anxiety symptoms in both conditions (P<.05). Collapsed over exposure and condition, there was a reduction in cognitive anxiety over time (i.e., from baseline to immediately post and 1-hour post-condition) (F(2,16)=9.63; $\eta_p^2=.36$; P<.05).

Conclusion: There appears to be an overall effect of general physical activity for attenuating cognitions of anxiety, irrespective of the physiological responses. Light-to-moderate intensity vinyasa-style yoga does not appear to be more efficacious than

a light stretching session for improving symptoms of anxiety and panic in response to the anxiety-provoking stimulus. The inhalation task administered in the present study is a reliable method for mimicking both acute panic and more generalized anxiety symptoms under laboratory conditions.

Relationship Between Food Addictive Behavior and Physical Activity in College-aged Students

Charlie Huberman, Rebecca Bryant, Stephen Van Rij, Erica Geisler, Sara Sharp, Bailey Koch, Stephen P. Bailey, FACSM.
Elon University, Elon, NC.

Email: chuberman@elon.edu

(No relationships reported)

Acute exercise has been associated with reduced cravings for addictive substances. Excessive exercise has been associated with maladaptive eating behavior. It is unclear if a relationship exists between physical activity and food addictive behavior. **PURPOSE:** The purpose of this investigation is to determine if food addictive behavior is influenced by physical activity in college-aged students. **METHODS:** 241 college-aged students (18-24 years of age; 55 male, 186 female) were recruited from University and Community College settings and asked to complete the Yale Food Addiction (YFA) Scale 2.0 and the International Physical Activity Questionnaire (Last 7-Days) (IPAQ) using an on-line platform. The YFA identifies up to 11 diagnostic indicators of food addiction and provides diagnoses of mild, moderate, or severe food addiction. **RESULTS:** 19 of 241 (7.9%) of participants were diagnosed with moderate (2.5%) or severe (5.4%) food addiction (FADD). Participants displayed 1.62±0.15 symptoms of food addictive behavior with 31.5% having 1-3 symptoms, 7.5% having 4-5 symptoms, and 10.4% having 6 or more symptoms. BMI was higher in participants with food addiction (Non-FADD=24.1±0.3 FADD=26.9±1.9, p=0.02); however, no differences were found in vigorous (Non-ADD=1851±251 MET-min/week, FADD=1920±799 MET-min/week), moderate (Non-ADD=777±107 MET-min/week, FADD=869±409 MET-min/week), or walking (Non-ADD=1262±139 MET-min/week, FADD=2051±583 MET-min/week) activity. The distribution of participants with Low (Non-FADD=13.5%, FADD=10.5%), Moderate (Non-FADD=42.1%, FADD=42.1%), and High (Non-FADD=44.4%, FADD=47.4%) levels of physical activity was similar between the groups. Interestingly, participants with High (2.10±0.27 symptoms) levels of physical activity displayed more symptoms of food addictive behavior than participants with Moderate (1.41±0.15 symptoms) and Low (1.06±0.27 symptoms) levels of physical activity (p=0.03). Participants with High (14.1%) levels of physical activity were also more likely to display 6 or more symptoms of food addictive behavior than participants with Moderate (4.9%) and Low (3.2%) levels of physical activity. **CONCLUSIONS:** The results of this investigation suggest that High levels of physical activity may be associated with more symptoms of food addiction.

3102 Board #7 June 2 2:00 PM - 3:30 PM
Neural Response to Food Cues After Moderate and Vigorous Exercise in Women: A Randomized Crossover Trial

Bruce Bailey, Jillesa Anderson, Chase Glenn, Michael Larson, James LeCheminant, FACSM. *Brigham Young University, Provo, UT.*

Email: bruce.bailey@byu.edu

(No relationships reported)

PURPOSE: This study examined the effect of different intensities of acute exercise on attention allocation to visual food cues.

METHODS: This crossover study utilized treatment conditions that were randomized and counter-balanced. Fifty-two adult women, 18-29 years, were compared under three separate conditions: no exercise, 45 min of moderate-intensity exercise at 3.9 METs and 22.5 min of vigorous-intensity exercise at 7.8 METs. To measure attention allocation to visual food cues, participants were shown a passive viewing task consisting of a continual stream of pictures of food (high and low calorie) and non-food stimuli while brain activity was monitored using an EEG. The late positive potential (LPP) component of the scalp-recorded event-related potential (ERP) was used for data analysis.

RESULTS: The 52 women included in the study were on average 21.4 ± 2.2 years old, weighed 62.4 ± 11.2 kg, and had a BMI of 22.7 ± 3.4 kg m⁻². EEG results were analyzed from 39 of the 52 women. There was no significant difference between picture type (high-energy dense, low-energy dense and neutral) and LPP response. There was a significant difference in condition (P = 0.045), with vigorous exercise resulting in a higher (1.94 ± 2.93 μ V) LPP response than either the moderate (1.45 ± 1.95 μ V) or non-exercise (1.40 ± 1.65 μ V) condition. However, the condition (no exercise, moderate exercise or vigorous exercise) by picture type (high calorie, low calorie or non-food) interaction was not significant (P = 0.184).

CONCLUSIONS: The results of this study shows that an acute bout of vigorous exercise did not alter neural response to visual food cues compared to neutral pictures.

There was a global response to all pictures, with the vigorous condition demonstrating a more pronounced LPP response. However, what this response means for appetite is not clear since it was not food specific.

3103 Board #8 June 2 2:00 PM - 3:30 PM
Impact Of Acute Aerobic Exercise On Cue Reactivity To High-fat Foods In College-aged Women

Rebecca Bryant, Carlie Huberman, Stephen Van Rij, Sara Sharp, Erica Geisler, Bailey Koch, Stephen Bailey, FACSM. *Elon University, Elon, NC.*

Email: rbryant4@elon.edu

(No relationships reported)

Acute aerobic exercise has been shown to reduce craving for various addictive substances like cigarettes and alcohol. A similar effect has been seen in children when examining brain fMRI responses to fatty foods. **PURPOSE:** The purpose of this investigation is to examine the impact of acute aerobic exercise on cue reactivity to fatty and healthy foods in typical college-aged women. **METHODS:** Six women (Age=24.7±0.9 years, BMI=26.6±2.5), VO_{2peak}=35.3±4.1 ml·kg⁻¹·min⁻¹) completed 2 experimental sessions. During one session subjects rested for 30 minutes and during the other session subjects exercised for 30 minutes at a moderate exercise intensity (77±1% of Peak HR) on a semi-recumbent bike. Treatments were applied in a counter-balanced fashion and subjects fasted for 4 hours prior to each session. Prior to and immediately following each session, EEG data were collected using a 64-channel EGI Geodesic EEG System 300 series while subjects were exposed to 280 images (40 Distractor (DIS), 120 Fatty Foods (FAT), 120 Healthy Foods (HEALTHY)). Images were presented in a random order and proceeded by a fixation stimulus using a variable time span (0.5 to 1.5 sec). After collection, data were processed to calculate the mean and peak voltage associated with the P300 (200-500 ms post stimulus) in all electrodes. For this investigation, only the electrodes associated with the parietal lobe of the brain were used for comparison and average EEG responses in these electrodes are presented here. **RESULTS:** Reaction time to distractor stimuli was reduced following exercise (Pre=513±8 ms, Post=483±10 ms, p=0.004) as compared to resting (Pre=530±17 ms, Post=522±15 ms, p=0.22) Acute aerobic exercise had no impact on the EEG response to FAT (Mean Response: Pre=0.35±1.42 μV, Post=0.42±1.66 μV; Peak Response: Pre=1.71±1.41 μV, Post=2.08±1.68 μV) or HEALTHY (Mean Response: Pre=-0.39±0.76 μV, Post=0.42±1.28 μV; Peak Response: Pre=1.74±0.82 μV, Post=2.63±1.52 μV) images. **CONCLUSION:** These findings suggest that acute aerobic exercise of moderate intensity does not influence cue reactivity to images of fatty and healthy foods in normal college-aged women.

3104 Board #9 June 2 2:00 PM - 3:30 PM
Neural Activation to Food Cues and Cognition in Sedentary Obese Endometrial Cancer Survivors Seeking Weight Loss

Nora L. Nock, Andrew Serger, Anastasia Dimitropoulos. *Case Western Reserve University, Cleveland, OH.*

Email: nln@case.edu

(No relationships reported)

PURPOSE: Sedentary behavior and obesity increase the risk of endometrial cancer (EC), particularly Type I forms, which are increasing in the U.S. Further, although death rates from most cancers are decreasing, overall mortality rates for EC are increasing; and, obese EC patients have significantly poorer survival rates compared to normal weight EC patients. No prior studies have examined neural activation in response to food cues as well as sedentary behavior and cognition in obese EC survivors. **METHODS:** Therefore, we evaluated appetitive behavior using a visual food cue functional magnetic resonance imaging (fMRI) task as well as sedentary behavior and cognition using Trails A & B and Symbol Digits Modalities Tests in 42 obese EC survivors seeking weight loss. **RESULTS:** We found increased activation in response to high-calorie food cues after eating a meal in brain regions associated with food-related reward (dorsolateral prefrontal cortex, amygdala; whole brain cluster corrected, p<0.05) in obese EC survivors. In addition, cognitive tests suggest scores in obese EC patients are lower than normative data for similar age and gender. We are currently evaluating correlations between sedentary behavior, cognitive scores and neural signals in differentially activated brain regions. **CONCLUSIONS:** To our knowledge, this is the first study to evaluate cognitive and sedentary behavior correlates of neural activation in response to food cues in obese EC survivors and, these data may also help inform future work in other adult obese populations with and without cancer.

This work was supported by NIH NCI R01-CA175100.

Neurocognitive Improvements Following a 12-Month Diet and Physical Activity Intervention

Jamie Cohen, Chelsea M. Stillman, Jennifer C. Watt, Renee J. Rogers, John M. Jakicic, FACSM, Kirk I. Erickson. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: John Jakicic, FACSM)

Email: jcohe7@gmail.com

(No relationships reported)

PURPOSE: Obesity is associated with decreases in cognitive function, including changes in working memory and executive control. Yet, we know very little about whether weight loss through an energy-restricted diet and increased physical activity (PA) improves cognitive function. The aim of this study was to evaluate whether weight loss following a 12-month dietary and physical activity intervention was associated with improved cognitive performance.

METHODS: 115 overweight and obese adults (89 female) participated in a 12-month diet and PA intervention. Participants were middle-age (mean at baseline=44.7±8.5 years) and well educated (mean=16.5±2.5 years). Participants were assigned to one of three groups: One group engaged in dietary restriction alone, while the other two groups engaged in either 150 minutes per week or 250 minutes per week of moderate intensity exercise, in addition to an energy-restricted diet. All participants completed neuropsychological tests measuring decision-making (Iowa Gambling Task; IGT), inhibitory control (color-word Stroop), working memory (N-Back), and processing speed/set shifting (Task Switch). Paired-samples t-tests compared baseline with post-intervention cognitive performance. The results reported below are collapsed across group, as the investigators remain blind to group assignment.

RESULTS: Following the intervention, participants' BMI decreased by 2.4±3.3 kg/m², p<.001. Participants performed significantly better post-intervention on the IGT [t(114)=-2.42, p=.016], N-Back [2-Back RT t(114)=2.686, p=.008], and Task Switch [RT t(113)=3.759; accuracy t(113)=-2.016, p=.046] compared to baseline. There were no significant changes in Stroop Task performance from baseline to follow-up. The changes in cognitive task performance were not significantly associated with change in BMI.

CONCLUSIONS: A 12-month diet and physical activity intervention in overweight and obese adults is associated with improved cognitive performance across multiple cognitive domains. **FUNDING:** This research was supported by funding from NIH/NIDDK grants R01095172 (PI: Erickson) and R01HL103646 (PI: Jakicic).

Benefits of Acute Aerobic Exercise on Neuroplastic Potential in Depression

Ryan E. Ross, Michael E. Saladin, Mark S. George, Chris M. Gregory, FACSM. *Medical University of South Carolina, Charleston, SC.* (Sponsor: Chris Gregory, FACSM)

Email: rossre@musc.edu

(No relationships reported)

Depression affects millions of Americans and is a leading contributor to disability and mortality in the United States. Evidence indicates that neuroplasticity is impaired in those with depression and successful treatment for depression appears to reestablish neuroplastic potential. Aerobic exercise (AE) has well-established antidepressant effects and has been shown to modulate neuroplasticity in non-depressed subjects. To date, the acute influence of exercise intensity on indices of neuroplastic adaptation have yet to be described. **PURPOSE:** To examine the efficacy of acute AE as a neuro-modulatory intervention in non-depressed control subjects. **METHODS:** Thirteen non-depressed subjects (8 female; 34.5 ± 8.7 years old) completed three experimental sessions that included assessment of corticospinal excitability (CE), AE (15 minutes) and paired associative stimulation (PAS) to determine neuroplastic potential. CE was assessed via transcranial magnetic stimulation and surface electromyography of the abductor pollicis brevis muscle before and after exercise, and for one hour after PAS. AE was performed on a stationary cycle ergometer at low intensity (LO), 35% heart rate reserve (HRR); high intensity (HI), 70% HRR; or a non-exercise control condition (CON). The primary outcome was change in peak-to-peak motor evoked potential amplitude relative to baseline assessment. **RESULTS:** Mean post-exercise CE across all time points was increased 26.2% in the LO condition, and 2.9% in the CON condition while the HI condition reduced CE 6.3%. Immediately following exercise, the LO condition produced a rapid 27.1% increase in CE while the HI condition produced a rapid 16.3% decrease in CE. Both the LO and HI conditions demonstrated a homeostatic response immediately post-PAS with a 15.0% reduction and 27.8% increase in CE, respectively. **CONCLUSION:** Lower exercise intensity appears to have a greater influence on increasing CE. Interestingly, the rapid effects of exercise appeared to be reversed by PAS suggesting the presence of homeostatic metaplasticity during these conditions. Modulation of CE via exercise in depression has yet to be established but may underlie the anti-depressant effects of AE. Work examining the influence of AE on CE in depression is currently in progress.

F-52 Free Communication/Poster - Activity Interventions and Programming in Youth

Improvements in Family Nutrition and Physical Activity during FitKids360: Associations with Adiposity Changes

Kim Delafuente¹, Jared Tucker², Kathy Howard³, Jill Graybill¹, Gregory Welk, FACS⁴. ¹*Spectrum Health, Grand Rapids, MI.* ²*Helen DeVos Children's Hospital, Grand Rapids, MI.* ³*Forest Hills Pediatrics, Grand Rapids, MI.* ⁴*Iowa State University, Ames, IA.* (Sponsor: Gregory Welk, FACS⁴)

(No relationships reported)

Purpose

The Family Nutrition and Physical Activity survey (FNPA) is a validated health behavior survey for assessing childhood obesity risk, but it has not been evaluated as a tool to track behavior change over time. The current study assessed FNPA in youth who completed a pediatric weight management program, and compared associations between FNPA and adiposity changes.

Methods

Youth 5-16 years old with a BMI \geq 85th percentile participated in FitKids360, a 6-week, multidisciplinary, family-based intervention aimed at improving physical activity, nutrition, and sedentary behaviors. The FNPA was parent-reported pre and post intervention, and height and weight were assessed via trained program staff. Total FNPA and subscale scores were calculated, including screen time, physical activity, family meals, food and beverage choices, parental food restrictions and rewards, and sleep routines. Participants were grouped based on BMI percentile (BMI%) changes during treatment, after which FNPA scores were compared across genders, age groups, and BMI-change categories.

Results

A total of 1102 youth (10.7 \pm 3.0 years) initiated treatment, and 790 completed the program (72% retention). Mean FNPA scores significantly increased 5.6 \pm 7.4 points ($p<0.001$) while BMI% decreased -0.43 \pm 2.12 percentile points ($p<0.001$). After adjusting for baseline FNPA, youth <11 years of age had higher post FNPA scores than older youth ($p<0.001$), but FNPA did not differ between genders. When grouped by high ($\leq-0.5\%$), moderate (-0.5 to 0.0%), and low ($\geq 0.0\%$) BMI% changes, youth with high reductions had healthier FNPA scores (63.2 \pm 7.8) than those with low BMI% changes (59.6 \pm 8.1) ($p=0.005$), and a trend towards higher scores than those with moderate reductions (61.7 \pm 7.3) ($p=0.080$). FNPA subscales also differed between BMI% groups, such that greater adiposity reductions were associated with healthier beverage choices ($p=0.034$) and lower screen time ($p=0.005$).

Conclusions

FitKids360 completers improved FNPA scores and reduced age- and sex-adjusted BMI. After adjusting for baseline differences, youth with the highest post-treatment FNPA scores had the greatest improvements in adiposity. The FNPA appears to be a useful tool for tracking progress in obesity-related health behavior changes during family-based pediatric weight management.

The Experimental Effect Of Parental Attentiveness On Children's Physical Activity

Michael J. Rebold¹, Cody Croall², Emily Cumberledge², Melanie Hall², Lindsey Raumikaitis². ¹*Hiram College, Hiram, OH.* ²*Bloomsburg University of Pennsylvania, Bloomsburg, PA.*
Email: reboldmike@gmail.com
(No relationships reported)

Current evidence supports the notion that children's physical activity levels may be influenced by parental interactions. One potential factor may be parent attentiveness. While evidence from non-experimental studies provides support that when parents are actively attentive it is positively associated with their children's physical activity, it is heretofore unknown what the causal impact of a parent being actively attentive versus non-attentive may be on the amount and intensity of their child's physical activity. **PURPOSE:** To assess the amount, intensity, enjoyment (i.e., liking), and preference of children's physical activity under two conditions; *parent actively attentive* and *parent non-attentive*. **METHODS:** Ten children ($n = 6$ boys, 4 girls) between the ages of 3-6 years old participated in each condition for 30-minutes in which they were taken to a gymnasium and had free-choice access to a variety of physical and/or sedentary activities. In addition to accelerometry data, at the end of each 30-minute session children were asked to indicate their liking. Children were then

asked if they would like to play for an additional 10-minutes. After both conditions were completed, each child indicated which condition was their favorite. **RESULTS:** More counts ($p = 0.04$) were accumulated during the *parent actively attentive* (96,547 \pm 33,075.26 counts) condition than the *parent non-attentive* (48,316.30 \pm 46,101.47 counts) condition. More time ($p = 0.01$) was allocated to sedentary activities during the *parent non-attentive* (19.50 \pm 13.30 minutes) condition than the *parent actively attentive* (2.80 \pm 3.55 minutes) condition. Children liked ($p = 0.004$) the *parent actively attentive* (9.05 \pm 1.21 cm) condition more than the *parent non-attentive* (4.42 \pm 3.18 cm) condition. There was no significant difference ($p = 0.56$) between the proportion of children who chose to participate in the additional 10-minute bonus period during the *parent actively attentive* (50%) condition and the *parent non-attentive* (40%) condition. **CONCLUSION:** When parents are actively attentive children's physical activity increased by 99.82% and reduced sedentary behavior by 85.64%. *Parental attentiveness* during bouts of physical activity may be an important component to consider when children are engaging in physical activity.

3109 Board #14 June 2 3:30 PM - 5:00 PM
Evaluation of a Teacher-Led Physical Activity Intervention in Preschool Children

Connie Tompkins, Lori E. Meyer, Erin K. Shoulberg, Anna Pirog, Caroline Martin, Betsy Hoza. *University of Vermont, Burlington, VT.*
Email: Connie.Tompkins@uvm.edu
(No relationships reported)

More than half of preschool-aged U.S. children spend their time in a structured preschool setting largely engaged in sedentary behaviors. Given the low levels- yet importance of physical activity (PA) for prevention of obesity, preschools may be an ideal environment to engage a large number of children at an early age. **PURPOSE:** To examine whether a teacher-led PA intervention increased moderate-to-vigorous physical activity (MVPA) in preschool-aged children. **METHODS:** An evidence-based PA curriculum was implemented in a local preschool over 12-weeks, 3 times per week by classroom teachers with assistance provided by UVM students enrolled in a service-learning course. Main outcomes were objectively measured, MVPA by accelerometry. Measures were performed at baseline, 2 intervention points, and 1-week post-intervention. A total of 35 children (4-5 years, 12 females, 23 males) who had at least 3 days of valid data were included in the analyses. **RESULTS:** Significant ($p<0.05$) changes were observed in minutes of MVPA/day, sedentary minutes/hour and MVPA/hr. Minutes of MVPA/day significantly increased from pre- to post-intervention (56.55 \pm 3.9 vs. 72.61 \pm 3.9). Significant increases were observed from baseline to both intervention point 1 and post-intervention (8.45 \pm 0.4 vs. 10.8 \pm 0.6 and 10.9 \pm 0.4, respectively). Sedentary time also significantly decreased from 43.42 \pm 0.6 min/hr at baseline to 40.61 \pm 0.5 min/hr at post-intervention. **CONCLUSIONS:** The findings from this study support a teacher-led intervention to increase MVPA in preschool-aged children. These findings are promising as teacher-led PA interventions may be a potentially viable and cost-effective means to accomplish a myriad of health-related goals. Further evaluation of the PA curriculum in a larger cohort and over a longer period of time is warranted.

3110 Board #15 June 2 3:30 PM - 5:00 PM
Effectiveness Of A Low-cost Exercise Intervention For Pediatric Obesity

Andrea M. Jacobo, Ryan G. Moran, Dana Kimberly, E Thomaseo Burton, Webb A. Smith. *University of Tennessee, Memphis, TN.*
Email: jacoboa.andrea@gmail.com
(No relationships reported)

PURPOSE: Regular physical activity improves health profiles and quality of life in youth with obesity (YWO), and participation in sport-specific events reportedly improves self-efficacy among youth with little athletic experience. This project retrospectively evaluated the feasibility and efficacy of an ongoing low-cost physical activity intervention to prepare YWO for an athletic event (5K run/walk).

METHODS: The Healthy Lifestyle Clinic (HLC), a multidisciplinary weight management clinic at Le Bonheur Children's Hospital, hosted a race team for a 5K run/walk event. HLC patients were offered a training program designed to be engaging, minimally burdensome for clinical staff, and focused on preparing exercise-naïve YWO to complete a 5K. Training included 3 weekly aerobic sessions (20-45 minutes) with duration and intensity increased based on rating of perceived exertion. Participants completed workout logs and were invited to workouts in the community with HLC staff members. Weekly phone calls were made to monitor progress, engagement, and individualize the program. On average, phone calls lasted <10 minutes. Retrospective review of medical records and patient communications, was IRB approved.

RESULTS: Initially 28 YWO expressed interest in the training program. Twelve YWO (11.4 \pm 2.6 yrs, 151.3.4 \pm 13.3 cm tall, 88 \pm 24.5 kg, 99.1 \pm 0.76 BMI %ile) actively engaged (reporting >70% adherence) with the training, and 6 participants completed

the 5K race (all 1st time racers). Almost 60% of participants attended all community workouts and those who completed the 5K had greater parent engagement than those who did not. Similarly, those who engaged in more frequent phone contact were more engaged in the training program. More than 80% of families who participated requested the program become a recurring HLC offering, indicating a desire for more exercise interventions. Themes of improved physical appearance, self-worth, and athletic competence emerged from patient reports. All those who completed the race expressed likelihood to attempt another race.

CONCLUSIONS: This program was feasible, minimally burdensome, and cost-effective. It had a positive effect on self-reported motivation, physical fitness, and self-efficacy. Parental involvement was a driving factor for program adherence and race completion.

3111 Board #16 June 2 3:30 PM - 5:00 PM
Effects Of 5-week Summer School Program On Inflammatory Markers And Oxidative Stress In Female Adolescents

Myung Dong Choi¹, Kyung Shin Park². ¹Oakland University, Rochester, MI. ²Texas A&M International University, Laredo, TX.
 Email: choi@oakland.edu
 (No relationships reported)

Physical inactivity and obesity in adolescents cause a complex health issue. Especially, physical activity levels are markedly decreased during summer vacation in low socio-economic status communities, compared to academic school periods. It was also reported that physical fitness was progressively declined in children who did not participate in exercise programs during summer vacation. Thus, this study seeks to provide further evidence for the role of summer school programs.

PURPOSE: To determine the effects of summer school programs including 2-hour exercise per day on systemic blood inflammation and total antioxidant status in female adolescents.

METHODS: Thirty high school female students were recruited and 15 students were assigned to the summer school attendant group (SA) and completed summer school programs with 2-hour exercise daily for 5 weeks and 15 students were in non-summer school attendant group (NSA). Plasma tumor necrosis factor alpha (TNF- α), C-reactive protein (CRP), and total antioxidants were measured immediately before and after summer vacation. One-way ANCOVA was used to determine differences in TNF- α , CRP, and total antioxidant changes between the groups.

RESULTS: Plasma TNF- α was reduced in SA group after summer vacation, compared with the NSA (7.79 \pm 2.0 pg/ml vs. 8.33 \pm 2.2 pg/ml, respectively, $P=0.001$). CRP level was decreased in the SA group after summer vacation, compared with the NSA (7.7 \pm 0.7 mg/L vs. 8.2 \pm 0.7 mg/L, respectively, $P=0.005$). Total antioxidant concentrations were elevated in the SA group after summer vacation, compared with the NSA (1.96 \pm 0.4 mM/L vs. 1.80 \pm 0.2 mM/L, respectively $P=0.018$).

CONCLUSION: Five weeks of exercise programs in summer school may ameliorate systematic inflammation and decrease oxidative stress in female adolescents. Thus, these findings may support that school-aged adolescents, while attending at summer school programs, have beneficial outcomes on the cardiovascular health, especially in low socio-economic status communities.

3112 Board #17 June 2 3:30 PM - 5:00 PM
Different Exercise Doses On Fitness , Fatness And Inhibition Control Of Adolescents.

Xin Li¹, xiaotong Li², zhengzhen Wang, FACSM², Yan Wang².
¹Chengdu Sport Institute, Chengdu, China. ²Beijing Sport University, Beijing, China.
 Email: lixin6232990@163.com
 (No relationships reported)

Purpose: To study the effects of different dose of exercise training on cardiorespiratory fitness, body fat percentage and inhibition control of adolescents.

Methods: A physical activity intervention program was conducted among 12-14 years' adolescents. 78 students (38 boys) were recruited into the plan after the approval of parents and teachers. According to the classes, we divided the participants into 3 groups. They were low-dose(30min/d,n=20) or high-dose(60min/d,n=23) aerobic training(12wk,5d/wk), or control condition(usual physical activity,n=24);rates of attendance was 55%. Training intensity was the 50%~70% heart rate reserve. We used the breath-by-breath technique to test the VO_{2peak}. The Bioelectrical Impedance analysis was used to measure the body fat percentage. Inhibition control was measured by a modified Eriksen flanker task. Between-group differences were tested using analysis of covariance(ANCOVA) with adjustment for baseline values and within-group differences were tested using t tests. For statistically significant analyses of variance ($P<0.05$)

Results: Participants had mean VO_{2peak} of 33.0ml/min/kg at baseline survey. 12 weeks later, after adjustment for the baseline value, compared with control group, the exercise groups increased VO_{2peak} greater($F=3.87,p=0.03$). The mean(SE) VO_{2peak}

was 38.78(1.10) in low-dose and 38.46(1.04) in high-dose. But the VO_{2peak} in control group was 34.98(1.03). There was no significant difference between low-dose and high-dose group. For girls, the decrease in body fat percentage in the high-dose physical training group, but not in the low-dose group, was significantly greater than that in the control group($F=3.94, P=0.03$). But there were no significant changes in fatness values of boys from baseline to 3 months. After adjustment for the baseline value, there were no significant changes in inhibition control values from baseline to 3 months in any of the exercise groups vs the control group.

Conclusion: Three months of 30 or 60 min/d aerobic training improved fitness, and demonstrated dose-response benefits on general adiposity for girls. However, the effects of exercise intervention on inhibition control for 12-14 aged students should do further research.

Exercise Intensity and Sleep in Obese Youth Before, During and After Weight Management Camp

Amanda Gier. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.
 (No relationships reported)

PURPOSE: To compare overall sleep time, sleep efficiency and exercise intensity of participants before, during and after a weight management camp for youth with obesity.

METHODS: Fifteen obese youth, ages 9 to 13 years, were recruited at an open house for an overnight weight management camp. Informed consent/assent was obtained. Subjects wore GENEActiv accelerometers 24 hours/day for approximately one week before, during, and after camp. Data were analyzed to determine the amount of time each participant spent in sedentary (SED), moderate (MPA) and vigorous (VPA), as well as total sleep time (TST) and sleep efficiency (EFF). The participants' activity levels and other subject characteristics were compared during the week of camp and weeks at home.

RESULTS: Complete usable data was obtained from 10 (67%) participants (6 boys, 4 girls). Mean age (\pm SD) was 11.7 \pm 1.2 years. Mean BMI was 32.25 \pm 5.1 kg/m². During camp, participants averaged less daily SED than at home (428.38 \pm 63.20 minutes, $p=0.0003$) and more MPA (363.4 \pm 38.63, $p=0.0001$) and VPA (55.05 \pm 33.96, $p=0.0055$). There was no significant difference in TST between weeks. There was a significant difference in EFF between weeks ($p=0.04$), with the highest EFF occurring during camp (86.7%). Neither BMI nor age were correlated to TST or EFF.

CONCLUSION: Obese youth exercise longer at higher intensities while participating in a summer weight management camp versus on their own at home. Sleep efficiency also improves while at camp. This suggests that accumulating more daily MVPA leads to improved sleep, and further studies are needed to more closely examine this relationship in obese youth.

3114 Board #19 June 2 3:30 PM - 5:00 PM
Effect Of A Physical Activity Intervention On Letter And Number Recognition In Preschoolers

Christine W. St Laurent, Sarah Burkart, Sofiya Alhassan, FACSM. University of Massachusetts Amherst, Amherst, MA.
 (Sponsor: Sofiya Alhassan, FACSM)
 Email: cstlaurent@umass.edu
 (No relationships reported)

There is considerable evidence that physical activity (PA) may improve some components of cognition and academic performance in preschool-aged children. Increasing PA in an effort to enhance learning in preschoolers may be ideal, particularly as this age group experiences a high rate of cognitive development and neurophysiological change. However, the literature on PA and academic performance related outcomes, such as school readiness skills, in preschoolers is limited.

PURPOSE: The purpose of this study was to examine the effects of a 12-week PA intervention on school readiness-related cognitive skills (i.e. letter and number recognition) in preschool children. **METHODS:** Two preschool centers (n=41 children; 53.6% male; mean \pm sd: age=4.3 \pm 0.7; BMI percentile=52.5 \pm 26.3) were randomized to a 12-week preschool-based PA intervention (INT; n=19 children) that incorporated short-bout PA lessons embedded into the Massachusetts Early Learning Standards or a health-tracking control group (CON; n=22). School readiness cognitive skills were assessed by recognition of symbols (i.e. letters and numbers) at baseline and at 12-weeks. Chi square and independent t -tests were used to compare baseline characteristics between groups. The effect of the intervention on letter and number recognition was assessed with repeated measures ANOVA. **RESULTS:** There were no significant baseline differences between groups. Mean change scores for letter recognition (INT: 3.5 \pm 6.8, CON: 5.5 \pm 4.9) and number recognition (INT: 0.9 \pm 4.3, CON 1.7 \pm 2.3) were higher in the CON group compared to the INT group. There was not a significant effect of the intervention on pre- to post-scores. **CONCLUSION:** The 12-week PA intervention utilized in this study did not elicit a significant improvement in the letter and number recognition of preschoolers. Further research may be valuable

to examine the benefits of a preschool PA intervention by utilizing longer intervention periods, additional bouts of academically-tailored PA, and more comprehensive measures of preschool cognitive skills.

3115 Board #20 June 2 3:30 PM - 5:00 PM
Effect Of A Curriculum-Based Physical Activity Intervention On Classroom Behavior Variables In Preschool-Age Children

Sarah Burkart, Christine W. St. Laurent, Sofiya Alhassan, FACSM. *University of Massachusetts Amherst, Amherst, MA.* (Sponsor: Sofiya Alhassan, FACSM)
 Email: sburkart13@gmail.com
 (No relationships reported)

Few studies have examined the impact of physical activity (PA) programs during the preschool day, with only two rooted in an academic curriculum. PA has been shown to improve components of classroom behavior in preschoolers. Poor classroom behavior can be indicative of early attention-deficit/hyperactivity disorder (ADHD) symptomology, which is seen in children as young as three years old. However, no studies have examined curriculum-based PA to improve classroom behavior. **PURPOSE:** To examine the impact of a curriculum-based PA intervention on classroom behavior variables in preschoolers. **METHODS:** Children (n=52, mean±sd: age=3.6±0.8 years, BMI percentile=50.1±27.1) attending two preschools were randomized to the Preschool Activity, Diet, and Sleep (PADS) intervention or the health tracking (CON) group. PADS consisted of integrating PA lessons into Massachusetts Early Learning Standards. The Strengths and Difficulties Questionnaire (SDQ) behavioral screening tool was used to assess classroom behavior which includes a total difficulties score and subscales encompassing hyperactivity/inattention, emotional problems, conduct problems, peer problems, and prosocial behavior. The SDQ was completed by classroom teachers for each child at baseline, 6 weeks, and 12 weeks. A repeated measures ANOVA was utilized to examine intervention effects on children's classroom behavior variables. **RESULTS:** Children at the CON school exhibited greater hyperactivity/inattention (PADS=2.3±2.5, CON=4.1±3.5), emotional problems (PADS=0.3±0.6, CON=2.6±2.4), conduct problems (PADS=0.8±1.3, CON=2.9±3.2), peer problems (PADS=0.3±1.0, CON=1.2±1.4), and total difficulties (PADS=4.0±3.8, CON=10.9±8.0) at baseline compared to the PADS school. There were no statistically significant effects of time or intervention by time for classroom behavior variables. **CONCLUSION:** These data suggest a curriculum-based PA intervention did not lead to change in teacher-reported classroom behavior variables. Lack of intervention effect in this population could be due to lack of specificity of intervention components targeting classroom behavior. Future studies should incorporate cognitive skills linked to early ADHD symptomology in PA lessons, include objective behavior measures, and utilize a larger sample size.

 (No relationships reported)

A number of healthy eating determinants such as area deprivation, family involvement, knowledge, and attitudes are associated with obesity prevention in children. School-based interventions have achieved improved weight status, health knowledge, attitudes, and behaviors. **PURPOSE:** Therefore, the purpose of this study was to determine immediate and long-term changes in body mass index and psychosocial variables following a 10-week school-based lifestyle intervention designed to improve weight status in children. **METHODS:** One hundred and thirty eight participants (8.67 ± 0.51 years of age, 64 boys and 74 girls) took part in the study. All participants had height, weight, and psychosocial variables assessed at pre-intervention, post-intervention, and 6-months post-intervention. The Pupil Questionnaire which measured healthy eating attitudes, knowledge and behaviors was used. A repeated measures study design was employed such that participants served as their own control and then completed a 10-week intervention consisting of healthy eating and physical activity education, physical activity, parental involvement, and behavior change. Changes in outcome measures within the group across time was assessed using a one-way repeated measures analysis of variance (RMANOVA) with adjustment for covariates where appropriate. **RESULTS:** Results from the RMANOVA revealed no significant within-group main effect for time. Subsequent analysis of the data indicated a significant within group effect of the intervention at different time points such that from pre-intervention to post-intervention, fruit attitudes (CI = -0.056 to -0.002, ES = -0.26, p = 0.02), vegetable attitudes (CI = -0.081 to -0.009, ES = -0.34, p = 0.005), and healthy eating

attitudes (CI = -0.22 to -0.02, ES = -0.29, p = 0.006) improved. From post-intervention to 6-months, vegetable attitudes approached a significant decrease (CI = -2.533E-5 to 0.07, ES = 0.13, p = 0.05) and HE attitudes decreased (CI = 0.005 to 0.19, ES, 0.26, p = 0.03). **CONCLUSION:** Fit for School may be an effective means for improving healthy eating attitudes and behaviors in primary school children in the short-term if the duration of the intervention is increased, but these changes may not be sustained without on-going support.

3117 Board #22 June 2 3:30 PM - 5:00 PM
Longitudinal Efficacy of Skiku on Physical Activity and Sleep Quality in Alaska Native Youth

Kira Leonard, Hannah Wing, Michelle Johannsen, Lars Flora, Robert H. Coker, FACSM. *University of Alaska Fairbanks, Fairbanks, AK.*
 (No relationships reported)

PURPOSE: Increased exposure to Western Civilization has led to an increased incidence of obesity in Alaskan Native villages. Physical activity and sleep patterns may be altered in these rural settings as well. The purpose of this study was to evaluate the efficacy of a novel cross country skiing program (ie., Skiku) on the levels of physical activity and sleep quality of Alaska Native children. **METHODS:** After a year of exposure to the Skiku program that included bi-annual instruction from high school- to Olympic-level coaches, we worked with the tribal elders to configure a culturally appropriate method of assessment devoted to physical activity and sleep quality. In order to gain a longitudinal understanding of the program efficacy, we visited the village during early April of 2014 and 2016. At both times, we requested that the children (age 7 to 15) wear ActiGraph activity monitors for a minimum of four days. Data collected from these time points were evaluated using ActiLife software algorithms to determine activity levels as well as sleep quality. **RESULTS:** The average amount of time spent performing moderate-vigorous activity significantly increased from 161.2±47.3 min/day to 468.0±98.6 min/day from 2014 to 2016, respectively. There was no change in sleep quantity (558.6±43.0 min/day and 552.8±61.9 min/day; 2014 and 2016 respectively) or quality (87.0±5.8% and 85.6±9.3%; 2014 and 2016, respectively) between the two years. **CONCLUSION:** The implementation of this program has significantly increased the activity levels of children involved. The World Health Organization recommends that children between the ages of 5-17 perform a minimum of 60 minutes of moderate to vigorous physical activity per day to maintain optimal metabolic health and psychological resilience. This program has demonstrated its long term efficacy in promoting healthy lifestyle changes by increasing moderate-vigorous activity in children.

University-Driven Exercise Programming Event Reduces Student Stress Prior to Final Exams

Tessa L. Koschel, James W. Navalta, FACSM, John Young, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.*
 Email: koschel@unlv.nevada.edu
 (No relationships reported)

Levels of sedentaryness and stress are at historical highs among college students. These occurrences are not mutually exclusive; a negative correlation exists between physical activity (PA) and mental health. This correlation, paired with evidence linking PA to increased brain activation and memory function gives cause for a PA intervention nearing final exams. Accordingly, UNLV implemented Fitness4Finals (F4F). **PURPOSE:** To determine the effect of F4F on end-of-semester physiological stress (PS), perceived academic stress (PAS) and academic self-efficacy (ASE) in college students, and examine the relationship between PS and PAS. **METHODS:** 24 participants were grouped by intent to participate in F4F (F4F, n=9) or not participate (Non F4F, n=15). PS (salivary amylase) and PAS were measured at three time-points: the Friday prior to study week (Base), the Friday prior to exam week (Post F4F) and prior to student's first final exam (Pre-Exam). Data were analyzed using a mixed-measures ANOVA, at the p<0.05 significance level. **RESULTS:** A significant group difference was found for PAS at Post F4F ($F_{(1,19)} = 4.403, p = .049$). Though not significant, mean scores revealed lower salivary amylase and PAS for the F4F group across time points. F4F group showed lower ASE at baseline, surpassing the Non F4F group at Post F4F and Pre-Exam time points, while Non F4F stayed unchanged (Table 1). Salivary amylase and PAS trended toward significant correlation at Base ($r = -.388, p = 0.091$) but not Post F4F or Pre-Exam. **CONCLUSION:** Participation in F4F eases academic stress, albeit temporarily. F4F participants display lower physiological and psychological stress overall and increase academic self-efficacy as they near exams. Acute physiological stress markers do not appear to correlate with reported academic stress. Overall, an end-of-semester, university-driven exercise program such as F4F is beneficial in combating climatic stress through increases in PA.

Table 1. Physiological stress, psychological stress and self efficacy across time

	BASE	POSTF4F	PRE-EXAM
F4F			
Salivary Amylase	155.4±159	226.2±239.2	219.2±188
Academic Stress	77±15.4	67.3±18.2	68.6±9.8
Self Efficacy	68.29±12.9	74.14±18.9	78.14±14.4
NonF4F			
Salivary Amylase	219.2±188	242.3±232.6	233.8±288.5
Academic Stress	81.2±14.8	82.6±14.5	75.4± 16.8
Self Efficacy	69.93±14.6	70.29±17.3	69.93±19.8

Examining The Effectiveness Of Spark And Active Video Games On Children’S Health-related Physical Fitness

Han Chen¹, HaiChun Sun², Eugene Asola¹, Lauren Griner¹.
¹Valdosta State University, Valdosta, GA. ²University of South Florida, Tampa, FL.
 Email: hanchen@valdosta.edu
 (No relationships reported)

Purpose: Active Video Game (AVG) has potential in increasing children’s physical activity participation. However, it is not clear whether AVG can help improve individuals’ health-related physical fitness. The purpose of this study was to examine the effectiveness of Sports, Play, and Active Recreation for Kids (SPARK) and AVG on children’s health-related fitness.

Methods: A total of 63 third and fourth graders participated in the study. The third graders (n = 29, 10 for boys) experienced the SPARK curriculum taught by a student teacher while the fourth graders (n = 34, 14 for boys) engaged in the AVG group practicing XBOX Kinect™ dance games. All participants completed three, 50-minute exercise sessions per week for six weeks. Health-related fitness was measured using FitnessGram including 15-meter PACER test, curl-ups, and push-ups tests prior to and immediately after the intervention. A one-way MANOVA with repeated measures by controlling for BMI and gender was conducted to assess the effects of time and interventions on fitness variables.

Results: No group difference in the pre-tests was found. There is a significant effect of time (F = 14.2, p < .001, η² = .20) and the interaction between time and intervention groups on the performance of the PACER test (F = 72.2, p < .001, η² = .56). The participants in both groups increased their PACER test scores with the AVG group demonstrated significantly higher improvement than the SPARK group. No time or intervention effects were found on the muscular strength and endurance tests.

Conclusion: AVG using XBOX Kinect™ seems to be effective in improving children’s aerobic fitness performance. Schools can use AVG as an alternative way to traditional physical activities for children to receive health benefits.

Establishing Classification Criteria for an Energy Balance Knowledge Test for Fourth and Fifth Grade Children

Yang Liu, Senlin Chen. Iowa State University, Ames, IA.
 Email: yliu1@iastate.edu
 (No relationships reported)

PURPOSE: Children show knowledge deficiency about energy balance, a key factor underlying body weight fluctuation. We previously developed and validated a written test, which has shown good validity and utility in capturing children’ knowledge about energy balance, but no criteria were established to classify scores for meaningful interpretation. The purpose of this study was to develop criteria to determine the knowledge levels.

METHODS: Six Iowa schools participated in this study, with 570 children completed the pre-test and 587 completed the post-test. An obesity prevention program was implemented between the two assessments. Data were screened for outliers and examined for normal distribution. Cluster analysis was conducted to establish three levels of energy balance knowledge: high, moderate, and low. ANOVA was subsequently used to verify the classification. Thresholds for knowledge levels were determined based upon the maximum and minimum values at each level. Scores measured at pre- and post-tests were evaluated by referencing to the new criteria.

RESULTS: The cluster analysis resulted in three knowledge levels: high (M: 75.3%, 66.7-96.3%; n=392), moderate (M=57.4%, 51.9-63.0%; n=436) and low (M=39.4%, 14.8-48.2%; n=328). Knowledge sum score was significantly different across the three groups (F_{(2,1153)}} = 2700.14, p<0.001). Differences between every two levels were clear (high vs. low: p<0.001; high vs. moderate: p<0.001; moderate vs. low: p<0.001).

The cut-points were 50.0% between low and moderate levels and 64.8% between moderate and high levels. The proportion of children in high, moderate and low levels were 20.9%, 41.9% and 37.2% respectively at pretest and 46.6%, 33.6% and 19.8% respectively at posttest.

CONCLUSION: The knowledge classification was found to be empirically sound. The obesity prevention intervention showed preliminary efficacy in knowledge increase, with more children placed in the high knowledge group and less children in the low knowledge group.

Playground And Garden Activity Levels In Young Children

Ashlyn Schwartz, Robyn Brookshire, Dawn Coe, FACSOM.
 University of Tennessee, Knoxville, TN.
 Email: ashlynschwartz1993@gmail.com
 (No relationships reported)

Outdoor time is mandated by most states in early childhood education settings. Most facilities have a playground for children to engage in physical activity (PA) during their outdoor time. However, garden programs are increasing in popularity for children, providing educational opportunities while contributing to children’s daily PA.

PURPOSE: To determine the differences in time spent in PA between two outdoor environments (playground and garden) in preschool children. **METHODS:** Ten children (4.7 ± 0.6 years) enrolled in a university laboratory preschool participated in this study. PA was assessed using an ActiGraph GT3X+ accelerometer that was worn on the right hip. Each child completed four randomly ordered free living conditions (30 min each), which included two bouts of unstructured PA on the playground and two bouts of semi-structured PA in the garden. Accelerometer data were classified as minutes in sedentary behavior and combined PA of varying intensities (light, moderate, and vigorous) using the Pate cut points. Data were combined to make one 60 min bout for each environment. Sessions were combined in order to determine the number of minutes per hour spent in sedentary and PA. This variable is consistent with the Institute of Medicine (IOM) recommendation of 15 minutes of PA per hour in order to determine whether these types of outdoor activity are supportive of meeting PA goals. Paired samples T-Tests were conducted to look at differences in PA (min/hour) between the playground and garden. **RESULTS:** On average, the children spent 35.8 min/hour in PA on the playground and 29.0 min/hour in PA on the garden. The children spent less time in sedentary behaviors (24.2±6.8 vs. 31.0±8.4 min/hour; p=0.025) and more time in moderate PA (15.3±5.1 vs. 10.8±6.1 min/hour; p=0.034) on the playground than in the garden. There were no differences in light (18.0±2.4 vs. 17.0±3.4 min/hour; p=0.365) or vigorous PA (2.6±2.1 vs. 1.2±1.9 min/hour; p=0.131) between the playground and the garden. **CONCLUSIONS:** Children spent less time being sedentary and more time in moderate PA on the playground than the garden. However, the children exceeded IOM activity guidelines in both environments. These results suggest that gardens may be a conducive environment to provide an opportunity for children to meet PA recommendations.

Physiological Change During a 13-Week Aerobic Dance Class Among College Age Women

Stephanie M. Otto. Gustavus Adolphus College, St. Peter, MN.
 (Sponsor: Robert Pettitt, FACSOM)
 Email: sotto@gustavus.edu
 (No relationships reported)

One predictor of lifelong activity participation is increased self-efficacy toward physical activity (PA) (Weiss, O’Loughlin, & Piatt, 2007). Many colleges and universities require PA but little emphasis is placed on whether students experience physiological change. If measurable changes were identified, it could improve self-efficacy and potentially lead to lifelong activity participation. **PURPOSE:** The purpose of this study was to see if a statistical change could be identified in a variety of physiological variables among a group of college age women enrolled in a PA course. **METHODS:** Thirty one women with an average age of 20.53 (±1.11) years participated. Participants were enrolled in either a 13-week aerobic dance fitness (FIT) course (n = 19) or a non-fitness course, which served as the control group (n = 12). Pre-test assessments were completed during the first week of the semester. The assessment included anthropometric measurements, resting systolic blood pressure (rSBP) and heart rate, a submaximal treadmill test, ACSM abdominal curl (ABcurl) and push up tests, ACSM Sit and Reach (SR), and bioelectric impedance for body fat assessment. Post-test assessments were completed during the final week of class. To be included in the study, participants must not have been absent for more than two days during the semester. **RESULTS:** Paired sample t-test statistics were conducted to determine significant changes in each group (p < .05). A significant decrease in rSBP (-4.63 9.11 mm/hg) was observed in the FIT group (t = 2.22, p = .041). Significant increases in SR (0.83 1.51 inches) as well as ABcurl (9.05 14.50) performance (t =

2.39, $p = .028$; $t = 2.72$, $p = .014$) respectively. No significant change was seen in the control group. However, when a Repeated Measures ANOVA analysis was conducted, all significant differences disappeared. This was likely due to the large standard deviations and non-normal distribution of the sample data. **CONCLUSION:** During a 13-week aerobic dance course, this study was unable to find statistically significant differences in a variety of physiological variables among a group of college age women when compared to a control group. More research is needed to determine if a larger sample size might uncover significant changes and whether these changes are sustained among this group. IRB# 1415-0009

Effects of Hypoxic/Altitude Training on Bone Health in Obese Adolescents under Weight Loss
 Lianshi Feng, Huan Gao, Li Zhang, Jianfang Xu, Yingli Lu.
China Institute of Sport Science, Beijing, China. (Sponsor: Tongjian You, FACSM)
 Email: fengls98@126.com
 (No relationships reported)

PURPOSE: To explore the effects of short-term stimulated hypoxic training or altitude training on body weight, bone mineral content (BMC), bone mineral density (BMD) and bone area (BA) in obese adolescents undergoing dietary weight loss.

METHODS: Forty seven healthy obese adolescents ($BMI=30.82-35.93 \text{ kg/m}^2$) were included in this study. The interventions lasted for four weeks. The plain group (PG, $n=18$) lived in the plain (Shanghai, China) and trained 5 hours every day. The altitude group (AG, $n=11$) lived in real altitude (Duoba, Qinghai, China; 2360m) and trained 5 hours per day. The hypoxic group (HG, $n=18$) slept in simulated 2300m normobaric hypoxia 8-10 hours every night and trained 2 hours in hypoxia and 3 hours in normoxia every day. All groups underwent dietary restriction and the energy intake ranged from 1322 to 2081 kcal/day. Heart rate was monitored every ten minutes during exercise to ensure the intensity was in the target range, which was 40% of the heart rate reserve and determined by the Karvonen equation. BMC, BMD and BA were measured by dual x-ray absorptiometry before and after intervention. A three (PG, AG and HG) by two (Pre and Post) analysis of variance (ANOVA) was used for statistical analysis.

RESULTS: Body weight decreased significantly after four weeks in all three groups (all $p<0.05$). There were significantly more weight reductions in the HG and PG groups than in the AG group (10.18% and 9.34% vs. 7.56%, both $p<0.05$). There was no significant group difference between the HG and PG groups. Total BMC increased significantly in the PG group ($p<0.05$) but not in the HG and AG groups. There were no significant group differences in changes of BMC. Total BMD increased significantly in all 3 groups (all $p<0.05$), but no significant group differences were seen on the BMD changes. Total BA did not change over the 4-week intervention in all groups.

CONCLUSIONS: Four weeks of diet plus plain training, diet plus stimulated hypoxic training and diet plus altitude training resulted in weight loss and similar improvements in BMD. Future studies are needed to identify the health benefits of hypoxic/altitude training for this population. (Supported by NSFC 31471139 and CISSFRF 16-18)

 Email: Juan.Colado@uv.es
 (No relationships reported)

Physical inactivity often increases during childhood as does the risk for early-onset of lifestyle-related diseases. The development of new sports, if deemed to be of sufficient intensity, may add diversity to the more traditional options in order to promote healthy lifestyles. **PURPOSE:** To compare children's average and maximum heart rate percentage (HRP) while playing a new racket sport with heart rate while playing two traditional sports. **METHODS:** 22 girls and 32 boys (age=10.4±0.1yr; body fat=23.2±1.5%; ht=147.4±0.9cm) played three sports for 25 minutes in a randomized order on different days: Soccer (SC), Basketball (BK) and Spiribol (SP). SP is played inside a 7m-diameter circle separated into two playing areas. A tennis ball attached to 2m of rope is suspended from a 2.2m-high pole in the middle of the circle. The goal of the game is to hit the ball with a racket and be the first to role the rope up the pole. Four SP familiarization sessions were performed prior to the study due to its novelty. Average and maximum HRP was measured with a Polar H7-Bluetooth 4.0. Body fat was measured with bioelectric impedance. A repeated measures ANOVA was used for analysis. **RESULTS:** Average HRP of the three sports were inside the thresholds for being considered healthy activities, although differences ($p<0.05$) were obtained between all of them (SC 80.9±1.3; BK 84.0±1.3; SP 73.4±1.2). However, average HRP in girls was not different between SC (78.3±2) and SP (73.8±2) but both were lower

than BK (83.6±2). In boys, average HRP for SC (83.4±1.5) and BK (84.4±1.6) was not different but both were higher than SP (73.1±1.5). Maximum HRP was similar for SC and BK (93.5±1.1 and 94.7±1, respectively) and both were higher than SP (85.3±1.2). Similar significant differences were observed when maximum HRP was differentiated by gender. **CONCLUSION:** SC and BK both elicit slightly higher HRP compared to SP. However, SP is a new sport that appears to provide heart rate responses within the healthy threshold of intensity for children so it could be a good alternative to traditional sports. In addition, SP can be played in a smaller area that makes it more practical when space is limited. Further research is needed to determine enjoyment and satisfaction levels when playing SP, as well as if more familiarization results in higher average and maximum HRP.

Can a Parental Modeling Physical Activity Intervention Improve Physical Activity and Body Composition in Adults and Young Children
 Katrina D. DuBose, FACSM, Deirdre Dlugonski, Kelli Soos.
East Carolina University, Greenville, NC.
 Email: dubosek@ecu.edu
 (No relationships reported)

PURPOSE: This study examined the impact of an 8-week parental modeling physical activity (PA) intervention on parent and child PA and body composition.

METHODS: Twenty-six parents participated in an 8-week PA intervention with their 1 - 5 year old child. The adults were randomly placed into an intervention ($n=19$) or control ($n=7$) group. The intervention group received weekly phone calls with a coach. The coach discussed strategies to change parent and child PA. PA (activity monitor) and body composition (height, weight, and circumferences) were assessed before and after the intervention. Body mass index (BMI) and BMI z-scores were calculated. Time spent in sedentary behavior, light, moderate, and vigorous PA was determined using cut points by Freedson et al. (adult), Trost et al. (1 - 2 year old children), and Butte et al. (3 - 5 year old children). Data analyses were conducted using the intention-to-treat method. A series of 2 (group: control/intervention) X 2 (time: pre/post) ANCOVAs were run to examine the effect of the intervention on PA levels in the parents and children adjusting for wear time. A series of 2 (group: control/intervention) X 2 (time: pre/post) ANOVAs were run to examine the effect of the intervention on body composition (weight, BMI, waist circumference) in the parents and children (BMI z-score). Effect sizes (ES) were calculated and significance was set at $p<0.05$.

RESULTS: Among the parents, group, time, and interaction effects were non-significant for PA levels, weight, BMI, and waist circumference ($p>.05$). ES indicated the intervention group had medium reductions in sedentary behavior (-.57) and increases in vigorous PA (.65), whereas controls had small reductions in sedentary behavior (-.14) and medium reductions in vigorous PA (-.76). Regarding the children's data, the PA levels and BMI z-scores were similar by group and time ($p>.05$). Small decreases in sedentary behavior (-0.18), light (-.21), and mod (-.11) PA were observed in the intervention children, whereas control children had small increases in sedentary behavior (.24), and large decreases in light (-.92) and moderate (-.90) PA.

CONCLUSIONS: A parental modeling PA intervention may have positive effects on parent's and children's PA levels. Supported by: Research/Creative Activity Award, East Carolina University

The Effects of Different Exercise on Chronic Inflammatory Markers in Obese Youth
 XU JIANFANG, ZHANG LI, FENG LIANSHI, LU YINGLI.
CHINA INSTITUTE OF SPORT SCIENCE, BEIJING, China.
 Email: xujianfang@ciss.cn
 (No relationships reported)

PURPOSE: With the increasing number of overweight and obese individuals around the world, it is not only a mental stress to the one who is overweight or obese, but also economic and social burden to the society. It is known to us that the obesity is a chronic inflammatory status, the purpose of this research is aimed to discuss the effects of aerobic and resistance exercise on chronic inflammatory in obese youth by testing some key chronic inflammatory markers.

METHODS: With the diet controlling, 37 volunteers (male-18, female-19) were divided into 2 groups, such as the aerobic exercise (AE, with the intensity of 30%-40% heart rate reserve for 1 hour per day for 4 weeks, 6 days/week by jogging or aerobics) group (male-10, female-10, 21.1±2.0 years, BMI=30.28±2.17) and resistance exercise (RE, with intensity of 80%-90% heart rate for 1 hour per day for 4 weeks, 6 days/week by resistance exercise) group (male-8, female-9, 21.1±1.6 years, BMI=30.10±2.35). The exercise time lasted for 4 weeks and there had three times to take the venous blood samples of the volunteers to test the contents of TNF- α and IL-6 by using ELISA AE the beginning, 4 weeks later and 8 weeks later (the last 4 weeks without diet controlling and exercise).

RESULTS: The body weight of AE and RE groups decreased significantly after 4 weeks, and it maintained AE a low level after 8 weeks (AE: 92.13±13.68 kg to

84.08±11.90 kg, then to 83.86±11.59 kg, RE: 86.68±13.91 kg to 79.79±11.82 kg ($p<0.01$) then to 79.72±12.36 kg). In addition, the body fat rate of the subjects also has the same tendency as the body weight (AE: 38.71±5.79% to 34.21±6.91% ($p<0.01$), then to 33.09±7.42%; RE: 38.84±5.54% to 34.65±6.51%, $p<0.01$, then to 33.99±7.33%). The level of TNF- α decreased significantly after 8 weeks in both groups (AE: 16.29±2.55 ng/ml to 14.93±2.48 ng/ml, RE: 16.60±2.22 ng/ml to 14.13±1.82 ng/ml, $p<0.05$). The contents of IL-6 decreased significantly after 4 weeks, but increased after 8 weeks later.

CONCLUSIONS: Both aerobic and resistance exercise are helpful to lose weight by reducing the body fat. And the chronic inflammatory of the body is inhibited after 4 weeks aerobic and resistance exercise by decreasing the level of TNF- α and IL-6.

School Based Pedometer Intervention: Are Standard Reporting Protocols Masking Potential Benefits In Previously Inactive Subpopulations?

Jade L. Morris¹, Andy Daly-Smith¹, Margaret A. Defeyer², Jim McKenna¹, Steven Zwolinsky¹, Melissa Fothergill², Pamela L. Graham², Scott Lloyd³. ¹Leeds Beckett University, Leeds, United Kingdom. ²Northumbria University, Newcastle upon Tyne, United Kingdom. ³Redcar & Cleveland Borough Council, Redcar, United Kingdom.

Email: jade.morris@leedsbeckett.ac.uk

(No relationships reported)

Intervention outcomes, expressed by mean changes, often overlook variable responsiveness. This may mask some intervention successes. **PURPOSE:** To explore individual variability in children completing a pedometer intervention. **METHODS:** Six schools ($n=152$) were ranked and paired by socio-economic status, with one per pair randomly allocated to a six-week teacher-led pedometer intervention (PI, $n=81$) or control (C, $n=71$). Actigraph GT1M accelerometers assessed physical activity (PA) for 7 days. Evenson cut points identified total daily sedentary (SED), light PA (LPA) and moderate-to-vigorous PA (MVPA) expressed as percentage (%) of total daily wear time. For analysis, a PA return of 480+ mins/d, ≥ 3 school days for pre and post-tests was needed. Mean pre daily MVPA mins were used to categorise subgroups; Non-Achievers <30 (NA1), NA 31-44 (NA2), NA 45-59 (NA3), Achievers >60 (ACH). **RESULTS:** From 84 included participants ($F=60\%$, 9.9 ± 0.3 yrs), no significant differences were found between PI ($n=52$) and C ($n=32$) for increases in % time in MVPA (0.30 ± 0.67 v 0.13 ± 0.29), LPA (2.03 ± 4.63 v -0.05 ± 4.25) and reducing % of SED time (2.33 ± 5.89 v -0.08 ± 5.52). More PI (17 to 27%) than C (16 to 19%) pupils met 60mins/d guidelines. Versus C, two PI groups improved MVPA. The greatest increases were in NA1 (1.52% above C) and $+2.05\pm 2.34\%$ from pre-test. PI-ACH decreased % time in MVPA from pre to post ($-2.75\pm 2.85\%$). All PI subgroups increased % time spent in LPA versus C, with NA2 improving 3.54% above C and PI-NA1 having the greatest improvement ($+3.60\pm 6.37\%$). All PI groups had more favourable SED results; three reducing SED time. The greatest reduction versus C was NA3 (3.95%). The greatest total reduction was in PI-NA1 ($-5.65\pm 7.80\%$). Greater proportions of participants met the 60mins/d guidelines in three PI groups versus C. The largest increase was seen in NA3 (+31%); both ACH groups showed a decline (PI 100 to 67%; C 100 to 40%). **CONCLUSIONS:** Despite no significant overall PI effects versus C, a greater % of participants met the 60mins/d guidelines. PI found clusters of responsiveness. Pre-PI NA benefited most demonstrating positive changes in eight of nine activity outcomes compared to C, maybe at the expense of the most active. While participant numbers are small, they justify examining sub-population variability in subsequent research.

High-intensity Circuit-training Improves Physical Capacity And Cardiometabolic Risk Markers In Overweigh Adolescents

Daniel Gonçalves¹, Joaquim Fontoura², Cristine Schmidt¹, Maria João Neuparth³, Carolina Canotilho¹, Francisca Serrão¹, Marta Sobral¹, Rita Ferreira³, José Oliveira¹. ¹CIAFEL, Faculty of Sport, Porto, Portugal. ²João Gonçalves Zarco High School, Matosinhos, Portugal. ³University of Aveiro, Aveiro, Portugal. Email: danielmgon@gmail.com

(No relationships reported)

Introduction: Despite the well-known benefits of exercise training of moderate intensity for improving cardiometabolic health in overweight adolescents, it remains to be determined the extent of benefits provided by high intensity exercise.

Purpose: to evaluate how much a high-intensity circuit-training (HICT) program would change health related fitness and cardiometabolic risk factors in overweight adolescents.

Material and Methods: 18 students (age 16 ± 0.9 yrs and BMI 28.2 ± 0.26) were submitted to HICT program (3 days/week, 1hour/session, for 9 weeks in their school

facilities). Before and after the HICT program, anthropometrics and body composition [body weight (BW), waist circumference (WC), and fat mass (FM) and free fat mass (FFM)], physical fitness (Fitnessgram), blood pressure and fasting biochemical analysis [Glucose (Gluc), low density lipoprotein-cholesterol (LDL-C), triglycerides (TG), alanine aminotransferase (ALT) and aspartate transaminase (AST)] were assessed.

Results: HICT induced significant reductions in BW (77.15 ± 13.01 vs. 75.96 ± 12.35 Kg), WC (93.10 ± 10.43 vs. 90.31 ± 11.66 cm), FM (27.80 ± 6.61 vs. 24.64 ± 6.29 Kg) and an increase in FFM (49.37 ± 9.33 vs. 51.33 ± 9.29 Kg) ($P<0.001$). Both systolic (128 ± 12.7 vs. 117 ± 7.2 mmHg) and diastolic (66 ± 7.8 vs. 62 ± 4.4 mmHg) blood pressure were also significantly reduced ($P<0.001$). Regarding physical fitness, the HICT resulted in a significant improvement in the curl-up (38.1 ± 25.6 vs. 59.5 ± 28.9 rep), push-up (9.7 ± 6.9 vs. 16.5 ± 6.4 rep), horizontal jump (131.3 ± 25.6 vs. 141.3 ± 28.9 cm) and 20m shuttle run test (29.1 ± 11.9 vs. 38.9 ± 6.4 laps) ($P<0.001$). Finally, Gluc (85.9 ± 12.4 vs. 76.8 ± 12.3 mg/dL), LDL-C (151.7 ± 25.8 vs. 93.9 ± 27.8 mg/dL), TG (66.5 ± 21.4 vs. 62.3 ± 23.5 mg/dL), ALT (18.1 ± 5.5 vs. 12.0 ± 4.1 U/L) and AST (18.0 ± 6.5 vs. 13.9 ± 3.1 U/L) were all significantly reduced ($P<0.001$) after the HICT program.

Conclusion: Our results support the notion that a short-term high-intensity circuit-training program improves physical fitness and modulate positively physiological health markers in overweight adolescents.

The Effects Of 6-week Agility Ladder Drills During Recess Intervention On SEBT In School Boys

Siu Kuen NG, Chung Wai Cheung, Kim Wai SUM. *The Chinese University of Hong Kong, Hong Kong, China.*

Email: sarobert1218@gmail.com

(No relationships reported)

PURPOSE: The purpose of this study was to examine the effects of 6-week agility ladder drills during recess time on dynamic balance ability in school boys aged 7-13.

METHODS: Seventy one school boys (9.82 ± 1.90 years; 1.38 ± 0.13 m; 33.28 ± 9.64 kg; BMI 17.25 ± 3.18 kg m⁻²) were assigned randomly into a control ($n = 37$) and experimental ($n = 34$) groups. The experimental group performed 3 agility ladder training sessions per week for 6 weeks. Each training session included six sets of the training programme which consisted of 6 exercises in the order of side jump, in and out, hopscotch, left and right leg hop, and icky shuttle, with 30 seconds rest between each set. Both groups were assessed using Star Excursion Balance Test (SEBT) before and after 6-week recess intervention.

RESULTS: A statistically significant increase in post-training SEBT scores from 6.2% to 19.1% was seen in all directions for the experimental group, with a score that was better than the control group for both limbs. Repeated measure ANOVA revealed a significant main effect for time was observed on the three normalised reach distances of left limb, $F(1, 69) = 2.054$, $p = .000$; partial $\eta^2 = .305$; three normalised reach distances of right limb, $F(1, 69) = 2.054$, $p = .000$; partial $\eta^2 = .313$; and six normalised reach distances of both right and left limbs, $F(1, 69) = 2.054$, $p = .000$; partial $\eta^2 = .305$. There was no statistically significant interaction effect between time and group (control and experimental group) on the three composited distances of left limb, $F(1, 69) = 2.054$, $p = .156$; partial $\eta^2 = .029$; three normalised reach distances of right limb, $F(1, 69) = 1.825$, $p = .181$; partial $\eta^2 = .026$; and six normalised reach distances of both right and left limbs, $F(1, 69) = 2.054$, $p = .000$; partial $\eta^2 = .305$.

CONCLUSIONS: The dynamic balance ability of the school boys was significantly enhanced in 6-week agility ladder drills training after recess intervention.

The Influence Of Contextual Factors On Recess Physical Activity Among Elementary School Children

Gabriella M. McLoughlin, Alicia Covello, Caitlyn Edwards, Nicholas Baumgartner, Morgan Curran, Toni Burkhalter, Kim Graber, Amelia M. Woods, Naiman Khan. *University of Illinois, Urbana, IL.*

Email: gmcloug2@illinois.edu

(No relationships reported)

PURPOSE: Childhood obesity remains a major public health concern in the United States. Physical activity (PA) opportunities, particularly within the school day, can prove particularly potent in attenuating childhood obesity etiology. Given the rapid decline in physical education in elementary schools, school recess has increasingly become a vital unstructured time during the school day that may facilitate positive behavior change and maximize opportunities for PA. However, the child characteristics and contextual/environmental factors that may influence engagement in PA during recess are unclear. Therefore, the aims of the present study were: (1) assess the

relationship between sex, weight status, and PA during recess; and (2) determine the influence of recess duration (15min vs. 30min) and timing (i.e., before lunch vs. after lunch) on recess PA, following adjustment of individual factors.

METHODS: Children in fourth and fifth grade (N=151, 91 females) were recruited from two public suburban schools in the Midwest. PA during recess was measured using accelerometry (ActiGraph WGT3x+) over five days. Height and weight measurements were used to determine BMI (kg/m²). Recess was offered either prior to or immediately following lunch in each school, for 15 or 30 minutes, respectively.

RESULTS: A negative relationship was found between BMI and vigorous PA ($r=-.207$, $p=.02$), as well as step count ($r=-.178$, $p=.05$). Further, sex was negatively correlated with MVPA ($r=-.315$, $p=.00$ [male=0, female=1]). Significant interaction effects for PA were found between recess timing and recess duration ($F = 11.68$, $p = .00$) whereby for children who had a longer recess duration, scheduling recess after lunch yielded the greatest MVPA. In contrast, for children in the shorter recess group, MVPA was significantly lower when recess was scheduled after lunch rather than beforehand. These interactions persisted even after adjusting for sex and BMI.

CONCLUSION: These findings reveal that individual and contextual factors such as recess timing and duration may influence the level of activity during recess; longer recess periods may yield greater MVPA outcomes when scheduled after lunch. Future experimental research is warranted to determine whether modification of these variables improves children's PA in the school setting.

Geographic Variances in Achieved Moderate-to-Vigorous Physical Activity Within a Structured Afterschool Program

Marlo Dell'Aquila, Ryan McVann, Zi Yan, Kevin Finn, Kyle McInnis, FACSM. *Merrimack College, North Andover, MA.*
(No relationships reported)

PURPOSE: The afterschool time has been identified as an important opportunity for achieving moderate-to-vigorous physical activity (MVPA) for children. For children's health, afterschool physical activity programs should be structured to yield maximal MVPA minutes. The purpose of this study was to examine the differences in the average MVPA during 30-minute period using a structured program design among children who participated at four different geographic locations. **METHODS:** Data was collected from a total of 2963 children who participated in a 30-minute after-school physical activity program (i.e., Active Science) in multiple YMCAs in the following regions: New England (n=688, male n=285, age M= 9.73 ± 0.63), Mid-Atlantic (n=758, male n=432, age M= 9.04 ± 0.98), Midwest (n=711, male n=339, age M=8.18 ± 0.51) and Southeast (n=806, male n=396, age M= 8.83 ± 1.59). Children wore accelerometers to track their MVPA during the program time. **RESULT:** The average time and standard deviation of MVPA for New England, Mid-Atlantic, Midwest, and Southeast were M=12.97 ± .39, M=10.605 ± .58 M=13.585 ± .72, M=8.355 ± .60 respectively. ANOVA showed that there were significant differences between the regions, $F(3,2959)=115.68$, $p \leq .001$. Post Hoc Test showed that New England and Midwest were significantly higher in MVPA than the Southeast $p \leq .001$ and Mid Atlantic $p < .01$. There was no significant difference between New England and the Midwest. **CONCLUSION:** Children participating in a standardized afterschool program at different geographic locations can obtain significantly different MVPA. While further research is needed to determine the causation of these geographical differences, the findings emphasize that the quality of program implementation (e.g., program strategies) should be considered in addition to the quantity of the program (e.g., program time). Regardless, afterschool physical activity programs should continue to focus on improving MVPA.

3132 Board #37 June 2 3:30 PM - 5:00 PM

The Correlation of Parental Support in Primary School Children Obesity and Physical Activity

Chiung Yun Chang¹, Ming Fen Hsu¹, Ssu Hsien Yu², Hsueh I Lin², Shih Chang Chen². ¹University of Taipei, Taipei, Taiwan. ²National Ilan University, Ilan, Taiwan.
(No relationships reported)

PURPOSE: The aim of this study was to determine the correlation of parental support between obesity and physical activity in primary school children.

METHODS: All data was collected from '2009 Taipei City School Children Physical and Mental Health Survey' in present study. We extracted the data from sixth grade students as analyze sample. The grouping criterion of parental support to exercise is whether the parents take children to exercise outside every week. The differences between two groups are analyzed by age-adjusted ANCOVA, Chi-square test and multivariate logistic regression analysis. Age-adjusted ANCOVA was used to determine the differences of anthropometric data, including weight, height, body mass index (BMI), waist circumference, hip circumference and waist-to-hip ratio (WHR). Chi-square test and age-adjust multivariate logistic regression analysis were used to analyze the proportion differences in children obesity, exercise partner choice preference. The statistical significant level was defined as $\alpha = 0.05$.

RESULTS: Children in the parent-support group had significantly lower height, weight, BMI, waist circumference, WHR and screen time compared to parent-non-support group ($p < .05$). Compared to the children in parent-support group, the children in parent-non-support group had higher proportion of obesity ($p=0.6$), proportion of finding exercise partner was 11.8% lower ($p < .05$). The proportion of children won't do exercise without partner was also 11.3% higher than those children in parent-support group ($p < .05$). Furthermore, the proportion of accumulating exercise time below 210 minutes per week was 2 % higher in parent-non-support group ($p < .05$). Moreover, the proportion of the obese parents was also noticeably higher in parent-non-support group.

CONCLUSIONS: Parental support is an important factor which affects children obesity status and physical activity. More importantly, the parents' obesity prevalence will affect whether they support their children to exercise or not. Our results suggest that parental participation and parental weight management may be included in the strategy of children obesity prevention.

Association between Physical Activity Self-efficacy and Physical Activity Engagement in Chinese College Students

Ying Tian, Zifei Wang, Yunqiu Liang, Bangli Peng, Xiaolin Cui. *Shenyang Normal University, Shenyang, China.*
Email: tianying2311@163.com
(No relationships reported)

Physical activity self-efficacy has been considered as an important correlate of physical activity behaviors. However, evidence on association between physical activity-related self-efficacy with different domains and physical activity engagement is still limited.

PURPOSE: To investigate the association between physical activity self-efficacy for learning efficiency, physical fitness, psychological functioning, and overall health status and physical activity engagement in college students. **METHODS:** This cross-sectional study was comprised of 1,836 college students (1,138 males, 698 females) in China. Physical activity engagement and physical activity self-efficacy were assessed by a self-administered questionnaire. For physical activity engagement assessment, the duration of physical activity in each physical activity participation was divided into four categories as follows: <20, 20-40, 40-60, and >60 minutes; and the frequency of physical activity was divided into six categories as follows: 0, 1, 2, 3, 4, and >5 times/week. Furthermore, physical activity self-efficacy for learning efficiency, physical fitness, psychological functioning, and overall health status was evaluated by five scales (1-5) from "not effective" to "effective". Higher scores indicate higher levels of physical activity self-efficacy. The association between physical activity self-efficacy and physical activity engagement was examined using chi-squared test. **RESULTS:** In male students, participants with higher physical activity self-efficacy for learning efficiency (P for trend = 0.006), physical fitness (P for trend = 0.006), psychological functioning (P for trend < 0.001), and overall health status (P for trend = 0.023) tended to have higher frequency of physical activity engagement. These findings were also observed in association between physical activity self-efficacy and duration of physical activity engagement (P for trend < 0.05 for all). Similarly, physical activity self-efficacy was also significantly associated with physical activity engagement in female students. **CONCLUSION:** This study indicates that higher physical activity self-efficacy is associated with higher physical activity engagement in Chinese college students. Prospective studies are warranted to confirm these findings.

The Differentiation Effect of College Students' Status on Physical Activity and Psychosocial Perception

Xiaoxia Zhang, Ping Zhu. *University of North Texas, Denton, TX.*
Email: XiaoxiaZhang@my.unt.edu
(No relationships reported)

An increasing number of young adults with physically vulnerable conditions are entering college each year (Maslow et al. 2011). Since only 50.4% of college students meet the physical activity (PA) recommendation, it is essential to find out the differences of college students who are healthy and who are vulnerable.

PURPOSE: This study is to examine the difference of PA behaviors (i.e. intensity, frequency, and time) and psychosocial perceptions (i.e. attitude, subjective norm, perceived behavioral control, and intention) among college students (healthy group vs. vulnerable group).

METHODS: A cross-sectional design was used and total 684 college students were recruited from five universities in Shanghai, China. There were 451 students in healthy group (67% were female, $M_{age} = 19.3 \pm 1.0$) and 234 students were in vulnerable group (71% were female, $M_{age} = 19.47 \pm 1.0$). Students were identified as vulnerable by certified physicians [i.e., specific diseases (49.6%), short-term injury (29.9%), physical weaknesses (18.8%), and disabilities (1.7%)]. All participants completed a validated questionnaire assessing their attitude, subjective norm, perceived behavioral control and intention (Hagger et al., 2007), and PA behaviors including intensive, time, frequency and overall PA (Yu et al., 2013).

RESULTS: A descriptive discriminant analysis (Hubery, 1994) revealed that the four subgroups (gender x group) differences accounted for 19% of the variance among the eight variables, and males in healthy group were significantly different from the other three subgroups. Among those, intensity (88.9%) and time (27%) in PA behaviors, and intention (15.4%) and attitude (4.7%) in psychosocial perceptions emerged as the promising dominant contributors to the group differences.

CONCLUSIONS: Consistently with previous studies, males in healthy group more likely participate in intensive PA and persist longer than other subgroups, and they have more positive attitude and intention to engage in PA. Colleges need to focus on PA interventions among females on both conditions and males with vulnerable conditions.

Using Theory of Planned Behavior to Examine Chinese Adolescents' Moderate and Vigorous Physical Activities

Hongxin Li¹, Tao Zhang¹, Tsz Lun Chu¹, Gene Lee Farren¹, Zhendong Zhang². ¹University of North Texas, Denton, TX. ²Zhengzhou University, Zhengzhou, China.
 Email: Hongxin.Li@unt.edu
 (No relationships reported)

In China, academic excellence is often considered the most important indicator of success in adolescents, while physical activity (PA) is often discouraged because it drains energy and garn time away from academic study (Yu et al., 2006). However, recent research has indicated vigorous PA (VPA) rather than moderate PA (MPA), emerges as the significant predictor of cardiovascular health, as well as a protective factor against mental health complaints (Gerber et al., 2014). The theory of planned behavior (TPB; Ajzen, 1985) is a prominent theoretical model that examines the antecedents (i.e., attitude, subjective norm, perceived behavioral control, and behavioral intention) of planned behaviors such as PA. As such, research has indicated higher VPA demonstrated higher behavioral intention, while higher MPA demonstrated lower behavioral intention in Western cultures (Rhodes & de Bruijn, 2010). **PURPOSE:** To test the measurement and structural parameters of the TPB among a sample of Chinese adolescents in a MPA and a VPA context. **METHODS:** Participants were 219 ninth grade students (53% female, $M_{age} = 16.33 \pm .55$) from three high schools in Zhengzhou, China. Participants completed validated questionnaires that assessed their attitudes, subjective norms, perceived behavioral control, behavioral intention, and self-reported MPA and VPA behaviors. **RESULTS:** Correlation analyses revealed a pattern of positive relationships among the study variables. Confirmatory factor analyses and structural equation models revealed good-fitting models within both the MPA model ($\chi^2 [84] = 180.77, p > .01, CFI = .94, RMSEA = .07, SRMR = .06$) and VPA model ($\chi^2 [84] = 189.37, p > .01, CFI = .93, RMSEA = .08, SRMR = .06$). Standardized path coefficients indicated attitude ($\gamma = .15$), subjective norm ($\gamma = .18$), and perceived behavioral control ($\gamma = .46$) were significantly positively associated with behavioral intention ($p < .01$). In addition, standardized path coefficients indicated behavioral intention was significantly positively associated with VPA ($\beta = .23, p < .01$), but not MPA ($\beta = .04, p = .55$). **CONCLUSION:** This study further supported the heightened relationship between behavioral intention and VPA in Chinese adolescents. Thus, the findings highlighted the importance of enhancing TPB constructs to foster VPA in Chinese adolescents.

3136 Board #41 June 2 3:30 PM - 5:00 PM
The Effects of Resistance Training Programs on the Physical Self-Perceptions of College Females

Kelsey L. Zachman, James Whitehead, FACSM, John Fitzgerald, Jesse Rhoades. University of North Dakota, Grand Forks, ND.
 (Sponsor: James Whitehead, FACSM)
 (No relationships reported)

While it is generally accepted that exercise enhances physical self-perceptions (PSPs), the impact of resistance training programs on females' self-perceptions is unclear. Because exercise is an important public health behavior, and because PSPs have motivational associations, research on this topic may have important implications for exercise promotion. **PURPOSE:** To investigate the effects of two different types of resistance training programs on the PSPs of college age females. **METHODS:** College students with no background in resistance training ($n = 20$) were randomized to a muscular strength (MSTR $n = 10$), or a muscular endurance (MEND $n = 10$) resistance training group. A comparison (COM) group ($n = 10$) was recruited from inactive college students. The resistance training groups followed strength- or endurance-oriented progressive resistance training programs for nine weeks. Participants completed the Physical Self-Perception Profile (PSPP) pre- and post-intervention. Height, weight, skinfolds and circumference measurements were also taken pre and post. **RESULTS:** Analyses utilized ANCOVAs followed by Bonferroni-adjusted (p set at $< .017$) pairwise comparisons. The only physical change was a significant reduction in the sum of skinfolds in the MSTR group ($p = 0.013$). Analyses of PSPP changes showed significant effects for MSTR on the physical condition subscale ($p = 0.004$,

and on the strength competence subscale ($p = 0.015$) and a near-significant effect on the attractive body adequacy subscale ($p = 0.018$) that may be practically significant. **CONCLUSION:** Strength-oriented resistance training produced improvements in some aspects of college females' physical self-perceptions.

3137 Board #42 June 2 3:30 PM - 5:00 PM
Family Factors Associated with Physical Activity and Sedentary Time in Children Living in Puerto Rico

Mario A. Muñoz¹, Scott E. Crouter, FACSM². ¹University of Massachusetts Boston, Boston, MA. ²The University of Tennessee, Knoxville, TN.
 Email: mario.munoz@umb.edu
 (No relationships reported)

PURPOSE: The purpose of this study was to examine associations among parental perceptions of their children's skills and participation in physical activity (PA) and parental intentions of changing health behaviors with objectively measured PA in Puerto Rican children. **METHODS:** Seventy-three children (mean±SD; age, 8.9±1.3 yrs; BMI 33.1±10.4 kg·m⁻²) wore an ActiGraph GT3X accelerometer on their right hip for seven days to estimate time spent in sedentary behaviors (SB), light (LPA) and moderate-to-vigorous (MVPA) PA, and total activity counts for the vertical axis (TAC_{va}) and vector magnitude (TAC_{vm}). Children also completed a motor proficiency test (MPT), a sit-up test (SUT), and sum of skinfolds (SOS) from two sites (triceps and sub-scapular) was obtained. Parents completed questions on their perceptions (PP) of their child's abilities and parental intentions (PI) to modify family health related behaviors. Partial correlations, controlling for accelerometer wear time, were used to examine relationships between PP, PI, MPT, SOS and SUT, with time spent in SB, LPA, MVPA, and TAC_{va} and TAC_{vm}. **RESULTS:** Significant differences were found between boys and girls for time spent in SB (239.3±74.6 vs. 296.2±128.4, respectively, $p=0.024$), and MVPA (126.4±40.7 vs. 85.7±42.3, respectively, $p<0.001$). In girls, PP of child's speed while running was associated with TAC_{va} ($r=0.43$) and TAC_{vm} ($r=0.39, p<0.05$). PP of how eating behaviors of the family influence eating habits of their children was correlated with SB ($r=0.43$), MVPA ($r=0.41$), TAC_{va} ($r=0.50$), and TAC_{vm} ($r=0.52$; all $p<0.01$). PI of limiting the amount of sweetened beverages was correlated with SB ($r=0.47$) and TAC_{vm} ($r=0.37$; all $p<0.05$). In boys, MVPA and TAC_{va} were negatively correlated with SOS ($r=-0.38$ and -0.35 , respectively; $p<0.01$). MVPA was positively correlated with PI to engage in 30-min of PA at least 5 d/wk. ($r=0.36, p<0.05$). TAC_{vm} was positively correlated with parental report of age that their child first walked without support ($r=0.36, p<0.05$). **CONCLUSIONS:** Several modifiable factors related to PP and PI are related to time spent in SB and PA in Puerto Rican children. Parents with intentions to positively make changes in behaviors could affect positively impact time spent in PA.

3138 Board #43 June 2 3:30 PM - 5:00 PM
Physical Activity Level Increase Follow Up Health Educational Program In Overweight And Obese Children: Pilot Study

Suliane B. Rauber¹, Henrique Lima Ribeiro¹, Alcyane Marinho², Bibiano Madrid³, Joyce Bomfim Vicente¹, Carmen Silvia Grubert Campbell¹. ¹Universidade Católica de Brasília, Águas Claras, Brazil. ²Universidade do Estado de Santa Catarina (UDESC), Santa Catarina, Brazil. ³Universidade Paulista (UNIP, Brasília, Brazil.
 (No relationships reported)

PURPOSE: This study aimed to investigate the impact of a Health Educational Program for Children at 5 days of Camp and 12weeks follow up on the physical activity level (PAL) and sedentary behaviour (SB) in overweight and obesity children. **METHODS:** Health Educational Program for Children (HEPchild) designed for children who are overweight or obese and was divided into two phases: The first phase (PHASE 1) consisted of pré assessments and five-day camp (CAMP); and PHASE 2 corresponded to the 3 months follow-up, and a post follow-up assessments. Thus, the sample that attended the PHASE 1 was 20 children (9.4 ± 1.1 years; 9 boys: 10.2 ± 0.9 years; 11 girls: 9.2 ± 1.3 years), 5-days summer camp on a farmplace to develop educational, with interdisciplinary team (Physical Educator, Endocrinologist, Psychologist, Educator and Nutritionist). The Phase 2 children and family's were followed for 3 months (a weekly meeting for two hours in a total of 12 meetings). The end of the study composed by 12 children (8 girls and 4 boys, 9.4 ± 0.96 years), who completed 75% of the meetings. To check the PAL and the SB was applied the questionnaire proposed by Militão et al. (2013) and analyzed physical activity level at sports, in leisure time during the week, level in leisure time during weekend, moving to and at school, sedentary behavior during the week and weekend. **RESULTS:** After FO 25% of children remained more active (> 1500 and <3000METs per week) in comparison to before CAMP. In contrast the amount of sedentary children (<600METs week) decreased by 15% and the insufficiently active (600 at 1500METs per week) increased by 15%. No child was classified as very active (> 3000METs per week) in any time. The PAL leisure time during the week and during the weekend significant

increase, 26.06% and 14, 1%, respectively, when comparing to pre CAMP and 12 weeks of follow-up. SB during the week and the weekend showed a significant mean reduction of 177.14 and 41.43 minutes respectively.

CONCLUSIONS: The Health Educational Program for Children contributed to the increase in physical activity level and reduced sedentary behaviour in overweight and obese children.

3139 Board #44 June 2 3:30 PM - 5:00 PM
Feasibility and Acceptability of Implementing Physical Activity Programs at a Residential Center for High-Risk Youth

Kari J. Hyslop (Hilgendorf)¹, Judy Knuth². ¹Western Washington University, Bellingham, WA. ²Washington State University, Spokane, WA.

(No relationships reported)

With increased health concerns among youth, establishing a healthy lifestyle at young ages is prudent. Even more, youth exposed to adverse experiences face compounded risks for health concerns; it is essential to equip caregivers and youth with tools to reduce risks. Well-established physical activity (PA) programs may be such a tool. **PURPOSE:** To determine feasibility and acceptability of implementing a group PA program at a care facility for high-risk youth, and success of reaching ACSM's moderate-vigorous physical activity (MVPA) guidelines. **METHODS:** Group exercise programs were implemented at a high-risk care facility for two summers. Activities of appropriate METs from Addendum of PA for Children were employed 3 days/week, 60 min/day, and aimed to keep all youth engaged throughout program duration. MVPA-momentary time sampling, 20-m dash tests for VO₂max estimation, and staff interviews were conducted. **RESULTS:** MVPA assessments indicated program success in engaging 34 of 37 children in ACSM's recommended PA guidelines throughout the duration of the program. Estimated maximal exercise capacity increased from pre- to post-program (9.7 ± 0.5 vs 11.0 ± 0.5 MET, $p = 0.047$). Qualitative interviews with staff indicated 100% acceptance rate and desirability of program return, and 80% of staff stated non-elicited, agreed-upon program outcomes for participants: reduced bickering, aggravation of peers, and sedentary time; and increased positive behaviors, state of calm, sleep patterns, desirability of participation in activities, and appetites. Identified components of program success were group- and individual-based mindsets, full participation of staff, and structure and consistency. **CONCLUSION:** Findings endorse feasibility and acceptability of establishing structured group MVPA programs in care facilities for youth, in addition to enhancing well-being outcomes for participants. Rigorous involvement in determining benefit of PA programs among this population is needed to justify work in providing refined, structured exercise programs to residential settings; doing so may provide an impactful tool for the care and well-being of these individuals.

Note: informed assent and consent forms were obtained for each participant. Supported by Washington State University.

3140 Board #45 June 2 3:30 PM - 5:00 PM
Examining The Relationship Between High School Physical Education With Current Fitness Outcomes In College Students

Melissa Bopp, FACSM, Zack Papalia, Christopher M. Bopp, Allison Burner, Alison Weimer. Pennsylvania State University, University Park, PA.

Email: mjb73@psu.edu

(No relationships reported)

Physical education during K-12 can positively impact fitness outcomes, though the transition to college often leads to a decline in regular physical activity (PA) participation. The impact of high school PE on fitness outcomes and PA participation in college is unclear. **PURPOSE:** To examine how PE experience in high school was related to fitness and PA outcomes among college students. **METHODS:** Participants were college student volunteers ($n=537$) that completed a fitness assessment and online survey. Aerobic fitness (YMCA cycle ergometer protocol), muscular endurance (push-up and curl-up tests), body composition (BMI and bioelectrical impedance) and blood lipids were assessed. The survey assessed participant demographics, current PA, and PE outcomes (number of semesters of PE in high school, PE enjoyment, taking PE when not required). All analyses were conducted separately for males and females. Pearson correlations examined the relationships between the fitness, behavioral and PE outcomes. Independent t-tests and ANOVAs were examined differences in fitness and behavioral outcomes by PE outcomes. **RESULTS:** The final sample was 56.6% male ($n=298$) and 43.4% female ($n=227$). Among males, PE enjoyment was related to VO₂max ($p=.04$), curl ups ($p=.03$), and PA ($p=.02$). Number of semesters of PE in high school was negatively associated with triglycerides ($p=.01$) and total cholesterol ($p=.02$) and positively associated with moderate physical activity ($p=.02$). Males who took PE when it wasn't required were more vigorously active ($p=.02$) than those who did not. Among females, number of semesters of PE in high school was negatively associated with triglycerides ($p=.004$) and total cholesterol ($p=.02$). PE enjoyment

was positively associated with VO₂max ($p=.04$) and push-ups ($p=.03$). Females who took PE when it wasn't required had a higher VO₂max ($p=.04$) and vigorous physical activity ($p=.03$) compared with those who did not. **CONCLUSIONS:** PE experience in high school is related to fitness and behavioral outcomes during college years, with different relationships for males and females. Enjoyment of PE should be examined further for long-term impact. PE programming and policy has the potential to impact health and behavior in later life stages and has implications for lifelong wellness.

3141 Board #46 June 2 3:30 PM - 5:00 PM
Sport And Physical Activity Lesson Participation And Health-related Variables In Low-income Youth

Jeanette Ricci¹, Karin A. Pfeiffer, FACSM¹, Kimberly A. Clevenger¹, James M. Pivarnik, FACSM¹, Sandra Sellers².

¹Michigan State University, East Lansing, MI. ²Crim Fitness Foundation, Flint, MI. (Sponsor: Dr. Karin A Pfeiffer, FACSM)

(No relationships reported)

Youth sports participation is positively associated with several psychosocial variables. Minimal research is available on associations between sports team and physical activity lesson (S/PA) participation and health-related outcomes. The benefits of S/PA may be particularly salient in low-income youth, who report low levels of physical activity, lower quality of life, and poor diet. **PURPOSE:** To explore the relationship between S/PA participation and physical activity, diet, and health-related quality of life (QoL) in low-income youth. **METHODS:** A sample of students ($N=754$, 10.4 ± 1.0 y; 53% males; 56.2% black, 30.1% multi-racial/other, 13.7% white; 44.0% overweight) completed a survey including the Physical Activity Questionnaire for Children (PAQ-C; 9 items, max 5), KidsScreen-27 (psychological, peer-, and parent-related dimensions, max 100), and School Physical Activity and Nutrition Survey (SPAN; 25 items, max 3 per item). Single items described fruit and vegetable intake, and a junk food index was calculated (6 items, max 18). Participants self-reported S/PA participation (sports teams and/or dance/martial arts class) during the last year. Height and weight were measured to determine body mass index. One-way ANOVA was used to determine if physical activity, diet, or health-related QoL differed among S/PA participants and non-participants. **RESULTS:** Approximately 59% of youth participated in at least one S/PA. Physical activity ($F(2,751)=15.011$, $p<0.05$), fruit intake ($F(2,746)=4.933$, $p<0.05$), parent-related QoL ($F(2,749)=10.413$, $p<0.05$), and peer-related QoL ($F(2,747)=6.170$, $p<0.05$) were higher in S/PA participants compared to non-participants. However, junk food intake was higher in S/PA participants compared to non-participants ($F(2,746)=6.490$, $p<0.05$). **CONCLUSIONS:** In this sample, S/PA participation was associated with higher physical activity, fruit intake, and peer- and parent-related QoL. Our findings support previous research in a similar population of youth sport participants who had healthier dietary behaviors than non-participants. Our finding that junk food intake was higher in S/PA participants could be explained by time constraints and/or the belief that junk food consumption is acceptable as a result of being physically active.

The Effects of Different Types of Exercise on Chinese College Students' Energy Expenditure

Nan Zeng¹, Xianxiong Li², Huimin Yang², Wenfeng Liu², Hui Xiong², Yanting Chen², Jiao Li², Wei He², Zan Gao, FACSM¹.

¹University of Minnesota, Minneapolis, MN. ²Hunan Normal University, Changsha, China. (Sponsor: Zan Gao, FACSM)

Email: zengx185@umn.edu

(No relationships reported)

Purpose: To examine the effect of light physical activity (LPA), moderate PA (MPA), vigorous PA (VPA), and active video games (AVGs) on college students' energy expenditure (EE). Gender differences in EE were also investigated.

Methods: Twenty-four college students (12 males; $M_{age} = 23.5$, $SD = \pm 1.06$) completed four separate 10-minute exercise sessions on LPA (treadmill walking at 3.0 kph), MPA (treadmill walking at 5.0 kph), VPA (treadmill running at 7.0 kph), and AVGs (Xbox 360 Kinect Just Dance play) in a highly controlled laboratory. EE (total calories) was objectively measured by ActiGraph accelerometers.

Results: Repeated-measures ANOVA revealed significant differences in EE across different exercise sessions [$F(1, 23) = 160.1$, $p < .01$, $\eta^2 = 0.88$]. In detail, VPA ($M_{EE} = 75.25$, $SD = 35.12$) yielded significantly higher EE than LPA and AVGs ($p < .01$). Similarly, MPA ($M_{EE} = 70.74$, $SD = 28.77$) triggered significantly greater EE than LPA and AVGs ($p < .01$). LPA ($M_{EE} = 30.04$, $SD = 13.38$) generated significantly higher EE than AVGs ($M_{EE} = 21.16$, $SD = 18.59$) ($p < .01$). Notably, no significant EE difference emerged between VPA and MPA ($p > .05$). In addition, independent t-tests indicated that males burned more calories than females in LPA ($M_{EE} 38.65$ vs. 21.42 , $p < .001$), MPA ($M_{EE} 84.49$ vs. 57.00 , $p < .01$), and VPA ($M_{EE} 100.74$ vs. 49.76 , $p < .001$). No significant gender difference in EE during AVGs play ($M_{EE} 23.58$ vs. 18.74 , $p > .05$).

Conclusion: Findings suggest that a 10-minute exercise session in treadmill running at 7.0 kph has the highest EE, followed by treadmill walking at 5.0 kph, 3.0 kph, and

AVGs in college students. Additionally, calories burned during treadmill walking at 5.0 kph is roughly equivalent to the energy cost of treadmill running at 7.0 kph. Notably, calories burned during AVGs play has not yet reached the light-intensity physical activity level of slow treadmill walking. It is plausible that the novelty of AVGs led to the low intensity of AVGs play. Lastly, males tend to expend more calories than females during treadmill walking/running but no significant EE difference was observed between genders during AVGs play. Future study may offer AVGs training tutorial prior to experiments to elicit greater EE.

Physical Activity Self-efficacy As A Predictor Of Achieving MVPA Guidelines In University Students

Jamie Faro¹, Jessica Whiteley¹, Laura L. Hayman¹, Samuel J. Simmens², Melissa Napolitano². ¹University of Massachusetts Boston, Boston, MA. ²The George Washington University, Washington, DC.

Email: Jamie.faro001@umb.edu

(No relationships reported)

Few studies have examined characteristics associated with physical activity levels in university students seeking weight loss treatment, though it has been shown that physical activity is associated with weight loss in interventions with general adult populations. Understanding the characteristics predicting university students' achievement of moderate- to- vigorous physical activity (MVPA) could better inform interventions designed to increase physical activity. **PURPOSE:** To identify predictors of meeting MVPA guidelines among university students enrolled in an intervention aimed at attaining or maintaining a healthy body weight. **METHODS:** At 2 campuses, 128 university students (66% female; mean age=21.6, SD=3.1; mean BMI=31.6 kg/m², SD=3.7) completed demographic questions, the International Physical Activity Questionnaire (IPAQ), and physical activity self-efficacy at baseline. MVPA was calculated for each participant based on the days and minutes of self-reported activity, with meeting guidelines defined as 150 minutes/week of combined MVPA. **RESULTS:** A higher percentage of males met the MVPA guidelines (73%) compared to females (58%) and published national averages (49%). Logistic regressions revealed that PA-SE ($p < 0.05$) was a significant predictor of meeting MVPA guidelines, while age, BMI, gender and race/ethnicity were not significant. No significant male/female differences in PA-SE were found. However, physical activity self-efficacy was a moderately strong predictor of achieving MVPA for both females (OR=2.22, $p < 0.05$) and males (OR=3.99, $p = 0.15$), although not statistically significant for males. **CONCLUSION:** Higher levels of physical activity self-efficacy appear to be substantially associated with the likelihood of whether or not female university students achieved MVPA guidelines, while no other demographic variables usually associated with MVPA levels were significant. Further examination is needed to determine if the effects of physical activity self-efficacy on meeting MVPA guidelines that were found here are causal and could therefore suggest different behavioral treatment strategies for the promotion of MVPA in male and female university students.

Household Support for Physical Activity in Adolescent Girls Recruited from Lower SES Neighborhoods

Kristie Rupp¹, Sharon E. Taverno Ross², Tiffany L. Gary-Webb², Thomas Akiva², John M. Jakicic, FACSM². ¹Brooklyn College, Brooklyn, NY. ²University of Pittsburgh, Pittsburgh, PA. (Sponsor: John M. Jakicic, FACSM)

Email: Kristie.Rupp@brooklyn.cuny.edu

(No relationships reported)

Tangible (e.g. adult facilitation) and intangible (e.g. encouragement) forms of support for physical activity engagement could be an important contributor of physical activity engagement for adolescent girls from low socioeconomic status (SES) households. However, limited research has examined associations between household support and physical activity in this population. **PURPOSE:** The purpose of this study was to examine the association between the perception of household support and physical activity levels of adolescent girls recruited from low SES neighborhoods. **METHODS:** Thirty-six girls, between the ages of 13-17 years, were recruited from lower SES neighborhoods. A trained researcher took participants' height and weight and administered two questionnaires to assess: (1) household support for physical activity (including support from the adult in the household the participant perceived themselves as being closest with and each additional adult in the household); and (2) minutes per day in moderate-to-vigorous physical activity (using the 3-Day Physical Activity Recall). Participants also reported their perception of barriers and facilitators of physical activity. **RESULTS:** Participants (N=36; 60% non-Hispanic black) had a median age of 14.9 [13.8, 15.9] and median BMI percentile of 90.5 [58.5, 97.0]. Total support ($r = 0.221$; $p = 0.224$), tangible support ($r = 0.126$; $p = 0.492$), and intangible support ($r = 0.197$; $p = 0.174$) from the closest adult in the household

was positively associated with physical activity but these results were not statistically significant (adjusted for age, BMI, and race/ethnicity). There were significant negative associations between BMI and both total adult household support for physical activity ($r = -0.514$; $p = 0.001$) and the support provided by the closest adult in the household ($r = -0.553$; $p < 0.001$). The most frequently reported facilitator of physical activity was support from family and friends ($n = 15$; 42%). **CONCLUSIONS:** While household support for physical activity was not significantly associated with measured physical activity, there was a significant negative association between BMI and household support for physical activity. This suggests adolescents with a higher BMI receive less support for physical activity, which may warrant further investigation.

Girl Scout Troop Meeting Time-segmented Patterns Of Physical Activity Driven By Task.

Chelsey R. Schlechter¹, Richard R. Rosenkranz, FACSM¹, David A. Dziewaltowski². ¹Kansas State University, Manhattan, KS.

²University of Nebraska Medical Center, Omaha, NE. (Sponsor: Richard R. Rosenkranz, FACSM)

Email: chelseyschlechter@ksu.edu

(No relationships reported)

Fewer than half of children are currently meeting recommended physical activity (PA) guidelines of at least 60 minutes of moderate-to-vigorous physical activity (MVPA) per day, with fewer girls than boys meeting guidelines. Girl Scouts (GS) is a potential target setting for increasing PA in girls, though little is known about the time-segmented patterns of PA and the systemic drivers of these patterns during troop meetings. **Purpose:** To determine the microsystem influences on GS troop meeting time-segmented patterns of PA. **Methods:** Girl Scout Troop leaders (troop $n = 7$) were randomized to receive an intervention training on implementing policies to promote physical activity and healthy eating or a standard control. Meetings (7 meetings/troop) were observed and girls in attendance ($n = 76$, 9-13 years old, mean \pm SD = 10.51 \pm 1.19 years) wore GTIM accelerometers. Two observers attended each meeting and recorded the start and stop point of time segments based on task (i.e., opening-closing, snack, active recreation [AR], Girl Scout curriculum [GSC]). The time-segmented episode accelerometer data were analyzed using Evenson cut-points. **Results:** A total of 182 time segments were observed (mean/day \pm SD = 3.77 \pm 1.24) with 24 AR (0.47 \pm 0.58), 63 GSC (1.31 \pm 0.80), 54 opening-closing (1.13 \pm 0.94), and 41 snack (0.85 \pm 0.58) segments. Mixed random effect models indicated treatment troops had significantly more AR segments per day (mean/day \pm SD = 0.89 \pm 0.12) than control troops (0.18 \pm 0.10). A significantly greater ($p < 0.01$) percentage of time was spent in MVPA during AR (mean \pm SE = 17.19 \pm 1.11%) compared to GSC (0.39 \pm 0.81%), opening-closing (3.22 \pm 1.06%), and snack (0.61 \pm 0.87%). A significantly greater percentage of time ($p < 0.01$) was spent in MVPA during opening-closing segments compared to GSC and snack. A significantly greater ($p < 0.01$) percentage of time was spent sedentary/inactive in GSC (67.9 \pm 3.6%) compared to AR (32.26 \pm 4.1%) and open-closing (55.28 \pm 3.66%), and during snack (72.2 \pm 3.6%) compared to open-closing and AR. **Conclusion:** Troop meeting time-segmented patterns of physical activity were influenced by task. Intervention leaders devoted more time segments to AR than control leaders. Adding time segments conducive to PA to GS troop meeting could increase the percentage of time spent in MVPA.

Parental Support for Physical Activity and Sedentary Behavior among Chinese Schoolchildren

Yang Liu, Yan Tang, Zhen-Bo Cao, Jie Zhuang, Zheng Zhu. Shanghai University of Sport, Shanghai, China.

Email: docliuyang@hotmail.com

(No relationships reported)

Physical activity is essential for the development of children and adolescents. Among different social and environmental factors, parental support plays important role on influencing young people's physical activity. However, the associations between different kinds of parental support and physical activity among Chinese children and adolescents have not been explored thoroughly with a large size of samples. **PURPOSE:** To explore the roles of different kinds of parental support (encouragement, accompany, financial support and model) on influencing moderate-to-vigorous physical activity (MVPA) and sedentary behavior (SED) among Chinese school-aged children. **METHODS:** The data used in analyses derived from the Physical Activity and Health of Children and Adolescents Survey 2015 in Shanghai, China. 78516 students (grade 1-12) from all 17 districts of Shanghai, representing 5% of the population of schoolchildren, were randomly selected to participate in the self-report questionnaire survey. Finally, the present study contains 61429 participants (girl 49.3%, mean age 11.77 years). Descriptive statistics and logistical regression were used to examine the associations between MVPA, SED and various kinds of parental support by gender. **RESULTS:** Compared to the low parental support groups, young people in high encouragement, accompany, financial support, and model (the highest among four factors) (boy: OR=1.60, 95% CI: 1.52-1.69; girl: OR=1.63,

95% CI: 1.54-1.73) groups are more likely to being at least 1h MVPA daily. On the contrary, compared to the high parental support groups, young people in low accompany and model groups are more likely to being at least 2h SED daily during both weekdays and weekend. **CONCLUSIONS:** Various kinds of parental support have influence in schoolchildren for them to be physically active regardless the gender. Parents as the model and parental accompany have the biggest influence for youth being active. This study suggests that efforts should be focused on parents and their behavior when design and implement interventions aiming to promote young people's physical activity. Supported by Shanghai Shuguang Program (14SG46), Shanghai Pujiang Program (16PJC075), and Science and Technology Commission of Shanghai Municipality (16080503400).

 (No relationships reported)

Studies show that energy imbalances cause the generation of obesity, metabolic markers play a fundamental role in the promotion and inhibition of satiety having as a consequence gain or loss weight, furthermore physical activity (PA) has been associated with endocrin regulation and with positive dietary changes.

PURPOSE: To assess the effect of a School-based Exercising and Nutrition Counseling Intervention On metabolic Markers (ghrelin, Leptin, Insulin) In School-aged Obese Adolescents from Monterrey México. **METHODS:** An experimental study with a sample of 51 adolescents (13±2 yrs) randomly distributed in two groups: Control (CG) and experimental (EG). CG had 4 weekly sessions of 60 minutes of PA and one weekly session of nutritional counseling. EG engaged in regular school activities. Metabolic markers were measured in serum and analyzed into LUMINEX platform. **RESULTS:** After pre-post test, results showed in EG at post-test that ghrelin significantly decreased (p=.005) the increase of leptin (p=.008) and insulin (p=0.05). No differences were observed after the comparison in CG. **CONCLUSIONS:** The change in the levels of leptin and ghrelin suggests a possible change in the metabolic behavior, showing that the practice of physical activity combined with nutritional counseling are factors of change in the integrated approach to obesity. In future studies, it is recommended to increase the duration of the program, and to suggest changes on diet.

3148 Board #53 June 2 3:30 PM - 5:00 PM
Patterns and Correlates of Sedentary Behaviour in Children Attending Child Care

Kelly R. Rice¹, Stewart Trost². ¹Eastern Oregon University, La Grande, OR. ²Queensland University of Technology, South Brisbane, Australia.
 (No relationships reported)

Public health authorities recommend that young children should not be sedentary for more than 30-60 minutes at a time. **PURPOSE:** 1) describe the frequency and duration of SED bouts, as measured by accelerometry, in a sample of children attending family day care; and 2) explore associations between selected child care policies and practices and patterns of SED. **METHODS:** A random sample of 41 registered family day care programs (FDCPs) participated in the study. Within each FDCP, participating children (N=193) wore an ActiGraph GT1M accelerometer for the duration of child care attendance. A SED bout was defined as ≥ 4 consecutive 15 sec epochs (1 min) with counts less than 25. Non-wear time was quantified by summing the number of consecutive 0 counts accumulated in sequences of 60 min or longer. Children were included in the analyses if they had ≥ 3 days in which wear time was ≥ 75% of the attendance time (N=127, 68 Boys, 59 girls, mean age = 3.5 ± 1.1 y). Provider reports of policies and practices related to SED were obtained using items from the Nutrition and Physical Activity Self-Assessment for Child Care. **RESULTS:** Boys accumulated 36.6 SED bouts daily, with median bout duration of 2.0 min. The daily number of bouts lasting 1-4, 5-9, 10-14 and 15+ min was 30.8, 3.3, 1.0, 0.8, and 1.4, respectively. SED time accrued in each category was 57.2, 22.2, 12.1, and 41.0 min, respectively. Girls accumulated 41.6 SED bouts daily, with median bout duration of 1.8 min. The daily number of bouts lasting 1-4, 5-9, 10-14 and 15+ min was 67.1, 22.9, 11.1, and 34.6, respectively. SED time accrued in each category was 57.2, 22.2, 12.1, and 41.0 min, respectively. Gender differences were statistically significant for the number of bouts and the frequency of SED bouts 1-4 min. Children attending FDCPs meeting child care standards for the provision of outdoor play, prolonged sitting, screen time, portable play equipment, and staff engagement during free play exhibited significantly

fewer SED bouts and accrued significantly less SED in bouts lasting 1-4 mins. **CONCLUSIONS:** SED during child care attendance is accumulated in mostly short bouts. Few children exhibited prolonged SED bouts ≥ 20 mins. Child care practices related to sitting time, screen time, and active play may reduce the frequency of SED bouts.

Effects Of A School-based Exercising And Nutrition Counseling Intervention On Sleep Parameters (Sleep Time, Sleep Latency And Number Of Awakenings) And Time In MVPA In School-aged Obese Adolescents From Monterrey México.

Oswaldo Ceballos-Gurrola, Marco A. Enriquez Martínez, Raúl Lomas-Acosta, Armando Cocca, José Valadez-Lira. UANL, Monterrey, Mexico.
 Email: osceguero@gmail.com
 (No relationships reported)

Obesity has positioned itself as a public health problem worldwide with multifactorial characteristics. Different studies define sleep time as obesogenic factor while others found a correlation with the levels of moderate to vigorous physical activity. (MVPA) **PURPOSE:** To assess the effect of a School-based Exercising and Nutrition Counseling Intervention On sleep parameters (sleep time, sleep latency and number of awakenings) and time in MVPA In School-aged Obese Adolescents from Monterrey México. **METHODS:** An experimental study with a sample of 51 adolescents (13±2 yrs) randomly distributed in two groups: Control (CG) and experimental (EG). CG had 4 weekly sessions of 60 minutes of PA and one weekly session of nutritional counseling. EG engaged in regular school activities. Sleep variables and levels of MVPA were monitored by triaxial accelerometer (ActiGraph wGT3X-BT) for at least 7 consecutive days. **RESULTS:**

Pre-post test comparison showed in de EG significative changes on sleep latency when MPVA increased (P=.006), other differences were observed on the decrease in awakenings on sleep (P<.001). No changes were observed on MPVA. CG increased only sleep latency (P<.001), on the other parameters no changes were found. **CONCLUSIONS:** The practice of physical shows a significant relationship with sleep parameters which seems to be a favorable factor in the treatment of obesity in adolescents. We suggest further studies to modify the duration of the intervention and use other indirect instruments for analyzing the quality of sleep

3150 Board #55 June 2 3:30 PM - 5:00 PM
The Effect of Physical Activity on Attention in Elementary School Students

Elizabeth K. Bailey, Alyssa C. Lucas, Robert L. Harper, Stephen P. Bailey, FACSM. Elon University, Elon, NC.
 Email: ebailey@elon.edu
 (No relationships reported)

Schools have always incorporated physical activity (PA) into the school day, but of late opportunities for PA have come under pressure. Research suggests that PA, particularly bilateral and coordinated PA, has a positive effect on attention in adolescent children, offering support for the continued inclusion of PA during the school day. **PURPOSE:** The purpose of this investigation is to compare the effects of bilateral and coordinated exercise, typical recess activities, and quiet reading on attention in elementary school children. The d2 test measures processing speed, rule compliance, and quality of performance. Performance on the test is determined by evaluating the total number (TN) of items processed, the number of errors made during the test, and by calculating concentration performance (CP). **METHODS:** 14 fifth grade students (6 girls and 8 boys, Age= 10.6±1 years) and 12 fourth grade students (8 girls and 4 boys, Age = 8.7±1 years) were included in this investigation. Students completed 3 sessions, separated by 7 days. In the first session students completed the d2 attention test after a regular academic class period to act as a control (CON). Subsequently, students were randomly assigned to a sequence of experimental conditions to be completed over the next 2 weeks. Fifth graders completed either 30 minutes of quiet reading (QR), or coordinated exercise (CE), while 4th graders completed either 30 minutes of typical recess (REC) activities or CE. Coordinated exercise consisted of a sequence of bilateral activities requiring gross and fine motor movement using various balls. Ten minutes following the activities, students completed the d2 test again in a quiet classroom. **RESULTS:** TN increased from baseline in each condition in 5th (CON=323+10, QR=416+16, CE=414+20, p<0.001) and 4th graders (CON=287+17, REC=381+19, CE=374+20, p<0.001). CP similarly increased from baseline in each condition in 5th (CON=138+3, QR=177+7, CE=178+10, p<0.001) and 4th graders (CON=131+9, REC=160+6, CE=157+8, p=0.001). **CONCLUSION:** It appears that a break from the concentration required in class is most beneficial to attention. However, the additive positive impact of PA on the reduction of risk for chronic disease supports the continued opportunity for PA during school as a more beneficial strategy to improve attention.

3151 Board #56 June 2 3:30 PM - 5:00 PM

Effects Of A Sit-stand Desk In A College ClassJeremy Frost¹, Donna Terbizan, FACSM². ¹St. Cloud State University, St. Cloud, MN. ²North Dakota State University, Fargo, ND. (Sponsor: Dr. Donna Terbizan, FACSM)

(No relationships reported)

Increased amount of daily sitting time has been linked to increased risk of disease, independent of the amount of daily physical activity. A number of devices have been developed to address prolonged sitting in work and educational settings (e.g., sit-stand desks, treadmill-desks, cycle-desks, stepping desks). However, very little research has investigated the effect of a sit-stand desk on cognitive mood and performance in the college classroom. **PURPOSE:** To determine the effect of using adjustable-height (sit-stand) desks in a college class on attention (AT), stress (ST), musculoskeletal discomfort (MD), anxiety (AN), and academic performance (EXAM). **METHODS:** A total of 18 subjects (12 intervention, mean age 22.1, mean credits 13.9) completed the 13 week intervention (week 3-15 of the semester). Adjustable-height sit-stand desks were placed in the back and one side of the classroom for students to use as they desired. Participants completed a weekly visual analogue scale (VAS) for AT, ST, MD, and AN, and were given space to provide optional comments on why they answered the way they did. Class sessions were video recorded to allow for direct observation of attention (OAT) in weeks 9, 12, and 13. Exams were taken at week 4, 6, 8, 10, 12, 14, and 15. **RESULTS:** The main findings indicated a significant interaction effect for AT ($F[12, 166] = 2.79, p = 0.002$) and ST ($F[12, 166] = 2.15, p = 0.017$), and significantly ($p=0.002$) lower overall MD for the intervention (12.81 ± 3.45) vs. control (35.12 ± 4.80) group. Exam scores were not different between groups. There was no difference in direct observation of attention (OAT) between groups (total $n=15$; control= 6) at week 9, 12, or 13. Age was correlated with overall observation of attention scores ($r=0.54, p=0.038$), and ST with AN scores all weeks except 5 and 11 (r range = $0.61-.95, p<0.05$). **CONCLUSION:** A strength of this study is the week to week data collection on various measures of cognitive mood and performance, and overall discomfort levels. Use of a sit-stand desk was associated with lower MD scores and more variability in AT and ST scores. Future studies should utilize increased sample sizes to determine the dose of standing that would result in changes in AT, ST, MD, AN, OAT, and EXAM in a university setting. This research was supported by a SCSU Faculty Research Grant.

3152 Board #57 June 2 3:30 PM - 5:00 PM

Percentage Of Time Spent In Physical Activity When Indoors Vs. Outdoors In Young ChildrenRobert T. Marcotte¹, David R. Bassett, Jr, FACSM¹, Jennifer I. Flynn², Dawn P. Coe, FACSM¹. ¹University of Tennessee, Knoxville, TN. ²Maryville College, Maryville, TN. Email: rmarcott@vols.utk.edu

(No relationships reported)

In the early childhood education setting, there is scheduled time during the day for outdoor physical activity (PA). Similarly, outdoor PA may occur during the day when the children are at home on the weekends. **PURPOSE:** To compare the percentage of waking time spent in PA (combined light, moderate, and vigorous intensities) when young children (ages 3 - 6y) are indoors vs. outdoors, on a school day and a weekend day. **METHODS:** Participants were 20 preschool and kindergarten children ($4.6\pm 0.8y$). PA was assessed using the ActiGraph GT3X+ accelerometer worn on the right hip, over the clothing, during one school day and one weekend day. Accelerometer data were filtered to remove the time period when the children were napping in order to capture only waking hours. Filtered data were analyzed using cut points by Pate et al. (2006) to determine the percentage of time children spent in PA. Environmental condition (indoors vs. outdoors) was determined using the lux values recorded by the ActiGraph GT3X+ and a previously validated cut point (240 lux) by Flynn et al. (2014). A 2x2 repeated measures ANOVA was used to examine the percentage of time in PA by environment (indoors vs. outdoors) and by day (school day vs. weekend day). **RESULTS:** Children spent a significantly greater percentage of time engaged in PA when they were outdoors vs. when they were indoors (59.2 ± 13.0 vs $26.7\pm 7.4\%$; $p<0.001$). Additionally, children spent a greater percentage of time in PA on the school day vs. the weekend day (50.1 ± 10.7 vs $35.8\pm 11.9\%$; $p=0.001$). There was no interaction between day and environmental condition. **CONCLUSIONS:** Children engaged in a significantly greater percentage of time in PA when outdoors, and on a school day (as opposed to a weekend day). These results may be due the outdoor environment being more conducive for PA. It appears that spending more time outdoors may help young children to meet guidelines for accumulating at least 120 minutes of PA per day (Active Start, 2009).

Comparisons Of Heart Rate And Energy Expenditure Across Three Exergaming Consoles In College-age Adults

Yoonsin Oh, Lora E. Johnson, Jesse R. Olson, Kaitlin R. Shea, Saori Braun. University of Wisconsin-Eau Claire, Eau Claire, WI. (Sponsor: Donald L. Bredle, FACSM)

Email: yoonsin@uwec.edu

(No relationships reported)

Purpose: Exergaming, playing video games that require players to be physically active, has opened up new avenues for increasing energy expenditure (EE). However, little research has compared the physiological benefits of the same game across different consoles. This study investigated: 1) the differences in degree of EE for the same song's dance in the same exergame across three different major gaming consoles each using a different method of recognizing player movement, and 2) whether exergaming could elicit moderate-to-vigorous levels of intensity ($\geq 40\%$ heart rate reserve [HRR]) based on heart rate average (HR_{avg}) measurements. **Methods:** Twenty-five healthy college-aged students (19 females and 6 males) participated in this study. Data collection comprised of baseline testing, a 30-second exergaming familiarization period with each console, and a play session. During gameplay, participants danced to a 3minute and 55second song on each console; they also danced to a non-interactive video of the same song lasting for the same duration. Participants rested for 5 minutes between sessions. Console order was counterbalanced across participants. EE was obtained from a chest-mounted heart rate (HR) monitor. The HR_{avg} was obtained from the heart rate monitor for each session. **Results:** One-way repeated measures ANOVA ($\alpha = .05$) indicated no significant differences in EE across the three gaming consoles and the control video, $F(2.74, 65.86) = 0.65, p = .570$. In terms of HR_{avg} , a paired-sample t -test indicated that the HR_{avg} during exergaming on one console (117 ± 18 bpm) was significantly greater than the control video (112 ± 16 bpm), $t(24) = -3.03, p = .006$. About a third (28%-36%) of the participants met moderate levels of exercise intensity while exergaming on all three consoles. **Conclusion:** Exergaming can be incorporated into daily physical activity to work toward meeting the current physical activity guidelines; however exploration on factors (e.g., psychological) influencing the motivational level of individuals engaging in exergaming is necessary to help reach the moderate-intensity. As limitation exists with the estimation of EE via the use of HR monitors, the use portable indirect calorimetry may increase the accuracy of EE measurement.

Comparison of Accelerometer Step Counts and Total Physical Activity in 2-year Old Child-Parent Dyads

Marion Bakhoya, Aston K. McCullough, Carol Ewing Garber, FACSM. Teachers College, Columbia University, New York, NY. (Sponsor: Carol Garber, FACSM)

Email: mb4169@tc.columbia.edu

(No relationships reported)

Step counts are a simple, practical way to monitor physical activity, and daily steps have been shown to be strongly correlated with accelerometer activity counts in adults and children as young as 3 years of age. However, no such data exists in 2-year-old children. **PURPOSE:** To compare daily step counts with accelerometer measured time spent in physical activity in 2-year olds, and to examine the interrelationships between parents' and childrens' steps. **METHODS:** Physical activity (PA) and step counts were recorded for one week using hip-worn accelerometers in 2-year-old children and one parent dyads attending an urban Early Head Start program. Data reduction was conducted in MATLAB, and estimates of total physical activity time (TPA) and steps/day were calculated. Costa (2014) and Freedson (1998) cut-points for PA intensity were used for children and parents, respectively. Tudor-Locke (2009) step cut-points were used to calculate adult steps/day. Standard accelerometer wear time procedures were applied to yield sufficient reliability ($r > 0.70$). Descriptive data are presented as Mean (standard deviation;SD), Median (interquartile range;IQR), or Frequencies (%). Spearman correlations were used to test for relationships of interest, with an *a priori* significance level of $p < 0.05$. **RESULTS:** Seventeen child-parent dyads meeting wear time reliability were included in the analysis shown in Table 1. There was a strong positive correlation ($\rho = 0.74, p < 0.01$) between TPA steps/day and total PA min/day in children, and a moderate correlation ($\rho = 0.58, p < 0.02$) in parents. There was no significant correlation between children's and parents' average TPA steps/day. **CONCLUSION:** Step counts were highly correlated with TPA time in both 2 year-olds and their parents, suggesting step counts can be used interchangeably with PA counts in 2-year-old children and parents. Parent and child steps were not correlated and, thus, their PA does not appear to be interdependent.

Variable	Child	Parent
Age	31(3) mo.	30(4) yr.
Female n(%)	11(64.7)	17(100)
Median Steps/day	5331(2365)	6491(2418)

Wear Days	6(2)	7(1)
Meeting Target Recommendation for PA n(%)	14(82.4)	3(17.7)

3155 Board #60 June 2 3:30 PM - 5:00 PM
Discordance Between The Perceived And Actual Activity-supportive Built Environment Among College Students

Dangaia Sims, Melissa Bopp, FACSM, Lauren Mazza, Zack Papalia, Christopher Bopp. *Penn State University, University Park, PA.* (Sponsor: Melissa Bopp, FACSM)

(No relationships reported)

An individual's environment has a major impact on their activities, travel mode, and health. Thus, to improve physical activity (PA), active transportation, and health, it is important to understand a society's awareness of their environment. **PURPOSE:** To evaluate discordance between perceived and actual presence of factors associated with the built environment. **METHODS:** A survey of 170 college students' (19±.89 years) familiarity with their environment for PA and PA participation was conducted in Spring 2015. Objectively measured environmental audits of the environment were conducted simultaneously using an environment audit (WASABE). Variables included for the present study include: presence of trails, presence of parks, sidewalk maintenance, and perceived activity of those in the neighborhood. A continuous discordance score (-4 to 4) was created by summing the frequency by which an individual differed from the audit on each variable. A score of -4 represents always perceiving the presence of a variable when there was not one (negative discordance). A score of 4 represents always perceiving the absence of a variable when there was one (positive discordance). Paired-samples t-tests assessed discrepancies between the perceived and actual environment. Pearson correlations examined the relationship between fitness and discordance. A linear regression identified which factors within the individual (i.e., demographics, PA and environmental) most predicted discordance. P values were set at <.05. **RESULTS:** T-tests indicated significant differences between perceived and actual results for: the presence of bike trails (t=10.69), the presence of parks (t=5.81), and the presence of people being physically active (t=2.49). Positive discordance was correlated with a lack of moderate PA (r=-.27). There were no significant correlations with negative discordance. Predictors of discordance in either direction included: not owning a bike (β=-0.83), rarely using bike trails/routes (β=-.27), and not living near a park (β=-1.33). **CONCLUSION:** Students are unfamiliar with their environment, which may influence their activities and travel mode. Those who do not participate in activities that would place them in their neighborhood environment are even more unaware of their surroundings than others.

Community Health and Fitness Programs for Children: Outcomes of the Fit Kids Program in Connecticut

Wendy Bjerke¹, Theresa Argondezzi², Kaitlin Latham², Tim Callahan². ¹*Sacred Heart University, Fairfield, CT.* ²*Norwalk Health Department, Norwalk, CT.* (Sponsor: Peter Ronai, FACSM)

Email: bjerke@sacredheart.edu

(No relationships reported)

PURPOSE: Obesity prevalence among children has tripled in the past 30 years. The majority of obese 5-10 year-olds have at least one chronic disease risk factor and have a 70% chance of remaining obese as an adult. Community based exercise and nutrition programs that take place in a school setting have the potential to reach up to 95% of children. The purpose of this study is to report the outcomes of the Fit Kids Program (FK) in Connecticut. FK was created collaboratively by a community health department and university and is provided to community schools three times per year. **METHODS:** FK consists of 8-12 weekly sessions comprised of 30 minutes each of physical activity and nutrition education that takes place after school. Sports skills and training such as endurance and agility are combined with nutrition education including food tastings and preparation demonstrations. FK has served over 500 school children. Variables routinely assessed pre and post include BMI, vertical jump (VJ), hand grip strength (HG), physical activity self efficacy (PASE) and content retention (CR). Descriptive and inferential statistics are assessed including mean changes and the level of significance via paired t-tests. For this study, data collected pre and post from 2012-2015 is reported and compared.

RESULTS: 215 children between 5 and 12 years of age (mean 8.2) were assessed between 2012 and 2015. Significant changes included consistent improvements in CR over all years. Increases in CR ranged from 13-30% (p value ranges = .000-.028). Significant increases in HG ranging from 6.25-11% (p value ranges = .027-.045) were observed in 2013 and 2014. Significant increases in PASE ranging from 5.3-6.4% (p value ranges = .006-.035) were observed in 2014. The most compelling changes relative to the number of variables were observed in 2015 including an increase of HG by 9% (p = .006), PASE by 25% (p = .000), and CR by 14.5% (p = .000). BMI and BMI percentiles did not change significantly over all years; however observed mean ranges for BMI between 17.3 and 21.00 and BMI percentile ranges between 55 and 63 were within normal limits. VJ did not increase significantly.

CONCLUSION:

Compelling and consistent improvements in CR among children in addition to increases in PASE and and HG support continuing a collaborative effort and commitment to the health of children.

Associations among Objectively-determined Physical Activity, Cardiorespiratory Fitness and Cognitive Function in Preschool Children

Jung Eun (June) Lee¹, Zachary C. Pope², Nan Zeng², Ying Zhang³, Zan Gao, FACSM². ¹*University of Minnesota, Duluth, MN.* ²*University of Minnesota, Minneapolis, MN.* ³*Zhejiang Normal University, Hangzhou, China.* (Sponsor: Zan Gao, FACSM)

Email: leex6924@umn.edu

(No relationships reported)

Purpose: Early childhood years (ages 4-6 years) are deemed a critical period to develop a physically active lifestyle to curb obesity epidemic. Evidence has shown that physical activity (PA) and cardiorespiratory fitness are linked to enhanced cognition in children. However, favorable results toward this linkage are still inconsistent in preschool children. Therefore, this study examined the associations among preschool children's objectively-determined PA, cardiorespiratory fitness and cognitive functioning across time.

Methods: Thirty-two preschoolers (16 boys; 59.4% Asian; $M_{age} = 4.72$, $SD = \pm .73$) participated in this study. Children's cognitive function, cardiorespiratory fitness, 5-day moderate-to-vigorous PA (MVPA) was assessed at baseline (Time 1) and 6 months (Time 2) later. Their cognitive function was assessed with the Executive Function Scale for Early Childhood. A modified YMCA 3-Minute Step Test and ActiGraph accelerometers were used for assessing children's cardiorespiratory fitness and MVPA, respectively.

Results: Pearson's correlation analyses showed different relation patterns among variables across time. In detail, there was a small positive relationship between MVPA and cognitive function at Time 1 ($r=0.14$, $p=0.23$), but negative relationship emerged between these two variables at Time 2 ($r=-0.27$, $p=0.08$). A small yet positive correlation was seen between fitness and cognitive function over time (Time 1, $r=0.02$, $p=0.46$; Time 2, $r=0.12$, $p=0.27$). Yet, regression results indicated that MVPA (Time 1, $\beta=0.14$, $p=0.47$; Time 2, $\beta=-0.29$, $p=0.14$) and cardiorespiratory fitness (Time 1, $\beta=0.05$, $p=0.98$; Time 2, $\beta=0.16$, $p=0.39$) failed to significantly predict children's cognitive function at both times (Time 1, $R^2=0.02$, $p=0.77$; Time 2, $R^2=0.10$, $p=0.27$). **Conclusions:** Findings suggest that the associations among preschool children's cognitive function, MVPA, and cardiorespiratory fitness may still be inconclusive. Based upon the regression analysis, many other factors other than PA and cardiorespiratory fitness would explain children's cognitive function. Future studies with a larger sample size and more reliable cognitive function assessment are warranted.

Effect Of Wu Qin Xi Exercise On Balance Function In College Students

Yu Wang, Derun Gao, Ning Li. *Chengdu Sport Institute, Chengdu, China.* (Sponsor: Tongjian You, FACSM)

Email: 626860728@qq.com

(No relationships reported)

Wu Qin Xi, created by Hua Tuo - a physician of the Eastern Han Dynasty, is a group of physical and breathing exercises imitating the movements of five animals. Previous studies show it has evident effects on improving cardiovascular function and neural function, and increasing bone mineral density in older adults. **Purpose:** The purpose of this study was to examine the effect of a 6-week Wu Qin Xi exercise program on balance function in college students. **Methods:** Twenty four college students (age: 19±1 years, 12 males, 12 females) were randomly divided into two groups (C: control group; E: exercise group) with 12 subjects in each group. Both groups maintained their routine daily activities, except that subjects in the E group participated in a Wu Qin Xi exercise program 30 min each time, 6 times each week, for 6 weeks. Before and after the 6-week period, all subjects were tested for postural

stability (PS), limits of stability (LOS) and fall risk (FR) by using the Biodex Balance System. Paired t-tests were used to determine changes within each group, and independent t-tests were used to determine group differences in changes over the 6-week period. **Results:** All 24 subjects completed the study. Over the 6-week period, there were no significant changes in PS, LOS and FR in the C group; however, there were significant improvements in PS (from 0.58 ± 0.17 to 0.51 ± 0.09 , $p < 0.05$) and LOS (from 40.08 ± 10.95 to 47.00 ± 11.04 , $p < 0.01$) in the E group. There was no significant change in FR in the E group. Compared to the C group, the E group had significant improvements in PS (C: -0.01 ± 0.00 vs. E: -0.08 ± 0.07 , $p < 0.05$) and LOS (C: -0.83 ± 0.75 vs. E: 6.92 ± 2.41 , $p < 0.01$) from baseline to the post-exercise assessment. There was no significant group difference in changes of FR over the 6-week period. **Conclusion:** A 6-week Wu Qin Xi exercise program significantly improved balance function in college students. Future, larger studies are needed to explore the effect of Wu Qin Xi exercise on fall risk in this population.

Parental Support for Moderate and Vigorous Physical Activity In Children and Adiposity as a Mediator.

Maria João Lagoa¹, Michael Duncan², Gustavo Silva¹, Jorge Mota¹, Luisa Aires¹. ¹Faculty of sport - University of Porto, Porto, Portugal. ²Coventry University, Coventry, United Kingdom.
 Email: mariajoalagoa@gmail.com
 (No relationships reported)

PURPOSE: To determine whether the associations between different types of parental support and children's MVPA is mediated by their adiposity. **METHODS:** The sample comprised 138 Portuguese children (mean age 8.08 ± 1.32 years); 29.9% were overweight and 37.2% obese. MVPA was objectively assessed during 7 days using accelerometers ActiGraph GTX3, Body Mass Index (BMI), and percentage of body fat (%BF) through DEXA (dual energy X-ray absorptiometry - model Explorer-Hologic). Parents self-reported their weight and height, and intangible/tangible parental support were assessed by questionnaire. Linear regressions and mediation (Sobel test) analysis were used. **RESULTS:** Children with lower %BF had higher MVPA levels ($\beta = -1.17$, $p < 0.05$) and were more supported by parents with intangible type ($\beta = -1.11$, $p < 0.05$). No associations were found between tangible parental support and children's MVPA. Additionally, children with higher levels of intangible support showed higher levels of MVPA ($\beta = 3.21$, $p < 0.05$), however, significant differences disappeared after controlling for %BF ($\beta = 1.91$, $p > 0.05$). The Sobel test showed that the positive association between intangible parental support and children's MVPA was full mediated by %BF ($z = 2.09$, $p < 0.05$), with a percentage of indirect effect of 40.5%. **CONCLUSION:** Intangible parental support is important predictor of children's MVPA, however this influence is mediated by children's adiposity. Supported by the FCT under grand number SFRH/BD/101410/2014 and UID/DTP/00617/2013

Association Between Active Commuting To School And Sleep Duration In Ecuadorian Youth

Emilio Villa-González¹, Palma Chillón², Francisco Javier Huertas-Delgado², Manuel Herrador-Colmenero², Carlos Rodríguez-López², Yaira Barranco-Ruiz¹. ¹National University of Chimborazo, Riobamba, Ecuador. ²University of Granada, Granada, Spain.
 (No relationships reported)

PURPOSE: Active commuting has been associated to longer sleep duration in adolescents, however, the literature is still limited. Thus, the aim of this study was to investigate the association between the mode of commuting to and from school and sleep duration in Ecuadorian youth. **METHODS:** A total of 732 students (13.6+2.1 years, 65.3% boys) belonging to 3 schools from Riobamba (Ecuador) were recruited via convenience sampling in class. Participants completed a self-reported paper-based questionnaire about personal data, usual mode of commuting to and from school and regular sleep-wake schedule at night on normal school days. Via sleep-wake schedule, sleep duration was calculated for each individual. They were classified as active (walk or bike), and passive (motorbike, bus, car or another motorized transport). Participants were also classified into two groups: sleeping at night for at least 8 hours/day or less than 8 hours/day. Binary logistic regression analyses were applied to examine the association between the mode of commuting (active vs passive) to and from school and the sleep duration (<8 hours/day and >8 hours/day) after correction for confounding factors (age, gender). **RESULTS:** The main mode of commuting used by Ecuadorian students was passive (86.4%), whereas active modes were less used (12.6%). The main passive mode chosen was the car ($\approx 40\%$), followed by public bus ($\approx 21\%$) and school bus ($\approx 17\%$). Active commuters were more likely to sleep at least 8 hours/day than passive commuters showing a trend towards an increase in the sleep duration (OR, 95% CI 1.50, 0.945 to 2.409, $p = 0.085$). **CONCLUSIONS:** Active commuting to school

could be associated with sleep duration in youth. The links between lifestyle factors, sleep duration and active commuting to school need to be investigated in greater depth in order to promote public health strategies in youth.

School Day Physical Activity and Classroom Behavior in Disadvantaged Children

Timothy A. Brusseau, Ryan D. Burns. University of Utah, Salt Lake City, UT.
 Email: Tim.brusseau@utah.edu
 (No relationships reported)

Increased physical activity has been shown to improve classroom behavior in children. No study has examined the relationship between classroom level behavior and school day physical activity in disadvantaged children from low-income schools. **PURPOSE:** The purpose of this study was to examine the cross-sectional relationship between classroom level on-task behavior and average school day physical activity throughout one school week. **METHODS:** A total of 106 classrooms were recruited from five low-income schools from a school district located in the Mountain West Region of the U.S. Classrooms were recruited from the 1st through 6th grades and class sizes ranged from 16 to 28 students. On-task classroom behavior was assessed at the beginning of the 2015-2016 academic school year using momentary time sampling methods for an observation duration time of 15-minutes. Classrooms were stratified into those that achieved 80% on-task behavior and those that did not. Physical activity was assessed at the student level using Yamax pedometers and Actigraph accelerometers that were worn for the entire school day for one school week. Step counts and time in MVPA were averaged at the classroom level to account for clustering of observations within classrooms. A multivariate analysis of variance (MANOVA) test was used to examine the relationship between a categorical classroom behavior variable and classroom-level physical activity. **RESULTS:** Classrooms that achieved at least 80% classroom behavior displayed higher school day step counts ($\Delta = 449$ steps, $p < 0.001$, Cohen's $d = 0.26$) and time in MVPA ($\Delta = 3.6$ minutes, $p < 0.001$, Cohen's $d = 0.28$) compared to classrooms that displayed lower classroom behavior. **CONCLUSION:** Classrooms that display higher levels of on-task behavior tend to record higher levels of average school day physical activity. The results provide further evidence of the relationships between favorable classroom behavior and physical activity. Future research needs to examine this relationship for potential causation and bi-directionality so that effective interventions can be employed.

3162 Board #67 June 2 3:30 PM - 5:00 PM
Parental Barriers And Active Commuting To School: An Association In Spanish Children And Adolescents

Palma Chillón¹, Emilio Villa-González², Manuel Herrador-Colmenero¹, Francisco Javier Huertas-Delgado³. ¹Facultad de Ciencias de la Actividad Física y el Deporte. Universidad de Granada., Granada, Spain. ²Facultad de Educación. Universidad de Almería, Almería, Spain. ³Centro de Magisterio La Inmaculada. Universidad de Granada, Granada, Spain.
 (No relationships reported)

PURPOSE: Active commuting may provide a significant source of physical activity in youth. Parental barriers may be important to promote active mode of transportation. This study analyzes the association between parental barriers and mode of commuting to school in Spanish children and adolescents. **METHODS:** Parents of children (n=628) and parents of adolescents (n=151) from Granada (Spain) completed a paper-based questionnaire about perceived parental barriers to active commuting to school and children's mode of commuting to school. Data were analyzed using the logistic regression analyses to determine the association between parental barriers and mode of commuting. **RESULTS:** Concerning the association between number of barriers and mode of commuting to school, the parents of children with higher number of barriers were associated with passive modes of commuting (Odds Ratio (OR): 1.128; 95% Confidence Interval (CI): 1.06-1.20; $p = 0.010$), but there were not significant associations for the parents of adolescents ($p = 0.087$). Regarding parents of children, the following barriers were associated with children's passive modes of commuting: crime (OR: 0.634; 95% CI: 0.42-0.94; $p = 0.025$), distance (OR: 2.95; 95% CI: 1.98-4.39; $p = 0.000$) and parents' convenience (OR: 5.83; 95% CI: 1.24-27.40; $p = 0.026$). Children were passive when their parents perceived distance and convenience as barriers for active commuting to school and did not perceive crime as a barrier. In parents of adolescents, traffic speed (OR: 1.928; 95% CI: 0.08-0.90; $p = 0.034$), absence of policeman (OR: 2.872; 95% CI: 1.02-8.08; $p = 0.046$) and distance (OR: 3.544; 95% CI: 1.64-7.67; $p = 0.001$) were associated with adolescents' passive modes of commuting. **CONCLUSION:** Parental barriers have a negatively effect on active modes of commuting to school in children but not in adolescents because they might be frequently more autonomous. Intervention programs to promote active commuting must be focused on parental barriers as parents' convenience for children and presence of police for adolescents and perception of distance for both of them.

3163 Board #68 June 2 3:30 PM - 5:00 PM
Building Resilience In Pre-adolescents, Through Physical & Artistic Recreation
 Cecilia E. Romero Barquero. *Universidad de Costa Rica, San José, Costa Rica.*
 Email: cecilia.romero@ucr.ac.cr
 (No relationships reported)

Abstract:

Purpose: The present study aimed to compare the effect of recreational programs in the overall value of resilience and each of its dimensions, according to measurement, group and sex of the population.

Methods: The intervention was carried out by performing 14 sessions of two types of recreational programs, one based on physical recreation and another on artistic recreation. Each treatment lasted 32 hours in total, with one session per week. The research design was quasi-experimental. Eighty-six (86) sixth grade students, ages 11 to 14, from a primary school in social vulnerability participated in the study. The sampling was non-probabilistic. School Resilience Scale (E.R.E) for children between 9 and 14 years old was used. A three-way analysis of variance 2x3x2 (ANOVA) for repeated measures in a factor (measurements * group * sex) was performed.

Results: There was significant interaction ($p < .01$) between measurements * group in the overall value of resilience. Bonferroni Post hoc analysis showed that physical recreation and artistic recreation treatment significantly improved ($p < .05$) the value of the overall resilience. In addition, the effect on resilience did not differ significantly by type of program, in the post-test measurement.

Conclusions: The findings support the use of recreational programs as a useful and effective way to build resilience in pre-adolescent students in areas of a social vulnerability context.

 (No relationships reported)

Purpose: Understanding parental barriers is crucial to promote active commuting to school (ACS). This study examines parental barriers for ACS among Spanish youths (aged 9-16) and their association with gender and usual mode of commuting of their children. **Methods:** Parents of children (n=628) and parents of adolescents (n=151) from Granada (Spain) completed a paper-based questionnaire about perceived parental barriers for ACS and their children's mode of commuting to school. Data were analyzed using the Chi-square test. **Results:** The most common barriers reported by parents of children were traffic volume (48.7%) and dangerous intersection (45.0%), whereas the most frequent barriers reported by parents of adolescents were distance to school (50.3%) and dangerous intersections (39.6%). Compared to parents of children, a greater proportion of parents of adolescents reported distance to school (children 37.1%; adolescents 50.3%; $p=0.003$) and crime (children 28.6%; adolescents 36.9%; $p=0.047$) and smaller proportion reported traffic volume (children 48.7%; adolescents 32.9%; $p=0.000$) as barriers to ACS. Among parents of children, crime was more reported as a barrier by parents of girls than parents of boys (girls 33.2%; boys 24.2%; $p=0.013$). In children, parents of non-active commuters to school more frequently reported absence of a policeman on crosswalks (passive 20.8%; active 14.5%; $p=0.044$), absence of adults to walk with (passive 28.9%; active 19.9%; $p=0.44$), no sidewalks or bike lines (passive 44.8%; active 36.6%; $p=0.041$), distance to school (passive 44.8%; active 36.6%; $p=0.000$), time required to ACS (passive 17.5%; active 9.1%; $p=0.002$) and weather conditions (passive 36.4%; active 27.7%; $p=0.023$) as barriers for ACS compared to parents of active commuters. In adolescents, parents of active commuters reported less importance to absence of a policeman on crosswalks (passive 30.1%; active 16.0%; $p=0.041$) and distance to school (passive 64.4%; active 37.3%; $p=0.001$) than their counterparts. **Conclusion:** The main parental barriers for ACS in children were traffic volume and intersection safety whereas for adolescents were distance and intersection safety. Among Spanish parents, parental barriers for ACS were influenced by children's age, gender and usual mode of commuting to school.

Eating Behaviour Correlates in Children Referred to a Telehealth Program for Overweight and Obesity Treatment
 Anne M. Lasinsky¹, Tanis V. Mihalynuk², Darren ER Warburton¹, Danika B. Dickson³, Donna Forsyth-Lukas², Kiran Kalkat², Genevieve Larrivee², Barbara Leslie², Shannon SD Bredin¹. ¹*University of British Columbia, Vancouver, BC, Canada.* ²*HealthLink BC, Burnaby, BC, Canada.* ³*The Physical Activity Line, Richmond, BC, Canada.*
 Email: anne.lasinsky@ubc.ca
 (No relationships reported)

Purpose: To describe the relationships between emotional eating behaviours and demographic, anthropometric, and behavioural characteristics of children referred to a comprehensive telehealth program for the treatment of overweight and obesity.

Methods: Correlational analyses were conducted using baseline scores from self-reports on the Dutch Eating Behavior Questionnaire for Children (DEBQ-C), the Dutch Eating Behavior Questionnaire (DEBQ), the Godin Leisure-Time Exercise Questionnaire (GLTEQ), and physician-reported anthropometric/demographic measures obtained from referrals to the program.

Results: Data from girls ($n = 20$), age 8-17 yr, revealed a significant positive correlation between the Emotional Eating subscale of the DEBQ-C and DEBQ and age ($r = 0.70, p = 0.0006$), a non-significant negative correlation with standardized BMI score ($r = -0.19, p = 0.4$), and a significant negative correlation with total physical activity ($r = -0.54, p = 0.01$), as reported through the GLTEQ. Data from boys ($n = 21$), age 8-18 yr, revealed a significant positive correlation between the Emotional Eating subscale of the DEBQ-C and DEBQ and age ($r = 0.62, p = 0.003$), a non-significant negative correlation with standardized BMI score ($r = -0.08, p = 0.7$), and a significant negative correlation with total physical activity ($r = -0.60, p = 0.004$), as reported through the GLTEQ.

Conclusion: In both boys and girls, emotional eating behaviors were reported to increase with age, decrease with higher levels of physical activity, and show no significant correlation with standardized BMI scores. This provides further evidence for the protective effect of physical activity in children. This research has important implications for the future treatment of children with overweight and obesity.

Funding was provided by the Childhood Obesity Foundation and the Provincial Health Services Authority.

Dual Energy X-ray Absorptiometry Is Comparable To Computed Tomography For Visceral Adiposity Measurement In Cancer Patients And Survivors
 Adriana M. Coletta, Ann H. Klopp, David Fogelman, Yisheng Li, Naveen Garg, Karen Basen-Engquist. *MD Anderson Cancer Center, Houston, TX.*
 (No relationships reported)

Purpose: New software to measure visceral adipose tissue area with dual energy x-ray absorptiometry (DXA) was developed and proposed as an alternative method to abdominal computer tomography (CT) scan. The DXA software has previously been validated in apparently healthy populations; however it is yet to be determined if visceral adiposity measurement by DXA is comparable to CT in a cancer patient population. Use of DXA instead of CT may provide various benefits to cancer patients, notably less radiation exposure. Therefore the purpose of this study was to determine the level of agreement between DXA and CT when measuring visceral adipose tissue area in cancer patients and survivors.

Methods: Patients seen in the gastrointestinal and diagnostic imaging clinics were pre-screened for eligibility and approached during their regularly scheduled visit. Interested patients underwent a CT scan at L₄-L₅, as part of their medical care, and a whole-body DXA scan within 48 hours of their CT scan. Bland-Altman analysis evaluated the difference between paired measurements against their mean, and the 95% confidence limits of the mean difference between CT and DXA measurements. Linear regression was also used to assess the correlation between methods. All analyses were conducted for the total sample and by sex.

Results: A total of 99 patients (62±12 years, 28.5±7.4 kg/m²), 53 female (61±13 years, 28.3±8.5 kg/m²) and 46 male (62±11 years, 28.6±5.9 kg/m²), participated in the study. The majority of patients were non-Hispanic (90%), Caucasian (89%), diagnosed with adenocarcinoma (76%) at the site of the pancreas (46%) or colon (20%), and had stage 4 cancer (46%). Compared to CT, DXA underestimated visceral adipose

tissue area by 6.0 cm² (95%CI 4.8, 16.8) or 4.4%. A significant positive correlation was observed for visceral adiposity measured by DXA and CT ($r=0.90$, $p<0.001$). For women, DXA overestimated visceral adipose tissue area by 10.3cm² (95%CI -20.4, 0.2) or 9.6%. For men, DXA underestimated visceral adipose tissue area by 24.8 cm² (95%CI 7.2, 42.5) or 14.7%. Significant positive correlations between methods were observed for women ($r=0.90$, $p<0.001$) and men ($r=0.90$, $p<0.001$).

CONCLUSIONS DXA scan has the potential to serve as an alternative to CT scan for measurement of visceral adipose tissue area in cancer patients and survivors.

Cardiac Rehabilitation In Men With And Without Prostate Cancer: A Retrospective, Case-control Analysis

Alis Bonsignore¹, David Field¹, Rebecca Speare², Paul Oh¹, Daniel Santa Mina¹. ¹University of Toronto, Toronto, ON, Canada. ²University of Guelph-Humber, Toronto, ON, Canada. Email: alis.bonsignore@uhn.ca

(No relationships reported)

Background: Prostate cancer (PCa) is the leading cancer diagnosis among men, second only to skin cancer. Advancements in detection and treatments have led to significant improvements in survival. Deleterious changes to metabolic health that often accompany PCa treatment paradigms have unfortunately increased cardiac morbidity in this population. Accordingly, men with PCa may be referred to cardiac rehabilitation (CR) programs following a significant cardiac event. While evidence supporting the role of exercise for cancer survivors is abundant, the differential effect of a CR program on men with and without a history of PCa is unknown. **Purpose:** To compare the effect of CR on cardiorespiratory fitness (measured via VO₂peak) and measures of body composition (body fat percent and body mass index) in men with and without a history of PCa. **Methods:** A retrospective, case-control analysis of men that have completed CR was performed. Cases (i.e. men with PCa) and controls (no PCa) were matched on age and cardiovascular morbidity requiring CR. All men completed the same program consisting of aerobic exercise (5 times per week) and resistance training (2-3 times per week) for a total of 26 weeks. Baseline comparisons between PCa and non-PCa CR participants were conducted by independent-samples t-test. The effect of PCa on CR outcomes was assessed using repeated-measures analysis of covariance comparing PCa and non-PCa participants using baseline outcome measures as covariates. **Results:** Twenty-seven (n=27) cases were matched with (n = 27) controls during CR participation that completed the program between January 2004 and January 2011. VO₂peak increased in both groups (PCa: 16.4 ± 4.2 to 20.2 ± 5.8 mL·kg⁻¹·min⁻¹, $p=0.001$; non-PCa: 16.9 ± 5.1 to 19.6 ± 6.2 mL·kg⁻¹·min⁻¹; $p=0.001$). There were no changes in body composition in either group following participation in CR. There were no statistically significant differences between groups in change in any of the outcomes ($p>0.05$). **Conclusions:** Men with and without PCa that participate in CR experience comparable improvements in VO₂peak.

A Home-based Walking Program Is Feasible For Cancer Patients Prior To Undergoing Bone Marrow Transplant.

Magnus Benetti¹, Alan De Moraes¹, Mirella Dias², Claudio Battaglini, FACSM³. ¹Santa Catarina State University (UDESC), Florianopolis, SC, Brazil. ²Santa Catarina Oncology Research Center (CEPON), Florianopolis, SC, Brazil. ³University of North Carolina at Chapel Hill, Chapel Hill, NC. (Sponsor: Claudio Battaglini, FACSM)

Email: magnus.benetti@udesc.br

(No relationships reported)

Previous research has shown that patients with low fitness level prior to stem cell transplant have higher incidence of post-transplant complications. **PURPOSE:** To examine the feasibility of a home-based walking intervention in Brazilian patients with hematological cancers prior to undergoing a stem cell transplant in the Sistema Unico de Saude (SUS). Pre to post intervention physical function and patient reported outcomes (PROs) were also evaluated. **METHODS:** This single arm study enrolled 11 patients who scored >50 on the Karnofsky performance status scale, presented no contra-indication for participating in light to moderate regular walking, and were cleared by their oncologist to participate in the study. The home-based walking intervention initiated with patients undergoing 20 minutes of moderate intensity (10-12 on the Original Borg Scale) per week progressing up to 150 minutes by week 7. After week 7, patients were asked to maintain the 150 minutes of walking at moderate intensity until transplant day. Feasibility was determined by the number of patients approached to participate in the study (>90%) and the number of patients (>60%) that were able to achieve at least 70% of the planned intervention. Physical function (6 minutes walk test (6MWT) and TUG test) and PROs (Depression (Beck Depression Scale), fatigue (Piper Fatigue Scale), and quality of life (QOL) (SF-36) were assessed prior and after the walking intervention. **RESULTS:** All (100%) eligible

patients enrolled in the study. Out of the 11 patients, 1 patient was excluded because stopped chemotherapy treatment. Out of 10 patients, only 1 was not able to adhere to the study intervention. All other patients completed at least 70% of the planned walking intervention with some (66%) engaged in more than 150 minutes per week. Significant improvements from pre to post intervention in the 6MWT (344.4 ± 117.8 and 490.6 ± 111.2 meters, $p=0.001$) and PROs (Depression, 12.11 ± 7.08 and 7.89 ± 4.65, $p=0.006$; Fatigue, 62.00 ± 25.98 and 26.22 ± 10, $p=0.002$; overall QOL 23.11 ± 4.34 and 26.33 ± 2.45) were observed. **CONCLUSION:** Brazilian patients enrolled in the SUS not only were able to participate in the home-based walking intervention, but improvements in physical function and PROs were observed.

3169 Board #74 June 2 2:00 PM - 3:30 PM

Smartphone Application to Home-based Exercise on Psychological Wellbeing and Physical Functioning for Breast Cancer Survivors

Xiangren Yi¹, Dezong Gao², Zan Gao, FACSM³, Yong "Tai" Wang, FACSM⁴, Zhigang Yu², Kaili Meng¹, Xiaoyu Guo¹, Jingpeng Yan¹. ¹Shandong University, Jinan, China. ²Shandong University Second Hospital, Jinan, China. ³University of Minnesota, Minneapolis, MN. ⁴the University of Texas at Tyler, Tyler, TX. (Sponsor: Yong "Tai" Wang, FACSM) Email: xrenyi@sdu.edu.cn

(No relationships reported)

Mobile technology has become an increasingly essential instrument for those who are responsible for healthcare and facilitating the interactions between health professionals and patients. **PURPOSE:** the purpose of this study is to design a smartphone application to self-monitoring resistance and exercise prescription, health knowledge, daily physical activity and compare this application to traditional intervention on psychological wellbeing (PW) and physical functioning (PF) in breast cancer survivor. **METHODS:** Thirty patients with breast cancer (age = 46 ± 7 year) were randomly assigned into control (CON) or intervention (INT) groups with 15 patients in each group. INT was provided a smartphone equipped with a mobile health application for self-monitoring of biometrics and performed a resistance and aerobic exercise prescription 5 times/week and 30 minutes/time. PW and PF measures were taken at baseline and 12th week. Fourteen patients in each group completed the study. Data were analyzed by means of independent t test. **RESULTS:** Result indicated that the INT had significant improvements than the CON on PW outcomes: anxiety ($t=2.93$, $P<0.05$) and depression ($t=3.34$, $P<0.05$) and on PF measures: 6 min walking ($t=3.57$, $P<0.00$, arm curl ($t=2.45$, $P<0.05$) sit and reach test ($t=2.75$, $P<0.05$). The body composition ($t=0.89$, $P=0.45$), weight ($t=1.08$, $P=0.14$), BMI ($t=0.99$, $P=0.74$), blood pressure ($t=0.61$, $P=0.87$) were not significantly different between groups, but the pain ($t=3.64$, $P<0.00$), fatigue ($t=3.98$, $P<0.00$) and sleep disturbance ($t=4.57$, $P<0.00$) decreased significantly between CON and INT during twelve weeks excises. **CONCLUSIONS:** This study suggested that the smartphone application significantly improve PB and may be the effective way to decrease depression and anxiety and enhance PF in breast cancer survivors. Future study should determine whether home-base smartphone system can promote them to maintain long-term exercise effect. The work presented in this article was supported by grant from the Ministry of Science and Technology of China (2015FY111600)

Translation Of An Aging-in-place Intervention To Reduce Disability And Sedentarism Among Rural Cancer Survivors

Rachel K. Walker, Patty S. Freedson, FACSM. University of Massachusetts Amherst, Amherst, MA.

Email: r.walker@umass.edu

(No relationships reported)

PURPOSE: Rural-dwelling cancer survivors face multiple socioeconomic, behavioral, and environmental barriers to achieving recommended levels of physical activity. Many older cancer survivors also report that symptoms of cancer and other chronic conditions interfere with functioning, leading to more time spent sitting or lying down. These prolonged periods of inactivity negatively impact overall health and cancer rehabilitation. Common symptoms such as fatigue, impaired sleep, and pain can also interfere with activities of daily life. Reducing sedentarism (conceptually distinct from promoting activity) may be a more achievable goal for rural-dwelling cancer survivors experiencing symptom-related disability. Therefore, we adapted an aging-in-place intervention originally developed for urban-dwelling disabled older adults, to meet the needs of rural-dwelling older cancer survivors living in the Northeast U.S. **METHODS:** Drawing on translational methods outlined by Dr. Anna Marie Napoles, we established the infrastructure for a translation partnership, identified clinician and community stakeholders and methodological experts, and sought their input via semi-structured interviews. Direct and interpretive content analysis methods, as described by Hsieh and Shannon, were used to code and interpret the interview data relevant to answering two primary questions: (1) What are the critical needs of cancer survivors

living in the region with relation to promoting activity and reducing disability?; and (2) How should the original intervention be adapted to meet those needs in a way that is feasible, acceptable, and sustainable? **RESULTS:** Participants indicated a need for an intervention that could be tailored to individual goals and was accessible in the community, outside of clinical settings. This presentation highlights cancer survivor, clinician, and multi-disciplinary perspectives on critical components of the adapted intervention and associated study protocols. **CONCLUSIONS:** Stakeholder input is essential to the design and translation of sustainable clinical interventions. This work lays the foundation for a phase 1 pilot study of the adapted approach.

Does Supervised Exercise Programming At Diagnosis Impact Future Physical Activity Levels In Breast Cancer Survivors?

Holly Wollmann¹, Amy A. Kirkham¹, Cheri L. Van Patten¹, Kelcey A. Bland¹, Alis Bonsignore², Donald C. Mackenzie¹, Karen A. Gelmon¹, Kristin L. Campbell¹. ¹UBC, Vancouver, BC, Canada. ²University of Toronto, Toronto, ON, Canada.
 Email: holly.wollmann@ubc.ca

(No relationships reported)

Purpose: Low physical activity levels are associated with increased risk of breast cancer recurrence and reduced survival. Only 32% of breast cancer survivors engage in ACSM's 150 mins of moderate to vigorous activity per week recommended guidelines. Women who engaged in regular physical activity post diagnosis had a 20-50% lower mortality risk from breast cancer than those who did not. The purpose of this analysis is to identify whether breast cancer survivors participating in the Nutrition and Exercise during adjuvant Treatment (NEXT) trial had changes in their physical activity levels during and 1-year post treatment.

Methods: Stage I-III female breast cancer survivors (51 ± 11 yrs.), participated in the NEXT trial. Six-month physical activity recall measured at baseline, end of study (EOS) (average length = 45 weeks) and one year follow up via Minnesota Leisure Time Physical Activity Questionnaire, scored as average weekly minutes of moderate to vigorous physical activity (MVPA). Due to non-normal distribution of physical activity, a generalized estimating equation with a gamma log link, with pairwise contrasts to determine changes in individual levels of activity between time points. Data are estimated marginal mean ± standard error.

Results: 73 women were assessed at baseline, 59 at end of study and 35 at one year follow up. MVPA did not statistically change from baseline to EOS (176 ± 23 to 192.23 ± 12.6 mins). There were statistically significant differences in MVPA between EOS and one year follow up (288 ± 50 min, p=0.04), and between baseline and one year follow up, (p<0.01). At baseline, 43% of participants did not meet the ACSM recommended 150 mins/week of MVPA, however this improved to 63% of participants at both end of study and one year follow up.

Conclusion: Breast cancer survivors enrolled in a supervised exercise program concurrent to and immediately after adjuvant treatment maintained MVPA levels. Furthermore, there was an increase in those meeting the current physical activity guidelines at both end of study and one year follow up.

Hydration Status In Cancer Patients: Exercise Is Not A Palliative Care

David Palmerini, Michele Corezzi, Laura Stefani, Giorgio Galanti. *Sports and Exercise Medicine, Florence, Italy.*
 Email: laura-stefani@tiscali.it

(No relationships reported)

PURPOSE: Hydration is a controversial area in cancer, associated to a compartmentalization of body fluids an increased mortality. Sedentary and cells toxicity contributes to this imbalance. The water's amount swings out of the reference ranges with a predominant percentage in the extracellular site. The role of aerobic and resistance exercise to reduce edema in a short - mid time in cancer is not well investigated. The study aims to evaluate the eventual efficacy of a mixed and individualized medium-long term exercise program in the improvement of the patients' hydration status. **METHODS:** From a large cohort of 145 cancer patients, a subgroup composed of 35 subjects (7 male and 28 female, 58±10 yrs, 72.6±16.3 kg, 26.7±5.9 BMI) affected by colon and breast cancer and clinically stable, were enrolled for the Exercises prescription program, aerobic and resistance, following the ACSM guidelines, for at least 12 months. Hydration status was evaluated by Bioelectrical Impedance Analysis (BIA) using 101, Akern-RJL Systems, at T0, T6, and T12. **RESULTS:** Significant changes were detected for what concerns the redistribution of body water. There was a significant improvement of Intra Cellular Water % at T6 (T0: 51.61±4.43 vs T6: 52.93±4.11; p<0.01) and at T12 (T0: 51.61±4.43 vs T12: 54.24±3.41; p<0.001). While it appears evident a significant reduction of Extra Cellular Water % at T6 (T0: 48.38±4.43 vs T6: 47.06±4.11; p<0.01) and at T12 (T0: 48.38±4.43 vs T12: 45.75±3.41; p<0.001) despite the absence of a significant variations of the Total Body water%. A significant (p<.005) improvement of Fatty Free Mass

(FFM) was also observed. **CONCLUSIONS:** Like a poplilip, a mixed moderate intensity exercise contributes to a correct water distribution in the active intracellular compartments in cancer patients. Those results appear to be already relevant after 6 months and they become even more evident after 12 months.

Strength Training Following Hematopoietic Stem Cell Transplantation: Designing Interventions for Eventual Translation into Clinical Practice

Eileen D. Hacker, Tara Peters, Ruby Erdmann, Eileen Collins. *University of Illinois at Chicago, Chicago, IL.*
 (No relationships reported)

PURPOSE: Intensive cancer therapy followed by hematopoietic stem cell transplantation (HCT) results in highly distressing symptoms, impaired functional ability and diminished quality of life. These problems are amendable to exercise interventions but dependent upon participant uptake for eventual translation into clinical practice. This study reports subject attrition, compliance, adherence, and progression from the strength training arm (n = 37) of our intervention study, Strength Training to Enhance Early Recovery (STEER) after HCT.

METHODS: This single-blind controlled study randomized subjects to STEER versus usual care plus attention control with health education. STEER consisted of a progressive resistance program using elastic resistance bands tailored to the individual's capabilities and integrated seamlessly into existing clinical practice. Subjects received instruction and began active range of motion two times per week while hospitalized for HCT followed by a six-week moderate intensity program (three sessions per week/18 sessions total) post hospital discharge. STEER employed a combined supervised/unsupervised approach.

RESULTS: Four subjects died during the course of the study, unrelated to the STEER intervention (attrition rate 10%). Post-hospitalization, subject compliance with STEER was high (83%, SD = 22) as well as adherence to the exercise prescription (89%, SD = 25). Most subjects (90%) were able to progressively increase their prescription by adding repetitions, sets, number of exercises or band resistance.

CONCLUSIONS: STEER was tested in a challenging group of patients during a period of complex, frequently changing needs. Our study took advantage of common clinical situations following HCT, such as frequent clinic visits during the first six weeks following hospital discharge and downtime in clinic when subjects wait to see their healthcare provider. Using downtime in clinic to exercise is an efficient use of subjects' time. The intervention was specifically designed to minimize subject burden and maximize benefits. Subjects had high compliance and adherence to the STEER intervention which (1) reflects a patient-centered approach; (2) demonstrates effective tailoring to HCT subject's capability; and, (3) facilitates eventual translation into practice.

Self-reported Ltpa Versus Expected Ltpa In Rural Cancer Survivors: Missing The Mark

Stephen LoRusso, Stephen Baker, Ivan Mulligan. *Saint Francis University, Loretto, PA.*
 Email: slorusso@francis.edu
 (No relationships reported)

The evidence of the benefits of exercise for those diagnosed with Cancer has grown significantly indicating that leisure time physical activity is associated with lower risks of many types of cancer. As part of an ongoing study of rural cancer survivors in West Central Pennsylvania we sampled subjects regarding their levels of leisure time physical activity and compared those levels to ACSM recommendations. **Purpose:** To describe the levels of self-reported total lifetime leisure time physical activity hours vs ACSM recommended expected hours. **Methods:** A sample of 39 rural cancer survivors completed questionnaires which included a modified Historical Leisure Activity Questionnaire. Grouped by age (13-17, 18-22, 23-34, 35-50, 51-65, and 66-80), Total MET Hours were calculated and compared to ACSM recommendations of 2.5 hours of moderate intensity activity per week. The comparator of a 5 MET activity was used in the calculation of the benchmark Total MET Hours value. This study was approved by the Saint Francis University IRB. **Results:** Thirty-three (33) questionnaires were returned and 27 were analyzed. Participants were predominantly white, non-Hispanic, with a mean age of 60 years (27 to 77 years). The mean age of Cancer diagnosis was 51 years, (9 to 70 years). Breast Cancer (n=11) and Prostate (n=4) were primary Cancers reported. Significant differences (p<0.05) from actual to expected Total MET hours were found for each age group, except for the 13-17 group. The following groups demonstrated significantly lower Total MET Hours than expected: 18-22 (p<.017), 23-34, (p<.016), 35-50 (p<.000), 51-65 (p<.001), and 66-80 (p<.043). Average percent difference ages 13-50 is 636% actual to expected MET Hours. **Conclusion:** This pilot data supports the evidence that reduced physical activity is associated with a cancer diagnosis, and suggests that lifetime physical activity levels may play a role in the incidence of Cancer in a rural population. Support was provided in part, by the Department of Physical Therapy.

Breast Cancer Survivors Speak about Triathlon and Dragon Boat Team Training

Linda B. Piacentine¹, Judy A. Tjoe², Leslie J. Waltke², Alexander V. Ng, FACSM¹. ¹Marquette University, Milwaukee, WI. ²Aurora Health Care, Milwaukee, WI. (Sponsor: Alexander Ng, FACSM) Email: linda.piacentine@marquette.edu

(No relationships reported)

Motivations for Breast Cancer Survivors (BCS) to exercise after cancer treatment are not well understood and many BCS do not exercise at recommended levels. Goal-oriented team exercise training, such as triathlon training and dragon boating, may improve exercise activity. **PURPOSE:** The overall objective of this study was to determine the motivations to participate in goal-oriented team triathlon training among a group of BCS dragon boat racers. **METHODS:** Female breast cancer survivors (age=63.5(SD 4.1)) yr, BMI =25.8(SD 4.4)) who were members of a BCS dragon boat team (membership length=6(SD 4.1) seasons) were recruited to participate in a focus group after completing a 14 wk individualized triathlon training program. Training comprised two supervised group sessions and three home-based sessions per week. The training program culminated with participation in a sprint triathlon (Athleta Iron Girl, 0.5 mi swim, 12 mi bike, 3.1 mi run). Dragon boat training occurred twice weekly during triathlon training. Common themes related to dragon boat and triathlon training participation were analyzed. **RESULTS:** Four women participated in the focus group from which the following themes emerged: (1) Champion for Exercise from personal contacts, (2) Team motivation to join another team, (3) Sharing Life Experiences while not focusing on cancer helped in supporting each other, (4) Having Fun and not focusing on cancer was important, and (5) Integrating New and Renewed types of exercise into daily lives. Overall, survivors recognized their improved activity levels during triathlon training. They also expressed a desire for future volunteer participation to encourage others in the program. **CONCLUSIONS:** Goal-oriented team triathlon training for BCS dragon boat racers can improve exercise activity. Structured exercise as a part of a team with a common goal may have facilitated successful participation. Thus, goal-oriented team training could lead to better health for BCS. **FUNDING ACKNOWLEDGEMENT:** Aurora Research Institute/Aurora Health Care

Effects Of Resistance Plus Aerobic Training On Body Composition In Breast Cancer Survivors On Aromatase Inhibitors

Thais R.S. Paulo¹, Kerri M. Winters-Stone, FACSM², Juliana Viezel³, Fabricio E.R. Rossi³, Silvia Seidinger³, Bruna Aro³, Ana Carolina Trindade³, Ismael F. Freitas Jr³. ¹Amazonas Federal University and Sao Paulo State University, Parintins and Presidente Prudente, Brazil. ²Oregon Health and Science University, Portland, OR. ³Sao Paulo State University, Presidente Prudente, Brazil.

Email: thais.reis.silva@hotmail.com

(No relationships reported)

Background: Treatment for breast cancer is multi-modal and often includes estrogen blockade that can alter body composition. Aerobic training can reduce body fat, while resistance training improves lean mass and, bone mineral density (BMD); however, it is unclear whether exercise retains its efficacy during aromatase inhibition. Our study determined the influence of combined aerobic + resistance training on body composition of breast cancer survivors (BCS) that use aromatase inhibitors. **Methods:** Women cancer survivors are randomized to 9 months of exercise [Resistance + aerobic training] (EX): n= 18 or stretching group (SG): n=18]. Body composition was measured by DXA (total body and trunk fat mass % body fat (BF); lean body mass (LBM); spine and total hip BMD at baseline, 3, 6 and 9 months. The exercise group performed by 40 minutes with 7 resistance exercises on machines followed by 30 minutes of treadmill (aerobic) training 3x/wk. Separate 2 x 3 repeated measure ANOVAs were used to compare groups. **Results:** Retention in the study was 94% in EX and 72% in SG. Adherence to training was 78.2%. Significant group x time interactions were found for total and trunk fat mass, and % body fat, (p<0.001), where women in EX lost fat compared to slight gains among women in SG. There were no significant group x time interactions for LBM, total hip or spine BMD.

Table 1. Mean score changes in EX and SG groups from baseline to 9 months

	EX M (SD)	SG M (SD)	*p value
Total Fat Mass (kg)	-2.43 (1.77)	0.26 (0.78)	0.03
Trunk Fat Mass (kg)	-1.26 (1.06)	0.66 (0.69)	0.01
Body Fat (%)	-2.23 (1.63)	0.65 (1.53)	0.01
Lean Mass (kg)	0.63 (1.02)	-0.51 (1.96)	0.12
Spine BMD (g/cm ²)	-0.03 (0.06)	-0.02 (0.03)	0.94
Total Hip BMD (g/cm ²)	-0.002 (0.04)	0.007 (0.01)	0.22

Conclusion: This study demonstrated the potential efficacy of combined training to decrease total and trunk fat mass, an indicator of central adiposity, in breast cancer survivors on aromatase inhibitor therapy, in which fat mass is considered risk factor for recurrence of cancer, metastasis and other chronic disease. A combined modality program did not slow bone loss in this population, thus modifications to the program to include specific osteogenic training may need to be considered to target this health outcome.

Exercise Effects on Symptom Cluster, Cortisol, Heart Rate Variability and QOL in Breast Cancer Survivors

Kenneth C. Banting¹, Linda B. Piacentine¹, Aidan Flannagan¹, Toni Uhrich¹, Judy A. Tjoe², Leslie J. Waltke², Angela A. Sinner², Alexander Ng, FACSM¹. ¹Marquette University, Milwaukee, WI. ²Aurora Health Care, Milwaukee, WI.

Email: jankenneth.banting@marquette.edu

(No relationships reported)

Exercise may mitigate a cluster of related symptoms in Breast Cancer Survivors (BCS). This cluster includes fatigue, sleep disturbances, pain, depression, and cognitive changes. In addition, Cortisol Awakening Response (CAR), a function of stress, Heart Rate Variability (HRv), an indication of cardiac autonomic balance, and quality of life (QOL) may relate to this symptom cluster.

PURPOSE: To examine the effect of triathlon training on a BCS symptom cluster and to determine the relationships between the symptom cluster and CAR, HRv and QOL. **METHODS:** Female BCS (N = 26; age = 49 (8) yr) participated in a 14 wk. sprint triathlon training program. Training consisted of 2 supervised and 3 unsupervised sessions per week. Pre- and Post- training measures included CAR, HRv, and QOL (FACT-B), along with fatigue (FACIT-F), and PROMIS questionnaires for cognition (Applied Cognition-General Concerns-Short Form), depression (Emotional Distress-Depression), pain (Pain Interference-SF), and sleep (Sleep Disturbance-SF). Except for QOL and FACIT-F, higher questionnaire scores represent worse function.

RESULTS: Data are mean (SD). After training, CAR decreased, (pre= 12.8 (6.8), post= 8.5 (7.3) nmol/L, p= 0.03) and HRv increased, (pre= 44.8 (28.2), post= 68.6 (55.4) ms, p= 0.04). Further, QOL (pre= 117.4 (14), post= 125.1 (11), p< 0.01), fatigue, (pre= 41.0 (9.1), post= 47.2 (4.1), p< 0.01), cognition (pre= 16.4 (8.4), post= 13.1 (5.8), p= 0.02), depression, (pre= 10.7 (4.6), post= 9.2 (2.5), p= 0.04), and pain improved (pre=10.6 (3.9), post= 8.9 (2.2), p= 0.03). Sleep did not change. No training variables were associated with CAR or HRv. Before training, QOL correlated with depression (rs= - 0.70), cognition (rs= -0.64) and fatigue (rs= 0.80). Further, sleep correlated with pain (rs= 0.37) and depression correlated with cognition (rs= 0.54). Similar correlations were observed after training.

CONCLUSIONS: Triathlon training for BCS improved all symptoms in a cluster except sleep. QOL was related to cognition, depression and fatigue. CAR and HRv were not related to any of the symptoms studied. However, the decreased CAR and increased HRv from exercise in BCS could have positive health implications.

Investigating Physical Activity Levels And Distance-delivered Interventions Amongst Survivors Of Childhood Cancer

David Mizrahi¹, Joanna Fardell¹, David Simar¹, Claire Wakefield¹, Briana Clifford¹, Qishan Lim¹, Veronica Quinn¹, Jordana McLoone¹, Frank Alvaro², Tom Walwyn³, Richard Cohn⁴. ¹University of New South Wales, Sydney, Australia. ²John Hunter Children's Hospital, Newcastle, Australia. ³Princess Margaret Hospital for Children, Perth, Australia. ⁴Sydney Children's Hospital, Sydney, Australia.

Email: d.mizrahi@unsw.edu.au

(No relationships reported)

Purpose: This study aimed to assess physical activity levels in childhood cancer survivors (CCS), compare these to recommended guidelines, and investigated the feasibility of distance-delivered physical activity interventions amongst CCS.

Methods: CCS (aged \geq 16) and parents (survivors aged $<$ 16) from 11 hospitals in Australia and New Zealand participated in this study. Participants self-reported their moderate-vigorous physical activity (MVPA). This was compared to American Cancer Society's physical activity guidelines (150 min/week for adults, 300 min/week for children). A systematic review and meta-analysis were conducted to determine the feasibility (adherence, retention and recruitment) and effect of distance-delivered interventions on physical activity levels, physical and psychological function after intensive treatment.

Results: 329 CCS (age=27.7 \pm 7.2years, 20.3 \pm 8.3years since diagnosis) and 254 parents of CCS (age=14.0 \pm 2.8years, 10.9 \pm 2.9years since diagnosis) participated. Adult CCS reported mean MVPA of 115.9 \pm 129.8 min/week and children had MVPA of 231.3 \pm 227.8 min/week, which was in both cases lower than recommended guidelines (both $p<0.001$). Only 31.3% of adults and 29.1% of children achieved recommended MVPA guidelines. Our systematic review included 13 studies (n=270 participants), while 4 (n=102 participants) were included in the meta-analysis. Distance-delivered physical activity interventions were feasible in CCS (mean recruitment rate=64%, retention rate=85%, adherence rate=88%), but did not increase physical activity levels from baseline to post intervention ($p=0.09$). Participation in physical activity interventions displayed a positive effect on physical function ($p=0.002$) and psychological outcomes ($p=0.001$).

Conclusion: Over two-thirds of child and adult CCS are not achieving recommended physical activity levels. Strategies including education and early monitoring are needed to increase MVPA levels to lower the risk of cardiovascular and metabolic co-morbidity. CCS may experience barriers including fatigue, access to facilities or lack of guidance, but our investigation into distance-delivered interventions to increase physical activity levels suggests that such interventions could represent a viable option to tackle this important issue.

Exploring Prostate Cancer Survivors' Exercise Motivation, Facilitators And Barriers Following Participation In The TrueNTH Program

Kaitlyn Boudreau¹, Patrick Evert¹, Nicole Culos-Reed², Ashley Zahavich³, Daniel Santa Mina⁴, Margaret L. McNeely¹.

¹University of Alberta, Edmonton, AB, Canada. ²University of Calgary, Calgary, AB, Canada. ³University of Dalhousie, Halifax, NS, Canada. ⁴University of Toronto, Toronto, ON, Canada.

Email: ksoudre@ualberta.ca

(No relationships reported)

The TrueNTH Lifestyle Management program is an international program aimed to improve the survivorship and wellness of men with prostate cancer. As part of the national network, an initial 12-week exercise program, 3 days per week, was carried out at a university-based location in Edmonton Canada.

PURPOSE: To better understand the motivation, facilitators and barriers to exercise following participation in the TrueNTH exercise program.

METHODS: An optional post-program satisfaction questionnaire was administered and a focus group session conducted with 16 of the 22 program participants (mean age: 65.5 years). Quantitative data from the patient satisfaction questionnaire were analyzed descriptively and qualitative data from the focus group were used to clarify and further describe quantitative results.

RESULTS: Main findings included high satisfaction with the program (100%) and mean improvements in 8 repetition maximum strength of 8.5 lbs for bench press and 31.6 lbs for the leg press. Results from the Behavioral Regulation in Exercise Questionnaire (Version 3) showed high scores for intrinsic (3.28) and identified integration (3.25), and low scores for amotivation (0.083) and external regulation (1.18). Qualitatively participants reported benefits for body image, muscular strength as well as psychosocial wellbeing. Facilitators of exercise included supervised exercise, social support of other prostate cancer survivors, and a positive exercise environment. Survivors reported feeling "safe" and "at home" at the centre despite incontinence, use of a catheter, and issues with body image. Barriers included limited options for class times and transportation issues.

CONCLUSION: Prostate survivors taking part in the TrueNTH program were highly motivated, enjoyed, and valued the benefits of the exercise program. This examination of site-specific exercise facilitators and barriers allows for adaptation of programming to the local context.

Effects of Exercise Training on Circulating Level of Sclerostin in Breast Cancer Survivors

Tae Ho Kim, Jae Seung Chang, In Deok Kong. *Yonsei Institute of Sports Science & Exercise Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic of.*

Email: thgy1125@naver.com

(No relationships reported)

Wingless and integration site growth factor (Wnt) signaling is a tumorigenesis-related signaling pathway. Sclerostin is one of endogenous negative regulators of Wnt/ β -catenin signaling. Accumulating evidences indicate that higher serum level of sclerostin is associated with osteoporosis and bone metastasis in breast cancer patients.

PURPOSE: To investigate whether exercise training elicits changes in the serum level of sclerostin in breast cancer survivors. **METHODS:** Thirty-nine breast cancer survivors after anti-cancer treatment and forty healthy women volunteers participated in this study. Breast cancer survivors were randomized to either an exercise group or a control group for 12 weeks. All participants completed health-related fitness tests and measurements of anthropometric and serological biomarker variables. Independent *t*-test and Wilcoxon signed-rank test were performed to analyze the changes of variables between- and within-groups, respectively. **RESULTS:** Breast cancer survivors showed higher levels of serum sclerostin compared to age-matched healthy women at baseline (115.6 \pm 58.8 vs. 86.5 \pm 53.2 pg/mL, $p=0.016$). Exercise training for 12 weeks remarkably improved muscle strength, endurance and flexibility, and reduced body fat percentage, waist circumference and visceral fat area in breast cancer survivors. The exercise training reduced the serum levels of insulin, leptin and interleukin-8 as well (all $p<0.05$). Moreover, circulating sclerostin levels were significantly decreased by the exercise training (124.4 \pm 17.0 vs. 106.3 \pm 42.6 pg/mL, $p=0.021$), but there were no differences observed in control group during this clinical trial periods (116.3 \pm 42.6 vs. 114.2 \pm 66.9 pg/mL, $p=0.295$). **CONCLUSION:** These findings suggest that sclerostin may be a notable serological parameter reflecting the beneficial effects of exercise training in breast cancer survivors.

F-54 Free Communication/Poster - Cardiorespiratory Responses to Acute Exercise

Assessment of Heart Rate Variability After Maximal Exercise in Trained Postmenopausal Women

Julia C. Orri, Elizabeth M. Hughes, Deepa G. Mistry, Antone H. Scala. *University of San Francisco, San Francisco, CA.*

Email: jorri@usfca.edu

(No relationships reported)

The increased parasympathetic tone achieved with endurance training may provide important cardioprotection after menopause. Inability to restore autonomic balance postexercise is a risk factor for sudden cardiac death as sympathetic stimulation has an arrhythmic effect. Until recently, most of the studies on recovery heart rate variability (HRV) have focused on young men. **PURPOSE:** The purpose of this study was to compare the HRV response from rest through maximal exercise and recovery in postmenopausal women (PNW) who trained at moderate (MOD) or vigorous (VIG) intensities. **METHODS:** Thirty-six PMW women volunteers who self-reported exercising at either MOD (3-5.9 METS; n = 18; 58.9 \pm 4.4 yr, 59.2 \pm 6.8 kg, 160.9 \pm 10.0 cm, 32.4 \pm 5.7 ml/kg/min), or VIG intensities (>6 METS; n = 18; 59.7 \pm 5.2 yr, 68.3 \pm 10.2 kg, 167.0 \pm 7.4 cm, 34.5 \pm 5.1 ml/kg/min) participated. HRV and cardiorespiratory fitness (Bruce protocol) were measured in the laboratory. The HRV was measured with a heart rate monitor at rest for 5 minutes in the supine position with the participant breathing normally. HRV was also measured in the last minute of the $\dot{V}O_2$ max test and after 2 minutes of active recovery. Comparison of HRV in MOD and VIG was performed using a factorial ANOVA with repeated measures on time. HRV values were log transformed due to skewness. An alpha of .05 was considered statistically significant. Data are presented mean \pm SD. **RESULTS:** The two groups (MOD, VIG) responded similarly over the three time periods for selected HRV indices of root mean square of sequential deviations (rMSSD), and high (HF) and low frequency (LF) power values ($p>.05$). There were significant main effects for rMSSD, HF and LF. Specifically, maximal exercise significantly lowered rMSSD (3.3 \pm 0.08 vs. 1.2 \pm 0.06) and lnLF (4.1 \pm 0.05 vs. 3.3 \pm 0.13) and increased lnHF (3.3 \pm 0.14 vs. 4.0 \pm 0.10; $p<.01$) from resting. However, two minutes of active recovery significantly restored lnHF (3.3 \pm 0.11) and lnLF (4.1 \pm 0.08) from maximal values ($p<.01$). **CONCLUSION:** Our findings suggest that both moderate and vigorous exercise

training enhance HRV recovery in the immediate postexercise period following one bout of maximal exercise in older women. These data further document the benefits of regular aerobic exercise in the improvement of cardiac electrical stability.

3182 Board #87 June 2 2:00 PM - 3:30 PM
Effects of Submaximal Downhill Running on Plasma Cytokine Expression in Young, Endurance Trained Individuals
 Jennifer Macko, Ryan M. Sapp, Rian Q. Landers-Ramos, Jack T. Skelton, James M. Hagberg. *University of Maryland, College Park, MD.*
 Email: jmacko@terpmail.umd.edu
 (No relationships reported)

Strenuous exercise has been shown to dramatically alter levels of anti- and proinflammatory cytokines; proteins involved in regulation of systemic inflammation. **PURPOSE:** To determine if a single bout of submaximal downhill running will elicit a change in expression of specific circulating cytokines. **METHODS:** Healthy endurance-trained men (n=5) and women (n=3) aged 18-35 were screened for exercise contraindications using a health history questionnaire, blood chemistry, and body composition. A VO_{2max} test and downhill running familiarization were completed to determine experimental running speed at 70% VO_{2max} . After abstaining from exercise, caffeine, alcohol, NSAIDs, and other drugs for 48 hours, subjects ran on a 15% decline for 30 minutes at 70% VO_{2max} and ~70% HRR. Fasting blood samples were obtained immediately before and after the run, as well as after 30 minutes, 60 minutes, and 24 hours of rest. Plasma was immediately separated, aliquoted, and stored at -80°C. ELISA kits specific to each cytokine were used to measure cytokine levels at each time point. Samples were run in duplicate. **RESULTS:** There were no significant changes in IL-15 or Myostatin at any time point. Compared to baseline, IL-1ra showed an increase of 46.9% (p=0.009), 60.9% (p=0.001), and 38.8% pg/ml (p=0.028) at 0 minutes, 60 minutes and 24 hours after exercise, respectively. For IL-10, there was an increase of 19.6% (p=0.01), 28% (p=0.003), and 37.1% (p=0.0009) at 30 minutes, 60 minutes, and 24 hours after exercise, compared to baseline. **CONCLUSION:** In endurance trained subjects, a 30 minute submaximal bout of downhill running caused an increase in the anti-inflammatory cytokines IL-1ra and IL-10 for up to one day, and no significant change in the inflammatory cytokines IL-15 or myostatin. IL-1ra exhibited the greatest increase 60 minutes after exercise, while IL-10 was increased significantly at 30 minutes, 60 minutes, and 24 hours, with the greatest effect seen the day after exercise. This increase in systemic anti-inflammatory cytokines is consistent with literature investigating cytokine levels immediately after eccentric exercise. Further, IL-15 levels were highly variable, and divided subjects into two groups that were not explained by any demographics studied. This result has not been previously reported and deserves further study.

Similar Oxygen Consumption and Metabolic Cost of Thermo-Neutral and Hot Yoga.
 Rachael K. Nelson¹, Corinne N. Boyd¹, Stephanie M. Lannan¹, Ricardo Mora-Rodriguez², Micah N. Zuhl¹. ¹Central Michigan University, Mount Pleasant, MI. ²University of Castilla-La Mancha, Toledo, Spain.
 (No relationships reported)

Hot yoga has gained enormous popularity in recent years due, at least in part, to increased environmental challenge associated with hot compared to traditional (thermo-neutral) yoga. However, it is not clear that hot yoga is more intense than traditional yoga and whether it meets current physical activity guidelines. **PURPOSE:** To examine energy expenditure as well as objective (i.e., % VO_{2max}) and subjective (i.e., RPE) measures of exercise intensity during identical yoga sessions performed in a hot and thermo-neutral environment in healthy adults. **METHODS:** Using a cross-over, randomized order design, 14 participants completed two identical 20-minute yoga sessions in a hot ("H"; 35.3 ± 0.8°C; humidity: 20.5 ± 1.4%) and thermo-neutral ("TN"; 22.1 ± 0.2 °C; humidity: 27.8 ± 1.6%) environment performed one week apart. Oxygen consumption (VO_2) was measured during steady-state yoga to determine exercise intensity (% VO_{2max}) and to determine energy expenditure (kcal/min). Heart rate and rate of perceived exertion (RPE) were also collected during steady-state yoga to determine exercise intensity (%HRmax) and participant perception of intensity using the Borg Scale (6-20). **RESULTS:** There were no differences in exercise intensity based on % VO_{2max} during hot vs. thermo-neutral yoga (30.9 ± 2.3 vs. 30.5 ± 1.8%, p=0.68) or energy expenditure (5.12 ± 0.50 vs. 4.97 ± 0.39 kcal/min, p=0.42). However, exercise intensity was significantly higher during hot vs. thermo-neutral yoga based on %HRmax (67.0 ± 2.3 vs. 60.8 ± 1.9%, p=0.01) and RPE (11.8 ± 0.9 vs. 10.7 ± 0.8, p=0.04). Furthermore, hot yoga would be classified as "light" intensity exercise based on % VO_2 but "moderate" intensity exercise based on %HRmax and RPE while thermo-neutral yoga would be classified as "light" intensity exercise based on % VO_{2max} , %HRmax, and RPE (according to established ACSM guidelines). **CONCLUSION:** Despite the added hemodynamic stress and perception that exercise

in a hot environment is more difficult than in a thermo-neutral room, we observed parallel responses in oxygen consumption during hot vs. thermo-neutral yoga resulting in relatively modest but equal objective measures of exercise intensity and energy expenditure.

Different Types Of Stability Balls Impact On Heart Rate And VO2 Responses To Arm Ergometry
 Charles R.C. Marks, Michelle Nguyen. *Oakland University, Rochester, MI.* (Sponsor: Steven Keteyian, FACSM)
 Email: marks@oakland.edu
 (No relationships reported)

Prior studies have demonstrated that sitting on a stability ball during arm ergometry elevates oxygen consumption about 10%; however, the influence that the characteristics of the stability ball has on this response has not been examined. **PURPOSE:** The purpose of this study was to determine if the type of material or size of a stability ball affects the heart rate or oxygen consumption levels during aerobic arm exercise. **MEHODS:** Ten apparently healthy young adults that were at least moderately active underwent two three minute stages of arm ergometry (increase heart rate by 20-40 b/min each stage) sitting on three different stability balls: 75 cm D made of stiff material (SB), 75 cm D made of elastic material (EB), and 65 cm D made of elastic material (SE) with the order randomized. VO_2 and heart rate (HR) were continuously monitored. **RESULTS:** Repeated measures ANOVA revealed that the type of stability ball did not significantly (p = .417) affect heart rate. However, VO_2 was significantly (p = .005) affected by ball type. The EB was 6 to 7% higher than the SB.

Table. Different Types of Stability Balls during Exercise				
	Stage 1 VO_2 L/min	Stage 2 VO_2 L/min	Stage 1 HR min ⁻¹	Stage 2 HR min ⁻¹
SB Mean + SD	0.613 + 0.306	0.829 + 0.406	118 + 12	143 + 12
EB Mean + SD	0.653 + 0.322	0.877 + 0.437	121 + 18	145 + 18
SE Mean + SD	0.622 + 0.286	0.851 + 0.413	117 + 18	141 + 16

CONCLUSION: It is concluded that a more elastic material making up a stability ball can elevate the metabolic response to arm exercise but might be attenuated by a smaller ball. In addition, the type of stability ball might not affect exercise training heart rates.

The Effect Of Exercise On Inter-arm Systolic Blood Pressure Difference
 Michael E. Holmstrup¹, Melanie M. Clarke¹, Cailin R. Conner¹, Yen-Kuan Lin², Brock T. Jensen¹. ¹Slippery Rock University, Slippery Rock, PA. ²Taiwan Medical University, Taipei, Taiwan.
 (No relationships reported)

Clinically, when a difference of ≥10 mmHg in systolic blood pressure (SBP) between arms exists, it is identified as inter-arm systolic blood pressure difference (ISBPD). At rest, ISBPD is linked with hypertension, peripheral vascular disease, and increased premature mortality. It is well known that exercise reveals underlying cardiovascular pathologies absent at rest. However, there have been no investigations to examine the effect of exercise on ISBPD. **PURPOSE:** To determine if exercise may alter ISBPD when measured at rest, or reveal ISBPD when not observed in the resting condition. **METHODS:** An experienced investigator sequentially measured SBP using standard auscultation in each arm (alternating order). ISBPD was quantified at rest (REST). Participants then completed a three-stage protocol on a cycle ergometer. A cadence of 50 rpm was maintained at a workload of 3 (EX-3; light) and 6 METS (EX-6; moderate) and during an active recovery (AR). At each stage, SBP was measured upon achieving steady-state heart rate. A logistic regression analysis was used to determine the change in odds ratio of ISBPD when exposed to exercise. **RESULTS:** Eighty-five healthy individuals (18-45y) completed the study. Thirteen percent (n=11) presented with ISBPD during REST. In these individuals, the difference in SBP between arms was lower at AR than at REST (3.81 mmHg; P<0.05). In individuals who did not present with ISBPD during REST (n=74), progression from EX-3 to EX-6 significantly increased the odds of ISBPD (4.31; P<0.05). **CONCLUSIONS:** In individuals with ISBPD at rest, active recovery from exercise attenuated the difference between inter-arm SBP. Moderate-intensity exercise resulted in ISBPD not otherwise present at rest.

The Relationship Between Changes In Rmssd And Rectus Femoris Cross-sectional Area Following Exercise

Thomas J. Kopec¹, Bailey A. Welborn², James E. Leeper², Elizabeth E. Hibberd², Phillip A. Bishop³, Mark T. Richardson², Michael R. Esco, FACSM². ¹Samford University, Birmingham, AL. ²The University of Alabama, Tuscaloosa, AL. ³Liberty University, Lynchburg, VA. (Sponsor: Michael R. Esco, FACSM)
Email: kopec001@gmail.com

(No relationships reported)

PURPOSE: The natural log transformation of the root mean square of successive R-R differences (lnRMSSD) is a parasympathetic measure of heart rate variability. The extent to the relationship between lnRMSSD and localized muscle damage following exercise is unknown. The purpose of this study was to examine the relationship between lnRMSSD and Rectus femoris CSA (CSA-RF) following an exhaustive bout of exercise over 72 hours. **METHODS:** Twelve participants were measured for pre-exercise lnRMSSD for five minutes in a seated position, followed by a CSA-RF measurement with musculoskeletal ultrasound 15 cm above the superior pole of the participant's right patella. Next participants completed an exhaustive exercise protocol. Finally, participants repeated the lnRMSSD and CSA-RF measures immediately following exercise termination with follow-up testing at 24-hours, 48-hours, and 72-hours. **RESULTS:** Repeated measures ANOVA revealed significant differences in lnRMSSD between pre-exercise and post-exercise measures ($p = .002$, Table 1), but no other significant differences. Likewise, there were significant differences in CSA-RF from pre-exercise to post-exercise ($p < .001$, Table 1), but no other differences were noted. There was a large near-significant correlation between the changes in lnRMSSD and CSA-RF from pre-exercise to post-exercise ($r = -.57$, $p = .055$), and large statistically significant correlation between the changes in lnRMSSD and CSA-RF from pre-exercise measures to 24-hour follow-up ($r = -.64$, $p = .025$). **CONCLUSIONS:** In this study lnRMSSD declined as CSA-RF increased immediately following exercise up to 24 hours. This inverse relationship is likely the result of vagal tone suppression and increased sympathetic outflow in cardiac control during and immediately following exercise. Tracking lnRMSSD following exercise may give practitioners further insight to the mechanisms of recovery.

	Pre-Ex	Post-Ex	24H-Post-Ex	48H-Post-Ex	72H-Post-Ex
lnRMSSD	3.99	2.60*	3.91	3.92	3.89
CSA-RF	7.12	7.73*	7.17	7.06	7.35

Heart Rate Variability Following a Short and Long Bout of High-Intensity Functional Training

Emily Bechke, Allyson Box, Wade Hoffstetter, Paul Serafini, Cassie Williamson, Yuri Feito, FACSM, Brian Kliszczewicz. *Kennesaw State University, Kennesaw, GA.* (Sponsor: Yuri Feito, FACSM)

(No relationships reported)

Depression of Heart Rate Variability (HRV) occurs following exercise and is influenced by the intensity and duration of the activity. High-Intensity Functional Training (HIFT) is a style of training performed using various modalities and durations. **Purpose:** To examine the effect of a short (< 5-min) and a long (15-min) bout of HIFT on HRV recovery. **Methods:** Ten apparently healthy males (28 ± 5 yrs) participated in this study. Two HIFT sessions were performed in a crossover fashion. Each visit consisted of three HRV recordings: at rest (PRE; 10-min), post exercise (P; 45-min), and two-hours post (P2HR; 10-min). The short bout (SHORT) consisted of 30 power clean-and-jerks (61 kg) for time, while the long bout (LONG) was a 15-min circuit of 250m row, 20 kettlebell swings (24 kg), and 15 dumbbell squat presses (16 kg). The HRV marker used was the Root Mean Square of Successive Differences (RMSSD) and was analyzed in 5-min segments: the last 5-minutes of PRE, eight segments during P (P1-P8) starting at the 5th minute, and the last 5-mins of P2HR. **Results:** Normality was violated and data underwent a natural log transformation (lnRMSSD). Repeated Measures ANOVA did not reveal any significant differences in lnRMSSD between the SHORT and LONG trials ($p = 0.822$). A significant time effect ($p = 0.023$) was observed in both trials, with lnRMSSD depression occurring from P1-P8 ($p < 0.05$) and recovering by P2HR ($p = 0.141$). **Conclusion:** This study indicates that SHORT and LONG bouts of HIFT result in similar HRV depression and recovery. Future research is needed to better understand various bouts of HIFT and its relationship with HRV.

Effects of Prior Aerobic Exercise and Prolonged Sitting on Postprandial Plasma Glucose and Triglyceride Responses

Craig W. Berry, Robert M. Duguid, Kevin D. Ballard. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)
Email: berrycw@miamioh.edu

(No relationships reported)

Sedentary behavior, particularly prolonged sitting, is common in modern society and is associated with numerous cardiovascular disease (CVD) risk factors, including impaired glucose metabolism and higher blood triglycerides. **PURPOSE:** The purpose of this study was to determine the effects of a single bout of aerobic exercise performed prior to a prolonged sitting challenge on postprandial plasma glucose and triglyceride responses. **METHODS:** Ten healthy men [21.2 ± 0.6 y; maximal oxygen consumption (VO_{2max}) = 49.6 ± 1.7 ml/kg/min (mean \pm SE)] participated in a randomized, cross-over study in which they completed a single bout of continuous treadmill exercise (45 min at 65% VO_{2max}) or 45 min of seated rest. A carbohydrate-rich snack [190 kcals; 29/7/3g (carb/fat/pro)] was ingested by participants 30 min before and 30 min following exercise (or seated rest). Plasma glucose and triglycerides were measured after an overnight fast (Pre), 1 hr following exercise (or seated rest) (Post), and at 1 hr intervals during a 3 hr prolonged sitting challenge. Study personnel monitored participants during the sitting challenge to ensure minimal lower extremity movement. Repeated-measures ANOVA and Bonferroni post-hoc tests were used to evaluate differences within and between trials. **RESULTS:** Treadmill exercise was completed at $65.4 \pm 1.3\%$ VO_{2max} (range = 60.9-72.6%). A main effect due to time ($P < 0.001$) was observed for plasma glucose. Relative to Pre, plasma glucose concentrations in the exercise trial increased at Post by 12.1% ($P = 0.05$) and were 8.6% and 14.5% lower ($P \leq 0.02$) at 1 and 3 hr of prolonged sitting, respectively. Plasma glucose concentrations in the seated rest trial increased at Post by 15.0% ($P < 0.01$) and returned to levels no different than Pre by 1 hr of prolonged sitting. Plasma triglycerides showed no time or treatment effects. **CONCLUSION:** These preliminary findings suggest that acute aerobic exercise performed prior to 3 hr of prolonged sitting lowers postprandial plasma glucose responses induced by a carbohydrate-rich snack in healthy men. Future studies should investigate individuals at increased CVD risk and utilize a larger postprandial challenge to further elucidate potential deleterious effects of prolonged sitting.

Effect Of Vitamin D At Rest And In Response To Maximal Exercise

Amanda L. Zaleski¹, Linda S. Pescatello, FACSM², Beth A. Taylor¹, Braden Armstrong², Priscilla Clarkson, FACSM³, Stuart Chipkin³, Charles Michael White¹, Paul D. Thompson, FACSM⁴. ¹University of Connecticut/Hartford Hospital, Hartford, CT. ²University of Connecticut, Storrs, CT. ³University of Massachusetts, Amherst, MA. ⁴Hartford Hospital, Hartford, CT. (Sponsor: Linda Pescatello, PhD, FACSM, FACSM)
Email: amanda.zaleski@hhchealth.org

(No relationships reported)

Conflicting evidence suggests insufficient vitamin D (VitD) levels are associated with high resting blood pressure (BP). However the relationship between VitD and the peak systolic BP (SBP) response to exercise, a predictor of future hypertension, has yet to be investigated. **PURPOSE:** We sought to examine the relationship among serum 25-hydroxy VitD (25[OH]D), resting BP, and the peak SBP response to a graded exercise stress test among a large sample ($n=417$) of healthy men (49%) and women (51%) over a broad age range (20-76 yr; mean age 44.1 ± 0.8 y). We hypothesized that individuals with clinically sub-optimal VitD would have higher resting BP and a peak SBP response to a graded exercise stress test compared to individuals with optimal VitD levels. **METHODS:** Fasting serum VitD, anthropometrics, resting BP, and peak exercise SBP were obtained at the baseline visit of a larger clinical trial (STOMP; NCT01140308). **RESULTS:** Mean VitD levels were 36.1 ± 0.7 ng/mL, with 41.2% of individuals classified as sub-optimal (< 32 ng/mL). Average resting BP was $118.9 \pm 0.6/75.3 \pm 0.5$ mmHg, with 41% of individuals having high BP ($n=174$) consisting of those with pre-hypertension (32.5%) and established hypertension (8.5%). Individuals with optimal VitD had higher resting SBP (120.6 ± 13.4 mmHg vs. 116.4 ± 12.7 mmHg; $p=0.002$) and DBP (76.0 ± 9.9 mmHg vs. 74.1 ± 9.1 mmHg; $p=0.048$) than individuals with sub-optimal VitD, respectively. Similarly, individuals with optimal VitD tended to have a greater peak exercise SBP response than individuals with sub-optimal VitD ($p=0.114$). **CONCLUSION:** In contrast to our hypothesis, VitD was positively associated with resting BP levels, but was not associated with peak SBP under maximal exercise conditions. Additional studies are needed to confirm our findings and to provide insight into mechanisms underlying these associations among individuals with high BP. TRIAL REGISTRATION: NCT01140308

Skeletal Muscle Force Production and Bioenergetics During All-out Exercise: Influence of Group III/IV Muscle Afferents
 Ryan M. Broxterman, Gwenael Layec, Thomas J. Hureau, David E. Morgan, Amber D. Bledsoe, Jacob E. Jessop, Markus Amann, Russell S. Richardson. *University of Utah, Salt Lake City, UT.*
 Email: ryan.broxterman@utah.edu
 (No relationships reported)

PURPOSE: To investigate the influence of group III/IV muscle afferent feedback on skeletal muscle force production and bioenergetics during all-out exercise.
METHODS: Phosphorous magnetic resonance spectroscopy was performed during a 5-min all-out intermittent isometric single-leg knee-extensor exercise, consisting of 60 maximal voluntary contractions (MVC), with intrathecal fentanyl (FENT), to attenuate group III/IV leg muscle afferents, and control (CTRL) conditions in 8 healthy men (age: 28 ± 5 yrs, stature: 178 ± 4 cm, and body mass: 77 ± 8 kg). Peak, integrated, and mean forces were determined per MVC and critical force (CF) was determined as the mean force of the final 6 MVCs. The intramuscular metabolic perturbation and adenosine triphosphate (ATP) synthesis rates were determined from intramuscular concentrations of phosphocreatine (PCr), inorganic phosphate (Pi), diprotonated phosphate ($H_2PO_4^-$), ATP, and pH. **RESULTS:** Peak force (FENT: 595 ± 113 vs. CTRL: 568 ± 126 N) and end-test force (FENT: 224 ± 50 vs. CTRL: 209 ± 52) were not significantly different between conditions. The cumulative integrated force was significantly greater for FENT than CTRL over the 1st min (17557 ± 2581 vs. 16154 ± 2825 N), but not thereafter (Figure 1). End-exercise [PCr] was not significantly different between conditions, while [Pi] and [$H_2PO_4^-$] were significantly greater for FENT. The estimated total ATP synthesis rate was significantly greater for FENT than CTRL over the 1st min (66 ± 16 vs. 57 ± 13 mM), but not thereafter (Figure 1). The estimated total ATP synthesis rate at CF arose from a significantly greater oxidative ATP synthesis (FENT: 77 ± 15 vs. CTRL: 83 ± 13 %) than anaerobic ATP synthesis (FENT: 23 ± 15 vs. CTRL 17 ± 13 %). **CONCLUSION:** Attenuation of group III/IV muscle afferent feedback augmented force production during the 1st min of all-out exercise, for which the increased energy demand was met, *en masse*, by the creatine kinase reaction, glycolysis, and oxidative metabolism.

Mechanisms By Which Isometric Handgrip Training May Improve Endothelial Dilator Function In Young Healthy Men.
 Kyriakos I. Tsitoglou, Janice M. Marshal, Una Martin. *University of Birmingham, Birmingham, United Kingdom.*
 Email: KXT442@student.bham.ac.uk
 (No relationships reported)

Isometric (IHG) handgrip training can reduce arterial blood pressure (ABP), especially in hypertensives, but the mechanisms remain unclear (1). We recently showed that IHG for 4-5weeks in healthy young White European (WE) and South Asian (SA) men augmented peak exercise hyperaemia and reactive hyperaemia in the *contralateral* arm by ~30% in WEs, but only ~15% in SAs (2,3). This suggested that IHG training of one arm improves endothelial dilator function systemically even in young men, but the effects are greater in WEs. **PURPOSE:** To determine the changes induced in forearm blood flow (FBF) in the contralateral arm (CA) during a single bout of IHG training, which might serve as a stimulus for improving endothelial function, and to test whether endothelium-dependent cyclooxygenase (COX) products contribute.
METHODS: In 10 WEs and 10 SAs (19-23 yrs), FBF was recorded by venous occlusion plethysmography in the CA during IHG contractions of the dominant arm at 30% maximum voluntary contraction (5 x 3min at 5 min intervals) on 2 different days in the absence or presence of the COX inhibitor aspirin (600mg p.o.).
RESULTS: Mean arterial pressure (MABP), recorded by finger photoplethysmography, increased similarly in WEs and SAs from 79.3±2.1 to 90.0±2.4mmHg in the 1st IHG and from 78.4±1.7 to 82.6±1.8mmHg in SAs. COX inhibition had no effect on baseline or IHG values of MABP. Concomitantly, FBF in the CA increased during each IHG in both WEs and SAs, but the changes were greater in WEs than SAs, for example by an average of 30.1±2.6 vs 18.5±2.6* ml/min/100g respectively in IHG 2 and by 37.0±2.8 vs 30.6±3.2*ml/min/100g in IHG 5 (*; RMANOVA, WEs vs SAs: P<0.05). After COX inhibition, the increases in FBF were attenuated in WEs (to 11.7±1.9 and 11.6 ± 1.9§ ml/min/100g in IHGs 2 and 5), but *augmented* in SAs (to 26.8 ± 2.9§ and 39.4 ± 3.5§ml/min/100g in IHGs 2 and 5, §; before vs after aspirin: P<0.05).
CONCLUSIONS: We propose that increased FBF and increased shear stress in the CA during IHG training may act as a stimulus to improve endothelium-dependent dilator function in young WE and SA men. Further, dilator COX products contribute to the increased FBF in WEs, whereas vasoconstrictor COX products limit the increased FBF in SAs, thereby limiting the effectiveness of IHG training on endothelial function. Blood Pressure Responses To Wearing An Abdominal Belt When Performing Differing Static Exercises
 Paul Reneau, Alex Swauger, Michael J. Ryan. *Fairmont State University, Fairmont, WV.*
 Email: preneau@fairmontstate.edu
 (No relationships reported)

Many people wear abdominal belts when exercising to aid in stabilization of their core. Static exercise has been shown to raise blood pressure; however minimal is known about how wearing an abdominal belt impacts blood pressure during static exercise.
PURPOSE: The purpose of this study was to investigate the impact of wearing an abdominal belt on blood pressure when subjects performed 3 static exercise positions.
METHODS: n = 16, 13 males & 3 females (age=21.5±1.3 years, ht=179.2±6.4 cm, wt=79.3±12.6 kg) served as subjects. Resting blood pressure was initially measured in a seated position. Subjects then participated in three static exercises including a Wall-Sit, Side Plank, and Static Back Extension. Subjects completed each exercise position once with an abdominal belt and once without. Test order of belt/no belt and exercise positions was randomized. Blood pressure was measured at the 45 second point for each exercise. Subjects were given recovery time between exercises for blood pressure to return to normal. A 2 x 3 Factorial ANOVA was performed on systolic (SBP) and diastolic blood pressure (DBP) data. It was determined a priori that appropriate post-hoc follow up tests would be performed as needed. **RESULTS:** Results for SBP are presented in table below. For SBP no significant interaction (p>.05) was found with the 2 x 3 ANOVA. When main results were investigated no significant difference (p>.05) was found between positions. A significant difference (p<.01) was found for the main effect of With Belt vs. No Belt. No significant (p>.05) results were found with all testing of DBP.

	Wall Sit	Side Plank	Static Back Extension	Total
No Belt	146.7 (7.0)	144.8 (5.6)	144.8 (6.1)	145.4 (6.2)
W/ Belt	151.7 (9.4)	150.3 (6.6)	151.6 (5.5)	151.2 (7.2)*
Combined	149.2 (8.5)	147.5 (6.6)	148.2 (6.7)	

*p<.01
CONCLUSIONS: The results indicate that wearing an abdominal belt when performing static exercises has minimal impact on DBP between wearing a belt and not. However, wearing an abdominal belt while performing static exercises appears to increase SBP irrelevant of body position compared to no abdominal belt. Subjects should be conscious/aware of this response when performing static exercises.

Post-Exercise Blood Pressure In 8-10 Year Old Boys
 Justin R. Bland, Kenneth R. Turley, FACSM. *Harding University, Searcy, AR.*
 Email: jrbland@harding.edu
 (No relationships reported)

INTRODUCTION: Adults often see a period of post-exercise hypotension (PEH) following moderate intensity exercise. It is not established if children experience PEH after aerobic exercise. **PURPOSE:** To investigate the changes in blood pressure (BP) occurring after a bout of exercise in prepubescent boys ages 8-10. **METHODS:** Ten boys visited the lab on four separate occasions. The first visit was to assess anthropometric measurements (height, weight and body composition via skinfolds) as well as perform a graded exercise test to exhaustion on an electronically braked cycle ergometer in order to establish aerobic capacity and peak power output (PPO). The subsequent visits (two exercise and one control) were randomized and counterbalanced and separated by at least 48hrs. The exercise visits were identical in protocol and required participants to arrive at the lab after an overnight fast. Resting BP measurements were obtained during 30 minutes of semi-recumbent seating. After the resting period, the child then performed 20 minutes of continuous cycling at 50% of their PPO. Upon cessation of the exercise test the child resumed the semi-recumbent position and BP measurements were obtained for minutes 5, 10, 15, 20, 30, 40, 50 and 60 post-exercise. Participants remained in the semi-recumbent position for the control visit; BP measurements were taken the same as the exercise visits. **RESULTS:** Data from exercise tests were averaged. When cycling at 50% of PPO the boys averaged 62% of their VO2peak. Resting systolic BP (110.7±14.2mmHg) did not significantly (p>0.05) differ when compared to post-exercise measurements at minutes 5 (125.3±23.0mmHg), 10 (113.0±16.1mmHg), 15 (111.0±15.7mmHg), 20 (108.7±14.3mmHg), 30 (108.9±16.1mmHg), 40 (106.4±16.1mmHg), 50 (107.3±15.2mmHg), 60 (104.8±16.1mmHg) or any measurements from the control visit. Furthermore, resting diastolic BP (61.0±3.9mmHg) did not significantly (p>0.05) differ when compared to post-exercise measurements at minutes 5 (58.1±5.1mmHg), 10 (61.7±1.8), 15 (61.1±4.3), 20 (59.2±3.9), 30 (60.2±5.7), 40 (60.6±5.0), 50 (63.3±5.2), 60 (61.2±5.4) or any measurements from the control visit. **CONCLUSIONS:** PEH was not observed in 8-10 yr old boys following a 20-minute exercise at 62% of VO2peak. It is unknown if a greater exercise intensity would elicit a PEH response.

The Effect of Acute Exercise on Coagulation Factors and the Mechanical Properties of Fibrin Fibers
 Peter H. Brubaker, FACSM, Georgia Holland, Wei Lei, Martin Guthold. *Wake Forest University, Winston-Salem, NC.*
 Email: brubaker@wfu.edu
 (No relationships reported)

PURPOSE: The objective of this study was to investigate the effect of acute exercise on coagulation factors and fibrin fiber properties in both younger healthy subjects and older subjects with cardiovascular disease (CVD). In addition, it was of interest to examine relationships between coagulation factors and fibrin fiber properties during acute exercise. **METHODS:** 5 male subjects were recruited to the younger, healthy (YH) group and 5 male subjects were recruited to the older group with CVD (OD). Each participant performed a single session of an acute exercise protocol, having blood drawn pre-exercise and post-exercise. Repeated measures ANOVA and Pearson's correlations were used to analyze the results. Effect sizes (η^2) were used to combat the small sample size and avoid type II errors. **RESULTS:** 2-way repeated measures ANOVA revealed only one significant interaction: VIII ($p = .001$, $\eta^2 = .778$). Paired sample t-tests showed the YH group had a significant increase in VIII from pre-exercise to post-exercise ($p = .002$) but the OD did not. Between group differences (YH vs. OD) were seen during exercise when measuring alpha-2-antiplasmin ($p = .018$, $\eta^2 = .552$), antithrombin ($p = .026$, $\eta^2 = .481$), and fibrin fiber extensibility ($p = .003$, $\eta^2 = .691$). A significant increase in platelet levels was seen within groups from pre- to post-exercise ($p = .048$, $\eta^2 = .507$). Pearson's correlations revealed significant inverse correlations between VIII and fibrin fiber extensibility post-exercise ($r = -.804$), and between platelets and fibrin fiber extensibility post-exercise ($r = -.711$). Significant inverse relationships were also seen between pre-exercise alpha-2-antiplasmin and post-exercise fibrin extensibility ($r = -.788$), and between pre-exercise antithrombin and post-exercise fibrin extensibility ($r = -.646$). **CONCLUSION:** Coagulation factors including VIII, alpha-2-antiplasmin, and antithrombin all appear to be affected by acute exercise. Furthermore, acute exercise appears to cause an increase in fibrin fiber extensibility in the OD group but not in the YH group. The four significant inverse correlations provide evidence fibrin fiber extensibility may decrease in response to exercise, by altering levels of pre-exercise VIII and platelets, and post-exercise alpha-2-antiplasmin and antithrombin.

The Age-related Decline In Vo2max: Role Of Peripheral Oxygen Transport And Utilization
 Jayson R. Gifford, Ashley D. Nelson, Joel D. Trinity, Ryan M. Broxterman, Gwenael Layec, Joshua C. Weavil, Russell S. Richardson. *University of Utah, Salt Lake City, UT.*
 (No relationships reported)

PURPOSE: Determine if decrements in peripheral factors, such as skeletal muscle oxygen delivery, oxygen diffusion and mitochondrial oxygen consumption, contribute to the well-established, age-related decline in aerobic capacity (*i.e.* VO_{2max}). **METHODS:** Eight young (25 ± 1 yrs) and eight old (74 ± 3 yrs) males matched for physical activity, and body mass index, performed a graded cycling exercise test to determine whole-body VO_{2max} (body VO_{2max} , Indirect Calorimetry). To determine the capacity of peripheral factors free from central constraints, participants also performed maximal single leg knee extension (KE), while single-leg VO_{2max} ($VO_{2max, KE}$), oxygen delivery ($Q_{O_{2max, KE}}$) and muscle oxygen diffusion ($D_{O_{2max, KE}}$) were determined with arterial-venous blood draws and Doppler Ultrasound (*i.e.* Direct Fick). Maximal skeletal muscle mitochondrial respiratory capacity ($VO_{2max, Mito}$) was assessed with mitochondrial respirometry of biopsied fibers from the vastus lateralis. **RESULTS:** Consistent with previous reports, during cycling exercise older individuals exhibited a 25-30% reduction in maximum power (Young: 244 ± 9 W, Old: 182 ± 16 W, $P < 0.05$) and body VO_{2max} (Young: 37 ± 2 ml/kg/min, Old: 26 ± 2 ml/kg/min, $P < 0.05$). Interestingly, during KE, which is free from central constraints, older individuals exhibited similar capacities in terms of KE power, $VO_{2max, KE}$, $Q_{O_{2max, KE}}$ and $D_{O_{2max, KE}}$ to the young (See Figure). Additionally, rather than being attenuated, $VO_{2max, Mito}$ was actually slightly greater in the old ($P < 0.05$). **CONCLUSION:** Despite exhibiting a lower VO_{2max} during whole-body exercise, the capacity for peripheral oxygen transport and utilization appears to be preserved in physical-activity matched, older adults. Thus, when physical activity is maintained the age-associated decline in aerobic capacity during whole-body exercise is likely dependent upon limited central factors, such as cardiac output, and not peripheral oxygen transport and utilization.

Acute Effects of Elevation Training Mask on Heart Rate Variability in Healthy Subjects
 Hyun Chul Jung¹, Nan Hee Lee², Soeun Jeon², John D. Smith², Michael Maspero², Sukho Lee². ¹University of Louisiana at Monroe, Monroe, LA. ²Texas A&M University-San Antonio, San Antonio, TX. (Sponsor: Minsoo Kang, FACSM)
 (No relationships reported)

Elevation training mask (ETM) is purportedly designed for providing simulated altitude training, which claims that increasing respiratory resistance during exercise could provide benefits in respiratory functions and aerobic fitness. We assumed that this changed respiratory resistance may alter the autonomic cardiac regulation especially Heart Rate Variability (HRV). **PURPOSE:** The purpose of this study was to examine the acute effect of an elevation training mask on HRV during cycling. **METHODS:** This study was conducted with randomized and crossover design. Fifteen healthy male ($N=9$) and female ($N=6$) collegiate students (27.0 ± 4.42 yrs) completed two trials with mask (Mask) vs without mask (CON). The 40-minute protocol included (1) rest, (2) 50% and (3) 70% of VO_{2max} cycling, and (4) recovery, each 10-minute phases. HRV variables including high frequency (HF), low frequency (LF), LF/HF ratio, were collected for 5 minutes at each phase with Activwave-Cardio (CamNtech, UK). A 2x4 repeated measures (RM) MANOVA was used to analyze the data. Significant level was set at .05. **RESULTS:** A RM MANOVA result showed that there was no significant interaction effect on HRV. However, there were significant trial (Pillai's $F[3,12] = 4.488$, $p = .025$) and time (Pillai's $F[9,126] = 5.383$, $p < .001$) effects on HRV. Follow-up univariate tests revealed that HF was significantly greater in Mask than CON trial ($F[1,14] = 7.484$, $G-G p = .016$). Both HF ($F[1.05,14.74] = 24.221$, $G-G p < .001$) and LF ($F[1.29,18.05] = 28.759$, $G-G p < .001$) were decreased as cycling intensity increased. **CONCLUSIONS:** In summary, acute wearing of ETM does not alter the HRV during cycling. However, a greater HF response was observed in Mask than CON trial. Future studies are needed to confirm the effects of long-term training with ETM on HRV.

Effects Of Acute Aerobic Repetition Exercise On The Vascular Endothelial Function
 Yasuaki Tamura¹, Hajime Miura¹, Kenichi Deguchi², Yuji Hashimoto¹, Miduki Ishikawa¹, Ayako Azuma¹. ¹Tokushima Univ., Tokushima, Japan. ²Naruto Hosp., Tokushima, Japan.
 Email: rlxfx338@ybb.ne.jp
 (No relationships reported)

PURPOSE: High-intensity interval exercise leads to greater improvements in the vascular endothelial function than continuous exercise at moderate intensity. However, few studies have been performed on the effects of repetition exercise consisting of high-intensity exercise and followed by complete rest of the arterial function. Therefore, the purpose of this study was to investigate the effects of repetition exercise on the vascular endothelial function determined by flow-mediated vasodilation (FMD). **METHODS:** Seven healthy male subjects completed two exercise sessions on a cycle ergometer in a counterbalanced order. The exercise sessions were (i) 20 min cycling at 50% VO_{2max} (CE) and (ii) 20 x 20-sec intervals at 100% VO_{2max} interspersed with 40-sec intervals at complete rest (RE). Before and after each protocol, the brachial systolic and diastolic blood pressure were measured in the supine position. The vascular endothelial function of the right brachial artery was also assessed by flow-mediated vasodilation (%FMD), and then the normalized FMD (nFMD) was calculated from the adjusted peak shear rate. **RESULTS:** In the CE trial, the nFMD (au) increased after exercise and returned to the baseline level after 60 min of recovery (0.9 ± 0.1 at baseline, 1.4 ± 0.2 at 30min after the trial, 1.2 ± 0.2 at 60 min after the trial). In the RE trial, the change in the nFMD (au) resembled those in the CE trial (0.9 ± 0.2 at baseline, 2.0 ± 0.3 at 30 min after the trial, 1.3 ± 0.3 at 60 min after the trial). The exercise-by-time interaction effect was not significant; in addition, the main effect of exercise was not significant. However, there was a significant main effect of time present ($P < 0.05$), indicating that the nFMD changed over time. **CONCLUSION:** Acute repetition exercise increases the systemic vascular endothelial function just as continuous exercises dose. These results suggest that repetition training might be useful for the prevention of cardiovascular disease.

Burn Injury Reduces Cardiac Output and Stroke Volume During Submaximal Aerobic Exercise in Children

Eric Rivas, Julianna M. Bores, David N. Herndon, Michael Kinsky, Oscar E. Suman, FACSM. *The University of Texas Medical Branch and Shriners Hospitals for Children, Galveston, TX.* (Sponsor: Oscar E. Suman, FACSM)
Email: eririvas@utmb.edu
(No relationships reported)

PURPOSE: Burn trauma causes a hypermetabolic-cardiac stress response that impairs resting cardiac function. It is currently unknown how burn trauma affects cardiovascular responses to submaximal exercise in children. We tested the hypothesis that burned children have reduced cardiac output and stroke volume during submaximal exercise at 6-12 months post-burn.

METHODS: Values are expressed as means \pm SD with significance set at $P < 0.05$. Five children with 49 \pm 4% total body surface area (BSA) burned (2 female, 11.7 \pm 1y, 40.4 \pm 18kg, 141.1 \pm 9cm) and nine similar ($P > 0.05$) non-burned controls (6 female, 12.5 \pm 2y, 59.0 \pm 16kg, 150.1 \pm 12cm) with comparable exercise capacity (VO_{2peak} : 31.8 \pm 11 vs 37.7 \pm 8 mlO₂·kg⁻¹·min, $P = 0.27$) participated. Burn children had a reduced growth BMI-for-age percentile compared to non-burn (54.6 \pm 36 vs 93.2 \pm 6 %tile; $P = 0.008$) at 9.4 \pm 3 mo post-burn injury. Oxygen consumption (VO_2), heart rate (HR), cardiac output (Q, via non-rebreathing), stroke volume (SV, Q/HR), and arteriovenous O₂ difference ((a-v) O₂ diff, Q/VO₂) were measured during a submaximal exercise protocol that entailed a pre-exercise (pre-EX) rest period followed by 3-minute exercise stages at 50% and 75% of their peak VO_2 .

RESULTS: Utilizing a 2-way factorial ANOVA (group (G) x exercise (EX)), Q at 50% and 75% VO_{2peak} were reduced by ~27% in burned (5.6 \pm 1, 6.9 \pm 1.6 L·min) compared to non-burn group (7.9 \pm 2, 9.1 \pm 3 L·min) (G x EX interaction, $P = 0.012$). SV did not differ from preEX to 50-75% VO_{2peak} in burn children (preEX: 41.7 \pm 15 to 50-75%: 43.8 \pm 8ml·beat) but, increased by ~21% in non-burned group (preEX: 47.7 \pm 16 to 50-75%: 60.7 \pm 16 ml·beat; main effect for EX, $P = 0.046$). (a-v) O₂ diff and VO_2 at preEX, 50-75% VO_{2peak} was not different ($P > 0.05$) between groups but HR response to exercise was reduced (G x EX interaction, $P = 0.02$). When normalized to BSA, SV(index) was similar between groups; however, Q(index) response to exercise remained attenuated in the burned (G x EX interaction, $P = 0.007$).

CONCLUSIONS: These preliminary data indicate that burn children have an attenuated cardiovascular response to submaximal exercise compared to non-burned children due to impaired cardiac function. Further examination of hemodynamic function during exercise will offer insight for cardiovascular rehabilitation medicine in burned children.

Microvascular and Nitric Oxide Responses to Acute Exercise with Resveratrol or Estradiol in Postmenopausal Women

Cemal Ozemek, K Joseph Hurt, Rachael Bok, Teresa Witten, Kerry L. Hildreth, Kerrie L. Moreau. *University of Colorado Anschutz Medical Campus, Denver, CO.*
Email: ozemek@uic.edu
(No relationships reported)

PURPOSE: Microvascular function measured via the reactive hyperaemic velocity time integral (VTI) has been shown to be more closely related to cardiovascular disease risk factors than macrovascular endothelial function, and is an independent predictor of cardiovascular events. Estrogen (E2)-deficient postmenopausal women have diminished endothelial adaptations to exercise training compared to age-matched men and E2-treated postmenopausal women. The polyphenol resveratrol, is an E2 receptor agonist that has been shown in animal models to enhance exercise training effects on cardiovascular function. No study has examined the effects of acute endurance exercise with E2 or resveratrol treatment on microvascular function or circulating nitric oxide (NO). Accordingly, the purpose of this study was to determine whether pre-treatment with acute E2 or resveratrol modulates microvascular function and NO responses to an acute bout of endurance exercise in postmenopausal women.

METHODS: VTI and circulating NO (via Griess assay) were examined before and following (120 minute) acute treadmill exercise (40 minutes at 60-75% of maximal heart rate) in 13 sedentary E2-deficient postmenopausal women (58 \pm 3 years; mean \pm SD) randomized, to either E2 (transdermal patch 0.05 mg/d starting 2 days before exercise visit), resveratrol (one 250 mg oral tablet 45 minutes before exercise) or placebo (inactive patch and tablet).

RESULTS: There were no significant differences in pre-exercise VTI and NO between placebo and resveratrol conditions or with E2 conditions. There were no significant differences in post exercise between group changes in VTI and NO.

	VTI (cm)			NO (µM)		
	Placebo	Resveratrol	E2	Placebo	Resveratrol	E2
Pre	81.1 \pm 25.2	94.6 \pm 21.7	91.1 \pm 23.5	123.7 \pm 60.6	142.8 \pm 65.6	119.5 \pm 51.2
120 min change	-9.5 \pm 17.4	-11.4 \pm 16.6	-4.8 \pm 22.7	-4.9 \pm 30.7	-18.5 \pm 64.1	-5.0 \pm 19.7

CONCLUSIONS: Acute E2 or resveratrol did not significantly alter basal microvascular function or circulating NO, nor did they modulate the response to an acute bout of moderate intensity treadmill exercise. Whether resveratrol would modulate vascular adaptations to chronic exercise training needs future exploration.

3200 Board #105 June 2 2:00 PM - 3:30 PM

Performance Related Hemodynamic Responses to an Aerobic Exercise Across Different Stages of the Menstrual Cycle

Patrick G. Murphy, 78520, Danny Dominguez, Brittany Esparza, Murat Karabulut. *University of Texas at Rio Grande Valley, Brownsville, TX.*
(No relationships reported)

PURPOSE: To examine the physiological changes, especially body water and hemodynamic measures that occur in females across their respective menstrual cycles in response to aerobic performance. **METHODS:** Eleven females (age = 21.2 \pm 1.4 yrs) performed four sessions of aerobic activity at 75% of their calculated VO_{2max} as determined by the Bruce Protocol. The speed for each subject's aerobic activity was then calculated using the ACSM metabolic running equation. The four sessions of aerobic activity were identical in format and performed on days 1, 7, 14, and 21 of each subject's menstrual cycle. Sessions began with measurements of body weight, body fat, heart rate (HR), and blood pressure (BP). Extracellular fluid (ECF), intracellular fluid (ICF), and fat-free mass (FFM) was also recorded via single-frequency and multiple-frequency bio-electrical impedance analysis (BIA) prior to aerobic activity. Subjects then completed 30 minutes of aerobic exercise at the calculated speed to yield an intensity of 75% VO_{2max} . Following the aerobic event, all measures taken pre-exercise, as well as RPE, were measured again at three separate time points post-exercise (post-0min, post-15min, and post-30min) while HR was monitored continuously. **RESULTS:** Day one systolic BP significantly correlated with day one Δ ECF at multiple time points ($r = -0.619$ to -0.680 , $p < 0.05$). HR also had significant correlations on day one with Δ ECF and Δ ICF ($r = -0.610$, $p < 0.05$; $r = 0.609$, $p < 0.05$). Day 7 had significant correlations between BP (systolic and diastolic) and ICF ($r = -0.610$ to -0.672 , $p < 0.05$) at multiple time points. **CONCLUSIONS:** The results showed that hemodynamic variables had notable correlations throughout most performance-related measures and across the different days of the menstrual cycle. From Day 1 to 7 there is an observable shift in correlation from BP and ECF to BP and ICF. This apparent shift in fluid may be due to the physiological responses associated with progressing through one's cycle from the menstrual to luteal phase in which a significant amount of body water is lost. These results demonstrate that there may be different responses to aerobic performance throughout the different phases of the menstrual cycle, but further investigation is required to make any kind of recommendations.

Sex Differences in Acute Effect of Exercise on Endothelial Function in Older Adults

Demetra D. Christou, Jeung-Ki Yoo, Michelle M. Pinto, Han-Kyul Kim, Chueh-Lung Hwang, Jisok Lim, Eileen M. Handberg. *University of Florida, Gainesville, FL.*
(No relationships reported)

There is growing evidence of sex differences in the chronic effect of aerobic exercise on endothelial function (flow-mediated dilation; FMD) in older adults. However, whether sex differences also exist in the acute effect of aerobic exercise on FMD in older adults is unknown. **PURPOSE:** To test the hypothesis that the FMD response to acute aerobic exercise will be different in older men compared with postmenopausal women and that exercise intensity will influence the FMD response. **METHODS:** Thirteen older men and fifteen postmenopausal women, free of major clinical disease, participated in this randomized crossover study (67 \pm 1 vs. 65 \pm 2 yrs, mean \pm SE, $P = 0.4$). Subjects completed a single bout of low-intensity continuous training (LIC; 47 min 50% peak heart rate (HRpeak)), moderate-intensity continuous training (MICT; 47 min 70% HRpeak) and high-intensity interval training (HIIT; 40 min: alternating intensities of 90% and 70% HRpeak) on the treadmill in a counterbalanced order. Brachial artery FMD was assessed at rest, at end of exercise and following 60-minute recovery. **RESULTS:** In older men, FMD was attenuated by 45% following HIIT (5.95 \pm 0.85 vs. 3.27 \pm 0.52%, $P = 0.003$) and by 37% following MICT (5.97 \pm 0.87 vs. 3.73 \pm 0.47%, $P = 0.03$; $P = 0.9$ for FMD response to HIIT vs. MICT) and was normalized following 60-min recovery ($P = 0.99$). In postmenopausal women, FMD did not

significantly change in response to HIIT (4.93 ± 0.55 vs. $6.31 \pm 0.57\%$, $P=0.14$) and MICT (5.32 ± 0.62 vs. $5.60 \pm 0.68\%$, $P=0.99$). In response to LICT, FMD did not change in postmenopausal women nor older men (5.21 ± 0.64 vs. $6.02 \pm 0.73\%$, $P=0.7$ and 5.70 ± 0.80 vs. $5.55 \pm 0.67\%$, $P=0.99$). **CONCLUSIONS:** Sex and exercise intensity significantly impact the FMD response to acute aerobic exercise in older adults. In older men, FMD is attenuated following acute HIIT and MICT but not LICT, whereas in postmenopausal women FMD is unaffected.

3202 Board #107 June 2 2:00 PM - 3:30 PM
The Acute Cardiorespiratory Responses to High versus Low Volume Interval Cycling Exercise in Healthy Adults

Andrew Scott, Danielle Kidd, Jodie Lawson. *University of Portsmouth, Portsmouth, United Kingdom.*
 Email: andrew.scott@port.ac.uk
 (No relationships reported)

PURPOSE: High intensity interval training (IT) is an increasingly popular exercise mode with possible health risks and benefits. Therefore the purpose was to compare acute responses to two volumes of IT in healthy untrained males.

METHODS: Ten males (aged 19.5 ± 1.13 years) completed two IT trials on a cycle ergometer in a counter-balanced repeated measures study, at least 48 hours apart. Low volume (LVIT) consisted of three 20 s sprints (3x20) at self-selected maximal cadence with 7% of body mass as resistance and 160 s active rest. High volume (HVIT) consisted of ten 60 s sprints (10x60) at self-selected maximal cadence with 3.5% of body mass as resistance and 60 s active rest. Oxygen uptake (VO_2), heart rate (HR) and power (W) were recorded continuously. In addition to these measures blood lactate [La] and systolic blood pressure (SBP) were recorded pre, post and every ten minutes post-exercise for 30 minutes. Oxygen pulse (O_2 pulse), % predicted peak heart rate (%HR_{peak}), elevated post-exercise oxygen consumption (EPOC), energy expenditure (EE), fatigue index and rate-pressure product (RPP) were calculated. Repeated measures ANOVA and effect sizes were applied.

RESULTS: 10x60 caused a significantly greater VO_2 (1548 ± 708 mL·kg⁻¹·min⁻¹ vs 1155 ± 476 mL·kg⁻¹·min⁻¹; $p < 0.001$), O_2 pulse (9.6 ± 5.5 mL·beat⁻¹ vs 7.5 ± 3.3 mL·beat⁻¹; $p < 0.001$), %HR_{peak} ($95 \pm 4\%$ vs $91 \pm 5\%$; $p = 0.010$), EPOC magnitude (35.3 ± 5.8 L vs 28.3 ± 7.1 L; $p = 0.018$) and EE (500 ± 53 kcal vs 235 ± 29 kcal; $p < 0.001$) than 3x20. EPOC duration was not significantly different (10x60: 16.51 ± 12.32 minutes vs 3x20: 10.84 ± 6.19 minutes; $p = 0.140$). There were no significant differences in mean SBP (10x60: 136.3 ± 2.6 mmHg vs 3x20: 134.6 ± 2.4 mmHg; $p > 0.050$) or RPP (10x60: 16179 ± 462 vs 3x20: 15957 ± 481 ; $p = 0.668$) between trials, however there was a clinically significant reduction in SBP 30 minutes following 3x20 (122 ± 15 mmHg) compared to pre-exercise (135 ± 8 mmHg) ($p = 0.053$, $d = 1.10$), but not following 10x60 (pre 131 ± 12 mmHg; post 126 ± 9 mmHg; $p = 0.303$). 3x20 caused significantly greater fatigue index ($36.5 \pm 11.3\%$ vs $23.0 \pm 10.1\%$; $p = 0.009$) and [La] (11.56 ± 2.13 mmol·L⁻¹ vs 7.79 ± 2.47 mmol·L⁻¹; $p = 0.010$; $d = 1.63$) 10 minutes post exercise.

CONCLUSIONS: 10x60 elicited significantly greater cardiorespiratory responses, whereas 3x20 produced a greater [La] and fatigue index.

Acute Effects of Heated Water Based Exercise on Ambulatory Blood Pressure and Heart Rate Variability in Long Term Treated Elderly Hypertensive Patients

Awassi Yuphiwa Ngomane, Bianca Fernandes, Julia Lara Balbo, Emmanuel Gomes Ciolac. *São Paulo State University – UNESP, BAURU, Brazil.*
 Email: awassiy@gmail.com
 (No relationships reported)

PURPOSE: Although heated water-based exercise (HEX) training has shown to largely reduce blood pressure (BP) in patients with resistant hypertension, the effect of a single exercise bout on ambulatory BP (ABP) in elderly subjects is unknown. Our purpose was to evaluate the acute effect of HEX versus land-based exercise (LEX) on ABP and heart rate variability (HRV) in long-term treated elderly hypertensive patients.

METHODS: Twelve sedentary elderly hypertensive patients (6 women) aged 60 ± 10 yr, under drug therapy for 15±3 yr, underwent a 30 min of HEX (walking inside the pool), LEX (walking on a treadmill) and nonexercise control session (CON) in random order (2-5 days between interventions). HEX and LEX intensity was set at 11-13 in the 6-20 RPE scale. HRV was analyzed before and after each intervention, and twenty-four hour (24-h) ABP monitoring was performed after each intervention.

RESULTS: There was a tendency toward ($P = 0.06$) increase in low-frequency (pre = 43 ± 7.3 n.u.; post = 57.9 ± 5.5 n.u.) and decrease in high-frequency (pre = 56.7 ± 7.3 n.u.; post = 42 ± 5.5 n.u.) HRV after LEX, but no changes were observed after HEX and CON. However, 24-h (-6 mmHg), daytime (-6 mmHg) and nighttime (-6 mmHg) systolic ABP were significant lower ($P < 0.05$) after HEX than after LEX and CON. Although daytime (-3 mmHg) and nighttime (-4 mmHg) diastolic ABP was lower after HEX than after LEX and CON, this reduction was not statistically significant.

CONCLUSIONS: Although there was an improvement in HRV after LEX, 24-h, daytime and nighttime systolic ABP reduced only after HEX. This result suggest that HEX may be superior than LEX to manage BP hypertension in long-term treated elderly hypertensive patients.

Effect of Acute Antioxidant Therapy on Cardiac Baroreflex Sensitivity in Young Healthy Men

Brandi Y. Stephens, Jasdeep Kaur, Jennifer R. Vranish, Jordan C. Patik, R. Matthew Brothers, Paul J. Fadel, FACSM. *University of Texas at Arlington, Arlington, TX.* (Sponsor: Paul J. Fadel, FACSM)
 (No relationships reported)

There is an emerging body of evidence in animals indicating that elevated oxidative stress impairs baroreflex sensitivity (BRS) function, however studies in healthy humans have yielded equivocal results. One potential reason for this discrepancy is that previous studies have used individual antioxidant treatments (e.g., Vitamin C only) to investigate the effect of oxidative stress on BRS. Recent studies in healthy humans have demonstrated significant reductions in reactive oxygen species using an antioxidant cocktail (AOC; Vitamin C, Vitamin E, and Co-enzyme Q10) suggesting the effectiveness of this treatment. Whether this AOC induced reduction in oxidative species affects BRS in young, healthy adults remains unknown. **PURPOSE:** We tested the hypothesis that AOC will improve cardiac BRS in young healthy adults. **METHODS:** Five young men were studied on two separate days: placebo (sugar pills) and AOC (2000 mg Vitamin C, 150 IU Vitamin E and 100 mg Co-enzyme Q10) performed in random order. Resting heart rate (ECG) and arterial blood pressure (automated sphygmomanometer and finger photoplethysmography) were measured 90 minutes after AOC or placebo (a time period this AOC has been shown to have peak effects on oxidative stress). Spontaneous cardiac BRS was determined for all sequences combined (overall BRS), and also separately for up (increase systolic blood pressure: increase R-R interval) and down (decrease systolic blood pressure: decrease R-R interval) sequences. **RESULTS:** Systolic blood pressure on AOC day tended to be lower relative to the placebo day (127 ± 4 vs. 131 ± 5 ; $p = 0.098$). However, no differences in overall cardiac BRS were found between placebo and AOC (18.0 ± 2.7 vs. 17.3 ± 2.6 ms/mmHg; $p = 0.59$). Likewise, up sequences (17.02 ± 2.9 vs 14.04 ± 4.0 ms/mmHg; $p = 0.51$) and down sequences (18.0 ± 2.7 placebo vs. 18.0 ± 2.6 ms/mmHg AOC; $p = 0.98$) were not different between conditions. Equal number of sequences were found between the placebo and AOC days. **CONCLUSION:** These preliminary data suggest that antioxidant treatment does not affect resting cardiac BRS in young, healthy men. The Effect of Acute Aerobic Exercise on Hemostasis in Obstructive Sleep Apnea

Ryan A. Martin, Gabrielle E. W. Giersch, Courtney L. Strosnider, Christopher J. Womack, FACSM, Trent A. Hargens, FACSM. *James Madison University, Harrisonburg, VA.*
 Email: Ryan.Martin4@rockets.utoledo.edu
 (No relationships reported)

Obstructive Sleep Apnea (OSA) is a prevalent sleep disorder affecting 2 – 4% of the middle-aged population. Individuals with OSA have an altered hemostatic balance favoring coagulation that may predispose them to cardiovascular disease and/or myocardial events. Although the resting hemostatic balance is well understood, the exercise response is less described.

Purpose: To determine the hemostatic response after acute aerobic exercise in Obstructive Sleep Apnea.

Methods: Eighteen males (nine OSA vs. nine Controls) aged 41 ± 13 yrs. and 28.4 ± 3.5 BMI were recruited from the university and local community without evidence of cardiovascular, pulmonary, or metabolic disease. Apnea-Hypopnea Index (AHI) > 5 was criteria for OSA. Subjects performed a treadmill exercise test at 35% and 70% predicted VO_2 reserve during the morning hours. Pre exercise blood samples were obtained after 15 minutes supine rest and within 2 minutes following exercise. Repeated Measures ANOVA were performed for Factor VIII antigen, tPA antigen, tPA activity, and PAI-1 activity. Correlational analysis compared resting and post exercise hemostatic factors with age, BMI, and AHI.

Results: Mean AHI was 13.00 ± 12.6 . No exercise x condition interactions were observed for hemostatic markers. There was a main effect for exercise in Factor VIII,

tPA antigen, and tPA activity in both groups. PAI-1 activity tended to be elevated in OSA (145%) compared to controls which remained after exercise (205%) ($P = 0.05$). Post exercise FVIII:Ag correlated with BMI ($r = 0.52$), while resting tPA:Ag correlated with AHI ($r = 0.49$), and age ($r = 0.50$).

Conclusion: The hemostatic response after acute aerobic exercise is unaffected in mild OSA although PAI-1 activity seems to be elevated. BMI is correlated with FVIII:Ag, while tPA:Ag is associated with AHI and age.

Reliability of Pulse Waveform Separation Analysis Responses to an Orthostatic Challenge

Andrew Borrer, Claudio Battaglini, FACSM, Lee Stoner. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Claudio Battaglini, FACSM)
Email: aborrer@live.unc.edu

(No relationships reported)

Purpose: Cardiovascular autonomic nervous system function can be assessed by recording arterial wave reflection responses to an orthostatic challenge. Using pulse wave analysis, arterial wave reflection can be estimated using pulse wave separation analysis, whereby a triangular or a physiologic flow waveform is assumed and the aortic wave is separated into its *forward* and timing-independent *reflected* (Pb) components. This study sought to determine the measurement precision (between-day reliability) of Pb responses to a modified tilt-table test. **Methods:** Twenty healthy adults (26.4 y (SD 5.2), 55% F, 24.7 kg/m² (SD 3.8)) were tested on three different mornings in the fasted state, separated by a maximum of seven days. Oscillometric pressure waveforms were recorded on the left upper arm, and aortic waveforms were generated using a generalized transfer function. The criterion for acceptable reliability was an intra-class correlation coefficient (ICC) of 0.75. To express the percentage change that must occur at a group and individual level, the standard error of measurement (%SEM) and smallest detectable change (%SDC) were calculated. **Results:** The criterion ICC (0.75) was exceeded at baseline (0.79), following 5 min tilt (0.75), and following 5 min recovery from tilt (0.75). The %SEM and %SDC for the 5 min tilt response were 7% and 19%, respectively. **Conclusion:** Arterial wave reflection responses to an orthostatic challenge can be assessed with acceptable between-day reliability using oscillometric pulse wave analysis.

(No relationships reported)

PURPOSE: Decreased heart rate variability (HRV) is associated with a higher risk of mortality and exercise training is effective to its increase in inactive adults. We investigated the effect of moderate versus high intensity interval exercise training on HRV indices in physically inactive adults. **METHODS:** Twenty inactive adults were randomly allocated to receive either moderate intensity training (MCT group) or high intensity interval training (HIT group). The MCT group performed aerobic training at an intensity of 55-75% of the walking on a treadmill at 60-80% heart rate max (HRmax) until expenditure of 300 kcal until the end of training. The HIT group performed running on a treadmill during 4 minutes at 85-95% peak HRmax and had a recovery of 4 minutes at 65% peak HRmax until expenditure of 300 kcal until the end of training. Supine resting HRV indices (time domain: SDNN, standard deviation of normal-to-normal intervals; rMSSD, Root mean square successive difference of RR intervals and frequency domain: HF_{Ln}, high frequency spectral power; LF, low frequency spectral power; and HF/LF ratio) and were measured at baseline and 12-weeks thereafter.

RESULTS: SDNN changes were 3.4 (8.9) ms in the MCT group, 29.1 (7.6) ms in the HIT group (difference between groups 32.6 [95% CI, 24.9 to 40.4 ($P = 0.01$)]). LF/HF_{Ln} ratio change in the MCT group 0.19 (0.03) ms and in HIT group 0.13 (0.01) ms (P between groups = 0.016). No significant group differences were observed in rMSSD, HF, and LF parameters. Finally, we observed stronger correlation between Ln rMSSD and to-R-R interval in HIT group ($r_s = 0.834$; $p < 0.001$) Figure 1A, and not significant correlation between Ln rMSSD and to-R-R interval in MCT group ($r_s = 0.396$; $p = 0.290$), Figure 1B. **CONCLUSIONS:** In inactive adults, this study showed that a 12-week HIT training program can increase short-term HRV, mostly in vagal mediated indices such as SDNN and HF/LF_{Ln} ratio power. **Trial registration.** ClinicalTrials.gov NCT02738385

Blood Pressure Cuff Selection: Does One Size Fit All?

Brock T. Jensen, Maureen A. Walsh, Tyler A. Kuhn, Jessica A. McFadden, Taylor M. Weeter, Michael E. Holmstrup. *Slippery Rock University, Slippery Rock, PA.*
Email: brock.jensen@sru.edu

(No relationships reported)

Blood pressure (BP) is one of the most commonly measured vital signs. Historically, tremendous focus has been dedicated to increasing the reliability of BP measurement by standardizing protocols and reducing error to the smallest possible increment. Errors in BP measurement may result in misdiagnosis, cardiovascular complications during exercise, and improper prescription of antihypertensives. 'Miscuffing' is a common and significant source of error in BP measurement. The '80% rule' (i.e. cuff $\geq 80\%$ of an individual's arm circumference) is the gold standard method for BP cuff size selection as recommended by the American Heart Association. Interestingly, BP cuff manufacturers routinely print their own cuff size recommendation, based on an arm circumference range, on their products and this method often differs in the suggested cuff size from the '80% rule'. **PURPOSE:** The current study examined the occurrence of 'miscuffing' and the outcome of BP measurement using the '80% rule' cuff selection method versus the manufacturer's recommendations. **METHODS:** Forty-four individuals had their upper arm circumference measured, and appropriate cuff(s) selected using the two sizing methods. An automated oscillometric device was used to measure BP in duplicate with a 1-minute interval in between measurements, and 2-minute interval between cuffs if necessary. If different cuffs were selected, the order of measurement was randomized. A dependent t-test was used to ascertain potential BP measurement differences between sizing methods. **RESULTS:** 'Miscuffing' as the result of method discrepancies between the '80% rule' and the manufacturer's recommendation, occurred in over two-thirds (70%, $n=31$) of the sample. In these individuals, there was a significant difference in systolic BP between recommended cuffs (7.9 mmHg; $p < 0.05$). Approximately 1 in 3 individuals, with two cuffs recommended (35%, $n=11$), had a smaller cuff suggested by the manufacturer, and were misclassified with a significantly elevated systolic BP (average increase 12.5 mmHg; $p < 0.05$). **CONCLUSIONS:** BP cuff-selection methods are not universal and contribute to reliability concerns. 'Miscuffing' was a common observation when utilizing the manufacturer's method for cuff selection and resulted in BP measurement error and misclassification.

Whole Body Vibration Training To Prevent Weight Gain In College Students: Early Findings From A Randomized Controlled Trial.

Mary E. Medysky¹, Lauren Bumgarner¹, Gianni Maddalozzo, FACSM², Kerri M. Winters-Stone, FACSM¹. ¹Oregon Health and Science University, Portland, OR. ²Oregon State University, Corvallis, OR. (Sponsor: Kerri Winters-Stone, FACSM)
Email: medysky@ohsu.edu

(No relationships reported)

At least 44 percent of adult Americans will be obese by 2030. When young adults go off to college and leave the structured environment of a household, they often adopt unhealthy behaviors, such as unhealthy eating and getting less exercise, leading to the risk of weight gain, popularly referred to as the "Freshman Fifteen". Unless interrupted, this pattern of weight gain in early adulthood can lead to obesity in later adulthood. Whole-body vibration training (WBVT) is a novel alternative approach to structured exercise for improving body composition for physically limited, time constrained, and/or unmotivated persons, but has not been studied yet in college students. **PURPOSE:** To determine if WBVT is a feasible and effective method of preventing weight gain in physically inactive students enrolled in undergraduate nursing or other 4-year programs. **METHODS:** Male ($n=5$) and female ($n=28$) undergraduate students were randomized to control ($n=14$, age=28.1 + 7.1, BMI=28.1 + 5.3) or WBVT groups ($n=19$, age= 28.5 + 9.0, BMI=27.5 + 3.8). The WBVT group completed three training sessions per week, progressing from low to high frequencies (30-50 Hz) and amplitudes (2-4mm), for six months. Control subjects were asked to maintain their usual diet and exercise habits. A 2 x 3 RM-ANOVA was used to detect

significant group x time interactions for weight and waist circumference measured at baseline, 3 and 6 months. **RESULTS:** Retention in the study was 75% and adherence to training was 60%. Weight differed significantly over time between groups at 6-months ($p < 0.02$, mean difference = 4.48 lbs, SE = 1.79), but not so for WC ($P = 0.131$, mean difference = -2.71 cm, SE = 1.75). **CONCLUSION:** Our preliminary findings suggest that WBVT may be both a feasible and effective method for preventing weight gain among inactive undergraduate students. Future studies should assess the effectiveness of self-monitored WBVT in the college recreation center setting.

Iron Homeostasis In Elite Athletes and Ultramarathon Runners
 Katerina P. Skenderi¹, George Papanikolaou¹, Tzortzis Nomikos¹, Yannis Kotsis¹, Maria Tsironi². ¹*Harokopio University, Athens, Greece.* ²*University of Peloponnese, Sparta, Greece.*
 Email: kskn@hua.gr
 (No relationships reported)

PURPOSE: The present study was aimed at determining the effect of two different types of exercise (elite athletes (EA) playing football and ultramarathon runners (UR)) on iron metabolism, and especially the role of hepcidin in iron homeostasis. **METHODS:** In our study two different groups of athletes were investigated. The first group consisted of 19 male elite football athletes and the second group of 41 ultramarathon runners. In both cases, blood samples were taken pre-race (t1), immediately post-race (t2), and 24 hours post-race for EA athletes and 36-48 hours post-race for UR athletes (t3). **RESULTS:** The iron levels in time t3 were found to have statistically significant decreases compared with the iron levels in pre-race and post-race period. Moreover, in both cases, ferritin levels were increased significantly in time t2 and t3. Hepcidin levels increased in time t2 after the race, in football players (from 27.45 ± 12.98 to 37.42 ± 13.74 ng/mL) and in time t3 decreased again. However, in ultramarathon runners, hepcidin levels significantly increased in time t2 (from 29.16 ± 10.92 to 58.81 ± 16.97 ng/mL) and remained increased in time t3 as well (37.69 ± 16.38 ng/mL), despite a trend for its decrease. In football players, sTfR levels did not change, contrary to ultramarathon runners where sTfR levels were found decreased after the race and in time t3. **CONCLUSIONS:** Iron metabolism in athletes can be impacted by the type of exercise. Ferritin is not a reliable marker for iron balance, because in the present study, it is more likely an acute phase protein. The main regulator of iron homeostasis, hepcidin increases, showing the body's response to inflammation, by trapping iron in the macrophages and by altering iron absorption. Finally, a strenuous and prolonged exercise can lead to sports' anaemia.

3211 Board #116 June 2 3:30 PM - 5:00 PM
Comparison Of Progressive High-intensity Aerobic Exercise And High-intensity Interval Training (HIIT) In Older HIV+ Adults
 Timothy R. Wamsley¹, Chani Jain¹, Alice S. Ryan², Nabil Jarmukli¹, Amitabh Parashar¹, Katherin Henley¹, Maribeth O. Capuno¹, Kris Ann K. Oursler¹. ¹*Salem VA Medical Center, Salem, VA.* ²*Baltimore Veterans Affairs Medical Center, The University of Maryland School of Medicine, Baltimore, MD.*
 (No relationships reported)

HIV+ adults have 40% lower $VO_{2\text{peak}}$ (VO_2) than age-matched healthy adults. High intensity aerobic exercise (AEX) increases VO_2 in older adults. A growing body of evidence demonstrates that HIIT can serve as an effective alternative to AEX. However, data in older HIV+ adults for both modalities is very limited even though a quarter of HIV+ Americans are over 50 years old. **PURPOSE:** To examine the effects of progressive AEX+RT and HIIT+RT on VO_2 and strength in HIV+ older adults vs. sedentary controls.

METHODS: Sedentary HIV+ men 50+ years of age were randomized to AEX+RT or delayed entry control groups. AEX+RT group received 16-weeks (48 sessions) of supervised center-based training with progression to a target of 45 minutes of continuous exercise at 70-80% HR_{reserve} . The RT protocol consisted of 6 exercises progressed to 80% of baseline 1-RM. Control participants remained sedentary. Both groups were tested at baseline and 16-weeks. The control group participants then started 16 weeks of HIIT in a cross over design. The HIIT group received the same duration of supervised training and identical RT protocol with repeated testing at 32 weeks. The HIIT protocol was performed using 4 intervals of 4 minutes of work ($90-95\% HR_{\text{max}}$) separated by 3 minutes of active rest ($50-60\% HR_{\text{max}}$) for a total time of 28 minutes. Paired t-test or Wilcoxon signed rank sum were used to test pre/post differences. Results are presented as mean \pm SE or median (range).

RESULTS: To date 8 patients have been enrolled and randomized to AEX+RT or Control with 16 week testing complete in all 8 and post-HIIT testing completed in 3. AEX+RT increased $VO_{2\text{peak}}$ (0.29 ± 0.03 L/min, $p = 0.03$) and lower body strength ($+37\%$ 1-RM, $p = 0.05$). Post-hoc comparison showed that HIIT+RT training had comparable increases in $VO_{2\text{peak}}$ (0.32 ± 0.09 L/min, $p = 0.07$) and lower body strength ($+31\%$ 1-RM, $p = 0.05$). There was a trend for increased lean mass (LM) measured

by DXA after AEX+RT (1.2 kg (-1.8 to 6.1)) and HIIT+RT (1.5 kg (1.2 to 6.1)) and decreased LM after the sedentary control period (-1.7kg (-4.1 to 1.6)). Changes in cross-sectional area of the thigh support these findings. **CONCLUSIONS:** Progressive high-intensity AEX+RT was well tolerated and effective in older HIV+ men. HIIT may be a more time efficient option that can equally improve VO_2 and strength in the growing population of older adults with HIV.

Resting And Post Exercise Autonomic Function In Active And Insufficiently Active People Living With HIV
 Norberto Quiles¹, Burak Cilhoroz¹, Joseph Ciccolo², Carol Ewing Garber, FACSM². ¹*Queens College, Flushing, NY.* ²*Teachers College Columbia University, New York, NY.* (Sponsor: Carol Ewing Garber, FACSM)
 (No relationships reported)

Autonomic dysfunction has been associated with cardiovascular disease (CVD) morbidity and mortality, and may be prevalent in people living with HIV/AIDS (PLWHA). Physical activity (PA) is associated with better autonomic function in healthy and cardiometabolic disease populations. However, there are few data on the resting and autonomic responses to exercise in PLWHA. **PURPOSE:** To determine whether physically active (Act) PLWHA have better autonomic responses compared with insufficiently active (IA) PLWHA.

METHODS: 23 participants (13 Active PLWHA and 10 age and gender matched IA PLWHA) were recruited. Active PLWHA performed ≥ 150 of moderate to vigorous aerobic PA, while IA PLWHA performed ≤ 30 minutes on ≤ 2 days per week of aerobic PA. Resting heart rate variability (HRV) was measured for 10 minutes before exercise from which high frequency power in normalized units (HF_{n.u.}), low frequency power in normalized units (LF_{n.u.}) and low frequency/high frequency (LF/HF) ratio were determined. Participants performed a maximal cardiopulmonary exercise test on a cycle ergometer. Heart rate recovery (HRR) was measured at 30, 60 and 120 seconds (sec.) after exercise. Parasympathetic reactivation was measured as Root Mean Square of Successive Differences (RMSSD) at 30 sec. and 10 minutes (min.) after the test. **RESULTS:** Active PLWHA showed significant parasympathetic reactivation (RMSSD) from 30 sec. to 10 min. after peak exercise while this did not occur in IA PLWHA. HRR over 120 sec. after exercise was not different between the study groups. Measures of parasympathetic modulation (HF_{n.u.} and LF/HF ratio) and sympathetic modulation (LF_{n.u.}) were enhanced in Active PLWHA, compared with IA PLWHA. **CONCLUSIONS:** Regular aerobic exercise is associated with enhanced autonomic function at rest and during the 10 minutes of recovery after exercise in PLWHA. These findings suggest a possible mechanism to support lower risk of CVD with exercise in PLWHA.

	HIV+ Act	HIV+ IA
Resting HRV Measure		
HF (n.u.)	41.0 \pm 15.6*	25.2 \pm 9.7
LF (n.u.)	55.6 \pm 15.8*	79.3 \pm 17.5

Alterations In Intraocular Pressure And Corneal Thickness Immediately Following A 161-km Foot Race
 Tracy B. Hoeg¹, Genevieve K. Corrigan², Martin D. Hoffman, FACSM¹. ¹*University of California-Davis, Sacramento, CA.* ²*El Dorado Hills Optometric Center, El Dorado Hills, CA.*
 Email: tracybethhoeg@gmail.com
 (No relationships reported)

Introduction: Significant visual impairment is estimated to occur in 3% of participants in 161-km ultramarathons. Initial research indicates this is most often due to a transient corneal edema. The normal physiological changes of the eye in response to prolonged exercise have not been previously reported.

Purpose: To determine the effect of prolonged exercise (14 to 30 hours) on intraocular pressure and corneal thickness.

Methods: Entries of the 2013 161-km Western States Endurance Run were invited to participate in our study via pre-race email. During the 2 days prior to the race, informed consent was obtained and pre-race testing was performed. Pre- and immediate post-race, binocular and monocular visual acuity was measured using an illuminated Snellen eye chart and intraocular pressure was measured in both eyes with Tonopen XL (Reichert Technologies, Depew, NY). Pre- and immediate post-race corneal thickness was measured three times in rapid succession using an ultrasonic pachymeter (Corneo-Gage Plus, Sonogage, Cleveland, OH) after corneal anesthesia with 0.5% proparacaine hydrochloride.

Results: Eight entrants completed the study among which, six reported a prior history of ultramarathon-associated visual impairment. Three had a history of bilateral refractive surgery. One participant reported a period of "tunnel vision" during the race. Beyond this, there were no reports of visual impairment during this race which had a temperature range of 5.0 to 39.0°C. Pre- and post-race visual acuity measurements were essentially unchanged. Pre- and post-race corneal thickness did not change ($p=.3$) with a mean (\pm SD) of 661 (\pm 82) mm pre-race and 667 (\pm 84) mm post-race. Post-race intraocular pressure decreased from pre-race values in 10 of 16 eyes, was unchanged in 2 and higher in 4, with mean (\pm SD) pressure being 12.3 (\pm 3.6) and 11.4 (\pm 3.5) pre-race and post-race, respectively ($p=0.5$).

Conclusions: Within this small sample, visual acuity, corneal thickness and intraocular pressure were not significantly altered by completion of a 161-km foot race. These findings offer some reassurance to athletes who might have concern about elevating intraocular pressure from ultramarathon running.

Strength Testing In Athletes Post ACL (Anterior Cruciate Ligament) Reconstruction: Does Graft Type Matter?

Dr. Brenda E. Castillo¹, Dr. Juan C. Galloza-Otero², Dr. William Micheo, FACSM³. ¹VA Caribbean Healthcare System, San Juan, PR. ²University of Texas Health and Science Center, Houston, TX. ³University of Puerto Rico- Medical Sciences Campus, San Juan, PR.

Email: brendi00@yahoo.com

(No relationships reported)

PURPOSE:

To evaluate hamstring and quadriceps strength after ACL (Anterior Cruciate Ligament) reconstructive surgery depending on type of graft used by determining if there is any deficit in knee extension with the use of a patellar tendon graft and knee flexion deficit with the use of a hamstring graft.

METHODS:

Chart review of athletes from 2010-2016 who met the following inclusion criteria's: age of subjects 15-50 yrs., isokinetic testing (CYBEX) performed \leq 1 yr. after surgery, completion of a structured rehabilitation program before the CYBEX test, no clinical signs of instability on evaluation, and having full painless knee range of motion. Graft type (Patellar Tendon and Hamstring) and CYBEX results (extension and flexion at 60°/sec and 180°/sec at peak torque) were compared for each athlete.

RESULTS:

A total of 40 subjects met inclusion criteria's, of which 31 had hamstring graft and 9 had patellar tendon graft. 35% of subjects with hamstring graft had weakness in the extensor mechanism of the knee, 13 had weakness in flexors and extensors (29% greater in extensors and 13% greater in flexors), 13% presented weakness in flexors and 10% had weakness in the extensors of the non-surgical knee. 9 subjects had a patellar tendon graft, of which 56% had weakness in extensors and 44% demonstrated weakness in both extensors and flexors (greater in extensors).

CONCLUSIONS:

Overall, our subject's demonstrated increased weakness in the extensor mechanism of the knee in both patellar tendon and hamstring graft groups.

Diminished Ventilatory Responses During Post-Exertional Malaise Contributes to Exercise Intolerance in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome

Chris Chuang¹, Staci Stevens², Todd Davenport¹, Christopher R. Snell², Jared Stevens², J. Mark VanNess¹. ¹University of the Pacific, Stockton, CA. ²Workwell Foundation, Ripon, CA.

(No relationships reported)

Reduced functional capacity and post-exertional malaise following physical activity are hallmark symptoms of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). The mechanisms producing exercise intolerance in the post-exertional state have not been adequately described. **PURPOSE:** To compare the ventilatory response

to repeated exercise stress in control and ME/CFS subjects. **METHODS:** 40 female subjects were recruited for the study, 20 ME/CFS patients and 20 age and weight matched controls. All underwent two maximal exercise tests 24 hours apart. Oxygen consumption, minute ventilation (V_E), tidal volume (TV), respiratory rate (RR), end-tidal oxygen and carbon dioxide (ET_{O_2}/ET_{CO_2}) were measured at rest, at the anaerobic threshold, and at maximal exercise. Multivariate analyses were performed for group (ME/CFS vs control), test (exercise test 1 vs test 2), and condition (rest vs anaerobic threshold vs maximal exertion) with univariate follow up. **RESULTS:** 15 ME/CFS subjects and 18 control subject reached criteria for maximal effort. The overall multivariate analysis was significant for group and condition. Follow-up univariate and post-hoc showed VO_{2E} , V_E and TV were lower in the ME/CFS group only on exercise test 2. Post hoc for condition was significant for ventilation at maximal exercise only. Respiratory rate, ET_{O_2} , and ET_{CO_2} were not different between tests or groups. **CONCLUSION:** In the absence of a second exercise test, the lack of any significant differences for the first test would appear to suggest no exercise intolerance in ME/CFS patients. However, the results from the second test indicate the presence of exercise intolerance and post-exertional malaise. Diminished ventilatory responses accompany reductions in work output and oxygen consumption during post exertional malaise in ME/CFS patients.

Leg Blood Flow and Fatigability In People With Type 2 Diabetes

Jonathon Senefeld, FACSM¹, Kathleen M. Lukaszewicz¹, Jacqueline K. Limberg², Sandra K. Hunter, FACSM¹. ¹Marquette University, Milwaukee, WI. ²Mayo Clinic, Rochester, MN.

Email: jonathon.senefeld@marquette.edu

(No relationships reported)

We have previously demonstrated that people with type 2 diabetes mellitus (T2D) have greater fatigability of the knee extensor muscles during a dynamic fatiguing contraction due to impairments within the skeletal muscle; however, the precise mechanism(s) are unknown. **PURPOSE:** To determine if impairments in leg blood flow are associated with greater fatigability of the knee extensor muscles during a dynamic fatiguing contraction in men and women with T2D.

METHODS: 5 individuals with non-insulin dependent T2D (60 - 70 years; 3 women) with no signs of diabetic neuropathy were matched based on age, BMI and physical activity with four non-diabetic controls (CON) (60 - 68 years; 2 women). Physical activity was assessed over four days with a tri-axial accelerometer. To assess fatigability, participants performed a 6-minute single-limb dynamic fatiguing contractions with the knee extensors while seated at 90° of hip and knee flexion. 120 maximal voluntary concentric contractions (MVCCs) were performed with a load equivalent to 20% maximal voluntary isometric contraction torque through a 90° range of motion. Doppler ultrasonography was used to assess femoral artery diameter and pulse wave blood velocity before and immediately after the dynamic fatiguing contraction.

RESULTS: The reduction in MVCC power was greater for T2D ($40.5 \pm 17.6\%$) compared with CON ($31.3 \pm 20.8\%$, $P < 0.05$) as assessed at the end of exercise. T2D and CON both demonstrated similar increases in leg blood flow after the dynamic fatiguing contraction ($71.7 \pm 41.1\%$ vs. $69.0 \pm 37.3\%$, respectively; $p > 0.05$).

However, greater reductions in MVCC power (i.e. greater fatigability) was associated with lower blood flow following dynamic fatiguing contractions ($p = 0.034$, $r = 0.633$).

CONCLUSIONS: Greater fatigability of the knee extensor muscles during dynamic fatiguing contractions was associated with lower blood flow. Impaired blood flow responses to exercise may limit exercise performance among T2D, and this work highlights the need for future studies that examine skeletal muscle perfusion during dynamic exercise in people with T2D.

Prolonged Bouts Of Sedentary Behavior Are Associated With Cardiometabolic Disease Risk Factors In Young Adults

Chantal A. Vella, FACSM¹, Katrina Taylor². ¹University of Idaho, Moscow, ID. ²Eastern Washington University, Cheney, WA.

Email: cvella@uidaho.edu

(No relationships reported)

Research indicates sedentary behavior is associated with obesity and cardiometabolic disease (CMD) risk factors. Less understood is the effect of prolonged bouts of sedentary time on CMD risk factors, particularly in young adults. **PURPOSE:** To determine the associations among prolonged bouts of sedentary behavior and CMD risk factors in young adults. **METHODS:** 125 men ($n=29$) and women ($n=96$) participated in the study (mean \pm SD: age 22.8 ± 4.8 y; BMI 26.4 ± 4.7 kg/m²; body fat $29.1 \pm 9.4\%$; and VO_{2peak} 40.9 ± 8.3 mL/kg/min). Sedentary behavior (<150 counts/min) and moderate-to-vigorous physical activity (MVPA, >2689 counts/min) were measured by an accelerometer worn during waking hours for 7 consecutive days.

Sedentary bouts were defined as greater than or equal to 20, 30 and 60 min. Body composition, waist circumference, blood pressure, glucose, insulin, triglycerides (TG), high-density lipoprotein, and low density lipoprotein (LDL) cholesterol were measured. Multiple regression analyses were used to assess associations among variables, while controlling for age, sex, race/ethnicity, accelerometer wear time and MVPA. RESULTS: Total time spent in sedentary behaviors averaged 8.7 ± 1.5 h/day. Sedentary bouts greater than or equal to 20, 30 and 60 min accounted for 36%, 23%, and 6% of total sedentary time, respectively. The average length for bouts of greater than or equal to 20, 30, and 60 min was 33.7 ± 4.1 min, 45.6 ± 6.6 min and 63.7 ± 40.5 min, respectively. Sedentary bouts of 20 min or more had the strongest relationships with CMD risk factors, compared to bouts of 30 and 60 min or more. Time spent in sedentary bouts of 20 min or more was independently associated with BMI ($R^2=0.13$, $\beta=0.24$, $p=0.01$), waist circumference ($R^2=0.15$, $\beta=0.25$, $p=0.01$), LDL ($R^2=0.28$, $\beta=0.27$, $p<0.01$), TG ($R^2=0.11$, $\beta=0.25$, $p=0.02$), insulin ($R^2=0.55$, $\beta=0.25$, $p<0.01$), and fat mass ($R^2=0.23$, $\beta=0.27$, $p<0.01$), after adjusting for all covariates. CONCLUSIONS: Our novel findings suggest that sedentary behavior, in bouts of 20 min or more, is significantly and independently associated with markers of CMD in young adults. These findings have important implications for CVD prevention programs for young adults and suggest that public health guidelines with regards to minimizing prolonged sedentary behaviors are warranted. Superior Acute Effects of High-Intensity Interval Exercise in Type 2 Diabetes Patients: A Pilot Study

Ariane Aparecida Viana¹, Bianca Fernandes¹, Guilherme Veiga Guimarães², Emmanuel Gomes Ciolac¹. ¹São Paulo State University – UNESP, Bauru, Brazil. ²Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

(No relationships reported)

PURPOSE: High-intensity interval training (HIIT) is a time-efficient intervention for preventing and treating type 2 diabetes (T2D). Rate of perceived exertion scale (RPE) is a simple and inexpensive tool for prescribing and self-regulating exercise. Our purpose was to analyze the hemodynamic and metabolic response to a HIIT session prescribed and self-regulated by RPE (HIIT_{RPE}) in T2D patients.

METHODS: Ten (two males) T2D patients (time since diagnosis = 9.1 ± 1.7 yr) aged 50.7 ± 2.8 yr underwent a symptom-limited CPX on a treadmill to determine their heart rate (HR) response to exercise. Patients were then assigned to perform of HIIT_{RPE} (4 min of warm-up and 21 min of jogging/running at 15-17 (1 min) alternating with walking at 9-11 (2 min) on the 6-20 RPE scale), HIIT prescribed and regulated by HR response to CPX (HIIT_{HR}, 4 min of warm-up and 21 min of jogging/running at 85% (1 min) alternating with walking at 50% (2 min) of reserve HR), continuous moderate exercise (CME) prescribed and self-regulated by RPE (30 min of walking at 11-13 on the 6-20 RPE scale), and control session (CON, sitting in a quiet environment) in a random order (3 to 7 days between intervention). Capillary glucose, endothelial function and carotid-femoral pulse wave velocity (PWV) were assessed before, immediately after and 45 min after each intervention. 24-h ambulatory blood pressure (ABP) after each intervention.

RESULTS: Exercise distance was not different between all interventions. Exercise HR and speed were also not different between HIIT_{RPE} and HIIT_{HR}. T2D patients showed similar reductions in capillary glucose after HIIT_{RPE} ($21.9 \pm 4.0\%$) and HIIT_{HR} ($25.2 \pm 4.8\%$), which were greater ($P < 0.05$) than the observed after CME ($16.4 \pm 6.2\%$). T2D patients also showed similar nighttime ABP reductions after HIIT_{RPE} and HIIT_{HR} when compared to CON; but the reduction was statistically significant ($P < 0.05$) only after HIIT_{RPE}. No ABP reductions was found after CME. No significant differences on endothelial function and PWV were observed during all interventions.

CONCLUSION: HIIT was superior to CME to acutely reduce capillary glucose and ABP, independently if it was prescribed and regulated by RPE or the HR response to CPX. This result suggest that the 6–20 RPE scale may be an efficient tool for prescribing and self-regulating HIIT in T2D patients.

Energy Expenditure in Yoga versus Other Forms of Physical Activity

Sally A. Sherman, Ph.D.¹, Renee J. Rogers, Ph.D.¹, Kelliann K. Davis, Ph.D.¹, Ryan L. Minster, Ph.D., M.S.I.S.¹, Seth A. Creasy, Ph.D.², Nicole C. Mullarkey, M.S.¹, Matthew O'Dell, M.S.¹, Patrick Donahue, B.S.¹, John M. Jakicic, Ph.D., FACSM¹. ¹University of Pittsburgh, Pittsburgh, PA. ²University of Colorado, Denver, CO. (Sponsor: John M. Jakicic, Ph.D., FACSM)

Email: sally.sherman@pitt.edu

(No relationships reported)

It is currently not clear whether yoga is an activity that meets the requirements for moderate-to-vigorous physical activity and how yoga compares in intensity to other forms of physical activity.

PURPOSE: This study compared energy expenditure during acute bouts of Vinyasa yoga (YOGA) and two treadmill walking protocols. **METHODS:** Data from were available on 28 participants (15 males, 13 females) who performed three 60-minute activity bouts on separate days that included: 1) YOGA, 2) treadmill walking at a self-selected brisk pace (SELF), 3) treadmill walking at a pace that matched their HR to that of their yoga session (HR-MATCH). Energy expenditure (kcal and metabolic equivalent of task [MET]) was measured with indirect calorimetry. **RESULTS:** When examining the entire 60 minute period of activity, energy expenditure was significantly lower in YOGA (285.1 ± 71.6 kcal, 3.7 ± 0.6 MET/min) compared to both HR-MATCH (367.3 ± 93.7 kcal, $p < 0.001$; 4.9 ± 0.8 MET/min, $p < 0.001$) and SELF (329.2 ± 82.1 kcal, $p = 0.003$; 4.4 ± 0.7 MET/min, $p < 0.002$), and in HR-MATCH compared to SELF (p -value for kcal = 0.012; p -value for MET/min = 0.016). Because the final 15 minutes of the YOGA session was restorative in nature, data analysis was repeated using only the initial 45 minutes of each activity session. For these analyses, energy expenditure was significantly lower in YOGA (234.0 ± 57.8 kcal, 4.1 ± 0.6 MET/min) compared to HR-MATCH (306.0 ± 77.6 kcal, $p < 0.001$; 5.4 ± 0.9 MET/min, $p < 0.001$) but not SELF (242.8 ± 60.7 kcal, $p = 0.393$; 4.3 ± 0.7 MET/min, $p = 0.650$), and in HR-MATCH compared to SELF (p -value for kcal < 0.001 ; p -value for MET/min < 0.001). Gender did not significantly influence the pattern of the results observed.

CONCLUSIONS: Across a 60-minute period, energy expenditure in YOGA is significantly lower than both SELF and HR-Match. When the restorative component of YOGA was removed from the analysis, energy expenditure in YOGA was comparable to SELF. Moreover, YOGA met the energy expenditure requirement (> 3 METs) for moderate-intensity physical activity, and therefore is likely to elicit health benefits similar to walking performed at a self-selected brisk walking pace. Interventions to directly compare YOGA to other forms of physical activity are warranted.

3220 Board #125 June 2 3:30 PM - 5:00 PM

Physical Activity and Physical Functioning in Persons with Down Syndrome

Benjamin J. Carlson¹, Jasmine S. Curtis¹, Fabio Bertapelli¹, Ben Abadie¹, Marquell Johnson², Stamatis Agiovlasis, FACSM¹. ¹Mississippi State, Mississippi, MS. ²University of Wisconsin-Eau Claire, Eau Claire, WI. (Sponsor: Stamatis Agiovlasis, FACSM)

(No relationships reported)

Persons with Down syndrome (DS) are generally considered to be less active than the general population. However, limited objective accelerometer data exist on their levels of physical activity (PA) and sedentariness. Furthermore, PA and sedentariness may be associated with low levels of physical functioning in persons with DS. **PURPOSE:** To examine the levels of PA and sedentariness in persons with DS, and whether these are associated with measures of physical functioning. **METHODS:** Seventeen persons with DS (9 women and 8 men; age 28 ± 14 y) participated in this study. They wore for 7 days on their right wrist an accelerometer (GT3X+, Actigraph). PA variables, time spent sedentary, and the percent of participants meeting the PA Guidelines for Americans were determined with the Freedson cut-points. Physical functioning variables included performance during the timed-up-and-go (TUG) test, as well as the distance covered and the energetic cost (oxygen uptake per meter measured with portable spirometry) during the 6 min walk (6MW) test. **RESULTS:** Participants accumulated an average of 83 ± 164 min per week of moderate-to-vigorous PA in bouts at least 10 min in duration. Only two participants with DS (12% of the sample) met the recommended amount of 150 min of weekly moderate-to-vigorous PA, and 15 participants (88%) did not. Participants performed light PA for 1427 ± 241 min per week (~ 3.5 h per day). Mean sedentary time was 3210 ± 210 min per week (~ 7.5 h per day). Mean performance on the TUG was 9.82 ± 3.22 s. Mean distance covered during the 6MW test was 284.7 ± 113.7 m and mean walking speed was 0.79 ± 0.32 m \cdot s⁻¹. The energetic cost during the 6MW was 0.34 ± 0.12 ml \cdot kg⁻¹ \cdot m⁻¹. Light PA had moderate and significant associations with TUG performance, 6MW distance, and 6MW energetic cost ($r = 0.61$, 0.61 , and 0.66 , respectively; $p < 0.03$). In addition, 6MW distance was associated with time spent sedentary ($r = 0.55$; $p = 0.02$). Low and

non-significant correlations were found between measures of physical functioning and other PA variables. **CONCLUSION:** Persons with DS have low levels of PA and high levels of sedentariness. Most persons with DS do not meet the PA Guidelines for Americans. They also have low levels of physical functioning. Lower levels of physical functioning are associated with greater participation in light PA among persons with DS.

3221 Board #126 June 2 2:00 PM - 3:30 PM Screen Time, Physical Activity, And Bmi Among Hispanic Children In Puerto Rico

David Colon, Lucia Del R. Martínez-Colón, Farah A. Ramírez-Marrero, FACSM. *Universidad de Puerto Rico Rio Piedras Campus, San Juan, PR.*
Email: mr.colon.edfi@gmail.com
(No relationships reported)

Screen time (ScT) represents a behavior usually, but not always, associated with reduced physical activity, and increased sedentary time and BMI among children. Childhood obesity is a major health problem, particularly among Hispanic children in Puerto Rico (PR). Little information is available regarding ScT and its association with BMI and moderate to vigorous physical activity (MVPA) in this population. **PURPOSE:** To evaluate ScT, including the use of passive vs. active video games (PVG and AVG), MVPA, and BMI among 6-8-year-old Hispanic children in PR. **METHODS:** A convenience sample of 100 children (54 boys and 46 girls) wore an accelerometer attached to an elastic band over the right hip area for 7-days, and their parents completed a physical activity questionnaire including information regarding their children's screen time. T-tests were conducted to detect sex differences, and correlation analyses to detect associations between variables. **RESULTS:** Total screen time (2.1 ± 1.5 hrs/day), including PVG (0.4 ± 0.6 hrs/day) and AVG (0.1 ± 0.4 hrs/day), and MVPA (4.1 ± 0.9 hrs/day) were not significantly different between boys and girls. An inverse correlation was observed between MVPA and AVG ($\rho = -0.20$, $P = 0.04$). No other significant correlations were detected between ST, MVPA, and BMI. **CONCLUSION:** ScT in the group of Hispanic children evaluated was in the recommended limit, and appear not to affect their level of MVPA, which exceeded current recommendations. They appear to spend more time using PVG than AVG, and those that spent more time in AVG also spent less time in MVPA. These results support other studies suggesting that ScT does not influence MVPA or BMI in young children.

3222 Board #127 June 2 2:00 PM - 3:30 PM Comparison Of Step Count During A Bout Of Pokémon Go Vs Traditional Aerobic Exercise

Katie M. Smith, Sadie Timms, Casey Reisen, Calvin A. Busby, Nicole L. Whalen. *Simpson College, Indianola, IA.*
Email: katie.smith@simpson.edu
(No relationships reported)

Traditional video game use employs sedentary behavior but exergames allow for such games to involve physical activity (PA). Pokémon Go is a live, real-time version of a popular video game involving the use of a mobile device's GPS capability to locate, capture, battle, and evolve virtual characters. Users transport to physical locations to advance in the game, meanwhile potentially using a mode of PA during play. **Purpose:** To compare the number of steps taken when playing Pokémon Go to a traditional bout of aerobic exercise, walking at a self-selected pace. **Methods:** Seventeen regular Pokémon Go users ages 18-65 years old wore a pedometer on their waist while playing the popular reality game for 30-minutes and walking for 30-minutes at a self-selected pace. The order of events were randomized and the game was played either as an individual or in a group depending upon the participant's normal type of play. Regular PA patterns and distance traveled (km) during habitual play were self-reported. A paired-sample t-test compared the number of steps taken during each activity; Pearson's correlations evaluated potential relationships between step count, type of play, distance traveled, and regular PA patterns. **Results:** Users were primarily intermediate or advanced players of the game (94%) and average level of play was 21 ± 5 (range 8-30). Mean step count while playing Pokémon Go was 2992 ± 548 vs 3379 ± 206 when walking at a self-selected pace for an equivocal amount of time ($P = 0.009$). Users accumulated an average of 388 fewer steps during 30-minutes of Pokémon Go than with traditional walking outdoors. Steps taken during the 30-min walk were significantly associated with regular PA patterns ($r = 0.594$, $p = 0.012$). No associations were noted between type of play and distance traveled in habitual play or step count of the study session. **Conclusion:** Significantly less steps were taken during

a 30-minute bout of Pokémon Go than participating in a traditional walk. However, the practical implications of the data imply a relatively small difference in overall PA in 388 steps. Playing the exergame as an individual or in a group did not influence steps taken during the study or km traveled during habitual play.

3223 Board #128 June 2 2:00 PM - 3:30 PM Patterns of Objectively-assessed Sedentary Behavior in Community-dwelling Japanese Older Adults

Shiho Amagasa, Noritoshi Fukushima, Hiroyuki Kikuchi, Tomoko Takamiya, Shigeru Inoue. *Tokyo Medical University, Tokyo, Japan.*
(No relationships reported)

Accumulated evidence suggests greater time spent in sitting is associated with adverse health outcomes. However, limited data on how sedentary behavior (SB) is patterned in older adults. **PURPOSE:** To examine patterns of objectively-assessed SB classified by duration of bout in community-dwelling Japanese older men and women.

METHODS: This cross-sectional study included 450 Japanese older adults (255 men, 70-79 years) who were randomly selected from resident registries and provided valid data (wearing at least four days of ≥ 10 hours/day) of accelerometer (HJA-350IT, Omron Healthcare, Japan). Descriptive analyses of the duration (min/day) and number of bouts (times/day) of SB (≤ 1.5 METs) were conducted, stratified by gender. Total SB time was further divided into five types according to the duration of SB: 1-9 min, 10-19 min, 20-29 min, 30-59 min, and ≥ 60 min. Gender differences in patterns of SB were assessed using analysis of covariance (ANCOVA) after adjusting for age and wear time.

RESULTS: The adjusted mean SB time (min/day) in men and women was 561.8 and 469.3, respectively ($P < 0.001$), and number of SB bouts (times/day) was 57.0 in men and 61.3 in women ($P < 0.001$). The number of SB bouts of less than 10 min was 42.9 in men and 49.4 in women ($P < 0.001$). On the other hand, the number of SB bouts of lasting 20-29 min was 2.9 and 2.3 in women, that of 30-59 min was 3.5 in men and 2.5 in women, and that of at least 60 min was 1.6 in men and 1.1 in women (all $P < 0.001$). Time accumulated by short-bout (1-9 min) SB in women was significantly longer than men (men:114.7, women:128.3), whereas time accumulated by long-bout SB in women was significantly shorter than men (20-29 min SB; men:70.4, women:55.6, 30-59 min SB; men:143.4, women:103.1, and ≥ 60 min SB; men:148.4, women:100.2).

CONCLUSIONS: Older women were less likely to be prolonged sedentary with more frequent interruption compared to older men. Effect of patterns of SB on health outcomes may differ by gender.

3224 Board #129 June 2 2:00 PM - 3:30 PM Exploring Associations Between Greenspace, Physical Activity, And Health Outcomes: Results From The 2011-2015 Illinois BRFS

Jong Cheol Shin, Diana S. Grigsby-Toussaint, 61820. *University of Illinois at Urbana-Champaign, Champaign, IL.*
Email: jshin57@illinois.edu
(No relationships reported)

PURPOSES: 1) To examine spatial effects of green space on health outcomes at various levels of geography; 2) To examine the potential mediating effect of physical activity on the relationship between green space and health outcomes.

METHODS: Socio-demographic (e.g., sex, race, poverty, age) and health outcome variables (e.g., obesity, diabetes, heart disease, and mental health) were derived from the 2010-2015 Illinois Behavioral Risk Factor Surveillance System (BRFSS). Measures of green-space were created using tree canopy data from the 2011 National Land Cover Dataset (NLCD). Residential area was defined using measures of urban density by counting dwellings per 10 hectares. Green space was calculated for three levels of buffers, specifically 300m, 500m, 1km for each residential unit and the entire county where the residential unit was located. ArcGIS 10.3 (ESRI, CA), was used to geoprocessing all data. Residential green space was used as the primary independent variable while accounting for socio-demographic variables in regression analysis.

RESULTS: Due to missing data, only 78 of 102 Illinois counties (76.47 %) were included in the analysis. The amount of green space, regardless of buffer level, has no association with health outcomes. Physical activity explained a significant proportion of variance only for diabetes all measures of green space: 300m, 500m, and 1000m for residential units ($\beta = -.12$, $p < .03$; $R^2 = .30$, $p < 0.001$); county level ($\beta = -.14$, $p < .02$; $R^2 = .31$, $p < .001$).

CONCLUSIONS: Although county level green space was negatively associated with physical activity, residential green space showed no association. This difference supports the importance of appropriately defining geographical units used for large-scale population-based. Further studies clarifying geographic units of analysis are required.

3225 Board #130 June 2 2:00 PM - 3:30 PM
The Impact of Public Transportation on Daily Walking Level

Kenta Okuyama, Colorado Department of Public Health and Environment, Denver, CO.
 (No relationships reported)

Background: Only 21% of the U.S. adults meet the recommended level of physical activity: 150 minutes of moderate intensity of physical activity per week, or 75 minutes of vigorous intensity of physical activity per week. Transportation is recognized as one of the most influential domains determining people's daily physical activity level. There are a few studies looked at the walking level of public transit users as well as socio-demographic traits. This study examined walking time difference between public transit users and non-public transit users to articulate how much walking time is derived from transit related walking more clearly, and how demographic characteristics differ among the two groups. Purpose: To investigate and articulate the impact of public transit on the walking activity level within the U.S. population in order to advocate the ongoing public transit improvement projects and policy changes toward walkable communities. Methods: The National Household Travel Survey conducted from March 2008 to May 2009 by the U.S. Department of Transportation was used to examine the association between public transit use and walking trip time for an assigned travel day. Multivariate linear regression model was applied to estimate the difference of walking time in minutes per day between public transit users (n=2,835) and non-public transit users (n=165,969). Results: People who used any forms of public transit walked 35.2 minutes more than people who did not use public transit during one travel day (p<0.01). 27.0 minutes of the 35.2 minutes difference was gained exclusively from transit related walking which includes access from or to public transit. In addition, people in low income group, minority population groups such as African American and Hispanic, people residing in bigger cities, and people perceiving the lack of access or availability of public transit as a big issue had longer daily walking time compared to the other groups (p<0.01). Conclusion: There is a significant association between public transit use and daily walking time. The results of this study will add on an evidence to the positive impact of public transit on physical activity level, and support ongoing project of public transit improvement, such as railway extension, as well as policy enactments with respect to public transit system.

Social Network Engagement and Adherence with Physical Activity Recommendations; The American Time Use Survey

Carlene A. Mayfield¹, Melinda Forthofer². ¹University of South Carolina, Columbia, SC. ²University of North Carolina Charlotte, Charlotte, NC.
 Email: carlene@email.sc.edu
 (No relationships reported)

Physical activity has numerous benefits in both primary and secondary prevention of chronic diseases. Current estimates suggest that most adults are not meeting the minimum recommended levels (PA-R) of leisure time physical activity (LT-PA) and these levels of adherence can vary by sociodemographic factors. Individuals' social networks may impact their health behavior choices through interpersonal support mechanisms. Many LT-PA intervention studies have utilized "buddy systems" or social network engagement (SNE), as a method of promoting adherence. Thus far, there have been no large-scale, population based examinations of the relationship between SNE and adherence to PA-R. PURPOSE: The current study used nationally representative data from the American Time Use Survey dataset to test the relationship between Social Network Engagement (SNE) and participants' adherence to minimum recommendations (PA-R) during leisure-time physical activity (LT-PA), and the impact of socio-demographic factors.

METHODS: Data were collected from each cross sectional year (2003-2014) of the American Time Use Survey dataset. Leisure Time-Social Network Engagement (SNE) was conceptualized as the participation of LT-PA with a member of an individual's social network. Adherence to PA Recommendations (PA-R) was calculated using an estimation of physical activity intensity through the PA compendium MET values and corresponding activity codes. MET-weighted minutes of LT-PA were dichotomized into a PA-R adherence estimation.

RESULTS: The data were stratified by gender for the analysis. Age group, the only significant covariate, was controlled for in the models presented here. Men (OR = 1.53; 95% CI: 1.11 to 2.11) and women (OR = 2.52; 95% CI: 1.90 to 3.34) engaging their social network during reported LT-PA were more likely to meet PA-R compared to participating alone. Men engaging a friend (OR = 2.80; 95% CI: 1.84 to 4.25) and women engaging a family member (OR = 4.39; 95% CI: 2.37 to 8.12) or a friend (OR: 3.08; 95% CI: 2.10 to 4.51) during LT-PA were more likely to meet PA-R compared to participating alone, and when controlling for age and other forms of SNE.

CONCLUSIONS: Social Network Engagement is associated with meeting PA-R. This relationship varies by gender and the type of SNE, but not other common sociodemographic factors.

Reported Walkable Destinations Across Age Groups Among US Adults — 2015

Geoffrey Whitfield¹, Susan A. Carlson¹, Emily N. Ussery¹, Kathleen Watson¹, David Berrigan², Janet E. Fulton, FACSM¹.
¹Centers for Disease Control and Prevention, Atlanta, GA.
²National Institutes of Health, Bethesda, MD. (Sponsor: Janet Fulton, FACSM)
 (No relationships reported)

The Guide to Community Preventive Services recommends community-scale design strategies as a way to increase physical activity. One example of this strategy is locating residences within walking distance of other destinations. Physical activity participation declines with increasing age. It is unclear if the prevalence of near-home walkable destinations also declines with age.

PURPOSE: To describe the prevalence of four types of walkable destinations across age groups in a representative sample of US adults aged ≥18 years. METHODS: Respondents to the 2015 National Health Interview Survey reported the presence of four walkable destination types near their home: shops, stores, or markets; bus or transit stops; movies, libraries, or churches; and places that help one relax, clear one's mind, and reduce stress. The proportion reporting each was calculated and stratified by age group. Differences between age groups were assessed with Wald tests corrected for multiple comparisons; trends were tested with orthogonal contrasts.

RESULTS: Overall, 71.8% reported walkable relaxing destinations, followed by shops (58.0%); transit (53.2%); and movies, libraries, or churches (47.5%). For shops; transit; and movies, libraries, or churches, adults aged 18–34 years reported similar values, beyond which the prevalence was progressively lower with increasing age (all p<0.05 for trend, Table). For relaxing destinations, the prevalence was similar among adults aged 18–44 years, and lower among those aged 45–64 and ≥65 years.

CONCLUSIONS: In general, the prevalence of walkable destinations among adults was lower with increasing age, and most consistently among adults aged ≥45 years. Community-scale design, including locating residences and other destinations within walking distance, can help promote physical activity across all ages. Addressing differences in the presence of walkable destinations between older and younger adults may be a community design priority.

% Reporting Walkable Destinations								
Age (years)	Shops, stores, markets		Bus or transit stops		Movies, libraries, churches		Places to relax, reduce stress	
	%	95% CI	%	95% CI	%	95% IC	%	95% CI
18-24	71.5a	68.8-74.1	62.7a	59.7-65.6	58.9a	56.0-61.7	75.8a	73.3-78.2
25-34	67.8a	65.6-69.9	62.1a	59.7-64.5	55.8a	53.5-58.1	76.4a	74.7-78.1
34-44	60.5	58.3-62.6	56.0	53.6-58.3	49.6	47.6-51.7	74.7a	72.7-76.6
45-64	54.3	52.5-56.0	49.6	47.9-51.3	44.8	43.3-46.3	71.3	69.9-72.7
≥65	44.7	42.8-46.6	42.8	40.8-44.7	35.2	33.5-36.9	63.3	61.5-65.0

The Effect of Ramadan Month on Changes in Objectively Assessed Physical Activity in Adults

Abdulaziz Farooq, Fuad Almudahka, Abdulla Al-Mohannadi, ASPETAR, Qatar Orthopaedic and Sports Medicine Hospital, Doha, Qatar, Doha, Qatar.
 Email: mohammed.farooq@aspetar.com
 (No relationships reported)

Ramadan is the Islamic month, when Muslims around the world participate in an intermittent fast for 29 to 30 days as a part of their religious obligation. During this period, Muslims abstain from eating and drinking during daylight hours. Studies have shown that Ramadan fasting has negative influence on sleep, physical performance and attention. However, the effects of Ramadan fasting on physical activity are not clear.

PURPOSE: To determine the impact of Ramadan month on objectively assessed physical activity among Muslim adults.

METHODS: Around 802 Muslim adults (Males 51.7%) ages ranging from 18 to 60 years, were sampled from a national community health program in Qatar representing two consecutive years. Physical activity was assessed daily using a pedometer (Omron HJ-720 ITC). Daily average step count and aerobic step count during the days of Ramadan month was compared during non-Ramadan months (one month prior and one month after Ramadan). For this longitudinal study design, a linear mixed model statistical procedure was adopted to adjust for demographic and environmental factors to test the study hypothesis.

RESULTS: Objectively assessed physical activity, i.e. daily average step counts per day, declined during the month of Ramadan compared to non-Ramadan months in this population. The average daily steps per day during Ramadan month was 7,267 (95% CI 7,180 to 7354) steps. When compared to one month prior Ramadan there was an average reduction of 619 steps (95% CI 483 to 755) per day $p < 0.001$. The decline in physical activity during Ramadan was higher men (-729±74) steps compared to women (-490±81). However, one month post Ramadan the physical activity levels defined by daily average step counts increased by average 548 steps (95% CI 407 to 688) compared to Ramadan ($P < 0.001$) and were similar to pre-Ramadan month ($P = 0.692$).

CONCLUSIONS: This study confirmed that in this population, due to the shift in time of activity as well as calorie intake from daylight to evening hours during Ramadan there was substantial decline in objectively assessed daily physical activity among Muslim adults. Interventions are needed to promote physical activity during this period.

Changes in Body Height And Weight Of Children And Adolescents In China During 1943-2014
 Yihong Zhang, Yu Pei. *Chengdu Sport Institute, Chengdu City, China.* (Sponsor: Zhengzhen Wang, FACSM)
 Email: 1688821@qq.com
 (No relationships reported)

PURPOSE: To compare body height and weight of 5-19 years old children and adolescents between 1943 and 2014 in China, and to determine the change in morphological development in Chinese children and adolescents over 71 years. **METHODS:** Based on the Student Physical Standard (made by the Physical Education Committee of the Ministry of Education of China, with unknown sample size) in 1943 and the National Physical Fitness Surveillance Report (from the General Administration of Sport of China, with sample size of 358725.) in 2014, the data in body height and weight of 5-19yr boys and 5-17yr girls were compared. The difference of height and weight average of children and adolescents in each age, and the growth of each age were calculated. And contrast chart were generated. Due to the sample size data could not be obtained when the Student Physique Standard is established, in this study we couldn't test the mean difference. Therefore this study used simple statistical description to reflect the growth trend of children and adolescents. **RESULTS:** The average height in each age for boys between 5-19yr and girls between 5-17yr in 2014 was significantly higher than that in 1943, the differences were 4.6(19yr)-20.4(13yr) cm for boys and 3.4(17yr)-14.7(11yr)cm for girls. The average weight in each age for boys between 5-19yr and girls between 5-17yr in 2014 was significantly higher than in 1943, and the differences were 2.4(5yr)-14.8(13yr)kg for boys and 1.2(5yr)-11.6(11yr) kg for girls. In 1943, boys between 5-14yr were at a lower physical development level than girls, but boys after 14yr were at a higher physical development level than girls. However, in 2104, boys between 10-11yr were at a similar physical development level compared to girls, in each of the other ages boys were at a higher level than girls. In 1943, the height growth spurt periods were from 12-13yr in girls and from 15yr in boys, and the weight growth spurt periods were from 12-15yr in girls, and from 14-15yr in boys. In 2014, the growth spurt periods for both height and weight were 11yr in girls and 13yr in boys. **CONCLUSION:** Compared to the data collected in 1943, Chinese children in 2014 were higher and heavier. Moreover, a 1-2 years gap was also observed in terms of the growth spurt age. Supported by the Sports Medicine key laboratory of General Administration of Sport of China(A2015C06).

Physical Literacy of 8-12 Year Old Children in Prince Edward Island, Canada
 Travis Saunders, Rachel Kays, Dany MacDonald. *University of Prince Edward Island, Charlottetown, PE, Canada.*
 (No relationships reported)

PURPOSE: Physical literacy is defined as the motivation, confidence, physical competence, knowledge and understanding to value and take responsibility for engaging in physical activities for life. The purpose of the present study was to assess the physical literacy of children and youth living in Prince Edward Island, Canada, using preliminary results from the RBC Canadian Assessment of Physical Literacy (CAPL).

METHODS: The CAPL includes tests in 4 domains: Motivation and Confidence (CSAPPA Questionnaire), Knowledge and Understanding (CAPL Physical Activity Questionnaire), Physical Competence (BMI, waist circumference, grip strength, PACER test, plank, sit and reach, and obstacle course), and Daily Behaviour (objectively measured steps/day and self-reported physical activity and sedentary behaviour). The scoring categories for each domain were: Beginning, Progressing, Achieving, or Excelling, with Achieving considered the minimum recommended score. **RESULTS:** Data were collected on 205 boys and 202 girls aged 8-12 years (mean: 10.7±1.1 years). The proportion of participants identified as Achieving or Excelling

in each domain was as follows: Motivation and Confidence: 40%; Knowledge and Understanding: 66%; Daily Behaviour: 64%; Physical Competence: 39%; Overall Physical Literacy: 63%.

CONCLUSIONS: Although two-thirds of participants were considered to have met the minimum recommended level of Knowledge, Daily Behaviour, and overall Physical Literacy, only a minority of children met the minimum recommended levels of Physical Competence and Motivation and Confidence.

FUNDING: Research funding was provided by the Children's Hospital of Eastern Ontario Research Institute through the RBC Learn to Play project, delivered in partnership with ParticipACTION and the Public Health Agency of Canada.

Geographical Distribution, Socioeconomic Status And Health-related Physical Fitness In Adolescents From A Large Population-based Sample From Bogotá, Colombia: The Ser Study

Diogo Rodrigues-Bezerra¹, Robinson Ramírez-Vélez², Jorge E. Correa-Bautista², Jose De Jesus Moreno-Montoya³, Gustavo Tovar³, Antonio Garcia-Hermoso⁴. ¹Centro de Estudios para la Medición de la Actividad Física «CEMA», Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogota, Bogotá D.C, Colombia. ²Centro de Estudios para la Medición de la Actividad Física «CEMA», Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogota, Bogota, Colombia. ³Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá D.C, Colombia. ⁴Laboratorio de Ciencias de la Actividad Física, el Deporte y la Salud, Universidad de Santiago de Chile, Santiago, Chile.
 Email: robin640@hotmail.com
 (No relationships reported)

PURPOSE: The negative gradient between socio-economic status and prevalence of non-communicable disease in adulthood has prompted investigation of potential foundations based in childhood. The objective of the present study is to examine the influence of socio-geographical variations and socioeconomic status on health-related physical fitness in adolescents from a large population-based sample of Colombian ninth graders.

METHODS: During the 2014-2015 school years, we examined a cross-sectional component of the SER Study is a cross-sectional Body mass, height, muscular fitness (standing broad jump and handgrip tests) and cardiorespiratory fitness (20 m shuttle-run) were measured in n=52,204 14-16-year-olds. Area-level socioeconomic status was categorized from 1 to 6. A model was built by means of a step-by-step process and gradient maps were created to show physical fitness in the quartiles and the trend of physical fitness across disaggregated in Zonal Planning Units (in Spanish UPZ) in Bogotá, for each of the five health-related physical fitness variables.

RESULTS: Socioeconomic status was used as the only group-level variable and this had a significant effect on the models for all health-related physical fitness parameters except for handgrip. Cardiorespiratory fitness, standing broad jump, and body mass index increased 6.31, 2.69, and 1.45 times, respectively, on average with the maximum increase in socioeconomic status categories, when we compared two random individuals in each stratum.

CONCLUSIONS: Our results suggest a significant association between health-related physical fitness variables and socio-geographical location in ninth grade adolescents from Bogotá, using a multilevel methodological approach.

Trends in Walking for Transportation or Leisure Among U.S. Adults — National Health Interview Survey, 2005-2015

Emily N. Ussery¹, Susan A. Carlson¹, Geoffrey P. Whitfield¹, Kathleen B. Watson¹, David Berrigan², Janet E. Fulton, FACSM¹. ¹Centers for Disease Control and Prevention, Atlanta, GA. ²National Cancer Institute, Bethesda, MD. (Sponsor: Janet Fulton, FACSM)
 Email: yzv4@cdc.gov
 (No relationships reported)

BACKGROUND: Physical activity confers considerable health benefits, but only half of U.S. adults report achieving levels of aerobic physical activity consistent with current guidelines. Walking is an excellent way for most people to increase their physical activity. The prevalence of walking among adults increased by 6 percentage points from 2005 to 2010, but it is unknown whether this increase has been sustained. **PURPOSE:** To evaluate trends in the prevalence of walking for transportation or leisure among U.S. adults between 2005 and 2015.

METHODS: Nationally representative data from the 2005, 2010 and 2015 National Health Interview Survey (NHIS) cancer control supplements (n=78,741) were analyzed

to estimate the age-adjusted prevalence of self-reported walking among adults ≥ 18 years. Walking was defined as engaging in at least one 10-minute bout of transportation or leisure walking in the past seven days. Estimates are reported for the total sample and stratified by sex. Linear and quadratic trends in walking prevalence from 2005 to 2015 were tested using logistic regression.

RESULTS: The overall prevalence of self-reported walking increased significantly from 2005 to 2015, although a leveling off was observed between 2010 and 2015 (2005: 55.7%, 2010: 62.1%, 2015: 63.9%; p-value for linear and quadratic trends ≤ 0.05). A similar trend was observed among men, with no significant difference in prevalence between 2010 and 2015 (2005: 54.3%, 2010: 61.8%, 2015: 62.8%; p-value for linear and quadratic trends ≤ 0.05). Among women, the prevalence of walking demonstrated a significant linear increase from 2005 to 2015 with no significant quadratic trend; the increase in prevalence between 2010 and 2015 was significant (2005: 57.5%, 2010: 62.5%, 2015: 65.1%; p-value for linear trend only ≤ 0.05).

CONCLUSION: Overall, the proportion of U.S. adults who reported walking significantly increased from 2005 to 2015; however, the results suggest that this increase has slowed in recent years, especially among men. This finding highlights the importance of implementing effective programs and policies that promote walking and improve the walkability of communities, as described in *Step it Up! The Surgeon General's Call to Action to Promote Walking and Walkable Communities*.

Findings from the 2016 Active Healthy Kids Scotland Report Card

ADRIENNE R. HUGHES¹, Avril Johnstone¹, Geraldine McNeill², John J. Reilly¹. ¹University of Strathclyde, Glasgow, United Kingdom. ²University of Aberdeen, Aberdeen, United Kingdom. (Sponsor: David Rowe, FACSM)
 Email: adrienne.hughes@strath.ac.uk

(No relationships reported)

The Active Healthy Kids Scotland Report Card provides a comprehensive assessment on the physical activity and health of Scottish children and adolescents. **PURPOSE:** To summarize the report card grades; to identify changes in report card grades since the previous report card published in 2013; to critique Scottish surveillance of physical activity and health in children and young people.

METHODS: Report card grades were assigned to 10 indicators related to physical activity and health (7 behavioral indicators and 3 policy and environment indicators). Grades were based on Scottish data which were: recent (published after the 2013 card), derived from nationally representative samples and affected by minimal bias, and determined by the percentage of Scottish children and adolescents meeting an evidence-based benchmark: A is 81% to 100%; B is 61% to 80%; C is 41% to 60%, D is 21% to 40%; F is 0% to 20%; INC is Incomplete data combined with lack of an evidence-based recommendation. Grades were assigned a '+' if trends had improved since the last report card and a '-' if there was a marked socio-economic inequality in the indicator. **RESULTS:** Overall Physical Activity, Sedentary Behavior and Obesity received F or F- grades. Active Outdoor Play and Organised Sport Participation were graded as INC. Active Transportation to School/Nursery was graded C, and Diet D-. Family and Peer Influence was graded as D-. Community and the Built Environment, and National Policy were both graded B. Issues with measurement and reporting of several physical activity indicators were identified: no surveillance of moderate to vigorous physical activity in children, no surveillance of active outdoor play and sports participation in children or adolescents, and summary surveillance data not reported in line with evidence-based recommendations.

CONCLUSIONS: Grades were similar to those in 2013. Scotland has a favorable environment for physical activity, but children and adolescents have low physical activity and high screen-based sedentary behavior. Better surveillance of physical activity and health in Scottish children and adolescents is required and would encourage more evidence-informed physical activity and health policy in Scotland in future.

Running Profiles And Their Associated Behaviors: A Proposal For Chilean Runners

Manuela Besomi¹, Jaime Leppe¹, Manuel Vicente Mauri-Stecca¹, Phillip S. Sizer². ¹Universidad del Desarrollo, Santiago, Chile. ²Texas Tech University Health Sciences Center, Lubbock, TX.
 Email: mbesomim@udd.cl

(No relationships reported)

Purpose: Identifying different runner profiles may improve running-related injuries (RRIs) prevention, education, and management. The aim of this study was to determine Chilean runner's profiles according to socio-demographic characteristics, motivations, training factors and behaviors associated with running during 2015-2016.

Methods: An email and web-based online cross-sectional survey were conducted. Runners from six different competitions and other running circuits were recruited. The survey collected information on 6 dimensions: (1)socio-demographics; (2)health; (3)motivations; (4)training factors; (5)behaviors associated with running; and (6) beliefs and perceptions. Profiles' construction was performed through a two-step cluster analysis using Bayesian Information Criterion and linear discriminant analysis to correctly assess subject classification. All statistical analyses were performed using SPSS22 with a significance level set at 5%. **Results:** A total of 821 runners (46% females), aged 36.6 (± 10.0) years were analyzed. Cluster analysis allowed the generation of 4 groups (n=752) according to years-of-running-experience, volume (km/week) and hours of training (hrs/week). Main variable for runners' classification was years-of-running-experience: "Beginner"(n=163); "Basic"(n=164); "Intermediate"(n=160); and "Advanced"(n=265). Statistically significant (p<0.05) and clinically relevant variables among the 4 groups were: sex, age, years-of-running-experience, training factors, previous injury(PI) and technological implements used for running practice. Beginners were mainly females (63.2%), aged 28.5 (± 8.4) years, having less than 1 year-of-running-experience, 32.5% reported PI, and accumulated a training volume of 18.3 (± 12.7) km/week. Advanced runners were mainly males (65.3%), aged 37.4 (± 10.9) years, 63.4% with more than 7 years-of-running-experience, 44.2% reported to have PI and accumulated a training volume of 38.2 (± 20.8) km/week. **Conclusion:** Advanced runners accumulate greater training load per week, were older, and with higher PI proportions when compared with Beginners. Future work should include a differentiated classification of runners, in order to identify clinically specific risk factors related to running injuries.

 Email: largo.wight@unf.edu

(No relationships reported)

PURPOSE: Active commuting and transportation behavior impacts obesity rates, wellbeing, and environmental health and quality. This study was designed to assess the relationship between active transportation, the built environment, and population perceived health in two comparable cities in the southeastern U.S.A.

METHODS: From 2006-2010, Charlotte, NC (city1) improved the built environment (e.g., shifting a motor vehicle lane to designated bicycle lane) and transportation policies (e.g., bicycle safety) to facilitate active commuting in the downtown area. Jacksonville, FL (city2) did not implement any changes to the built environment to foster active commuting. Data from the Behavioral Risk Factor Surveillance System [BRFSS] from 2006 (pre intervention) to 2012 (post intervention) were analyzed for both cities.

RESULTS: There were no significant differences between city1 and city2 in sample size and demographic make-up (age, race, gender, sex). Over the period 2006 to 2012, the annual difference between the percentage of Charlotte respondents rating physical health as good and those in Jacksonville rating physical health good increased at a rate of 13% per year based on an exponential growth regression model (p = 0.0213). That is, over time the difference between the two cities grew in favor of Charlotte.

CONCLUSIONS: Supportive urban and transportation policies aimed at facilitating healthy behaviors are associated with healthier communities in this convenience sample of two cities This study's findings were consistent with past findings that highlight the importance of the built environment and transportation policies on population health. Future research is needed to assess rates of active commuting and examine the populations and outcomes longitudinally.

Physical Activity Among U.S. Adults With Mobility Disability, Brfss, 2015

Dianna D. Carroll, Qing C. Zhang, Elizabeth A. Courtney-Long, Alissa C. Stevens. *Centers for Disease Control and Prevention, Atlanta, GA.*

Email: feu9@cdc.gov

(No relationships reported)

The 2008 *Physical Activity Guidelines* recommends that all adults avoid inactivity and engage in activities based on their abilities. Mobility disability is the most prevalent disability type among US working-age adults and is related to poor health outcomes. Understanding physical activity (PA) patterns among this group can aid development of inclusive interventions to increase PA participation in ways that meet their needs and abilities. **PURPOSE:** To assess prevalence of PA levels among adults aged 18-64 years with mobility disability and determine the most common PA types by activity level. **METHODS:** Using the 2015 Behavioral Risk Factor Surveillance System (n=269,486), we classified respondents reporting serious difficulty walking or climbing stairs as having mobility disability (n=35,140). We calculated moderate-intensity-equivalent minutes/week (2*vigorous min/wk + moderate min/wk) from self-reported type, frequency, and duration of PA in the past month. Three PA levels were: active (≥150 min/wk), insufficiently active (10 - 149 min/wk), and inactive (no PA for ≥10 min/wk). Weighted prevalence estimates and 95% confidence intervals (CI) were calculated for PA levels and for activity types. **RESULTS:** Overall, 10.5% of 18-64 year old adults reported mobility disability. Among these adults, a significantly higher percentage were inactive [51.0% (95% CI: 50.0, 52.0)] than insufficiently active [19.1% (95% CI: 18.3, 20.0)] or active [29.9% (95% CI: 29.0, 30.9)]. Among those who were insufficiently active, walking was the most commonly reported activity (78.1%), followed by gardening/yard work (3.8%), and bicycling (3.3%). Among active adults, walking was the most commonly reported activity (61.3%) followed by gardening/yard work (9.4%) and bicycling (6.2%). **CONCLUSION:** Nearly 5 in 10 working-age adults with mobility disability avoid inactivity, primarily through walking. However, the other half of this group are inactive and missing the opportunity to protect or improve their health by regularly engaging in PA. These results highlight the need for PA promotion strategies in which all adults have opportunities to participate according to their abilities and the need to evaluate how specific activities, such as walking or wheelchair rolling, may increase PA among adults with mobility disabilities.

Assessing Street-scale Supports For Walking In The U.S. Virgin Islands — 2016

John D. Omura¹, Emily Ussery¹, Dana McGuire¹, Lillianne Lewis¹, John Orr², Prabasaj Paul¹, Erin L. Peterson¹, Janet E. Fulton, FACSM¹, Kathleen Arnold-Lewis², Esther Ellis², Susan A. Carlson¹. ¹US Centers for Disease Control and Prevention, Atlanta, GA. ²US Virgin Islands Department of Health, Christiansted, United States Minor Outlying Islands.

Email: ydk8@cdc.gov

(No relationships reported)

PURPOSE: Streets can be designed to provide safe and easy places that encourage walking by providing street-scale supports such as destinations, sidewalks, lighting, and traffic calming features. The prevalence of street-scale supports for walking across the US Virgin Islands (USVI) was assessed and differences determined by residential or commercial land use type.

METHODS: A two-stage sampling method was used to select representative street segments: (1) Estates (census subdivisions in the USVI) were selected using stratified random sampling (n=46 selected of 336) and (2) street segments were then randomly selected from within Estates (n=1550). The Microscale Audit of Pedestrian Streetscape Abbreviated Tool was locally adapted and used by trained auditors to conduct objective assessments of several key elements of street-scale design, including destinations, traffic calming features, street lighting, and sidewalks. Descriptive statistics were weighted to be representative of the total street length within the sampling frame. Audits were conducted on 1114 street segments (unweighted: 94.6 km of street length; weighted: 1456 km).

RESULTS: Overall, 22.1% of street length had at least one destination, 27.9% had at least one traffic calming feature, 53.0% had at least some street lighting, and 11.2% had sidewalks (TABLE). Significant differences were found by type of land use for the presence of several features, including number of destinations, the degree of street lighting, and sidewalks (Pearson's chi-square test, p<0.001).

CONCLUSION: Across the USVI, street-scale features that support walking were uncommon and were less prevalent on residential streets than on commercial streets. Implementing policies and projects relating to street-scale design in the USVI could improve walkability, particularly those that focus on residential areas.

TABLE. Prevalence of built environment features among audited street length, US Virgin Islands, 2016

Features	Overall (N=1456 Km)		Residential land use		Commercial land use		Pa
	%	95% CI	%	95% CI	%	95% CI	
Total	--	--	85.3	(76.0-91.4)	14.7	(8.6-24.0)

Fitness And BMI Levels In Children Of The City Of Barcelona Related To Their Socio-economical Level (POIBA Project)

Josep Cabedo. *Universitat Ramon Llull, Barcelona, Spain.*

Email: josepcs@blanquerna.url.edu

(No relationships reported)

PURPOSE: To study the fitness and the BMI levels of children from Barcelona (Spain), related to their socio-economical level.

METHODS: 3279 children (1634 boys) of 7-10 yr. were recruited from schools of three different socio-economical levels: low (n=343), medium (n=850) and high (n=1808), and participated in the study after the approval of the Clinical Ethics Committee research CEIC- Parc Salut Mar. The participants' families gave informed consent for their children to participate. Height, weight and BMI of all of them were obtained. A battery of fitness tests was performed: vertical jump, ball throwing, long jump, zig-zag running test, 20 m running velocity test and 20m shuttle run test (EUROFIT, 1993; Welk & Meredith, 2008). Descriptive for all variables were obtained, ANOVA and Bonferroni were applied to compare the three groups.

RESULTS: Significant differences appeared between the three groups, with worse values in the low socio-economic level for all the fitness tests, except for vertical jump test.

CONCLUSIONS: As a low socio-economical group showed worse fitness levels than medium and high groups. Moreover, their overweight/obesity levels could have conditioned the fitness levels. The study was partially funded by the "Fondo de Investigación Sanitaria (FIS)" (PI09/02259), of the Carlos III Health Institute (Ministry of Economy and Competitiveness, Spanish Government. Authors declare no conflict of interest.

Characteristics and Fitness test values compared between socio-economical levels							
Variables	Socio-economic level	HighMean (SD)	MediumMean (SD)	LowMean (SD)	P1	P2	P3
Descriptive

Objective And Subjective Measures Of Walkability And Bikability At Westfield State University
 Christina A. Lankarge, Melissa W. Roti, FACSM. *Westfield State University, Westfield, MA.*
(No relationships reported)

PURPOSE: Walking and bicycling are popular forms of active transportation that help an individual engage in physical activity. College campuses present unique opportunities for all of its members to engage in physical activity as they are moving on and around campus and these forms of active transport should be encouraged for all campus members. This study aims to compare objective walkability measurements of Westfield State University's (WSU) pathways and roadways and how they support walking and biking versus student and faculty/staff perceptions of infrastructure support for walking and biking. **METHODS:** Mixed methods were used to obtain data: selected segments of WSU campus were objectively measured using a modified CDC Walkability Audit tool; the results of the audits were compared to results of an online survey distributed to WSU students and faculty/staff about their perceptions of ease of walking and biking on and around the campus. Two open-ended response questions were given to each group to propose recommendations to facilitate walking and biking. **RESULTS:** Selected path segments (n=26) on and connecting the WSU campus were audited for their objective walkability/bikability. The segments received a mean score of 62.9±18.4, giving WSU a grade C. Only 31% of audited segments received a grade A or B while the remaining 68% received a grade C or F, indicating fair or poor conditions for walking and biking. Students (n=389) and faculty/staff members (n=78) responded to the survey. Student age was 20.4±1.7 years and 48.72% self-reported their daily physical activity level as a mix of both sedentary and activity. Faculty age was 48.2±13.2 years and 46.75% self-reported their daily physical activity level as mostly sedentary with some activity. For the open-ended questions, the top answers for both students and faculty/staff were posting more motivational signage about walking and installing bike racks and outdoor bike storage. **CONCLUSIONS:** The objective audit supports current student and faculty/staff perceptions of campus walkability and bikability. Both subjective and objective measures can be used when designing a long-term campus master plan as well as physical activity interventions.

A National Survey of Popular Physical Activities among U.S. Children and Youth
 Fan Guo¹, Hai Yan², Weimo Zhu, FACSM³. ¹*Southeast University, Nanjing, China.* ²*University of Illinois at Urbana-Champaign, Urbana, IL.* ³*University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)
 Email: fanguo@illinois.edu
(No relationships reported)

PURPOSE: Understanding what children and youth enjoy to play is beneficial in helping design intervention and other physical activity (PA) related programs to help improve children's fitness levels. The aim of this study was to determine the popularity of different PA among children and youth aged from 3 to 15 yr. old. **METHODS:** The national representative data (N = 53,669,505; 51.12% male; 3-15 yr.) from the 2012 NHANES National Youth Fitness Survey were employed for the analysis. Descriptive analysis was applied to examine the popularity of different type of PA and t-tests were used to determine the sex difference and ANOVAs were applied to examine the age difference on total PA participation. **RESULTS:** Among the 30 types of PA listed, including running, football, basketball, soccer, swimming, dance, and walking, etc., the most popular PA for children and youth in all age groups is running (33.30%), followed by bike riding (27.86%), and backyard games (21.71%). The 3 most popular PA for boys are running (35.18%), basketball (30.31%), and bike riding (29.90%), and for girls are running (31.33%), bike riding (25.73%), and walking (21.55%). About 16.9% of children/youth participated in no activity, but about 18.7% took part in at least one activity and about 64.4% took part in more than one activities; on average, children/youth took part in 2.59 ± 2.18 (M±SD) activities and boys (2.81±2.31) participated in more activities than girls (2.36±2.02; t=758.544, p<0.00, effect size = .10). From 3 to 11 yr., as the children got older, they participated in more PA, but the PA participation decreased after 12yr. **CONCLUSIONS:** Running is the most popular PA for the US children and youth, and some gender and age impact on PA participation was found.

Physical activity participation in age and gender difference among U.S. children and youth					
	3-7 yr.	8-11 yr.	12-15 yr.	F	p-value

Do New Zealand Women's Age and Ethnicity Contribute to Achieving Physical Activity Guidelines?
 Wendy J. O'Brien¹, Sarah P. Shultz², Bernhard H. Breier¹, Rozanne Kruger¹. ¹*Massey University, Auckland, New Zealand.* ²*Massey University, Wellington, New Zealand.*
 Email: w.j.obrien@massey.ac.nz
(No relationships reported)

Regular participation in physical activity (PA) has overwhelming positive implications on long-term health and on disease prevention. Despite established government guidelines to improve health through PA, over half of New Zealand women reportedly fail to meet these criteria. Barriers to achieving minimum physical activity levels may include demographic characteristics (i.e. age, ethnicity), but the contribution of each factor is unclear. **PURPOSE:** To understand how age and ethnicity affect a New Zealand woman's ability to meet PA guidelines. **METHODS:** Healthy New Zealand women (n = 350) of three ethnicities (Māori, Pacific, European) aged 16-45y (stratified as 16-25y, 26-35y, 36-45y) wore triaxial accelerometers for 7 days. Levels of moderate-vigorous PA (MVPA; ≥2020 counts.min⁻¹) were assessed. Participants were categorized as achieving or not achieving PA guidelines. PA guidelines are commonly reported as either ≥150 min.wk⁻¹ MVPA (Basic) or ≥150 min.wk⁻¹ MVPA in bouts of 10+ min (Basic10+), therefore both of these classifications were considered. **RESULTS:** Basic10+ guidelines were met by only 32% of New Zealand women; a further 34% of women (66% in total) met Basic guidelines. There were no significant differences between the three age groups when ethnicity was not also considered. Achievement of Basic guidelines was lower in Pacific women (37%) than Maori (65%; p=0.001) or European (75%; p<0.001) women. Specifically, fewer Pacific women in the 16-25y and 36-45y age groups achieved Basic PA guidelines than women of the same age but different ethnicity. More European women (38%) met Basic10+ guidelines than Maori (22%; p=0.011) or Pacific (22%; p=0.012) women. These differences between ethnicity were not specific to any age group. **CONCLUSION:** Although only two-thirds of New Zealand women achieved Basic PA guidelines, the prevalence was substantially higher than overall national statistics (48%). Given the extremely low rates of PA for periods of 10 or more minutes, a strategy is needed to increase the length of time women spend in bouts of MVPA. The findings further suggest that ethnicity, more so than age, is a contributing factor to achieving PA guidelines.

Comparison Of Weekend And Weekdays Physical Activity Levels In Korean Professional Golfers.

Jin-Su Seok¹, Seoungki Kang¹, Minkyoung Nam¹, Hyun-Sung An², Jung-Min Lee, 68182². ¹*Yong In University, Yong In, Korea, Republic of.* ²*University of Nebraska at Omaha, Omaha, NE.*
Email: sucsoi@gmail.com

(No relationships reported)

The dominance of the U.S based LPGA/PGA tour by Korean-born golfers over the past decade has been well recognized. The sheer volume of quality golfers being produced by this relatively small golfing nation has certainly caught the attention of the field of golf. However, the level of physical activity in Korean professional golfers has never been systematically examined. **PURPOSE:** The present study was to describe the baseline characteristics of the participant and to compare the physical activity level between weekdays and weekends in Korean professional golfers using objective physical assessment tools (i.e., Accelerometer). **METHODS:** Fourteen (male=7; female=8) young Korean professional golfers (23 ± 2.4 yrs; height = 171±7.5 cm; weight = 73.7±7.5 kg, experience = 6.6 yrs) consented to participate in the study. Participants were asked to wear the accelerometer (i.e., Actigraph) on their right wrist for 24 hours/day, 7 consecutive days to provide data on time in moderate and vigorous physical activity (MVPA). ActiLife software (version 6.11.2) was used to download all data. Raw data were processed with the R package GGIR and associated Hilderband milling (mg) cut points. Descriptive for all variables was calculated and Pearson product moment correlations were used to test for relationships between weekdays and weekends. A paired sample t-test was used to evaluate differences between weekday and weekend physical activity level. **RESULTS:** The accelerometer wear compliance was excellent 6.8 days, 98% of the time. Time in MVPA was 99.5 ± 35.79 mins/day and 136.4 ± 35.2 mins/day for weekends, weekdays, respectively. There is no significant difference on physical activity levels on weekdays ($t(12) = .379, p = .329$) and weekends ($t(12) = -.004, p = .997$) between male and female golfers. No correlation was observed between weekdays MVPA and years of experience. However, weekends MVPA were inversely correlated with years of experience ($r = -.215, p = .48$). Similar correlations were found between weekdays MVPA ($r = -.432, p = .141$) and weekends MVPA ($r = -.438, p = .134$) with golfers' age. **DISCUSSIONS:** Our data demonstrates that Korean professional golfers were highly active during weekdays compared to weekends. Experienced golfers were associated with little time spent in MVPA regardless of the days of the week.

Effect Of Work Intensity On The Kinetics Of W'

Kyle H. Yost, Philip F. Skiba. *Lutheran General Hospital, Park Ridge, IL.*

Email: kyleyost08@gmail.com

(No relationships reported)

PURPOSE:To assess the effect of work intensity on the W'_{BAL} model during intermittent exercise**METHODS:**

After determining VO_{2max} , critical power (CP), and W' , 10 untrained subjects completed three separate exercise tests on a cycle ergometer on different days, and in random order. In each case, subjects were asked to perform severe-intensity work intervals lasting 60s, followed by 30s of recovery at 20W. The intervals were repeated until volitional exhaustion. The work interval power was different during each visit, and was set using the 2-parameter CP model. Subjects were exercised at either the power predicted to result in exhaustion at 1.5, 3, or 4 min (P1.5, P3, P4). All subjects completed all trials. These data were entered into a continuous integrating equation predicting balance of W' remaining, assuming exponential reconstitution of the W' (W'_{BAL} model; Skiba 2012). The time constant ($\tau W'$) was varied by iterative process until the remaining modeled $W' = 0$ at the time of athlete exhaustion. $\tau W'$ was compared across trials, and predicted $\tau W'$ was compared to calculated $\tau W'$, using ANOVA. Results are reported as group means ± SD.

RESULTS:

Calculated $\tau W'$ was not significantly different between trials (mean P1.5 = 507 ± 547s, P3 = 436 ± 266s, P4 = 463 ± 268s, $p = 0.91$). Model predicted $\tau W'$ (mean = 443 ± 45) was not significantly different from the calculated $\tau W'$ in any of the experimental trials ($p = 0.96$). However, considerable inter-individual variability was noted, resulting in high SD. In particular, three subjects showed unexpectedly slow recovery of the W' during the experimental trials.

CONCLUSIONS:

These data suggest that the recovery of the W' is insensitive to work intensity within the power ranges studied. These data provide further support for the utility of the W'_{BAL} model over a variety of work intensities, but also suggest the possible need to develop athlete specific models with a customized $\tau W'$.

Energy Expenditure In Low-load Resistance Exercise With Slow Movement Using Body Mass Alone As Load

Takashi Nakagata¹, Yosuke Yamada², Hisashi Naito¹. ¹*Juntendo University, Inzai, Japan.* ²*National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan.*

(No relationships reported)

PURPOSE: Energy expenditure (EE) and MET values have been reported for many different physical activities and exercises. Resistance exercise using free weights and training machines at 3.5-6.0 METs has been defined as conditioning exercise. However, little research has been conducted on low-load resistance exercise with slow movement, such as squats and push-ups, using body mass alone as load. This study aimed to determine the EE and MET values in low-load resistance exercise using body mass alone as load. **METHODS:** Sixteen men aged 20-26 years performed 6 resistance exercises in random order, using body mass alone as load. The exercises consisted of squats, single-leg lunges, sit-ups, push-ups, heel raises, and hip lifts. The eccentric and concentric phases of the exercises were completed with 3-second slow movements, performed in 2 sets of 10 repetitions of each exercise. Oxygen consumption (VO_2) was continuously measured during exercise, and EE was calculated by applying the VO_2 and VCO_2 to the Weir equation. We measured resting EE for 30 min before exercise, and 1 MET was calculated by dividing gross oxygen consumption (ml/kg/min) by individual resting EE. **RESULTS:** The mean EE and MET values for low-load resistance exercise using body mass alone as load were 3.2 0.8 kcal/min and 2.6 0.7 METs, respectively. Squats involved multiple major muscle groups, with the quadriceps showing the highest EE and MET values for 6 exercises, at 4.1 1.0 kcal/min and 3.4 0.4 METs, respectively. Heel raises showed the lowest values of 2.2 0.6 kcal/min and 1.8 0.3 METs, respectively. **CONCLUSIONS:** The EE and MET values for low-load resistance exercise using body mass alone as load were lower than the values observed during the use of free weights and training machines, and were equivalent to those for low-to-moderate-intensity exercises such as walking in daily life.

Energy Expenditure of Collegiate Golfers in a Competitive Setting

Kaela M. Hierholzer¹, Peter J. Chomentowski, III¹, Steven M. Howell¹, Amanda J. Salacinski², Craig E. Broeder, FACSM³. ¹*Northern Illinois University, DeKalb, IL.* ²*University of Massachusetts-Lowell, Lowell, MA.* ³*Exercising Nutritionally, LLC; Northern Illinois University, Lisle, IL.* (Sponsor: Craig E. Broeder, FACSM)

Email: z1755566@students.niu.edu

(No relationships reported)

Tracking daily energy expenditure via wearable devices has become very popular. However, few in-lab and field studies validating these devices have been published. **PURPOSE:** To determine the accuracy of a wrist-based activity tracking device in a lab setting and during a NCAA style golf tournament. **METHODS:** Eight NCAA golfers [4 males; 4 females; Age: 19.3±2.0 yrs; WT: 149.5±13.4 lbs; Bag WT: 22.3±2.0 lbs; Bag Wt./Body Wt.: 15.0±1.8%; HT: 67.7±3.6 in; % BF: 20.0±7.3%] were tested. In-lab testing consisted of a VO_{2max} test with golf bag wt. simulation and two 6-min run/walk steady-steady (SS) tests (one with bag wt., one without). The golf tournament consisted of completing two, 18-hole rounds while carrying their own golf clubs. Variables collected during tournament play were HR, distance, time, speed, device kcals, kcals from the metabolic cart (MET kcals), pace, and score. Unpaired, paired t-test, and a repeated measures ANOVA were used to determine significant differences. Correlation and step-wise multiple regression were used to determine which variables had the largest influence on determining kcals expended. **RESULTS:** During the in-lab testing, the device overestimated kcals expended compared to the actual MET kcals (+22.4%; $p = 0.01$) for the 6-min SS tests. Step-wise regression showed that HR had the largest impact on kcal expenditure ($p = 0.04$) during the SS tests. During the golf tournament, males had lower mean HRs (males: 111.00 ± 4.31 bpm; females: 121.99 ± 15.26 bpm). The device showed females burned more tournament kcals (1,642.33 ± 442.98 kcals), but less kcals per hour (348.59 ± 78.09 cal/hour) than males (1,583.13 ± 145.80 kcals; 357.13 ± 30.21 cal/hour). Comparing MET kcals and device kcals, the device underestimated females by 6.22% (not significant, NS) and overestimated males by 5.3% (NS). Looking at the device kcals for all golfers across all rounds, step-wise regression showed that calories/hour and playing duration time ($p \leq 0.01, p \leq 0.01, r\text{-squared} = 0.99$) were the primary independent device kcal determinants. **CONCLUSION:** The in-lab tests showed the device overestimated kcals expended.

During the golf tournament, the device overestimated males and underestimated the female kcals expended showing a possible golf tournament wearable kcal gender measurement tracking bias.

Muscle Oxygen Extraction is a Key Performance Adaptation in Sprint Canoe-Kayak

Myriam Paquette, François Billaut. *Université Laval, Québec, QC, Canada.* (Sponsor: David Bishop, FACSM)

Email: myriam.paquette.2@ulaval.ca

(No relationships reported)

Background The aerobic contribution to sprint canoe-kayak performance ranges from ~37% to ~85% of total energy expenditure from shortest (200m) to longest (1000m) events. While systemic $\dot{V}O_{2\max}$ is a strong predictor of performance in 500m and 1000m races, the respective role of central and peripheral adaptations is poorly understood.

Purpose The purpose of this study was therefore to characterize the changes in oxygenation derived from portable near-infrared spectroscopy (NIRS) in various muscles during a $\dot{V}O_{2\max}$ test and two on-water time trials (TT: 200m and 500m or 1000m), and to examine the link between muscle oxygenation, cardiac output and performance.

Methods Twenty one well-trained sprint canoe-kayak athletes (12 men: 8 kayakers (MK) and 4 canoeists (MC); 9 women: 4 kayakers (WK) and 5 canoeists (WC)) participated in three testing sessions: 1) an incremental $\dot{V}O_{2\max}$ test on a canoe or kayak ergometer; 2) a 200-m TT; and 3) a 500-m (WK and WC) or 1000-m (MK and MC) TT. NIRS monitors were placed on the *latissimus dorsi* (LD), *biceps brachii* (BB), and *vastus lateralis* (VL) during the 3 testing sessions to assess changes in muscle O_2 saturation (SmO_2 , % from baseline). Cardiac output was measured by impedance during the $\dot{V}O_{2\max}$ test in a subset of 9 athletes.

Results Performance in the 200m time trial correlated with both LD final SmO_2 ($R=0.700$, $p=0.01$) and VL final SmO_2 ($R=0.568$, $p=0.02$). Performance during the 500-1000m time trials correlated with BB final SmO_2 obtained during the $\dot{V}O_{2\max}$ test ($R=0.519$, $p=0.033$) and with $\dot{V}O_{2\max}$ (L/min: $R=-0.560$, $p=0.03$). Maximal cardiac output was low (men: 26.2 ± 4.7 L/min, women: 24.0 ± 2.6 L/min) and did not correlate with 200m ($R=0.253$) or 500-1000m ($R=0.028$) performance.

Conclusion These results confirm that systemic $\dot{V}O_{2\max}$ is related to performance in the longer canoe-kayak events, and suggest that peripheral adaptations (i.e., the muscle ability to extract oxygen during the effort) rather than central factors better contribute to success in this sport. The ability to extract oxygen during the effort appears to be a predictor of performance for both short and long events. These results indicate that training for sprint canoe-kayak athletes should emphasize the development of the peripheral component of oxygen consumption.

Gender Differences In Resting Energy Expenditure In Athletic Populations

Andrew Jagim¹, Carl Foster, FACSM¹, Joel Luedke¹, Jamie Ochsenwald¹, Jacob Kisiolok¹, Margaret Jones, FACSM², Jonathan Oliver³. ¹University of Wisconsin - La Crosse, La Crosse, WI. ²George Mason University, Fairfax, VA. ³Texas Christian University, Fort Worth, TX. (Sponsor: Carl Foster, FACSM)

Email: ajagim@uwlax.edu

(No relationships reported)

Gender differences in energy expenditure and fuel utilization have been observed during exercise. However, less is known about whether or not these differences are also evident at rest, particularly in athletic populations, and it is currently unknown whether these differences remain when adjusted for body mass (BM) and fat-free mass (FFM). **PURPOSE:** The purpose of this study was to determine the differences in resting metabolism between men and women athletes when adjusted for body mass and fat-free mass. **METHODS:** Twenty-one men (20.1 y; 180.8 6.3 cm; 97.7 17.3 kg; 17.2 8.5% BF) and nineteen women (20.1 y; 166.1 5.2 cm; 64.5 7.2 kg; 23.4% 4.4% BF) athletes were recruited to participate in a single testing session. Resting metabolism was estimated using Resting Energy Expenditure (REE) measurements through indirect calorimetry (TrueOne® 2400 Metabolic Measurement system, ParvoMedics, Sandy, UT) and body composition analyses via air displacement plethysmography (BODPOD, Cosmed, USA) to determine fat mass (FM) and FFM. Athletes reported to the lab in a rested (>48 hrs. from strenuous exercise) and fasted (>8 hrs.) state. During REE assessment, athletes remained in a supine position, motionless for 15-20 minutes while maintaining conscious awareness. Data recordings were then obtained when criterion variables (i.e., $\dot{V}O_2$ L/min) experienced less than a 5% alteration during the final five minutes of data collection. A one-way analysis of variance was used to compare differences in REE and body composition. **RESULTS:** Body mass and FFM were significantly greater in men ($p<0.001$). Women had higher body fat percentages (M: 17.2 ± 8.5 vs. W: 23.4 ± 4.4 %; $p=0.007$) however no differences between groups

were observed for FM ($p=0.361$). Absolute REE was significantly higher in men athletes (M: $2,480.8 \pm 208.6$ vs. W: $1,583.1 \pm 192.8$ kcals; $p<0.001$). When expressed relative to BM and FFM there were no differences in REE observed between men and women athletes (M: 25.8 ± 3.5 vs. W: 24.6 ± 1.9 kcals/kg of BM; $p=0.183$), (M: 31.2 ± 3.1 vs. W: 32.1 ± 3.1 kcals/kg of FFM; $p=0.357$) respectively. **CONCLUSIONS:** Based upon the results of the current study it appears as though the greater REE observed in men athletes are likely attributable to their increased BM and FFM.

Exercise-induced Changes In Plasma Adenosine Triphosphate Concentration In Highly-trained Sprinters And Triathletes

Krzysztof Kusy¹, Ewa M. Slominska², Ewa Zarebska¹, Monika Ciekot-Soltysiak¹, Lukasz Kruszynski³, Zbigniew Krasinski³, Jacek Zielinski¹. ¹Poznan University of Physical Education, Poznan, Poland. ²Medical University of Gdansk, Gdansk, Poland. ³Poznan University of Medical Sciences, Poznan, Poland.

Email: kusy@awf.poznan.pl

(No relationships reported)

PURPOSE: It is known that plasma adenosine triphosphate (ATP) concentration increases during exercise and depends on its intensity. There are no reports about the effect of specific long-term training adaptation on plasma ATP levels during exercise. The aim of our study was to compare the exercise-induced plasma ATP release in athletes specialized in speed-power vs endurance disciplines. **METHODS:** Nine sprinters, 9 triathletes at national/international level, and 9 amateur runners (controls), aged 23.8 ± 2.8 y, 23.1 ± 4.3 y, and 25.2 ± 2.7 y, respectively, were studied. They underwent an incremental exercise test until exhaustion on a motorized treadmill. Venous blood samples were drawn at rest, at exhaustion (maximum intensity), and after 10 and 30 min of recovery. Blood samples were immediately centrifuged for 30 s at 14,000 rpm and 4°C, frozen in liquid nitrogen, stored at -86°C, and then analyzed using high-performance liquid chromatography. Comparisons between groups and exercise phases were made using two-way ANOVA with repeated measures and Scheffe post-hoc test. **RESULTS:** In all three groups, a significant increase in plasma ATP was observed between rest and exhaustion, as well as after 30 min of recovery (see: Figure). A significantly greater plasma ATP concentration was observed in sprinters than in triathletes and controls at exhaustion and after 10 min of recovery. No significant between-group differences were observed at rest and 30 min after exercise. **CONCLUSION:** Plasma ATP response to incremental exercise until exhaustion is different depending on specific training adaptation. Training based on speed-power exercise brings about much greater plasma ATP release than endurance training. Underlying mechanisms, connected with exercise-induced vasodilation and its mediators, erythrocyte function, skeletal muscle activity, and other factors, need further research. Energetics of Semi-contact Karate in Trained Young Athletes

Yongming Li¹, Wen Tian², Bo Li¹, Xinxin Wang¹, Lv Miao¹.

¹Shanghai University of Sport, Shanghai, China. ²Civil Aviation University of China, Tianjin, China.

Email: 59058729@163.com

(No relationships reported)

PURPOSE: Karate will have its debut in the 2020 Olympic Games. Understanding the energetics in karate as a contact sport event may provide information for performance training. However, the existing studies on karate have limited mainly on non-contact fighting. The aim of this study is to determine the energetics of semi-contact karate in trained young athletes.

METHODS: Nine females (18.3 ± 1.7 yrs, 166 ± 4.7 cm, 57.2 ± 4.5 kg, 2.1 ± 1.7 yrs training experience) and nine males (16.7 ± 2.0 yrs, 176 ± 8.2 cm, 61.1 ± 9.4 kg, 2.4 ± 1.7 yrs training experience) from the Chinese national youth team participated in one round of semi-contact karate, with the duration of 2 min and 3 min, respectively. A portable spirometric system (MetaMax 3B, Cortex, Germany) was utilized to measure the inspired oxygen uptake. Capillary blood was taken from the earlobe prior to and post the karate, and analyzed with blood lactate analyzer (Biosen C-line, EKF, Germany). Athletes were encouraged to fight as in real matches, but without touching the spirometric machine. The energy contributions were calculated based on the accumulated oxygen uptake and blood lactate during karate, as well as the fast component of oxygen debt during the recovery.

RESULTS: The peak blood lactate values after karate were 3.36 ± 1.15 and 5.14 ± 1.70 mM for females and males. The averaged oxygen uptakes during karate were 30.6 ± 4.6 and 40.5 ± 5.0 ml/min/kg for females and males. The energy contribution from anaerobic alactic, anaerobic lactic, and aerobic pathways were 27.3 ± 11.8 (27.7 ± 8.1 %), 7.5 ± 4.4 (7.4 ± 3.3 %), and 61.6 ± 10.7 (64.9 ± 9.3 %) kJ for females, and 31.1 ± 10.8 (17.7 ± 5.3 %), 13.0 ± 5.9 (7.1 ± 2.7 %), and 132.7 ± 22.2 (75.2 ± 5.3 %) kJ for males.

CONCLUSIONS: Karate is an aerobic-dominant sport event, while the anaerobic energy system may play an important role in high-intensity fighting. These findings are consistent with existing studies on non-contact karate.

3250 Board #155 June 2 3:30 PM - 5:00 PM

A Comparison of Energy Expenditure Between Motorized and Non-Motorized Treadmills

Andrew G. Hatchett, Brian B. Parr, Lianna R. Epstein, Harli R. Eggenberger, Rachel L. Herring. *University of South Carolina Aiken, Aiken, SC.* (Sponsor: Micheal J Turner, FACSM)
Email: andrewwhat@usca.edu
(No relationships reported)

Non-motorized, arced treadmills are becoming more popular in fitness settings and are thought to require greater effort than walking or running on a traditional motorized treadmill. However, little research has been conducted to evaluate this type of exercise equipment.

PURPOSE: The purpose of this study was to compare the energy expenditure (EE) required to complete one mile on a non-motorized, arced treadmill (AT) and a motorized treadmill (TM).

METHODS: Nine recreationally trained healthy participants (4 male, 5 female) ages 26.1±9.6 years walked or ran 1-mile at a self-selected speed on a motorized treadmill (TM) and a non-motorized arced treadmill (AT) while VO₂, EE, and heart rate (HR) were measured. The EE in kcal•min⁻¹ and kcal•mile⁻¹ was calculated from VO₂ measured after subjects achieved steady-state. The tests were counterbalanced so half of the subjects completed the TM trial first and half completed the AT trial first.

RESULTS: Nine participants completed the 1-mile effort at an average speed was 125.1±32.6 m•min⁻¹ (range: 88.4–160.8 m•min⁻¹). The mean VO₂, EE, and HR were significantly higher during the TF trial compared to the TM trial:

	TM	AT	p
VO ₂ (L•min ⁻¹)	1.6±0.9	2.2±1.1	0.0006
EE (kcal•min ⁻¹)	7.9±4.6	10.9±5.4	0.0005
EE (kcal•mile ⁻¹)	98.4±35.4	144.8±32.2	0.0001
HR (beats•min ⁻¹)	152.0±29.3	164.9±23.3	0.005

Values expressed as mean±SD

CONCLUSION: Use of a non-motorized arced treadmill resulted in a significantly higher VO₂, EE, and HR compared to a traditional treadmill at the same speed. This could be due to the unique design of the arced treadmill that requires a different movement pattern and additional effort to propel the non-motorized belt. This may have implications for fitness applications in which EE is of interest.

3251 Board #156 June 2 3:30 PM - 5:00 PM

Energy Expenditure Characteristics of Overweight Women at the Same Speed of Jogging and Walking

Peizhen Zhang¹, Xiangrong Shi, FACSM². ¹*Beijing Sport University, Beijing, China.* ²*UNT Health Science Center, Fort Worth, TX.*
(No relationships reported)

PURPOSE: Jogging and walking are two common exercises in overweight people. However, the relationship between energy expenditure of jogging and walking in overweight people is still not clear. This paper probes into characteristics of energy expenditure and physiology of overweight adult women at the same speed of jogging and walking.

METHODS: Twenty six overweight and twenty five normal weight adult women (age: 22.0±1.6 years) participated in the study. The resting energy expenditure and the energy expenditure of overground walking and jogging were measured by Cortex portable gas metabolism system. The overground walking speed from low to high were 4.0km/h, 4.5km/h, 5.0km/h, 5.5km/h, 6.0km/h, 6.5km/h and 7.0km/h. The overground jogging speed were 6.0km/h, 7.0km/h and 8.0km/h. The duration of each speed was 6 minutes. Net energy expenditure of each speed was calculated as energy expenditure minus resting energy expenditure.

RESULTS: When the jogging speed over 7.0km/h (including 7.0km/h) and walking speed over 5.5km/h (including 5.5km/h), the net energy expenditure, energy expenditure and heart rate of overweight women were significantly higher than normal weight women (P<0.05). When walking speed was 6.0km/h, net energy expenditure (5.44±0.95 vs 6.51±1.65 kcal/min) and energy expenditure (6.49±0.91 vs 7.55±1.64 kcal/min) of overweight women were significantly lower than jogging at the speed of 6.0km/h (P<0.01). However, when walking speed was 7.0km/h, net energy expenditure (9.60±1.48 vs 8.69±1.57 kcal/min), energy expenditure (10.64±1.50 vs 9.73±1.56 kcal/min), heart rate (170±10 vs 158±14 BPM) and RPE (17±1 vs 13±2) of overweight women were significantly higher than jogging at the speed of 7.0km/h (P<0.05).

CONCLUSIONS: The differences of BMI will result in differentiations of energy consumption and physiological indexes of women when walking and jogging at a

certain speed. When speed reach and exceed 7.0km/h, walking will consume more energy than jogging. As far as the weight control of overweight people is concerned, the effect of walking at this speed is better than that of jogging.

3252 Board #157 June 2 3:30 PM - 5:00 PM

Comparisons Of Caloric Expenditure During- And Post- Treadmill Activity Vs. Racquetball In Apparently Healthy College-aged Adults

Stephen Hodgson Jr, Anna Kurilla, Katrina Von Arx, Brittany Luteyn, Jayden Dobbs, Saori Braun, Jeffrey Janot. *University of Wisconsin - Eau Claire, Eau Claire, WI.*
Email: hodgsonstephenjr@gmail.com
(No relationships reported)

PURPOSE: The purpose of this study was to examine the possibility that alternative modes of exercise, specifically racquetball, may provide similar caloric benefits as traditional aerobic physical activity guidelines defined by the American College of Sports Medicine. Alternative modes of physical activity can be used to counteract many common physical activity barriers. This study examined the caloric expenditure (Kcal) differences during and post treadmill activity in comparison to racquetball.

METHODS: Twenty-six university students, aged 18-22 years, participated in this study. All participants completed a 30-minute racquetball session and a 30-minute treadmill running session (at 40-60% heart rate reserve), each session followed by a 30-minute of post-exercise monitoring of oxygen consumption (VO₂) using a metabolic cart. Minute-by-minute VO₂ and respiratory exchange ratio were utilized to calculate the total Kcal over the 30-minute recovery period, during which participants were laying supine. To obtain Kcal during exercise, accelerometer connected to heart rate monitor was utilized. **RESULTS:** Out of 26 participants, 4 were excluded from the analyses due to equipment malfunctioning during testing, resulting in N = 22 (Male n=11, Female n = 11). A two-way (sex x modality) repeated measures ANOVA, using an alpha level of .05, indicated that there was a significant modality (treadmill vs. racquetball) effect on Kcal post activity, F(1,20) = 5.61, p = .028, meaning that Kcal was significantly higher post treadmill activity vs. post racquetball session. A two-way repeated measures ANOVA indicated that there was a significant modality (racquetball vs. treadmill) effect on Kcal during activity, F(1,20) = 5.08, p = .036. More specifically, Kcal expended during racquetball activity was significantly higher than Kcal expended during treadmill activity. Ultimately, a two-way repeated measures ANOVA indicated that modality was not a significant predictor of total (during- and post-exercise) Kcal expenditure, F(1,20) = 1.33, p = .262. **CONCLUSION:** These findings suggest that participating in a recreational activity, such as racquetball, will yield similar total energy expenditure benefits compared to simple aerobic running exercise among apparently healthy college-aged males and females.

Acute Metabolic Responses of Exercise with a Sauna Suit

Lexie B. Loring, Karrie M. Butler, Stephanie R. Sheley, Elyza E. Montano, Sadie N. Carrillo, Christina A. Buchanan, Lance C. Dalleck. *Western State Colorado University, Gunnison, CO.*
Email: lexie.loring@western.edu
(No relationships reported)

Purpose: The purpose of this study was to examine acute metabolic responses of exercise with a sauna suit (SS) under different exercise intensity and duration conditions. **Methods:** Twelve physically active men (age = 27.1±7.5 yrs, height = 175.4±6.3 cm, weight = 75.6±7.9 kg, maximal oxygen uptake - VO_{2max} = 38.6±7.8 mL•kg⁻¹•min⁻¹) completed four experimental trials on a cycle ergometer: 1) 30min moderate-intensity (MI) exercise (55-60% heart rate reserve-HRR) with SS, 2) 20min vigorous-intensity (VI) exercise (75-80% HRR) with SS, 3) 30min MI exercise (55-60% HRR) without a sauna suit (CON), and 4) 20min VI exercise (75-80% HRR) CON. Trials were separated by 24-96 hours and performed in randomized order. Exercise energy expenditure (EE), one hour excess post-exercise oxygen consumption (EPOC), and one hour post-exercise weight loss (PEWL) were measured for each trial. **Results:** There were significant differences (p<0.05) in exercise EE, one hour EPOC and one hour PEWL between SS and CON under both MI and VI conditions. MI results: exercise EE was greater with SS vs. CON (282.6±34.7 kcal vs. 247.8±40.2 kcal), one hour EPOC was greater with SS vs. CON (69.9±4.3 kcal vs. 45.2±3.0 kcal), and the SS condition resulted in greater change in one hour PEWL (0.52±0.14 kg vs. 0.37±0.15 kg). VI results: exercise EE was greater with SS vs. CON (204.7±24.2 kcal vs. 184.6±21.3 kcal), one hour EPOC was greater with SS vs. CON (87.7±7.0 kcal vs. 72.1±3.4 kcal), and the SS condition resulted in greater change in one hour PEWL (0.63±0.15 kg vs. 0.39±0.12 kg). **Conclusion:** Our findings support the feasibility of exercise training with a sauna suit—and the amplified exercise EE and EPOC—to contribute to long-term energy balance and thus improve cardiovascular health.

Impact of Alternative Footwear on Human Energy Expenditure

Teresa Wiczynski¹, Cody E. Morris¹, Harish Chander², Samuel J. Wilson³, Mark Loftin, FACSM³, Chip Wade⁴, John C. Garner⁵. ¹Western Kentucky University, Bowling Green, KY. ²Mississippi State University, Mississippi State, MS. ³University of Mississippi, University, MS. ⁴Auburn University, Auburn, AL. ⁵Troy University, Troy, AL. (Sponsor: Mark Loftin, FACSM)
Email: teresa.wiczynski406@topper.wku.edu
(No relationships reported)

PURPOSE: Use of alternative footwear options such as flip-flop style sandals and minimalist athletic shoes are becoming increasingly popular footwear choices. The purpose of the investigation was to analyze the energy expenditure and oxygen consumption requirements of walking at preferred pace while wearing flip-flops, slip-on style shoes, and minimalist athletic shoes.

METHODS: Eighteen healthy male adults participated in this study. In addition to an initial familiarization session, participants were tested in three different footwear conditions [thong-style flip-flops (FF), slip on shoes (CROC), and minimalist shoes (MIN)]. Then after a brief warm-up, participants walked a one-mile distance at their preferred pace. Immediately following completion of the one-mile walk, participants stood quietly on the treadmill for an additional period to assess excess post-exercise oxygen consumption (EPOC).

RESULTS: A repeated-measures ANOVA showed that the following variables did not show evidence of a significant differently value between conditions: preferred pace ($p = 0.392$), average oxygen consumption ($p = 0.804$), energy expenditure per mile ($p = 0.306$), or EPOC ($p = 0.088$). There was shown to be a significantly higher RER during exercise in CROC compared to MIN ($p = 0.031$) with no significant differences observed when comparing CROC to FF ($p = 0.106$) or FF to MIN ($p = 0.827$).

CONCLUSIONS: Based on the results of the current study, it appears that the alternative footwear selected for evaluation do not lead to a substantial alteration of walking pace or overall EE. However, the significant difference in RER suggesting a slightly elevated exercise intensity while wearing the CROC could perhaps be related to the softer sole, influencing overall mechanical efficiency.

Energy Expenditure of College Students

Danielle Ludlam, Sarah M. Henry, Ashby M. Williamson, G. William Lyerly, FACSM. Coastal Carolina University, Conway, SC.
Email: dnludlam@g.coastal.edu
(No relationships reported)

A great deal of research has made it evident that an increase in physical activity (PA) leads to a decrease in risk for developing health issues such as cardiovascular disease (CVD). While persons of all ages and skill levels can increase their PA, young adults often have the ability to focus on decreasing their risk of CVD early in life through avoiding sedentary lifestyles and meeting PA guidelines (PAG). The 2008 PAG suggest that a 70 kg person expends approximately 1198.75 kcals/week, which equates to 0.12 kcals/min, at 50% HR_{max} intensity to elicit health benefits. **PURPOSE:** To determine the PA level of college students as compared to PAG through monitoring their level of energy expenditure (EE) as kilocalories per minute (kcals/min) burned. **METHODS:** Twenty-three college students (20 y.o.; 69.93 kg) wore an Actigraph accelerometer on the waist during daily activities to determine EE. The following measurements were also collected: 1) medical history, 2) demographic info, 3) BP, 4) HR, 5) height, 6) weight. **RESULTS:** The average EE for one week was approximately 0.1641 kcals/min±0.11988. **CONCLUSION:** Our data indicate that college students met and exceeded the PAG of 0.12 kcals/min (1198.75 kcals/week) by 0.0441 kcals/min. This PAG is based off recommendations that one should exercise 150 min/week at moderate intensity. However, through calculating PAG as 0.12 kcals/min, we were able to apply recommendations that are based off activity level throughout an entire week at various intensities. Further research is warranted to better understand whether one should focus on intensity of exercise or expending the recommended number of kcals to elicit/maintain health benefits.

3256 Board #161 June 2 3:30 PM - 5:00 PM

Metabolic Demands of Stationary ElliptiGO Cycling Compared to Treadmill Running

Kyle Barnes, Alex McBride. Grand Valley State University, Allendale, MI. (Sponsor: Stephen Glass, FACSM)
Email: barnesk@gvsu.edu
(No relationships reported)

Trained runners often face injury due to the high impact nature of the sport and lower limb strain. When injury occurs, runners commonly substitute alternative low-impact exercises modes like cycling and swimming. While these modes promote cardiovascular fitness they do not mimic the biomechanical patterns of running. An alternate form of training, ElliptiGO cycling, combines the low-impact of elliptical training with the mechanical patterns of running. However, the metabolic demands of ElliptiGO cycling have not been investigated.

PURPOSE: To compare the metabolic demands of stationary ElliptiGO cycling with treadmill running. **METHODS:** In a randomized cross-over design, 17 trained runners (9 males; 8 females, age 21.4 ± 1.1 yr, body mass 60.8 ± 9.2 kg, height 1.70 ± 0.07 m, body fat 12.6 ± 5.9%) completed 5×3 min stages while either cycling on a stationary ElliptiGO bike or running on a treadmill during which heart (HR), rating of perceived exertion (RPE), and expired gases were collected using a metabolic analyzer during each exercise bout. Subjects increased one gear or 1 mph every 3 min during cycling or running respectively. Pedaling cadence was fixed at ~70 rpm using a metronome. Linear regression analyses were performed for each physiological variable and speed. Metabolic demand data for running and ElliptiGO were matched to determine equivalent running and cycling speeds. The other physiological measures were then matched with the corresponding running and ElliptiGO cycling speeds. **RESULTS:** For each testing intensity, metabolic demand (VO₂), HR, and V_E were significantly higher during running ($p < 0.05$), however the RPE for each intensity was similar ($p > 0.05$). The relationship between speed and VO₂ during running had a steeper slope compared to ElliptiGO. As a result, the ElliptiGO speed that was equivalent to the VO₂ of each running speed increased at a greater rate (4 mph run = 10.2 mph ElliptiGO, 7 mph = 17.1 mph, 10 mph = 24.1 mph). When matched for VO₂, the HR, V_E, and RPE were significantly higher for ElliptiGO compared to running. **CONCLUSION:** ElliptiGO cycling is a practical training device that will elicit a similar metabolic demand, but higher HR, V_E, and RPE compared to running at faster cycling speeds. Supported by the Student Summer Scholars program at Grand Valley State University.

Accounting For The 'Dehydration Factor' In The Athlete Biological Passport

Katherine Mitchell, Robert Kenefick, FACSM, Samuel Cheuvront, FACSM. USARIEM, Natick, MA. (Sponsor: Samuel N. Cheuvront, FACSM)
(No relationships reported)

The Athlete Biological Passport (ABP) was implemented by the World Anti-Doping Agency in 2008 to monitor elite athletes for banned substances. The potential for dehydration to bias the ABP by elevating parameters such as hemoglobin (Hb) and hematocrit (Hct) deserves careful attention before integration into detection models. **PURPOSE:** To examine biological variation in euhydrated Hb and Hct for comparison against changes observed in response to a standardized loss of total body water (~3-4% body mass) achieved using two distinct types of dehydration. **METHODS:** Ten participants (7M, 3F; 23 ± 4 years) completed three days of controlled euhydration (EUH) from which the within-subject biological variation (CVw) and analytical variation (CVa) were used to estimate a meaningful change (unidirectional 95% level). Two trials of controlled dehydration via sweating (HYP) and diuretic administration (DIUR) followed. **RESULTS:** The CVw and CVa for Hb and Hct were both ~2% and 0.5%, respectively. When properly summed [$RVCV = 2^{1.5} \times 1.65 \times (CVa^2 + CVw^2)^{0.5}$] they explain a relative increase of ~5% (0.7 Hb units and 2.0 Hct units) between any two successive values measured 24 hours apart. Participants achieved body mass losses of 3.13 ± 0.44% (HYP) and 3.70 ± 0.54% (DIUR). The change in Hb was 0.6 units (HYP) and 1.4 units (DIUR) ($P < 0.05$) vs EUH. The change in Hct was 2.1 units (HYP) and 4.2 units (DIUR) ($P < 0.05$) vs EUH. Only with the diuretic was the change in Hb and Hct (1.4, 4.2) well beyond expected values due to biological variation (0.7, 2.0). **CONCLUSION:** Dehydration by ~3-4% of body mass produced changes in Hb and Hct beyond day-to-day variation (> unidirectional 95% level) only when achieved using a diuretic. These findings have important implications for claims made against dehydration as a bias factor in the ABP and also provide important insight related to hydration testing in general. Funded by USAMRMC; author views not official US Army or DOD policy.

Nrf-2 Activation by Palm Fruit BioactivesShawn M. Talbott, FACSM¹, Cory Grand², Kevin L. Ohashi³, Joseph De Angelo³. ¹*EQQIL, Draper, UT*. ²*Wasatch Scientific Services, Salt Lake City, UT*. ³*Phenolaeis, Cambridge, MA*.**Reported Relationships:** S.M. Talbott: Consulting Fee; Scientific advisor to Phenolaeis.

PURPOSE: Overexposure to reactive oxygen species has been implicated in the pathogenesis of a wide range of chronic conditions, including cardiovascular disease, cancer, and the aging process (e.g. "free radical theory of aging"). While some early studies have shown the benefits of "direct" antioxidants (e.g. vitamins A, C, E) in reducing oxidative cellular damage, more recent evidence suggests that mega-doses of antioxidants (e.g. E, beta-carotene, resveratrol) may interfere with internal cellular protection pathways, disrupt redox balance, and suppress several important exercise-induced adaptations. In contrast, up-regulation of endogenous "indirect" antioxidant pathways has been proposed as a mechanism for optimizing redox balance. Activation of nuclear factor (erythroid-derived 2)-like 2 (Nrf2), a transcriptional regulator of phase II antioxidant enzymes, has been suggested as an important step in attenuating oxidative stress. A number of natural phytonutrients have been shown to activate Nrf2, including turmeric and green tea. Palm Fruit Bioactives (PFB), a standardized 5-polyphenol blend, has been shown to exhibit anti-hypertensive, anti-atherogenic, anti-diabetic, and chemo-preventive effects in animal models. The purpose of this study was to evaluate the effect of palm fruit bioactives (PFB) on activation of the Nrf2 pathway in cell culture as one potential mechanism of action for PFB's health effects. **METHODS:** AREc32 cells (MCF-7 cell line stably transfected with a vector containing firefly luciferase under the control of the Antioxidant Response Element, ARE) were cultured in RPMI 1640 culture medium with L-glutamine and supplemented with 10% fetal bovine serum and antibiotic/antimycotic. AREc32 cells were seeded at a density of 500 cells/well and exposed to PFB at varying concentrations from 0.125% to 20% for 6-24h. **RESULTS:** PFB increased cell viability at 6h (0.125% and 3.3%) and 24h (2% and 3.3%). At both time points, PFB increased Nrf2-activation expression over untreated controls by a factor of 9-20 fold (0.25% and 7.5% at 6h; 0.125% and 5% at 24h). **CONCLUSIONS:** These data demonstrate potent Nrf2-activation by PFB which may provide a potential mechanism of attenuating oxidative stress and explaining previously observed cardiovascular, metabolic, and cell-protection effects.

Effects Of Seaweed Supplementation On Oxidative Stress And Blood Glucose Regulation After Resistance Training In RatsChun-Tai Chen¹, Chi-Hong Lu¹, Chi Yang¹, Yu-You Wu¹, Ching-Hung Lin², Chien-Wen Hou¹. ¹*University of Taipei, Taipei, Taiwan*. ²*Yuan Ze University, Taoyuan, Taiwan*.

(No relationships reported)

PURPOSE: To investigate the effects of resistance training and supplement seaweed on oxidative stress and blood glucose regulation in rats.

METHODS: The five-week-old SD rats were randomly divided into four groups: C group (control group), S group (seaweed group), E group (exercise group) and ES group (exercise plus seaweed group). The rats in E group and ES group were trained with climbing resistance every two days, S group and ES group were given seaweed immediately after exercise. C group and E group were given placebo at the same time. After 10 weeks training, the ability of blood glucose regulation and oxidative stress of muscle would be test.

RESULTS: HOMA-IR of ES group were significantly higher than C group (C group $2.3 \pm 0.2 < ES$ group 3.8 ± 0.8). TBARS of E group were significantly higher than C group (E group $1.3 \pm 0.2 \text{ umole/g} > C$ group $1.0 \pm 0.05 \text{ umole/g}$), but ES group were significantly lower than E group (ES group $1.0 \pm 0.05 \text{ umole/g} < E$ group $1.3 \pm 0.2 \text{ umole/g}$). SOD of ES group and S group were significantly higher than C group (ES group $0.61 \pm 0.04 \text{ U/mg} > C$ group $0.47 \pm 0.05 \text{ U/mg}$, S group $0.60 \pm 0.04 \text{ U/mg} > C$ group $0.47 \pm 0.05 \text{ U/mg}$). Resistance training was significantly increased for GSH, but supplemental seaweed had no effect. While in the GSSG, supplementation of seaweed was significantly reduced.

CONCLUSIONS: Ten weeks of resistance training and supplementation of seaweed immediately after exercise may reduce oxidative stress, but reduce insulin sensitivity.

Flavanol-Rich Lychee Fruit Extract Prevents Diabetes-Induced Muscle Loss And Palmitate-Induced Myotube LossHung-Wen Liu¹, Sue-Joan Chang². ¹*National Taiwan Normal University, Taipei, Taiwan*. ²*National Cheng Kung University, Tainan, Taiwan*.

Email: hwliu@ntnu.edu.tw

(No relationships reported)

Diabetes-induced muscle loss is associated with stimulated the muscle RING-finger protein 1 (MuRF1), a muscle specific E3 ubiquitin ligase. Elevated lipid metabolites impair myogenesis. Flavanol-rich lychee fruit extract (FRLFE) exhibited anti-diabetic and -obesity properties which would be an alternative approach for maintaining muscle homeostasis. **PURPOSE:** The underlying mechanisms of FRLFE on maintaining muscle homeostasis was studied *in vivo* and *in vitro*. **METHODS:** Dietary (10 wk) FRLFE supplementation (200 mg/kg diet) on the skeletal muscle size and transcription factors such as NF- κ B and Foxo3a involved in regulation of MuRF1 were investigated in diabetic db/db mice (n=10/per group). The roles of FRLFE on cell cycle and senescent phenotype were investigated in palmitate-induced insulin resistance in C2C12 muscle cells. The statistical significance of the differences among the groups ($P < 0.05$) was determined by one-way ANOVA and following post hoc assessment by Student-Newman-Keuls Method. **RESULTS:** The average cross-sectional area was significantly increased by 1.6-fold after administration of FRLFE compared with non-treated db/db mice ($420 \mu\text{m}^2$). Prevention of muscle loss by FRLFE was associated with down regulation of MuRF1 mRNA expression (410% vs. 100%, $p < 0.05$). Decreased NF- κ B expression in the nuclear fraction was observed in FRLFE treated db/db mice compared with untreated mice (260% vs. 60%, $p < 0.05$). At transcriptional level, FRLFE abated ceramide-induced MuRF1 promoter activity (200% vs. 100%, $p < 0.05$). Restoration of SIRT1 expression (30% vs. 150%, $p < 0.05$) prevented Foxo3a nuclear localization in FRLFE treated db/db mice. A strong β -galactosidase staining positive signal was observed in the palmitate-treated myoblasts. For cell cycle analysis, significantly increased proportion of cells in G2-phase by palmitate was observed compared with group without palmitate treatment (28.9% vs. 18.3%). Weak β -galactosidase staining positive signals in accordance with decreased proportion of cells in G2-phase (21.7%) were observed in FRLFE-treated myoblasts. **CONCLUSION:** The efficacy of FRLFE on preserving skeletal muscle mass and myogenic process indicates that FRLFE acts as an effective supplement for diabetes and/or obesity-induced muscle atrophy.

No Adverse Effects of Matcha Green Tea Powder on Metabolic and Physiological Responses during RunningMark E. Willems, Julianne Doherty, Sam D. Blacker. *University of Chichester, Chichester, United Kingdom*.

Email: m.willems@chi.ac.uk

(No relationships reported)

Matcha is powder made from green tea leaves that had restricted light exposure to enhance composition. Consumption of the powder in Matcha green tea drinks ensures substantially higher intake of catechins and caffeine than normally brewed green tea. Green tea effects are commonly examined with epigallocatechin gallate (EGCG) or green tea extract with evidence to support enhanced fat oxidation and increased endurance performance. The metabolic and physiologic responses of short-duration intake of Matcha green tea powder during exercise are not known.

PURPOSE: To examine the metabolic and physiological responses of Matcha green tea powder during submaximal treadmill running. **METHODS:** Twelve male recreational runners (mean \pm SD, age: 31 ± 9 years, height: 185 ± 9 cm, body mass: 79 ± 11 kg, maximum oxygen uptake ($\dot{V}O_{2\text{max}}$): $55 \pm 6 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$) completed a 40-minute treadmill run at 55% of the running speed at $\dot{V}O_{2\text{max}}$, i.e. running at $10.0 \pm 0.8 \text{ km} \cdot \text{h}^{-1}$. In the Matcha condition, participants were supplemented with 3x3 capsules on the day before and 3 capsules one hour before exercise in a fasted state. Each capsule contains 77 mg total catechins of which 37.5 mg EGCG and 12 mg caffeine. Expired air, heart rate and rating of perceived exertion (RPE) were collected at 10-minute intervals and analysed with two-way repeated measures and Bonferroni *post hoc* testing. Significance was accepted at $p < 0.05$. **RESULTS:** There was no condition effect of Matcha green tea powder at any time point on minute ventilation, oxygen consumption, fat oxidation, carbohydrate oxidation, heart rate and RPE. For example, fat oxidation values and heart rates during 9-10 min, 19-20 min, 29-30 min and 39-40 min were 0.63 ± 0.18 , 0.65 ± 0.24 , 0.71 ± 0.17 , $0.80 \pm 0.24 \text{ g} \cdot \text{min}^{-1}$ and 0.63 ± 0.22 , 0.67 ± 0.26 , 0.67 ± 0.22 , $0.73 \pm 0.24 \text{ g} \cdot \text{min}^{-1}$, and 139 ± 13 , 145 ± 14 , 148 ± 14 , $150 \pm 14 \text{ beats} \cdot \text{min}^{-1}$ and 140 ± 13 , 144 ± 13 , 147 ± 13 , $150 \pm 13 \text{ beats} \cdot \text{min}^{-1}$, for the control and Matcha condition, respectively. **CONCLUSION:** Short-duration intake of Matcha green tea powder had no adverse effects on metabolic and physiological responses during submaximal

intensity running. Future studies should address whether there is an effect of long-duration intake of Matcha green tea on metabolic and physiological responses and exercise performance.

Matcha capsules were provided by OMGTEA Ltd, United Kingdom.

Beyond Ginseng And Echinacea: A Meta-analysis Of Herbal Supplement Use By Athletes

David S. Senchina, *Drake University, Des Moines, IA.*

Email: david.senchina@drake.edu

(No relationships reported)

Herbal supplements are noteworthy components of athletes' nutritional supplement regimens. Recent reviews have characterized use of herbal supplements vaguely, or ginseng and echinacea specifically, but neglected less common supplements such as ginkgo, spirulina, St. John's Wort, and others. **PURPOSE:** To determine the frequency of athletes' use of specific herbal supplements beyond ginseng and echinacea through a meta-analysis of previously published surveys. **METHODS:** Thirty-two studies (published between 1985 and 2016) that reported specific herbal supplement data were identified through a combination of systematic database searching and citations from previous works. Usage rates for specific herbs were tabulated and overall prevalence calculated. When available, demographic information including age, sex, sport, and athlete country-of-origin were also tabulated. **RESULTS:** 11,855 athletes were in the final data set. All-supplement usage averaged 58.7%. Average individual herbal supplement usages were: ginseng (9.6%), echinacea (9.6%), ephedra (3.8%), ginkgo (3.0%), garlic (2.8%), St. John's Wort (0.6%), and spirulina or blue-green algae (0.4%); others ($\leq 0.3\%$) included chamomile, ciwujia, yohimbe, flaxseed, green tea, arnica, evening primrose, guarana, kava kava, tribulus, goldenseal, kola nut, and peppermint. Several additional studies reported that athletes consumed various lesser-known herbal supplements including these and others (such as tea tree oil), but did not provide usage statistics. Multi- or poly-herbal supplements (2.0%) and "other" unspecified herbal supplements (4.9%) usage averages were also reported. Surveyed athletes were predominantly male (61.6%), from North America (40.3%), and college-aged (38.9%); most surveys sampled athletes from multiple sports. **CONCLUSION:** While ginseng and echinacea are (unsurprisingly) the herbal supplements most frequently consumed by athletes, over a dozen other herbal supplements are also consumed and warrant better attention in both athlete nutrition surveys and research. Certain athlete populations are underrepresented in the current literature, including females, those hailing from the southern hemisphere, non-college-aged athletes, and athletes with impairments.

Seaweed Supplement Harmed The Exercise Effect In Ovariectomy Rats

Ji-Hong Lu, Chun Tai Chen, Jian Liu, Yu You Wu, Chi Yang, Ching Hung Lin, Chien Wen Hou. *University of Taipei, Taipei, Taiwan.* (Sponsor: Chia Hua, Kuo, FACSM)

Email: campbell-fans@hotmail.com.tw

(No relationships reported)

Purpose

This study aimed to find out the effect on blood glucose regulation after 10 weeks resistance exercise of ovariectomized rats with seaweed supplementation.

Method

12-month-old Sprague Dawley female rats were subjected to bilateral ovariectomy and then were randomly divided into 3 groups: Control (C), Exercise (E), Exercise-Seaweed (ES). Resistance exercise started 2 weeks after the surgery and operated 5 days/week in E and ES group. In ES group, 50 mg/kg of seaweed gavage was given immediately after exercise. In C and E group, rats also receive the same volume of water gavage after exercise. Oral glucose tolerance test (OGTT) and serum insulin level was evaluated after 10 weeks of resistance training

Result

After 10 weeks of resistance training, ES had higher fasting and 60 min blood glucose compared to E. (Fasting glucose: $E 96.9 \pm 3.12 < ES 105.0 \pm 3.32$ mg/dl; 60min glucose: $E 141.4 \pm 6.39 < ES 161.7 \pm 9.51$ mg/dl. $p < 0.05$). E had lower fasting blood insulin level than C and ES. ($E 0.4 \pm 0.1 < C 0.8 \pm 0.2$; $ES 0.9 \pm 0.2$ ug/dl $p < 0.05$)

Conclusion

10 weeks of resistance exercise significantly improve the ability of blood sugar regulation on ovariectomized rats. However, if combined with seaweed supplementation, the benefits of exercise were eliminated.

Capsaicin Induces Metabolic Gene Expression in C2C12 Myotubes

Michele A. Johnson¹, Jamie K. Schnuck¹, Lacey M. Gould¹, Nicholas P. Gannon², Roger A. Vaughan¹. ¹*High Point University, High Point, NC.* ²*Medical College of Wisconsin, Milwaukee, WI.*

(No relationships reported)

PURPOSE: Capsaicinoids may possess thermic effects resulting in increased energy expenditure, leading some to consume concentrated capsaicin supplements for weight loss. Capsaicin has been shown to activate select molecular targets contributing to increased metabolism, however the effects of capsaicin on many molecular targets have yet to be determined. This study investigated the effects of capsaicin on metabolic gene expression in cultured skeletal muscle. **METHODS:** C2C12 myotubes were treated with either DMSO control or capsaicin at 0.25 μ M, 0.5 μ M, 1.0 μ M, or 2 μ M for 24 hours. Gene expression of several regulators of mitochondrial biogenesis and oxidative metabolism including peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1 α), nuclear respiratory factor 1 (NRF1), and mitochondrial transcription factor A (TFAM) were measured via qRT-PCR. Mitochondrial content was quantified via fluorescence which was confirmed visually using fluorescent microscopy. Cellular lipid content was determined by oil red o colorimetric staining. **RESULTS:** Gene expression experiments identified capsaicin at 0.5 μ M to be the most optimal concentration for inducing myotube mitochondrial biogenesis. Specifically, capsaicin at 0.5 μ M significantly elevated PGC-1 α (18.6 fold ± 14.5), NRF1 (4.6 fold ± 1.7), and TFAM (5.0 fold ± 2.3) gene expression following 24-hour treatment. Cells treated with capsaicin at 0.5 μ M also exhibited significantly greater mitochondrial staining (7.5% $\pm 4.5\%$). Moreover, capsaicin induced the expression of several related metabolic genes such as Forkhead Box O1 (Foxo1) and Sirtuin 3 (Sirt3). Lastly, despite unaltered peroxisome proliferator-activated receptor gamma (PPAR γ) expression, capsaicin-treated cells exhibited significantly reduced lipid content suggesting lipid oxidation may be enhanced following capsaicin treatment. **CONCLUSION:** Capsaicin appears to stimulate several genes which govern mitochondrial biogenesis and cellular energetics. These findings suggest capsaicin may provide metabolic benefits, however, these data require verification at the protein and functional level.

The Effect Of Chlorella Supplementation On Exercise Performance And Inflammation-related Blood Cells After Dehydration.

Chia-Pei Lin¹, Chung-Fu Chi², Ming-Fen Xu¹, Szu-Haien Yu³. ¹*University of Taipei, Taipei, Taiwan.* ²*Taipei Medical University, Taipei, Taiwan.* ³*National Iilan University, Taipei, Taiwan.*

Email: r.roseice@gmail.com

(No relationships reported)

PURPOSE: The purpose of this present study was to investigate the effect of chlorella supplementation on aerobic performance and complete blood count (CBC) after dehydration.

METHODS: Twelve male college students with exercise habit were recruited in this double-blind, crossover designed study. All subjects were divided into control and Chlorella groups. All subjects performed an acute treadmill exercise at 40% VO₂max in 35°C and 70% relative humidity environment until reaching dehydration to 3% body weight. Subjects of Control and Chlorella were given 130 ml of placebo or chlorella drink respectively immediately after dehydration, and then all subjects were rehydrated with sports drink (6% sucrose and 0.04% NaCl), 1.5 times amount of weight loss within 2 hours after dehydration. Blood samples were obtained before, 1h to 4h, 24h, and 48h after dehydration. The maximal aerobic exercise capacity was determined before, 4h, 24h and 48h after dehydration. White blood cells, neutrophils, lymphocytes and blood glucose levels were measured from blood samples.

RESULTS: The results showed that dehydration caused a significant reduction in exercise time and a significant increase in white blood cells and neutrophils numbers. The exercise time of Chlorella group was significantly higher than that of control group 4 hours after dehydration. White blood cells and neutrophils numbers in Chlorella group were significantly lower than that of the control group within 2 to 4 hours after dehydration. However, blood glucose level and the lymphocytes number showed no significant differences between control and Chlorella groups.

CONCLUSIONS: Our results concluded that Chlorella supplementation can improve aerobic exercise capacity and reduce Inflammation after dehydration.

High Intensity Intermittent Training And Chlorella Intake Enhance Muscle Glycolytic And Oxidative Metabolism In Rats.

Naoki Horii¹, Natsuki Hasegawa¹, Shumpei Fujie¹, Masataka Uchida¹, Eri Miyamoto-Mikami², Takeshi Hashimoto, FACSM¹, Izumi Tabata, FACSM¹, Motoyuki Iemitsu¹. ¹*Ritsumeikan University, Kusatsu, Japan.* ²*National Institute of Fitness and Sports in Kanoya, Kanoya, Japan.* (Sponsor: Izumi Tabata, FACSM)

(No relationships reported)

Chronic chlorella intake enhances aerobic exercise capacities, i.e. exercise tolerance. High intensity intermittent exercise (HIIE) training enhances aerobic and anaerobic exercise capacities via elevation of muscle glycolytic and oxidative metabolism. However, the additive effects of combination of HIIE training and chlorella intake on exercise performance and muscle glycolytic and oxidative metabolism remain unclear. **PURPOSE:** The purpose of this study was to investigate the effect of chronic chlorella intake alone or in combination with HIIE training on exercise performance and muscle glycolytic and oxidative metabolism in rats. **METHODS:** Male 12-week-old Sprague-Dawley rats were randomly assigned to the four groups; sedentary control, chlorella intake (0.5% chlorella powder in normal feed), HIIE training, and combination of HIIE training and chlorella intake for 6 weeks (n = 10 each group). HIIE training comprised 14 repeats of a 20-s swimming session with a 10-s pause between sessions, while bearing a weight equivalent to 16% of body weight, 4 days/week. Exercise performance was tested after the interventions by measuring the maximal number of HIIE sessions that could be completed. **RESULTS:** Chlorella intake and HIIE training significantly increased the maximal number of HIIE, and enhanced the expression of monocarboxylate transporter (MCT)1, MCT4, and peroxisome proliferator activated receptor γ coactivator-1 α concomitantly with the activities of lactate dehydrogenase (LDH), phosphofructokinase, citrate synthase (CS), and cytochrome oxidase (COX) in the red region of the gastrocnemius muscle (p<0.05). Furthermore, the combination further augmented the increased exercise performance and the enhanced expressions and activities (p<0.05). By contrast, in the white region of the gastrocnemius muscle, MCT1 expression and LDH, CS, and COX activities did not change. **CONCLUSIONS:** These results showed that compared to only chlorella intake and only HIIE training, chlorella intake combined with HIIE training has a more pronounced effect on exercise performance and muscle glycolytic and oxidative metabolism, in particular lactate metabolism.

Effects of Energy Drink on Metabolic Parameters and Exercise Performance Following Basketball Game Simulation

Soon-Mi Choi¹, Kristin Russell¹, Frank B. Wyatt¹, Deok Su Yoo². ¹*Midwestern State University, Wichita Falls, TX.* ²*Kyung Hee University, Yongin, Korea, Republic of.*
Email: soonmi.choi@mwsu.edu

(No relationships reported)

PURPOSE: Intermittent sports are characterized by intermittent bursts of high-intensity exercise and are dependent upon a combination of anaerobic and aerobic energy systems, both of which rely on carbohydrate as an important fuel source. A potential reason for athletes to use energy drinks is due to the conception the energy drinks would promote improvement of performance and this practice has been common among athletes in recent history. This study examined the effects of energy drink on metabolic parameters and exercise performance following basketball game simulation (BGS).

METHODS: Six female college basketball players, aged 21.5 \pm 1.9 yrs, volunteered for this study which was designed by a randomized counterbalanced experimental design with repeated measures under two different trials: energy drink (ED, extrication glucose 20 g from corn, citrus juice 2% from pure Calamansi fruit, branched chain amino acid 600 mg and taurine 600 mg) and placebo (PO, aspartame) with a double-blind experiment. The drink, either ED or PO is provided for the participants right after BGS, and the participants has a 20 min recovery period (POST). The BGS consisted of major basketball movements such as walking, jogging, running, low and high shuffles, dribble, jump, sprint, and pass which are all performed during 20 min. Height, body weight, blood pressure, and heart rate, blood glucose (BG), blood lactate (BL) were measured at a baseline (BASE). Vertical jump, 10 m \times 5 shuttle run and Wingate tests were performed prior to BGS and POST to evaluate muscular power, agility, and anaerobic power, respectively. BG and BL were measured at right after SBC (PRE) and POST. Data were analyzed by two-way ANOVA with repeated measures.

RESULTS: BG decreased significantly in PO (PRE: 106.5 \pm 13.2 mg \cdot dL⁻¹, POST: 91 \pm 5.1 mg \cdot dL⁻¹, p=.018) and BL decreased significantly in the both ED (PRE: 5.5 \pm 1.8 mmol \cdot L⁻¹, POST: 3.1 \pm 1.4 mmol \cdot L⁻¹, p=.0001) and PO (PRE: 5.0 \pm 0.9 mmol \cdot L⁻¹,

POST: 3.5 \pm 0.8 mmol \cdot L⁻¹, p=.000). Vertical jump (BASE: 58.0 \pm 7.3 cm, POST: 55.5 \pm 8.2 cm, p=.012) and anaerobic work (BASE: 12.3 \pm 1.3 KJ, POST: 11.4 \pm 1.5 KJ, p=.035) decreased significantly in PO.

CONCLUSIONS: The results indicate that energy drink may replenish a deficiency of fuel source and promote improvement of muscular and anaerobic power during recovery period.

3268 Board #173 June 2 2:00 PM - 3:30 PM

Seven Days Of Mushroom Blend Supplementation Improve Measures Of Aerobic And Anaerobic Performance

Wesley D. Dudgeon, D. David Thomas, William J. Dauch, Michelle M. McLeod, Timothy P. Scheett. *College of Charleston, Charleston, SC.*
Email: dudgeonw@cofc.edu

(No relationships reported)

PURPOSE: The purpose of this study was to determine the effects of one week of mushroom blend supplementation (PeakO2, Compound Solutions, USA) on maximal oxygen uptake, peak power output, time to fatigue, and submaximal aerobic economy in apparently healthy young adults.

METHODS: Forty recreationally active men and women volunteered to participate, were randomized into one of two groups, and completed the testing protocol. At baseline each participant completed a maximal oxygen consumption (VO₂max) test, which included a 5 minute economy state from minutes 3-8 along with a Wingate cycle ergometer test (peak power) at least 24 hrs later. The treatment group (T, n=23, mean \pm standard deviation, Age = 23.5 \pm 5.2 yrs, Height = 172.9 \pm 8.8 cm, Body Mass = 72.4 \pm 12.1 kg) consumed 12.0 g /day of mushroom blend (PeakO2) along with 12.0 g of Gatorade powder for one week. The control group (C, n=17, Age = 22.5 \pm 4.6 yrs, Height = 172.4 \pm 8.4 cm, Body Mass = 72.3 \pm 11.8 kg) consumed placebo (whole wheat flour) and Gatorade powder in identical fashion.

RESULTS: There were no differences between groups in any variables at baseline. Analysis was conducted stratifying each group by VO₂max at baseline, in which the top 50% of each group was compared to the bottom 50% (Treatment top, TT, Treatment bottom, TB, Control top, CT, Control bottom, CB). TB increased VO₂max significantly (1.95 \pm 2.76 ml \cdot kg⁻¹ \cdot min⁻¹, p = 0.02) while TT, CT, and CB did not change significantly. PPO did not change significantly in any group, however; a trend (p = 0.059) for increased PPO in TB by was observed. Submaximal HR was lower (3.5 \pm 18.5 bpm, p=.0167) in TT, but these changes were not different from changes in TB, CT, CB. TTF increased significantly (p < 0.05) in both TT and CT but changes between groups were not significant.

CONCLUSIONS: Seven days of supplementation with 12.0 g/day of PeakO2 may improve aerobic and anaerobic power output in less aerobically fit, healthy individuals. Those higher fit, apparently healthy individuals may see an improvement (e.g. lower HR) in economy during submaximal aerobic exercise.

3269 Board #174 June 2 2:00 PM - 3:30 PM

Increased Time to Fatigue Following Twenty-Eight Days of Mushroom Blend Supplementation

Dennison D. Thomas, Wesley D. Dudgeon, William J. Dauch, Timothy P. Scheett. *College of Charleston, Charleston, SC.*

(No relationships reported)

PURPOSE: There is evidence to suggest a commercially available, Cordyceps militaris-containing mushroom blend supplement (Peak O2, Compound Solutions, USA) improves tolerance to high-intensity exercise. However, the optimal dosing strategy remains unclear. Therefore, the purpose of the present study was to determine the effects of Peak O2 on indices of maximal and submaximal aerobic performance following 28 days of low-dose (1.0 g/day) supplementation in apparently healthy young adults.

METHODS: Twenty-one individuals (Mean \pm standard deviation, Age = 23.0 \pm 3.2 yrs, Height = 169.7 \pm 6.4 cm, Body Mass = 70.3 \pm 12.9 kg) participated in this randomized, blinded, placebo-controlled study. The treatment group (T, n=11) was given 1.0 g/day mushroom blend while the control group (C, n=11) received 1.0 g/day of color-matched wheat flour as placebo for 28 days. A graded maximal cycle ergometer test was used to evaluate maximal oxygen consumption (VO₂max), time to fatigue (TTF), two-minute heart rate recovery following exhaustion (HRR), submaximal oxygen consumption (VO₂) and blood lactate (BL) following 28 days of supplementation.

RESULTS: Dependent measures t-tests were used to evaluate changes within groups. TTF increased by 56.7 \pm 80.4 sec (p = 0.04) in T while there was no change in C (-2.1 \pm 31.3 sec, p = 0.42). VO₂max increased in both groups (M, 1.9 \pm 2.6 ml \cdot kg⁻¹ \cdot min⁻¹, p < 0.05; C, 1.0 \pm 1.6 ml \cdot kg⁻¹ \cdot min⁻¹, p < 0.05). HRR, VO₂ and BL at submaximal workload showed no change in either group from pre to post.

CONCLUSIONS: Twenty-eight days of supplementation with a mushroom blend (1.0 g/day) may increase TTF in young, recreationally active adults.

The Effect Of Blackcurrant Polyphenols On Recovery And Performance In Elite Endurance Athletes In Preparation For The World Championships

Nathan A. Lewis¹, Richard Burden¹, Georgie Bruinvels², James Cheeseman¹, Stuart Pickering¹, Chris Price¹, Kevin Currell¹, Jan Bartu³, Glyn Howatson, FACSM⁴, Charles R. Pedlar⁵. ¹English Institute of Sport, Bath, United Kingdom. ²St Mary's University, London, United Kingdom. ³British Modern Pentathlon, Bath, United Kingdom. ⁴Northumbria University, Newcastle, United Kingdom. ⁵Massachusetts General Hospital, Boston, MA.

Email: nathan.lewis@eis2win.co.uk

(No relationships reported)

Strategies that enable athletes to tolerate a higher training load may be advantageous for athlete health and performance.

PURPOSE: To examine the effects of New Zealand blackcurrants polyphenols (NZBK) on recovery and physical performance in elite athletes during a period of intensified training.

METHODS: Nine male modern pentathletes were tested at baseline (T1), after 7 days of receiving a placebo (P; T2) and after 7 days of receiving a blackcurrant supplement (NZBK; T3). Training volume was 30% higher during the second week. The test battery included a counter movement jump (CMJ) a running test (4 x 800 m), a mood state questionnaire (Recovery-Cue), and an extensive panel of blood tests including haematology and biochemistry. CMJ, lactate, a biomarker of oxidative damage (FORT) and anti-oxidant defense (FORD) were measured at rest and immediately before and after the 4 x 800 m run. A general linear model, with Tukey's post-hoc test for pairwise comparisons was used to determine differences between conditions, with Cohen's effect sizes (*d*) to calculate the magnitude of the standardised difference in means where significant; reported as 0.2 (small), 0.5 (moderate), 0.8 (large), and 1.3 (very large). Data are presented as mean ± SD. **RESULTS:** No effects were seen for P or NZBK on hormonal, haematological biochemistry markers, mood state, or running performance (*p*>0.05). NZBK reduced inflammation in comparison to P (HS-CRP 0.8±0.3 mg·L⁻¹ at T3 vs. 1.3±0.4 mg·L⁻¹ at T2, *p*=0.024, *d*=1.41), despite the increased training volume. There was a trend and effect for NZBK on reducing FORT (1.7±0.31 mmol·L⁻¹ at T1 vs. 1.62±0.31 mmol·L⁻¹ at T2 vs. 1.50±0.25 mmol·L⁻¹ at T3; *p*=0.063) and FORD (1.53±0.1 mmol·L⁻¹ at T1 vs. 1.54±0.16 mmol·L⁻¹ at T2 vs. 1.34±0.18 mmol·L⁻¹ at T3; *p*=0.015, *d*=1.17). Of interest, oxidative damage (FORT) correlated with testosterone, cortisol, CMJ and mood state (*p*<0.05).

CONCLUSIONS: NZBK reduces inflammation and oxidative stress in the presence of an increased training volume, with no effects on performance. Furthermore, the monitoring of oxidative damage in endurance athletes may be effective for tracking fatigue and well-being given the relationship with measures of recovery (e.g. hormones, CMJ and mood state).

The Effects Of Cissus Quadrangularis On Body Composition And Blood Lipids

Eric E. Noreen, Cara E. Pietrolongo, David S. Gilmore.
 Gettysburg College, Gettysburg, PA.

Email: enoreen@gettysburg.edu

(No relationships reported)

PURPOSE: The purpose of this study was to determine the effects of 6 wks of supplementation with *Cissus Quadrangularis* (CQ) on body composition and blood lipids in healthy college aged adults. **METHODS:** A total of 27 healthy college aged adults (13 males, 14 females, 21.0±0.6 y; mean±SD) completed this study. All testing was done first thing in the morning following an overnight fast. Baseline body composition was assessed by whole body densitometry using air displacement plethysmography, and blood lipids and glucose were assessed using whole blood obtained via finger puncture. Following baseline testing, subjects were randomly assigned in a double blind manner into one of two groups: 3.2 g/d of CQ; or 3.2 g/d of a maltodextrin placebo (PL). Subjects consumed half of the daily dose in the morning and half in the evening on an empty stomach. All testing was repeated following 6 wks of treatment. Pre to post differences were analyzed using a treatment by time repeated measures ANOVA. **RESULTS:** Compared to the PL group, there was a significant increase in fat free mass following treatment with CQ (CQ= 0.3±1.2 kg, PL= -0.6±0.9 kg, *p*=0.03), a significant decrease in fat mass (CQ= -0.7±1.2 kg, PL= 0.8±1.4 kg, *p*=0.005), a significant decrease in body fat percentage (CQ= -0.7±1.4 % body fat, PL= 1.1±1.8 % body fat, *p*=0.006), and a significant increase in HDL (CQ= 0.01±0.18 mmol/L, PL= -0.20±0.2 mmol/L, *p*=0.009). No significant differences were observed for body mass (CQ= -0.4±1.2 kg, PL= 0.0±1.5 kg, *p*=0.41), total cholesterol (CQ= -0.11±0.42 mmol/L, PL= -0.23±0.29 mmol/L, *p*=0.39), LDL (CQ= -0.12±0.39 mmol/L, PL= -0.08±0.35 mmol/L, *p*=0.93), glucose (CQ= -0.06±0.46 mmol/L, PL= 0.14±0.45 mmol/L, *p*=0.28) or triglycerides (CQ= -0.09±0.61 mmol/L, PL= 0.22±0.30 mmol/L, *p*=0.10). **CONCLUSION:** 6wk of supplementation with CQ prevented

the drop in HDL that was seen in the PL group, with no other changes observed for blood lipids or glucose. CQ significantly increased lean mass and decreased fat mass, resulting in a significant decrease in body fat percentage.

Previous studies examining the effects of short-term tart cherry (TC) ingestion are primarily limited to inflammatory markers and markers of oxidative stress. Short-term ingestion of nitrate-rich supplements have shown improvements in exercise performance. **PURPOSE:** The primary aim of the study was to determine if short-term TC concentrate ingestion would enhance exercise performance via increased serum nitrate levels, and subsequent increased muscle oxygenation (SmO₂). **METHODS:** Healthy college-age males were randomly assigned to a TC supplement treatment (*n*=18) or a placebo treatment (PL) (*n*=12). Peak VO₂ and baseline measures were obtained. 48 hours later, participants returned to the lab following an overnight fast. The TC or PL supplement was provided and blood was drawn from the cubital vein 30 minutes, 1 hour, and 2 hours after supplement consumption. Subsequently, participants were given additional supplements to consume over the next 6 days. Following supplementation, participants cycled at a power output achieved at 60% of VO₂ peak for a maximum of 60 minutes or until exhaustion. Near-Infrared Spectroscopy sensors were placed on the vastus lateralis of each leg. Serum was analyzed for total nitrate levels via colorimetric assay. All samples were analyzed in duplicate. Results are presented as mean ± SEM. **RESULTS:** A repeated measures ANOVA revealed blood nitrate (µM/L) levels at 30 minutes (TC = 13.01 ± 1.80, PL = 10.78 ± 0.53) 1 hour (TC = 11.70 ± 0.66, PL = 11.00 ± 0.64) and 2 hours (TC = 9.25 ± 1.79, PL = 10.07 ± 0.77) were not significant for treatment, (*F* = 0.14, *p* = 0.71) time, (*F* = 1.89, *p* = 0.18) or treatment by time interaction (*F* = 0.75, *p* = 0.49). One way ANOVA revealed SmO₂ in the left leg (TC = 0.69 ± 0.05, PL = 0.82 ± 0.06; *F* = 2.68, *p* = 0.12) and right leg (TC = 0.65 ± 0.04, PL = 0.78 ± 0.11; *F* = 1.94, *p* = 0.18) were not significantly different between groups. An independent *t*-test revealed no significant differences for time (min) to exhaustion between groups (TC = 39.11 ± 5.66, PL = 42.94 ± 6.06; *t* = 0.46, *p* = 0.65). **CONCLUSIONS:** TC concentrate ingestion does not acutely increase blood nitrate levels. Furthermore, short-term TC ingestion does not increase muscle oxygenation during cycling exercise nor does it improve exercise performance, likely due to an absence of change in blood nitrate levels.

Effects Of Aquarobic Exercise And Burdock Extract On Blood Lipids And Vascular Compliance In Elderly Women

Min-Seong Ha¹, Do-Yeon Kim¹, Jong-Won Kim², Ji-Hyeon Kim¹, Ji-Hoon Kim¹, Su-Jin Hyun¹, Jung-Sook Kim¹, Su-Han Koh¹. ¹Pusan National University, Busan, Korea, Republic of. ²Busan National University of Education, Busan, Korea, Republic of.

(No relationships reported)

The elderly's health issues are often complex and tend to lead to chronic diseases; such issues can be due to a fitness decline resulting from a lack of physical activities. **PURPOSE:** The present study aims to determine the effects of aquarobic exercise and burdock intake on blood lipid profiles and vascular compliance in elderly women, by implementing the 16-week program. **METHODS:** Thirty eight healthy elderly female volunteer subjects aged 75.27 ± 4.32 years comprised the control group (*n*=8), aquarobic exercise group (*n*=10), aquarobic exercise and burdock intake combination group (*n*=10), and burdock intake group (*n*=10). This intervention trial was designed to compare pre-and post-exercise intervention variables. Changes from baseline to the end of the intervention were determined by a paired *t*-test and one-way analysis of variance (ANOVA). The variables of body composition, serum blood lipids, and vascular elasticity were measured in all participants before and after the 16-week study. **RESULTS:** TC(176.45 ± 20.61 vs. 189.18 ± 24.28 mg/dl), TG(112.45 ± 38.73 vs. 127.27 ± 48.19 mg/dl), LDL-C(145.83 ± 30.03 vs. 152.32 ± 30.04 mg/dl), glucose(94.00 ± 16.25 vs. 93.18 ± 12.18 mg/dl), and insulin(7.77 ± 3.77 vs. 7.03 ± 5.09 uU/mL) decreased significantly in the aquarobic exercise group and aquarobic exercise and burdock intake combination group(*p*< 0.05). However, no statistically significant changes were found within or between groups in high-density lipoprotein cholesterol and HOMA-IR. No statistically significant changes were found within or between groups in pulse wave velocity before and after participation in the 16-week aquarobics exercise program and /or burdock intake program. **CONCLUSIONS:** The findings of the present study discussed so far suggest that aquarobic exercise and burdock extract

intake had positive effects on risk factors of cardiovascular diseases in elderly women. It is likely that aquarobic exercise prevents and improves cardiovascular disease, and that burdock acts as a supplement against cardiovascular diseases.

No Effect of Acute Beetroot Juice Supplementation on Moderate and Vigorous Intensity Aerobic Exercise

Ryan Fiddler, Nicole Lindel. *SUNY-Cortland, Cortland, NY.*
Email: ryan.fiddler@cortland.edu
(No relationships reported)

Nitric oxide (NO) plays a critical role in regulating blood flow to skeletal muscle. NO production in humans is 1) oxygen-dependent via NO-synthases that convert L-arginine to NO and 2) oxygen-independent via the nitrate-nitrite-NO pathway. The latter pathway is largely dependent on the intake of nitrate-rich foods, such as beetroot and beetroot juice supplements (BR). Consumption of BR has been shown to lower resting blood pressure and the volume of oxygen (VO₂) required to perform submaximal aerobic exercise. **Purpose:** The purpose of the present study was to investigate the acute effect of a low dose of BR compared to placebo (PL) during moderate and vigorous intensity aerobic exercise. **Methods:** Ten female division-3 collegiate club-level volleyball players (mean ± SD: age = 19.3 ± 1.3 yr, VO_{2peak} = 37.4 ± 3.3 ml·kg⁻¹·min⁻¹) completed three exercise trials consisting of an initial graded test to exhaustion and two performance trials on a motorized treadmill. For the performance trials, participants consumed either 60 mL of BR or PL, three hours prior to five minutes of walking/jogging at 45%, 65%, and 85% of volume of oxygen uptake reserve (VO_{2R}). **Results:** Separate two-way repeated measures ANOVAs were run to determine the effect of treatment (BR or PL) and exercise intensity (45%, 65%, and 85% VO_{2R}) on VO₂, heart rate (HR), and rating of perceived exertion (RPE). Paired samples t-tests were run to compare differences between resting systolic (SBP) and diastolic blood pressure (DBP) between treatments. All data are reported mean ± standard deviation with statistical significance accepted at p < 0.05. There were no statistically significant interactions between treatment and exercise intensity for VO₂, HR, or RPE. The main effect of treatment was not statistically significantly different for VO₂ (BR: 19.9 ± 6.6 vs. PL: 20.4 ± 6.5 ml·kg⁻¹·min⁻¹; p = .360), HR (BR: 131.3 ± 25.8 vs. PL: 135.4 ± 25.3 beats·min⁻¹; p = .172), or RPE (BR: 9.8 ± 2.2 vs. PL: 9.9 ± 2.4; p = .504). There were no statistically significant differences in resting SBP (BR: 110.6 ± 6.8 vs. PL: 112.7 ± 8.0; p = .166) or DBP (BR: 70.8 ± 5.5 vs. PL: 73.3 ± 6.6; p = .275) between treatments. **Conclusions:** These results suggest that a low dose of BR taken three hours prior to moderate and vigorous intensity aerobic exercise has no effect on VO₂, HR, RPE, or resting SBP and DBP.

Email: popebs@email.sc.edu
(No relationships reported)

PURPOSE: Transient Receptor Potential (TRP) channel activation in the mouth, esophagus and stomach after ingestion of spicy food extracts can have direct effects on central nervous system (CNS) function that have been linked to increased maximal power output and decreased muscle cramps. However, no studies have evaluated the effects of consuming TRP agonists on exercise performance. **METHODS:** This "proof of concept" study was designed to test the effects of a spice-TRP channel activator drink (1.7 fl oz with organic spice extracts, known TRPV1 and TRPA1 agonists; STA) on intermittent high-intensity cycling (IHI) using a randomized, double-blinded, placebo-controlled (PLA), crossover design in 20 healthy, active, college-aged men (n=10) and women (n=10). Subjects performed 2 trials (STA and PLA), each trial consisting of a 30-s maximal sprint (MS), 10-min rest, 45-min IHI (60% VO_{2max} ride with 1-min 100% VO_{2max} sprints every 5 min), 15-min rest, and a 10-min time trial (TT). Drinks were given before MS and TT. Performance measures included power output during MS (5-s intervals, mean, total), and distance covered during TT. Leg muscle pain (pain), heart rate, mean arterial pressure, core body temperature, profile of mood state (mood), plasma glucose, IL-6, and IL-10 were also measured at multiple times during exercise and rest. Data were analyzed via paired t-tests and 2-way repeated-measures ANOVA. **RESULTS:** No significant differences (p<0.05) were found between STA and PLA for any of the variables. However, there was a consistent trend toward benefits of STA, including increased muscular power output (5s intervals, mean, total, p=0.09), increased TT distance (13 of 19 subjects, p=0.20), reduced pain (p=0.17), and enhanced mood (p=0.20); all except TT produced moderate-to-large

effect sizes (Cohen's d and partial Eta²). Meanwhile, no treatment differences were observed for cardiovascular, metabolic, and inflammatory measures. **CONCLUSION:** Results of this "proof of concept" study support further research on the CNS benefits of consuming natural spice-derived TRPV1 and TRPA1 agonists as a novel intervention to improve performance during intermittent high-intensity exercise, with no apparent adverse side effects. Supported by Flex Pharma, Inc.

Effect Of A Nutraceutical Product On Energy, Fatigue, And Perceived Exertion In Healthy Active Adults

Marcus W. Kilpatrick, FACSM¹, Danielle K. Williams¹, Priscila P. Lamadrid¹, Larry H. Collins¹, Paula C. Bickford¹, Cyndy D. Sanberg². ¹University of South Florida, Tampa, FL. ²Natura Therapeutics, Tampa, FL.
Email: mkilpatrick@usf.edu
(No relationships reported)

PURPOSE: Evaluate the effectiveness of a commercially available nutraceutical product on levels of exercise-related energy, fatigue, and exertion before and after 4 weeks of supplementation. Primary ingredients within the product include a proprietary blend of blueberry extract, green tea extract, L-carnosine, and Vitamin D3 (NT-020) and rhodiola rosea, a plant that purports to boost energy. **METHODS:** Twenty-seven participants (12 female, 15male, mean BMI = 23) completed baseline assessment of aerobic fitness (mean VO₂ peak = 40 mL x kg⁻¹ x min⁻¹) before being randomized into a placebo or supplement condition for four weeks. All participants were involved in regular physical activity three or more days per week. Assessment of energy, fatigue, and perceived exertion responses during and after moderately intense cycle ergometry exercise was conducted before and after the 4-week ingestion period during which participants were instructed to maintain existing exercise activities. **RESULTS:** Data were analyzed by way of repeated measures ANOVA and dependent t-tests to determine the presence of significant differences across time and between the supplement and placebo conditions. Participants receiving the supplement reported: greater levels of energy and lower levels of fatigue during the initial moments after completing the exercise trial (p < 0.05), greater levels of energy at the midpoint of the exercise trial (p < 0.05) but not at the end of the exercise session (p > 0.05), and lower perceived exertion at four of the six measurement points during exercise (p < 0.05). No differences were observed from pre to post intervention within the placebo condition (p > 0.05). **CONCLUSIONS:** Findings indicate that a commercially available supplement marketed to boost energy and reduce fatigue can deliver the purported benefits at least in part. Related findings that supplementation for a 4-week period can allow for equal work at a lower rating of perceived exertion provides further, though limited support that this product may have efficacy.

Betalain-Rich Concentrate Supplementation Improves Exercise Performance and Recovery in Competitive Triathletes

Cristhian F. Montenegro, David A. Kwong, Gretchen Casazza, Brian A. Davis, FACSM. *University of California, Davis, Davis, CA.*
Email: cmontenegro@ucdavis.edu
Reported Relationships: C.F. Montenegro: Salary; VDF FutureCeuticals, Incorporated.

INTRODUCTION: Beetroot juice has been shown to have ergogenic effects on endurance exercise due to its high nitrate concentration, which increases mitochondrial coupling and blood flow. Another possible reason for the ergogenic effects of beetroot could be the abundance of betalains, which have been shown to have anti-oxidant and anti-inflammatory properties at rest, and could therefore be responsible for part of the ergogenic effects of beetroot during exercise.

PURPOSE: We aimed to determine the effects of a betalain-rich concentrate (BRC) of beetroots, containing no sugars or nitrates, on exercise performance and recovery. **METHODS:** Twenty-two (9 men and 13 women) triathletes (38 ± 11 yrs) completed two double-blind, cross-over, randomized trials (BRC and placebo) starting 7 days apart. Each trial was preceded by 6 days of supplementation with 100 mg·d⁻¹ of BRC or placebo. On the 7th day of supplementation, exercise trials commenced 120 min after ingestion of 50mg BRC or placebo and consisted of 40 min of cycling (75±5 % VO_{2max}) followed by a 10-km running time trial (TT). Subjects returned 24 h later to complete a 5-km running TT to assess recovery. **RESULTS:** 10-km TT duration (49.5±8.9 versus 50.8±10.3 min, p=0.03) was faster with the BRC treatment. Despite running faster, average heart rate and ratings of perceived exertion were not different between treatments. 5-km TT duration (23.2±4.4 versus 23.9±4.7 min, p=0.003), 24 h after the 10-km TT, was faster in 17 of the 22 subjects with the BRC treatment. Creatine kinase, a muscle damage marker, increased less (40.5±22.5 versus 49.7±21.5 U·L⁻¹, p=0.02) from baseline to after the 10-km TT and subjective fatigue increased less (-0.05±6.1 versus 3.23±6.1, p=0.05) from baseline to 24 h after the 10-km TT with BRC. **CONCLUSION:** BRC supplementation improved 10-km TT performance in

competitive male and female triathletes. Improved 5-km TT performances 24 h after the 10-km TT and the attenuated increase of CK and fatigue, suggest an increase in recovery while taking BRC.

Effects of Korean Wild Ginseng Drink on Recovery from Acute Strenuous Exercise

Nan Hee Lee¹, Hyun Chul Jung², Gina Ok¹, Soeun Jeon¹, Minsoo Kang, FACSM³, Sukho Lee³. ¹Texas A&M University San Antonio, San Antonio, TX. ²University of Louisiana at Monroe, Monroe, LA. ³Middle Tennessee State University, Murfreesboro, TN. (Sponsor: Minsoo Kang, FACSM)
(No relationships reported)

Korean Wild Ginseng (KWG) has been known to have efficacy not only in physical stamina but also in anti-oxidative and anti-inflammatory properties. However, its effect on performance recovery by acute strenuous exercise is not well known.
PURPOSE: To investigate the effects of KWG Drink on performance recovery from acute strenuous exercise (ASE). **METHODS:** This study was conducted in double-blind, counterbalanced, placebo-controlled design with 14 days washout periods. Ten healthy male volunteers (27.1 ± 4.33 years old) were randomly assigned to one of two parallel trials. KWG (2g of KWG; 16.8 mg of ginsenosides/package) or placebo supplementation were consumed right after ASE and following 4 days (2 packs/day). The ASE program consisted of downhill running and jumping exercise. Subjects performed downhill running (-10 %) for 20 minutes at 60 % of VO₂ max. After downhill running, subjects performed jumping exercise that consisted of five sets of 20 maximal drop jumps from height of 60 cm with a 10 seconds interval between jumps and 2 minutes rest between each set. Peak and mean power, isometric muscle strength, electromyography activity, cognitive function, cortisol, interleukin-6 (IL-6), myoglobin, total antioxidant capacity (TAC), and muscle soreness were assessed at each time points: baseline, 2, 48, and 96 hours after ASE. A series of 2 x 4 repeated measures ANOVA, and MANOVA were used to determine differences according to the supplementation. **RESULTS:** There were no statistical differences in performance (F= 0.368, p= .970), cognitive function (F= 0.366, p= .983), blood variables (cortisol: F= 0.598, p= .584; IL-6: F= 1.662, p= .206, myoglobin: F= 0.574, p= .544, TAC: F= 1.508, p= .241), and muscle soreness (F= 0.760, p= .462) according to the supplementation. **CONCLUSION:** Supplementation of KWG extract has no efficacy for performance recovery from acute strenuous exercise in healthy male subjects. Dosage and short duration of KWG application may produce non-significance results. Further studies are needed to investigate the different dosage and duration of KWG supplementation on performance recovery.

Effects of Ursolic Acid Supplementation on Early Strength Gains and Body Composition

Ashton Roman, Chi-An W. Emhoff. *Saint Mary's College of California, Moraga, CA.*
(No relationships reported)

PURPOSE: Ursolic Acid (UA) is a compound commonly found in apple peels and other fruit skins. Previous studies in animal models have shown that UA may inhibit skeletal muscle atrophy, as well as increase the size and strength of skeletal muscle. In humans, one study lasting eight weeks showed significant effects of combined UA supplementation and resistance training on increased muscle strength and decreased body fat percentage, but the mechanisms are unclear. Another study found acute effects of UA supplementation during exercise included stimulating the pathway for muscle hypertrophy in resistance-trained men. Our study was designed to investigate whether any potential effects of UA supplementation on muscle strength gain occur during the early phase of neuromuscular adaptations to resistance training. We hypothesized that oral consumption of 150 mg of Ursolic Acid (UA) three times a day in combination with resistance training would lead to increased muscle strength gain but no effect on body composition over four weeks compared to equivalent training with Placebo. **METHODS:** Twelve untrained adults (six in each group of Placebo or UA) were recruited to participate in our four-week training study. Subjects ingested either a Placebo or 150 mg of UA 3 times a day with every meal, for a total of 450 mg per day for four weeks. A 1 Repetition Maximum (1RM) bench press test was used to assess muscular strength pre and post resistance training. Resistance training consisted of two supervised sessions per week of three sets of 10 repetitions of flat bench press, incline bench press, and flat dumbbell flies at 60-80% of 1RM. Pre and post resistance training body fat percentage was measured via hydrostatic weighing. **RESULTS:** After four weeks of resistance training, subjects experienced a significant increase in muscular strength as measured by a 1RM bench press test and no change in body fat percentage. There were no significant differences in muscle strength gain between the Placebo and UA supplementation groups. **CONCLUSION:** We conclude that any potential ergogenic effects of UA supplementation are unlikely to involve neuromuscular adaptations in the early strength gains of a resistance training program.

3280 Board #185 June 2 2:00 PM - 3:30 PM

Effects of Peppermint Oil Supplementation on the Ventilatory Threshold in Young Women

Julianna M. Oates, Chi-An W. Emhoff. *Saint Mary's College of California, Moraga, CA.*
(No relationships reported)

PURPOSE: Peppermint oil (*mentha piperita*) has been shown to have cooling effects in animals and humans, as well as beneficial influences on pulmonary function tests possibly due to bronchodilatory mechanisms. In a previous study in our lab, we found that a single supplementation of one milliliter of peppermint oil mixed in one cup of water significantly raised the ventilatory threshold measured as %VO_{2max} with no effect on VO_{2max}, in endurance-trained and moderately active men. In this current study, we replicated the methods in recreationally active women and hypothesized that peppermint oil supplementation would increase ventilatory threshold, but not VO_{2max}, in the female population. **METHODS:** Ten female participants (age 20.4 ± 0.6 yr) performed two maximal oxygen consumption (VO_{2max}) tests on a cycle ergometer under randomized, single-blind trials of peppermint oil and placebo. For each exercise test, ventilatory threshold was determined by detecting the onset of hyperventilation in the ventilation vs. time curve. **RESULTS:** In the recreationally active female population, peppermint oil supplementation had no effect on the ventilatory threshold measured as a percentage of VO_{2max} compared to placebo (peppermint 61.5 ± 4.1 % of VO_{2max} vs. placebo 63.5 ± 2.5 % of VO_{2max}). Additionally, VO_{2max} values were not different between the two conditions (peppermint 36.6 ± 2.1 ml/kg/min vs. placebo 35.8 ± 1.8 ml/kg/min). **CONCLUSION:** Our findings suggest that peppermint oil supplementation may not play a significant role in the ventilatory threshold of recreationally active women, despite a significant effect having been observed in age-matched men. The ventilatory threshold phenomenon is complex, and sex differences may explain the inconsistent responses between men and women in peppermint oil supplementation during incremental exercise.

Heteropterys Tomentosa A. Juss. Extract Improved The Physical Performance And Presented A Powerful Antimutagenic Effect

Fabricio Azevedo Voltarelli, Dr., Géssica Alves Fraga, Ms., Emilly Della Pasqua Espindola, Ms., Domingos Tabajara de Oliveira Martins, Dr.. *Federal University of Mato Grosso (UFMT), Cuiabá-MT, Brazil.*
Email: faunesp8@yahoo.com.br
(No relationships reported)

PURPOSE: Studies which evaluated the *Heteropterys Tomentosa A. Juss* extract (EHHt)-induced mutagenesis and its effects on swim performance in the animal models are non-existent. Thus, we verified, for the first time, the mutagenic potential (*in vitro*) as well as the acute ergogenic activity of the EHHt (in rats). **METHODS:** Step one: CHO-k1 cells were used for *in vitro* micronucleus (MN) assay; these cells were treated with vehicle, 10, 30, and 100 mg/kg of EHHt; DOXO at 0.03M was used as positive control. Step two: Twenty-four male Wistar rats (90 days old; weight 180 to 220 grams) were divided into vehicle, EHHt 25mg/kg, EHHt 100 mg/kg, EHHt 400 mg/kg and subjected to swimming progressive load test (overload equivalent to 3% of body weight plus 0.5%, every 5 min, until exhaustion); caffeine at 5mg/kg was used as positive control. **RESULTS:** Step one: The MN frequency was extremely lower (P=0.01) at 10 (5.33 ± 0.57), 30 (10.66 ± 4.04), and 100 (19.0 ± 1.41) mg/kg of EHHt if compared to vehicle (24.75 ± 5.18) and DOXO (90.7 ± 3.1), being vehicle < DOXO. Step two: The rats administered with EHHt 25mg/kg presented higher values of time-to-exhaustion [TTE; min] (67.64 ± 7.23; P=0.011) and exercise overload [EO; %] (9.6 ± 0.96; P = 0.019) if compared to vehicle (TTE: 46.28 ± 6.30; EO: 7.3 ± 0.75), EHHt 100 mg/kg (TTE: 51.49 ± 7.8; EO: 7.9 ± 0.96), EHHt 400 mg/kg (TTE: 53.86 ± 7.91; EO: 8.1 ± 0.74), and caffeine (TTE: 59.17 ± 9.43; EO: 8.6 ± 0.89). **CONCLUSIONS:** EHHt acutely improved the performance of the animals subjected to swimming exercise until exhaustion at 25 mg/kg dose and, importantly, showed a strong antimutagenic effect at all doses administered. Further studies are needed in order to better understand the bioavailability of EHHt and which substance(s), in isolation, is(are) the main inductor(s) of these two interesting outcomes and the possible correlation between them.

A transient augmentation in the energy efficiency of working skeletal muscle is the purported basis for dietary nitrate (NO₃⁻) supplementation amongst competitive and recreational athletes alike. Previous studies support the ergogenic benefits of NO₃⁻ as results indicated improved microvascular blood flow, skeletal muscle oxygenation, and exercise performance with relatively short-term supplementation. As with most ergogenic aids, the optimum duration of supplementation prior to performance or competition, i.e. loading phase, is a critical determinant for efficacy. **Purpose:** Therefore, the purpose of this study was to investigate the effects of long-term vs. single dosing NO₃⁻ supplementation on skeletal muscle oxygenation and cycling performance. **Methods:** In a randomized, placebo controlled, double blind, parallel design study, healthy, recreationally active male (n=15) and female (n=14) subjects (age= 18-29 yrs.) completed a 5-mi simulated cycling time trial before and after a 14-day supplementation period with either a NO₃⁻ supplement (pre-nitrate loading; PRE) (n=14) or placebo (single nitrate dosing; SGL) (n=15). Both groups consumed a single dose of the NO₃⁻ supplement 2 hours prior to the post-treatment time trial. In addition, skeletal muscle oxygenation was measured via near-infrared spectroscopy during each time trial. **Results:** Fourteen days of NO₃⁻ supplementation (i.e. PRE) significantly decreased time to completion (TTC) (p=0.01) and increased average power (PWR_{AVG}) (p=0.04) and speed (SPEED_{AVG}) (p=0.02) from pre- to post-treatment while a single dosing (i.e. SGL) produced no significant changes to these measures. There were no significant differences over time and across treatments for any other measures including muscle oxygenation variables. **Conclusion:** Overall, long-term NO₃⁻ supplementation appears to have slight benefits over a single pre-exercise dosing in terms of cycling performance. However, this ergogenic response cannot be explained by changes to skeletal muscle oxygenation, thus controverting previously purported mechanisms of action.

 (No relationships reported)

PURPOSE: To test the hypothesis that inorganic nitrate (NO₃⁻) supplementation would improve muscle oxygenation, oxygen uptake (O₂) kinetics and exercise tolerance (T_{lim}) in normoxia and that these improvements would be augmented in hypoxia and attenuated in hyperoxia.
METHODS: In a randomized, cross-over study, ten healthy males completed work-to-work step cycle tests to exhaustion following acute consumption of 210 mL NO₃⁻-rich beetroot juice (BR; 18.6 mmol NO₃⁻) and NO₃⁻-depleted beetroot juice placebo (PL; 0.12 mmol NO₃⁻). These tests were completed in normobaric normoxia (FIO₂: 21%), hypoxia (FIO₂: 15%) and hyperoxia (FIO₂: 40%). Pulmonary O₂ and quadriceps tissue oxygenation index (TOI), derived from multi-channel near-infrared spectroscopy, were measured during all trials.
RESULTS: Plasma [nitrite] was higher in all BR compared to all PL trials (P<0.05). Quadriceps TOI was higher in normoxia compared to hypoxia (P<0.05) and higher in the hyperoxia compared to hypoxia and normoxia (P<0.05). T_{lim} was improved after BR compared to PL ingestion (250 ± 44 vs. 231 ± 41 s), with the magnitude of improvement being negatively correlated with quadriceps TOI at exhaustion (r = -0.78), in the hypoxic trials (P<0.05). T_{lim} tended to be improved with BR in normoxia (BR: 364 ± 98 vs. PL: 344 ± 78 s; P=0.087), but was not improved in hyperoxia (BR: 492 ± 212 vs. PL: 472 ± 196 s; P>0.05). BR ingestion increased peak O₂ in hypoxia (P<0.05), but not normoxia or hyperoxia (P>0.05).
CONCLUSIONS: NO₃⁻ supplementation is more likely to improve T_{lim} and peak O₂ as skeletal muscles become increasingly hypoxic.

ABSTRACT Muscle oxidative capacity and recovery time of muscle oxygenation following maximal exercise decline with the aging. Although dietary nitrate supplementation has been shown to improve muscle oxygenation in health subjects, these effects in elderly has not been addressed. **PURPOSE:** To evaluate the effect of a beetroot-based nutritional gel (BG) on forearm muscle oxygenation, blood volume and handgrip strength in elderly with cardiovascular risk factors. **METHODS:** 12 elderly participated in a randomized, double-blind and crossover study. Maximal voluntary contraction (MVC) was collected for baseline, immediately and 20 min after exercise in both BG (100 g of beetroot-based gel containing approx. 12 mmol nitrate) or PLA (100 g of nitrate-depleted gel nitrate-depleted) were provided. After 150 min of ingestion of each intervention, elderly performed a rhythmic handgrip exercise which consisted of one 1-min sets at 30 % of the MVC of each subject following 1 min of quiet recovery after exercise. Muscle deoxygenation (SmO_{2min}), muscle reoxygenation (SmO_{2max}), muscle deoxygenation time (SmO_{2sDT}), muscle reoxygenation time (SmO_{2sRT}) and blood volume (tHb) were continuously monitored using an NIRS device. **RESULTS:** significant reduction in SmO_{2min} and SmO_{2sDT} was observed during exercise and SmO_{2sRT} during recovery, as it was in the ΔMVC (BG: -18.56±13.8 vs. PLA: -26.18±14.6 N; P<0.05) only 20 min after handgrip exercise. Significant increase in tHb during and after exercise was observed in BG. There was no significant difference in SmO_{2max} between interventions. **CONCLUSION:** Single dose of BG improve microvascular hemodynamic which may accelerate the muscle recovery after short exercise in elderly with cardiovascular risk factors.

Muscle Damage and Inflammation Following a Marathon: Influence of Beetroot Juice
 Tom Clifford¹, Dean Allerton¹, Meghan Brown¹, Liam Harper¹, Steven Horsburgh¹, Karen M. Keane¹, Emma J. Stevenson², Glyn Howatson, FACSM¹. ¹Northumbria University, Newcastle, United Kingdom. ²Newcastle University, Newcastle, United Kingdom. (Sponsor: Glyn Howatson, FACSM)
 Email: tom.clifford@myport.ac.uk
 (No relationships reported)

Purpose The present study examined whether consuming an antioxidant-rich beetroot juice (BTJ) would attenuate markers of inflammation and muscle damage following a marathon. **Methods:** Using a double blind, independent groups design, 34 marathon runners (~16 previous marathons completed) consumed either BTJ (~3mmol/L Trolox equivalent antioxidant capacity; polyphenol content: ~405 mg of Gallic Acid Equivalents) or an isocaloric placebo (PLA) for 3 days following a marathon race (3 x 250 ml per day). Maximal isometric voluntary contractions (MIVC), countermovement jumps (CMJ), muscle soreness, serum cytokines, leucocytosis, creatine kinase (CK), high sensitivity C-reactive protein (hs-CRP) and aspartate aminotransferase (AST) were measured pre, post, and on the 2 days after the marathon. **Results:** Muscle function (CMJ and MIVC) was significantly reduced after the marathon (P<0.05) but no group differences were observed at any time point (P>0.05). At 48 h post-marathon, CMJ was similarly depressed in the BTJ and PLA groups (95 ± 6 vs. 95 ± 9 % of baseline values, respectively), with MIVC returning to baseline levels in both groups (100 ± 13 vs. 99 ± 10 %, respectively). Muscle soreness was increased in both groups in the day after the marathon (BTJ; 45 ± 48 vs. PLA; 46 ± 39 mm) and had returned to baseline by day 2, irrespective of supplementation (P>0.05). Cytokines (Interleukin-6; IL-6, interleukin-8, tumour necrosis factor-α) were increased immediately post-marathon but apart from IL-6 (~0.9 fold change in BTJ and ~0.5 in PLA) had returned to

baseline values by day 1 post. No group differences were evident ($P < 0.05$). Leucocytes increased 1.7 fold immediately after the race and remained elevated 2 days' post, irrespective of supplement. CK, AST and hs-CRP were all still elevated 2 days after the marathon ($P < 0.05$), but no group differences were present. **Conclusions:** Beetroot juice supplementation was no more effective than a PLA for attenuating inflammation and functional markers of muscle-damage following a marathon race.

 (No relationships reported)

PURPOSE: Dietary nitrate supplementation in the form of beetroot extract (BRE) has recently emerged as a potential modulator of exercise capacity. To date, the impact of BRE ingestion on lactate kinetics, a key determinant of endurance exercise performance, has not been rigorously assessed.

METHODS: We performed a single-blinded, randomized crossover study in which competitive masters rowers underwent graded stepwise (3 mins, 20W increment) rowing ergometer testing to define lactate handling profiles. Each participant was tested 2.5 hours after ingestion of a commercially available BRE product (Beet-It Sport Shot, Ipswich, UK) and blackcurrant juice placebo (R.W. Knudsen Just Black Currant, Chico, CA). Capillary lactate concentrations were measured at the completion of each testing stage to develop lactate handling curves.

RESULTS: Participants ($n = 12$, 50% men, age = 54 ± 5 years, peak $\dot{V}O_2 = 47 \pm 7$ ml/kg) with 24 ± 12 years of rowing experience completed all aspects of this protocol. Heart rate, oxygen consumption, respiratory exchange ratio, and perceived effort were similar at all exercise intensities during testing following ingestion of BRE and placebo. Similarly, parameters of lactate handling including absolute lactate concentrations at each exercise intensity, workload at onset of blood lactate accumulation, and workload at 4 mmol lactate concentration were similar following ingestion of the active BRE compound and placebo (Figure).

CONCLUSION: Ingestion of a single dose of commercially available BRE does not appear to have a significant impact on lactate handling. Performance during activities that depend on lactate handling may be unresponsive to BRE ingestion.

Figure. Capillary lactate concentrations during stepwise rowing ergometer exercise testing following ingestion of beetroot extract (BRE) and placebo.

Dietary Nitrate Supplementation Improves Sprint and High-Intensity Intermittent Running Performance

Christopher Thompson¹, Anni Vanhatalo, FACSM¹, Harry Jell¹, Jonathan Fulford¹, Lara Nyman², Stephen J. Bailey¹, Andrew M. Jones, FACSM¹. ¹University of Exeter, Exeter, United Kingdom. ²Gatorade Sports Science Institute, Barrington, IL.
 (No relationships reported)

The influence of dietary nitrate (NO_3^-) supplementation on indices of maximal sprint and intermittent exercise performance is unclear. **Purpose:** To investigate the effects of NO_3^- supplementation on sprint running performance, and cognitive function and exercise performance during the sport-specific Yo-Yo Intermittent Recovery level 1 test (IR1). **Methods:** In a double-blind, randomised, crossover study, 36 male team-sport players received NO_3^- -rich (BR; 70 mL·day⁻¹; 6.4 mmol of NO_3^-), and NO_3^- -depleted (PL; 70 mL·day⁻¹; 0.04 mmol NO_3^-) beetroot juice for 5 days. On day 5 of supplementation, subjects completed a series of maximal 20-m sprints followed by the Yo-Yo IR1. Cognitive tasks were completed prior to, during and immediately following the Yo-Yo IR1. **Results:** BR improved sprint split times relative to PL at 20 m (1.2%; BR 3.98 ± 0.18 vs. PL 4.03 ± 0.19 s; $P < 0.05$), 10 m (1.6%; BR 2.53 ± 0.12 vs. PL 2.57 ± 0.19 s; $P < 0.05$) and 5 m (2.3%; BR 1.73 ± 0.09 vs. PL 1.77 ± 0.09 s; $P < 0.05$). The distance covered in the Yo-Yo IR1 test increased by 3.9% (BR 1422 ± 502 vs. PL 1369 ± 505 m; $P < 0.05$). The reaction time to the cognitive tasks was shorter in BR (615 ± 98 ms) than PL (645 ± 120 ms; $P < 0.05$) at rest but not during the Yo-Yo IR1 (BR: 612 ± 104 vs. PL: 621 ± 92 ms; $P > 0.05$). There was no difference in overall response accuracy (BR: 34.7 ± 1.4 vs. PL: 34.6 ± 1.5 correct responses; $P > 0.05$) and there were no differences in response accuracy at any specific time point. **Conclusion:** Dietary NO_3^- supplementation enhances maximal sprint and high-intensity intermittent running performance in competitive team sport players. Our findings suggest that NO_3^- supplementation has the potential to improve performance in single-sprint or multiple-sprint (team) sports.

Acute Nitrate Supplementation Improves Ischemic Exercise Tolerance in Post-Menopausal Women

PURPOSE: Inorganic nitrate supplementation elicits its most consistent ergogenic benefits during conditions of low muscle oxygen availability. In the present study we tested the ability of acute dietary nitrate supplementation to attenuate perceived effort and increase time to volitional fatigue during blood flow-restricted exercise in post-menopausal women. **METHODS:** Eleven post-menopausal women (57 to 64 yr) performed intermittent isometric handgrip squeezes (10% of MVC, 30 per min) during progressive upper arm cuff inflation (+20 mmHg per min) on 3 study visits, with 7 to 10 days between visits. Approximately one week following visit 1, participants randomly consumed 140 ml of nitrate-concentrated (0.8 gm of nitrate; BrJ_{nitrate}) or nitrate-depleted (BrJ_{placebo}) beetroot juice (James White Beet-It Sport; IND#119978), with handgrip exercise beginning two hours post-consumption. Ratings of perceived exertion (Borg RPE) were assessed each minute. Venous blood was collected (before, 90 min post, 180 min post consumption) on both BrJ visits for measurement of plasma nitrate [NO_3^-] and nitrite [NO_2^-]. **RESULTS:** Compared to responses observed during the BrJ_{placebo} consumption visit, BrJ_{nitrate} consumption raised plasma [NO_3^-] (13-fold) and [NO_2^-] (4-fold), delayed the initial rise in RPE (+50 sec), and increased time to volitional fatigue (526 ± 46 vs. 567 ± 50 sec) (all $p < 0.05$).

CONCLUSIONS: These findings provide further support for the ergogenic potential of nitrate supplementation under conditions of restricted muscle blood flow/oxygen availability. Funding: Penn State Hershey Family & Community Medicine (JAFPE Endowment)

Dietary Nitrate Supplementation Reduces The Oxygen Cost Of Submaximal Arm Crank Exercise

Lee J. Wylie¹, Stephen J. Bailey¹, Anni Vanhatalo, FACSM¹, Sascha Kranen¹, Ana C. Sousa², Andrew M. Jones, FACSM¹. ¹University of Exeter, Exeter, United Kingdom. ²University of Porto, Porto, Portugal.
 (No relationships reported)

There is evidence to suggest that the ingestion of > 5 mmol inorganic nitrate (NO_3^-) can enhance exercise economy [lower pulmonary oxygen uptake [$\dot{V}O_2$]] and performance during cycling and running exercise. However, the effect of dietary NO_3^- supplementation on economy and performance during isolated upper-body exercise is less clear. **PURPOSE:** To test the hypothesis that dietary NO_3^- supplementation would improve economy and performance during arm cranking exercise. **METHODS:** Eight recreationally-active males were assigned in a randomized, double-blind, crossover design to receive NO_3^- -rich beetroot juice (BR; 12.2 mmol NO_3^- ·day⁻¹) and NO_3^- -depleted beetroot juice (PL; 0.01 mmol NO_3^- ·day⁻¹) for 7 days. On days 5 and 7 of supplementation, subjects completed two bouts of moderate-intensity exercise and one bout of severe-intensity exercise that was continued until exhaustion on an arm-crank ergometer. Resting venous blood samples were obtained, for later determination of plasma nitrite concentration ([NO_2^-]) and breath-by-breath $\dot{V}O_2$ were measured during all exercise tests.

RESULTS: Plasma [NO_2^-] was higher following BR, compared to PL (PL: 86 ± 51 nM vs. BR: 542 ± 285 nM; $P < 0.05$). BR supplementation lowered steady-state $\dot{V}O_2$ during moderate-intensity exercise by 3% (PL: 0.93 ± 0.24 L·min⁻¹ vs. BR: 0.90 ± 0.23 L·min⁻¹; $P < 0.05$). Exercise economy and time-to-exhaustion (PL: 459 ± 102 vs. BR: 474 ± 135 s; $P > 0.05$) were not impacted by BR supplementation during severe-intensity arm cranking.

CONCLUSIONS: Short-term dietary NO_3^- supplementation improved moderate-intensity exercise economy, but not severe-intensity exercise economy or tolerance, during arm-cranking exercise in recreationally-active subjects.

PURPOSE: Beet juice is a potential source of inorganic nitrates in the diet. Inorganic nitrates have been shown to improve exercise performance. Increased levels of nitrates may reduce the ATP cost of force production and may influence mitochondrial efficiency leading to a reduction in the energy cost of exercise. Most studies to date assessed high intensity endurance performance with time trials lasting 15 - 138 min. However, there is a lack of research on the effect of nitrates on intermittent exercise similar to that performed in soccer. The purpose of this project was to examine the effects of acute beet juice supplementation on performance during a simulated soccer match.

METHODS: 8 female college soccer players (VO_{2max} : 52.3 ± 8.5 ml/kg/min; mean \pm SD) each completed two trials in a randomized, double-blind design. Participants ingested one nitrate rich beet juice shot (BR; ~ 6.5 mmol of nitrate per 70 ml) or one nitrate depleted beet juice shot (PL; ~ 0.04 mmol nitrate per 70 ml) 3 h before performing a modified Loughborough Intermittent Shuttle Test (LIST), separated by 7 days. Participants performed a Yo-Yo intermittent shuttle test to estimate maximal aerobic speed used in the modified LIST. The LIST consists of six 15 min periods of walking, running, sprinting and shooting. Each 15 min period is separated by a 3 min break. O_2 consumption and heart rate were measured continuously using a portable metabolic system. Values were averaged over the last 5 min of each 15 min period. Lactate and RPE were collected every 15 min.

RESULTS: There was no significant difference at any time point in any of the measured variables between PL and BR trials. The average VO_2 between the PL and BR trial was 33.8 ± 4.4 vs 34.2 ± 4.1 ml/kg/min. In both trials the VO_2 was significantly higher in the first 15 min compared to all other time points ($p < 0.05$). The average heart rate between the PL and the BR trial was 172 ± 18 vs 175 ± 6 bpm. The average lactate value between the PL and the BR trial was 3.8 ± 2.0 vs 3.2 ± 1.5 mmol. RPE values between the PL and the BR were 15.4 ± 1.2 vs 15.8 ± 1.6 . In both trials the RPE was significantly lower in the first 15 min compared to all other time points ($p < 0.05$).

CONCLUSIONS: Acute ingestion of nitrate rich beet juice did not improve simulated soccer performance.

Studies have shown that FIR emitted by materials can, without change temperature, enhance cell metabolism and function, increase cellular availability of nitric oxide (NO) and Ca^{2+} , improve blood circulation and an *ex-vivo* study of skeletal muscle has shown the effect of delay fatigue. However, the effectiveness of FIR fabric as ergogenic aid and its related mechanism in humans remains unknown. **PROPOSE:** Analyze the effect of fabric made by polyamide fiber mixed to FIR emitting substances on exercise bioenergetics, oxidative stress, NO and exercise tolerance. **METHODS:** Eighteen active men performed two ergospirometric tests, two familiarizations and two testing days composed by a square-wave cycling exercise at moderate intensity (2 sets of 10 min), followed by very heavy intensity until exhaustion. Tests occurred two weeks apart and after 96 hours of FIR or Placebo fabric usage, in a crossover, double-blind, placebo-controlled design. The exercise oxygen uptake, lactate accumulation and fast VO_2 off-kinetics were used to calculate Aerobic (Ae), Anaerobic Lactic (ANL) and Anaerobic Alactic (AnA) metabolism relative to total energy expenditure values, using the GEDAE-LaB software. High temperature was measured by an infrared thermometer, oxidative stress by gas chromatography-tandem mass spectrometry measurements of F_2 -isoprostanes, NO by chemiluminescence analysis of Nitrite and Nitrate. **RESULTS:** There were no differences for any variable between FIR and Placebo fabrics pre-tests and post-moderate exercise. For the very heavy exercise until exhaustion, exercise time was higher for FIR than Placebo (403 ± 127 s vs.

338 ± 110 s, $p = 0.004$). Relative energy system contributions (%) were as followed: Ae (FIR 66.48 ± 10.91 - Placebo 61.44 ± 15.58 , $p = 0.04$); ANL (FIR 21.41 ± 5.63 - Placebo 23.02 ± 6.53 , $p > 0.05$); AnA (FIR 12.10 ± 9.38 - Placebo 15.53 ± 13.69 , $p > 0.05$). Temperature ($^{\circ}C$) were not different between fabrics (FIR 31.8 ± 1.6 - Placebo 31.9 ± 2.2 , $p > 0.05$). F_2 -isoprostanes (pg/dl) just increase for Placebo (pre 216.75 ± 52.78 - post-VH 291.53 ± 88.95 , $p = 0.005$). **CONCLUSION:** Far-infrared emitting fabric enhances aerobic metabolism, reduced oxidative stress and improves exercise tolerance during very heavy intensity exercise, independent of NO availability.

 (No relationships reported)

PURPOSE: The aim of this study was to compare the effectiveness of beetroot power in pill supplementation on cycle exercise performance as well as oxidative damage measured by Malondialdehyde (MDA) concentration. **METHODS:** Twenty-four untrained subjects (20.92 ± 3.60 years) performed on a Monark cycle ergometer exercise session for 15 minutes three times a week for four weeks. The Institutional Review Board (IRB) has approved all experimental procedures and subjects have been considered low risk according to the American College of Sports and Medicine. The subjects were split up randomly into two groups, control versus experimental. Twelve subjects (six females and six males) took two pills of beetroot power (500mg) and the other twelve took a placebo. Urine samples were taken on the last day of weeks 2, 3 and 4. During each exercise session times were noted when the subject reached 85% of their heart rate max and then finished out their 15mins at their 85%. Subjects were provided water during each meeting to make sure they were well hydrated. Since water has a various pH level the same bottle of water was provided for all subjects. Urine was stored at $-20^{\circ}C$ until all samples were collected. Urine creatine levels were measured by using a Specimen Validity Test and a MDA Assay kit (Northwest Life Science Specialties, 2014) was used to determine MDA levels in the urine at the time the subject reach 85% of their heart rate max. A single factor ANOVA was performed on all data to see if there was significance. **RESULTS:** No significant difference ($p > 0.05$) was in any of the parameter that were observed (Time to reach 85% of max heart rate, RPE, MDA concentrations). **CONCLUSION:** Beetroot supplementation had no effect on exercise performance nor did it alter oxidative damage measured via MDA Concentrations.

 (No relationships reported)

Recently, we have created a new fermented drink (FD) containing lots of carbohydrates, amino acids, citric acids, and so on. However, physiological activities which the FD has are still unclear.

PURPOSE: This study investigated the effects of post-exercise FD supplementation on glycogen restoration in rat skeletal muscle and liver.

METHODS: Male Wistar rats (10-weeks-old) were randomly divided into two main groups: sedentary control (Con) and exercise. Following 12 h fasting, rats in the exercise group swam for 2.5 h in five 30-min bouts separated by 5 min of rest in order to deplete skeletal muscle and liver glycogen. The rats were orally ingested either water, glucose solution, or FD 0.5, 1, 1.5, and 2 h after the swimming. Immediately and/or 4 h after the exercise, soleus and deep portion of gastrocnemius (GasD) muscles and liver were dissected and analyzed.

RESULTS: Swimming exercise resulted in an approx. 20-60% reduction of glycogen concentration in all collected tissues compared with the value of fasted Con animals. Thereafter, the glycogen level in both skeletal muscles and liver increased significantly above the fasted Con level at 4 h after the swimming exercise only when either glucose or FD ingestion were performed during the recovery period ($p < 0.05$). The degree of this increase was significantly greater in FD-treated than in glucose-treated animals, particularly in the liver ($p < 0.05$). A similar trend was also observed in the GasD, but not in the soleus muscles.

CONCLUSIONS: These results suggest that FD supplementation will be an effective method for enhancing post-exercise glycogen restoration in both skeletal muscle and liver.

Prescription Strength Ibuprofen Interferes with Prophylactic Adaptations to Heavy Unaccustomed Resistance Exercise

Jessica G. Ehrbar¹, Michael J. Saunders, FACSM¹, M K. Todd¹, Andrew C. D'Lugos², Nicholas D. Luden¹. ¹James Madison University, Harrisonburg, VA. ²Arizona State University, Phoenix, AZ. (Sponsor: Michael J. Saunders, FACSM)
(No relationships reported)

Skeletal muscle typically experiences a repeated bout effect (RBE) following a single bout of heavy unaccustomed exercise, characterized by rapid adaptations aimed at protecting against a subsequent insult. Previous research indicates that non-steroidal anti-inflammatory drugs such as ibuprofen (IBU) may interfere with key mechanisms governing early skeletal muscle adaptive responses. **PURPOSE:** This proof-of-concept study was designed to assess the influence of prescription strength IBU on the RBE following heavy exercise.

METHODS: In a double-blinded crossover design, eight males (23 ± 4 yr) completed two separate testing phases separated by a washout period (7 d). Each phase consisted of two sessions of unilateral eccentric resistance exercise (RE; 10 sets, 10 reps, 120% 1 RM), separated by 10 d. During each phase, subjects consumed either a prescription dose (800 mg) of IBU or placebo (PLA) 45 min prior to RE and in 8 h increments for 72 h following RE. Muscle recovery variables [muscle soreness, peak isokinetic torque, total isokinetic work during 30 reps and plasma creatine kinase (CK)] were measured 24 and 72 h following each RE session (Initial RE = RE₁; RE 10 d later = RE₂). Magnitude-based inferences were used to evaluate treatment effects on muscle recovery variables.

RESULTS: Changes in post-exercise muscle soreness 24 h following RE₂ were 'likely' reduced with PLA (RE₁: 43 ± 15 mm to RE₂: 27 ± 14 mm) compared to IBU (RE₁: 39 ± 23 mm to RE₂: 39 ± 15 mm). In addition, reductions in total work output 72 h following RE₂ were 'likely' attenuated with PLA (RE₁: -598 ± 614 J to RE₂: -13 ± 445 J), but not IBU (RE₁: -335 ± 481 J to RE₂: -343 ± 284 J). The impact of IBU on measures of peak muscle torque and CK were 'unclear'.

CONCLUSION: In general, ibuprofen consumption appeared to interfere with the RBE, compared to PLA. These data suggest that prescription-strength dosing of IBU following skeletal muscle trauma may be detrimental to the initial adaptive responses following heavy exercise.

Acute Naproxen Dose On Gastrointestinal Distress And Performance During Moderate-intense Cycling In The Heat

Dawn M. Emerson¹, J M. Davis, FACSM², Stephen CL. Chen³, Toni M. Torres-McGehee², Charles C. Emerson⁴, Craig E. Pfeifer², Joseph D. Bivona², Justin V. Stone², J L. Durstine, FACSM². ¹University of Kansas, Lawrence, KS. ²University of South Carolina, Columbia, SC. ³Bob Jones University, Greenville, SC. ⁴University of Missouri - Kansas City, Kansas City, MO.
(No relationships reported)

Non-steroidal anti-inflammatory drugs are often perceived as performance enhancing due to their anti-inflammatory and analgesic effects. However, these drugs are known to cause gastrointestinal (GI) damage and alter cardiovascular function, which could be detrimental to performance. **PURPOSE:** To determine the effects of naproxen on GI distress and performance in hydrated humans cycling in the heat. **METHODS:** A double-blind, randomized and counterbalanced, cross-over design was utilized. Four trials: 1) placebo and ambient (Control [C]; ambient = $22.7 \pm 1.8^\circ\text{C}$, $52.4 \pm 5.5\%$ humidity); 2) placebo and heat (H; heat = $35.7 \pm 1.3^\circ\text{C}$, $53.2 \pm 3.2\%$ humidity); 3) naproxen and ambient (N; 1 - 220 mg naproxen sodium pill every 8 hrs for 24 hrs); and 4) naproxen and heat (NH) were completed. Eleven volunteers (6 male, 5 female; age = 27.8 ± 6.5 yrs, weight = 79.1 ± 17.9 kg, height = 177 ± 9.5 cm, and $\dot{V}O_{2\text{max}} = 41.4 \pm 5.7$ ml/kg) cycled 80 min at a heart rate (HR) corresponding to 70% $\dot{V}O_{2\text{max}}$ before completing a 10 min time trial for maximum distance. Heart rate, rate of perceived exertion (RPE) and GI symptoms were measured throughout cycling. Gastrointestinal symptoms were also assessed pre-, post-, 3 hrs post-, and 24 hrs post-cycling. Fecal occult blood was measured 24 hrs pre- and 24 hrs post-cycling. **RESULTS:** No statistically significant differences were found between conditions. Max HR was higher during N (176.2 ± 15 bpm) than C (175.7 ± 14.2 bpm) and NH (179.0 ± 18.0 bpm) than H (177.8 ± 18.2 bpm). Mean distance covered was greatest during N (3.3 ± 0.8 miles) and lowest in NH (2.8 ± 0.8 mile). During exercise, GI symptoms

occurred in 64% of all trials (C = 82%, N = 73%, H = 45%, and NH = 55%). At 3 hrs post-exercise, C experienced more frequent and serious upper, lower, and systemic GI symptoms than any other condition. Compared to other trials, H experienced higher serious upper (18%) and systemic (5%) GI scores 24 hrs post-exercise. NH resulted in more serious lower GI symptoms (12%) 24 hrs post-exercise. **CONCLUSION:** Although naproxen did not significantly affect performance or GI distress during 90 min of exercise in the heat, a possible negative interaction between naproxen and heat stress may exist, as indicated by higher max HR and lower distance during NH, which warrants further research.

Gender, Past Prescription, and Knowledge of Abuse Impact College Students' Feelings on Prescription Pain Killers

Evan C. Johnson, Ainsley E. Huffman, Gretchen Sewczak-Claude, Derek T. Smith. University of Wyoming, Laramie, WY.
Email: evan.johnson@uwyo.edu
(No relationships reported)

Roughly 12% of college students report non-medical use of prescription opioid pain killers (OPK). The risk of overdose and addiction are great and information needs to be gathered for creation of effective prevention programs. **PURPOSE:** To determine what factors contribute to college students' perceptions related to their own use of OPKs and how perceptions are influenced by a brief education intervention. **METHODS:** 234 college students (21 ± 3 y, 70% female) completed three separate questionnaires. After responding to demographic questions, participants replied to Likert-style statements regarding responsible use of prescription opioids after being asked to imagine themselves in a situation where they had become injured and prescribed OPKs. The questionnaire was completed a second time after hearing an educational intervention regarding the costs, overdose rates, and OPK alternatives. **RESULTS:** Initially, females disagreed more strongly than males regarding the sharing of OPKs ($t = -3.15$, $p = .002$). Compared to never-prescribed, students that had previously been prescribed OPKs disagreed more strongly that they would finish their prescription regardless of pain ($t = 4.44$, $p < .001$). Those that knew at least one person who was addicted to OPKs, compared to those who did not know an OPK addicted person, were more in favor of prescription monitoring programs ($t = -3.19$, $p = .002$). The intervention positively influenced responses to statements regarding taking OPKs without first visiting a doctor, sharing unused OPKs, favorability of OPK monitoring programs, and agreement with doctors describing the risks of OPKs upon prescription (all $p < 0.002$). Participants were more concerned about the risks of OPKs and agreed more strongly that over-prescription of OPKs is a problem following the intervention (both $p < .001$). **CONCLUSIONS:** Gender and past OPK exposure influence initial feelings regarding OPKs. A brief low-cost and low-intensive educational intervention appears to have potential for positively influencing college students' ratings related to responsible OPK usage.

Hydrogen-rich Water Modulates Redox Status Repeated Three Consecutive Days Of Strenuous Exercise.

Yudai Shibayama, Kaito Takeuchi, Shohei Dobashi, Katsuhiro Koyama. University of Yamanashi, Kofu, Japan.
(No relationships reported)

PURPOSE: Repeated sprint exercise breaks redox balance, leading to cause oxidative stress. Excessive oxidative stress is considered as detrimental and thus as a likely cause of cell damage associated with severe exercise. In contrast, there is a growing evidence that the molecular hydrogen reacts with harmful oxidants such as hydroxyl radical in cells, and is proposed its potential for preventive and therapeutic applications. Therefore, we hypothesized that hydrogen-dissolved water drinking might attenuate accumulative fatigue imposed by intensive exercise for 3 consecutive days, by inhibiting excessive oxidative stress generation. To test this, we investigated the effects of hydrogen-rich water on oxidative stress induced by maximal pedaling exercises for three straight days.

METHOD: Eight male volunteers participated in this single blind, crossover, randomized controlled study. They completed two 3-day consecutive cycling exercise tests under the two conditions (i.e., hydrogen-rich and placebo water). The cycling exercise test was two 6-min sprint cycling consisted of 3 repetition of 10-s maximal effort against a resistance of 7.5 % body mass and 110-s active rest (no load pedaling). Before the first exercise test, and after the second exercise test, subjects drank the 500 ml of hydrogen-rich (5.14 ± 0.03 ppm) or placebo water. Seven hours before exercise tests on day 1 as a baseline, and 17 hours after exercise each day, blood sample was obtained to analyze the BAP/d-ROMs as an index of oxidative status.

RESULTS: The cycling performance in both conditions were not significantly changed over three consecutive days. In placebo trial, the relative changes in BAP/d-

ROMs from baseline level gradually decreased, as the day passed (Day 1 and Day 2 vs. Day 3, $P < 0.05$, respectively). However, the hydrogen-rich water drinking suppressed the reduction in BAP/d-ROMs.

DISCUSSION: Our present findings suggest that hydrogen-rich water drinking might contribute to maintain the redox status during consecutive days of strenuous exercise. This indicates that molecular hydrogen might have a potential to reduce exercise-induced oxidative damage.

3299 Board #204 June 2 3:30 PM - 5:00 PM

Effect of Astaxanthin Supplementation on Cardiorespiratory Function in Runners

Julie Talbott¹, Don Hantla², Shawn M. Talbott, FACSM¹.

¹EQQL, Draper, UT. ²Treehouse Athletic Club, Draper, UT.

Reported Relationships: S.M. Talbott: Contracted Research - Including Principle Investigator; study was funded by Beijing Ginko Group (BGG).

PURPOSE: Astaxanthin (AX) is a naturally occurring carotenoid, synthesized primarily by marine microalgae, with powerful antioxidant and anti-inflammatory properties. Rodent studies suggest that AX supplementation improves fat utilization and exercise endurance (Ikeuchi 2003). In athletes, AX supplementation (4mg/day for 4 wks) resulted in significant improvements in power output and cycling performance (Earnest 2011), however, a higher dose of AX (20mg/day for 4 wks) in well-trained cyclists and triathletes, yielded no significant changes in total antioxidant capacity, oxidative damage, rate of fat oxidation, or time trial performance (Res 2013). The purpose of this study was to assess the effects of 8 wks of AX supplementation (12mg/day) on cardiorespiratory function during higher and lower intensity exercise in recreational runners. **METHODS:** Using a double-blind parallel design, 28 recreational runners (male = 14, female = 14, age = 42) were supplemented for 8 wks w/ 12mg/day of AX (*Haematococcus pluvialis* algal extract) or a placebo. Before and after the supplementation period, subjects performed a maximal running test (VO_{2max} on treadmill) and a maximal cycling test (watts on cycle ergometer). **RESULTS:** There was no improvement in maximal oxygen uptake (running VO_{2max}) or maximal power output (cycling watts) with AX supplementation. Interestingly, subjects in the AX group showed a significant ~10% lower average heart rate at submaximal running intensities (aerobic threshold, AeT; AX 130±17 v. PL 145±14; and anaerobic threshold, AT; AX 139±20 v. PL 154±11, $p < 0.05$) compared to placebo. **CONCLUSIONS:** Supplementation with 12mg/day of AX for 8 wks reduced running heart rate at submaximal endurance intensities (AeT & AT), but not at higher "peak" intensities. These results suggest that AX may be a beneficial ergogenic aid for long/ultra-distance endurance athletes, but not necessarily for athletes competing in shorter higher intensity efforts. In addition, these data are also suggestive of a general "cardiotonic" effect of AX, that should be investigated in non-athletic populations including elderly subjects and those with cardiac complications including post-myocardial infarction, heart failure, statin usage, mitochondrial dysfunction, chronic fatigue, and related conditions.

Effect Of Low Dose Cobalt Administration On Erythropoiesis

Walter FJ Schmidt¹, Torben Hoffmeister¹, Nadine Wachsmuth¹, Dirk Schwenke², William C. Byrnes, FACSM³. ¹University of Bayreuth, Bayreuth, Germany. ²University of Dresden, Dresden, Germany. ³University of Colorado, Boulder, CO. (Sponsor: William C. Byrnes, FACSM)

Email: walter.schmidt@uni-bayreuth.de

Reported Relationships: W.F. Schmidt: Ownership Interest (Stocks, Bonds); W.F.J. Schmidt is a managing partner of Blood tec GmbH.

Before recombinant EPO became available cobalt chloride has been used as a therapeutic drug to treat anemic patients. Nowadays, cobalt (Co) is offered as nutritional supplement for endurance athletes as it is supposed to stimulate erythropoiesis also in small dosages. As a consequence, WADA has put cobalt on the list of prohibited substances although no information is available on the efficacy of low dose Co application on red cell production. **Purpose:** To evaluate the effect of low dose oral Co administration on erythropoietic activity. **Methods:** Three studies were performed: 1. application of a single dose of either 5mg Co (n=6) or 10mg Co (n=7); 2. application of 5mg (n=9) or 10 mg (n=7) per day for 5 days, and 3. application of 5 mg Co/day for 3 weeks followed by a 3-week wash-out period (n=16). In all studies a control group was included. Venous EPO concentration was determined in all studies, reticulocytes (ret%) and immature reticulocyte fraction (IRF) in study 2 and 3 and tHbmass in study 3 by the optimized carbon monoxide re-breathing method. **Results:** 10 mg Co significantly increased plasma EPO until 7h after the single dose (from 8.7 ±2.6 to 11.5 ±2.4 mU/ml) and after the 5-day administration (from 10.6 ±2.6 to 13.1 ±4.2 mU/ml, $p < 0.05$). 5 mg Co had only a slight effect 5h after a single application (from 8.8 ±4.3 to 10.6 ±5.5 mU/ml, $p < 0.05$). During the 3-week administration 5mg Co transiently increased EPO by 30% (from 9.5 ±3.0 to 12.4 ±5.2 mU/ml after 2 weeks, $p = 0.01$). IRF increased after 5 days of 10mg Co administration (from 0.60

±0.22 to 0.87 ±0.27, $p < 0.001$), but not after short or long-term dosage of 5 mg. Ret% slightly increased in study 3 after 2 weeks (from 1.16 ±0.42 to 1.25 ±0.41%, $p < 0.05$). In study 3, tHbmass slightly increased until week 2 (+17.2 ±22.1g, $p = 0.01$) and remained at higher level thereafter. **CONCLUSIONS:** Low dose cobalt administration which can be achieved with nutritional supplements slightly increases erythropoietic activity and total hemoglobin mass. Supported by WADA Grant 13D21DS.

3301 Board #206 June 2 3:30 PM - 5:00 PM

Using Polyphenol-Based Soap Ameliorates Eccentric Exercise-Induced Muscle Damage

Bo-Huei Huang, Hsin-Yi Lin, Kuei-Hui Chan, Chi-Huang Huang. National Taiwan Sport University, Taoyuan City, Taiwan. Email: 1040609@ntsu.edu.tw

Reported Relationships: B. Huang: Honoraria; Hong Kong Small Biomolecules Laboratory.

Exercise-induced muscle damage (EIMD) would impair the muscle strength, elevate the activity of creatine kinase (CK), and make individual perceive fatigue. Reactive oxygen species play an important role in EIMD, and supplement with antioxidants might attenuate the undesirable physiological effects. Polyphenols are chemical compounds with antioxidant property extracted from fruit and vegetables. Moreover, studies showed that some kinds of them can be absorbed via skin.

PURPOSE: To determine the effect of using dermal absorbable polyphenol-based soap (PBS) upon EIMD after a single bout eccentric endurance exercise. **METHODS:** Thirteen healthy adults (40±5 yrs) were recruited for a double-blind, cross-over, counter-balanced study. Graded exercise test (GXT) was performed to determine the maximal oxygen consumption (V̇O_{2max}) of subjects one week before eccentric exercise. Thereafter, subjects took a single bout of -5% grade downhill running (DHR) for 60 min at a speed eliciting 75% on a level grade. After the DHR, subjects took showers twice a day (at 12 h intervals) with PBS or commercial neutral soap (CNP) for three days. Before, immediately after, 2 h, 48 h, and 72 h after DHR, capillary fingertip blood was collected and profiles of mood states (POMS) questionnaire were recorded for analyzing the activities of serum CK and the scores of fatigue. Fifteen minutes after blood sampling, isokinetic strength test with 3 maximum voluntary contractions at 150°/s. Data was analyzed by two-way repeated measures ANOVA to compare the differences between treatments and between time points. **RESULTS:** The activities of serum CK were significantly lower in PBS treatment at 48h and 72h after DHR (170±62 U/l vs. 258±146 U/l, 166±67 U/l vs. 287±227 U/l, respectively, $p < 0.05$) when compared to CNP treatment. In PBS treatment, muscle strength at 48h after DHR tended to be larger (133±24 N/kg BW vs. 124±32 N/kg BW, $p = 0.08$) when compared to immediately after DHR. On the contrary, there were no significant differences in fatigue scores between treatments. **CONCLUSION:** Using polyphenol-based soap might attenuate the activities of serum CK after a single bout DHR, and help muscle strength recovery. However, fatigue score of POMS questionnaire didn't reflect this efficacy.

Effect of an Alpha-GPC Supplement on Physical Performance in Division 2 Football Players

Matthew Gage, Kevin Phillips, Byungjoo Noh, Tejin Yoon. Michigan Technological University, Houghton, MI.

Email: mgage@mtu.edu

(No relationships reported)

Previous research relating to Alpha-GPC supplementation and physical performance has been limited to researching Alpha-GPC as a single ingredient supplement. Further research is needed to investigate the effect of Alpha-GPC in combination with other ergogenic ingredients on physical performance. **Purpose:** The purpose of this study was to investigate the acute effect of a supplement on physical performance in Division 2 football players. **Methods:** 14 male Division 2 football players (20.4 ± 1.0 years) participated in a randomized double blind crossover experiment separated by at least 7 days. Subjects were given either supplement or placebo 60 minutes prior to any physical testing measures. Testing consisted of, maximum vertical jumps, maximum voluntary isometric contractions (MVIC), maximal voluntary concentric contractions (MVCC), and fatiguing contractions. Subjects performed 3 maximum vertical jumps with 1-minute rest between jumps. Four MVICs were performed with the knee extensor muscles while seated on a dynamometer at 90° of hip flexion and knee flexion, with 2-minute rest between trials. Seven sets of 2 MVCCs at various loads (1 Nm; 10%, 20%, 30%, 40%, 50% and 60% MVIC torque) were completed with 30-seconds of rest between each set. During the fatiguing tasks, 120 MVCCs (4 set x 30 reps) were performed with a load equivalent to 20% MVIC through 60° range of motion. Recovery measures consisting of one MVIC and 7 MVCCs were taken 10 minutes post completion of fatiguing task. **Results:** MVIC torque was similar between supplemental and control sessions (243.6 ± 41.1 vs. 240.2 ± 29.7 Nm, respectively, $P = 0.34$). Rate of torque development (highest slope of torque during the first 400 ms during MVIC) was greater for the supplement than the control session (1801 ± 336 vs.

1720 ± 346 Nm/s, respectively, $P=0.03$). Impulse for all MVIC significantly increased at time points 30, 50, 100 and 200 ms during the supplemental session ($P<0.05$). No significant differences were found in vertical jump, power and fatigability between sessions. **Conclusion:** Although maximal strength, power and vertical jump did not improve with supplementation, the significant increases in rate of torque development and impulse could be beneficial for a variety of athletes.

Dietary Anti-oxidant Cocktail Supplementation Against Metabolic And Functional Alterations Induced By Physical Inactivity In Humans

Anthony DAMIOT. *IPHC - CNRS, STRASBOURG cedex 02, France.*

Email: anthony.damiot@gmail.com

(No relationships reported)

PURPOSE: Recent studies showed several nutrients taken individually, i.e. resveratrol, quercetin, ω -3 fatty acids, vitamins and others, partially prevent metabolic alterations induced by physical inactivity. We hypothesized additive effects will be obtained when these nutrients are taken as a cocktail. In a pilot study, we tested the efficacy of such a cocktail, composed of polyphenols (530mg/d), ω -3 (2.1g/d), selenium (80 μ g/d) and vitamin E (168mg/d) during 20 days of enforced physical inactivity coupled during the last 10 days with fructose supplementation (3.5g/kg/d) to trigger metabolic deterioration. **METHODS:** Twenty healthy active (14000 steps/d measured by accelerometer) young men, randomized in a control ($n=10$) and a cocktail supplemented group ($n=10$), were asked to stop exercise and reduce their daily physical activities (2800 steps/d). Body composition, glucose tolerance, substrate oxidation, blood anti-oxidant capacities and *v. lateralis* muscle biopsies were assessed before and after intervention. Analyses used linear mixed models taking into account repeated measures. **RESULTS:** Twenty days of deconditioning reduced by 20% total and type 2-myosin heavy chain cross sectional areas in the control group that was prevented in the supplemented group ($p<0.01$ for both). While insulin sensitivity was only modestly affected in the two groups, plasma adiponectin was higher in the supplemented than in the control group at the end of the intervention ($p<0.05$). The supplementation counteracted the increase in fasting plasma triglycerides ($p<0.02$) and HDL ($p<0.0001$) induced by reduced activity, was associated with greater fat oxidation ($p<0.02$) and higher muscle FATP1 protein content. The supplemented group had higher blood anti-oxidant capacities ($p<0.01$). **CONCLUSION:** These results are very promising as they can have a number of scientific and clinical implications for both the general sedentary populations and hospitalized bed rested patients.

3304 Board #209 June 2 3:30 PM - 5:00 PM
Folic Acid-layered Double Hydroxide (LDH) Nanoparticles To Improve Endurance Capacity In Mice

Qin Lili, Hui Juan, Lu Tianfeng, Feng Linlin, Sun Jingyu, You Songhui. *Tongji University, Shanghai, China.*

Email: qinlili@tongji.edu.cn

(No relationships reported)

PURPOSE: Folic acid possesses a significant antioxidant effect and reduces oxidative stress. Folic acid-layered double hydroxides (LDH) nanoparticles have been successfully prepared in our previous study. In this study, we determined whether folic acid-LDH nanoparticles could improve the endurance capacity in mice, the increase the anti-fatigue and anti-oxidation effect. **METHODS:** Sixty mice were randomly divided into six groups with ten mice each: two control groups, two folic acid treatment groups, and two folic acid-LDH treatment groups. Endurance was measured on a treadmill enclosed in a plexiglass chamber that was outfitted with a shock grid at the rear of the belt to keep the animal running during the test. For the folic acid, folic acid-LDH and control mice groups, the speed was first set at 15 m/min with a 5 incline. The speed was then gradually increased from 15 to 24.6 m/min and was maintained at 24.6 m/min until exhaustion. The creatine kinase (CK) and lactate dehydrogenase (LDH) activities in blood were determined using commercial diagnostic kits. The antioxidative enzymes superoxide dismutase (SOD), catalase (CAT) glutathione peroxidase (GSH-Px) and activities were determined using assay kits. **RESULTS:** In the treadmill test, folic acid-LDH treated mice could prolong the running time by 25% and 49% compared to folic acid and control groups, respectively. Additionally, plasma creatine kinase (CK) levels of exhausted mice were significantly lower in the folic acid-LDH treated group ($P < 0.05$). While lactate dehydrogenase (LDH) level of mice was significantly increased for folic acid-LDH mice ($P < 0.05$). It also improved the endogenous cellular antioxidant enzymes in mice by increasing the activities of SOD, CAT and GSH-Px. Therefore, folic acid-LDH nanoparticles could significantly improve the endurance capacity in mice; it also can alleviate fatigue of the mice and had an anti-oxidative effect. **CONCLUSION:** These results imply that folic acid-LDH antioxidant system increases the endurance capacity and facilitates recovery from fatigue. It might be used as a novel antioxidant and anti-fatigue sports nutritional supplement. Future work will focus on the study of antioxidant and anti-fatigue mechanisms at the molecular level.

Effects Of Calcium & Magnesium Lactate Supplementation On Vo2peak & OBLA

Aaron Russ, Albino Schifino, Zachary McCulloch, Jason Melnyk, Kimberly Kostelis, Chee-Hoi Leong. *Central CT State University, New Britain, CT.*

Email: russ@my.ccsu.edu

(No relationships reported)

Professional and recreational athletes use nutritional ergogenic aids to enhance aerobic performance, facilitate training adaptations, and reduce exercise recovery time. While the use of sodium bicarbonate and beta alanine as ergogenic aids have been investigated extensively, support for the use of calcium and magnesium lactate supplementation to improve aerobic performance has been mixed. To the best of our knowledge, the effectiveness of calcium and magnesium lactate supplementation on aerobic performance markers (i.e., VO_{2peak} and the onset blood lactate accumulation) has not been investigated. **PURPOSE:** The purpose of this study was to examine the effect of calcium and magnesium lactate supplementation on VO_{2peak} and the onset blood lactate accumulation (OBLA). **METHODS:** Eighteen healthy individuals (24±5 yrs) participated in a double-blind, placebo controlled study and randomly assigned to one of 2 groups: placebo (PLA, $n=8$), or supplement (SUP, $n=10$). Prior to and following supplementation, participants performed a graded exercise test on a cycle ergometer to volitional failure. VO_{2peak} , time to exhaustion (TTE), OBLA power, heart rate (HR) at OBLA, VO_2 at OBLA, and rating of perceived exertion (RPE) at OBLA were determined. 2×2 mixed repeated measures analysis of variance (ANOVA) procedures were performed to determine differences in group and time. **RESULTS:** There were no significant differences between PLA and SUP in direct markers of aerobic performance (all $P>0.05$; Table 1). **CONCLUSION:** Lactate supplementation did not present an advantage over a placebo in improving aerobic performance in healthy individuals. The results from this study support those by previous investigators suggesting that there is no physiological rationale for using lactate supplementation to improve performance. Consequently, athletes should explore the use of alternative and/or well-established forms of ergogenic aids to extend the limits of sports performance.

Astaxanthin Formulation Induces Muscle Strength and Endurance Increases Beyond High Intensity Training in Elderly Subjects

Sophia Z. Liu¹, Amir Ali¹, Matt VanDoren², Baback Roshanravan¹, Eric Shankland¹, Kevin Conley¹. ¹University of Washington, Seattle, WA. ²Fred Hutch Prevention Center, Seattle, WA.

Email: sophia21@uw.edu

Reported Relationships: S.Z. Liu: Contracted Research - Including Principle Investigator; AstaMed.

Purpose: Reduced muscle strength and endurance is strongly associated with functional decline in older adults. We conducted a randomized, double-blind, placebo-controlled trial of the impact of daily oral astaxanthin treatment with high intensity interval training (HIIT) in the elderly. Astaxanthin is a natural product that combined with vitamin E has both anti-inflammatory and anti-oxidant properties that may improve muscle adaptation to exercise training in the elderly. **Methods:** Healthy males and females ($n=44$), age 65-82 yrs, undertook 3 months (3x/week for 30 min) of HIIT using an incline treadmill protocol (target 85% HRmax). Participants were randomly assigned to formulation (astaxanthin; 12 mg/day and vitamin E; 10 mg/day) or placebo groups. Tibialis anterior muscle (TA) strength and endurance were measured in an exercise tolerance test to fatigue using dorsiflexion exercise. Treadmill and 6-minute walking tests were also performed. **Results:** TA muscle maximal force (MVC) increased by 11% only in the astaxanthin group ($\Delta 8.7 \pm 4.0$ N mean \pm SEM, $P=0.029$). Improvement in TA exercise endurance were found only in the supplemented group as measured by an increase in total contractions of 46% ($\Delta 192 \pm 79$ contractions, $P=0.015$) and in total force generated by 28% in the exercise test ($\Delta 77 \pm 26$ N, $P=0.004$). Similar improvements in treadmill exercise time, exercise efficiency, VO_{2peak} (Balke method), and reduced respiratory exchange ratio in addition to greater 6 minute walking distance were observed in both groups ($P<0.025$ for all). **Conclusion:** In healthy elderly, astaxanthin improved TA muscle strength and endurance with HIIT significantly more than placebo. These results suggest that the anti-inflammatory and anti-oxidant properties from the astaxanthin formulation enhance training adaptations in elderly subjects. An important impact of these findings is the potential to improve exercise tolerance with less frequent or intense training in elderly subjects. Supported by AstaMed NIH/NIA T32 AG000057

Evaluating a Second Generation Phytochemical Nrf2 Activator on Proteostasis and Cytoprotective Gene Expression in Vivo
 Jaime L. Laurin, Justin J. Reid, Gaia R. Bublitz, Frederick R. Peelor, III, Benjamin F. Miller, FACSM, Karyn L. Hamiton, FACSM. *Colorado State University, Fort Collins, CO.*
 (No relationships reported)

Aging is associated with increases in oxidative stress. Redox imbalance occurs when production of reactive oxygen species (ROS) exceeds the capacity of antioxidant enzymes to eliminate ROS. Increased levels of intracellular ROS can compromise proteostasis by causing irreversible damage to proteins. The transcription factor nuclear factor erythroid-derived 2-like 2 (Nrf2) mediates the cellular endogenous antioxidant defense system by regulating antioxidant enzymes that are cytoprotective against ROS. Nrf2 can be activated phytochemically through the supplement Protandim. Previous work from our lab has demonstrated that a phytochemical based Nrf2 activator improves proteostasis in skeletal muscle in vivo. Recently, we have begun to characterize a second generation Nrf2 activator (PB125) that has increased anti-inflammatory action in addition to anti-oxidant properties. Since inflammation can blunt protein synthetic responses, we speculated that PB125 might provide additional benefits on proteostatic processes. **PURPOSE:** The purpose of the present study was to examine in vivo the effects of three different doses (10, 100, and 300 ppm) of PB125 supplementation on Nrf2 activation and proteostasis. **METHODS:** 60 male CB6F1 mice aged 10-11 months were assigned to diets containing low, medium, or high doses of product PB125 in a 5 week feeding study. Mice were isotopically labeled with 8% deuterium oxide (D₂O) to simultaneously measure protein and DNA fractional synthesis rates (FSR) in liver, heart, and skeletal muscle. Nrf2 activation was assessed through analysis of gene expression profiles via Affymetrix GeneChip microarray. **RESULTS:** Proteostatic mechanisms were increased in the liver mitochondrial fraction in the 10 ppm treatment group (18.9 vs 16.3 FSR%/day, p<0.05). However, there were no differences in proteostatic mechanisms in heart or skeletal muscle. At 100 ppm, there was up-regulation of Nrf2-dependent cytoprotective genes (Akr1d1, Gpx2, Gclm, Fth17b, 3.82, 1.84, 1.42, 1.64-fold increase). **CONCLUSION:** From our data we were able to conclude that all three doses were safe, and that 100 ppm was effective at activating Nrf2. In addition, there was an indication of increased proteostatic processes in the liver, but not heart or skeletal muscle, perhaps due to the healthy status of the mice.

The Effects of Vitamin D3 on Musculoskeletal Performance in College Aged Males
 David Bellar¹, Kellie Murphy¹, Gregory Davis¹, Lawrence Judge², Randy Aldret¹. ¹University of Louisiana at Lafayette, Lafayette, LA. ²Ball State University, Muncie, IN.
 Email: davidbellar@mac.com
 (No relationships reported)

Vitamin D (Vit D) plays an important role in the musculoskeletal system and additionally can be deficient in some segments of the population. **PURPOSE:** The present study examined the effects 4 weeks of Vit D supplementation versus placebo on musculoskeletal and psychomotor performance. **METHODS:** The participants were 32 college age males (Age: 22±4 y, Height: 177.7±8.3 cm, Weight: 81.5±14.6 kg, BF%: 19.6±7.9, Vit D: 20.0±7.2ng/ml). Participants were randomly assigned to group (Vit D vs placebo) and remained blind to the treatment throughout the study. The treatments consisted of 4000 IU of Vitamin D3 or similarly sized placebo (dextrose) administered daily for 4 weeks. The participants underwent baseline testing for isometric strength, explosive ability and psychomotor performance, which was repeated at week 2 and week 4. Isometric tests consisted of an isometric mid thigh pull (IMTP) on a force plate and an upper body isometric test (UBIST) using a load cell. Peak force during a countermovement jump (CMJ) was also determined via force plate. A psychomotor vigilance test (PVT) was used to measure sustained reaction time. **RESULTS:** For UBIST there was a significant effect of group (F=4.52, p=0.04) but not a significant group*time interaction (F=0.18, p=0.84; Vit D pre: 553.7±168.3N, post: 585.5±150.2N; Placebo pre: 677.7±182.3N, post: 649.8±236.9N). For IMTP no significant effect of group (F=0.92, p=0.34) nor significant group*time interaction (F=0.17, p=0.83; Vit D pre: 2596.4±342.3N, post: 2606.9±378.3N; Placebo pre: 2684.0±432.9N, post: 2762.6±440.4N) was found. CMJ analysis did not reveal a significant main effect for group (F=0.75, p=0.39) or interaction effects for group*time (F=1.63, p=0.21; Vit D pre: 4429.7±1619.0N, post: 4938.5±2374.8N; Placebo pre: 5537.3±3027.0N, post: 6266.9±4577.3N). For PVT (mean reaction time) there was no significant main effect for treatment (F= 1.29, p=0.29) or interaction effects for group*time (F= 1.08, p=0.35; Vit D pre: 0.304±0.041sec, post: 0.301±0.053sec; Placebo pre: 0.295±0.044sec, post: 0.284±0.029sec). **CONCLUSION:** Four weeks of Vitamin D supplementation was not effective in increasing musculoskeletal or psychomotor performance in college aged males. Further research is needed to clarify the effect of vitamin D on recreationally active persons.

Abstract: Low back pain (LBP) is a common clinical disease, and most patients require long-term treatment. **PURPOSE:** To observe the change in core stability before and after a 6-week Pilates program in young individuals with low back pain. **METHODS:** Twenty subjects with LBP (age: 22±2 years, 11 males and 9 females) completed a 6-week Pilates exercise intervention. Before and after the intervention, the Y-balance test (YBT) and abdomen bridge test (ABT) were used to assess the core stability of the subjects. During the YBT, which measures the dynamic balance and coordination of core and lower extremity, values on three directions (anterior - A, posteromedial - PM, and posterolateral - PL) of both sides and the difference value(D-value) between the two sides were determined. During the ABT, which measures the core control ability and includes eight levels, the attained level and endurance time of every level were measured. Paired t-tests were performed to compare results before and after the intervention. **RESULTS:** After the 6-week intervention, compared with the baseline values, there were significant improvements in all three directions of the YBT (see table). Specifically, the overall performance score increased significantly on both sides (both p<0.05). Compared with the baseline values, there was an improvement of more than one level and endurance time increased from 95.06±53.50 sec to 117.50±54.99 sec on the ABT (p<0.05). **CONCLUSION:** A 6-week Pilates exercise program improved core stability, as evaluated by YBT and ABT, in young individuals with LBP. Future randomized, controlled studies are needed to confirm these findings.

Microvascular Circulation in Mouse Leg Muscles After A Contusion Injury Examined By Histochemistry Using Lectin
 Hisashi Maeda, Tomoyuki Kurose, Seiichi Kawamata. *Hiroshima University, Hiroshima, Japan.*
 Email: hisashi.gogo.tf@gmail.com
 (No relationships reported)

Traumatic muscle injury can lead to microvascular perfusion failure; however, the effect of muscle contusion on microvascular circulation is not fully understood due to methodological limitations. We studied microvascular circulation in injured skeletal muscles after a contusion injury by histochemistry using Lycopersicon esculentum lectin. **PURPOSE:** To examine the acute effects of contusion injury on microvascular circulation in mouse leg muscles. **METHODS:** Eighteen ICR male mice (39.0 ± 2.9 g) aged 8 and 9 weeks old were used. Microvascular circulation in leg muscles was examined immediately (n=5), 3 h (n=4), 6 h (n=4) and 24 h (n=4) after contusion injury. Both legs of the mice were injured using a standardized "weight-drop" device with a 250-g weight falling from 15 cm onto the top of the impactor (impact area, radius 6 mm) that directly contacted

the skin over the posterior leg muscles. After the contusion, mice were allowed to recover. One mouse was without contusion and was used as a control. Fluorescein isothiocyanate (FITC)-labeled *Lycopersicon esculentum* lectin was injected into the caudal vein and allowed to circulate for 3 min before sacrifice. Endothelial cells of open and functioning blood vessels were labeled by this lectin for 3 min. Leg muscles were removed, frozen and 3 serial cross-sections (10 µm) were obtained from each specimen using a cryostat. Open and functioning capillaries were detected by immunostaining for lectin using one section, while all capillaries were detected by immunostaining for PECAM-1 (CD31) using an adjacent section. The third section was stained with hematoxylin and eosin for histological assessment. Photographs of these sections were carefully compared.

RESULTS: Muscle swelling was observed immediately after contusion. Myofibers were disorganized due to the expansion of interfiber spaces. At 24 h after muscle contusion, disrupted myofibers with infiltrated cells were observed. Some non-flowing capillaries were found within the injured area by immunostaining for lectin from immediately after contusion to 24 h.

CONCLUSIONS: The present study clearly demonstrated non-flowing capillaries within the injured muscle area after contusion injury for the first time by histochemistry. This method is useful for examining microvascular circulation after muscle contusion.

High Concentration CO₂-water Immersion Promotes A Recovery From The Muscle Hardness Induced By Resistance Exercise

Noriyuki Yamamoto, 090-0011¹, Tadashi Wada², Fumiko Takenoya³, Masaaki Hashimoto⁴. ¹Japanese Red Cross Hokkaido College of Nursing, Kitami, Japan. ²Kokushikan Univ., Tokyo, Japan. ³Hoshi Univ., Tokyo, Japan. ⁴Teikyo. Univ. Sci., Tokyo, Japan.

(No relationships reported)

Clinical observations of CO₂-hot spring (CO₂ ≥1000 ppm) immersion revealed the effects, such as an immersed part reddening, skin blood flow improvements, blood catecholamine decrease, etc. In response to the CO₂-water bath, the reduction of sympathetic nerve activity may imply the facilitation of muscle fatigue recovery.

PURPOSE: We investigated whether the immersion of extremities including agonist muscles into artificially made high concentration CO₂-water (CO₂ ≥1000 ppm) influences recovery of muscle hardness in fatigue after resistance exercise. **METHODS:** The healthy male college students (n=11, age; 18-19 yrs, height; 168.6±4.5 cm, weight; 66.2±9.3 kg) participated in this study. The subjects were randomly divided into the CO₂-water foot bath group (n=6) and the tap-water foot bath group (n=5). A laser Blood flow in the immersed skin (BF) and electrocardiogram (ECG) were recorded continuously throughout the experiment. The subjects performed 100 times calf raise resistance exercise and immersed lower legs into tap-water or artificial CO₂-water at 35 °C for 10 minute after exercise. MG dominant muscle hardness was evaluated using ultrasound real-time tissue elastography and visual analog scale in muscle (VAS) at pre-exercise, immediately exercise, after 10 min recovery. The strain ratio (SR) between the MG and a reference material was calculated. **RESULTS:** BF_{min} in the CO₂-water foot bath was significantly higher than in the tap-water foot bath (CO₂-water vs. tap-water, 5.7±2.4 vs. 1.5±0.6 ml·min⁻¹·100g⁻¹, p<0.05). After 10 min recovery, in the CO₂-water foot bath compared with the tap-water, SR significantly decreased quicker (1.37±0.38 vs. 0.62±0.07, p<0.05). In addition, VAS after 10 min recovery became smaller in the CO₂-water than the tap-water (22.2±13.5 vs. 38.8±13.5 mm, p<0.05). **CONCLUSIONS:** The present study suggested that high concentration artificial CO₂-water foot bath may contribute to rapid recovery from the high intensity exercise-induced muscle hardness.

Using DT-MRI and 31P-MRS to Assess Muscle Damage Following Unaccustomed Eccentric Exercise

Wenqian Deng¹, Lu Wang¹, Ping Li¹, Rui Xia², Lei Wang². ¹Chengdu Sport Institute, Chengdu, China. ²Sichuan University, Chengdu, China. (Sponsor: Tongjian You, FACSM)
 Email: deng_wen_qian@163.com

(No relationships reported)

PURPOSE: To detect the musculoskeletal structure and metabolism changes in vivo by diffusion tensor magnetic resonance imaging (DT-MRI) and ³¹P-Magnetic resonance spectroscopy (³¹P-MRS) after a single bout of eccentric exercise.

METHODS: Thirty two male Sprague Dawley rats (body weight 238±15g) were randomly divided into either a sham group (n=8) or a downhill running group (n=24). Rats in the downhill running group ran 120 min on treadmill at a speed of 20 m/min at -16 degrees grade. DT-MRI and ³¹P-MRS were performed in right lower limb at pre-exercise (sham), immediately, 24 hr and 48 hr post-exercise at 7T MR. The MR sequence included RARE T2, RARE T1 and EPI-DTI. MRS observational indices included the peak areas of inorganic phosphate concentration (Pi), phosphocreatine

concentration (PCr) and the ratio of Pi/PCr. The morphological changes were confirmed by histological and immunohistochemical methods. One-way ANOVAs and Tukey's test were used to assess the differences among different time points.

RESULTS: On diffusion tensor tractography images, a single bout of downhill running significantly disrupted muscle fiber structure. The peak areas of Pi were significantly higher after exercise (pre-exercise: 4.1±0.8 mM; 0 hr post-exercise: 4.7±1.4 mM; 24 hr post-exercise: 6.6±1.9 mM; 48 hr post-exercise: 6.1±1.7 mM; all P<0.01). Muscle PCr did not differ between pre- and post-exercise; consequently, Pi/PCr values were significantly higher following EIMD (pre: 0.14±0.05; 0h post: 0.18±0.05; 24h post: 0.22±0.08; 48h post: 0.2±0.08; all P<0.05). According to the histological detection, Z-band streaming was higher post-exercise compared with baseline (all P<0.05). The histopathological indices of damage coincided with changes in DT-MRI parameters of fractional anisotropy and apparent diffusion coefficient.

CONCLUSIONS: The data suggest that exercise-induced muscle damage was accompanied by structural and metabolic alterations in skeletal muscle following a single bout of downhill running. The ability of DT-MRI and ³¹P-MRS to accurately detect these changes *in vivo* makes them promising approaches to evaluate skeletal muscle damage after unaccustomed exercise. Relationship Between Knee Extensor Strength And Dynamic Balance Stability In Partial ACL Injury

Geon Park, Do Kyung Kim, Won Hah Park, Professor. Samsung Medical Center, Seoul, Korea, Republic of.

Email: pk90007@naver.com

(No relationships reported)

PURPOSE: Anterior cruciate ligament (ACL) injury are known to develop muscular weakness in the quadriceps. Also, ligament injuries contribute to loss of stability and function. The purpose of this study was to assess the correlations between dynamic balance stability and isokinetic extensor strength measurements in subjects after partial anterior cruciate ligament injury.

METHODS: We examined 38 men (mean age, 26.3 ± 7.0 years) with partial ACL tear. The isokinetic strength of extensor and flexor muscles was evaluated by using the CSMi isokinetic testing device. The peak torque was determined at speeds of 60°/s and 180°/s. The value of the highest peak torque for each velocity was compared with the uninjured side, and described as a percent of strength deficit. The balance stability was measured with single-leg by using the Biodex Stability System. Correlations between the ability of single-leg balance and knee extensor muscle strength were determined. **RESULTS:** The knee extensor strength deficit of 22.5±18.9% was found in the injured leg that compared to the uninjured leg at 60°/s, and extensor strength deficit was 18.8±17.2% at 180°/s. Single-leg balance stability at 22.1 ±15.8% was required the level of improvement of balance stability. Significant correlations were found between deficient of each extensor muscles in injured knees at 60 and 180°/s and dynamic balance stability (r = 0.61, P = 0.025; and r = 0.58, P = 0.035, respectively).

CONCLUSION: The ability of single-leg balance with injured knees appeared to be influenced by knee extensor muscle strength. The results contribute to the evidence indicating the importance of knee strength for dynamic balance stability for partial ACL injury.

Knee Extensor Strength is Associated with Femoral Cartilage Thickness in Individuals with ACL Reconstruction

Mike N. Vakula, Melissa M. Montgomery, Tyler J. Moffitt, Kevin Choe, Derek N. Pamukoff. California State University, Fullerton, Fullerton, CA. (Sponsor: Dr. Lee Brown, FACSM)

(No relationships reported)

PURPOSE: To (1) determine the relationship between quadriceps function and femoral cartilage morphology in individuals with anterior cruciate ligament reconstruction (ACLR), and (2) compare quadriceps function and femoral cartilage morphology between injured and uninjured limbs.

METHODS: Quadriceps function and femoral cartilage was assessed with unilateral ACLR in 20 subjects (women=15, age= 22.3±3.3years, time since ACLR=44.9±32.8 months). Quadriceps function was assessed using peak isometric knee extension torque (PT) and rate of torque development (RTD) at 45 degrees of knee flexion, and peak isokinetic knee extensor torque at 60, 180 and 240°/sec. Femoral cartilage morphology (area and thickness) were obtained via ultrasound imaging at 140° of knee flexion. Partial correlations were used to evaluate the associations between indices of quadriceps function, and cartilage area and thickness accounting for time since reconstruction. Paired samples t-test were used to evaluate interlimb differences.

RESULTS: The ACLR limb produced smaller isometric peak torque (2.56±0.42 vs. 2.75±0.30 Nm/kg, p=0.04), slower isometric rate of torque development (38.12±13.27 vs. 47.81±17.99 Nm/sec/kg, p=0.03), and isokinetic peak knee extensor torque at 60°/sec (2.38±0.54 vs. 2.80±0.63 Nm/kg, p≤0.01) compared to the uninjured limb.

No differences were found in isokinetic peak torque at 180 or 240°/sec ($p=0.06$ and 0.60 , respectively). After accounting for time since ACLR, a positive association was found between isometric peak torque and medial femoral cartilage thickness ($r=0.41$, $p=0.04$).

CONCLUSIONS: The ACLR limb demonstrated deficits in quadriceps function. We found a moderate association between isometric peak torque and medial femoral cartilage thickness. Our results suggest that restoring quadriceps strength may delay femoral cartilage thinning following ACLR.

Musculoskeletal Pain as Predictors of Health Behavior: Implications for an Ergonomic Intervention

Pouran Faghri, FACSM, Carnisha M. Gilder, CPHNEW Team.
University of Connecticut, Storrs, CT.
Email: carnisha.gilder@uconn.edu
(No relationships reported)

Background: Work-related musculoskeletal disorders (WMSDs) are significant problems in the workplace that are extremely costly to employees, employers, and society. One of the most common symptoms of WMSDs is musculoskeletal pain which has been associated with detrimental effects to health behaviors including a decrease in physical activity levels. Lower levels of physical activity have been associated with elevated levels of obesity which increases the risk for the negative health consequences associated with a higher BMI.

Purpose: To compare the prevalence of obesity, musculoskeletal pain, and the difficulty to engage in physical activity of Correctional Officers (COs) to the U.S. adult general population at two time points. Furthermore, to explore the associations between musculoskeletal pain and health behaviors amongst COs.

Design: Seventy-seven Correctional Officers from two maximum security correctional facilities in the Northeastern United States were enrolled in the study. The health profiles (musculoskeletal pain, difficulty to engage in physical activity, and BMI characteristics) of participants were collected at two time points (Time 1 (2011) and Time 2 (2013)) and compared to the U.S. adult general population. The health profiles of COs were also used to investigate associations between musculoskeletal pain and the difficulty to engage in physical activity at two time points. Also to explore if musculoskeletal pain at Time 1 predicts the difficulty to engage in physical activity at Time 2.

Results: Correctional employees exhibited a significantly higher prevalence of overweight and obesity, musculoskeletal pain, and difficulty to engage in physical activity than the U.S. adult general population at both time points ($p<.05$). Musculoskeletal pain was associated with a difficulty to engage in physical activity at both time points ($p<.05$). Musculoskeletal pain was predictive of the future difficulty to engage in physical activity ($p<.05$).

Conclusions: As a result of the musculoskeletal pain, COs report difficulties to engage in physical activity. The results of this study provide a rationale for the implementation of feasible ergonomic interventions in the environment of corrections to alleviate musculoskeletal pain and improve the health behaviors of COs.

Effects Of Methol Gel On Delayed-Onset Muscle Soreness (DOMS) In Sedentary Young Adults

Michael E. Rogers, FACSM¹, Jolaolu M. Jimoh¹, Sri Valli Chekuri¹, Duane C. Button². ¹Wichita State University, Wichita, KS. ²Memorial University of Newfoundland, St. John's, NL, Canada.
Email: michael.rogers@wichita.edu
(No relationships reported)

Delayed-onset muscle soreness (DOMS) is common 24 hr after engaging in resistance training. Topical analgesics containing menthol are often used to treat DOMS but little is known about their effectiveness. **PURPOSE:** To determine how long menthol gel may reduce pain associated with DOMS. **METHODS:** Sedentary young men ($n=3$) and women ($n=6$) (age = 23.9 yr; wt = 70.1 kg) participated in the study and were instructed to refrain from exercise and consuming or applying any type of anti-inflammatory medication 24 hr before, and throughout the duration of, the study. After determining 1-RM, participants performed 10 sets of 10 repetitions of barbell back squats at 60% of their 1RM to elicit DOMS. Squats were performed to a predetermined depth using stacked 5-cm spacers so the femurs were parallel to the floor at the end of the eccentric phase. 24 hr later, a gel containing 4.0% menthol was applied (1ml of gel per 200 cm² of surface area) to one quadriceps and the same dose of a menthol-scented placebo gel was applied to the other quadriceps. Application was randomized to each leg and participants were blinded to the gel identity. Prior to application, participants rated pain in each leg using a scale ranging from 0 (no pain) to 10 (pain as bad as it could be). Following application, participants completed this rating scale every 30 min for 8 hr. **RESULTS:** Pain was reported to be exactly the same for both legs at 24 hr (6.67 - severe pain). After application of the menthol gel, pain declined ($p<0.05$) to a minimum at 60 min (pain rating = 5.28; 21% decline) that was classified as moderate

pain. Although pain tended to increase after 1 hr, pain remained less ($p<0.05$) than placebo for 5 hr. **CONCLUSION:** A 4.0% menthol gel reduces DOMS-related pain by ~20% 60 min after application in sedentary young adults and then a lower plateau of pain perception is achieved for 5 hr following application. Our previous study using the same protocol with recreational athletes who had lower ($p<0.05$) levels of pain (4.65) 24 hr after exercise also reported maximum pain relief 1 hr after application. Although a 31% relative decline, their absolute pain scores declined similarly (1.4 points) compared to the current study. Further research is needed to determine whether declines in pain can be attained in less time and/or if a greater decline can be achieved. Supported by Performance Health.

Exercise Intervention Effects On Winged Scapula And Postural Pain: A Case Study

Emily Mulcahy, Cody Baglow, Melissa W. Roti, FACSM.
Westfield State University, Westfield, MA.
(No relationships reported)

Researchers have shown that more than 80% of the American workforce has a sedentary lifestyle that can leave people sitting for upwards of 10 hours a day (OECD, 2014). In turn this has a negative influence on posture and back pain. "Molly", a 52 year-old, sedentary individual that has experienced right subscapular pain due to her posture, had developed protracted shoulders and winged scapula. Molly volunteered to take part in an 8-week Community Fitness Partner program as part of Westfield State University's Exercise is Medicine on Campus intervention. A student trainer developed an 8-week total body exercise prescription. **Purpose:** The purpose of the study was to determine if resistance training postural exercises (RTPE), stretches, and self-myofascial release (SMR) could be used to counteract the protracted shoulder posture resulting in her upper back pain. RTPEs have been shown to help healthy population to neutralize the shoulder girdle and improve the overall health of the upper extremity. **Methods:** Initial meetings included goal setting and fitness screening. Subject characteristics include: Height= 1.74m, Body Mass=65kg, BMI=22.4, Resting HR=68bpm, Resting BP= 115/70mmHg and FMS shoulder mobility of left arm grade III and right arm grade II. The program included RTPE, stretching, SMR, and cardiovascular training. After each workout specific exercises, stretches and/or SMR modalities were performed to target her upper back and pectoral area to help with shoulder girdle imbalances. Pre and posttest measures included assisted push-ups, curl ups, and self-awareness of back pain. **Results:** Molly's upper body strength increased from 19 assisted pushups to 35, Curl-ups improved from 23 to 42. Improved alignment of her shoulders were observed in an axillary line with her ear and superior iliac crest. Additionally, she reported changes that included: an increase in overall mood, more energy, reduced upper back pain, improvement in body image and fewer aches throughout the day. **Conclusion:** An 8-week training program consisting of resistance training and specific postural exercises can effectively improve posture and decrease upper back pain. Through a multimodal approach, including strengthening and lengthening of muscles and tendons, posture can be improved which may lead to a decrease in pain.

Comparison of Knee Strength And Stability In Primary And Revision Acl Reconstruction

do kyung kim, Geon Park, Won Hah Park. *Samsung Medical Center, seoul, Korea, Republic of.*
Email: hrmax1@naver.com
(No relationships reported)

PURPOSE: The number of primary anterior cruciate ligament (ACL) reconstructions has increased in parallel with graft failures, with a resultant effect on revision surgery. Primary ACL reconstruction is successful for most patients, but some have had persistent giving-way symptoms and recurrent ruptures, such that revision surgery is required. Knee strength deficits are among the consequences of muscle weakness after ACL reconstruction. This study compared knee strength and stability in primary and revision ACL reconstruction.

METHODS: This was a cross-sectional study with a total of 78 participants, in whom 38 revision surgeries were performed at a single hospital between April 2013 and May 2016. All revision reconstructions used tibialis anterior tendon allografts. Forty patients underwent primary ACL reconstruction using double-looped semitendinosus and gracilis autografts. Strength and stability results were compared in primary and revision ACL reconstruction. All participants were measured with an isokinetic device to assess the main outcome of knee strength; a KT-2000 arthrometer was used to measure anterior laxity. Knee function status was evaluated using International Knee Documentation Committee and Lysholm scores. Knee strength and stability results were compared for primary and revision ACL at 12 months post operatively.

RESULTS: The stability results with revision surgery were inferior to those with primary reconstruction (1.5 ± 1.1 mm vs. 2.6 ± 1.5 mm; $p = .001$). However, there were no significant differences in knee extensor deficits at 60°/sec or 180°/sec (respectively,

$p = .213, p = .994$) or in flexor muscle strength between primary and revision ACL reconstruction (respectively, $p = .473, p = .609$). The statistical comparison of functional scores in primary and revision surgery showed no significant differences. **CONCLUSIONS:** Knee extensor deficits and flexor muscle strength show no differences in a comparison of revision and primary ACL reconstruction. However, the results for stability were inferior to those of primary ACL reconstruction.

Threshold Number Of Low-intensity Eccentric Contractions Of The Elbow Flexors To Induce Muscle Damage

Trevor C. Chen¹, Ming-Ju Lin², Hsin-Lian Chen², Kazunori Nosaka³. ¹National Taiwan Normal University, Taipei City, Taiwan. ²National Chiayi University, Chiayi County, Taiwan. ³Edith Cowan University, Joondalup, WA, Australia.
 Email: tcchen@ntnu.edu.tw
 (No relationships reported)

No indication of muscle damage is evident after 30 or 60 low-intensity (10% of maximal voluntary isometric contraction strength: MVC) eccentric contractions (LIEC) of the elbow flexors (EF; Chen et al., 2012) or the knee flexors and extensors (Chen et al., 2013, 2015). Nosaka & Newton (2002) reported that a large number of LIEC of the EF (lowering a dumbbell of 9% MVC 1800 times) resulted in significant changes in MVC torque, range of motion (ROM), upper arm circumference, muscle soreness (SOR) and plasma creatine kinase (CK) activity lasting for 4 days post-exercise. It appears that LIEC induce muscle damage when the number of contractions exceeds a certain level, but the level has not been determined. **PURPOSE:** This study investigated the threshold number of LIEC of EF resulting in significant changes in indirect muscle damage markers. **METHODS:** A pilot study showed no indication of muscle damage after 480 LIEC, but muscle damage markers changed significantly after 960 LIEC. Thus, the present study focused the number of contractions between 600 and 960. Fifty-two young men who had not performed resistance training were recruited and assigned randomly to one of the four groups ($n=13$ per group) based on the number of LIEC performed in the exercise in which a dumbbell set at 10% was lowered repeatedly either 600, 720, 840 or 960 times by the non-dominant arm. Maximal voluntary concentric contraction torque (MVC-CON), ROM, SOR, CK activity and echo-intensity (EI) were measured before, immediately after and for 5 days post-exercise, and their changes were compared among the groups. **RESULTS:** The 600, 720 and 840 groups showed significant ($P<0.05$) decreases in MVC-CON (8-10%) and ROM (2-3%) immediately post-exercise only, without changes in SOR, CK and EI. All variables changed ($P<0.05$) for the 960 group (peak change, MVC-CON: -18%, ROM: 3%, SOR: 20-mm, CK: 410%, EI: 8%) lasting for 3-4 days post-exercise. **CONCLUSIONS:** These results show that no muscle damage is induced when the number of LIEC is less than 840 for EF. It is interesting to investigate further what changed between 840 and 960 contractions to make the muscles susceptible to muscle damage. Supported by MOST, TAIWAN (MOST105-2410-H-003-052-MY3).

Circulating Mitochondrial Damage-Associated Molecular Patterns (mtDAMPs) Following Skeletal Muscle Contraction-Induced Injuries: Pilot Endpoint PCR Studies

Chad Markert, Michael McKenzie, FACSM. Winston Salem State University, Winston Salem, NC. (Sponsor: Michael McKenzie, FACSM)
 (No relationships reported)

PURPOSE: The purpose of these pilot studies is to validate PCR primer sets intended to describe mitochondrial damage-associated molecular patterns (mtDAMPs, which influence the immune system) in human plasma samples, after the muscle injury evoked by extreme exercise, such as a marathon. We hypothesize that circulating concentrations of mtDAMPs—specifically, mtDNA—are elevated post-marathon relative to pre-marathon. With quantitative PCR, evaluation of the change in mtDAMP levels pre- vs. post-marathon is enabled via comparing these levels to an internal reference (“housekeeping”) gene that is unaffected by exercise. **METHODS:** All procedures were IRB approved and all subjects ($n=11$) provided informed consent. Blood was obtained by antecubital venipuncture at baseline and within 48 hours post-race. Blood was centrifuged, plasma aliquotted, and stored at -80°C for further analyses. Plasma DNA was isolated using a commercially available mini kit (Qiagen). Primers for human mtDNA (cytochrome B, cytochrome C oxidase subunit III, NADH dehydrogenase), and bacterial 16S rRNA were synthesized by Eurofins Genomics using published sequences. The human sequences have no significant homology with DNA found in any bacterial species published on BLAST. To determine whether levels of 3 candidate housekeeping genes are consistent pre- vs. post-marathon, the housekeeping primer sequences were added to pre- and post-marathon DNA samples, amplified via thermocycling in routine endpoint PCR, and visualized on 1.5% agarose-

EtBr gels. Amplicons of the mtDNA primer sets were similarly assayed. **RESULTS:** Pilot endpoint PCR studies of 3 candidate housekeeping genes (one primer set for beta-actin, and two distinct GAPDH primer sets) indicate that a specific GAPDH primer set provides data which are unaffected by marathon participation, and also indicate that the pattern of these data is consistent among individuals. Additionally, endpoint PCR validated the mtDNA primer sets. **CONCLUSION:** These pilot studies validated the following human primer sets: Housekeeping gene—GAPDH; cytochrome B; cytochrome C oxidase subunit III; NADH dehydrogenase. Supported by the WSSU Research Initiation Program.

The Effects Of An Ergonomic Mat on Musculoskeletal Symptoms and Health Behaviors

Carnisha M. Gilder, Pouran Faghri, FACSM, Robert Henning. University of Connecticut, Storrs, CT. (Sponsor: Pouran Faghri, FACSM)
 Email: carnisha.gilder@uconn.edu
 (No relationships reported)

Background: Prolonged standing on hard concrete surfaces has been associated with musculoskeletal pain and discomfort of the lower extremities. Musculoskeletal pain negatively affects health behaviors including sleep quality and levels of physical activity. Ergonomics mats have been reported as an effective intervention for reducing the musculoskeletal pain and discomfort of the lower extremities in occupational settings. Understanding the alleviating effects of ergonomic mats on the musculoskeletal symptoms of the lower extremities may aid in the improvement of the musculoskeletal health and health behaviors amongst prolonged standees. **Purpose:** To investigate the feasibility of implementing ergonomic mats in a correctional facility to decrease the perceived musculoskeletal symptoms (pain, discomfort, and fatigue) of the lower extremities amongst Correctional Officers (COs). Furthermore, to evaluate the potential improvement of reported health behaviors (sleep quality, sleep quantity, and physical activity) during the course of an ergonomic mat intervention. **Design:** Seven overweight and obese ($\text{BMI}<25$) Correctional Officers from a correctional facility in the Northeastern United States participated in the 21-day ergonomic intervention. Musculoskeletal symptoms, physical activity levels, and sleep quality were compared with a 2-phase panel evaluation (with and without the ergonomic mat) and a pre-post evaluation. **Results:** The perceived musculoskeletal discomfort and fatigue of the lower back and discomfort of the foot significantly decreased ($p<0.05$) at the follow-up. There were no significant changes in health behaviors. **Conclusion:** Ergonomic mats are practical to implement in correctional facilities. Following implementation, the reported musculoskeletal discomfort and fatigue of the lower back and foot were reduced. Future research should repeat this feasibility study with a larger sample size and longer intervention duration to investigate the effects of ergonomic mats on musculoskeletal health and health behaviors.

The Effect Of Cold Water Immersion Treatment On Inflammation Factor and MMP-1 Releasing In Post-exercise Patellar Tendon

Bo Wang, Sheng Chao Bai, Wen Bo Li, Jiu Xiang Gao, Lin Wang. Beijing Sports university, Beijing, China.
 Email: wangbodc002@163.com
 (No relationships reported)

The patellar tendinopathy is a common overuse injury. After high intensity exercise, patellar tendon tissue releases mass of TNF- α , IL-1 β , IL-6 that induce COX-2 and MMP-1 releasing, which correlate to inflammation and tissue degeneration. Cold water immersion (CWI) therapy has been considered an effective way to reduce the inflammation and injury in muscle tissue. **Purpose:** To determine the effect of CWI on TNF- α , IL-1 β , IL-6, MMP-1, COX-2 releasing and in post-exercise patellar tendon. **Method:** 66 New Zealand rabbits (18 mon, 2.8 ± 0.2 kg) were divided three groups. In high intensity jumping (HIJ) group, 30 rabbits jumped 150 times by low current electrical stimulation, the jumping force were limited between 80-110N. In cold water immersion (CWI) group, 30 rabbits received 15 minutes 4°C CWI treatment on posterior limbs after 150 times jumping. Rest of 6 animals were control (CON) group which identified as baseline. The patellar tendons were harvested at 0 hour, 6 hour, 24 hour, 48 hours after exercise in HIJ group or after treatment in CWI group. TNF- α , IL-1 β , IL-6, COX-2 and MMP-1 mRNA expression assessed by RT-PCR. All the data was analysis by two-way ANOVA with multiple-comparison test. **Result:** IL-1 β mRNA expression reached peak value at the 0 hour (CWI: 22.89 ± 5.48 , HIJ: 20.47 ± 6.24 vs. CON: 0.99 ± 0.40 , $P<0.01$), and no significant different between exercise groups. TNF- α mRNA expression reached peak value at the 0 hour (CWI: 23.21 ± 6.02 , HIJ: 39.30 ± 8.17 vs. CON: 0.63 ± 0.33 , $P<0.01$), and significantly higher in HIJ group at 0 hour (CWI vs. HIJ, $P<0.05$). IL-6 mRNA expression reached peak value at the 0 hour (CWI: 23.49 ± 5.83 , HIJ: 35.40 ± 6.55 vs. CON: 0.73 ± 0.22 , $P<0.01$), and

significantly higher in HIJ group at 0 hour (CWI vs. HIJ, $P < 0.05$). MMP-1 mRNA expression reached peak value at the 6 hour (CWI: 12.10 ± 3.71 , HIJ: 13.31 ± 5.78 vs. CON: 0.99 ± 0.09 , $P < 0.01$), and significantly higher in HIJ group at 0 hour (CWI: 1.40 ± 0.70 vs. HIJ: 8.72 ± 1.18 , $P < 0.05$). COX-2 mRNA expression reached peak value at the 0 hour (CWI: 7.57 ± 2.01 , HIJ: 18.02 ± 4.17 vs. CON: 0.78 ± 0.29 , $P < 0.01$), and significantly higher in HIJ group at 0 hour and 6 hour (CWI vs. HIJ, $P < 0.01$). **Conclusion:** The CWI treatment transiently reduces the inflammation factors, MMP-1 and COX-2 releasing in patellar tendon after exercise.

Altered Joint Loading Affects Cartilage Degeneration and Limb Function in Rats following Knee Meniscal Transection
 Liang-Ching Tsai¹, Elana S. Cooper², Kevin M. Hetzendorfer³, David S. Reece³, Young-Hui Chang³, Caroline R. Waters¹, Robert E. Gulberg³, Gordon L. Warren, FACSM¹, Nick J. Willett². ¹Georgia State University, Atlanta, GA. ²Emory University, Atlanta, GA. ³Georgia Institute of Technology, Atlanta, GA. (Sponsor: Gordon Warren, FACSM)
 Email: ltsai@gsu.edu
 (No relationships reported)

PURPOSE: Either reduced or elevated joint loading has been associated with post-traumatic osteoarthritis (OA); however, which altered loading condition may be more detrimental to cartilage health post-injury remains unknown. This study examined the effects of reduced and elevated joint loading on cartilage degeneration, knee locomotion kinematics, and degree of voluntary activity in rats following medial meniscal transection (MMT).
METHODS: A total of 22 male Lewis rats (weight: 304 ± 57 gm) underwent MMT in their left hind-limbs and were assigned to one of the three conditions: 1) regular loading (N = 7), 2) reduced loading via hind-limb immobilization (N = 8), or 3) elevated loading via daily treadmill running (N = 7). A sham surgery was performed in 7 separate rats. Rats were evaluated pre-MMT and 8 weeks post-MMT for the amount of voluntary daily run time/distance on a running wheel and hind-limb joint kinematics during treadmill locomotion (speed: 30 m/min) using a 3D X-ray motion analysis. Rats were euthanized after 8 weeks and the 3D microstructure and composition of the tibial plateau cartilage and subchondral bone was quantified using contrast-enhanced microcomputed tomography.
RESULTS: When compared to the elevated-loading group at the 8th week post-MMT, the reduced-loading group demonstrated a greater reduction in voluntary run time (47.7 ± 46.8 % vs. 18.0 ± 69.9 %, $P = 0.043$) and distance (57.2 ± 38.3 % vs. 19.7 ± 81.2 %, $P = 0.029$). Cartilage data from 4 rats per group indicated that the elevated-loading rats had the greatest lesion/exposed bone area and subchondral bone volume (0.50 ± 0.35 μm^2 and 1.16 ± 0.24 mm^3 , respectively), followed by the regular-loading rats (0.43 ± 0.19 μm^2 and 1.06 ± 0.22 mm^3) and reduced-loading rats (0.14 ± 0.17 μm^2 and 0.97 ± 0.03 mm^3). All three MMT groups demonstrated a more extended knee position (by about 8-18°) at mid-stance during locomotion when compared to the sham rats.
CONCLUSIONS: Our current findings suggest that while elevating joint loading (via treadmill running) exacerbated post-traumatic OA, reducing joint loading (via joint immobilization) may delay OA progression in MMT rats. However, the difference in cartilage degeneration among different loading conditions may not correlate with the behavior changes in voluntary activity and knee locomotion kinematics.

Prevalence of Joint Pain Before and After Bariatric Surgery and Impact on Physical Activity
 Alexandra Sirois, Ryan E.R. Reid, Kathleen M. Andersen, Nicolas V. Christou, Ross E. Andersen, FACSM, Susan J. Bartlett. McGill University, Montreal, QC, Canada.
 (No relationships reported)

Consistent physical activity (PA) is one of the strongest predictors of successful long-term weight loss maintenance. However, joint pain is common among severely obese patients and is a significant barrier to regular PA. **PURPOSE:** Our goal was to compare the prevalence of hip, knee, and back/other pain before and after bariatric surgery and explore interrelationships among joint pain, BMI, and PA. **METHODS:** Data were drawn from a convenience sample of adults undergoing bariatric surgery at an urban academic center. In a phone survey, participants reported whether they had experienced knee, hip, and/or back/other pain prior to surgery, and changes in joint pain post-surgery. We compared BMI and PA by pain status (improved vs. same/worse) using t-tests and chi-square. **RESULTS:** The 285 participants had undergone surgery a mean (SD) of 10 (3) years earlier. At follow up [FU], participants had an average age of 51 (10), BMI of 34.4 (8.4), and change in BMI of -19.0 (9.4); 191 (68%) had a BMI ≥ 30 . Prior to surgery, 21-45% reported joint pain; at FU, 123 (43%) reported no pain; 80 (28%); 66 (23%); and 16 (6%) reported pain in 1, 2, or 3 joint regions, and 62 (22%) were on NSAIDs or analgesics. Participants who reported having less joint pain had greater reductions in BMI, and a significantly larger proportion reported being

more active than prior to surgery (Table 1). Those with improved knee and back pain were also more likely to meet recommended PA guidelines. **CONCLUSION:** Joint pain was common among bariatric surgery patients and had improved in 34-40% even 10 years later. Improvements in pain were associated with greater reductions in BMI, greater likelihood of being more active, and of meeting PA guidelines. For the >60% with similar/worse joint pain, effective pain management strategies may be needed to facilitate reaching PA goals.

	Improved	Same/Worse	Mean Difference (95% CI)	P value
Knee (n=164)	n=61 (37%)	n=103 (63%)		
Initial BMI	56.3 (11.1)	53.5 (10.2)	2.8 (-3, 6.2)	.098

Best, FACSM², Mazen Ali³, Eric Lespessailles¹, Hechmi Toumi¹. ¹Service de Rhumatologie, Centre hospitalier régional d'Orléans, Orleans University, Orleans, France. ²Department of Orthopedics, Division of Sports Medicine, Miami, FL. ³service orthopédique, CHR Orleans, Orleans, France. (Sponsor: Thomas Best, FACSM)
 Email: hechmi.toumi@univ-orleans.fr
 (No relationships reported)

Importance of subchondral bone in the pathogenesis and management of osteoarthritis retain recently the interest of both clinicians and researchers community. In fact, the integrity of articular cartilage relies on subchondral bone to provide mechanical support and nutrition supply. Herein, we investigated the relation between bone and cartilage structures and the vascular supply in human knee OA. **Methods:** 37 osteoarthritic tibial plateaux were collected after a total knee replacement surgery. Samples from macroscopically different ICRS grades were prepared from tibial plateaux. Sample were scanned using the micro-computed tomography at 10µm resolution (Skyscan 1072, Bruker), projections were reconstructed using the manufacturer software. A manual segmentation has been performed on each sample to separate subchondral from trabecular bone and microarchitectural analysis was performed. The same samples were processed for histology, decalcified in 14% EDTA, sectioned into 4µm slides, coloured with HES and scored into 6 groups, based on histological OARSI score. Subchondral bone surface and thickness and articular cartilage surface were calculated. The number of vessels in the subchondral bone area were visually counted by two different operators and a VEGF immunofluorescent staining was performed. **Results:** bone volume fraction, trabecular thickness, spacing, and number were positively correlated OARSI grades. Also, blood vessels significantly increased from grade 1 to 5 ($p < 0.05$). Yet, in grade 6 they significantly decreased ($p < 0.05$). Yet, they were significantly less vessels in grade 6 compared to grade 5. **Conclusion:** Taken together, our data indicate an interplay and dynamic load-bearing structures between subchondral bone and cartilage. Understanding the signaling pathways, the cartilage-bone biochemical unit in joints and the intercellular communication between cartilage and subchondral bone may lead to development of more effective strategies for treating OA patients.

Early Unloading and Loading Exercises for Preventing Posttraumatic Osteoarthritis after Anterior Cruciate Ligament Injury
 Yanjmaa Erdenekhuyag. Sports medicine, Ulaanbaatar, Mongolia.
 Email: Yanjmaa_oksana@yahoo.com
 (No relationships reported)

How to prevent posttraumatic osteoarthritis remains controversial. However, a suitable unloading and/or loading exercise offers stimulus to reduce articular joint inflammation

and facilitate cartilage regeneration. Continuous passive motion (CPM) and active treadmill exercise (TRE) have been shown to increase cartilage repair in knee stability condition. **PURPOSE:** To understand the protective effects of early unloading CPM, and loading TRE after ACL rupture. **METHODS:** Sixteen adult New Zealand White male rabbits were studied and randomly assigned to two groups: (I) CPM group, rabbits performed the CPM exercise for continuously 7 days post ACLT. (II) TRE group, rabbits performed active treadmill exercise at the third week for two weeks after ACLT. All animals received the ACL transection of right knee. Left knee was for the sham group. All animals sacrificed at 4 weeks after surgery. All knees were taken out for whole knee evaluations including gross appearance, histology, and OA quantitative scores as well as inflammatory reactions. **RESULTS:** Regarding gross appearance, the TRE group had more obvious cartilage abrasion than the CPM group. The CPM group demonstrated the better cartilage smooth than the TRE group. The total OA scores in the TRE group (13.14) were significantly higher than the CPM group (7.88) ($p < .01$). Regarding histological aspect, the TRE group showed the more severe cartilage degeneration, while the CPM group showed no degeneration status. On the basis of H&E and Alcian blue stainings, the TRE group showed much cell disorganized, decreased of cartilage cells, and decreased of GAG. In contrast, CPM had smoother surface of cartilage, retained GAG, cell density and oriented arrangement of chondrocyte, indicating protecting articular cartilage. We also found that the CPM group had the least TNF- α and caspase-3, suggesting anti-inflammation and sound chondrocyte growth. However, the TRE group had the significantly increased TNF- α and caspase-3 ($p < .01$), particularly in superficial and middle layers of the cartilage. **CONCLUSION:** CPM in the early stage after ACL injury provides the protection of cartilage. In contrast, active treadmill exercise may lead to osteoarthritis. CPM after acute ACL injury for short-term articular cartilage protection is beneficial, while TRE should be judiciously applied.

Rock Climbers' Utilization Of Healthcare In The Management Of Hand Injuries

Jillian Gold¹, Keaton Piper¹, Ryan Bodkin², Erik Rueckmann², Camille Martina². ¹University of Rochester School of Medicine, Rochester, NY. ²University of Rochester Medical Center, Rochester, NY.
Email: jillian_gold@urmc.rochester.edu
(No relationships reported)

PURPOSE: Examine rock climbers' behaviors and perspectives on utilizing healthcare systems for climbing-related hand injuries.

METHODS: Participants meeting inclusion criteria were identified at seven climbing locations in the Rocky Mountain and Sierra Nevada ranges. Qualitative data was collected via recorded and transcribed semi-structured interviews. Participants were asked about their healthcare utilization and outcomes for each climbing related hand injury.

RESULTS: Twenty-eight climbers were interviewed, with a lifetime injury burden of 88 climbing specific hand injuries. Forty-six injuries occurred when climbers had health insurance. Of those, 78% did not see healthcare professionals. Rationales for not seeking care included (1) trusting one's own and peers' knowledge, (2) trusting medical advice in climbing media, (3) beliefs the injuries would heal on their own, and (4) concern that healthcare providers lack experience managing climbing specific hand injuries. Lack of proper injury management resulted in repeated injury in 42% of the climbers and lasting pain or deformity in 28%. Ten injuries (11%) were evaluated by primary care providers, hand specialists, and/or physical therapists. Climbers sought medical care due to: (1) repeated or worsening injuries, (2) injury requiring urgent intervention such as joint relocation, and (3) knowing a trusted provider. Four were satisfied with the care they received, four were dissatisfied, and two were indifferent.

CONCLUSIONS: Climbers in our study avoided seeking medical care for their climbing-related hand injuries. They preferred to use knowledge from within the climbing community and media to self-manage hand injuries. There was a thematic trust gap between the climbers and healthcare systems. Further study could elaborate on short and long-term negative outcomes from not seeking care. Secondly, further study could evaluate how healthcare provider knowledge of climbing specific hand injuries could help close the trust gap.

Effects of Athletic Tape, Leukotape P, and Prophylactic Bracing During a Dynamic Postural Control Test
Karlee Burns, Will F.W. Wu, Tiffanye Vargas, Mimi Nakajima.
CSULB, Long Beach, CA.
Email: burns_karlee@yahoo.com
(No relationships reported)

Context: Athletic tape (AT), leukotape P (LEU), and prophylactic ankle bracing (BR) are commonly used in sport activity where dynamic postural control is important in optimal performance. The relationship between balance and these different types of tape and bracing have not been extensively studied. **Purpose:** The purpose of this study was to examine the effect of no intervention (NO), AT, LEU, and BR on modified Star Excursion Balance Test (SEBT) reach distance. **Participants:** Twenty-four healthy volunteers (9 males, 15 females; age: 22.13 \pm 2.37 years; height: 164.99 \pm 8.71 cm; mass: 70.06 \pm 12.42 kg) who were self-reported recreationally active and have not experienced a lower extremity injury in the past six months participated. **Methods:** NO, AT, LEU, and BR were applied during four randomized trials. Reach distance during a modified SEBT were recorded for individual directions and as composite scores for each leg and standardized by leg length. **Results:** One-way repeated measures ANOVA showed a significance F omnibus value between type of tape and reach distance for right composite score, $F(3, 20) = 10.071$, $p = .000$, right anterior reach $F(3, 21) = 7.082$, $p = .002$, and left anterior reach $F(3, 21) = 6.231$, $p = .003$. Post hoc comparisons revealed that AT condition had significantly less right composite score compared to LEU condition; $t(22) = -3.85$, $p = .001$ and BR condition; $t(22) = -4.12$, $p = .000$. Right anterior reach for AT condition was less than NO, $t(23) = 4.179$, $p = .000$ and BR condition, $t(23) = -3.045$, $p = .006$. Left anterior reach for AT was also less compared to NO, $t(23) = 4.579$, $p = .000$; and LEU; $t(23) = -3.690$, $p = .001$. **Conclusion:** AT is often used to address ankle instability, however it may limit dynamic postural control stability. Using other tape or braces may exhibit the same stabilizing effect without impeding dynamic postural control.

Effect of Cold Water Immersion or Contrast Water Therapy on Muscle Soreness After Exercise
Christine Lauber, Shelby Hickle, Jordayn Jargstorf, Casey West.
University of Indianapolis, Indianapolis, IN. (Sponsor: Matthew Beekley, FACS M)
Email: clauber@uindy.edu
(No relationships reported)

Sponsor: Matthew Beekley, FACS M; matthewbeekley@depauw.edu
Tissue damage leads to delayed onset muscle soreness (DOMS), often resulting in pain or discomfort that gradually increases within the first 24 hours post-exercise, and typically peaks at 48 hours post activity. Cold-water immersion (CWI) and contrast water therapy (CWT) are commonly used as interventions for reducing DOMS; however, it remains unclear which treatment is more beneficial. **PURPOSE:** To determine if post-exercise cold-water immersion decreases muscle soreness compared to contrast water therapy at 48 hours post DOMS inducing exercise. **METHODS:** Thirty-nine healthy college student volunteers (20 males; 19 females) with ages ranging from 18 to 23 years ($M = 20.36$; $SD = 1.35$) agreed to perform 5 sets of 20 drop jumps from a 0.6m box to induce DOMS. Subjects identified perceived muscle soreness on a 11-point (0 = no pain; 10 = most intense pain imaginable) numeric pain rating scale (NPRS) measured at baseline, immediately post exercise, and at 24, 48, 72, and 96 hours post exercise. Subjects were randomly assigned to a CWI (10^o C) or CWT (1:1 ratio of 40^o C and 10^o C) intervention up to the iliac crest for 10 minutes immediately, 24, 48, and 72 hours post-exercise. An independent-samples *t*-test was used to compare muscle soreness between groups at 48 hours with an alpha level of 0.05 for statistical significance. **RESULTS:** There was a statistically significant difference in NPRS scores for the CWI ($M = 2.90$, $SD = 1.92$) and CWT ($M = 4.32$, $SD = 2.41$); $t(37) = 2.04$, $p = 0.049$, interventions at 48 hours. Further, Cohen's effect size value was $d = -0.66$. **CONCLUSIONS:** CWI significantly decreased muscle soreness compared to CWT 48 hours post DOMS inducing exercise. CWI can be considered superior to CWT to decrease muscle soreness associated with DOMS 48 hours post-exercise. Additionally, the effect size indicates the intervention had a moderate effect. These results add to previous literature indicating CWI is more effective than CWT to treat muscle soreness.

Can Weakness in End-Range Plantarflexion after Achilles Repair Be Prevented?Karl F. Orishimo, Sidse Schwartz-Balle, Timothy F. Tyler, Benjamin Bedford, Steven J. Lee, Stephen J. Nicholas, Malachy P. McHugh, FACSM. *Nicholas Institute of Sports Medicine and Athletic Trauma, New York, NY.* (Sponsor: Malachy P. McHugh, FACSM)

Email: karl@nismat.org

(No relationships reported)

Purpose

Disproportionate end-range plantar flexion weakness, decreased passive stiffness, and inability to perform a heel rise on a decline after Achilles tendon repair, are thought to reflect increased tendon compliance or anatomical tendon lengthening. Since this was first noted, we have performed stronger repairs and avoided stretching into dorsiflexion for the first 12 weeks after surgery. It was hypothesized that these treatment changes would eliminate end-range plantar flexion weakness and normalize passive stiffness.

Methods

Achilles repairs with epitendinous augmentation were performed on 18 patients. Plantar flexion torque, dorsiflexion ROM, passive joint stiffness, and standing single-leg heel rise on a decline were assessed 43±24 months after surgery (range, 9 months-8 years). Maximum isometric plantar flexion torque was measured at 20° and 10° of dorsiflexion, neutral, and 10° and 20° of plantar flexion. Passive dorsiflexion ROM was measured goniometrically. Passive joint stiffness was computed from the increase in passive torque from 10° to 20° of dorsiflexion measured before isometric contractions. Tendon thickness was measured by digital calipers. Plantarflexor EMG was recorded during strength and functional tests. ANOVA and Wilcoxon tests were used to assess weakness and function.

Results

Marked weakness was evident on the involved side at 20° plantar flexion (deficit 26±18%; $P<0.01$) with no weakness at 20° dorsiflexion (deficit 6±17%; $P=0.39$). Compared to the noninvolved side, dorsiflexion range of motion was decreased 6±8° and tendon thickness was 7±3 mm greater ($P<0.001$) on the involved side. Passive joint stiffness was similar between the involved and noninvolved sides. Only 3 of 18 patients could perform a decline heel rise on the involved side versus 18 of 18 on the noninvolved side ($P=0.01$). There was no difference in EMG amplitude between the involved and noninvolved sides during all tests.

Conclusion

Normalized passive joint stiffness and reduced dorsiflexion ROM were likely due to a stronger, protected repair. EMG data confirmed that end-range weakness was not due to neural inhibition. Weakness with the plantar flexors in a shortened position may be due to inefficient transmission of contractile forces through the thickened tendon when the muscles are in a shortened position.

A Comparison of Two Equipment Removal and Spinal Restriction Protocols on Cervical Spine and Head Motion during Football Player Stretcher TransferTyler Melnicove, Jennifer Kalash, Steven Leigh. *Montclair State University, Montclair, NJ.*

(No relationships reported)

Current research suggests full spinal immobilization is not effective and is potentially harmful during the treatment of spinal injuries. EMS agencies nationwide have adopted new spinal motion restriction protocols in response to these findings. However, these protocols do not account for the protective equipment worn by many athletes. Removing protective equipment from an athlete is necessary for treatment but causes potentially harmful motion of the head and spine. Optimal time on task for equipment removal is also unknown. **PURPOSE:** To compare the differences in time and head/neck kinematics when transferring a football player with a scoop stretcher between full and partial equipment removal. **METHODS:** A stratified sample of twenty students representing a football team (20.8 ± 1.7 years; 1.71 ± 0.12 m; 84.0 ± 15.9 kg). Participants were fitted with football equipment and placed supine. EMS spinal restriction protocols were conducted with helmet and shoulder pad removal (remove) and face mask removal only (keep). Participants were transferred to an ambulance cot with a scoop stretcher. Time to completion, linear/angular head, trunk, cervical spine, and helmet motion were measured in 3-D with an electromagnetic motion tracking system. **RESULTS:** Time on task was twice as fast during keep versus remove (42 s vs 78 s, $p < 0.001$). Cumulative cervical flexion was about 40% less (407° vs 571°, $p = 0.038$) and cumulative cervical rotation was about 50% less (246° vs 378°, $p = 0.026$) during keep versus remove. Cumulative linear head motion was about 1.5 times greater (0.15 m vs 0.35 m, $p = 0.018$) during keep versus remove. Maximum angular and linear motions were similar between conditions. **CONCLUSIONS:** There was considerable head and neck motion during both removal protocols. Motion was cumulatively greater during full equipment removal. Maximum linear and angular head and neck motion was similar between protocols and any deviation from neutral

could put pressure on the spinal cord. Coupled with faster time of task, these findings suggest face mask removal only, before transferring patient to an ambulance cot, is preferred.

Vitamin D3 Supplementation and Stress Fracture Occurrence in High-Risk Collegiate AthletesKevin A. Williams, Christian Askew, Christopher Mazoue, Jeffrey Guy, Toni M. Torres-McGehee, J. Benjamin Jackson III. *Palmetto Health Richland, Columbia, SC.*

Email: kwillmd@gmail.com

(No relationships reported)

Previous vitamin D research analyzes the regulation of calcium and phosphate levels, as well as bone mineralization and turnover. Very little is known about vitamin D's role in the prevention of stress fractures in high level athletes. **PURPOSE:** We aim to investigate vitamin D's role in the prevention of stress fractures in collegiate athletes. **METHODS: Prospective:** 118 NCAA Division I athletes were recruited from the high risk sports of track and field, cross country, soccer, and basketball. Blood samples were procured in August and February to determine fall and spring baseline 25(OH)D levels. Subjects with serum 25(OH)D <30 ng/ml were supplemented with 50,000 IU of vitamin D3/week for 8 weeks. Treated subjects were re-tested to ensure serum 25(OH)D levels rose to sufficient status. All enrolled subjects were monitored for the development of stress fractures.

Retrospective: A retrospective chart review of non-supplemented athletes from the same sports teams was conducted to determine the incidence of any reported stress fractures. **RESULTS: Prospective:** 112 of the 118 enrolled subjects were tested in August. 61 were of sufficient status (40.2 ng/ml ±8.28) and 51 were either insufficient or deficient (22.7 ng/ml ±4.89). 104 of the 118 enrolled subjects were tested in February. 56 were of sufficient status (40.7 ng/ml ±9.47) and 48 were insufficient or deficient (21.6 ng/ml ±5.87). 2 stress fractures were diagnosed in 118 currently enrolled subjects (1.69%).

Retrospective: 34 stress fractures were diagnosed in 453 subjects from 01/2010-05/2015 (7.51%).

CONCLUSIONS: In our population, almost half of the tested athletes proved to be vitamin D insufficient or deficient by the current normative value standards. Despite vitamin D supplementation, hypovitaminosis D was prevalent throughout the winter months. With vitamin D supplementation in this particular year, the stress fracture rate in our particular cohort significantly decreased from 7.51% to 1.65% ($p=0.009$) following vitamin D supplementation.

The knee is one of the most commonly injured body regions, accounting for nearly 15% of all sports-related injuries. Patient-reported outcomes such as the Knee Injury Osteoarthritis Outcomes Score (KOOS) have been used to evaluate changes in function following knee injury. Despite its clinical use, ceiling effects have been found across KOOS subscales in the general population. Ceiling effects diminish the clinical usefulness of the KOOS as function improves during recovery. In patients with a high functional ability, such as athletes, it is likely that this problem is even more pronounced. Evaluating the measurement properties of the KOOS in athletes is necessary to determine its clinical value. **PURPOSE:** To calibrate the 42-item KOOS using the Rasch Rating Scale Model. **METHODS:** One-hundred thirty adults (age 29.63 yrs ± 11.32) completed the KOOS. We used the Rasch Rating Scale Model to examine the KOOS. First, model-data fit was evaluated by examining mean square residuals for each item. Second, item difficulty, and person's level of knee-function was estimated. Third, an item-map distribution was evaluated to determine the distribution of knee-function items compared to the person-ability measures. Lastly, the rating scale was evaluated for proper functioning. **RESULTS:** Overall, model-data fit was poor with mean square residuals outside the acceptable range (≤ 0.5 and ≥ 1.5) for many items. The item difficulties ranged from -3.96 to 0.07 logits, where a higher value represents a more difficult item. However, the mean person ability estimate was 0.0 ± 1.41 logits. The item "Have you modified your life style to avoid potentially damaging . . . your knee" represented the least difficult item, while "Pain with . . . stairs" was the most difficult. Item-map distribution indicated poor item distribution with insufficient items covering higher functioning individuals. In addition, the five-category structure of the KOOS demonstrated poor rating scale function.

CONCLUSIONS: The KOOS has limited measurement capabilities for athletes, as the items do not measure the high end of functional ability. For the KOOS to be clinically applicable to athletes, difficult items should be developed.

Knee Rotation Related to Knee Angle and Applied Torque

Seiya MASEGI. *Niigata University of Health and Welfare, Niigata-shi, Niigata-ken, Japan.*

Email: masegi@nuhw.ac.jp

(No relationships reported)

INTRODUCTION: Rotational knee laxity is known as an intrinsic risk factor for anterior cruciate ligament (ACL) injury. However, there was no convenient way to measure rotational range of motion (ROM). To this end, we developed the RotorMeter, a simple and non-invasive external device intended to measure rotational ROM of the knee, which we reported to be reliable and valid at the ACSM2016 Annual Meeting.

PURPOSE: The purpose of this current study is to use the RotorMeter to clarify the characteristics pertaining to ROM of the knee in healthy subjects under varying conditions.

METHODS: A total of 10 healthy women (20 knees) participated in the study (20.8 ± 1.8 years). Torques of 2.5 Nm, 5 Nm and 7.5 Nm were applied at 90°, 60°, and 30° angles of knee flexion and the examiner's apprehension of End-Point-Feel (EPF) was used to measure full range of motion using the RotorMeter. One-way ANOVA was used for statistical analysis.

RESULTS: Total (internal + external) ROM of each condition is shown on Figure 1. No laterality was observed at any flexion angle and applied torque. When different torques were applied at the same flexion angle, total rotation significantly increased at all flexion angles with increased torque. Furthermore, with regard to EPF, a significant difference was observed only in comparison with 2.5 Nm. When the same torque was applied at different flexion angles, a significant difference was observed only between 90° and 30° when a torque of 2.5 Nm was applied, whereas when torques of 5 and 7.5 Nm were applied, no significant difference in total rotation was observed at any of the flexion angles.

CONCLUSION: Knee ROM increased when greater torque was applied, but it was not affected by the knee flexion angles during the measurement.

This study was supported by a Grant-in Aid Exploratory Research from NUHW (2013-A-30).

Platelet-rich Plasma Injections For Accelerating Treatment Of Hamstring Tear Injuries

Ahmed Gaballah¹, Azza Abdalaziz², Adham Elgeidi³, Naglaa Shkrah², Eadric Bressel⁴. ¹*Damietta University, Damietta, Egypt.* ²*Alexandria University, Alexandria, Egypt.* ³*Mansoura University, Mansoura, Egypt.* ⁴*Utah State University, Logan, UT.*

Email: ahmed.gaballah@aggiemail.usu.edu

(No relationships reported)

Platelet-rich plasma (PRP) is an autologous concentration of human platelets and has been used for treatment of tendon, ligament, and muscle injuries. However, it contains deleterious cytokines and growth factors that can cause fibrosis and inhibit muscle healing. PRP therapy has grown in popularity over the past few years but the effect of the PRP with physical rehabilitation is not clear. **PURPOSE:** To assess the effect of physical rehabilitation with PRP injection on treatment of hamstring strain injuries. **METHODS:** Eight physically active males (age 22.7 ± 3.6 yrs) with acute hamstring strain injuries and nine matched controls (age 21.9 ± 2.8 yrs) were recruited as research participants. Approximately 60 mL of blood was drawn from an antecubital venipuncture then centrifuged to approximately 5-6 mL of PRP by a BioMet System. A single dose of PRP was injected into the biceps femoral muscle using ultrasound guidance after 5-7 days of injury and before an 8 wk rehabilitation program. Before and 48 hrs after the PRP injection, the following blood markers were recorded and compared: Vascular endothelial growth factor (VEGF) (0.346 ± 0.182 vs 1.504 ± 0.463 pg/L), platelet-derived growth factor (PDGF) (0.352±0.11 vs 5.72±1.57 pg/L), and Insulin-like Growth Factor-1 (IGF-1) (0.577±0.28 vs 1.101±0.381) (p < 0.05 for all comparisons). Maximal hamstring force (HF) and knee flexion range of motion (ROM) were recorded after an 8-wk physical rehabilitation program. **RESULTS:** There were no significant differences between the PRP and control groups for HF (105.8 ± 3.18 N vs 107.1 ± 1.64 N; p > 0.6), and ROM (148.6 ± 0.78° vs 147.4 ± 0.88°; p > 0.5). **CONCLUSIONS:** Despite the theoretical benefits of PRP to regenerate muscle tissue and expedite return to activity, results indicated that PRP did not affect HF or ROM values when compared to a control group after 8 wk of physical rehabilitation.

Functional Outcomes of ACL Reconstruction with Tibialis Anterior Allograft, Hamstring or Quadriceps Tendon Autograft

Hande Guney-Deniz¹, Defne Kaya², Mahmut Nedim Doral³. ¹*Hacettepe University Faculty of Health Sciences Physiotherapy and Rehabilitation, Ankara, Turkey.* ²*Uskudar University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Istanbul, Istanbul, Turkey.* ³*Hacettepe University, Faculty of Medicine, Department of Orthopedics and Traumatology, Ankara, Turkey.*

Email: hande.guney@hacettepe.edu.tr

(No relationships reported)

PURPOSE: The quadriceps index is a measure of the relative strength of the involved quadriceps compared to the uninvolved quadriceps. The purpose of this study was to investigate the changes in quadriceps strength in patients undergoing anterior cruciate ligament (ACL) reconstruction using anterior tibial tendon (ATT) allograft and hamstring tendon (HT) and quadriceps tendon (QT) autograft.

METHODS: Fourteen patients (mean age: 26.8±5.8 years, BMI: 22.9±2.4 kg/m²) with ATT allograft and 15 patients (mean age: 27.1±5.4 years, BMI: 23.8±2.8 kg/m²) with HT autograft and 11 patients with QT autograft (mean age: 28.1±4.4 years, BMI: 22.6±3.8 kg/m²) were included in the study. All patients (n=40) were received the same reactive neuromuscular rehabilitation protocol after surgery. Quadriceps strength of the patients was measured at 60°/sec and 300°/sec angular speeds, using the Biodex System 3 (Biodex® Corp., Shirley, NY, USA). Functional outcomes of the lower extremity were measured with hop test and International Knee Documentation Committee Scoring System (IKDC) and the fear of movement was assessed with Tampa Kinesiphobia Scale. All measurements were applied at postoperative first year. Kruskal Wallis test was used for the comparison of variables between groups.

RESULTS: The quadriceps indices were found similar at 60°/sec (p=0.308) and 300°/sec (p=0.716) angular speeds between the groups. There were no differences in IKDC (p=0.237) and fear of movement (p=0.059) scores between groups.

CONCLUSIONS: Patients undergoing primary ACL reconstruction with ATT allograft, HT or QT autografts had satisfactory and similar objective and subjective clinical results. Functional rehabilitation would be the key factor to improve the functional status for different type of graft use in ACL reconstruction patients.

Effects of Tourniquet Use during Total Knee Arthroplasty on Global Cytokine Changes Associated with Ischemia Reperfusion Injury

Timothy R. Macaulay, Brian Wu, Ryan Graff, Ido Badash, Joseph Skeate, Christianne Lane, Ibrahim Mansour, Ravi Rao, Anthony Yi, Jarrad Merriman, George R. Hatch, III, Larry Dorr, Paul Gilbert, E. Todd Schroeder. *University of Southern California, Los Angeles, CA.* (Sponsor: E. Todd Schroeder, FACSM)

(No relationships reported)

Purpose: The use of tourniquets during total knee arthroplasties (TKA) has been debated given the possibility that prolonged application of a tourniquet may result in ischemia-reperfusion injury (IRI), potentially contributing to post-operative muscle atrophy. The goal of this study was to elucidate the influence that tourniquet use may have on the induction of IRI in muscle tissue following TKA surgeries. We hypothesized that tourniquet use during TKA causes larger global increases in pro-inflammatory cytokines, indicating the occurrence of IRI.

Methods: 50 patients undergoing TKA surgeries were separated into 3 groups: no tourniquet (NoT; n=17), operative tourniquet (OT; n=15), and tourniquet during implant cementation (TDC; n=18). Induction of IRI was evaluated by measuring changes in fifteen cytokines present in blood samples collected from an antecubital vein immediately before and after surgery. Pre- to post- surgery changes in cytokine concentrations were compared between groups.

Results: Compared to immediately before surgery, cytokine levels generally decreased after surgery in the NoT and OT groups, but increased in the TDC group. Despite these differences, pre- to post- operation changes in IL-1β, IL-10, IFNγ, IL-4, IL-5, IL-7, IL-8, Eotaxin, IP-10, MCP-1, MIP-1α, MIP-1β, RANTES, and TNFα concentrations were not significantly different between groups. However, significant differences were found for IL-12, a pro-inflammatory cytokine (p=0.01). After surgery, IL-12 concentrations decreased in the NoT (pre: 72.8 ± 89.8 pg/mL, post: 41.3 ± 28.6 pg/mL) and OT (pre: 92.1 ± 142.2 pg/mL, post: 82.9 ± 167.4 pg/mL) groups, and increased in the TDC group (pre: 52.0 ± 85.1 pg/mL, post: 63.0 ± 116.7 pg/mL). However, Cohen's d effect sizes between groups were small (NoT vs OT = 0.08; NoT vs TDC = 0.12; OT vs TDC = 0.18).

Conclusions: Using global changes in pro-inflammatory cytokine levels as an indicator of IRI, these data suggest that the use of a tourniquet does not significantly contribute

to induction of IRI in TKA surgeries. However, additional studies comparing local plasma cytokine changes near the tourniquet site and utilizing larger sample sizes are necessary to determine if tourniquets should be used in TKA without inducing IRI.

To What Extent is Weakness after ACL Reconstruction due to Central Inhibition versus Muscle Atrophy? A Magnetic Stimulation Study.

Takumi Fukunaga, Malachy P. McHugh, FACSM, Christopher D. Johnson, Stephen J. Nicholas. *Northwell Health Lenox Hill Hospital, New York, NY.* (Sponsor: Malachy P. McHugh, FACSM)
 Email: tfukunaga@northwell.edu
 (No relationships reported)

PURPOSE: Quadriceps weakness is common after ACL reconstruction. Studies using electrical stimulation suggested that limited central nervous activation may have a role in the weakness. The purpose of this study was to test for deficits in quadriceps strength and activation, using magnetic stimulation, in patients at 3 mo and 6 mo post ACL reconstruction.

METHODS: Ten patients (7M/3F; age 34.7±8.3 yrs; BMI 26.0±4.8 kg/m²) who had ACL reconstruction with BPTB autograft were recruited. Patients underwent standard physical therapy after surgery. At 3 and 6 mo post-op, patients' knee extension maximum voluntary isometric contraction (MVIC) was measured. All tests were done bilaterally at 30° and 65° of knee flexion on a dynamometer. MVIC was augmented with a superimposed burst magnetic stimulation to the femoral nerve. The stimulator coil was placed over the femoral nerve and a 3-sec, 35-Hz pulse train was delivered at 100% intensity after 2 sec of MVIC. Peak torque before (T_{pre}) and after (T_{post}) stimulation delivery was measured, and central activation ratio (CAR) was calculated using the formula: CAR = T_{pre}/T_{post}. MVIC and CAR were analyzed using 3-way repeated measures ANOVA (time x side x angle).

RESULTS: Patients had marked deficits in MVIC (side effect P<0.001), with improvement from 3 mo to 6 mo (side x time P=0.015) that was more apparent at 65° vs 30° (side x time x angle P=0.022): at 3 mo, MVIC deficit was 34.6±14.1% at 30° and 34.7±8.6% at 65°; at 6 mo, MVIC deficit was 27.0±13.0% at 30° and 22.0±12.2% at 65°. CAR was lower on the involved side vs the noninvolved side (side effect P=0.02) and this effect was more prominent at 3 mo vs 6 mo (side x time P=0.026): combining the angles, mean CAR on the involved and noninvolved sides, respectively, was 91.4±7.6% and 97.5±5.3% at 3 mo, and 93.0±7.8% and 95.8±6.8% at 6 mo. **CONCLUSIONS:** At 3 and 6 mo after ACL reconstruction, there were significant deficits in quadriceps strength and activation. The levels of activation were high (>90%) for both sides at both time points. The substantial strength deficits at these postoperative time points may be largely due to muscle atrophy with only a limited contribution from central inhibition. Rehabilitation interventions to normalize quadriceps strength should emphasize hypertrophic stimuli as opposed to neuromuscular activation strategies.

Magnetic Resonance Imaging Detection of Meniscal Injuries in Pediatric and Adolescent Patients with ACL Tears

Alana M. Munger¹, Nicholas R. Gonsalves², Emily Clarke¹, Curtis VandenBerg², James L. Pace². ¹Keck School of Medicine of USC, Los Angeles, CA. ²Children's Hospital Los Angeles, Los Angeles, CA.
 Email: amunger@usc.edu
 (No relationships reported)

PURPOSE: Prior research has shown decreased sensitivity and negative predictive value of meniscal injury detection using MRI in the setting of acute anterior cruciate ligament (ACL) tears in an adult population. This has yet to be investigated in a younger population. The objective of this study was to assess the diagnostic ability of MRI in detecting meniscal injuries for pediatric and adolescent patients undergoing arthroscopic ACL reconstruction.

METHODS: From August 2012 - June 2016, 175 arthroscopic ACL reconstructions were performed at our institution. A total of 83 patients were included in our final analysis. The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of meniscal tears on MRI were calculated. ANOVA and two-sample t-tests were used to compare event rates between medial meniscal (MM) and lateral meniscal (LM) tears.

RESULTS: The median age of our cohort was 15 (range: 7-18). Figure 1 shows the accuracy of MRI for patients with arthroscopically confirmed meniscal tears with a concurrent ACL tear. There were 25 (30.1%) cases in which a meniscal injury not detected on MRI was discovered arthroscopically (MM: 5 knees, LM: 19 knees, both: 1 knee). These false negative MRIs were more commonly a LM tear (p<0.001) and of the vertical tear type (13/25 tears, 52.0%). The posterior horn was the most common

location for a missed LM tear (p<0.001). In comparison to an adult cohort studied previously (median age: 32, range: 16-61), the MRIs of our patients with LM tears had a decreased NPV (p<0.001).

CONCLUSIONS: For our younger patients with ACL injuries, there were 25 (30.1%) cases in which preoperative MRI failed to detect a meniscal tear. LM tears in the posterior horn were more commonly missed on MRI versus MM tears. Also, a vertical tear was the most commonly missed tear type. In comparison to an adult cohort, the MRIs of pediatric and adolescent patients with LM tears had a decreased NPV.

Figure 1: Sensitivity, Specificity, PPV, and NPV of 1.5T and 3.0T MRI

MRI Finding	Arthroscopic Finding			Total
	Tear Present (+)	Tear Absent (-)		
Tear Present (+)	47	5		52
Tear Absent (-)	25	6		31
Total	72	11		83
Sensitivity	65.3%			
Specificity	54.5%			
PPV	90.4%			
NPV	19.4%			

3341 Board #246 June 2 2:00 PM - 3:30 PM
Body Mass Index is Associated with Cartilage Turnover in Individuals with ACL Reconstruction

Amy R. Lane, Matthew S. Harkey, Brittney A. Luc-Harkey, Hope C. Davis, J Troy Blackburn, Anthony C. Hackney, FACSM, Brian Pietrosimone. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*
 Email: lanea@email.unc.edu
 (No relationships reported)

Obesity is a risk factor for idiopathic knee osteoarthritis, yet little is known regarding how body mass index (BMI) affects metabolic changes that increase the risk of post-traumatic osteoarthritis (PTOA) **PURPOSE:** Determine the association between BMI and the type II cartilage turnover ratio in individuals with a unilateral anterior cruciate ligament reconstruction (ACL). **METHODS:** Forty-five individuals with unilateral ACLR (31 female; 21.8±2.9 yr; 25.6±4.2 kg/m²; 48.3±38.2 months post ACLR) that had been cleared for unrestricted physical activity participated in this study. Physical activity level prior to ACLR (Tegner score) as well as current level of disability (International Knee Documentation Committee [IKDC]) were assessed. BMI (kg/m²) was calculated from objectively measured height and mass. Following 20 min of rest, serum was obtained to measure Type II cartilage turnover (C2C:CPII), which was quantified as the ratio of degradation (collagen type II cleavage product [C2C]) to synthesis (collagen type II C-propeptide [CPII]). Sera were put on ice to clot then spun at 4000 rpm at 4°C for 10 minutes. After centrifugation, sample aliquots were stored at -80° until analysis. Spearman rank order correlations (ρ) were used to determine the bivariate association between BMI and C2C:CPII. Secondary, partial correlations (r) were used to determine associations after controlling for covariates (IKDC and Tegner). All analyses were then repeated with males and females assessed separately. **RESULTS:** Overall greater BMI was associated with greater C2C:CPII (ρ =0.30, P=0.048). After controlling for covariates, we found a similar association between BMI and C2C:CPII (Partial r=0.42, P=0.009). In females, greater BMI was moderately associated with greater C2C:CPII before (ρ =0.51, P=0.004) and after controlling for covariates (Partial r=.50, P=0.01). There was no association between BMI and C2C:CPII (ρ =0.03, P=0.93) in males only. **CONCLUSIONS:** Greater BMI may influence greater collagen turnover in those with ACLR, potentially increasing the risk for developing deleterious cartilaginous alterations that are consistent with PTOA onset. By maintaining a lower BMI or reducing BMI, individuals, especially females, may be able to positively affect the cartilage turnover ratio following ACLR.

Quadriceps Muscle Strength Recovers Faster Than Hamstring Strength After ACL Reconstruction With Hamstring Tendon Autograft

Gulcan Harput¹, Hamza Ozer², Gul Baltaci, FACSM³. ¹Hacettepe University, Ankara, Turkey. ²Gazi University, Ankara, Turkey. ³Private Guven Hospital, Ankara, Turkey. (Sponsor: GUL BALTACI, FACSM)
 Email: aktasgulcan@gmail.com
 (No relationships reported)

Strength measurements are extensively performed following anterior cruciate ligament (ACL) reconstruction to better understand the strength recovery of the patients over time and to make the patients return to their sports safely.

PURPOSE: The aim of this study was to investigate the quadriceps and hamstring strength recovery after ACL reconstruction with hamstring tendon autograft (HTG). **METHODS:** Fifty individuals (Age: 27.3±7.6 years; body mass index: 24.8±3.7 kg/m²) who had undergone ACL reconstruction with HTG were included in the study. All participants attended a regular six-month rehabilitation program. Quadriceps and hamstring isometric strength was measured at first, third and sixth months after surgery. Limb symmetry index [(involved/uninvolved limb strength)×100] (LSI) was used to define the muscle strength recovery. Two-way (muscle X time) repeated measures of ANOVA was performed for statistical analysis.

RESULTS: Muscle by time interaction was found significant for LSI ($F_{(2,98)}=4.43, p=0.01$). Quadriceps LSI was lower than hamstring LSI at first month ($p=0.02$) but no difference was observed between quadriceps and hamstring LSI at third ($p=0.62$) and sixth months ($p=0.64$) postsurgery. Both quadriceps and hamstring LSI gradually increased after ACL reconstruction ($p<0.001$). (Table 1)

Table 1. Quadriceps and hamstring strength recovery after ACL reconstruction

	First month	Third months	Sixth months	p value
Quadriceps (%)	49.35±17.17	79.27±14.97	84.09±12.55	<0.001
Hamstring (%)	55.04±12.13	77.87±12.19	85.19±11.29	<0.001
p value	0.02	0.62	0.64	Not applicable

CONCLUSION: Quadriceps strength decrement was greater than the hamstrings' at first month postsurgery when compared to contralateral limbs' strength. However, quadriceps and hamstring LSI's were found similar at third and sixth months postsurgery which showed quadriceps strength recovered faster than hamstring strength. Although the participants attended a regular ACL neuromuscular training program, their LSI for strength could not reach 90% at 6 months after surgery when patients usually return to sport.

Knee Flexor Strength and Activation Levels During Testing After ACL Reconstruction with a Semitendinosus Graft.

Kristin Briem, Árni Traustason, Katrín Björgvinsdóttir, Þórarinn Sveinsson. *University of Iceland, Reykjavík, Iceland.*
Email: kbriem@hi.is

(No relationships reported)

PURPOSE: Assessment specific to medial (MH) vs. lateral (LH) hamstrings may be indicated after graft harvesting from semitendinosus for anterior cruciate ligament (ACL) reconstruction. The purpose of the study was to assess strength and muscle activation levels of MH and LH during isometric strength testing where knee flexion was coupled with medial (MR) vs. lateral (LR) rotation of the tibia in elite athletes 1-5 years after ACL reconstruction, contrasting outcome measures with the non-surgical limb.

METHODS: Maximal isometric strength of 35 athletes (18 male, 17 female) was tested with a Kin Com dynamometer at 40° and 80° of knee flexion. Participants maintained concurrent volitional MR or LR of the tibia to facilitate preferential activation of the MH and LH components, respectively. Maximum values within each of a total of four 5 second trials were thereby collected for both lower limbs. Pre-amplified, wireless surface electrodes were used to collect muscle activity of each hamstring component during testing. Maximum values of smoothed data were identified within each test condition, the highest of which was used for normalization purposes. A mixed model repeated-measures ANOVA was used for analysis and alpha set at 0.05.

RESULTS: A significant interaction of limb by test position by sex was found for strength ($p=0.016$), as males had lower strength values for the surgical side only at 80° whereas females had lower strength at both 80° and 40° with no effect of tibial rotation. Muscle activation data did not specifically reflect this interaction found in strength measures. However, analysis of MH data showed a significant test position by sex interaction ($p=0.003$) across limbs, due to lower MH activation levels found at 40° compared to 80°, a difference not found for males.

CONCLUSIONS: Males and females may use different strategies during rehabilitation. Inhibition of MH activation may contribute to lower strength output during testing and influence readiness of return-to-sports.

The Modified Thomas Test: Does It Matter How It Is Performed?

Sean A. Horan, Neil Tuttle. *Griffith University, Gold Coast, Australia.*

Email: s.horan@griffith.edu.au

(No relationships reported)

The Modified Thomas Test is a clinical physical therapy test used to examine hip extension, typically in patients presenting with low back or hip pain. Multiple versions are described, with little consensus on which is the most useful with respect

to measurement error, practicality, and patient comfort. **PURPOSE:** To compare the repeatability of the most commonly described variations of the Modified Thomas Test. **METHODS:** Two trained, blinded testers, measured hip extension in 10 volunteers (age: 20-30 years), over two consecutive days. For each volunteer, testers performed six different versions of the Modified Thomas Test. Test variations included: two start positions (perched or supine on plinth), and three positions of the contralateral hip (hip ninety degrees, lumbar spine neutral or hip fully flexed). Additionally, two methods of measuring the hip angle with an inclinometer were used (lateral or anterior thigh). **RESULTS:** No differences were observed between testers, sides, or measurement method, however significant differences in start position (perched:17°; supine:14°) and contralateral hip position (hip ninety:21°; lumbar spine neutral:15°; hip fully flexed:10°) were observed. Notably, there were no differences in repeatability of methods or testers, with mean errors between 3.4 - 4.0° for repeated measures of all test versions. **CONCLUSIONS:** Given that the different versions of the Modified Thomas Test exhibit similar levels of repeatability, it seems reasonable to recommend that clinicians use the simplest, safest and most comfortable version of the test. That is, having patients starting by lying supine on the bed and holding their contralateral hip in 90° of flexion.

Competitive Bass Anglers: A New Concern in Sports Medicine

Connor R. Read, Shawna L. Watson, Jorge L. Perez, A Reed Estes. *UAB Hospital, Birmingham, AL.*

Email: connor.r.read@gmail.com

(No relationships reported)

Background: Angling is a popular pastime for many Americans. Competitive angling involves sport fishing against other anglers while targeting a specific species of fish. Due to the rapidly growing popularity of high school competitive bass angling in Alabama and the similarity of the casting motion to that of overhead athletes, we sought to examine the prevalence of sports-type injuries in this population.

Hypothesis: High school anglers who regularly compete will have a high prevalence of sports-type injury; likely due to the similarity of casting motion to the motions of many overhead athletes.

Study Design: Cross-sectional study

Methods: In spring 2016, an anonymous survey was distributed across two large scale competitive high school fishing tournaments, allowing for a broad sampling of anglers throughout the state of Alabama. Survey items included demographic information, relevant past medical history, and various pains associated with the shoulder, elbow and wrist. Results were recorded and analyzed electronically using Microsoft Excel and IBM SPSS statistical software.

Results: A total of 257 surveys were recorded. The mean age of participating anglers was 15 years old. The majority (42%) of anglers fished year round. On average, anglers casted nearly 1,000 more times while competing versus fishing recreationally. Approximately 15% of anglers experienced shoulder, elbow, and wrist pain. The most common factors associated with pain

included higher tournament cast counts, number of competitive years, number of tournaments/year, number of tournaments, and use of light weight lures. **Conclusion:** Roughly 15% of high school competitive anglers experience upper extremity pain. Knowledge of angling factors associated with pain allow for the creation of a modifiable routine to help reduce pain in affected anglers and prevent pain in healthy anglers.

Comparison Study On Early Postoperative Functional Exercises Of Simple Olecranon Fracture

ZIYI QI. *Chengdu Sport Institute, Chengdu, China.*

Email: 373677971@qq.com

(No relationships reported)

Olecranon fracture of the elbow joint is one of the common injuries, especially intra-articular fracture. Due to the anatomical characteristics of the elbow joint, it is easy to cause dysfunction after trauma. Therefore, early postoperative rehabilitation can maximize the recovery of limb function. Early and appropriate active or passive joint activities, not only can draft joint capsule, ligaments, tendons and soft tissue surrounding the joint but also can prevent contracture and improve joint nutrition metabolism. **Purpose** Currently, both active functional exercise and passive functional exercise are used clinically, but there is no uniform standard about how to practice early functional exercise of postoperative olecranon fractures properly. The purpose of the study further compared active and passive functional exercise in order to choose the appropriate training method. **Methods** Seventeen postoperative patients (age: 45.3±15.7 years, 8 males, 9 females) with simple olecranon fractures were randomly divided into two groups (Group A: 9 cases; Group P: 8 cases) and evaluating effects of the two groups with JOA Elbow-Performance after different functional trainings during early rehabilitation stage, respectively (A: active functional training; P: passive functional training). **Results** All 17 subjects completed the study. On the second postoperative day (1st assessment), all patients had to test JOA. The total JOA scores

of two groups showed that there was no significant difference between two groups (A: 49.2 ± 9.3 , poor; P: 54.6 ± 10.9 , poor, $p = 1.09 > 0.05$). Over four-week-exercise period (2nd assessment), A was better than P. There was a significant difference of JOA scores (A: 94.3 ± 2.9 , excellent; P: 79.3 ± 6.9 , good, $p = 0.00 < 0.01$). However, the improvement rates of A and P had no significant difference ($p = 0.26 < 0.05$). Improvement rate = (2nd assessment - 1st assessment) / 1st assessment. **CONCLUSION** Both active functional training and passive functional training are beneficial to postoperative patients with simple olecranon fractures, but active functional training method is the first choice.

Sedentary Behaviour in People with Total Knee Arthroplasty and Those Awaiting Surgery

Sandra C. Webber, Shaelyn M. Strachan, Navjot S. Pachu.
University of Manitoba, Winnipeg, MB, Canada.
Email: sandra.webber@umanitoba.ca

(No relationships reported)

High levels of sedentary behaviour are associated with functional decline, elevated blood pressure, weight gain, and increased risk for metabolic conditions in people with osteoarthritis independent of time spent in moderate-to-vigorous physical activity. While physical activity levels do not change substantially after total knee arthroplasty (TKA), the effects on sedentary behaviour have not been investigated. **PURPOSE:** To compare sedentary behaviour patterns in people with osteoarthritis awaiting TKA and individuals recovered from TKA. **METHODS:** Sedentary behaviour was measured with the 7-day Sedentary and Light Intensity Physical Activity Log (SLIPA), the Longitudinal Aging Study Amsterdam Sedentary Behavior Questionnaire (LASA-SB), and 7 day accelerometry (ActiGraph GT3X+, < 100 activity counts/min) in 32 participants awaiting TKA and in 38 individuals one year after TKA (69.9 ± 5.3 SD and 67.9 ± 7.3 yrs of age respectively). T-tests and Mann-Whitney Rank Sum tests were used to detect differences between groups. A one-way RM ANOVA was used to detect differences between measures of sedentary time. **RESULTS:** There were no differences between pre- and post-operative groups for GT3X+ wear time (13.9 ± 1.1 hours/day vs. 14.4 ± 1.1 respectively, $p = 0.09$), total sedentary time (9.3 ± 1.4 hours/day vs. 9.2 ± 1.4 , $p = 0.62$), and number of sedentary bouts/day ≥ 30 min in duration (median 3.4 [1.9 IQR] vs. 3.1 [2.0], $p = 0.37$). In addition, SLIPA and LASA-SB scores did not differ between groups ($p = 0.17$ and $p = 0.14$ respectively). Measures of sedentary time (combined groups) were all statistically different from one another: GT3X+ 9.2 ± 1.4 hours/day, SLIPA 6.7 ± 2.5 hours/day, LASA-SB 10.3 ± 3.7 hours/day (all comparisons $p < 0.05$). **CONCLUSIONS:** Self-reported and objective measures of sedentary behaviour do not differ between people on the wait-list for TKA and one-year recovered from TKA. This suggests that after TKA there is still an increased risk for physical disability and cardiovascular health conditions related to high levels of sedentary behaviour. In addition to promoting increased physical activity after TKA, individuals would benefit from education regarding strategies to reduce sedentary behaviour.

F-62 Free Communication/Poster - Performance

Variations in Verbal Encouragement Modify Isokinetic Performance at High Speeds

Nicole K. Rendos¹, Rebecca C. Regis², Taislaine Alipio², Kysha Harriell², Joseph F. Signorile². ¹Florida International University, Miami, FL. ²University of Miami, Coral Gables, FL. (Sponsor: Arlette Perry, FACSM)

(No relationships reported)

Verbal directions and encouragement are common in exercise testing; however, the verbiage used during each is rarely controlled despite the likelihood it may affect the participant's performance. **PURPOSE:** To examine the effects of four variations in verbal encouragement verbiage on isokinetic performance during alternating concentric knee extensions and flexions. **METHODS:** Fourteen healthy participants (8M, 6F, height = $1.73 \pm .09$ m, mass = 70.0 ± 20.2 kg, age = 24.2 ± 3.9 y) completed four isokinetic knee extension and flexion testing sessions on a Biodex isokinetic dynamometer. Each session consisted of 5 repetitions at $1.05 \text{ rad}\cdot\text{s}^{-1}$ ($60^\circ\cdot\text{s}^{-1}$), 10 reps at $3.14 \text{ rad}\cdot\text{s}^{-1}$ ($180^\circ\cdot\text{s}^{-1}$), and 15 reps at $5.24 \text{ rad}\cdot\text{s}^{-1}$ ($300^\circ\cdot\text{s}^{-1}$), separated by 5 min passive recoveries. Participants received the same methodological instructions before each session. Variations in verbal encouragement, however, were randomized during each testing session using the following statements: (1) "as fast as you can" (FAST); (2) "as hard as you can" (HARD); (3) "as hard and as fast as you can" (BOTH); and (4) no verbal encouragement (NONE). Repeated measures ANOVAs were conducted to evaluate differences in isokinetic performance metrics. **RESULTS:** FAST produced

significantly higher total work ($M_{\text{diff}} = 172.2$, $SE = 44.3$, $p = .011$), relative work (work/body weight) ($M_{\text{diff}} = 9.0$, $SE = 2.3$, $p = .009$), work first third ($M_{\text{diff}} = 71.0$, $SE = 19.2$, $p = .016$) and average power ($M_{\text{diff}} = 32.0$, $SE = 7.5$, $p = .006$) than NONE during knee flexion at $300^\circ/\text{s}$, with no further differences for any speed or movement direction.

CONCLUSION: Verbal encouragement stating "as fast as you can" is recommended to increase work and power during high speed isokinetic knee testing since it consistently produced the best performances.

3349 Board #254 June 2 3:30 PM - 5:00 PM

Physiological Adaptation, Safety And Finishing Rate To Half Ironman Training For Age Group Triathletes

Francois Lalonde, J3L 1C6¹, Sarah-Maude Martin¹, Marquita Thériault¹, Jean-François Tremblay¹, Christopher Bonneau Mercier¹, Vincent Gosselin Boucher¹, Mélanie Roch², Mathilde Baudet³, Marc Gosselin⁴, Tournoux François³, Alain Steve Comtois¹. ¹Université du Québec à Montréal, Montréal, QC, Canada. ²Université de Sherbrooke, Sherbrooke, QC, Canada. ³Centre Hospitalier de l'Université de Montréal, Montréal, QC, Canada. ⁴Medical director for IronmanTM and Ironman 70.3TM Mont-Tremblant, Mont-Tremblant, QC, Canada.
Email: triathlonfrank@gmail.com

(No relationships reported)

Within the past few years, long distance triathlon has gained in popularity amongst the general population, which is by itself good news, since it leads to adopting an active lifestyle. Amateur athletes engaged in such a demanding challenge must prepare themselves wisely in order to achieve their goals without injury. Coaches establish training programs based upon their knowledge, personal experience and on approved training principles. Up to now, no training programs or methods have been evaluated scientifically in order to evaluate its effect on health and on success rate for age group athletes. **PURPOSE:** To evaluate a triathlon training program on the success rate of completing a half Ironman in neophyte amateur athletes. **METHODS:** A triathlon training program was conducted by the research team from February to June 2016 to follow age group athletes for their preparation to the Mont-Tremblant half Ironman. The training program adapted by a certified coach/registered kinesiologist included endurance and strength training in specific areas of running, cycling and swimming. Each participant did a full fitness assessment that included body composition, aerobic and musculoskeletal testing in January and two weeks prior to the event. Training volume was noted each week and injuries were reported to the team's physical therapist. **RESULTS:** Out of the 31 amateur triathletes (19 Males and 12 Females; mean age of 40 ± 9 years old; body weight of 74 ± 12 kg and a height of 172 ± 10 cm), only one did not complete the event. For a mean training volume of 410 ± 201 min per week, the mean finishing time was 6 hours 28 minutes and two participants obtained a qualification for the World Championships. Maximal oxygen consumption (46 ± 8 to 49 ± 7 ml/kg/min, $p < 0.05$) as well as maximal power output (293 ± 62 to 308 ± 57 W) were significantly increased by the training program. Ventilatory thresholds were also significantly increased (158 ± 40 to 175 ± 40 W, $p < 0.05$). No significant changes were observed in body weight (% of body fat and % lean mass), maximal grip strength and flexibility tests. Seven cases of minor injuries were reported during the six months of training. **CONCLUSION:** A 24 week training program adapted by a certified coach/registered kinesiologist is safe and provides a high success rate for amateur athletes that aim to finish a half-Ironman triathlon.

3350 Board #255 June 2 3:30 PM - 5:00 PM

Kinematics of Softball Hitting Off of a Tee versus Front Toss

Jessica K. Washington, Sarah S. Gascon, Gretchen D. Oliver,
FACSM. Auburn University, Auburn, AL.
(No relationships reported)

Hitting a baseball or softball is one of the most difficult skills in sport. Use of a batting tee as a training technique is viewed as principle for establishing and improving basic fundamentals of hitting.

PURPOSE: To determine lower extremity (knee flexion, pelvis rotation) and trunk (flexion, lateral flexion and rotation) kinematics hitting off a tee and hitting front toss. It was hypothesized that there would be no difference in lower extremity and trunk kinematics between the two conditions. **METHODS:** Nineteen National Collegiate Athletic Association (NCAA) Division I collegiate softball players (20.51 ± 1.53 yrs; 68.99 ± 7.68 kg; 166.87 ± 6.00 cm) participated. Participants were instructed to execute five maximal effort swings hitting from a tee and five maximal effort swings hitting front toss from a pitcher at 9.14 m (30 ft). The hitting motion was divided into five events: stance (ST), load (LD), foot contact (FC), ball contact (BC), and follow-through (FT). **RESULTS:** Data failed the test of normality; therefore, a Wilcoxon signed-rank test was used to determine if there were median differences in hitting kinematics between two hitting conditions during each hitting event. Results revealed kinematic differences in trunk flexion at load ($z = -2.55$, $p = 0.01$). No other significant results were found between hitting events and examined variables during

each condition. **CONCLUSION:** Though there were minimal kinematic differences in the two hitting conditions, these differences were at swing initiation and not exhibited beyond ball contact. These findings are beneficial for this population as decreased variability in swing mechanics across various conditions is desired. Therefore, it is suggested that future research continue to examine hitting mechanics from not only a kinematic approach but also from a kinetic and performance approach.

3351 Board #256 June 2 3:30 PM - 5:00 PM
Handedness (right Or Left Handed) Effect On Bilateral Transfer To Non-dominant Hand

Laura Laviolette, Patricia Bauer, Renee Jeffreys-Heil. *Florida Gulf Coast University, Fort Myers, FL*. (Sponsor: Mitchel L. Cordova, FACSM)
 Email: rjeffreysheil@fgcu.edu
 (No relationships reported)

Bilateral transfer is a common source of experimental study in motor learning. It is suggested that successful transfer from a non-dominant hand to dominant exists in the area of speed. However, there may be a difference between left and right-handed individuals in the interhemispheric transmission of visuomotor information. Left handed may have lower accuracy in trials.

PURPOSE: The focus of this work was to quantify the amount of bilateral transfer of subjects and determine if there is preferred dominant hand for the greatest amount for transfer.

METHODS: Participants first completed a handedness survey to establish laterality. They were then asked to trace a printed star pattern as quickly and accurately as possible while gazing at a mirror image of the pattern. The pattern for tracing was as follows: 1 time with non-dominant hand, 7 times for dominate hand, 1 time for non-dominant hand with 30 second breaks in between. Errors were measured by marks made outside of the star pattern. The distance outside the line was measured with a ruler.

RESULTS: A total of 14 college age students were enrolled in this study, 50% (N=7) were female, and 35% (N=5) were left handed. Significant differences were found in the pre to post test scores in both the number of errors (means \pm standard deviation, significance) pre = 18.14 \pm 8.68, post = 6.93 \pm 4.12, $p=0.0001$ and time to complete the task in minutes (means \pm standard deviation, significance) pre = 1:48 \pm 0:03, post = 1:00 \pm 0:02, $p=0.005$. When stratified by dominant hand (left or right), only time to complete task was significantly different ($p=0.04$); whereas, the number of errors was not significantly different ($p=0.09$).

CONCLUSIONS: This study suggests that there may be significant skill transfer from the dominant to non-dominant hand. It does appear that perfection of a task (number of errors) is as easily transferred, regardless of which hand is dominant. The later may have implications for athletics whose participation in sports requiring perfection of movement is important.

The Physiological Responses Of A Mandibular Repositioning Mouthguard And Their Effects On Athletic Performance

Ricardo Martins, Patrick Girouard, Evan Elliott, Saïd Mekary. *Acadia University, Wolfville, NS, Canada*.
 Email: said.mekary@acadiau.ca
 (No relationships reported)

PURPOSE: The purpose of this study is to understand the physiological responses of a mandibular repositioning mouthguard on athletic performance. We hypothesize that MG designs that produce anatomically desirable jaw adjustments for an increase in the upper airway may have the ability to elicit ergogenic effects thereby improving respiratory capacity and athletic performance.

METHODS: Twenty-four active participants volunteered for this study and were randomly counterbalanced submitted to six performance tests and 3D volumetric imaging with both conditions, without mouthguard (NMG) and with the mouthguard (MG).

RESULTS: The results demonstrated that the mandibular repositioning mouthguard has a significant effect on both aerobic ($p < 0.01$) and anaerobic performances ($p < 0.05$). The MG condition increased the pulmonary ventilation by 9% and maximal aerobic capacity by 5%. In addition, the MG condition increased anaerobic power production by 3% and decreased the 20- and 40-meter sprint time by 4% and 2% respectively. All results were statistically significant ($p < 0.05$). Imaging results demonstrated a 7% increase of the upper airway volume when comparing the MG to NMG conditions ($p < 0.05$).

CONCLUSIONS: Our results support our hypothesis that jaw-repositioning custom-made mouthguards can induce an increase in oropharynx width in the upper airways and these changes may be the cause for an increase in athletic performance.

Inspiratory Muscle Performance is Significantly Related to Agility and Speed in Collegiate Tennis Players

Magno F. Formiga, Marlon L. Wong, Luis A. Feigenbaum, Anthony A. Musto, Michele A. Raya, Robyn P. Rice, Lacey Scrima, Matthew T. Kuik, Lawrence P. Cahalin. *University of Miami, Miami, FL*. (Sponsor: Dr. Thomas Best, FACSM)
 Email: magno@miami.edu
 (No relationships reported)

The Illinois Agility Test (IAT) measures sport agility by combining multi-directional skills with sprints. The Test of Incremental Respiratory Endurance (TIRE) evaluates inspiratory muscle strength and endurance via Maximal Inspiratory Pressure (MIP) and Sustained Maximal Inspiratory Pressure (SMIP). The relationship between athletic agility and inspiratory muscle performance (IMP) is unclear. **PURPOSE:** To examine the association between IMP and IAT results of Collegiate Tennis Players (CTP). **METHODS:** IMP of 7 male CTP (mean \pm SD age = 20.3 \pm 0.8 years, height = 186.2 \pm 3.4 cm, and weight = 77.7 \pm 6.5 kg) and 8 female CTP (age = 20.9 \pm 0.8 years, height = 168.9 \pm 6.2 cm, and weight = 64.7 \pm 6.5 kg) was assessed via TIRE with the best of 3-5 trials providing MIP [measured from residual volume (RV)] and SMIP (measured from RV to total lung capacity). The IAT was performed twice with a 10-min rest between trials. The first and last intervals of the IAT comprised sprints to and from cones set 10 m apart, while the second interval involved weaving back and forth through four cones placed 3.3 m apart. A custom mobile app and tablet were used to time each IAT interval. **RESULTS:** MIP and SMIP of men were significantly ($p < .05$) greater than women (134.5 \pm 19.4 vs. 99.5 \pm 35.3 cm H₂O and 791.1 \pm 193.9 vs. 471.7 \pm 162.8 PTU, respectively). Men were significantly ($p < .05$) faster during all IAT intervals and had a significant ($p < .05$) negative correlation between MIP and last sprint times of both trials ($r = -.77$ and $-.89$, respectively). In women, significant ($p < .05$) negative correlations existed between weaving time and SMIP of the first trial ($r = -.77$) and MIP and SMIP of the second trial ($r = -.93$ and $-.89$, respectively). **CONCLUSIONS:** IMP was significantly correlated to IAT time in CTP but gender differences existed. The correlation between MIP and last sprints in men suggests that men depend on IMP for speed. MIP and SMIP were related to the weave interval in women suggesting that women depend more on IMP for agility. Stronger correlations existed between IMP and IAT during the second IAT trials suggesting that greater IMP provides less susceptibility to performance decrement associated with fatigue. Greater IMP may provide greater balance and contribute to greater agility in women and speed in men, resulting in improved performance in CTP.

3354 Board #259 June 2 3:30 PM - 5:00 PM

An Analysis of Governed vs Different Focal Points on Vertical Jump Performance in Males

Christopher Carver, Andy Bosak, Austin Smith, Jon Houck, Matthew Sokoloski, Jared Feister. *Liberty University, Lynchburg, VA*. (Sponsor: James Schoffstall, FACSM)
 Email: ccarver3@liberty.edu
 (No relationships reported)

Previous research has suggested that overhead goals (i.e. overhead focal point) can have a positive impact on drop jump performance. It stands to reason that with an increase in jump height, there is an increase in power output. However, there appears to be limited research on focal points and their impact on vertical jump (VJ) performance. **PURPOSE:** To compare the potential differences between no set focal point, a set focal point (i.e. governed), and a sport specific focal point on VJ performance in no less than average fit males. **METHODS:** Thirty-four average fit college aged males participated in this study. After descriptive data and reach height was recorded, subjects completed an 8-min warm-up on a leg cycle ergometer followed by 4-min of passive recovery (i.e. standing still). Subjects then completed 4 practice (i.e. familiarization trials) counter-movement jumps (CMJ) utilizing a VJ measurement device. Upon completion of 2-min of passive recovery the subjects then completed, in a counter-balanced order, 3 different jump series consisting of 4 maximal effort CMJs with 30-sec between each jump. The various jump series were as follows: No Set Focal Point (FPN), Focal Point (FP), and Sport Specific Focal Point (FPS). The highest jumps for FPN, FP, and FPS were compared using ANOVA statistical techniques with an alpha level of 0.05. **RESULTS:** FPS (69.19 \pm 9.40 cm) was significantly different ($p = 0.001$) than FPN (67.77 \pm 10.08 cm). Also, FPS was significantly different ($p = 0.0003$) than FP (67.92 \pm 9.92 cm). Conversely, there was no significant difference ($p = 0.308$) between FPN and FP. **CONCLUSION:** The results suggest that individuals who use a sport specific focal point tend to jump higher than those who use no set focal point or a governed focal point. Therefore, it may be prudent to suggest that a sport specific focal point, as selected by the subject, should be utilized during VJ assessment. Future studies should assess the impact of a sport specific focal point on VJ performance using male athletes who participate in sports with jumping movements.

3355 Board #260 June 2 3:30 PM - 5:00 PM

The Effect of Sport Specific, Governed, and Non-Controlled Focal Point on Female Vertical Jump PerformanceRobert T. Sanders, Andy Bosak, Christopher Carver, Austin Smith, Jonathan Houck, Matthew Sokoloski, Jared Feister. *Liberty University, Lynchburg, VA.* (Sponsor: James Schoffstall, FACSM)*(No relationships reported)*

Few studies have assessed factors that directly impact vertical jump performance in females. Prior studies investigated varying warm-up protocols as a means to enhance jump performance without seeking to manipulate the target (i.e. sport specific focal point, non-controllable, or governed focal point) that the female subjects focused on to complete the jumps. A previous focal point vertical jump study utilizing male subjects suggested that vertical jump performance increased when using a sport specific focal point. However, this has not been assessed using a female population to the best of the researchers' knowledge. **PURPOSE:** To determine if a sport specific focal point contributes to an increase in jumping performance compared to non-controllable (i.e. no set focal point), and a governed (i.e. set focal point) in averagely fit females. **METHODS:** Thirty averagely fit female participants had descriptive data collected (i.e. age, HT, WT, BF). Participants completed an 8 min warmup, which avoided static movements, and then received a 4 min passive recovery. After completing four familiarization jumps in a counter movement manner participants completed four jumps per each jump trial with thirty seconds of rest between jumps and 2 min of passive rest between each trial. The jump series protocol consisted of three separate counterbalanced trials which included a sport specific (FPS), governed (FP), or non-controllable focal point (FPN). FPN, FP, FPS were compared using ANOVA with significance determined at an alpha level of 0.05. **RESULTS:** FPS (51.56 cm 8.69 cm) was significantly different ($p = .0005$) versus FP (50.67 cm 8.70 cm) and FPN (50.50 8.83 cm). Also, there was no significant difference ($p = .245$) between FPN and FP. **CONCLUSION:** It appears that using a sport specific focal point may elicit a higher jump in averagely fit females as compared to the jumps when females utilized a non-controlled focal point or a governed focal point. Further research is necessary in order to evaluate the use of a sport specific focal point on vertical jump performance with females who participate in jumping sports (i.e. basketball, volleyball) at the high school, collegiate, and professional level.

Is Breakthrough Power an Effective Assessment of Team Performance of University Rugby Football ?Masanori Takemura¹, Koji Kurita², Setsuo Komatsu³, Arijit Banerjee⁴, Hayato Yamamoto⁵, Mitsuharu Kaya⁶, Junzo Tsujita⁷. ¹*Ichihashi Clinic, Kobe, Japan.* ²*Physical Conditioning Production, Osaka, Japan.* ³*Tenri University Rugby Football Club, Tenri, Japan.* ⁴*Amagasaki-city Board of Education, Amagasaki, Japan.* ⁵*Yamamoto Trainers Project, Kyoto, Japan.* ⁶*Hyogo University of Health Science, Kobe, Japan.* ⁷*Institute of Health & Sports Medical Science, Osaka, Japan.*
Email: masa_takemura27@yahoo.co.jp*(No relationships reported)*

PURPOSE: We reported in a previous study (ACSM's 60th Annual Meeting) that kinetic energy ($\text{kg}\cdot\text{m}^2/\text{s}^2$) calculated from body weight (kg) and 30m sprint (m/s; maximum value), called breakthrough power (BT), was good as a performance assessment of running with body contact during rugby. The purpose of this study was to determine if the BT of individual players can explain team performance in rugby football.

METHODS: For four years the top level teams of university rugby football in Japan were investigated retrospectively (the number of players of 86 [regular 16, reserve 70] in 2010-11 season, 60 [18, 42] in 2011-12, 96 [19, 77] in 2012-13, and 113 [19, 94] in 2013-14). Every season, number of players of regular and reserve (individual player's performance level) were included in the high BT group (number of the regular players of the season) and in the low BT group. Odds ratio and Fischer's exact test were calculated, and compared to team performance of the Japan university championship. **RESULTS:** Odds ratio (p value as Fischer's exact test) of each season was 28.6 (0.00) in 2010-11, 19.24 (0.00) in 2011-12, 8.40 (0.00) in 2012-13, and 2.88 (0.09) in 2013-14. The adjustment of odds ratio that standardized the player total number of each season to 60 players at the minimum of four seasons was 17.16 (0.00), 19.24 (0.00), 3.95 (0.05), and 0.99 (1.00), respectively. Apart from 2013-14, the regular player group had higher BT than the reserve group. Team result finished second in the Japan university championship in 2010-11 and 2011-12, but defeated in the first round of the championship in 2012-13, and defeated in the qualifying round in 2013-14. In the season when odds ratio was high, i.e. most players with high BT participated in a game as regular players, team result was high.

CONCLUSIONS: In the 2013-14 season, the contribution of breakthrough power, i.e. fitness level to assessment of player performance (regular or reserve) was low, thus

team fitness was low. As result, the team performance was low. Thus the contribution of fitness factor to assessment performance level is important in rugby football. Breakthrough power is an effective assessment of team performance of university rugby football.

3357 Board #262 June 2 3:30 PM - 5:00 PM

Relationships Between Squat Strength, Velocity, And 40-yard Dash Time In College Softball And Football PlayersMichael F. Carter, Lindy M. Rossow, Christopher A. Fahs. *Lindenwood University Belleville, Belleville, IL.* (Sponsor: Michael G. Bembien, FACSM)*(No relationships reported)*

One-repetition maximum (1RM) back squat and 40-yard dash time are common performance assessments in college athletes. Measuring bar velocity during the concentric portion of barbell exercises can be a useful tool to provide feedback for regulating resistance training intensity. Average bar velocity during a 1RM back squat is lower in experienced squatters compared to novice squatters but it is unknown if bar velocity during a 1RM back squat is related to strength or speed in athletes. **PURPOSE:** To determine the relationships between 1RM back squat strength, bar velocity, and 40-yard dash time in college softball and football players. **METHODS:** Thirteen college football (22 ± 1 yrs) and eight college softball players (20 ± 1 yrs) performed the 40-yard dash and 1RM back squat protocol while peak and average concentric bar velocities were measured. Height (m), body mass (kg), squat experience (years), squat frequency (days/week), and femur length (cm) were also measured. Squat relative 1RM was calculated as 1RM (kg) divided by body mass. Independent samples t-tests were used to compare data between athletes (softball vs. football) and Pearson correlations were used to determine the relationship between variables. **RESULTS:** Absolute squat 1RM (153.7 ± 28.8 vs. 86.8 ± 18.8 kg) was greater in football players compared to softball players ($p < 0.001$) but relative 1RM squat (1.45 ± 0.34 vs. 1.24 ± 0.22), 1RM average bar velocity (0.30 ± 0.05 vs. 0.29 ± 0.06 m/s), 1RM peak bar velocity (0.71 ± 0.20 vs. 0.76 ± 0.19 m/s), and 40-yard dash time (5.40 ± 0.57 vs. 5.70 ± 0.40 s) were similar between football and softball players ($p > 0.05$). 40-yard dash time was inversely correlated with relative 1RM squat ($r = -0.720$; $p < 0.001$) and peak 1RM bar velocity ($r = -0.612$; $p = 0.003$). **CONCLUSIONS:** These data suggest that faster athletes were relatively stronger and had a greater maximum bar velocity during the 1RM back squat. Measurement of peak bar velocity during back squat 1RM testing may be a useful indicator of speed in college athletes.

Carbohydrate Mouth Rinsing Procedure during Repeated-sprints Exercise in Fasted State: Effects on Physical and Cognitive PerformanceKarim Chamari¹, Anissa Cherif¹, Romain Meeusen, FACSM², Joong Ryu³, Lee Taylor¹, Karim Kammoun⁴, Mohamed Amine Fenni⁵, Abdulaziz Farooq¹, Abdul Rashid Aziz⁶, Bart Roelands². ¹*Aspetar, doha, Qatar.* ²*Bruxelles University, Bruxelles, Belgium.* ³*Aspire, doha, Qatar.* ⁴*ISSEP Ksar-Said, Tunis, Tunisia.* ⁵*Sousse University, Sousse, Tunisia.* ⁶*Singapore University, Singapore, Singapore.* (Sponsor: Dr Randall Wilber, FACSM)

Email: karim.chamari@aspetar.com

(No relationships reported)

Intermittent fasting (IF) is used for many reasons across the globe. Three-days IF (3-d IF: no eating/drinking during daylight hours) has been shown to reduce physical and cognitive performance in a repeated sprint effort session. Carbohydrate (CHO) mouth rinse (CHO-MR) has shown efficacy in attenuating some of these decrements for different efforts (i.e., endurance exercise), yet CHO-MR has not been utilized within a repeated sprint (RS) exercise 3-d IF paradigm with associated cognitive performance assessment. **PURPOSE:** Determine carbohydrate mouth rinsing (CHO-MR) effects on physical and cognitive performance during repeated-sprints (RS) after 3 days of intermittent fasting (abstaining from eating/drinking during daylight hours). **METHOD:** In a randomized, counter-balanced and double-blinded manner, 15 active healthy males performed a RS-protocol (RSP) [2 sets (5x5-s maximal sprints interspersed with 25-s rest periods and 3-min of recovery between sets) on an instrumented motorized treadmill with embedded force plates] in three conditions [Control (CON)(no-MR), Placebo-MR (PLA-MR; 0% maltodextrin), and CHO-MR (10% maltodextrin)]. Participants rinsed their mouth with either 10-mL of PLA-MR or CHO-MR solution for 5-s before each sprint in the PLA-MR and CHO-MR conditions. Reaction time (RT) tasks (simple and complex) were assessed pre-, mid- and, post-RSP. ANOVA with repeated measures was used to analyze the data. **RESULTS:** There was no statistical main effect of CHO-MR on sprints (i) mean power, (ii) mean speed, and (iii) vertical stiffness compared with PLA-MR and CON conditions. There was also no statistical main effect of CHO-MR on simple- and complex-task (i) accuracy,

(ii) movement time, and (iii) reaction time. **CONCLUSION** Though CHO-Mouth rinsing has been shown to be effective at improving performance in other exercise modalities, the present study showed that frequent CHO mouth rinsing did not affect sprint performance or reaction time during an intensive repeated sprint protocol.

3359 Board #264 June 2 3:30 PM - 5:00 PM
Difference in Power Measures Across Age-Cohorts
 Matthew S. Stone¹, Michelle Gray¹, Emily Janssen². ¹University of Arkansas, Fayetteville, AR. ²University of Kansas Medical Center, Kansas City, KS.
 Email: mss06@email.uark.edu
 (No relationships reported)

Muscular power declines 6-10% per decade throughout life. It is unknown, however, when the decrease is most apparent. Therefore, it's important to examine the difference in power amongst different age cohorts. **PURPOSE:** The purpose of this study was to examine the difference in power output measures among adults over the age of 18 years, separated into age decade cohorts (18-29, 30-39, 40-49, 50-59, 60-69, 70-79, and 80-89 years). **METHODS:** A total of 160 men and women participated in the study (40.6 ± 20.1 years; 71.1 ± 14.0 kg), spanning in age from 18-86 years. Power was assessed using the Tendo power analyzer during a sit-to-stand (STS) task. Participants sat on a standard height (0.47 m) chair, arms crossed over their chest and performed five separate STS trials, rising from a seated to full standing position as quickly as possible; one-minute rest periods provided between each trial. The Tendo was positioned on the floor in alignment with the participant's heel and the Kevlar string attached to the participant's hip with a carabiner clip and belt. With each STS task, peak (PPOW) and average (APOW) power, as well as peak (PVEL) and average (AVEL) velocity were recorded in watts (W) and meters per second (m/s), respectively. PPOW, APOW, PVEL, and AVEL were recorded for each stand, with the average taken. **RESULTS:** One-way ANOVA analysis indicated a significant difference between groups for PPOW, APOW, PVEL, and AVEL measures ($p < .05$). Younger subjects produced significantly greater PPOW and APOW than individuals in age cohorts over 40 years ($p < .05$). When assessing PVEL and AVEL, the younger age cohorts produced significantly greater values than the older age cohorts ($p < .05$). **CONCLUSION:** Findings indicate muscular power to be significantly greater among younger cohorts (≤ 40 years), as compared to older cohorts (> 40 years); however, among older cohorts, there was no significant decline in power. This gives an indication that decline in muscular power may occur around the age of 40, which is when the decline becomes less apparent. Based on findings, preservation of muscular power is necessary before 40 years of age.

Lunar Phases Effects On Short-term, Explosive Physical Performance Among Young Trained Athletes
 Youssi Narimen¹, Mohamed Arbi Mejri¹, Amri Hammami², Omar Hammouda³, Anis Chaouachi¹, Karim Chamari⁴. ¹National Center of Medicine and Science in Sport, Tunisia, Tunisia. ²Faculty of Medicine Sousse, Sousse, Tunisia. ³Université Paris Ouest Nanterre La Défense, Paris, France. ⁴Aspetar, doha, Qatar. (Sponsor: Prof. Joann Eickhoff Shemek, FACSM)
 Email: youssinarimen@gmail.com
 (No relationships reported)

Beliefs in lunar effect on human physiology and behavior started back in ancient times. Outcomes recently revealed that (i) aggressive behavior increased around full moon (FM), and (ii) a physical fitness index increased in sedentary students at new moon (NM) and FM compared to other moon phases. This has been attributed to the alteration of cardiovascular parameters (i.e., heart rate (HR) and blood pressure (BP) which were affected by the gravitational pull of the moon. However, there was no attention on the effect of lunar cycle (moon illumination and Gravitational pull) on physical performance in athletes. **PURPOSE:** to evaluate whether short-term explosive performance can be influenced by the different phases of lunar cycle. **METHODS:** Methods: Fourteen young male taekwondo athletes (Age: 16.9±0.7years, Height: 159.7±50.6 cm, Body Mass: 62.85±7.84 kg, Body Fat: 10.9±4.7) performed: squat jump (SJ), countermovement jump (CMJ), and 10-m sprint tests to assess explosive physical performance during the different phases of the lunar cycle (NM, FQ (First Quarter), FM, and LQ (Last Quarter)). The testing sessions at the different moon phases were performed in a counterbalanced order. Tests' order was kept the same (SJ, CMJ, then 10-m sprint) and all sessions were performed at evening times (6:00 to 8:00 p.m.) on the first day of each concerned lunar phase. Each parameter was measured over two consecutive lunar months in the calendar (April and May 2016). Astronomical data (lunar phases) were acquired from the United States Naval Observatory astronomical applications department data services (<http://aa.usno.navy.mil/data/>).

RESULTS: ANOVA showed that there was no significant lunar cycle effect for all explosive tests measures $F_{(3, 93)}=1.834$; $p>0.05$; $\eta_p^2=0.124$.

CONCLUSIONS: Moon phases did not affect evening explosive performances (mainly phosphagens' pathway based efforts) among young trained athletes. Therefore, it seems that moon phase / illumination do not have an effect on short term physical performance in young trained adolescents. Future studies may evaluate whether High Intensity (predominance of the "glycolytic pathway" in addition to the "phosphagen's pathway") and Endurance (predominance of "oxidative phosphorylation"), performances would be affected by lunar cycle in athletes.

The Effects Of Lower Body Fatigue On Vertical Jump Ground Reaction Forces
 Christina N. Cooper, Nicole M. Sauls, Judith Davis, Jasmine Wimbish, Ashley Vazquez, Nicole C. Dabbs. California State University, San Bernardino, San Bernardino, CA. (Sponsor: Bryan Haddock, FACSM)
 (No relationships reported)

PURPOSE: Ground reaction forces may be used as an indicator of lower body performance and fatigue. It is known that a decrease in muscular force-generating capacity is an indicator of fatigue. Therefore, the purpose of this investigation is to determine the effects of lower body fatigue on ground reaction force measures. **METHODS:** Nineteen recreationally trained males and females (age 22.84 ± 1.77yrs; height 168.82 ± 10.22m; weight 68.70 ± 14.87kg) participated in a combined familiarization and testing session. During familiarization, participants signed an informed consent and anthropometrics were recorded. Participants then performed a dynamic warm-up and were familiarized with two types of vertical jumps and fatiguing protocol. Three trials for both the static jump (SJ) and countermovement vertical jump (CMVJ) were performed on a force plate, pre and post Bosco fatigue test. The dependent variables calculated from the force plate were rate of velocity development (RVD), peak force (PF), impact force (IF), peak velocity (PV), and peak power (PP). Paired-sampled t-tests were used to analyze pre/post differences for each dependent variable. **RESULTS:** There was a significant difference between pre and post PF ($p=0.003$; pre=1,523.68 ± 360.65N; post= 1,464.03 ± 342.24N), IF ($p=0.001$; pre= 1,175.02 ± 1142.37N; post= 1355.05 ± 987.34N), peak velocity ($p=0.002$; 2.63 ± .36; post= 2.38 ± .51m/s), and PP ($p=0.001$; pre= 3373.09 ± 1088.92m/s; post= 2922.89 ± 1100.00m/s) measures for CMVJ. There was a significant difference between pre and post measures for SJ peak force ($p=0.001$; pre= 1298.95 ± 261.97N; post= 1230.60 ± 261.97N). **CONCLUSIONS:** For CMVJ, the Bosco protocol significantly decreased PF, IF, PV, and PP. The fatigue protocol also significantly decreased PF for SJ. This is due to the decrease in force generating capacity in lower-body musculature following fatigue. A decrease in force production may lead to an overall increase in injury risk. As force production decreases, so does ability to maintain proper mechanics. This study shows performing a fatiguing activity, such as the 60s Bosco protocol, significantly alters force production in recreationally trained populations, indicating that programming high-intensity multi-joint activities before maximal vertical jump performance can lead to muscle fatigue.

The Relationship Between Bilateral Asymmetries And Explosive Lower-Body Performance
 Nicole M. Sauls, Luis E. Segura, Christopher Perez, Henry Velasquez, Jason Ng, Guillermo Escalante, Nicole C. Dabbs. California State University, San Bernardino, San Bernardino, CA. (Sponsor: Bryan Haddock, FACSM)
 Email: nicolemsauls@gmail.com
 (No relationships reported)

PURPOSE: Bilateral symmetry of the lower extremities may be a critical component of lower-body explosive performance. Therefore, the purpose of this investigation was to determine the relationship between bilateral asymmetry and explosive lower-body performance.

METHODS: Forty-five recreationally trained males and females (age, 23.04 ± 2.36 y; height, 166.45 ± 24.40 cm; mass, 73.86 ± 13.33 kg) volunteered to participate in this study. Day one (familiarization), participants filled out an informed consent and physical activity readiness questionnaire followed by familiarization of vertical jump, sprinting, and isokinetic torque protocols. Day two (testing), participants performed a dynamic warm-up followed by 3 countermovement vertical jumps utilizing the Vertec® and force plates to obtain maximum vertical jump height and peak force. Maximal vertical jump height of the three trials was used for analysis. Participants performed 3 trials with 2 min rest in between of a 40-yard sprint with timing gates positioned at 20 and 40 yards. The fastest times of the three trials were used for analysis. Isokinetic torque was assessed with the Biodex System 4 Isokinetic dynamometer to measure concentric isokinetic torque of both hamstrings and quadriceps, with 5 repetitions on each leg. The maximum isokinetic torque from each leg was used for analysis and bilateral quadriceps (BQ%) and hamstrings (BH%)

percent differences were calculated and used for analysis. Pearson's *r* correlations were conducted to analyze the relationship between hamstring and quadriceps percent differences and lower body explosive performance variables.

RESULTS: There was no significant correlation between BQ% and total sprint time ($r = -.02$; $p = .85$), vertical jump height ($r = .06$; $p = .68$), and peak power ($r = -.13$; $p = .36$). There was no significant correlation between BH% total sprint time ($r = .22$; $p = .14$), vertical jump height ($r = -.001$; $p = .99$), and peak power ($r = -.26$; $p = .08$).

CONCLUSIONS: No relationship was observed between bilateral asymmetry and any lower body explosive performance in this particular population. The lack of a relationship may be due to the type of participants involved in the investigation; since they were recreationally trained there may be varied training experience.

3363 Board #268 June 2 3:30 PM - 5:00 PM
The Importance of Skating Economy to Performance on a Repeated Shift Test in Ice Hockey

Nicholas R. Lamoureux, 58203, John S. Fitzgerald, Grant R. Tomkinson. *University of North Dakota, Grand Forks, ND.*
 (Sponsor: James R Whitehead, FACSM)

(No relationships reported)

Ice hockey is a sport characterized by repeated high intensity bouts, with the ability to resist fatigue both between and within bouts conferring competitive advantage. However, there is no evidence to support skating economy as a factor in fatigue resistance.

PURPOSE: To determine the importance of skating economy to fatigue during repeated high-intensity efforts of a simulated ice hockey shift.

METHODS: Forty-five collegiate and Junior A male ice hockey players (aged 18-24 years) performed a continuous protocol graded exercise test to volitional exhaustion using a skate treadmill, as well as an on-ice repeated shift test. Breath-by-breath data for $\dot{V}O_2$ and respiratory exchange ratio were collected and used to derive energy expenditure (EE) averaged over the final 10 seconds of each stage. Economy was determined as the slope of the regression line relating $\dot{V}O_2$ and EE against skating speed separately. Participants who completed fewer than three stages of the graded exercise test were excluded to increase reliability of regression slope measures. Participants also completed eight bouts of maximal ice skating through a course designed to simulate the duration and skating skills of a typical shift, with three separate TC Speed Trap-II wireless timing gates used to determine first half, second half, and total fatigue decrement as calculated by a percent decrement score (Decrement Score = $(100 \times [\text{Total Sprint Time} \div \text{Ideal Sprint Time}] - 100)$). Each bout lasted approximately 23 seconds, with 90 seconds of passive recovery allowed between bouts. Partial correlation was used to determine the association between economy measures and decrement during the repeated shift test.

RESULTS: Twenty-six participants met the inclusion criteria and were included in the data analysis. Skating economy measures (both relative $\dot{V}O_2$ and EE) were moderate and statistically significant correlates of total fatigue decrement ($\dot{V}O_2$: $r = 0.46$, $p \leq 0.05$; EE: $r = 0.44$, $p \leq 0.05$), but not with first or second gate decrement.

CONCLUSION: Our results indicate that skating economy may play an important role in fatigue resistance over repeated on-ice sprints designed to simulate a typical shift. This may lend support to the use of technical skating coaches and training techniques to enhance skating economy as a valid way to improve ice hockey performance.

The Influence Of Pace On Performance During A Five-week Online Fitness Competition.

Cassie Williamson, Yuri Feito, FACSM, Brian Kliszczewicz, Gerald Mangine. *Kennesaw State University, Kennesaw, GA.*
 (Sponsor: Dr. Yuri Feito, Ph.D., FACSM, FACSM)
 Email: cwill397@kennesaw.edu

(No relationships reported)

Purpose: To determine the influence of exercise pace on individual performance during an annual five-week online fitness competition. **Methods:** Competition pacing data was collected from individuals with more than six-months of experience during the first (16.1; $n = 12$) and last (16.5; $n = 8$) weeks of the competition. For 16.1, competitors completed as many repetitions as possible (AMRAP) in 20 minutes of a circuit that included: 25-ft. overhead walking lunges (L1), 8 bar-facing burpees, 25-ft. overhead walking lunges (L2), and 8 chest-to-bar pull-ups (PU). For 16.5, competitors completed a workout with a 21-18-15-12-9-6-3 descending repetition scheme with barbell thrusters (BT) and bar-facing burpees (BB). Pearson product-moment correlation coefficients were calculated between the average (AVG), fastest (FST), and slowest (SLW) times to complete each exercise and round (RD), in addition to the competitors' score for 16.1 (total repetitions) and 16.5 (time to completion). Significantly correlated variables were entered into a stepwise linear regression to determine the best indicator for success. **Results:** Significant ($p < 0.05$) relationships were observed between 16.1 score and PU_{AVG} ($r = -0.83$), $L1_{FST}$ ($r = -0.61$), $L2_{FST}$ ($r = 0.75$), PU_{FST} ($r = -0.66$), and PU_{SLW} ($r = -0.86$). Of these, PU_{SLW} was most influential

of 16.1 score ($r^2 = 0.74$, $p = 0.001$). Significant ($p < 0.05$) relationships were observed between 16.5 score and BT_{FST} ($r = -0.78$), BB_{FST} ($r = -0.78$), RD_{FST} ($r = -0.88$), BT_{SLW} ($r = -0.79$), RD_{SLW} ($r = -0.93$), BT_{AVG} ($r = -0.85$), and RD_{AVG} ($r = -0.97$). RD_{AVG} was most influential of success for workout 16.5. **Conclusion:** These data suggest that pacing affected score during these two workouts. Specifically, for a 20-minute AMRAP that included pull-ups, lunges, and burpees, the pace of the pull-ups was most influential. However, maintaining a low average round time was most important during a workout with a descending repetition scheme. It is unknown whether these strategies would be consistent in other, similarly-designed workouts.

The Effect Of Drop Jump Height On Post-activation Potentiation As Measured By Vertical Jump Performance

Monica Taylor¹, Erica Thomas², Amy Marszalek², Hannah Dohm², Laura Moorman². ¹*University of the Sciences, Philadelphia, PA.* ²*St. Ambrose University, Davenport, IA.*
 (Sponsor: Elizabeth Nagle, FACSM)

Email: m.taylor@uscience.edu

(No relationships reported)

Post-activation potentiation (PAP) is an enhanced contractile response within the muscles due to prior voluntary activation that has the potential to be used as a warm-up strategy prior to short, high intensity activities. **Purpose:** The purpose of this study was to compare the effects of two different drop jump heights on PAP as measured by subsequent vertical jump performance. **Methods:** 76 male and female NAIA collegiate athletes (19.9±0.2 yrs) completed three different testing session protocols. During the first session, the participants performed a pre-treatment vertical jump test and were familiarized with drop jumps. The second and final testing sessions included five drop jumps with rebound from an 18 and 30 inch box followed by a post-treatment vertical jump test. Three t-tests were performed in order to compare data from both treatments to the pre-treatment vertical jump data and the two treatments to each other. **Results:** The mean pre-treatment vertical jump was 22.2±0.6 inches while the 18 inch treatment mean was 21.3±0.6 inches and the 30 inch treatment mean was 21.8±0.5 inches. Two-tailed t-tests comparing the vertical jump after the varying drop jump heights did not show any significant differences. Delta in vertical jump height between the two treatment groups were also examined, revealing no significant changes in jump height. **Conclusion:** Neither of the drop jump treatments were found to significantly influence vertical jump performance when compared to the pre-treatment vertical jump heights. Therefore, these results do not support the use of this volume of 18" or 30" drop jumps to induce PAP in collegiate level athletes.

Effect of Crank Arm Length on Oxygen Consumption and Mechanical Efficiency During Forward Grinding

Jesper Franch, Christian G. Olesen, Olav T. Larsen, Simon N. Thomsen, Nikolai L. Toft, Mathias K. Poulsen. *Aalborg University, Aalborg, Denmark.*
 Email: jfranch@hst.aau.dk

(No relationships reported)

In America's Cup yacht racing grinding is a major factor for boat handling. Resent changes in race regulations concerning number and anthropometry of crew members as well as the need for maintaining hydraulic pressure for boat maneuvering may emphasize the importance of optimizing grinding equipment for optimal aerobic efficiency during grinding. **Purpose:** To investigate the effect of crank arm length on oxygen consumption, mechanical efficiency and perceived exertion during forward grinding. **Methods:** Eight trained male subjects participated (Age: 31.3 ± 11.5 yrs; Body weight: 85.7 ± 9.5 kg; Height: 185.4 ± 3.1 cm; Arm span: 187.9 ± 7.4 cm; Grinding $\dot{V}O_{2peak}$: 49.0 ± 1.4 ml O_2 $kg^{-1} min^{-1}$). Whole body oxygen uptake, mechanical efficiency (net and gross), rate of perceived exertion (local and overall) and time to exhaustion (TTE) were compared during grinding with two different crank arm lengths (Standard: 228,6 mm vs. Long: 298,6 mm). Testing was performed as an incremental discontinuous test, consisting of 3-minute bouts of forward grinding at 70 revolutions per minute separated by a 1-minute pause. Testing started at 90 W and was increased by 30 W until exhaustion. Oxygen uptake was measured using the Jaeger Oxycon Pro metabolic cart and grinding was performed at a Harken@ prototype grinding ergometer (Olesen et al. Eur. J. Sport Science, 2015). Prior to the two test sessions resting metabolic rate was measured in supine position. Data were analyzed using a two-factor ANOVA repeated measures and paired t-test. **Results:** The standard crank arm length elicited lower oxygen consumption ($p < 0.05$) and was more efficient ($p < 0.05$) than the long crank arm length at workloads < 180 W. Interestingly, rating of perceived exertion for local muscular fatigue (local RPE) was significantly higher ($p < 0.05$) for the standard crank arm length at workloads > 90 W and TTE for the standard crank arm length was significantly shorter (1078 ± 44 sec vs 1144 ± 53

sec; $p < 0.05$). **CONCLUSION:** The long crank arm is less efficient than the standard crank arm at lower workloads. Conversely, lower local RPE at high exercise intensities and superior TTE were found with the long crank arm. The authors wish to thank Harken® for building the prototype of the grinder ergometer. No other conflicts of interest, financial or otherwise.

The Relationship Between Academic Stress and Skeletal Muscle Performance

Voon Chi Chia, Angie Wei, Cynthia Villalobos, Nicole A. Laskosky, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
Email: v_chia@u.pacific.edu

(No relationships reported)

Student athletes are required to perform both in the classroom and on the field; balancing these commitments can be stressful. It is common to question the burden of athletic demands on student scholarship. However, the inverse is seldom asked: how do scholastic stresses affect athletic performance? **PURPOSE:** To test the effect of psychological stress on skeletal muscle performance in college students. **METHODS:** We enrolled 23 recreationally active students (10 men, 13 women) from a D1 university. Skeletal muscle function was assessed via quadriceps extension and hamstring flexion using a Cybex HUMAC NORM dynamometer. Psychological stress was measured with the Cohen Perceived Stress Scale. Subjects were evaluated at two time points: a high stress period (exams) and a low stress period (no exams). A history of injury excluded subjects from participation; nightly sleep, history of exercise, and recent exercise were controlled. Independent variables were stress, sex, age, weight, BMI, academic load, and participation in organized sports (club or intramural). Dependent variables were peak torque (ft/lb) and time to achieve peak torque (sec). Differences in muscle performance between high and low stress periods were assessed with t-tests. Linear regressions analyzed the effect of psychological stress on muscle performance. **RESULTS:** Subjects were 20.2 ± 1.1 years old, had peak flexor torque of 87.4 ± 19.7 ft/lb (achieved in 0.58 ± 0.12 sec), and peak extensor torque of 145.2 ± 37.5 ft/lb (achieved in 0.58 ± 0.15 sec). T-tests found no differences between low and high stress periods in peak torque or time to achieve peak torque ($p > 0.090$). Linear regression found increases in psychological stress to correlate with improvements in the overall rate of force development ($p = 0.004$). The effect was strongest with flexors: for each point that stress increased, time to achieve peak torque was 2.4% faster ($p = 0.002$). **CONCLUSION:** Despite a small sample size, these findings suggest psychological stress may enhance force development. A possible mechanism could be sympathetically-mediated potentiation of calcium release. While academic stress presents many challenges for student-athletes, it does not appear to be detrimental to muscular performance.

Effect of Cleat Position during Cycling on Running Performance in Elite Triathlete

Ik Jin Kwon, Yong Bin Han, Chi Hoon Park, Min Gi Jung, Yun Bin Lee, Dae Taek Lee. *Kookmin University, Seoul, Korea, Republic of.*

Email: jojimang@hotmail.com

(No relationships reported)

PURPOSE: To evaluate the effect of cycle shoes cleat position during cycling on subsequent running time in simulated duathlon in elite triathletes. **METHODS:** Nine male national team caliber triathletes (25.9 ± 2.4 yrs, 69.1 ± 4.4 kg, 176.1 ± 3.7 cm) participated in two occasions of simulated duathlon. In each occasion, they cycled 20 km on a fixed bicycle immediately followed by running 5 km on a treadmill. During cycling, they wore cycle shoes of either traditional cleat position (TCP) or middle cleat position (MCP, approximately 5 cm behind of TCP). During cycling and running, they changed and controlled the speed as well as the cycle gear combinations. The testing order was balanced. They were asked to perform their best. During the exercises, distance, time, speed, the transit time, and heart rate (HR) were recorded. The distance of running was divided into three phases; as 0-2, 2-4, and 4-5 km, and the time record was compared. **RESULTS:** The total time record of the exercises excluding the transit was 3126 ± 137 in TCP and 3096 ± 103 sec in MCP ($p > 0.05$). The cycling time was 1956 ± 69 in TCP and 1967 ± 54 sec in MCP ($p > 0.05$). The running time was 1170 ± 88 in TCP and 1129 ± 66 sec in MCP ($p > 0.05$). The running time was faster in MCP than TCP by 5.4% at the phase of 0-2 km (460 ± 24 in MCP vs. 486 ± 40 sec in TCP, $p < 0.05$), but not at 2-4 km (447 ± 25 in MCP vs. 462 ± 37 sec in TCP, $p > 0.05$). The average HR was 166.7 ± 8.8 in MCP and 165.5 ± 7.0 bpm in TCP during cycling, and 175.3 ± 11.6 in MCP and 175.4 ± 8.1 bpm in TCP during running. No differences were found in HR during the exercises. **CONCLUSION:** The cleat position did not change the total time record of simulated duathlon in elite triathlete. However, the time record of early stage of running following cycling was faster when they cycled with the shoes of middle cleat position. It appears that cleat position during cycling have some influence on muscle recruitment during running in trained elite triathletes.

Electrolytes Drink Increases Performance During Repeated Exhaustive Exercise Tests

runghchai C. chaunchaiyakul. *mahidol university, Nakhonpathom, Thailand.*

Email: gmrungchai@gmail.com

(No relationships reported)

Purpose: To investigate the effects of electrolyte drink on subsequent exhaustive exercises, 14 male-university students voluntarily participated. They were healthy and passed medical screening and physical exam prior to three exercise tests of at least 1 week apart. **Methods:** Two consecutive exhaustive exercise tests, with 2 hours recovery period in between, were done within a day. After the first exhaustive exercise, subject was randomly intervened by drank one of the followings fluids: a) water (WT), b) placebo (PLA, only sucrose 7%, dextrose 4%) and sports drink (SD, NaCl 0.13%, KCl 0.03%, sucrose 7%, dextrose 4%). During 2 hrs recovery period, the amount of energy drink given was divided into 3 parts: first at 50% body weight (BW) at immediately after finished glycogen depletion, then at two sessions of 25% BW at 30 minutes and 60 minutes respectively Exhaustive exercise testing was conducted on cycle ergometer. This study was approved by Mahidol University IRB. Statistical analysis was done using two-ways repeated ANOVA at $p < 0.05$. **Results:** Increasing in most of cardiorespiratory variables (heart rates, stroke volumes, cardiac outputs, end-diastolic volumes, total peripheral resistance, breathing frequencies, tidal volumes, minute ventilations, maximum oxygen consumptions and carbon dioxide productions) are not significantly different among the groups with an exception of ejection fraction where SD was higher than WT ($p < 0.05$). Estimations of substrate utilizations revealed that fat oxidation was higher in WT ($p < 0.05$) where carbohydrate oxidations in PL and SD were higher than WT ($p < 0.05$). On the second exhaustive exercise, SD had significantly higher time to exhaustion and work done than WT and PLA ($p < 0.05$). **Conclusion:** In addition to carbohydrate alone, sports drink-containing electrolytes found to increase endurance performance on the subsequent exercise. The presence of these electrolytes are found to enhance carbohydrate absorption in human gastrointestinal tract and may possibly act as co-enzymes in metabolic pathways. Supported by T.C. Pharmaceutical Industries Co.Ltd. Thailand.

The Effect of Green Tea Extract on Fat Oxidation during 1hour Arm Cycle Exercise

sofie blicher, jochen kressler. *san diego state university, san diego, CA.*

Email: sofie_blicher@hotmail.dk

(No relationships reported)

Purpose:

Decaffeinated Green Tea Extract (GTE) supplementation can increase fat oxidation during leg exercise, but many people cannot perform leg exercise. The purpose of this study was to investigate the effect of GTE supplementation on fat utilization during 1h arm cycle exercise. We hypothesized that GTE supplementation will increase lipolysis and fat oxidation.

Methods:

This was a randomized, controlled, triple blind study with a crossover design. 8 healthy adults (4 females, 23-37yrs) performed an incremental arm cycle test to exhaustion followed by 4 time trials at fixed workloads. After an 8h fast subjects did 1h of arm cycling at 50% W_{peak} . Subjects were randomly assigned to either decaffeinated GTE (650mg, 611mg EGCG) or placebo (PLA) for 4wks. Subjects then repeated the 1hr arm cycle trial. A 4wk washout period was followed by the corresponding crossover trial. 5ml of blood were drawn pre and post exercise while respiratory gases were collected continuously. Plasma glycerol and free fatty acid (FFA) concentrations were assessed with commercially available analysis kits. The study was powered at $1 - \beta > 95\%$, with $\alpha = 0.05$ given a reported effect size of $F = 3.39$ for the time by treatment interaction.

Results:

Mean VO_2 during all 1hr trials showed no significant differences (83.89 ± 19.25 L/min, $p = .460$). Similarly, mean total energy expenditure (EE) showed no differences across all trials ($264.58 - 266.15$ kcal, $p = .420$). The percentage of total EE from fat oxidation was higher after GTE supplementation compared to PLA, but this difference was not significant (22.83 ± 11.57 to $25.38 \pm 11.3\%$ vs. 23.39 ± 9.97 to $20.69 \pm 8.9\%$, $p = .532$). There were no significant changes in g/min of fat oxidized between treatments before and after supplementation (GTE = $.11 \pm .08$ to $.12 \pm .06$ vs. PLA = $.10 \pm .05$ to $.09 \pm .04$, $p = .220$). Blood Glycerol concentration increased post exercise in all trials, with no significant differences between treatments (8.55 ± 3.44 mg/dl to 8.47 ± 2.6 vs. 10.05 ± 2.86 to 8.99 ± 3.51 mg/dl, $p = .527$). FFA concentration was also increased post exercise for both groups with no significant difference between treatments (8.30 ± 3.8 mg/dl to 8.69 ± 2.59 vs. 9.06 ± 4.49 to 7.16 ± 3.79 , $p = .234$).

Conclusion:

These results suggest that there is no effect of 1m GTE supplementation on fat utilization during 1hr arm cycle exercise at 50% W_{peak} .

The Effects Of Varying Levels Of Crossfit Experience On VO₂max
 David Furrow, Christopher Buschmann, Johnathon Childress, Michael Harris, Adrian Aron. *Radford University, Radford, VA.* (Sponsor: Trent A. Hargens, FACSM)
 (No relationships reported)

High intensity interval training (HIIT) training has been shown to improve maximal oxygen uptake (VO_{2max}). CrossFit is an adapted high intensity, strength and conditioning program implementing multi joint movements. Recent studies have demonstrated how CrossFit can lead to improved aerobic fitness; however, these results are reported from studies lasting a maximum of 3 months.

PURPOSE: The aim of this study was to investigate the effect on VO_{2max} from the length of CrossFit participation.

METHODS: The participants were 22 male subjects, age 34.8 ± 8.0 months, with at least two months of CrossFit training prior to enrolling in this study. Two groups were formed based on continuous participation in the CrossFit program above 18 months. The participants underwent a VO_{2max} graded exercise maximal exertion test using a modified treadmill protocol. Subjects warmed up for 3 minutes at 8km/h and 0% grade, then started running at 9km/h with 0.5km/h increase every 30 seconds until exhaustion. Exhaustion was defined as three of the four criteria: plateau of VO₂ for at least two consecutive readings, RPE higher than 18, RER > 1.1 and maximal heart rate (HR) within 10 beats of the age predicted maximum HR. The VO₂ data was collected using the ParvoMedics TrueOne 2400 Metabolic System.

RESULTS: The two groups were significantly different in their training participation; 31.6 ± 8.5 months compared to 9.1 ± 4.1 months, P < 0.001. The experienced individuals had a greater VO_{2max} (51.3 ± 5.5 ml/kg/min) compared to the novice individuals [45.3 ± 4.8 ml/kg/min (P = 0.02)]. A forward regression analysis indicated that weight alone was a significant predictor for VO_{2max} (adjusted R² = 0.47, P < 0.001). This group difference appears to be mediated primarily by body weight, as individuals exposed longer to CrossFit were leaner (88.0 ± 9.4 kg) compared to the novice individuals (97.5 ± 14.7 kg, P = 0.03).

CONCLUSIONS: These results suggest that CrossFit provides the appropriate stimulus to increase an individual's VO_{2max} over time. This could be due to increased cellular oxidative metabolism caused by the high intensity nature of the exercise and the ability of more experienced CrossFit athletes to endure workouts at a greater intensity. Most of these adaptations seem to be mediated by the effects of the training program on body weight.

Relationship Between Marathons Completed and Libido in Endurance-Trained Males
 Gabriel H. Zieff, Amy R. Lane, Johna K. Register-Mihalek, Colin B. O'Leary, Anthony C. Hackney, FACSM. *University of North Carolina Chapel Hill, Chapel Hill, NC.*
 (No relationships reported)

High levels of endurance training are known to depress testosterone production in males, (EJAP 2003;89:480), which plays an important role in libido maintenance. Research suggests that endurance exercise training (EET; intensity, duration in years) may impact libido status in endurance trained males (MSSEx 2016;48:267).

PURPOSE: This study examined libido status among EET men with varying levels of marathon participation (at least 1 to > 5). **METHODS:** A cross-sectional survey design was used to collect data. Respondents completed the survey via the Qualtrics™ online survey portal. Of the 1,366 respondents, 1,077 were valid (≥ 18 yr age, males, complete data sets). A total of 594 had completed marathons and were included in this analyses. Validity checks were conducted on the data. EET was assessed with components of the IPAQ and Baecke questionnaires. Questions from 3 validated sources (Androgen Deficiency in the Aging Male, Sexual Desire Inventory, Aging Male Symptoms Scale) were selected to make up the libido questionnaire, which was reviewed by a fertility specialist to ensure content validity. Total libido score (TLS) was calculated as the sum score of these questionnaire items. TLS was categorized into high, normal, and low libido categories. A between-groups ANOVA was performed to examine the number of completed marathons (1, 2, 3, 4, 5, >5) and TLS.

RESULTS: Individuals who completed >5 marathons had a significantly lower TLS (p < 0.05; Mean difference [CI], -10.0% [-5.8, -14.2%]) than those who completed 1 marathon. In addition, a cross-tab analysis showed that 30 of the 41 individuals (73.2%) who were in the low TLS category had completed > 5 marathons.

CONCLUSION: Findings suggest the EET necessary for performing multiple marathons may be a factor contributing to lower libido in endurance trained men.

Lactate Response During High Frequency Pitching Among Baseball Players
 Ching-Yu Tseng¹, Sun-Chin Yang², Chia-Chi Wang³. ¹*Fu Jen Catholic University, New Taipei City, Taiwan.* ²*Shih Hsin University, Taipei, Taiwan.* ³*Shih-Hsin University, Taipei, Taiwan.* (Sponsor: Kuo, Chia-Hua, FACSM)
 Email: 015844@mail.fju.edu.tw
 (No relationships reported)

PURPOSE: To determine lactate and glucose responses during a high frequency pitching in adult pitchers.

METHODS: Seven pitchers voluntarily participated in this randomized counter-balanced trials. Each pitcher threw 15 fastballs per inning at their best effort for 7 innings. Rest interval trials were 8, 12, and 20 sec between pitches. Blood lactate and glucose concentrations were measured at the end of each inning.

RESULTS: Plasma lactate and glucose levels remained stable over the course of 7 innings during the 20-sec trial. Significant increases in lactate occurred only during the 8-sec trial at the end of 6th and 7th innings. Increases in glucose among pitchers were modest, and no significant difference among trials was observed.

CONCLUSIONS: The increased lactate response during the high frequency throwing (8-sec pace) trial may be associated with greater motor unit recruitment of throwing muscle than the low frequency trials (12-sec and 20-sec trials).

Knee Isokinetic Strength And Fat Free Mass Correlate To Anaerobic Output Among Air Force Operators
 Meleesa Wohleber¹, Andrew Simonson¹, Mita Lovalekar¹, Deirdre Rafferty², Timothy Sell³, Andrew Reinert⁴, Christopher Connaboy¹. ¹*University of Pittsburgh, Pittsburgh, PA.* ²*University of Colorado, Aurora, CO.* ³*Duke University, Durham, NC.* ⁴*University of Montana, Missoula, MT.*
 Email: mew119@pitt.edu
 (No relationships reported)

Air Force Special Tactics (ST) Operators have unique tactical demands requiring optimal body composition, strength, and anaerobic energy to perform operationally relevant tasks, i.e. casualty carry or sprints between cover positions. Identified modifiable injury risk factors such as body composition and strength could affect anaerobic performance. **PURPOSE:** To determine relationships of fat free mass and knee isokinetic strength to anaerobic power and capacity in ST Operators.

METHODS: A total of 158 ST Operators (Age = 27.57 ± 4.95yrs, Height = 177.60 ± 5.92cm, Mass = 84.23 ± 8.33kg) participated. Subjects underwent right and left knee flexion (RKF, LKF) and extension (RKE, LKE) strength testing using an isokinetic dynamometer. A BodPod measured fat mass (FM) and fat free mass (FFM). A Wingate testing protocol for anaerobic power (PAnP) and capacity (MAnP) was conducted using the Veletron. The variables included RKF, LKF, RKE, LKE (average peak force), FM, FFM, PAnP and MAnP. Non-parametric statistical analysis was utilized with Spearman's rho significance set at p < 0.05 *a priori*.

RESULTS: Pairwise correlations were statistically significant for RKF and PAnP/MAnP (r = 0.449, p = 0.001/r = 0.454, p = 0.001), LKF and PAnP/MAnP (r = 0.515, p = 0.001/r = 0.503, p = 0.001), RKE and PAnP/MAnP (r = 0.511, p = 0.001/r = 0.443, p = 0.001), LKE and PAnP/MAnP (r = 0.525, p = 0.001/r = 0.419, p = 0.001), FFM and PAnP/MAnP (r = 0.731, p = 0.001/r = 0.803, p = 0.001).

CONCLUSIONS: Air Force ST Operators' isokinetic knee strength and FFM significantly correlated to anaerobic power and capacity. Additional muscle fiber recruitment availability and increased torque generation at the knee could explain these anaerobic output relationships. Optimizing anaerobic pathways could improve Operator tasks requiring short bouts of energy and movements needing power. Knee strengthening and gaining lean mass while decreasing fat mass could reduce injury risk for the Operator. Human performance programming addressing knee strength, body composition, and anaerobic power could positively affect tactical readiness. Opinions, interpretations, conclusions, and recommendations are those of the author and not necessarily endorsed by the Department of Defense, US Air Force, or US Air Force Special Operations Command. Effects Of Gaelic Football Match Play On Markers Of Muscle Damage, DOMS And Neuromuscular Performance

Dermot M. Sheridan, Kevin Reilly, Eoin Durkan, Javier Monedero, Enda Murphy, Barry Watters, Niall M. Moyna, FACS.M. *Dublin City University, Dublin, Ireland.*
 Email: dermot.sheridan36@mail.dcu.ie

(No relationships reported)

PURPOSE: This study examined the alterations in circulating creatine kinase (CK) levels, leukocyte trafficking, delayed onset muscle soreness (DOMS), neuromuscular function and sprint performance in response to Gaelic football match-play.

METHODS: Participants (n=30, age 17.41 ± 0.78 yr, height 176.42 ± 7.13 cm, and mass 72.03 ± 6.49 kg) played a single competitive 15-a-side Gaelic Football game of 60 min duration. Blood samples were taken before the game, immediately post game (Post), 24 h post game (+24 h), 48 h post game (+48h) and 72 h post game (+72 h). Subjective muscle soreness, sprint performance and muscle power were measured Post, +24 h, +48h and +72 h. Heart rate and movement patterns were continuously measured throughout the game using telemetry and GPS tracking, respectively. Heavy to severe impacts were classified as acceleration G-forces ≥ 7 recorded via portable accelerometry.

RESULTS: Participants covered an average distance of 6.1 ± 1.1 km during match play. The majority (72%) of the distance involved walking and jogging. High speed and maximal running accounted for 10% of the total distance. There were a total of 155 impacts ≥ 7 G-forces. CK levels were significantly higher than baseline immediately post-game and 12h+ and returned to pregame values at +36 h. Compared to pre-match values circulating leukocytes and granulocytes were significantly higher than pre-game values post game and decreased significantly below pre-games values at +12h, +36 h and +60 h. Circulating lymphocyte numbers were significantly decreased below pre-game levels at +36 h. Compared to pre-game values, there was a significant decrease in peak force at +12 h and +60 h and a significant decrease in 5 m and 20 m sprint times at +12 h, +36 h and +60 h. Compared to pre-games values there was no changes in any of the other measured neuromuscular performance indices (flight time, jump time and jump height performance) at any time point. DOMS scores were significantly higher than pre-games values at +12h and +46 h and lower (p<0.05) than pre-game values at +60 h. There was no significant relation between impact and CK levels.

CONCLUSIONS: Competitive Gaelic football match results in significant changes in CK levels, DOMS, leukocyte trafficking, peak force development and 5 m and 20 m sprint performance.

Relationships between Maximal and Rapid Velocity Characteristics of the Leg Extensors and Vertical Jump Performance

Jose G. Pineda, Ty B. Palmer. *Texas Tech University, Lubbock, TX.* (Sponsor: C. Roger James, FACS.M)

(No relationships reported)

Maximal voluntary contractions (MVCs) of the leg extensors on an isokinetic dynamometer have recently been used to evaluate maximum velocity (Vmax) and rate of velocity development (RVD) in young adults. It has been hypothesized that Vmax and RVD characteristics of the leg extensors may be important predictors of athletic performances for movement activities such as balance recovery and running. However, limited data exist regarding how these parameters associate with vertical jump performance. **PURPOSE:** To examine the relationships between vertical jump height and maximal and rapid velocity characteristics of the leg extensors in healthy young men. **METHODS:** Fifteen young men (mean ± SD: age = 23 ± 3 years; height = 176 ± 8 cm; mass = 80 ± 9 kg) performed three countermovement vertical jumps (CMJs) followed by two MVCs of the leg extensors using an isokinetic dynamometer programmed in isotonic mode. CMJ height was measured based on flight time during the CMJs using a jump mat. For each MVC, participants sat in an upright position and were instructed to extend the right leg as "hard and fast as possible" against a controlled resistance of 20% of the individual's isometric maximum strength. RVD was calculated as the linear slope of the velocity-time curve from the onset of velocity to the point where the velocity reached 2°-s⁻¹ below the maximum velocity. Vmax was the maximum velocity attained during the MVC. Pearson product-moment correlation coefficients (r) were used to evaluate the relationships among CMJ height and Vmax and RVD. **RESULTS:** A significant positive relationship was observed between CMJ height and RVD (r = 0.656, P = 0.008); however, no relationship was observed between CMJ height and Vmax (r = 0.487, P = 0.065). **CONCLUSION:** The present findings of a significant relationship between CMJ height and RVD of the leg extensors suggest that rapid velocity capacities of the lower extremity musculature may play an important role in vertical jump performances in young adults. Based on these findings, coaches and practitioners may consider implementing training programs aimed at increasing leg extensor RVD, which may be beneficial for improving vertical jump height and possibly overall athletic ability.

Determining the Impact of Anthropometric Factors on Rock Climbing Performance

Scott R. Richmond¹, Ryan T. Mitchell², Thiomias S. Altena², Hugh M. Gibson². ¹*Lindenwood University, St. Charles, MO.* ²*Missouri State University, Springfield, MO.*
 Email: SRichmond@Lindenwood.edu

(No relationships reported)

Rock climbing is an increasingly popular fitness activity; however, little information is available regarding the physical characteristics associated with climbing walls of differing difficulty. **Purpose:** The purpose of this study was to determine which anthropometric factors had the greatest affect on overall rock climbing performance using three different difficulties of rock walls. **Methods:** Fourteen recreational rock climbers participated in this study (9 males, 5 females, Age: 21.9+/-2.6y, Height: 176.8+/-11.1cm, Weight: 73.4+/-18.7kg). Prior to climbing, all participants were assessed on push-ups, sit-ups, pull-ups, vertical jump, and sit and reach performance. Participants then climbed the three different rock walls (easy = 5:6, medium = 5:8 and hard = 5:9) each wall for 10 minutes. The overall climbing performance is represented through the number of successful climbs, average distance traveled, and RPE scale. **Results:** A stepwise regression test showed BMI was significantly (p<0.001) related to average distanced covered for all walls. Total number of successful accents at the easy wall were predicted by pull-ups (p<0.001) & age (p<0.05); while vertical jump (p<0.01) was the sole predictor for the medium difficulty wall; and success for the hard wall was most related to sit-and-reach scores (p<0.05). As the difficulty of climbing wall increased, so did the average RPE. The remaining anthropometric factors showed little predictive capacity. **Conclusion:** Lower BMI, leg strength, and flexibility are key anthropometric factors in overall rock climbing performance; however, quality of climbing experience may also play an equally critical role based on the level of difficulty of the wall.

3378 Board #283 June 2 3:30 PM - 5:00 PM
Comparing Balance and Power to Baseball Throwing Velocity in Collegiate Baseball Pitchers

Jason V. Slack, Kyle Valgardson, Michael Bohne, Andrew Creer. *Utah Valley University, Orem, UT.* (Sponsor: Scott Drum, FACS.M)

Email: jason.slack@uvu.edu

(No relationships reported)

In baseball, one game or a season can depend greatly on the pitcher's performance. A pitcher's success can be greatly affected by velocity and their ability to maintain that velocity throughout the game. A better understanding of what physical attributes and training protocols affect a pitcher's velocity would be helpful in designing training programs. **PURPOSE:** To examine variables that may potentially impact baseball throwing velocity (BTV). **METHODS:** 12 Division I collegiate baseball pitchers (height=186.7±9.3 cm, weight=91.2±12.4 kg and age=20.5±2.3 years) underwent assessments for upper and lower body power and balance. Lower body power data was collected using the vertical jump test VERTEC (Jump USA, Sunnyvale, CA), and an incline 4.5 kg medicine ball chest press to measure upper body power. Balance was assessed using the BIODEX Balance System SD (Biodex, Inc, Shirley, NY) and measured in the one legged follow through position of the pitch. BTV was collected while pitcher's participated in actual games, off speed pitches were not used in this analysis and the number and type of pitches thrown varied depending upon the circumstance of the game, BTV was recorded using a Stockersport II (Applied Concepts INC, Plano TX) radar gun.

RESULTS: Overall power output was highly correlated to BTV (r²=0.51, p=.006) with the majority of that correlation coming from lower body power (r²=0.47, p=.01) and upper body (r²=0.33, p=.039). Body weight also correlated with BTV (r²=0.74, p=.001), neither height (r²=0.16, p=.167) or balance (r²=0.07, p=.365), anterior/posterior (r²=0.087, p=.33), and medial/lateral (r²=0.11, p=.208) correlated with BTV. Game BTV was significantly decreased when comparing innings 1-3 to innings 4-6 respectfully (x=88.06 mph, x=86.57 mph; p=.039).

CONCLUSIONS: There is a strong correlation between power and BTV, more specifically lower body power. With no correlation between height and balance with BTV, but a strong correlation with weight. In addition, fatigue appears to negatively impact BTV. Based on these findings it appears that baseball pitchers may benefit from a conditioning program focused on lower body power to increase the velocity of their pitches. Future investigations could help establish if this type of training could also reduce the impact of fatigue on BTV in the later innings of a game.

Effects of Speed and Agility Training on Combine Performance in Young Male Athletes

Amelia A. Miramonti¹, Joel T. Cramer, FACSM¹, Nathaniel D.M. Jenkins², Zachary M. Gillen¹, Brianna D. McKay¹, Todd J. Leutzinger¹. ¹University of Nebraska - Lincoln, Lincoln, NE. ²Oklahoma State University, Stillwater, OK. (Sponsor: Joel T. Cramer, FACSM)

Email: amelia.miramonti@unl.edu

(No relationships reported)

PURPOSE: Examine the effects of 9 wks of speed and agility training (SAT) on combine test performance in 7 to 13-year-old male athletes.

METHODS: Forty-six boys (7.6 to 13.4 years; height = 152.3 ± 9.9 cm, mass = 44.5 ± 12.1 kg) participated in this study by completing 3 testing sessions: combines 1 and 2 (C1 and C2) were separated by up to 4 days for familiarization and test-reliability, while combine 3 (C3) was performed 9 wks after C2. Combine measures included vertical jump (VJ, cm), broad jump (BJ, cm), pro-agility drill (PA, s), L-cone drill (LC, s), and 40-yd sprint (S40, s) with 10- and 20-yd splits (S10 and S20, s). The SAT group (n = 23) participated in a 9-wk SAT camp with 1 session-wk⁻¹ (1.5 hr-session⁻¹). The control (CON) group (n = 23) was age-matched, did not perform the SAT, but maintained their regular sports activities.

RESULTS: There was no difference in sports participation hours reported between the SAT and CON groups (p = 0.17). There were no group × time interactions (p ≥ 0.12), no main effects for group (p ≥ 0.28), but there were main effects for time for BJ and PA (p ≤ 0.01). There were systematic improvements in PA, LC, and S10 (p ≤ 0.01) from C1 to C2, but not VJ, BJ, S20 or S40 (p ≥ 0.06). Intraclass correlation coefficients (ICC_{3,1}), coefficients of variation (CV, %), standard errors of measurement (SEM), and minimum detectable changes (MDC) were [test: ICC (CV, SEM, MDC)] VJ: 0.91 (8.6%, 3.4 cm, 9.5 cm); BJ: 0.89 (6.8%, 10.5 cm, 29.2 cm); PA: 0.89 (3.7%, 0.22 s, 0.61 s); LC: 0.84 (4.5%, 0.42 s, 1.18 s); S10: 0.68 (6.8%, 0.15 s, 0.42 s); S20: 0.91 (3.8%, 0.14 s, 0.40 s); S40: 0.72 (7.7%, 0.52 s, 1.44 s). Over the 9 wks, 1 boy exceeded the MDC for BJ and LC; 5 exceeded MDC for S10; and 3 exceeded MDC for S20. Seventeen boys exceeded the SEM for VJ; 16 exceeded the SEM for BJ; 11 exceeded the SEM for PA; 12 exceeded the SEM for LC; 15 exceeded the SEM for S10 and S20; 2 exceeded the SEM for S40.

CONCLUSIONS: The SAT (1 session-wk⁻¹; 9 wks) did not enhance combine performance beyond normal sports participation in young male athletes. Sensitivity, as evaluated by reliability and boys exceeding the MDC (and SEM) after a familiarization session and the 9-wk intervention period, was greatest for the VJ, BJ, PA, LC, S10, and S20 tests. Future studies aiming to examine combine performance enhancement training in youth athletes may consider using these tests.

A Comparison of Infant Physical Activity in Daycare vs Homecare Environments

Kailey Snyder, Jung Min Lee, Danae Dinkel. University of Nebraska at Omaha, Omaha, NE. (Sponsor: Dustin Slivka, FACSM)

Email: kailey.snyder@yahoo.com

(No relationships reported)

The impact a childcare environment has on a child's cognitive and behavioral development has been widely studied. Differences have been found between children primarily cared for at home by a stay-at-home parent (homecare) compared to a child who attends full-time daycare. Positive findings can be found in both environments with homecare children potentially showing less aggressive and impulsive behaviors and daycare children achieving cognitive development milestones earlier. However, little work has assessed a child's, particularly an infant's (<12 months old) physical development (i.e., physical activity level) in both environments. **PURPOSE:** To compare the level of infant physical activity in homecare vs daycare environments. **METHODS:** Twelve homecare infants (age = 6.5 ± 0.5 month, weight = 8.20 ± 1.17 kg and length = 66.54 ± 2.66 cm) and fourteen daycare infants (age = 6.5 ± 0.5 month, weight = 8.71 ± 1.34 kg, and length = 68.94 ± 3.02 cm) were recruited to participate in the study. Infant physical activity was assessed using Actigraph GT9X Link accelerometers. Infants wore two accelerometers, left wrist and ankle, for two consecutive weekdays. Accelerometer data from typical daycare hours from 8 am to 5 pm were only utilized for the data analyses. Two-day total (i.e., 18 hours) ankle and wrist vector magnitude counts (VMC) were used as the physical activity indicator.

Statistical analyses were performed using independent sample t-tests for homecare and daycare infants. **RESULTS:** Homecare infants had significantly lower VMC ($t(24) = -1.20, p = 0.036$) at the wrist (VMC=1689546.13) compared to daycare infants (VMC=2091775.09). However, there was not a significant difference in physical activity at the ankle ($t(24) = -0.542, p = 0.800$) between homecare infants (VMC=1300498.16) and daycare infants (VMC=1438831.43). **CONCLUSION:** Daycare infants appear to be achieving more physical activity than homecare infants. Further research studies are needed to understand this variation and to determine why infants may be achieving more physical activity in the daycare environment. Future research should consider utilizing larger sample sizes as well as assessing variables such as infant to caregiver interaction and the type of infant play.

Construct Validity And Test-retest Reliability Of The International Fitness Scale (ifis) In Colombian Children And Adolescents Aged 9-17.9 Years: The Fuprecol Study

Daniel H. Prieto-Benavidez¹, Robinson Ramírez-Vélez¹, Jorge E. Correa-Bautista¹, Antonio Garcia-Hermoso². ¹Centro de Estudios para la Medición de la Actividad Física «CEMA», Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogota, Bogota, Colombia. ²Laboratorio de Ciencias de la Actividad Física, el Deporte y la Salud, Universidad de Santiago de Chile, Santiago, Chile.

Email: robin640@hotmail.com

(No relationships reported)

PURPOSE: There is a lack of instruments and studies in Spanish for evaluating physical fitness, and this hampers establishing the current status of this important health indicator regarding the Latin population, especially in Colombia. The aim of the study was two-fold: to examine the validity of the International Fitness Scale (IFIS) on a population-based sample of schoolchildren from Bogota, Colombia; and to examine the reliability of the IFIS in children and adolescents from Engativa, Colombia.

METHODS: Participants comprised 1,875 Colombian youths (56.2% girls) aged 9 to 17.9 years old. We measured adiposity markers (percentage of body fat, waist-to-height ratio, skinfold thicknesses and body mass index), blood pressure, lipids profile, fasting glucose, and physical fitness levels (self-reported and measured). A validated cardiometabolic risk index score was also used. An age- and sex-matched sample of 229 schoolchildren, originally not included in the study sample, fulfilled the IFIS twice for reliability purposes.

RESULTS: Our data suggest that both measured and self-reported overall fitness levels were associated inversely with percentage of body fat indicators and a cardiometabolic risk index score. Overall, schoolchildren who self-reported "good" and "very good" fitness had better measured fitness levels than those who reported "very poor" and "poor" fitness (all p<0.001). Test-retest reliability of IFIS items was also good, with an average weighted kappa of 0.811.

CONCLUSIONS: Our findings suggest that self-reported fitness, as assessed by the IFIS, is a valid, reliable, and health-related measure, and it can be a good alternative for future use in large studies with Latin schoolchildren from Colombia.

The Continuous Metabolic Syndrome Score, Physical Activity, and Inflammation in Adolescents

James A. Janssen¹, Nathaniel T. Berry¹, Lilly Shanahan², Zachary A. Kincaid¹, Jessica M. Dollar¹, Cheryl A. Lovelady¹, Susan D. Calkins¹, Susan P. Keane¹, Laurie Wideman, FACSM¹. ¹UNCG, Greensboro, NC. ²University of Zurich, Zurich, Switzerland.

(Sponsor: Laurie Wideman, FACSM)

Email: jajansse@uncg.edu

(No relationships reported)

Recent reports suggest that metabolic syndrome (MetS) may emerge as early as childhood or adolescence, but no universal definition of MetS is available for these age groups. Continuous metabolic syndrome (cMetS) scores—standardized-normalized z scores based on the 5 components of MetS—take into account the severity of a single risk factor, and subclinical values. This composite score may more appropriately distinguish cardiovascular risk when compared to the traditional dichotomous outcome. **PURPOSE:** To investigate the use of cMetS scoring in a sample of adolescents, and determine associations with physical activity (PA) and inflammation. **METHODS:** As part of a larger study, a subset of 16 y.o. (N=107; 57% female; 68% Caucasian) completed a blood draw, anthropometric (BMI, waist circumference (WC)), and blood pressure measurements. Self-reported PA was assessed using the Godin Leisure-Time Exercise Questionnaire. Blood was analyzed for metabolic and immune markers; glucose, triglycerides (TG), c-reactive protein (CRP), and HDL were used in the present analyses. The cMetS score was calculated as the sum of the z scores based on sample means and standard deviations of each of the 5 factors that make

up MetS (glucose, TG, HDL-inverse, WC and mean arterial pressure). Correlations were performed to assess associations between cMetS, individual MetS components, PA, BMI and CRP. **RESULTS:** Consistent with previous findings, MetS was low in our sample (6/107). Of the 45 participants with the highest cMetS scores, 44 did not achieve clinical MetS criteria. Neither total nor strenuous PA were associated with cMetS, however PA was correlated with WC ($r = -0.49, p < 0.001$). Higher levels of CRP ($r = 0.38, p < 0.001$) and increased concurrent BMI ($r = 0.534, p < 0.001$) were associated with higher cMetS scores. **CONCLUSION:** In populations where clinical MetS is low, cMetS may provide increased resolution and reflect a more global assessment of cardiovascular risk. This is supported in our findings, which show that cMetS scores were not necessarily indicative of the number of clinical MetS risk factors in adolescents. Since cMetS is unrelated to self-reported PA, future work should attempt to identify whether associations exist with other health behaviors or objective PA measures.

 (No relationships reported)

PURPOSE: Examine clustered metabolic risk (cMetS) score in adolescents classified as not overweight/active (NOA), not overweight/not active (NONA), overweight/active (OA), and overweight/not active (ONA). **METHODS:** Sample (n=875) included adolescent (12-17 years) participants in the 2007-2012 National Health and Nutrition Examination Survey. The cMetS score included triglycerides, high-density lipoprotein cholesterol, fasting blood glucose, and mean arterial pressure. Age- and sex- specific body mass index percentiles were utilized. Activity data included self-reported frequency of moderate-to-vigorous physical activity (PA). Adolescents reporting ≥ 60 min/d of PA were considered "active". A six-year fasting sample weight was applied to the analyses. Findings were adjusted for age, sex, and race/ethnicity. **RESULTS:** The cMetS scores were significantly ($p < 0.05$) higher in OA and ONA adolescents when compared to NOA ($\beta = 1.08$ and $\beta = 1.57$, respectively). In ONA males, cMetS was significantly ($p < 0.01$) higher when compared to NOA males. In OA and ONA females, cMetS scores were significantly higher ($p < 0.05$ for both). **CONCLUSIONS:** The cMetS scores were higher in OA and ONA adolescents when compared to NOA.

Muscular Strength And Endurance And Cardio-metabolic Health In Low-income Hispanic Children

Ryan D. Burns, Timothy A. Brusseau. University of Utah, Salt Lake City, UT.
 (No relationships reported)

The predictive relationship between muscular strength and endurance and cardio-metabolic health, independent of aerobic fitness, is not clear in disadvantaged Hispanic children. **PURPOSE:** The purpose of this study was to examine the predictive relationship between muscular strength and endurance and clustered cardio-metabolic risk, controlling for aerobic fitness, in Hispanic children from low-income schools. **METHODS:** Participants were 320 Hispanic children (Mean age = 10.1 ± 1.1 years; 164 girls, 156 boys) recruited during the 2014-2015 and 2015-2016 academic years from five low-income schools from the state of Utah in the U.S. Muscular strength and endurance was assessed using the push-up and curl-up tests and estimated $\text{VO}_2^{\text{peak}}$ was calculated from the Progressive Aerobic Cardiovascular Endurance Run. A clustered metabolic syndrome composite score (MetS) was calculated from cardio-metabolic health measurements consisting of HDL cholesterol, triglycerides, waist circumference, blood glucose, and mean arterial pressure (MAP). Multi-level general linear mixed effects models were used to examine the predictive relationship between muscular strength and endurance and MetS, controlling for the effect of aerobic fitness and the clustering of children within classrooms and schools. **RESULTS:** Children who were in the middle and upper tertiles for muscular strength and endurance associated with a lower (more favorable) MetS score (middle tertile: $\beta = -2.59, 95\% \text{ C.I. } [-4.23, -0.95], p < 0.05$; upper tertile: $\beta = -1.57, 95\% \text{ C.I. } [-3.20, -0.16], p < 0.05$). **CONCLUSION:** The results suggest that higher levels of muscular strength and endurance have a protective effect on cardio-metabolic risk, independent of aerobic fitness, in Hispanic children from low-income schools.

The Association Between Physical Activity And Health Risk Behaviors in Brazilian Adolescents

Fabio E. Fontana¹, Michael P. Da Silva², Edmar R. Fantinelli³, Nicolau Malta³, Gabriela C. Martins³, Eliane D. A. Bacil³, Wagner Campos³. ¹University of Northern Iowa, Cedar Falls, IA. ²Iowa State University, Ames, IA. ³Federal University of Paraná, Curitiba, Brazil. (Sponsor: Gregory J. Welk, FACSM)
 Email: fabio.fontana@uni.edu
 (No relationships reported)

Adolescence is a critical period where major physical and psychologic changes occur. It is also a period where several lifelong health related behaviors are adopted and established. Behaviors such as unhealthy eating, tobacco use, alcohol use, and physical inactivity are related to major causes of morbidity and mortality among young and adults. Physical activity (PA) is an important behavior during adolescence not only because it is associated with general health, but also because it may be associated with other health-related risk behaviors.

PURPOSE: To examine the association of physical activity with health risk behaviors in adolescents from Curitiba- Brazil.

METHODS: A cross-section study was carried out with a representative sample of 928 (mean age 14.06 ± 1.91 years old, 467 girls) adolescents enrolled in 14 randomly selected public schools from Curitiba, Brazil. The Brazilian version of the Youth Activity Profile survey evaluated PA levels and the YRBS survey evaluated fruit, vegetable, alcohol, and tobacco consumption in the past 30 days. The Adolescent Sedentary Questionnaire evaluated total screen time. Binary Logistic regression measured the association between PA levels and risk behaviors after controlling for gender, age, BMI status, income status, and parent educational level.

RESULTS: PA was inversely associated with low fruit consumption (OR = .50, 95% IC = .38 - .66, $p < 0.001$), low vegetable consumption (OR = .55, 95% IC = .42 - .73, $p < .001$), and high screen Time (≥ 3 hours/day) (OR = .79, 95% IC = .65 - .96, $p < .001$).

Additionally, PA was positively associated with the consumption of at least one dose of alcohol in the past 30 days (OR = 1.47, 95% IC = 1.15 - 1.88, $p < .001$), and with the excessive consumption of alcohol (OR = 1.73, 95% IC = 1.29 - 2.33, $p < 0.001$). PA was not associated with Tobacco consumption (OR = 1.01, 95% IC = .67 - 1.52, $p = .96$).

CONCLUSION: The results indicated that adolescents with higher PA levels consumed more fruits and vegetables and spent less time in front of electronic screens. However, adolescents with higher levels of PA were also more likely to report alcohol consumption in the past 30 days. The social characteristics of alcohol consumption may explain its positive relationship to PA.

Understanding the Relations between Physical Activity and Obesity among Chinese Children and Adolescents

Qiang Guo¹, Xiaozan Wang², Allen Jackson, FACSM³. ¹Ning Bo University, Ning Bo, China. ²East China Normal University, Shanghai, China. ³University of North Texas, Denton, TX.
 (Sponsor: Allen Jackson, FACSM)
 Email: matthewgq@gmail.com
 (No relationships reported)

Purpose: The purpose of this study was to examine the relations between self-reported physical activity and obesity among children and adolescents in China.

Methods: The participants are 18424 students (51.9% boys, 49.1% girls) aged 8-18 years old in grades 3 to 12 from six provinces in China. They were divided into three groups by age: 8-12, 13-15, and 16-18. Physical activity level (PAL) was measured by Physical Activity Questionnaire for Children and Adolescents in Chinese (PAQ; Chen, 2008; Li, 2015; Jing, 2016). The summary scores of the PAQ were classified into three PAL categories "low (PAL ≤ 2), medium ($2 < \text{PAL} \leq 3$), and high (PAL > 3)".

In addition, physical fitness including high and weight were measured according to national standards of physical fitness during physical education classes. Weight status was classified into four categories "malnutrition, normal, overweight and obese" using BMI cut-points. Descriptive analysis, independent t-tests, ANOVA and Chi-square were used in the study.

Results: The distribution of PAL decreased for girls with age and the PAL of boys was significantly higher than girls in all three groups ($t = 9.12, t = 18.91, t = 16.72, p < 0.01$). The percentage of PAL of girls in the low category dramatically increased from 15 years (47%) to 18 years (66%). Significant differences in PAL were found across obesity classifications (for 8-12, $f_{\text{boys}} = 12.39, f_{\text{girls}} = 6.86$; for 13-15, $f_{\text{boys}} = 11.88, f_{\text{girls}} = 7.66, f_{\text{girls}} = 6.69, p < 0.001$) except girls aged 13-15 years ($f = 1.42, p > 0.05$). Furthermore, the distribution of PAL in obesity classifications presents like a "U" that shows values of PAL were higher in the classifications of malnutrition and obesity than values in normal and overweight. Obesity status was significantly related to PAL (for 8-12, $\chi^2_{\text{boys}} = 34.86, \chi^2_{\text{girls}} = 28.07$; for 13-15, $\chi^2_{\text{boys}} = 27.80$; for 16-18, $\chi^2_{\text{boys}} = 21.56, \chi^2_{\text{girls}} = 29.04, p < 0.01$), but not girls aged 13-15 ($\chi^2 = 5.81, p > 0.05$).

Conclusions: PAL was significantly related to weight status in Chinese children and adolescents. Boys demonstrated higher levels of PA across all age groups. Girls demonstrated a 19% decrease in PAL across 15 to 18 years of age.

The Correlations Between Types of Families and Physical Activity Levels of Adolescents in Shanghai, China
 Fan Xiang¹, Zhu Zheng², Zhuang Jie², Liu Yang², Tang Yan², Chen Pei jie², Cao Zhen bo². ¹Shanghai Jiao Tong University, Shanghai, China. ²Shanghai University of Sport, Shanghai, China. (Sponsor: Mitsuru Higuchi, FACSM)
 Email: fansheva@sjtu.edu.cn
 (No relationships reported)

Previous studies have indicated that families can influence adolescents' physical activity. The fifth census in China (2010) showed that 65.3% of the families in China are nuclear, but few studies have explored the association between the various types of families and the physical activity (PA) levels of adolescents in China using a large sample survey.

PURPOSE: To determine the correlations between types of families and the PA levels of adolescents aged 9-19 years while accounting for background demographic factors, such as age, gender, and socioeconomic status, in Shanghai, China.

METHODS: In 2014, 9-11-year-old ($N=13,237$), 12-14-year-old ($N=11,157$), and 15-19-year-old ($N=8,819$) adolescents and their guardians were randomly sampled from 17 districts in Shanghai, China. The adolescents' moderate-to-vigorous physical activity (MVPA) levels, information about the type of family, and the guardians' sociodemographic factors were collected via a questionnaire completed by the adolescents and guardians.

RESULTS: Analysis of covariance revealed that, after controlling for socioeconomic status and the age of the adolescents, 9-11-year-old boys from two-parent families spent more minutes per week in MVPA (297.4 ± 120.4) than those who live with their grandparents (286.9 ± 120.1) and those from single-parent families (284.6 ± 129.4 , $P < 0.05$). Regarding the girls aged 12-14 years, those who live with their grandparents spent more minutes per week in MVPA (274.4 ± 105.7) than those from two-parent families (271.9 ± 105.1) or single-parent families (257.3 ± 107.0 , $P < 0.05$). Regarding the adolescents aged 15-19 years, we did not find significant differences between the boys and girls. Logistic regression analysis showed that 9-11-year-old adolescents those who live with their grandparents had 28% for boys (OR 0.72, 95% CI 0.61-0.84) and 16% for girls (OR 0.84, 95% CI 0.72-0.98) decreased odds of did not reach the recommended level (≥ 60 min/day MVPA), respectively, compared with those who from single-parent families. **CONCLUSION:** Being from a single-parent family and living with grandparents are two important factors that influence adolescents' MVPA levels in Shanghai, China.

Self-Reported Physical Activity of High School Students in Southern Maine
 Karen Croteau, FACSM¹, Rose Angell¹, Laurie Milliken, FACSM². ¹Saint Joseph's College, Standish, ME. ²University of Massachusetts Boston, Boston, MA.
 Email: kcroteau@sjcme.edu
 (No relationships reported)

Knowledge of high school students' physical activity (PA) can assist in identifying areas of programmatic need within physical education (PE) and for out of school programs. **PURPOSE:** The purpose of this study was to assess the PA levels and patterns of high school students in southern Maine. **METHODS:** Participants were 142 students (86 females, 56 males) from 4 high schools in southern Maine (one urban, one suburban, two rural). Mean age was 14.9 years with 87% of the sample in grade 9. The validated Physical Activity Questionnaire for Adolescents (PAQA) was used in this study to assess PA. The PAQA asks participants to recall their PA during the previous 7 days. Surveys were administered to students enrolled in PE and were part of a larger study examining attitudes toward PA and PE. **RESULTS:** Mean overall score for the PAQA was 2.62 ± 0.60 (1=low PA, 5=high PA), with a range of 1.18 to 4.29. Males were slightly more active than females overall (2.75 ± 0.72 vs 2.53 ± 0.66 , $p = 0.068$) and reported more PA during evenings (2.96 ± 1.37 vs 2.50 ± 1.29 , $p = 0.044$) and the weekend (2.70 ± 1.08 vs 2.32 ± 1.00 , $p = 0.036$). Students in urban (3.98 ± 0.81) and suburban schools (4.30 ± 0.76) reported significantly greater activity in PE classes than rural students (3.54 ± 0.86) ($p < 0.05$) while students in rural schools (1.65 ± 1.23) reported greater activity during lunch than urban (1.23 ± 0.43) and suburban students (1.12 ± 0.39) ($p < 0.05$). Jogging, walking, basketball, and soccer were the most cited activities overall. Females preferred walking, jogging, dance and skipping rope while males preferred jogging, basketball, walking and soccer. Overall, 10% reported daily activity while 14% reported no activity. In PE, 73% reported doing vigorous activity quite often. At lunch, 80% reported sitting. After school, 46% were very active while 28% reported no activity. During evenings, 29% reported being very active while 29%

reported no activity. Over the weekend, 52% reported being very active 2 or more times, with 21% reporting no activity. **CONCLUSIONS:** These findings provide information on high school students' PA from a sample of southern Maine schools. In addition to PA levels and patterns, knowledge of student preferences for PA would help in PA program development both in PE and for out of school programs.

ICT USE Influence on Activity Pattern & Body Composition Of University Students In Kwara State
 Olufunmilola L. Dominic, EDM¹, Iliasu Y. Seidina¹, Faatihah A. Niyi-Odomosu, EDM², Bamidele V. Owoyele, EDM¹.
¹University of Ilorin, Ilorin, Nigeria. ²National Centre for Sports and Exercise Medicine, Loughborough University, Loughborough, Leicestershire, United Kingdom.
 Email: lolafunmidom@gmail.com
 (No relationships reported)

The use of ICT is a prominent aspect of students' lifestyle in tertiary institutions. ICT creates efficiency in performing tasks but encourages sedentariness, alters body composition and may affect health. **PURPOSE:** To determine influence of ICT use on physical activity pattern and body composition of tertiary institution students. **METHODS:** The study design was Ex-post facto. Multistage sampling was used to select 2,442 students with mean age 22.8 years from three tertiary institutions in Kwara state, Nigeria. Body composition was determined using height scale, body fat/hydration monitor scale (brand number 7032497) and two birds non-elastic tape rule. Validated ICT Use and Physical Activity Questionnaire (IUPAQ) (Rho of .71) was used to assess level of ICT use and physical activity pattern. Approved Ethical Clearance from University of Ilorin and informed consent were duly obtained. Inclusion criteria were penultimate and final year students. Percentage, Mean, and Standard Deviation described the data. Hypotheses were tested at 0.05 alpha level using PPMC, ANOVA and Multiple Regression. **RESULTS:** Many of the students did not perform the recommended physical activity ($n = 1,065$; 43.6%) and their physical activity pattern was sedentary-based (14 hours per day). Average ICT time per day was 9 hours (65%) of which mobile phone time was 4 hours (25%). Strong positive relationship existed between ICT use and sedentariness $r = .84$, $p = .001$; physical activity pattern and ICT use $p = .001$, $r^2 = 15\%$; and ICT use and body composition $p = .001$. Sedentariness was the highest predictor of excessive ICT use $Beta = .120$, $p = .001$ & BMI predictor of risk factor $Beta = .156$. However, light to vigorous intensity physical activity levels indicated low predictive ability of ICT use $p > .05$; Significant difference in the level of ICT use based on age range, $p = .001$ and type of institution of participants $p = .001$ existed. **CONCLUSION:** Prolonged ICT use causes sedentariness and alters body composition with BMI as the highest predictor of risk. This study advocates for institutional physical activity awareness for regulated ICT use campaign.

 (No relationships reported)

PROPOSE: to evaluate physical activity (PA), time expended in sedentary activities and cardiorespiratory fitness (CF) in boys and girls before and after 3 months of regular school.

METHODS: children were evaluated at school after summer vacation and 3 months after regular classes. Weight (kg), height (m), maturational stage was evaluated. CF was evaluated by determining the maximum volume of oxygen during the Test Come and Go 20 meters by Léger. In addition, a questionnaire about PA and screen time during 3 days (3-DPAR instrument) was applied. Data are expressed as average and standard deviation. T Student and Wilcoxon tests were applied to estimate the difference between averages. Level of significance of 5 % was adopted. **RESULTS:** 319 students were included, 146 boys (age 13.6 ± 1.2 yrs) and 173 girls (age 13.6 ± 0.9 yrs). For girls, first VO_{2max} was 43.5 ml/kg/min and second was 48.3 ml/kg/min ($p < 0.002$). For boys, respective numbers were 45.8 ml/kg/min and 49.8 ml/kg/min ($p > 0.05$). No significant difference was found among boys and girls. No difference was found for PA > 300 min/week between the two evaluations and among boys and girls. In time spent with sports, only girls increased significantly from the first to the second assessment ($p < 0.001$). Boys spent more time in sedentary activities (TV, computer and video game) and increased this time between initial evaluation and re-evaluation ($p < 0.001$). **CONCLUSION:** Girls became more active after school start, with increment of VO_{2max} and less time in sedentary activities.

3391 Board #296 June 2 2:00 PM - 3:30 PM
Daily Musculoskeletal Pain Affects Health And Sports Performance Negatively In Youth Athletes

Julia Malmberg¹, M. Charlotte Olsson¹, Stefan Bergman², Ann Bremander¹. ¹Halmstad University, School of Business, Engineering and Science, Halmstad, Sweden. ²Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden.
 Email: julia.malmberg@hh.se
 (No relationships reported)

In sports, musculoskeletal pain (MSP) is often studied from the perspective of sport specific injuries, why little is known about the prevalence of daily or multisite MSP that does not affect participation in sports. It is also unclear if daily or multisite MSP is a risk factor for worse health-related quality of life (HRQoL) and worse sports performance in youth athletes.

PURPOSE: To study how HRQoL and sports performance is affected by daily MSP in youth athletes that are able to participate in sports.

METHODS: 136 Swedish youth athletes attending a sport school (13 to 14 years, boys n=83, girls n=53) completed the EQ-5D measuring HRQoL (range 0 to 1, worst to best), a pain questionnaire including current pain (yes/no), pain in 18 body regions (never to rarely/monthly to weekly/more than once a week to almost daily), and pain intensity in the last week (0 to 10, best to worst), anthropometric measures to estimate biological age, and sports performance tests (grip strength, 20 meter sprint, and countermovement jump(CMJ)).

RESULTS: 109 to 117 of the 136 students answered the different pain questions. 53 of 113 (47%) reported current MSP, and 28 of 109 (26%) experienced MSP 'more than once a week to almost daily' from one or more body regions (frequent MSP group), while 28% (n=30) stated 'never to rarely' in MSP (no MSP group). Boys in the frequent MSP group reported worse HRQoL, higher pain intensity, performed worse in all sports performance tests, and had a younger biological age than boys in the no MSP group. Girls in the frequent MSP group reported worse HRQoL and higher pain intensity than the girls in the no MSP group. No other differences were found (table).

CONCLUSIONS: Every other youth athlete attending a sport school reported current MSP and one out of four reported almost daily MSP. MSP affects HRQoL negatively in both boys and girls, and sports performance negatively in boys. The prevalence of MSP in youth athletes is concerning since pain in younger ages may predict pain in adult ages.

Appropriate Physical Activity on Mental Health in Early Adolescents

Saki Kawakatsu¹, Shohei Kokudo², Ryoji Kasanami³, Mayumi Nagano⁴, Kojiro Ishii⁵. ¹Graduate School of Human Development and Environment, Kobe University., KOBE city, Japan. ²Kobe University, KOBE city, Japan. ³Nara University of Education, NARA city, Japan. ⁴Fukuoka Women's University, Fukuoka city, Japan. ⁵Doshisha University., KYOTANABE city, Japan.
 Email: 137d833d@stu.kobe-u.ac.jp
 (No relationships reported)

The appropriate intensities, amount and details of physical activity (PA) for mental health (MH) have not yet been elucidated for adolescents.

PURPOSE: To investigate the PA factors (intensity, time, activity details [ADs]) that affect MH characteristics, such as depression tendency (DT), in early adolescence

METHODS: The International Physical Activity Questionnaire, including ADs and the Depression Self-Rating Scale for Children, was conducted on 6,969 children (grades 5–8) in Japan. Decision tree analysis was applied to four groups (primary- and secondary-school students for each gender) in order to investigate the effect of PA on DT. The dependent variable was the factor score of decline of fun and activity (F_{DFA}) and depression mood (F_{DM}). The independent variables were amount of time of vigorous-intensity PA (VPA, min/week), moderate-intensity PA (MPA, min/week), walking time (WT, min/week), sedentary behavior on the weekdays (SB_w) and on holidays (min/day), VPA + MPA (MVPA), MVPA + WT (total MVPA), and ADs.

RESULTS: For the results of F_{DFA} excluding ADs, the first classification variable was VPA for primary-school boys (PB), total MVPA for primary-school girls (PG) and secondary-school boys (SB), and MVPA for secondary-school girls (SG). The branch points for F_{DFA} improvement were as follows: PB 4 h 40 min for VPA; PG 5 h and 12 h 45 min for total MVPA; SB 13h 30min and 21h 30min for total MVPA; SG 3h 30min and 21 h for MVPA. When ADs was included in the analysis, the results were same as those for PB and PG but significantly differed for SB and SG. ADs was the only classification variable for SG and was the second classification variable for SB; and sports activities were better than cultural activities for SB & SG.

For the results of F_{DM} , MPA contributed for PB, SB_w for PG, and WT for SG, but these branch points were not confirmed. ADs were associated with F_{DM} for SB, and sports activities were better than cultural activities.

CONCLUSION:

MVPA is a determinant for reduction of DT, such as F_{DFA} , in early adolescence. ADs are an important factor for secondary-school students. Recommended MVPA time is minimally 5 h/week for all early adolescents, >10 h/week for primary-school children, and >21 h/week for secondary-school students.

Supported by Grant-in-Aid for Scientific Research (B) (15H03108), Japan.

Physical Activity and Diet Behavior Patterns of U.S. Adolescent Girls with Different Weight Status

Yaorong He, Hai Yan, Weimo Zhu, FACSM. *University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)
 Email: yaorong2@illinois.edu
 (No relationships reported)

Purpose: The study was to identify the physical activity and diet behavior patterns of U.S. adolescent girls with different weight status.

Method: Data was derived from the 2012 National Youth Fitness Survey. A representative/weighted sample of 7,785,784 girls, aged 12-15 yr. old responded to both the physical activity and diet behavior and nutrition questionnaires. ANOVA analysis was applied to determine the difference in physical activity patterns and eating behaviors among girls with different weight status (underweight, normal weight, overweight, and obese defined by the CDC percentile classifications).

Results: Significant differences were detected in the physical activity and diet behaviors patterns, and the results are displayed in the table below:

	Under-weight	Normal weight	Over-weight	Obese	Total	F	p-value
Vigorous-intensity work (min)	71.54±35.33	81.72±54.62	0	0	97.86±91.52	3168.29	<.001
Moderate-intensity work (min)	32.78±15.95	58.65±45.41	60.37±36.81	51.29±9.92	57.06±47.28	22446.75	<.001
Sedentary activity (min)	530.97±132.19	506.04±154.50	522.75±125.89	489.72±156.12	508.88±150.59	8608.16	<.001
# of times/week get school lunch	3.16±2.24	3.17±2.24	3.96±1.56	4.17±1.40	3.29±2.18	45525.19	<.001
# of times/week get school breakfast	1.09±2.06	1.28±2.08	1.64±2.07	.65±1.23	1.28±2.06	15198.79	<.001
# of meals not home prepared/week	2.29±2.62	1.87±1.85	1.98±2.04	.99±1.08	1.88±1.92	31966.502	<.001
# of ready-to-eat foods in past 30 days	.27±.95	.88±2.91	1.00±2.51	1.35±1.61	.87±2.74	12704.638	<.001
# of frozen meals/pizza in past 30 days	3.23±3.85	2.61±4.06	1.86±3.00	2.42±2.67	2.57±3.91	14507.226	<.001

Conclusion: Overweight and obese girls tended to have less vigorous work and more ready-to-eat food.

The Effect of Bullying on Health Behaviors in Adolescents

Kayla M. Baker¹, Jeanette M. Garcia¹, Sean Healy², David J. Rice³. ¹University of Central Florida, Orlando, FL. ²Humboldt State University, Arcata, CA. ³Florida Southern College, Lakeland, FL.
 Email: kayla.baker@ucf.edu
 (No relationships reported)

PURPOSE: To examine the association of bullying with physical activity, sedentary behaviors, and participation in organized sports in a sample of adolescents living in Ireland. **METHODS:** The sample consisted of 7,314 adolescents (13 years of age; 55 % female) who were part of the Growing Up in Ireland (GUI) study, a national study that focused on a broad range of adolescents' characteristics, experiences, and development. Adolescents completed a series of questionnaires assessing whether participants had been victims of bullying, and their feelings associated with bullying (fear, isolation, and anger). Participants also reported amount of time engaging in vigorous physical activity (VPA), sedentary behaviors (SB) (watching the television, playing computer games, and playing video games), playing an organized sport (SPORTS), and the number of friends who engage in these activities with participants. Multiple regression analysis was used to examine the association of bullying with

VPA, SPORTS, and SB. Significance was set at $\alpha \leq 0.05$. **RESULTS:** Engaging in greater amounts of VPA was associated with lower levels of SB ($\beta = -0.03$, $p < 0.0001$), and a greater number of friends ($\beta = 0.20$, $p < 0.0001$), however, bullying did not affect participation in VPA. Increased participation in sports was associated with lower levels of SB ($\beta = -0.02$, $p < 0.0001$) and a greater number of friends ($\beta = 0.09$, $p < 0.0001$), however, participants who reported bullying were less likely to participate in sports ($\beta = -0.12$, $p < 0.002$). Greater time spent in SB was associated with increased anger as a result of being bullied ($\beta = 0.64$, $p = 0.03$). **CONCLUSION:** Greater attention should be paid to the prevention of bullying in schools. In addition to the negative psychological effects on adolescents, bullying may deter adolescents from participation in sports, and indirectly increase time spent in SB.

(No relationships reported)

Childhood obesity is a public health concern with the trajectory into adult obesity. Increasing moderate-to-vigorous physical activity (MVPA) and decreasing sedentary behavior (SB) are associated with lowered childhood obesity. Environmental factors, such as outdoor time and TV viewing time (TVVT), may contribute to MVPA and SB in preschool children. The child-care environment influences MVPA and SB, and is an area for improving activity patterns. **PURPOSE:** The purpose of this study is to determine the relationship between outdoor time and TVVT with physical activity in preschool children at the child-care center, while adjusting for classroom similarities. **METHODS:** An observational study at child-care centers was conducted during 2011-2014. Outdoor time was defined as time children spent in an outdoor play space, and TVVT was defined as time children spent watching TV. Outdoor time and TVVT were observed on two days using a digital wrist watch. Physical activity intensity and duration was measured for the entire school-day using waist-worn accelerometers. Data were recorded in 15-second epochs and analyzed with age-specific cut points to determine intensity. Dependent movement variables included minutes of SB, light physical activity (LPA), MVPA, and total steps. Hierarchical models were adjusted for weather, and used for the clustering of children within the classroom. **RESULTS:** Participants ($n = 202$) of 34 classrooms were 3.7 ± 0.7 years old, 51% male, and 60% Caucasian. Children took 4453 ± 1655 steps, 310 ± 83 minutes of SB, 36 ± 13 minutes of LPA and 19 ± 10 minutes of MVPA. Outdoor time was observed in 87% of classrooms for 77 ± 65 minutes, and TVVT was observed in 52% classrooms for 57 ± 39 minutes. In hierarchical modelling, outdoor time was associated with SB ($p < 0.01$), LPA ($p < 0.01$), MVPA ($p < 0.01$) and steps ($p < 0.01$). At the classroom level there were mixed results on the impact of outdoor time, some classrooms with higher outdoor time exhibited higher LPA, MVPA and steps, while others engaged in more SB. TVVT was only associated with MVPA ($p < 0.01$), with differing directions of association at the classroom level. With higher TVVT, some classrooms showed more and others less MVPA. **CONCLUSIONS:** Investigating the differences between classrooms and the role of the teacher may help increase children's physical activity.

Time Segment Specific Physical Activity During School Hours In Six- Nine- And 15-year-olds

Knut Eirik Dalene, Bjarne H. Hansen, Ulf Ekelund, FACSM, Sigmund A. Anderssen, Fabian Andersen, Elin Kolle. Norwegian School of Sport Sciences, Oslo, Norway. (Sponsor: Jorunn Kaiander Sundgot-Borgen, FACSM)

Email: k.e.dalene@nih.no

(No relationships reported)

It is recommended that youth spend ≥ 60 min/d in physical activity (PA) of moderate-to-vigorous intensity (MVPA). Because the vast majority of children attend school, this environment can provide an ideal arena for PA promotion and it has been argued that schools should provide opportunities to accumulate ≥ 30 min/d of MVPA (i.e., $\geq 50\%$ of recommended daily minimum). However, the current knowledge of MVPA accumulated during school is limited by small sample sizes, short duration of observation and inaccurate segmentation of periods during the school day. **Purpose:** To examine time segment specific MVPA during school hours, using accurately segmented accelerometer data collected over a full school week in a representative, population-based sample of 6-, 9-, and 15-year-olds attending a diverse sample of schools. **Methods:** We used accelerometer data (ActiGraph GT1M/ GT3X+) from a sub-sample of the PA among Norwegian Children Study. Participants attended 34 different schools (82 classes) that provided class schedules describing the exact start

and end time of the school day, recess periods and physical education (PE) classes. To classify time segment specific MVPA, we summed all 10 sec epochs within the different time segments containing > 333 activity counts (vertical axis). We applied random effects linear regression models, accounting for the clustered nature of the data. **Results:** Among 6- ($n = 166$), 9- ($n = 296$) and 15-year-olds ($n = 323$), 57%, 35% and 9% accumulated ≥ 30 min of MPVA per school day, respectively. Boys accumulated significantly more MVPA than girls during school hours, recess and PE (adjusted for wear time (WT) and month, $p \leq 0.011$). We found an inverse association between age and school hour MVPA ($p < 0.001$), whereas the association was inverted and J-shaped with age (adjusted for WT, month and sex, $p < 0.001$) for recess MVPA. We found no association between age and MVPA during PE ($p \geq 0.154$). **Conclusion:** Low proportions of 6-, 9- and 15-year-olds accumulated ≥ 30 min of MVPA during school hours, and girls accumulated less MVPA than boys throughout the school hours in all age groups. Our results indicate that self-organised MVPA (recess), but not teacher organized MVPA (PE), declines with age. This suggest that schools should provide opportunities for structured PA during recess, especially for adolescents and girls.

Day-to-day Reciprocal Associations Between Sleep Health, Physical Activity, And Sedentary Behavior In Adolescents

Youngdeok Kim¹, Masataka Umeda², Marc Lochbaum¹, Steven Stegemeier¹. ¹Texas Tech University, Lubbock, TX. ²University of Texas at San Antonio, San Antonio, TX.

Email: youngdeok.kim@ttu.edu

(No relationships reported)

Physical activity (PA) has been continuously examined as one of the modifiable lifestyle factors influencing sleep health in adolescents. However, the evidence is inconclusive and scarce data are available exploring temporal, bidirectional relationships between PA, sedentary behavior (SB), and sleep health in this population. **PURPOSE:** This study examined the day-to-day reciprocal associations of objectively measured PA, SB, and sleep parameters in young adolescents. **METHODS:** 263 adolescents (135 boys) in 6th-8th grades were asked to wear the ActiGraph GT9X accelerometer on their non-dominant wrist for 24-hour across three consecutive school days while completing sleep quality survey every morning. The parents recorded daily screen time of their child. Total sleep time (TST), sleep efficiency, and sleep fragment index (SFI) were estimated using the Sadeh algorithm. The % of moderate and vigorous PA (MVPA) and SB, relative to total wear time in a day, before and after school ends (BS and AS, respectively), were estimated using the Chandler's cut points for each measurement day. Multilevel models were constructed to examine the day-to-day reciprocal associations between study variables after adjusting for the repeated measures within participants as well as study covariates. **RESULTS:** MVPA and SB on one day were significantly associated with TST on that night. The reduced TST was associated with increased MVPA-AS ($b = -2.72$; $p = .045$) and SB-AS ($b = -2.62$; $p < .001$) while an inverse relationship was observed with SB-BS ($b = 2.20$; $p < .001$). The increased SB-AS was associated with improved sleep efficiency ($b = 0.16$; $p = .006$) and SFI ($b = -0.24$; $p = .002$), and screen time was associated with a decreased likelihood of having good sleep quality ($OR = 0.89$; 95% $CI = 0.82, 0.97$). Meanwhile, TST on previous night was associated with SB-BS ($b = -0.02$; $p < .001$) on next day, and lower sleep quality was associated with decreased MVPA-BS ($b = -0.24$; $p = .042$), increased SB-AS ($b = 1.62$; $p = .022$) and screen time ($b = 14.54$; $p = .049$) on next day, respectively. **CONCLUSIONS:** The current study suggests that, in general, a good perceived sleep quality on the previous night can potentially promote PA and reduce SB on next day. However, the temporal effects of PA and SB on sleep health are still inconclusive that warrants future study.

3398 Board #303 June 2 2:00 PM - 3:30 PM
Recess, Regular Physical Activity Outside Of School And Academic Achievement In U.S. Elementary School Students

Beate Henschel, Andrea Kaye Chomistek. Indiana University, Bloomington, IN. (Sponsor: Georgia C. Frey, FACSM)

Email: bhenschel@indiana.edu

(No relationships reported)

Physical activity (PA) in general, but also time for recess, has declined in recent decades among children in the U.S. Carlson et al (2008) found small beneficial effects of time spent in physical education on math and reading scores but did not include recess or other PA measures.

PURPOSE: To assess the association between recess, regular PA outside of school, and math scores in U.S. elementary school students. **METHODS:** We used the Early Childhood Longitudinal Study, Kindergarten Class of 1998-1999 (ECLS-K) for this analysis. Students in the ECLS-K cohort were followed from Kindergarten (KG) through 1st, 3rd, 5th and 8th grade; but here only data from full-time KG, 3rd and 5th grade was used ($N = 1036$). Mixed models with random effects were estimated to account for clustering by schools and repeated measures by students.

RESULTS: We confirmed the decline of recess over time; however, the majority students in KG, 3rd and 5th grade had daily recess. In the unadjusted models, we found significantly higher math scores in 5th grade among students with more than average ($\beta=4.3$), average ($\beta=4.1$) and below average ($\beta=4.4$) time for recess compared to students with no recess (all $p<0.001$). The effect of recess in 3rd grade was similar but less strong. Additionally, regular PA/exercise outside of school resulted in significantly higher math scores in 3rd grade students ($\beta=4.9$) and 5th grade students ($\beta=3.3$) compared to children without regular exercise (all $p<0.001$). However, once we adjust for race, parental education and gender, the majority of effects of recess on math scores did not remain significant. Only students with a low amount of recess compared to no recess in 5th grade had significantly higher math scores ($\beta=2.1$, $p=0.03$). Also, regular exercise outside of school was positively associated with math scores in 3rd grade ($\beta=2.5$, $p=0.001$).

CONCLUSIONS: Academic achievement is related to future health since school outcomes are highly correlated with future socio-economic status which itself is correlated with health status in adults. We conclude that - compared to race and SES - recess and regular PA seem to be beneficial but of lower importance for academic achievement. Nonetheless, both PA measures are modifiable factors and thus can potentially play a vital role in both health promotion and improved school outcomes.

3399 Board #304 June 2 2:00 PM - 3:30 PM
Tracking Of Clustered Metabolic Syndrome Risk Factor In Japanese Children

KENSAKU SASAYAMA¹, MINORU ADACHI². ¹Okayama University of Science, Okayama, Japan. ²Okayama University, Okayama, Japan.
(No relationships reported)

PURPOSE: Longitudinal studies about "tracking" of metabolic syndrome (MetS) risks are limited in Asian children. It is also unclear whether fitness and/or fatness level are contribute the tracking of MetS risk. The purpose of this study was to investigate tracking clustered metabolic syndrome (MetS) risk taking into account of fatness and aerobic fitness from childhood to adolescence in Japanese children.

METHODS: This cohort study included 113 participants (47 boys and 66 girls) who were measured for MetS risk factors at 9 years and 12 years of age. This study was performed in Ibara city of Okayama prefecture in Japan. All participating children and their parents provided written informed consent before participation. MetS risk scores were calculated from the total sex-specific values (z-scores) of the following five parameters: waist to height ratio, predicted $\dot{V}O_{2peak}$, triglycerides, high density lipoprotein cholesterol, and mean arterial pressure. All measurements were investigated at baseline (September, 2008) and follow-up (September, 2011). Partial correlation coefficients were calculated to determine the tracking of MetS risk variables and clustered MetS risk score from childhood to adolescents. A correlation ranging from 0.00 to 0.29 indicates low relationship, a correlation from 0.30 to 0.59 indicates a moderate relationship, and a correlation from 0.60 to 1.00 indicates a high relationship.

RESULTS: Sex-adjusted partial correlation coefficients were higher for HDL-c ($r=0.804$, $p<0.001$), W/H ($r=0.753$, $p<0.001$) and $\dot{V}O_{2peak}$ ($r=0.715$, $p<0.001$). TG ($r=0.436$, $p<0.001$) and MAP ($r=0.3970$, $p<0.001$) indicated a moderate relationship. In addition, Met risk score ($r=0.647$, $p<0.001$) indicated a high relationship. Correlations coefficients of MetS risk score between 9 and 12 years in high W/H ($r=0.713$, $p<0.001$) was higher than that in low W/H ($r=0.402$, $p<0.01$). In addition, that in low $\dot{V}O_{2peak}$ ($r=0.630$, $p<0.001$) was higher than that in high $\dot{V}O_{2peak}$ ($r=0.452$, $p<0.01$).

CONCLUSIONS: We found that MetS risk was stable from childhood to adolescence in Asian children. Furthermore, our results show that both the fatness and fitness are crucial for tracking clustered MetS risk factors.

The Association of FNPA Score and Nighttime Sleep with Preschooler Body Size and Adiposity

Emily Hill Guseman¹, Cassandra L. Ayres¹, Susan B. Sisson, FACSM². ¹University of Wyoming, Laramie, WY. ²University of Oklahoma Health Sciences Center, Oklahoma City, OK.
Email: eguseman@uwyo.edu
(No relationships reported)

Purpose: The purpose of this study was to examine the cross-sectional associations between characteristics of preschoolers' home environment and sleep habits with body size and adiposity. **Methods:** Parents of 2-5 year-old children completed the Family Nutrition Physical Activity (FNPA) tool and Children's Sleep Habits Questionnaire (CHSQ). Child height and weight were determined according to standard procedures and BMI percentile was determined using the 2000 CDC growth charts. Adiposity was assessed using skinfold thicknesses (tricep, subscapular, suprailiac) and sum of skinfolds was calculated. **Results:** To date, 19 children (10 boys, 9 girls; mean age 3.1 ± 0.9 y) have participated in the study. Boys and girls did not differ in terms of any anthropometric variables; therefore, analyses are not divided by sex. Twenty-one percent of the sample ($n=4$) met criteria for overweight or obesity based on BMI percentile. Correlations between anthropometric variables and the FNPA total score did

not reach statistical significance. Nap duration tended to be inversely related to BMI percentile ($r=-0.51$, $p=0.06$) and z-score ($r=-0.50$, $p=0.07$). The FNPA total score was strongly correlated with total daily sleep ($r=0.88$, $p<0.0001$), indicating that children who live in generally healthy family environments are more likely to demonstrate healthy sleep habits. **Conclusion:** To our knowledge, this is the first study to use the FNPA as a measure of the family environment in a preschool-aged sample. Our results suggest that sleep characteristics may be associated with the family environment and adiposity in preschoolers; however, additional research with larger sample sizes is necessary to confirm these findings.

Physical Activity Levels of 7th and 8th Graders During a Studio-Based Learning Experience

Megan E. Holmes, D. Kay Brocato, Katherine E. Wood.
Mississippi State University, Mississippi State, MS.
Email: mholmes@colled.msstate.edu
(No relationships reported)

Schools are viewed as optimal settings for intervention efforts aimed at reducing childhood obesity. Identification of ways to increase physical activity throughout the school day is an important public health issue. Modest modifications to curriculum delivery or physical environment provide direct avenues to address this issue.

PURPOSE: The purpose of this study was to examine physical activity levels of middle school-aged students during a studio-based learning experience. The studio-based learning environment utilizes the "purpose, critique, iterate" cycle of repetitive thinking and learning that comes from the system of training used by designers across many professional fields. **METHODS:** Eleven 7th and 8th grade students who were identified as being "at-risk" for dropout were invited to participate in an educational service project aimed at developing areas of core curriculum by working on design problems in a studio-based learning environment. The studio-based learning experience was conducted between the hours of 8AM and noon (240 minutes) for two weeks in the summer. Participants were issued an Actigraph GT3x+ accelerometer upon arrival and monitors were collected at the end of each day. Physical activity was also measured the following fall semester in the same students. General anthropometric measurements were also assessed. **RESULTS:** Height approximated the 50th percentile for both boys and girls. Weight and BMI approximated the 90th percentile for boys and the 75th percentile for girls. Participants took part in an average of 25.0 and 7.2 minutes of moderate and vigorous physical activity, respectively, during the studio-based learning experience. During the regular school year, these students participated an average of 7.4 and 3.1 minutes of moderate and vigorous physical activity, respectively, during the hours of the school day corresponding with the summer experience. **CONCLUSIONS:** Studio-based learning may provide a viable option for increasing physical activity levels while addressing academic performance. This is particularly important for students classified as "at-risk" for dropout as they are often the same population affected by health disparities.

Metabolic Syndrome And Activity Levels In College Students

Joshua M. Miller, Andrew Hudson, Natali Contreras, Daniel Serrano, Guanrong Cai, Kristen Morgan, Brian D. Street.
California State University, Bakersfield, Bakersfield, CA.
(Sponsor: Kathleen Knutzen, FACSM)
Email: jmiller68@csub.edu
(No relationships reported)

PURPOSE: It is estimated that greater than 30% of young adults attending college are overweight or obese. Many of the known risk factors that are often associated with obesity also place an individual at risk for developing metabolic syndrome (MetS). In particular, physical activity has been shown to insulate against future risk of such metabolic disorders. The purpose of this study was to examine the relationship of the risk factors associated with MetS and activity levels in college students.

METHODS: Twenty-one college students (age: 23.1 ± 4.2 years; BMI: 28.1 ± 6.2 kg/m²) participated in the study. The following information was obtained from each participant; body anthropometrics, fasting glucose and lipoproteins, and accelerometry measured activity levels. Participants wore, at the waist, the wireless activity monitor (wGT3X-BT, ActiGraph, Pensacola, FL) for seven consecutive days. MetS was determined if the participants met three of the five criteria utilizing the NCEP guidelines.

RESULTS: Metabolic syndrome was prevalent in 9.5% of the population. The average daily step count for the participants were 7982.6 ± 2209.6 steps/day. The observed categorical activity levels (not including while asleep) for the participants included $84.3 \pm 0.05\%$ spent in a sedentary state and $0.04 \pm 0.01\%$ engaged in moderate to vigorous physical activity.

CONCLUSIONS: Metabolic syndrome is becoming more prevalent in all populations including college students. Current levels of activity in college students do not meet the CDC's established guidelines for total steps/day, elevating their risk of acquiring

metabolic disorders. In order to reduce the increasing prevalence of MetS, increasing the total number of steps/day in conjunction with a focus on moderate-vigorous physical activity levels may reduce the risk factors associated with MetS later life. On-going participant collection will continue, looking to establish correlates between MetS criteria and physical activity.

3403 Board #308 June 2 2:00 PM - 3:30 PM
Discrepancies Among Children at the 99th Percentile

Karissa L. Peyer, Ashley Ewald. *University of Tennessee at Chattanooga, Chattanooga, TN.* (Sponsor: Gregory Heath, FACSM)

(No relationships reported)

PURPOSE: Use of the body mass index percentile curves (BMI%) allows for consideration of growth and maturation throughout childhood but creates a ceiling effect for children with severe obesity who are classified at the 99th percentile. This study aimed to evaluate variances by age and gender of alternative measures of weight status in children and adolescents.

METHODS: Age, height and weight from all children ages 3-18 were obtained from NHANES 2009-2010, 2011-2012, and 2013-2014 and BMI variables were calculated. These included raw BMI (kg/m²), BMI%, BMI z-score, and percent over the 50th and 95th percentile. Means and variances of these variables were calculated for all children with BMI% of 99% as well as 50% for comparison purposes. Analyses were conducted for 3-6, 7-11, and 12-18 year-old age groups.

RESULTS: Data was available for 9049 subjects. Raw BMI for all subjects with BMI% = 99 ranged from 19.06 - 57.1 kg/m² and mean BMI was 22.5, 29.6, and 39.6 kg/m² for 3-6 year olds, 7-11 year olds, and 12-18 year olds, respectively. The range was much narrower among children at the 50th percentile (15.2 - 22.0 kg/m²). Average BMI z-score for subjects at the 99th percentile ranged from a low of 2.5 in 7-11 year olds to a high of 2.9 in 3-6 year olds. Percent over the 50th percentile ranged from 22.3% - 155.8% in 3-6 year olds, 44.6%-189.6% in 7-11 year olds, and 60.0%-169.1% in 12-18 year olds. These ranges were narrower in children at the 50th percentile (-0.3% to 0.9%, -0.8% to -0.4%, and -0.9% to -0.2%, respectively). Among subjects at the 99th percentile, percent over the 95th percentile ranged from 6.5%-114.1% in 3-6 year olds, 17.8%-122.7% in 7-11 year olds, and 20.8%-99.6% in 12-18 year olds.

CONCLUSIONS: Alternative weight variables including percent over the 50th percentile and percent over the 95th percentile may allow for better distinction among children and adolescents presenting with severe obesity.

3404 Board #309 June 2 2:00 PM - 3:30 PM
Tracking BMI in Childhood Through Adulthood

Ashley Ewald¹, Celina Partida¹, Greg Welk, FACSM², Kara Hamilton¹, Karissa Peyer¹. ¹*University of Tennessee at Chattanooga, Chattanooga, TN.* ²*Iowa State University, Ames, IA.*

(No relationships reported)

Does a child's BMI percentile change from 1st to 10th grade?

Purpose: Obesity, specifically in childhood, has become an important public health concern because of possible long-term correlations with heart disease and chronic illnesses in adulthood. However, there is limited evidence measuring the link between childhood to adolescent BMI by trained professionals. The purpose of this study is to track BMI measurements in 1st graders and later in 10th graders to analyze BMI trends from childhood to adolescence.

Methods: Child height and weight were measured in 1st grade (by school nurses) and 10th grade (by Physical Education teachers) and converted to Body Mass Index percentiles (BMI%) for sex and age using standard CDC SAS code. Subjects were grouped into BMI Categories (Cat) based on 1st grade BMI% with all children with BMI% less than 10% in Cat0, BMI% from 10-19% in Cat1 and so forth, up to Cat9 with 1st grade BMI% of 90% or higher. Average 10th grade BMI% and average change in BMI% from 1st to 10th grade were computed for each BMI Category.

Results: Complete data was available for 559 subjects. Average 10th grade BMI% ranged from 35.8% in Cat1 to 90.2% in Cat9. Average BMI% change was 2.86% from 1st to 10th grade. Average BMI% in Cat0 increased by 31.4% while Cat9 showed an average decrease of 6.9%. Cats 7, 8, and 9 all showed overall decreases in BMI% while Cats 0-6 showed increases

Conclusion: Categories 7, 8, and 9 show a decrease in BMI; however, that may be due to the maximum category limit. Childhood and adolescent obesity is an important public health concern as it shows an increased risk of becoming overweight and obese in adulthood, placing them at higher risk for chronic illness and heart disease. Obesity remains an issue and should continue to be monitored from childhood to adolescents. Singh, A. S., Mulder, C., Twisk, J. W. R., Van Mechelen, W. and Chinapaw, M. J. M. (2008). Tracking of childhood overweight into adulthood: a systematic review of the literature. *Obesity Reviews*, 9: 474-488. doi:10.1111/j.1467-789X.2008.00475.x Cole Tim J, Bellizzi Mary C, Flegal Katherine M, Dietz William H. Associations between Physical Activity, Sedentary Time and Percent Body Fat in Chilean Adolescents

Maribel Parra-Saldias¹, Farah A. Ramirez-Marrero, FACSM². ¹*Universidad de Los Lagos, Santiago, Chile.* ²*University of Puerto Rico, San Juan, Puerto Rico.*
Email: mparrasaldias@gmail.com

(No relationships reported)

The prevalence of overweight and obesity among Chilean adolescents in 8th grade has increased from 41% in 2014 to 45% in 2016. However, physical activity (PA) and sedentary characteristics in this group of adolescents has not been evaluated. **PURPOSE:** To evaluate PA and sedentary time (ST) and their association with percent body fat among 8th grade adolescents in Chile. **METHODS:** A group of 156 adolescents (87 males, 69 females, mean age= 13.4±0.7 yrs) were recruited from 4 public schools in the metropolitan region in Chile. Measures of height, weight, and percent body fat using bioelectrical impedance were obtained. Physical activity and sedentary behavior were measured with ActiGraph GT3X+ accelerometers that adolescents wore in the right hip area attached to an elastic waist band for 8 consecutive days. T-tests were conducted to detect gender differences, and Pearson correlations and linear regressions were used to evaluate associations between PA, ST, and percent body fat. **RESULTS:** Males and females were not different in ST (9.0±2.6 vs. 8.9±2.8 hr/day, P=0.97), but females had higher percent body fat compared with males (27.8±5.9 vs. 17.2±7.1; P<0.001), lower moderate to vigorous PA (MVPA) (170.7±112.8 vs. 285.3±161.1 min/week; P<0.001), and lower steps/day (5951±2139 vs. 7181±2668; respectively, P=0.002). MVPA was inversely associated with percent body fat (r= -0.30, P=0.0004) but ST was not associated with percent body fat. However, a strong inverse association was observed between percent of the day in ST and MVPA (r= -0.62, P<0.001). **CONCLUSION:** This group of Chilean adolescents had high ST and no compliance with PA recommendations, particularly females; and those with less MVPA had higher percent body fat. To help control the obesity trend among adolescents in Chile, school programs that incorporate more PA and reduce ST is warranted.

Associations with Physical Activity and Sedentary Behavior with Physical Fitness in Chinese Children and Adolescents

Zheng Zhu, Peijie Chen, Zhen-Bo Cao, Yan Tang, Jie Zhuang, Yang Liu. *Shanghai University of Sport, Shanghai, China.*

(No relationships reported)

Associations with Physical Activity and Sedentary Behavior with Physical Fitness in Chinese Children and Adolescents

Zheng Zhu^{1,2}, Peijie Chen^{1,2}, Zhen-Bo Cao^{1,2}, Yan Tang^{1,2}, Jie Zhuang^{1,2}, Yang Liu^{1,2}
1. Shanghai University of Sport
2. Shanghai Research Center for Physical Fitness and Health of Children and Adolescents

PURPOSE: The purpose of this study is to examine the associations of physical activity and sedentary behavior with physical fitness in Chinese children and adolescents. **METHODS:** A total of 33,414 participants (boys:48.9%, age:12.5±2.5 yr, weight:48.0±14.9 kg, height:154.6±13.9 cm, BMI:19.7±3.9 kg/m²) completed physical activity and sedentary behavior questionnaire and physical fitness test including Body Mass Index (BMI), lung capacity, sit and reach, jump rope/long jump, sit-ups/pull up and shuttle run /800meter/1000meter run. The participants were categorized into either "fit" or "unfit" by using National Students Physical Fitness Standard depending on whether they met the standard or not. Multiple logistic regressions were performed to examine the associations of physical activity and sedentary behavior with physical fitness after controlling for gender, age and BMI. **Results:** After adjusting gender, age and BMI, physical activity and sedentary behavior were significantly associated with physical fitness, independently. The children and adolescents who did not meet the recommendation of 60 min/day of moderate and vigorous physical activity (MVPA) had 1.97 times the odds of being unfit compared to those meeting guideline (95% confidence interval [CI] of Odds Ratio:1.69-2.30). The children and adolescents who did not meet the sedentary behavior guideline had 1.27 times the odds of being unfit (95% CI of Odds Ratio: 1.07-1.50). In joint association analysis, children who did not meet physical activity nor sedentary behavior guidelines had 2.26 times higher odds of being unfit than children who met both guidelines (95% CI of Odds Ratio: 1.61-3.17). **CONCLUSION:** The results demonstrated that being physically active and reducing the sedentary behavior are independently and positively associated with physical fitness in children and adolescents.

Anthropometric Measures are Associated with Canadian Agility and Movement Skill Assessment Scores

Kevin Belanger¹, Mark S. Tremblay, FACSM¹, Patricia E. Longmuir¹, Joel Barnes¹, Dwayne Sheehan², Jennifer L. Copeland³, Sarah J. Woodruff⁴, Brenda Bruner⁵, Barbi Law⁵, Luc J. Martin⁶, Angela M. Kolen⁷, Michelle Stone⁸, Kristal Anderson⁹, Kirstin N. Lane⁹, Nathan Hall¹⁰, Melanie Gregg¹⁰, Travis J. Saunders¹¹, Dany MacDonald¹¹, Francois Trudeau¹², Claude Dugas¹². ¹Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada. ²Mount Royal University, Calgary, AB, Canada. ³University of Lethbridge, Lethbridge, AB, Canada. ⁴University of Windsor, Windsor, ON, Canada. ⁵Nipissing University, North Bay, ON, Canada. ⁶Queen's University, Kingston, ON, Canada. ⁷St. Francis Xavier University, Antigonish, NS, Canada. ⁸Dalhousie University, Halifax, NS, Canada. ⁹Camosun College, Victoria, BC, Canada. ¹⁰University of Winnipeg, Winnipeg, MB, Canada. ¹¹University of Prince Edward Island, Charlottetown, PE, Canada. ¹²Université du Québec à Trois-Rivières, Trois-Rivières, QC, Canada.

(No relationships reported)

PURPOSE: Recent literature suggests that anthropometric measures are correlates of gross motor competence in children. The purpose of this study was to determine if body mass index (BMI) or waist circumference (WC) are associated with children's scores on the Canadian Agility and Movement Skill Assessment (CAMSA).

METHODS: Children aged 8-12 years ($n = 7,773$), with parental consent, from 7 Canadian provinces had their physical literacy level measured using the Canadian Assessment of Physical Literacy (CAPL). CAPL testing was completed between 2012-2016 and administered by trained research staff. As part of the CAPL tests, movement competence was measured using the CAMSA which evaluates fundamental, combined, and complex movement and motor skills. Children were scored on time to complete the CAMSA (range 1-14 points) and ability to demonstrate the movement skill criteria (range 0-14 points) for a combined score out of 28, with the best of two trials used for analyses. BMI was calculated from measured height and weight and converted to BMI z-score using the World Health Organization's (WHO) BMI-for-age charts and formulae based on the LMS method. WC was measured in duplicate using an elastic tape measure at the level of the iliac crest and recorded in centimeters, with the average of the two measures used for analyses. Children were grouped for analysis based on those meeting (≥ -2.0 to ≤ 1.0) and not meeting (< -2.0 or > 1.0) the WHO's recommended level of BMI z-score. Separate multiple linear regression models were used to predict CAMSA score for BMI z-score and WC, with both models adjusting for age and sex.

RESULTS: The difference in CAMSA scores between BMI z-score groups was significant ($p < 0.001$, Cohen's $d = 0.3$). In the BMI z-score model, results of the regression ($F [3,7455] = 353, p < 0.0001, R^2 = 0.12$) indicated that CAMSA scores were lower by 0.3 units for every 1 unit increase in BMI z-score. In the WC model, results of the regression ($F [3,7455] = 402.2, p < 0.0001, R^2 = 0.14$) found lower CAMSA scores of 0.1 units for each 1 centimeter increase in WC. Age and sex were strongly associated with CAMSA score in both models, as expected.

CONCLUSIONS: These results align with previously reported findings suggesting that anthropometric measures have a moderate relationship with children's performance on movement competence assessments.

The Relationship Between Fundamental Motor Skills and Physical Activity in College Age Students in Puerto Rico

L. Romero Maysonet¹, M. Amaral-Figueroa². ¹Universidad de Puerto Rico, Recinto de Mayagüez, Mayagüez, Puerto Rico. ²Universidad de Puerto Rico, Rio Piedras Campus, San Juan, Puerto Rico.

Email: lilliana.romero@upr.edu

(No relationships reported)

Physical activity (PA) is associated with disease prevention and maintaining a healthy lifestyle. It is expected that individuals with higher levels of Fundamental Motors Skills (FMS) would be more physically active. The lack of PA is currently a global problem for it has caused 1.9 million deaths. Furthermore, only 33.8% of the population in Puerto Rico meets the current PA guidelines, thus placing in the top position with the lowest percentage among all the states and territories of the United States. **PURPOSE:** To investigate the relationship between PA and FMS in college-age students in Puerto Rico. **METHODOLOGY:** Participants were 91 college-age students that completed the International Physical Activity Questionnaire (IPAQ)

and used the Walk 4 Life Pedometer for 7 days. Also completed a series of motor skills tests: running 60 meters, overhand throw, and horizontal jump. A Spearman correlations analysis was used to identify relationships between variables.

RESULTS: The results showed that students did not fulfill the current PA recommendation assessed by pedometer (6,546.6 steps/day + 3234). Nevertheless, according to IPAQ, the population obtained a moderate/vigorous PA (5,499 METS + 6993), and engaged an average of 285 min/day of sedentary time in their most active day. Total FMS score averaged was 19.4 ± 4.38 . PA (step/day) and METS were not correlated with FMS ($r^2 = .034, p = .75$) and ($r^2 = .124, p = .24$). PA (METS) was significantly correlated with overhand throw ($r^2 = .255, P = .02$).

CONCLUSION: In conclusion, the participants did not comply with the total amount of daily steps recommended for PA and did not reach the expected level of FMS.

Physical Activity Levels In Preschool Children During Winter & Summer

Karin Helene Danielsen¹, Gunnar E. Mathisen¹, Jarle Stålesen². ¹UIT The arctic University of Norway, Tromsø, Norway. ²University of Agder, Kristiansand, Norway.

Email: karin.danielsen@uit.no

(No relationships reported)

Background: The Norwegian Directorate of Health recommends that children between 3 to 5 years accumulate at least 60 minutes of moderate- to vigorous-intensity physical activity daily. However, knowledge about physical activity levels in preschoolers is limited.

PURPOSE: To compare physical activity levels in kindergarten preschool during summer and winter in children aged 3-5 years.

METHODS: From Monday to Wednesday, physical activity levels were monitored using the Actigraph GT3X between 07.30 am and 4.30 pm. ($n = 81$; 4... yrs). Physical activity levels were measured twice, in February ($n = 81$; 4.45 ± 0.86 years), ($n = 71$; 4... yrs) and in June. June ($n = 71$; 4.75 ± 0.89 years). The primary physical activity outcome was time spent at different activity intensities. We defined moderate-to-vigorous physical activity (MVPA) as all activity above 2000 counts/min. As used previously (Ekelund et al., 2004).

RESULTS: During the winter period, 64 % of the children reached MVPA the recommendations of 60 minutes physical activity daily, whereas 29% was in MVPA between physically active 30-59 minutes per day, and 6% were in MVPA active <29 minutes. During the summer period less children reached MVPA, physical activity were lower, as 50 % reaches MVPA active > 60 minutes per day, while 39% were active reached MVPA between 30-59 minutes per day, and 11% was in MVPA less than were active <29 minutes. In total for bout periods the boys spent significantly more time in MVPA, (84.11 minutes ± 37.97) compared to girls (63.46 minutes ± 31.39) ($p < 0.001$). In the winter, 65.8% of the boys met the recommendations, and the percentage was reduced to 58% in the summer. For girls, the respective numbers were 34 % and 41%. Boys were significantly () more active than girls () in both periods.

CONCLUSION: More than 2/3 of preschoolers do not reach the recommendations of 60 minutes moderate-to-vigorous physical activity. More children in preschool reached the recommendations of MVPA above 60 minutes in the winter, compared with the summer period.

Changes in Sedentary Behaviour, Physical Activity and Body Mass Index in Schoolchildren: A 3-Year-Longitudinal Study

Amanda Santos¹, Sandra Silva-Santos¹, Michael Duncan², Renata M. Willig¹, Susana Vale³, Jorge Mota¹. ¹Faculty of Sport, University of Porto, Porto, Portugal. ²Coventry University, Coventry, United Kingdom. ³High School of Education, Polytechnic Institute of Porto, Porto, Portugal.

Email: amanda637@hotmail.com

(No relationships reported)

There is growing interest in sedentary behaviour (SB) and its association with health outcomes. However, few studies have considered the changes in SB its association with change in MVPA and BMI in schoolchildren longitudinally and it is need better understanding. **PURPOSE:** To describe the 3-years changes in objectively measured SB, moderate-to-vigorous physical activity (MVPA) and body mass index (BMI), and to investigate changes in SB and its association with change in MVPA and BMI in a 3-year follow-up. **METHODS:** The sample consisted in 68 children ($n = 39$; 57.4% female) aged 6 to 9 years-old, from schools in metropolitan area of Porto, Portugal. Height and weight of children were measured and BMI was calculated (kg/m^2). SB and MVPA were measured by accelerometer. Changes between 2009/2012 and between 2010/2013 in SB, MVPA and BMI indicators were computed as the value recorded in the end of the follow up minus the value recorded in the baseline (Δ). Differences between baseline and follow-up SB, MVPA and BMI were examined by paired-sample

t-tests. ΔSB and its associations between ΔMVPA and ΔBMI were assessed using a multivariate linear regression model, adjusted for gender and baseline values of age, SB, MVPA and BMI. **RESULTS:** The SB and BMI baseline increased significantly compared with follow-up (562.51 ± 46.81 and 577.29 ± 49.81 min/day; $p = 0.033$; 17.55 ± 2.44 kg/m², 19.61 ± 3.21 kg/m²; $p = 0.0001$, respectively) and MVPA was not significantly different (67.23 ± 15.38 and 65.24 ± 20.73 ; $p = 0.380$). Multiple linear regression analyses showed that ΔSB was negatively related to ΔMVPA (β : -0.609; 95%CI: 2.30, -1.39; $p = 0.0001$), however it was not associated significantly with ΔBMI (β : -0.088; 95%CI: -6.79, 1.58; $p = 0.218$). **CONCLUSIONS:** The increase of SB with age could displace the time spent in MVPA, although the influence of the BMI values remained unclear for the children sample presented here. This reinforces public health measures and suggests the need of interventions focusing in decline SB and increase MVPA during childhood. Supported by the CIAFEL under grant number UID/DTP/00617/2013; FCT under grant number SFRH/BD/86538/2012; CNPq under grant number 206862/2014-8 and CAPES under grant number 6099/13-0.

3411 Board #316 June 2 2:00 PM - 3:30 PM

Effect of a Lifetime Health and Fitness Class on College Students

Tiffany Young Klockziem¹, Chinaro Kennedy². ¹Bethany Lutheran College, Mankato, MN. ²Centers for Disease Control and Prevention, Atlanta, GA.
Email: tyoung@blc.edu
(No relationships reported)

PURPOSE: A pre-post, quasi-experimental study was conducted to evaluate the association between a health and fitness class, physical education 215 (PHED 215) and chronic disease risk, cardiorespiratory fitness (CRF) level, body fat percentage, self-motivation, exercise self-efficacy, and transtheoretical model (TTM) physical activity stage of change progression among male and female college students ($n = 64$).

METHODS: Secondary data were analyzed via descriptive statistics, paired *t* test (or Wilcoxon signed-rank test if data were not normal), and Bowker's test of symmetry.

RESULTS: Results showed a statistically significant association between PHED 215 and 2 dependent variables: cardiorespiratory fitness level ($p = 0.0001$) and progressive movement through the TTM stages of change ($p = 0.0061$). No statistically significant difference was found between PHED 215 and 4 dependent variables: disease risk, body composition, self motivation, and self-efficacy.

CONCLUSIONS: Because college age students are shaping their adult behaviors, positive health change adopted during this critical time could increase CRF, establish lifelong exercise habits, improve quality of life, and delay and decrease obesity risk and chronic disease and related costs. While further study in different settings is warranted, PHED 215 could be used as a blueprint for other interventions in the education, community, and healthcare settings.

Variable	Measurement Tool
Disease risk	ACSM Guidelines for Exercise Testing and Prescription (2010) Table utilizing combination of BMI and waist circumference to obtain disease risk
Cardiorespiratory fitness	Three Minute Step Test (Powers & Dodd, 2009)
Body fat percentage	Bioelectrical Impedance (Tanita 350 Body Composition Analyzer)
Self-motivation	Self-Motivation Inventory (Dishman & Ickes 1981; Merkle, 1997)
Exercise self-efficacy	Exercise Self-Efficacy Scale (Bandura, 1997)
Stage of change	Assessing Physical Activity Stages of Change (Marcus & Forsythe, 2003; ACSM Resource Manual, 2010)

Moderate to Vigorous Physical Activity during Recess and Physical Education by Gender and Body Fat

JAVIER A. HALL LOPEZ, PAULINA YESICA OCHOA. Autonomous University of Baja California, Mexicali, Baja California, Mexico.
Email: javierhall@uabc.edu.mx
(No relationships reported)

PURPOSE: To compare the intensity of physical activity using accelerometers and heart rate monitor during physical education class and recess in students of third and fourth grade of primary education according to gender and body fat percentage.

METHODS: In order to determine the intensity of physical activity accelerometers ActiGraph GT9X Link and heart rate monitors Polar bluetooth smart were used, in 28 boys and 26 girls during 8 physical education classes and recess periods, to determine the percentage of body fat as normal or high bioelectrical impedance analysis was performed using the 720 Inbody equipment.

RESULTS: Student *t* test for independent samples resulting a *P*-value less than $\alpha \leq 0.005$ with significant differences in physical education classes between the averages of moderate to vigorous physical activity (men:0,003 women:0,001) and heart rate beats/min (men:0,001 women:0,000) in participants with normal body fat percentage compared to high.

CONCLUSIONS: The intensity of physical activity during recess was higher in relation to physical education classes and with a moderate to vigorous physical activity less than 50% of the duration of the class, due, is important a feedback for the teachers in strategies for involving the students with increased risk of obesity in moderate to vigorous physical activity.

Effects Of Moderate To Vigorous Program On Vo2max And Body Fat In Overweight Children
 PAULINA Y. OCHOA, JAVIER A. HALL. *Autonomous University of Baja California, Mexicali, Baja California, Mexico.*
 Email: pochoa@uabc.edu.mx
 (No relationships reported)

PURPOSE: To evaluate the effect of a program of physical activity with moderate to vigorous under the model of CATCH on body fat percentage and aerobic capacity in overweight or obesity children.

METHODS: Twenty-six children (15 male and 11 female (age 9.4±0.3 years), diagnosed with overweight or obesity participated in a program of physical activity with moderate to vigorous under the model of CATCH, 2 times a week over a period of 10 months, consisting of exercise intensity of 56% evaluated by the system for observing fitness instruction time (SOFIT), before and after the program body fat percentage was evaluated determined by the equation Slaughter with the anthropometrics measurements of triceps and media calf skinfolds. Aerobic capacity (VO_{2max}) was determined through the test course navette 20 meters. **RESULTS:** The results of student T test showed significant improvement ($p<0.05$) comparing before and after the program in VO_{2max} ($p=0.000$) and percentage change ($\Delta\%$) of 11.3. **CONCLUSIONS:** Physical activity with moderate to vigorous under the model CATCH was able to enhance aerobic capacity in overweight or obesity children, however, will be appropriated in the future more studies to better clarify the possibilities of improvements improvement in the percentage of body fat.

The Relationship between Sit & Play and Gross Motor Coordination in Preschoolers
 Sandra Silva-Santos¹, Amanda Santos¹, Michael Duncan², Susana Vale³, Jorge Mota¹. ¹University of Porto. Faculty of Sport., Porto, Portugal. ²Coventry University, Coventry, United Kingdom. ³High education school, Polytechnic institute of Porto, Porto, Portugal.
 Email: sandrcris@gmail.com
 (No relationships reported)

Gross motor coordination (GMC) is positively associated with physical activity (PA) and inversely associated with sedentary behaviour (SB) in childhood. Although children behave sedentarily while sitting and playing there is effectively movement in this behaviour. We considered the transition between SB (≥ 150 c.p.m) and light physical activity (LPA) (≤ 800 c.p.m) as sit & play (SP), that is when preschoolers are sitting but there is some movement playing. No studies to date have examined how GMC is related to SP. **PURPOSE:** To examine the association between SP and GMC during the early years regardless physical activity levels.

METHODS: The sample comprised 209 children aged 3-6 years, GMC was assessed according to the Movement Assessment Battery for Children (MABC-2). The battery comprised the aiming & catching and balance component. We summed the item standard scores for each component. The GMC was categorized in the red zone, as poor GMC, and the green zone, as high GMC. Body mass index (BMI) was assessed as mass (kg)/stature squared (m^2), LPA, moderate vigorous physical activity (MVPA), SB and SP were assessed by accelerometer. SP was defined between ≥ 150 c.p.m until ≤ 800 c.p.m. For data analysis, the SP and SB were divided into two categories by median split.

RESULTS: The sample was 42.5% in the red zone for the aiming & catching component and 14.9% in the red zone for the balance component. Binary logistic regression analysis showed that preschoolers who had a low level of SP were 2.9 times more likely to be classified as having poor GMC level in aiming & catching than their counterparts with high SP level. (OR: 2.9; IC: 1.3-6.6) regardless gender, SB, BMI, LPA and MVPA. No statistical significant association was found for balance. Further binary logistic regression that examined the relationship between SB and GMC, did not show statistical significant association.

CONCLUSIONS: This study showed an association between low SP levels with poor GMC regardless of physical activity levels. Thus, children are sitting position, doing some movement playing looks good for GMC. No association has been found between SB and GMC. Further longitudinal studies are needed to confirm this data. Supported by the CIAFEL under Grant UID/DTP/00617/2013; FCT under Grant SFRH/BD/86538/2012; and CAPES under Grant 6099/13-0.

Postpartum Mothers' Physical Activity & Sleep: A Comparison of Overweight/Obese and Normal Weight Mothers
 Shane Warehime, Kailey Snyder, Jung-Min Lee, Danae Dinkel. *University of Nebraska at Omaha, Omaha, NE.* (Sponsor: Dustin Slivka, FACSM)
 (No relationships reported)

Lack of physical activity (PA) and sleep are associated with several negative health outcomes. Two populations that are particularly vulnerable to these risk factors are postpartum mothers (<1 year of childbirth) and overweight/obese individuals. Thus, postpartum mothers who are also overweight/obese may be especially susceptible to issues related to lack of PA and sleep. However, research exploring this topic is lacking. **PURPOSE:** To compare PA and sleep of overweight/obese and normal weight mothers. **METHODS:** Physical activity and sleep levels were objectively measured using accelerometers worn on the non-dominant wrist. A total of 21 mothers (n = 13 overweight/obese, n = 8 normal weight) were recruited as part of a larger study. Mothers' PA and sleep levels (minutes) were assessed three times - when their infant was three months old, the onset of their child's sitting (~5 months of age), and one month post onset of sitting (~6 months of age) - for four days (two weekdays, two weekend days). Anthropometric measures (i.e., height weight) were collected at each visit to calculate BMI. Average BMI was used to classify mothers as normal weight or overweight/obese. A mixed-design ANOVA was used to examine differences between visits while comparing normal weight and overweight/obese mothers. **RESULTS:** Increases ($p < 0.05$) in normal weight mothers' PA was observed between visits one ($M = 78.98 \pm 20.83$ min/day) and three ($M = 99.89 \pm 14.57$ min/day, $p = 0.01$), and visits two ($M = 84.49 \pm 17.33$ min/day) and three ($p = 0.045$). Overweight/obese mothers displayed no significant change in PA over time. No significant change in sleep over time was observed in either group. No significant differences were observed between the PA and sleep levels of overweight/obese and normal weight mothers. **CONCLUSION:** Normal weight mothers tended to increase PA levels while overweight/obese mothers did not significantly change their PA levels over time. These findings can help guide future efforts aiming to increase the health of postpartum mothers, especially those that are also overweight/obese.

Factors Associated With Household And Job Physical Activity In Low-income Pregnant Women: Ecological Perspective
 Alicia B. Stannard¹, Lanay M. Mudd, FACSM², James M. Pivarnik, FACSM³, Jean Kerver³, Lorraine Weatherspoon³. ¹Sacred Heart University, Fairfield, CT. ²National Center for Complementary and Integrative Health, Bethesda, MD. ³Michigan State University, East Lansing, MI.
 Email: stannarda@sacredheart.edu
 (No relationships reported)

Low-income pregnant women are less likely to meet physical activity (PA) recommendations compared to higher income counterparts. Some studies suggest that the difference in activity levels is diminished when household (HPA) and job physical activities (JPA) are considered but little is known about factors that may influence HPA and JPA levels. **PURPOSE:** To examine personal, social, and environmental factors impacting HPA and JPA during pregnancy in low-income women based on the Ecological Model. **METHODS:** Low-income pregnant and postpartum women were recruited nationwide using an online platform. Participants (n=109) recalled pregnancy HPA and JPA using the International Physical Activity Questionnaire (IPAQ) and answered a survey on personal (demographics, self-efficacy, lifestyle beliefs), social (social support, social perceptions, social roles strain) and environmental factors (safety, community involvement). Descriptive statistics were assessed for all variables. Median split was used to categorize HPA and JPA. Correlation matrices were created for personal, social, and environmental factors. Based on established criteria, significant variables were selected to be included in confirmatory factor analysis (CFA). A CFA model for each personal, social, and environmental latent factor and two structural equation models were created for predicting HPA and JPA. **RESULTS:** Participants' mean age was 29.5 years (± 5.6) and 51.9% of women were on Medicaid. Median, range HPA was 28, 0-354 MET-hrs/wk and JPA was 0.2, 0-367 MET-hrs/wk. Latent personal, social, and environmental factors were not significantly related to HPA or JPA. However, significant interactions occurred between personal and environmental factors (-0.218 , $p<0.05$) and social and environmental factors (-0.207 , $p<0.05$) in the HPA model as well as personal and environmental factors

(-0.221, $p < 0.05$) in the JPA model. **CONCLUSIONS:** Reported HPA and JPA levels were low, varied widely, and could indicate a lack of understanding of PA questions. Latent factors were not related to HPA or JPA, but the interactions among latent factors indicate that this analysis might not capture the complexity of PA behaviors. Other correlates not included in this study, such as job type, may have greater influence on HPA and JPA among low-income pregnant women.

3417 Board #322 June 2 2:00 PM - 3:30 PM
The Relationships Among Social Support and Self-Efficacy on Physical Activity during Pregnancy
 Ashley E. Boggs, Rebecca A. Schlaff, Meghan Baruth, Samantha Deere. *Saginaw Valley State University, University Center, MI.*
 Email: aeboggs@svsu.edu
 (No relationships reported)

There is some evidence to suggest that social support and self-efficacy aid in goal directed behaviors and may increase levels of physical activity (PA). **PURPOSE:** To examine the relationship between social support from family and friends, self-efficacy, and PA in a sample of pregnant women. **METHODS:** Participants ($n=23$) ≥ 18 years of age and 14-20 weeks gestation were enrolled in a nutrition and physical activity intervention. A survey assessing demographics (age, marital status, education, and race) was administered. Social support and self-efficacy for engaging in PA was also assessed. Height and weight were objectively measured to calculate body mass index (BMI). An accelerometer was worn to assess percent of day spent sedentary, in light PA, and in moderate to vigorous PA. Relationships were examined utilizing Pearson correlation coefficients. **RESULTS:** On average, participants were 27.2 ± 4.4 years of age and had a mean BMI of 26.7 ± 5.7 kg/m². A majority of the sample was married (82.6%), had some college education (78.3%), and was white (81.8%). The sample spent 57.5% of the day sedentary, 41.0% in light PA, and 1.5% in moderate to vigorous PA. For social support from friends, Pearson correlations showed a significant negative relationship with light PA ($r=-0.43$, $p=0.04$), a significant positive relationship with moderate to vigorous PA ($r=0.45$, $p=0.03$) but no relationship with sedentary time ($r=0.36$, $p=0.09$). Pearson correlations also indicated significant positive relationships between self-efficacy and sedentary time ($r=0.43$, $p=0.03$) and light PA ($r=0.45$, $p=0.02$), but no relationship with moderate to vigorous PA ($r=0.07$, $p=0.71$). No significant relationships were found between social support from family and any intensity of PA. **CONCLUSIONS:** Findings indicate that social support from friends may be an important factor to consider when encouraging participation in moderate to vigorous PA during pregnancy. Future research is needed to fully understand the effects of social support and self-efficacy on PA during pregnancy. Prospective research with larger sample sizes should consider including more diverse samples of pregnant women. Furthermore, relationships between social support from family and friends, self-efficacy, and PA should be assessed across trimesters.

Why are Pregnant Women Physically Active or not?
 Katrine M. Owe¹, Hanne K. Hegaard², Hanne T. Wolf³, Linn Marie Sørbye⁴. ¹*Oslo University Hospital, Oslo, Norway.* ²*University of Copenhagen, Copenhagen, Denmark.* ³*Copenhagen University Hospital, Copenhagen, Denmark.* ⁴*University of Bergen, Bergen, Norway.*
 Email: owekam@outlook.com
 (No relationships reported)

Physical activity (PA) during pregnancy has an important impact on public health as it reduces the risk of common pregnancy complications and chronic diseases and provides numerous protective factors for pregnant women and their children. Although national and international guidelines have recommended regular PA for all pregnant women since the 1980s, only a small proportion of women achieve the recommended levels of PA during pregnancy, and longitudinal studies have shown a decline in PA levels as pregnancy progresses. PA levels are also lower in pregnant women compared to their non-pregnant counterparts. Understanding correlates of PA during pregnancy is crucial in order to target effective interventions to preclude inactivity among pregnant women.

PURPOSE: To systematically review the literature regarding different correlates of PA during pregnancy including studies from all over the world.

METHODS: A comprehensive and systematic search of the Medline, Embase, PsychInfo, Cochrane Library, SweMed+, Sociological Abstracts and Web of Science databases up until January 14 2016 was conducted by a professional librarian. Only studies in which PA was assessed prospectively during pregnancy were included. We conducted the present review as suggested by the PRISMA group and used a predefined PICO (Population, Intervention, Comparison, and Outcome) worksheet.

RESULTS: Out of 342 records, we reviewed 16 original studies. Half of these used a cross-sectional design. We identified different types of correlates and categorized them into 1) demographic or biological variables; 2) psychological variables; 3) behavioral variables; and 4) social and cultural variables. Most studies reported demographic (e.g. maternal age, education and ethnicity) and biological correlates (e.g. pre-pregnancy

PA, smoking and diet) of PA during pregnancy but the results varied widely. Pre-pregnancy PA was the most robust correlate reported. None of the studies reported environmental correlates such as neighbourhood, transport, or weather conditions. **CONCLUSIONS:** PA before pregnancy was the most consistent correlate of pregnancy PA across studies. We need more knowledge on psychological, social and environmental correlates of pregnancy PA, particularly from low- and middle income countries.

3419 Board #324 June 2 2:00 PM - 3:30 PM
The Effects of Exercise Training on Cardiorespiratory Fitness in Obese Sedentary Pregnant Women
 Eva C. Diaz Fuentes, Aline Andres, Kartik Shankar, Elisabet Børshiem. *Arkansas Children's Nutrition Center, and University of Arkansas for Medical Sciences, Little Rock, AR.*
 (No relationships reported)

Purpose: Maternal obesity has profound detrimental effects on the offspring's risk of obesity and cardiometabolic health. Although pre-conception interventions are preferable, exercise during pregnancy can potentially mitigate the effects of maternal obesity on metabolic health in both the mothers and the offspring. The Expecting study is an ongoing RCT in obese sedentary women aiming to determine if combined resistance and aerobic exercise during pregnancy improves maternal health and decreases the risk of obesity in the offspring. The purpose of the current analysis was to assess the effects of 11 weeks of exercise training on markers of cardiorespiratory health in women participating in the study for whom data are available at gestation week (GW) 12 and 24. **Methods:** Women ($n=40$) were recruited at GW 12. Body composition and submaximal aerobic capacity were assessed at GWs 12 and 24 using air displacement plethysmography and an incremental treadmill test, respectively. Twenty-one women were randomized to receive standard of care (SOC) and 19 received a combined exercise intervention (EX) 3 times/week. Oxygen consumption (VO_2 , ml·kg⁻¹·fat-free-mass⁻¹) and oxygen pulse [OP, ml/beat, (VO_2 /heart rate)] are reported for the work load corresponding to a rate of perceived exertion of 15 on Borg's scale (RPE-15). The intervention effect was assessed using analysis of covariance where baseline measurements and incline were used as covariates. Data are presented as mean \pm SE. **Results:** at GW 12, groups were comparable in terms of age (EX=30 \pm 4 vs. SOC=29 \pm 4 years, NS), BMI (37.4 \pm 5.2 vs. 37.8 \pm 6.6, NS), body fat mass (48.8 \pm 5.4 vs. 47.8 \pm 5.2%, NS), and body fat free mass (51.1 \pm 5.9 vs. 51.4 \pm 7.5 kg, NS). Mean attendance to EX sessions was 80 \pm 9% (2.4 \pm 0.3 visits/wk.) After 11 weeks of training, the EX group had higher VO_2 (34.0 \pm 0.8 vs. 30.3 \pm 0.7, $p=0.002$) than the SOC group. Oxygen pulse was also higher in the EX group compared to the SOC group (11.6 \pm 0.3 vs. 10.6 \pm 0.3). **Conclusion:** A structured exercise intervention during pregnancy in obese sedentary women is not only well-received and easy to adhere to, but also results in improved aerobic fitness. Supported by USDA-ARS # 6026-51000-010-05S, ACRI, and Arkansas Biosciences Institute, the major research component of the Arkansas Tobacco Settlement Proceeds Act of 2000.

 Email: hechmi.toumi@univ-orleans.fr
 (No relationships reported)

Abstract

Purpose. To examine the effect of trunk exercise program on pain, quality of life (QoL) and physical health (PH) in the late pregnancy and post-partum periods as well as baby weight and size and delivery.

Methods. 90 nulliparous women allocated to a training group (TG) or to a control group (CG). TG carried out a structured program with exercises for flexibility, balance and strengthening for the majority of skeletal muscles specifically for the spinal ones, between the 24th and 36th week of pregnancy. Both TG and CG are evaluated for the pain at the beginning of the program (T1), at the end of the program (T2) and two months post-partum (T3). (QoL) at (T1; T2 and T3). (PH) at T1 and T3.

Results. At T1, no significant difference was found between the two groups in: pain intensity (pain interference $p=0.317$), QoL ($p=0.18$) and PH (flexibility $p=0.06$; walking $p=0.85$). At T2, women of TG had a lower intensity of pain than CG (legs ($p=0.029$), low back ($p<0.0001$), upper back ($p=0.022$), pelvis ($p=0.017$), groins ($p=0.043$), lower pelvis ($p=0.009$) and interference of pain ($p<0.0001$)). At T3, TG had a lower intensity of pain than CG, in low back and upper back ($p<0.0001$) and interference of pain ($p<0.0001$). Best scores of QoL were observed in TG compared to

CG at T2 ($p<0.0001$) and at T3 ($p<0.0001$). PH was not different between the groups in T1 but the best one was in TG compared to CG in T3 (flexibility $p=0.002$, walking, balance, curling-ups and Ruffier $p<0.0001$). TG is associated with more than four times less of caesarean and 4.5 hours less of labor time.
Conclusion. Strengthening exercises centered on the trunk reduce pain, increase QoL and PH in late pregnancy and at two months in the post-partum period.

Pregnancy Physical Activity Beliefs and Attitudes in a Non-pregnant Population

Mallory R. Marshall, 35229, Katie Hammond, Christian Watts, Caroline Ellis, Bailey Gray, Emily Stallings, John Petrella, FACSM. *Samford University, Birmingham, AL.*
Email: mmarshall@samford.edu
(No relationships reported)

PURPOSE: The purpose of this study was to examine the attitudes and beliefs about pregnancy physical activity (PA) in non-pregnant individuals.

METHODS: Participants were non-pregnant individuals between the ages of 20 and 60 years and were recruited by word-of-mouth and social media, or through one of five doctor's offices located in the southeastern United States. 738 participants completed at least some of the survey and 454 have complete data. The survey consisted of 27 items in five sections: basic demographic information, PA over prior six months, agree/disagree questions regarding safety and efficacy of PA during pregnancy, importance of exercise and lifestyle for pregnant women, and safety of moderate or vigorous intensity PA for mother and offspring. For analysis, participants were dichotomized by age (20 to 40 years; 41-60 years), sex (male; female), and education (Bachelor's degree; no Bachelor's degree).

RESULTS: For age, the older group (age 41 to 60) was more likely to view pregnancy PA favorably ($p=0.001$ to 0.010). Females were more likely than males to view pregnancy PA positively ($p=0.007$ to 0.024). Participants with a college degree were more likely to agree that pregnant women can begin an exercise program during pregnancy ($p=0.047$) and benefit from moderate exercise ($p=0.017$), but were less likely to believe PA is safe for mother and baby ($p=0.000$ to 0.001).

CONCLUSIONS: Overall, participants who were older, female, and did not have college degrees viewed pregnancy PA more favorably.

Associations Of DXA-derived Appendicular Lean And Fat-Free Adipose Tissue Mass With A Single Forearm Ultrasound Image

Takashi Abe¹, Jeremy P. Loenneke², Robert S. Thiebaud³, Eiji Fujita¹, Takuya Akamine¹, Mark Loftin, FACSM². ¹*National Institute of Fitness and Sports in Kanoya, Kanoya, Japan.* ²*The University of Mississippi, Oxford, MS.* ³*Texas Wesleyan University, Fort Worth, TX.* (Sponsor: Mark Loftin, FACSM)
Email: tabe@nifs-k.ac.jp
(No relationships reported)

Dual-energy x-ray absorptiometry (DXA) is used to assess appendicular lean soft tissue mass (aLM), however, the aLM measured by DXA contains non-skeletal muscle tissue components (fat-free adipose tissue, FFAT). These components, if not accounted for, could falsely inflate the aLM in individuals with a relatively high amount of adipose tissue mass. Ultrasound is an imaging technique used to estimate body composition. Recently, we developed prediction equations for estimating aLM, (which includes FFAT) from ultrasound-derived muscle thickness and the forearm ulna (MT-ulna) was the single best predictor. For sarcopenia screening, a single ultrasound measurement may be advantageous for community-based physical examinations. However, it is unknown whether DXA-derived FFAT can be predicted from the forearm ultrasound image. **PURPOSE:** To investigate the relationships between DXA-derived appendicular fat mass and forearm adipose tissue thickness (AT-forearm) measured by ultrasound and DXA-derived and ultrasound-predicted aLM in older adults.

METHODS: Two hundred fifteen older adults (91 men and 124 women) aged 60-79 had appendicular fat mass and aLM measured by the DXA as well as AT-forearm and MT-ulna measured by ultrasound. Appendicular FFAT was calculated based on the results of a previous study (Appendicular FFAT = appendicular fat mass/0.85 x 0.15). AT-forearm and MT-ulna were measured as the distance between the appropriate tissue

interfaces. aLM was estimated from MT-ulna using a previously published equation ($aLM = 4.89 \times MT\text{-ulna} \times \text{body height} - 9.15$). Pearson correlation coefficients were performed for all variables. Statistical significance was set at $p<0.05$. **RESULTS:** There was no significant difference between DXA-derived ($17.1 [SD 4.0]$ kg) and ultrasound predicted ($16.9 [SD 3.9]$ kg) aLM. The ultrasound predicted aLM was strongly correlated to DXA-derived aLM ($r=0.910$, $p<0.001$). In addition, DXA-derived appendicular FFAT was significantly correlated to AT-forearm ($r=0.680$, $p<0.001$).

CONCLUSIONS: Ultrasound forearm measurement correlates well with both aLM and FFAT. This one site measurement might be a quick and useful method for estimating muscle mass in older adults.

Ultrasonic Imaging Before and After Bilateral Tenotomy in a Collegiate Basketball Player: A Case Study

Scott K. Crawford, Aaron J. Engel, Greg R. Bashford, Jack W. Ransone, FACSM. *University of Nebraska-Lincoln, Lincoln, NE.*
(No relationships reported)

Patellar tendinopathy is a debilitating condition that often occurs in athletes who participate in jumping sports, such as volleyball or basketball. Ultrasound imaging has previously been used as a diagnostic tool in identifying tendon morphology. However, previous research has not tracked the time course of patellar tendon morphology changes following tenotomy. **PURPOSE:** The purpose of this study was to track and quantify changes in tendon morphology after bilateral patellar tenotomy in a female collegiate basketball player. **METHODS:** A Division I female basketball player (height=1.9 m, weight=85 kg) with chronic bilateral patellar tendon pain was recruited for participation in the study. Longitudinal B-mode images were taken of the patellar tendon with a research-grade ultrasound machine (Verasonics Inc, Kirkland, WA, USA) and high frequency (5-12-MHz) linear transducer at a center frequency of 10 MHz. The subject performed all rehabilitation exercises as prescribed by the athletic trainer and returned for weekly imaging sessions. As secondary measures of recovery, perceived pain and knee function were evaluated using the Victorian Institute of Sport Assessment (VISA) scale which was completed at each visit. Tendon micromorphology was evaluated using a custom MATLAB code (MathWorks, Natick, MA, USA). A region of interest was manually selected from the images and a two-dimensional fast Fourier transform was performed. The peak spatial frequency radius (PSFR) parameter was used to assess the micromorphology of the tendon, where higher PSF values were associated with increased collagen organization.

RESULTS: At the time of abstract submission, the subject had completed two post-surgical visits. The average PSKR increased for both knees (right: 1.00 vs. 1.28; left: 1.07 vs. 1.54). There was a small increase in the total VISA score between visits (5 vs. 8). **CONCLUSION:** Ultrasonic imaging was used to characterize initial micromorphology changes in the patellar tendon following bilateral tenotomy. Preliminary results showed increased collagen organization and improved VISA scores. Future findings may suggest a correlation between self-reported measures of knee pain and function and tendon morphology.

Diagnostic Ultrasound Imaging In Assessing Medial Elbow Joint Space In College Baseball Pitchers

Shawn D. Felton, Arie J. van Duijn, Eric Shamus, Mitchell L. Cordova, FACSM. *Florida Gulf Coast University, Fort Myers, FL.* (Sponsor: Mitchell L. Cordova, FACSM)
Email: sfelton@fgcu.edu
(No relationships reported)

Athletes participating in overhead throwing sports such as pitchers, volleyball players, and javelin are prone to ulnar collateral ligament (UCL) injuries of the elbow. UCL sprains typically occur when the elbow is subjected to repetitive or sudden valgus stress causing the UCL to exceed its tensile limits. Recently, the use of musculoskeletal ultrasound (MSK) during a valgus stress exam of the UCL has gained great interest. **PURPOSE:**

To examine medial elbow joint space (MJS) opening changes during a constant valgus load to the UCL through MSK in collegiate baseball pitchers during 6 weeks of a competitive season.

METHODS:

Thirteen Division I college baseball pitchers with a mean age of 20.4 ± 1.45 yrs and body mass index of 24.56 ± 1.78 participated. Ultrasound images of the medial joint space on the participant's throwing arm were obtained using a GE LOGIQ E ultrasound unit. The participants were placed in a supine position with a wedge placed underneath their throwing hand to maintain their elbow angle at 30 deg. A hand held dynamometer was used to apply a 3 kg valgus force 20 cm distal to the medial epicondyle to maintain a constant 5 Nm valgus stress to each participant. The medial joint space of the elbow was imaged at the beginning of the spring baseball season

then 16 games or 6 weeks after baseline testing. Three images were taken during each session, where specific measurements from the apex of the trochlea to the apex of the ulna were taken.

RESULTS:

The MJS width increased approximately 15% from an initial baseline testing value of .49 cm±.06 to .56 cm±.02 after 16 games or 6 weeks [F(1,10)= 8.51, p=.015]. The covariates of total innings pitched [F(1,10) = 0.19 p = 0.68] and year of participation [F(1, 10) = 0.11 p = 0.75], were not significant factors in the change of MJS width over time.

CONCLUSIONS:

The results of this investigation demonstrate that MJS width and UCL integrity can be assessed accurately using diagnostic ultrasound during a valgus stress test. Moreover, these data indicate that total innings pitched during a season and year of participation did not have an influence on the MJS width. Further research is recommended to perform multiple imaging testing throughout the entire year (Fall and Spring seasons) to determine specific time points at which MJS width changes in collegiate baseball pitchers.

Assessing UCL Width during Valgus Load for College Baseball Pitchers using Ultrasound Imaging**

Arie J. van Duijn, Shawn D. Felton, Eric Shamus, Brandon Smith, Mitchell L. Cordova, FACSM. *Florida Gulf Coast University, Fort Myers, FL.* (Sponsor: Mitchell L. Cordova, FACSM)
Email: avanduij@fgcu.edu
(No relationships reported)

Injuries to the Ulnar Collateral Ligament (UCL) of the elbow are common in overhead throwing athletes. A repetitive valgus force during the throwing motion places significant stress on the UCL. More research needs to be conducted to investigate new methods to assess potential thickening of the anterior bundle of the UCL in order to understand ligament changes that may occur throughout the season. **PURPOSE:** To examine the reliability of ultrasound imaging measurements of UCL width at 2 different anatomical locations using 5Nm valgus stress; and to determine if a difference in ligament width exists between the two measurements 4 weeks apart within the season.

METHODS:

Thirteen Division I college men's baseball pitchers participated with a mean age of 20.4 ± 1.45 SD) and body mass index (BMI) 24.56 ± 1.78 SD). Ultrasound images were obtained of the anterior band of the UCL on the participant's throwing arm using a GE LOGIQ E ultrasound unit with a linear probe at 12Mhz. Participants were placed in a supine position with a wedge placed underneath their forearm to maintain their elbow position at a 30 deg. flexion angle. A 5 Nm valgus stress was applied 20 centimeters distal to the medial epicondyle. Measurements at the mid substance and the apex of the trochlea were taken at the beginning of the baseball season and then again 4 weeks later. Three images were measured during each session.

RESULTS:

Intra-rater reliability as expressed by ICC (3, 3) was .929 (SEM= 0.18mm) & .935 (SEM= 0.20mm) for the apex of trochlea measurement site and .861 (SEM= 0.22mm) & .920 (SEM=0.16mm) for the mid-substance measurement site, indicating excellent intra-rater reliability. There was no difference between the measurements obtained on the two testing dates (Apex of trochlea mean width 2.90mm & 2.92mm; t= -.155; p ≥ 0.05) and (Mid-substance mean width 4.49 mm & 4.44 mm; t= .571; p ≥ 0.05)

CONCLUSIONS: Excellent intra-rater reliability was found at all four measurement sites. There was no significant difference in UCL width from the beginning of the season and one-month into the season. Further research is recommended to perform multiple imaging sessions throughout the year to determine the long term physiological effects of overhead throwing on the anterior band of the UCL and to study the connection between UCL width changes, tissue quality, and injury risk.

**3426 Board #331 June 2 2:00 PM - 3:30 PM
Epidemiological Study of Achilles Tendon Morphology Using Ultrasound Tissue Characterization Technology**

Angela R. Lucero, Laura E. Stanley, Madison F. Kennedy, Quefeng Li, Mark Dyson, David J. Berkoff. *UNC Chapel Hill, Chapel Hill, NC.*
(No relationships reported)

Ultrasound tissue characterization (UTC) imaging is a novel technology to objectively quantify tendon structural integrity. Previous UTC studies have primarily been performed in small, homogeneous samples, and varied in analysis parameters. No studies to date have examined a large, asymptomatic population.

PURPOSE: To characterize asymptomatic Achilles tendon (AT) structure in an adult population, identify factors that may be associated with tendon structure variation as measured by UTC, and provide a foundation for future research. **METHODS:** 575 asymptomatic subjects (male: 217, female: 291) were recruited. Each subject completed a medical history questionnaire and underwent UTC scanning of the right

AT. The motorized tracking device moved an ultrasound probe along the long axis of the AT capturing 598 transverse images at intervals of 0.2 mm over 12 cm. UTC algorithms quantified the stability of pixel brightness over every 17 contiguous images into four echotypes (ET): (I) aligned tendon bundles, (II) waving tendon bundles, (III) mainly fibrillar tissue, and (IV) mainly amorphous matrix. A region of interest (ROI) was selected from the calcaneus to the musculotendinous junction. Tendon borders were outlined manually in the transverse view at intervals no greater than every 25 frames (0.5 cm) across the ROI. Contours were interpolated to generate average percentages (%) of each ET for the total tendon volume. 67 subjects were excluded due to poor quality scans or not meeting inclusion criteria, resulting in 508 subjects in final analysis. **RESULTS:** Average ET % for the volume was: I-65.73% (SD±6.61, range 35.29-80.17), II-32.00% (SD±6.47, range 18.41-62.48), III-1.74% (SD±0.85, range 0.54-6.22), and IV-0.57% (SD±0.45, range 0.07-3.59). Differences between subgroups were compared and p-values <0.05 were considered significant. Higher % of ET I and lower % of ET II were associated with age 50-65 years old, male gender, African American race, and hypertension. Higher % of ET III was associated with age 50-65 years old, BMI>30, diabetes, and COPD. **CONCLUSION:** This work provides a baseline ET distribution that can be used in future AT research. We have shown numerous associations between tendon morphology and patient demographics/health that begin to help stratify differences in asymptomatic Achilles tendons.

Micro-vascular Blood Flow During Post-Occlusive Reactive Hyperemia Assessed By Diffuse Correlation Spectroscopy**

Kaylin D. Didier, Shane M. Hammer, Andrew M. Alexander, Jacob T. Caldwell, Shelbi L. Sutterfield, Carl J. Ade, Thomas J. Barstow, FACSM. *Kansas State University, Manhattan, KS.* (Sponsor: Thomas J. Barstow, FACSM)
Email: kaylind@ksu.edu
(No relationships reported)

PURPOSE: The purpose of this investigation was to determine if Diffuse Correlation Spectroscopy (DCS) provides a reproducible measure of micro-vascular blood flow during post-occlusive reactive hyperemia (PORH). Previous techniques utilized to assess forearm muscle blood flow include brachial artery blood flow and Near Infrared Spectroscopy (NIRS). DCS provides a novel ability to examine red blood cell (RBC) flux within the muscle microvasculature. We hypothesized that DCS would provide a reproducible measure of muscle microvasculature RBC flux during PORH.

METHODS: 7 healthy male subjects (25.9 ± 4 yrs) performed 3 trials of brachial artery PORH tests. The DCS probe was placed on the *flexor digitorum superficialis m.* of the cuffed arm and provided Blood Flow Index (BFI). Brachial artery blood flow was assessed using Doppler Ultrasound to provide time-averaged maximum velocity (TAMAX). Following a 10 min supine rest period baseline measurements were performed for 1 min at which time a pneumatic cuff was inflated to at least 250 mmHg for 5 minutes. Measurements continued to be made for the 5 min of occlusion and 3 min post cuff release. The subjects were given 10 min rest between trials.

RESULTS: The peak TAMAX of the brachial artery for PORH1, PORH2, and PORH3 occurred at 7.3 ± 3.4, 6.0 ± 2.4, and 6.4 ± 2.7 sec respectively (p=0.397). The peak in BFI for PORH1, PORH2, and PORH3 occurred at 25.6 ± 4.5, 26.4 ± 8.3, and 22.3 ± 3.5 sec respectively (p=0.311). The time to peak for TAMAX was significantly different from the time to peak in BFI (p<0.001).

CONCLUSIONS: Similar time to peak for BFI across trials indicates that the DCS provides a reproducible signal of muscle microvasculature blood flow during PORH conditions. We speculate that the significant difference between time to peak for TAMAX and BFI may be due to compliance between the brachial artery and the microvasculature.

F-66 Free Communication/Poster - Weight Control

Sugar-Sweetened Beverages And Short-duration Exercise On Glycemic Response And Subjective Appetite In Young Boys**

Julia O. Totony de Zepetnek, Kerry Miller, Melissa Da Silva, Nick Bellissimo. *Ryerson University, Toronto, ON, Canada.*
Email: jtotosy@ryerson.ca
(No relationships reported)

PURPOSE: Sugar-sweetened beverage consumption is thought to be a contributor to weight gain through its effects on the control of food intake and glucose homeostasis. It has been suggested that energy from sugar-sweetened caloric beverages bypass

physiologic systems regulating food intake, leading to weight gain. Despite a lack of reported evaluation, short-duration exercise is promoted in schools as a means of achieving energy balance and glucose homeostasis. The purpose of the present study was to investigate the interaction between sugar-sweetened beverage consumption and short-duration exercise on glycemic response and subjective appetite in young boys. **METHODS:** Eight normal weight boys (age: 11.25 ± 0.7 years) consumed isovolumetric amounts (240mL) of either a commercial fruit drink or 1% chocolate milk, matched for available carbohydrates (25g) two hours after a standardized breakfast. The boys then exercised on a motorized treadmill at their ventilatory threshold or sat quietly for 15min, followed by 45min of quiet sitting. Subjective appetite and capillary blood glucose were assessed at baseline, and at 15 and 60min during the test condition. **RESULTS:** There was a beverage (fruit drink vs. chocolate milk) x test condition (exercise vs. rest) x time (0, 15, 60min) interaction for blood glucose response ($p < 0.01$). There was a main effect of beverage on glucose response ($p < 0.01$). Exercise increased subjective average appetite to 60min compared to quiet sitting ($p < 0.05$). **CONCLUSIONS:** Fifteen minutes of moderate-intensity exercise attenuates the rise in blood glucose following sugar-sweetened beverage consumption. Chocolate milk has the lowest glycemic response, which may be due its milk protein and fat content and effect on gut hormone release. Further investigations are required to determine whether increased subjective appetite following short duration exercise would result in greater next-meal food intake.

Self-monitoring As A Predictor For Weight Loss In A Family-based Pediatric Obesity Treatment Program
 Ava Coughlin, Kate Heelan, FACSM, Todd Bartee. *University of Nebraska at Kearney, Kearney, NE.*
 Email: coughlinat@lopers.unk.edu
 (No relationships reported)

Family-based pediatric obesity treatment programs for children in the 95th-99th BMI percentile are suggested to be comprehensive and multidisciplinary to change behaviors and decrease weight. Self-monitoring (SM) has shown to be an effective strategy in child weight loss. **PURPOSE:** To determine if child and parent SM of weekly nutrition (NUTR), physical activity (PA), and body mass (BM) predict weight loss during a 12-week pediatric obesity treatment program. **METHODS:** 51 children (age: 9.8 ± 2.3 years, BMI percentile: 98.0 ± 1.3), 45 mothers (age: 41.5 ± 6.2 years), and 37 fathers (age: 41.5 ± 6.2 years) participated in 12 weekly healthy living education sessions. SM scores were determined as the number of weeks participants logged energy intake (SM-NUTR), monitored steps per day (SM-PA), and weighed-in (SM-BM) over the 12 weeks. A sum score (SM-SUM) of the three SM components was created. Stepwise multiple regression models were used to predict parent and child weight loss from SM scores. **RESULTS:** In 12 weeks, children lost $5.1 \pm 4.4\%$ of BM, mothers lost $5.3 \pm 8.0\%$ of BM, and fathers lost $8.2 \pm 4.7\%$ of BM. SM-SUM was 79% for fathers, 81% for children, and 88% for mothers. Table 1 represents Pearson correlation coefficients between percent body mass loss and self-monitoring scores.

Table 1. (* $p < 0.05$)	Child % BM loss	Mother % BM Loss	Father % BM Loss
SM-NUTR	$r = 0.33^*$	$r = 0.41^*$	$r = 0.49^*$
SM-PA	$r = 0.20$	$r = 0.36^*$	$r = 0.17$
SM-BM	$r = 0.13$	$r = 0.38^*$	$r = 0.15$
SM-SUM	$r = 0.34^*$	$r = 0.49^*$	$r = 0.36^*$

Stepwise multiple regression models suggested that Child's SM-SUM accounted for 19% of the variance in Child's % BM loss after 12 weeks ($R^2 = 0.19$, $p < 0.05$). Mother's SM-NUTR score ($R^2 = 0.47$, $p < 0.05$) and Child's SM-SUM score ($R^2 = 0.08$, $p < 0.05$) accounted for 55% of the variance in Mother's % BM loss ($p < 0.05$). Father's SM-NUTR score accounted for 29% of the variance ($R^2 = 0.29$, $p < 0.05$) in Father's % BM loss. **CONCLUSION:** SM-NUTR, SM-PA, and SM-BM all appear to play a role with family weight loss, with SM-NUTR being most influential. Continuation of self-monitoring post-intervention and its influence on weight loss should be examined.

3430 Board #335 June 2 3:30 PM - 5:00 PM
Effects Of Physical Exercise On The Modulation Of Aquaglyceroprotein 7 From Visceral Adipose Tissue
 Jorge Beleza, Sílvia Rocha-Rodrigues, Inês O. Gonçalves, António Ascensão, José Magalhães. *Faculty of Sports, University of Porto, Porto, Portugal.*
 (No relationships reported)

A role for aquaglyceroprotein 7 (AQP7) in the control of lipid accumulation in white adipose tissue (WAT) has been hypothesized; however limited information is available regarding the impact of physical exercise. **PURPOSE:** We aimed to analyze the role of voluntary physical activity (VPA) and endurance training (ET) on WAT AQP7 expression of HFD-fed rats. **METHODS:** Male Sprague-Dawleys rats were assigned into sedentary (S), VPA and ET groups fed an isoenergetic Lieber-DeCarli-liquid diet:

a standard diet (35% fat-derived Kcal) or a high fat-diet (HFD), (70% fat-derived Kcal), as follows: SS, SVPA, SET, HS, HVPA and HET, during 17 wks. VPA groups had free access to running wheel throughout the entire protocol. After 9 weeks of HFD, SET and HET animals were submitted to 8-wks of ET on treadmill while maintained dietary treatments. Plasma non-esterified fatty acid (NEFA), glycerol and insulin levels were determined and epididymal white adipose tissue (eWAT) was used to determine gene and protein expression of AQP7 and fatty acid translocase (FAT/CD36). Diet and exercise effects were performed using 2-way ANOVA. **RESULTS:** The relative caloric intake was constant between groups. HFD increased visceral adiposity index (9.0 ± 0.2 vs. 11.8 ± 0.4 ; $p < 0.0001$) and adipocyte area mean (3716.1 ± 301.4 vs. 5348.6 ± 471.5 ; $p < 0.001$), ET reduced these obesity-related anatomical features ($p < 0.001$). Both AQP7 and FAT/CD36 protein and gene expression remained unchanged after HFD regimen. VPA decreased plasma glycerol levels (12.6 ± 0.8 vs. 12.5 ± 0.6 ; $p < 0.001$) and eWAT AQP7 gene expression ($p < 0.001$) in S diet-fed animals and had no impact neither on plasma NEFA levels nor FAT/CD36 protein content. Eight-wks of ET decreased NEFA (SS vs. SET, 16.4 ± 0.5 vs. 12.0 ± 0.4 ; HS vs. HET, 14.7 ± 0.7 vs. 10.8 ± 0.7 , $p < 0.001$) and glycerol (SS vs. SET, 17.4 ± 0.7 vs. 12.5 ± 0.6 ; HS vs. HET, 15.6 ± 0.5 vs. 10.3 ± 0.9 ; $p < 0.001$) plasma levels. ET decreased gene and protein expression of AQP7 ($p < 0.001$) in eWAT in both diet types and increased FAT/CD36 gene ($p < 0.001$) in SET group and its protein expression ($p < 0.001$) in both diet types. **CONCLUSION:** Our data suggest that 8-wks of ET decreased AQP7 expression, which might play an important role preventing lipid overaccumulation in visceral adipose tissue of obese rats. Effects Of Intermittent Periods Of Severe Negative Energy Balance On Weight Maintenance During US Special Operations Forces Training
 John J. Sepowitz, Nicoles J. Armstrong, Stefan M. Pasiakos, FACSM. *USARIEM, Natick, MA.* (Sponsor: Stefan M Pasiakos, FACSM)
 (No relationships reported)

Physically active individuals often fail to meet energy requirements during sustained periods of increased physical activity, resulting in negative energy balance. Failure to increase energy intake during periods of high energy expenditure may compromise body mass and subsequent performance. Whether individuals adequately restore body mass between intermittent periods of severe negative energy balance during long-term training is not well characterized. **PURPOSE:** To examine energy balance and changes in body mass during US Special Operations Forces (SOF) training. **METHODS:** Energy expenditure (EE, doubly labeled water), energy intake (EI, 24 h recalls), energy balance (EB, intake - expenditure) and body mass were measured in 22 US Marines (mean \pm SD, 25 ± 2 y, 86 ± 10 kg) during the 4 most physically demanding phases of a 261 d SOF training program [days 15-29 (I), 115-123 (II), 191-201 (III), and 243-261 (IV)]. **RESULTS:** EE was highest during phase II (6376 ± 712 kcal/d) compared to phase I (4011 ± 475 kcal/d), III (4189 ± 476 kcal/d), and IV (3735 ± 314 kcal/d) ($P < 0.05$). EI was lowest during phase I (300 ± 0 kcal/d) compared to phase II (2410 ± 338 kcal/d), III (2816 ± 488 kcal/d), and IV (2702 ± 738 kcal/d) ($P < 0.05$). EB was more negative during phase I (-3711 ± 475 kcal/d) and II (-3966 ± 776 kcal/d) compared to phase III and IV ($P < 0.05$). Body mass was lost during phases I, II, and IV, and the degree of body mass lost was equivalent between phase I ($6.5 \pm 1.5\%$; 5.6 ± 1.7 kg) and phase II ($5.8 \pm 2.0\%$; 4.9 ± 1.9 kg), and greater than phase IV. Initial body mass predicted the loss of body mass ($r = -0.67$, $P < 0.05$) during phase I. Body mass did not change during phase III. Body mass was restored before the start of each subsequent phase and was not different between the start (86.4 ± 9.8 kg) and end of the 261 d training (86.7 ± 9.0 kg). **CONCLUSION:** These data suggest that well-trained Marines adequately compensate EI to restore body mass between intermittent periods of severe negative EB. 3432 Board #337 June 2 3:30 PM - 5:00 PM
Retrospective Analysis Of Weight Loss Relative To Protein Intake During Short-term Exercise Training In Women
 Conrad P. Earnest, FACSM¹, Brittanie Lockard¹, Claire Baetge², Mike Greenwood¹, Richard B. Kreider, FACSM¹. ¹Texas A&M University, College Station, TX. ²University of Texas at San Antonio, San Antonio, TX.
Reported Relationships: C.P. Earnest: Salary; Nutrabolt. Contracted Research - Including Principle Investigator; Catapult Health and Naturally Slim.

PURPOSE: To retrospectively examine the effects of circuit weight training (10-wk) in 663 sedentary, overweight/obese women (age $46 \pm y$, BMI 34.85 ± 6.17 kg/m²) on weight loss, anthropometry and indices of cardiovascular health relative to PRO ingestion.

METHODS. Eight exercise-training studies performed from 2002–2014 were examined relative to tertiles of PRO ingestion (Low, <0.8 g/kg/d; Moderate; >0.8–1.2 g/kg/d; High >1.2 g/kg/d). The Primary outcome is clinically significant weight loss (CSWL, 5%). Secondary outcomes include anthropometry and measures of cardiovascular health. Data were analyzed using GLM adjusted for age, study and respective baseline values. Chi-square and adjusted residual analyses were used to determine categorical differences.

RESULTS. Protein ingestion was: Low (n=278; 0.65 g/kg/d \pm 0.12; range 0.24–0.80), Moderate (n=225; 0.98 g/kg/d \pm 0.12; range 0.891–1.19) and High (142 (n=142; 1.66 g/kg/d \pm 0.42; range 1.20–3.28). Weight change was: Gained weight (12%; 1.01 kg, 95% CI, 0.24, 1.78), exhibited non-CSWL (50%; -1.81 kg, 95% CI, -2.04, -1.59) and achieved CSWL (39%; -7.17 kg (95% CI, -7.42, -6.92). Post-hoc assessment showed that High PRO consumers did not gain a significant amount of weight (0.70 kg, 95% CI, -0.42, 1.81), while Low (0.97 kg, 95% CI, 0.30, 1.64) and Moderate PRO consumers did (1.36 kg, 95% CI, 0.84, 1.89). No other significant differences were observed for weight loss or lean body mass relative to PRO tertiles. Interestingly, 57% of those consuming higher PRO (1.66 \pm 0.42 g/kg/d) achieved CSWL vs. ~33% in low (0.65 g/kg/d) and moderate PRO (0.98 g/kg/d \pm 0.12) consumers (*P*-for-trend, 0.001). Further comparison demonstrated that Low PRO consumers were significantly unlikely to achieve CSWL (*adjres* = -3.1), while those ingesting High PRO were significantly more likely to achieve CSWL (*adjres* = 4.9).

CONCLUSION. Despite the lack of difference for magnitude of weight loss between PRO groups, high PRO consumers were significantly more likely to achieve CSWL during a short exercise intervention consisting of resistance and aerobic training. Equally, higher PRO consumption may offset the magnitude of weight gain vs. lower PRO intakes if weight loss is not achieved.

Effect Of Fat-sugar Snacking, With And Without Exercise Training, On Body Composition And Cardiometabolic Fitness

Wesley J. Tucker¹, Catherine L. Jarrett², Andrew C. D'Lugos², Jared M. Dickinson², Siddhartha S. Angadi², Glenn A. Gaesser, FACSM². ¹University of Texas at Arlington, Arlington, TX. ²Arizona State University, Phoenix, AZ. (Sponsor: Glenn Gaesser, FACSM)

(No relationships reported)

PURPOSE: Diets high in fat and sugar have been implicated in the pathogenesis of obesity, diabetes and cardiovascular disease. Exercise aids in the prevention of weight/fat gain, and may prevent adverse cardiometabolic changes during periods of energy excess. We examined the interactions of fat-sugar snacking, with and without exercise training, on anthropometry, oral glucose tolerance and cardiorespiratory fitness in overweight and obese men. **METHODS:** Twenty-seven, healthy overweight/obese (BMI >25 kg/m²) men were fed a fat-sugar snack (2 donuts per day; ~600 kcal), 6 days/wk for 4 wks, while being asked to maintain their habitual diet. In addition, all participants were randomized to one of three groups: sedentary Control or isocaloric supervised exercise (250kcal/session, 4 days/wk for 4 wks): either moderate-intensity continuous training (MICT) (50% VO₂peak), or high-intensity interval training (HIIT) (90-95% peak heart rate). A two-way repeated measures ANOVA was used to assess changes in body composition, oral glucose tolerance and cardiorespiratory fitness between and within groups. **RESULTS:** Body weight (Pre: 96.0 \pm 7.7kg, Post: 97.4 \pm 7.9kg, *p*=0.002) and lean mass (Pre: 64.2 \pm 4.9kg, Post: 65.1 \pm 4.7kg, *p*=0.02) increased significantly in HIIT and were unchanged in MICT. Trends for an increase in body weight (Pre: 93.1 \pm 11.8kg, Post: 94.0 \pm 12.8kg, *p*=0.07) and lean mass (Pre: 61.1 \pm 5.9kg, Post: 61.8 \pm 6.5kg, *p*=0.11) were observed in Control. Fat mass was unchanged in control and MICT, with a trend for increase in HIIT (Pre: 28.3 \pm 5.3kg, Post: 28.9 \pm 5.3kg, *p*=0.11). Glucose AUC (mg/dl 120 min) during the 2-h OGTT improved significantly in MICT (Pre: 3,801 \pm 2,453, Post: 2,518 \pm 2584, *p*=0.01) and Control (Pre: 5,666 \pm 2826, Post: 4,214 \pm 2,194, *p*=0.002) with no change in HIIT. VO₂peak (L/min) increased significantly in both HIIT (Pre: 3.21 \pm 0.49, Post: 3.60 \pm 0.49) and MICT (Pre: 3.06 \pm 0.73, Post: 3.36 \pm 0.79) (*p*<0.001), with no change in Control. **CONCLUSIONS:** The addition of ~14,500 kcal of fat-sugar snacks in the form of donuts over a 4-week period was insufficient to induce deleterious changes in body composition in overweight/obese young men. Surprisingly, oral glucose tolerance was improved in Control. MICT may be preferable to HIIT during extended periods of snacking on foods comprised mainly of fat and sugar.

3434 Board #339 June 2 3:30 PM - 5:00 PM
Dose Response Effect of a Whey Protein on Appetite Profile, Energy Metabolism and Intake

Svetlana Nepocatych, Caroline E. Melson, Takudzwa A. Madzima. *Elon University, Burlington, NC.*

(No relationships reported)

PURPOSE: To determine the effects of high (HWP) and low whey protein (LWP) at breakfast [TM1] on appetite profile, thirst, energy metabolism and subsequent energy intake. **METHODS:** Seventeen healthy participants (age 27 \pm 7 y, BF 21.5 \pm 6.9%, BMR 1741 \pm 391 kcal/day) consumed one of three smoothies at breakfast on three separate days in randomized order. The energy intake from smoothies consisted of control (10% fat and 90% carbohydrate), LWP (20% whey protein, 10% fat and 70% carbohydrate) and HWP (40% whey protein, 10% fat and 50% carbohydrate), followed by an *ad libitum* lunch 3 hours later. Appetite profile was completed using a visual analog scale (VAS) before, at 0, 60, 120, and 180 minutes. Resting metabolic rate (RMR) 30 minutes before and thermic effect of a meal (TEM) at 45-60, 105-120, and 165-180 minutes were measured by indirect calorimetry to determine oxygen consumption (VO₂) and respiratory quotient (RQ). The accepted level of significance was set at *p* < 0.05. **RESULTS:** Energy intake at lunch was higher (*p* = 0.02) following control (770 \pm 289 kcal) compared to HWP (654 \pm 252 kcal) and LWP (671 \pm 217 kcal). Participants hunger, desire to eat, and perceived amount were significantly higher, whereas, satiety and fullness were lower after control compared to HWP and LWP. A significant difference over time was observed in thirst and cravings of sweet, salty savory and fatty, however there were no significant condition by time interactions. Additionally, a lower RQ (*p* < 0.001) and higher VO₂ (*p* < 0.001) was observed for HWP (4.3 \pm 0.6, 4.2 \pm 0.5, and 4.0 \pm 0.5 ml \cdot kg⁻¹ \cdot min⁻¹) compared to LWP (4.1 \pm 0.6, 3.9 \pm 0.5, and 3.5 \pm 0.5 ml \cdot kg⁻¹ \cdot min⁻¹) and control (4.0 \pm 0.6, 3.7 \pm 0.5, and 3.5 \pm 0.4 ml \cdot kg⁻¹ \cdot min⁻¹) at 45-60, 105-120, and 165-180 minutes, respectively. **CONCLUSION:** Breakfast with HWP and LWP were rated as more satiating coinciding with reduced subsequent energy intake at lunch. In addition, these results suggest a dose-response effect of whey protein on energy metabolism over 3 hours following breakfast.

Sex Differences In Total Pyy And Glp-1 After Moderate-intensity Continuous And Sprint Interval Cycling Exercise.

Jennifer L. Copeland¹, Logan K. Townsend², Jillian Hallworth¹, Jon Doan¹, Tom J. Hazell³. ¹University of Lethbridge, Lethbridge, AB, Canada. ²University of Guelph, Guelph, ON, Canada. ³Wilfrid Laurier University, Waterloo, ON, Canada. Email: jennifer.copeland@uleth.ca

(No relationships reported)

Exercise is often used as a weight-loss strategy, however, exercise interventions are sometimes less effective in females than males for improving body composition. One possible explanation is that exercise affects appetite regulating hormones differently in males and females such that females increase post-exercise energy intake. Recently, sprint interval training was shown to reduce body fat in females despite relatively low energy expenditure during exercise. **PURPOSE:** To examine sex differences in circulating anorexigenic hormones and perceived hunger following an acute session of sprint interval training (SIT) and moderate-intensity continuous training (MICT). **METHODS:** Twenty-one active participants (11 females in early follicular phase) participated in 3 sessions in a randomized crossover design: 1) MICT, 30 min cycling at 65% VO₂max; 2) SIT, 6 x 30 sec "all-out" cycling sprints with 4 min recovery periods (27 min total); and 3) control (CTRL; no exercise). Participants arrived at the lab fasted and consumed a standardized breakfast 1 hour before exercise. Blood samples were collected pre-exercise, immediately and 90 min post-exercise for the measurement of total peptide tyrosine tyrosine (PYY) and glucagon-like peptide-1 (GLP-1). Subjective perceptions of hunger were assessed using a visual analogue scale before breakfast and before all blood draws. Hormone data were analysed as change in concentration from baseline. Changes in hormones and hunger were analysed using a 3 x 3 x 2 mixed factor (session x time x sex) repeated measures ANOVA. **RESULTS:** Increases in GLP-1 and PYY were greater during the MICT session (*P*<0.05) and SIT session (*P*<0.01) compared to CTRL. Total PYY increased more immediately post-exercise in males than females (*P*=0.030). GLP-1 increased only in females following MICT (*P*=0.034) and SIT (*P*=0.024) compared to CTRL. Perceived hunger was lower immediately post-MICT (*P*=0.016) and SIT (*P*=0.006) compared to CTRL, but there were no sex differences. **CONCLUSION:** Total PYY and GLP-1 appear to respond similarly to submaximal and supramaximal exercise, however, these results suggest they may respond differently to exercise in males and females over 90 min. The post-exercise hormonal response we observed in females would not be expected to create a compensatory increase in energy intake.

12-Week Treadmill Program Elicits Low Energy Availability Without Changes in Serum Testosterone in Male Rats

Lyra R. Clark, Thomas Wilson, Michael Dellogono, Erin Chenette. *University of Massachusetts Lowell, Lowell, MA.*
 (No relationships reported)

Male endurance athletes have been reported to have lower testosterone concentrations than their sedentary counterparts, which may have detrimental health effects including increased risk of musculoskeletal injury and fertility complications secondary to decreased sex hormone production. Cholesterol supplementation has been reported to increase serum sex hormones. **PURPOSE:** The purpose of this study was to investigate whether a treadmill endurance exercise program would cause exercise-induced reproductive dysfunction in male rats and assess the impact of increased dietary cholesterol on sex hormone levels. **METHODS:** Male Sprague-Dawley Rats (n=20) were randomly assigned to a control group (C) or an exercise training group (EX) that performed treadmill running 40 min/day, 6 days/wk for a duration of 12 wks. At study midpoint (wk 6), rats were randomized to receive either a High-Cholesterol (HC) Diet (n=10) or remain on standard purified diet (n=10). Fasting blood samples were collected at baseline, wk 6, and wk 12. Serum testosterone (T) and leptin were measured via ELISA. Serum lipids (TC, HDL, LDL, TG) were measured via clinical chemistry analyzer. Body weight (BW) and voluntary food intake (EI) were measured weekly. **RESULTS:** At end of wk 6, EX had significantly lower BW (494.3±34.7g versus 565.3±47.9g, p=0.001), mean daily EI (77.5±3.5 kcal versus 91.6±5.2 kcal, p<0.001), and serum leptin (90.8±40.1 pg/mL versus 635.7±225.6 pg/mL, p=0.001) in comparison to C. No difference was observed between EX and C in serum T (12.7±6.0 ng/mL versus 12.9±5.8 ng/mL). At end of wk 12, exercise groups (EX and EX+HC) had significantly lower BW (539.4±40.6g versus 645.1±60.7g, p<0.001), mean daily EI (81.7±2.9 kcal versus 87.8±1.9 kcal, p<0.01), and serum leptin (132.8±110.1 pg/mL versus 519.2±300.8 pg/mL, p=0.001) in comparison to C and C+HC. HC diet did not have significant impact upon serum T in comparison to standard diet (3.8±3.4 ng/mL versus 4.9±2.4 ng/mL). **CONCLUSIONS:** Despite low energy availability, exercise-induced reproductive changes may not occur in training programs <12 weeks. Lower EI observed in exercise groups despite higher energy expenditure may indicate that low energy availability in endurance-trained individuals may be inadvertent. Supported by American Egg Board Graduate Fellowship Research Grant

3437 Board #342 June 2 3:30 PM - 5:00 PM
The Effect of Increased Water Intake on Food Consumption

Briana McCloskey¹, Naomi McKay², Jennifer Temple². ¹*Simpson College, Indianola, IA.* ²*University at Buffalo SUNY, Buffalo, NY.*
 Email: briana.mccloskey@my.simpson.edu
 (No relationships reported)

Increased water consumption has potential to promote weight loss but previous interventions have been equivocal. **Purpose:** To examine the effects of hydration on energy intake at lunch and the remainder of the day. **Methods:** Ten males and 12 females attended 3 study sessions where they drank either 1, 3, or 4 bottles (500 ml) of water throughout the morning before lunch. Each participant was their own control (drinking one bottle), hydrated (three bottles), and overhydrated (four bottles). Food items were weighed and arranged on a tray in large portion sizes to allow for their desired amount of lunch intake. Participants rated hunger on a visual analog scale at three different time points before lunch and once after. When the participants selected to stop eating, food was reweighed to calculate caloric intake. Participants kept a food and beverage log for the remainder of the day. The detailed logs were then reviewed with the participant at the next visit and entered into the Nutritionist Pro software. Repeated-measures ANOVA determined if there was an effect between level of hydration and the amount of energy consumed at lunch and for the remainder of the visit day. **Results:** Hydration status, based on water consumed throughout the morning, significantly influenced energy intake for the remainder of the day. Hydrated males, males who drank three bottles of water throughout the morning, significantly increased energy consumed the rest of the day compared to when they were in the control group, 1686 ± 256 kcal vs. 990 ± 203 kcal (p=0.027). When energy intake at lunch was taken into account there was an effect of hydration status on daily energy intake. For women, energy consumed at lunch and the remainder of the day was not significant when compared with water intake (p=0.081 vs p=0.074, respectively). **Conclusion:** Drinking water throughout the morning had no effect on energy intake during lunch. Furthermore, energy intake was not suppressed even when 2L of water (4 bottles) was consumed over a 3.5-hour period. Males increased the amount of energy consumed for the remainder of the day when in the hydrated condition. Increased hydration may have adverse effects on energy intake due to the volume of water consumed prior to a meal.

3438 Board #343 June 2 3:30 PM - 5:00 PM
Effects of Moderate Consumption of Non-Nutritive Sweeteners on Glucose Tolerance and Body Composition in Rats

Ashley P. Tovar, John C. Young, FACSM, Debra Tacad, Tara Kenny, Laura Kruskall, FACSM, James Navalta, FACSM.
University of Nevada Las Vegas, Las Vegas, NV. (Sponsor: John C. Young, FACSM)
 (No relationships reported)

Introduction: To combat the effects of excess energy intake on obesity and glucose intolerance, non-nutritive sweeteners (NNS) have been used as a replacement for more energy dense traditional sweeteners. However, limited research has been completed regarding the metabolic effects of moderate consumption of non-nutritive sweeteners. **Purpose:** The purpose of this study was to determine the effect of moderate consumption of NNS (aspartame and sucrose) on glucose tolerance and the insulin response to an oral glucose load, and on body composition in an animal model. **Methods:** Male Sprague-Dawley rats (N=30) were given aspartame (ASP, n=10, 8.5 mg/kg/day) or sucralose (SUC, n=10, 2.6 mg/kg/day) in drinking water, or untreated water as a control (n=10) for 6 weeks. In the morning, after overnight fasting, rats underwent an oral glucose tolerance test (2g/kg 50% dextrose w/v by gavage). Blood was obtained by tail clip; glucose was measured by glucose meter and insulin was measured by radioimmunoassay. Following euthanasia, lean mass and fat mass were determined by dual energy x-ray absorptiometry; epididymal fat pads were removed and weighed. **Results:** No significant differences were found between groups in area under the curve for glucose or insulin response to an oral glucose load. Significant differences in serum insulin were seen 15 minutes after the glucose load between both the ASP (0.72 ± 0.06 ng/mL vs 0.94 ± 0.08 ng/mL, p=0.035) and SUC group (0.72 ± 0.07 ng/mL vs 0.94 ± 0.08 ng/mL, p=0.048) compared with the control. While percent body fat was not different between groups, epididymal fat pad mass was significantly higher in the ASP group compared with the control group (5.50 ± 0.34 g vs 4.55 ± 0.19 g, p=0.042), while the ratio of trunk fat to total fat was significantly lower in the SUC group compared with controls (0.49 ± .02 vs 0.60 ± .14, p<0.01). **Conclusion:** Moderate consumption of aspartame or sucralose had no effect on percent body fat. Fifteen minutes following a glucose load, serum insulin was significantly lower in both NNS groups compared with the control, suggesting a potential suppression in insulin response. Both aspartame and sucralose altered body fat distribution. These results may have implications for addressing abdominal obesity.

Evaluation of Weight Loss Advice from Pharmacists and Supplement Retailers

Katelynn C. Kletzli, Tianna N. Wikert, Amy D. Rickman, FACSM, Jeff S. Lynn. *Slippery Rock University, Slippery Rock, PA.* (Sponsor: Amy Rickman, FACSM)
 (No relationships reported)

Approximately half of adult Americans report the desire to lose weight and 17 million take dietary supplements for the purpose of weight loss. People may seek weight loss advice where dietary supplements are sold including pharmacies and retail shops. **PURPOSE:** The purpose of the study was to evaluate the effectiveness and safety of weight loss advice provided by pharmacists and retailers. A secondary purpose was to evaluate whether either recognized symptoms associated with serious cardiovascular concerns and if appropriate follow-up advice was given. **METHODS:** Two college-aged women of normal BMI individually visited 51 pharmacies and 22 retailers with a standardized script that included a desire to lose weight and the presentation of multiple cardiovascular disease symptoms including heavy chest, light-headedness, breathlessness, and a tingling jaw. Immediately upon departure, all pertinent advice given was recorded. **RESULTS:** Descriptive analyses revealed that only 47% of pharmacists and 9% of retailers suggested reducing energy intake and/or increasing energy expenditure for weight loss. Cardiovascular symptoms were correctly identified and directly addressed by 4% of pharmacists and 0% of retailers. Other interpretations of symptoms included asthma (n=4), dehydration (n=1), electrolyte imbalance (n=1), allergies (n=1), or vitamin deficiencies (n=1), but 75% of the time, symptoms were ignored entirely. Forty-nine percent of pharmacists and 100% of retailers recommended a total of 55 different supplements including diuretics, fat binders, and vitamins. Twelve percent of pharmacists and 95% of retailers recommended stimulants, which could be particularly harmful for a person with cardiovascular disease. **CONCLUSIONS:** Although pharmacists gave better weight loss advice than retailers with regard to both effectiveness and safety, both gave enough ineffective and unsafe advice that consumers should use extreme caution when interpreting weight loss advice from pharmacists and retailers.

3440 Board #345 June 2 3:30 PM - 5:00 PM
Awareness Levels of the Misuse of the 3500 Calorie Rule Predicting Long Term Weight Loss

Laurie Milliken, FACSM, Lauren Pringle. *Univ. of Massachusetts Boston, Boston, MA.*
 (No relationships reported)

Recently, a new rule has been suggested to replace the 3500 calorie rule to predict long term weight loss (WL) but whether practitioners are aware of this is not known. **PURPOSE:** To assess the awareness of recent facts related to the misuse of the 3500 calorie rule for predicting WL and to determine whether awareness differs by certification status, a person's training level and their perceived WL knowledge. **METHODS:** Students (S), faculty (F), and professionals (P) [n = 352, 68% female, 31 ± 13.5 years] responded to an anonymous online survey sent via email lists and social media platforms. Each participant responded yes or no regarding their awareness of 8 statements focused on the misuse of the 3500 calorie rule, compensation that takes place with WL, the recommendation of a new rule, and the nonlinear nature of WL. Participants reported current exercise and nutrition certifications and were grouped as certified or not certified. They also reported their level of WL knowledge on a 5 point Likert scale and were divided into 2 groups for analysis: very good or excellent (EX) knowledge vs good, fair and poor (Poor) knowledge. Chi squared analyses were used to test for differences in the proportions of respondents who were aware of each statement between knowledge, certification, and training level groups. **RESULTS:** The % who were aware of WL statements was lower in S (p<0.05) and ranged from 26.1 - 61.8% for S, 19.4 - 93.5% for F and 19.7 - 84.5% for P. The lowest awareness for all groups was regarding the new rule to predict WL and did not differ between groups (26.1%, 19.4%, and 19.7% for S, F, and P, respectively; p=0.48). For 7 of 8 statements, more of those with EX self-reported knowledge had an awareness (30.4 - 83.0%) of WL statements than those with Poor knowledge (18.4 - 63.3%; p<0.05). For 4 of the 8 statements, more of those who were certified (71.7 - 82.8%) had an awareness of WL statements than those without a certification (54.4 - 65.0%; p<0.05). **CONCLUSIONS:** S were the least aware of the newest developments in the misuse of the 3500 calorie rule while F were the most aware, though awareness of some concepts were low for all. Awareness levels were highest in those who self-reported EX knowledge. Those with certifications had higher awareness levels of some WL concepts. More dissemination is needed to raise awareness of WL concepts.

3441 Board #346 June 2 3:30 PM - 5:00 PM
Assessment of the Relationship Between Macronutrient Intake and Browning of White Fat in Adult Males

Andres E. Carrillo¹, Petros C. Dinas², Angelica Valente³, Marnie Granzotto⁴, Marco Rossato⁴, Roberto Vettor⁴, Natalie A. Davies¹, Athanasios Z. Jamurtas⁵, Yiannis Koutedakis⁵, George S.  (No relationships reported)

Research conducted in rodents and humans present conflicting results on the relationship between caloric intake and the browning of subcutaneous white adipose tissue (scWAT). For example, exercise combined with caloric restriction did not change browning indices measured from human scWAT samples. In another study, caloric restriction in mice resulted in the browning of both scWAT and visceral white adipose tissue. Few investigators, however, have examined the relationship between differences in macronutrient intake and browning processes of human scWAT. **PURPOSE:** The purpose of this study was to investigate the relationship between macronutrient intake and browning indices assessed from scWAT of healthy adult males. **METHODS:** Forty-six healthy adult males [age (years): 35.2±6.9, body mass index (BMI): 27.3±4.2 (kg/m²)] completed a 3-day dietary recall within one week, and had a scWAT biopsy done to assess the mRNA of uncoupling protein one (UCP1) - a direct measure of browning processes. mRNAs of peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1α), peroxisome proliferator-activated receptor alpha (PPARα) and peroxisome proliferator-activated receptor gamma (PPARγ) that indirectly indicate browning processes of scWAT were also assessed. Carbohydrate (CHO), protein (PRO), and fat (FAT) intake data as a percentage of total caloric intake were used for analysis. Waist-to-hip ratio, body composition, and resting energy expenditure were also measured. **RESULTS:** Spearman's correlation coefficient revealed a moderate positive association between CHO and PPARγ (rho = 0.375, p = 0.01). CHO was also negatively associated with fat mass (assessed as a percentage of total body mass) (rho = -0.297, p = 0.04). No other significant associations were detected (p > 0.05). **CONCLUSIONS:** Carbohydrate intake as a percentage of total kilocalories was positively associated with PPARγ in scWAT from healthy adult males. It is, however, difficult to determine if the association between carbohydrate intake and

PPARγ indicates browning processes in scWAT given that the mRNA of UCP1 was not related to macronutrient intake. More research is needed to expand on these findings with the use of longitudinal intervention based studies.

Liposomal Encapsulated Alpha-Lipoic Acid, Benfotiamine and Curcumin Prevent Overfeeding Mediated Increases in Waist Circumference

Nathan C. Grimm, Jeremy Theisen, Timothy Brodsky, Simon Fredericks, Jessie R. Wilburn, Brittney C. Sly, Gregory P. Dooley, Christopher Bell. *Colorado State University, Fort Collins, CO.* (Sponsor: Raoul F. Reiser II, FACSM)
 Email: nathan.grimm@colostate.edu
 (No relationships reported)

PURPOSE: To determine if liposomal (L) encapsulated alpha-lipoic acid (0.5g), benfotiamine (0.5g) and curcumin (2.0g) (ABC) would prevent the unfavorable metabolic consequences of sedentary high-fat overfeeding in healthy young adults. **METHODS:** 29 young (18-30 years), healthy, physically active men and women were randomly assigned to ingest placebo (n=9), ABC (n=10), or L-ABC (n=10) twice daily for 28 days. Between days 22 and 28 all participants abstained from their normal regular exercise and consumed a high calorie, high fat diet. **RESULTS:** On Day 29, circulating alpha lipoic acid was greater (p<0.01) in L-ABC (412±73 ng/mL) compared with ABC (154±33 ng/mL). During the sedentary high fat overfeeding, dietary intake was not different (p>0.6) between groups (~3,400 kcal/day; ~50% from fat). Sedentary high fat overfeeding increased (P<0.05) waist circumference in the placebo (+2.7±2.7 cm) and ABC (+3.3±2.0) groups but not the L-ABC group (+0.7±2.7). The magnitudes of increase (p<0.05) in body mass (1.7±0.3 kg), fat mass (0.7±0.2 kg), and blood pressure (3±1 mmHg) and decrease (p<0.05) in insulin sensitivity (Matsuda Index: -2.9±0.9) after overfeeding were not different between groups (all p>0.5). **CONCLUSIONS:** Liposomal encapsulated alpha-lipoic acid, benfotiamine and curcumin: 1) promoted alpha-lipoic acid bioavailability; and, 2) prevented sedentary high-fat overfeeding mediated increases in waist circumference in usually active healthy young adults. These data may have important public health implications for periods of inactive overconsumption such as during seasonal celebrations.

3443 Board #348 June 2 3:30 PM - 5:00 PM
The Effect Of High-intensity Interval Exercise In Hypoxia On Appetite Regulations In Female Athletes

Chihiro Kojima, Nobukazu Kasai, Aya Ishibashi, Yukako Murakami, Kumiko Ebi, Kazushige Goto. *Ritsumeikan University, Shiga, Japan.* (Sponsor: Robert R Kraemer, FACSM)
 Email: sh0007ek@ed.ritsumei.ac.jp
 (No relationships reported)

PURPOSE: Effect of high-intensity interval exercise (HIIT) in hypoxia has been investigated recently. However, the effect of HIIT in hypoxia on appetite regulation among female athletes remains unclear. The present study aimed to determine the time-courses changes in appetite-regulating hormones, subjective feeling of appetite, and energy intake after HIIT in hypoxia in trained female athletes. **METHODS:** 15 female team sport athletes (age: 20.7 ± 0.2 years, height: 159.6 ± 1.7 cm, weight: 55.3 ± 1.4 kg, BMI: 21.7 ± 0.4) participated three trials on different days: either HIIT in hypoxia (HYP), HIIT in normoxia (NOR) or rest in normoxia (CON). We have collected data from 15 subjects, but three of 15 athletes were excluded for analyses (n = 12, age: 20.8 ± 0.2 years, height: 158.7 ± 1.9 cm, weight: 54.8 ± 1.3 kg, BMI: 21.8 ± 0.4) because the menstrual phase did not match among trials. Exercise trials (HYP, NOR) consisted of two successive sets of 8 repeated bouts of 6-s maximal sprint separated with 30-s rest. A 10-min rest was provided between sets. Blood sample were obtained to measure plasma acylated ghrelin, GLP-1 and other hormonal and metabolite concentrations before, immediately and 30 min after exercise. Time-course of changes of subjective feeling of appetite and fatigue were also measured following exercise. Energy and macronutrient intake during ad-libitum buffet test meal were evaluated 30 min after exercise or rest. **RESULTS:** Plasma acylated ghrelin concentrations were significantly decreased after exercise (P < 0.001), whereas a significant difference was not observed between HYP and NOR. Plasma GLP-1 concentrations were not altered significantly after exercise (P = 0.507), with no significant difference between HYP and NOR at any point (P = 0.242). Although absolute energy intakes in both HYP (634 ± 67 kcal) and NOR (597 ± 63 kcal) were significantly lower than CON (756 ± 63 kcal, P = 0.006), no significant difference was not observed between HYP and NOR. **CONCLUSIONS:** These results show that HIIT under hypoxic and normoxic conditions lowered plasma acylated ghrelin concentrations and energy intake, whereas these responses were not augmented by exposure to hypoxia during exercise.

Unexpected Weight Gain Following Long Term Increased Mvpa Is Linked To Elevated Respiratory Quotient

Robin P. Shook¹, Gregory A. Hand, FACSM², John Thyfault, FACSM³, Tarin Phillips⁴, Steven N. Blair, FACSM⁵. ¹Children's Mercy Hospital, Kansas City, MO. ²University of West Virginia, Morgantown, WV. ³University of Kansas Medical Center, Kansas City, MO. ⁴Iowa State University, Ames, IA. ⁵University of South Carolina, Columbia, SC. (Sponsor: Steven Blair, FACSM)
Email: rpsbook@cmh.edu

(No relationships reported)

Purpose: Randomized controlled trials demonstrate that exercise alone, if completed in adequate amounts, will result in weight loss for most individuals but with large variation in amount. The purpose of the current study is to evaluate the role of respiratory quotient (RQ), which represents contributions in substrate oxidation of stored carbohydrates and fats, on weight change among young adults who increased their moderate-to-vigorous physical activity (MVPA).

Methods: Participants included 417 young adults; during the 12-month observation period, 114 participants increased their MVPA and were included in the subsequent analyses. Body composition was assessed via dual-energy X-ray absorptiometry, MVPA via arm-based activity monitor, self-reported energy intake (EI) via 24-hour dietary recalls, and RQ via indirect calorimetry; all were assessed every 3 months, except for RQ which was assessed every 6 months.

Results: Participants were classified according to 12-month weight change; weight loss (n=38; group mean±SD, -4.0±3.7 kg), weight maintenance (n=38; 0.3±0.8 kg), and weight gain (n=38; 2.9±1.4 kg). The weight maintenance and loss groups were subsequently combined. Between group analysis at baseline indicated no difference in body weight (P=0.13), fat mass (P=0.51), fat-free mass (P=0.29), MVPA (P=0.07), EI (P=0.8), or percent of carbohydrates in the diet (P=0.83). RQ was lower in the maintenance/loss group compared to the gain group (0.782 vs. 0.801, P=0.02). At 12-month follow-up, there was no between-group difference in MVPA (P=0.14), self-reported EI (P=0.83) or percent of carbohydrates (P=0.18). Total MVPA was significantly higher in the maintenance/loss group (103.7 vs. 78.1 min/day, P=0.05).

Linear modeling of fat mass change indicated a positive association with RQ at baseline (P=0.06) after adjustment for baseline values and changes in MVPA and EI.

Conclusion: These results suggest that resting substrate oxidation may explain the unexpected body weight responses following increases in physical activity. These findings support previous research, which suggests that lower levels of fat oxidation, independent of changes in energy intake and physical activity, contribute to changes in fat mass.

(No relationships reported)

PURPOSE: The hypothalamus controls the energy homeostasis integrating of hormonal and nutritional signals. In this context, glucose plays a critical role in the control of energy balance acting in specific hypothalamic neurons. It has been demonstrated that the lost selective of glucose sensibility in the hypothalamic neurons are related to the hyperphagia and obesity. Recently, the hypoxia-inducible factor 2 alpha (HIF2α) have emerged as regulated important in maintenance of glucose sensibility in hypothalamic neurons. In this context, the maintenance of neuronal HIF2α function can be considered a determinate strategy for maintenance of lean phenotype. At the same time, the physical exercise is considered a main contributor to the control of body weight and energy expenditure. Thus, sought evaluate the effects of physical exercise on HIF2α protein levels and on glucose sensibility in the hypothalamus of rodents.

METHODS: Physical exercise, Western blot and stereotaxic surgery were combined to explore HIF2α protein levels and hypothalamic glucose sensibility. The intracerebroventricular (ICV) injection of glucose was performed to measure the food intake and the quantification of HIF2α pathway in hypothalamus of both lean and obese (diet-induced obesity) male *Wistar* rats. For statistical analysis were used the ANOVA one-way.

RESULTS: We observed the reduction of hypothalamic glucose sensitivity in obese mice, which was accompanied by a lower protein expression of HIF-2α, as well as reduction of prolyl hydroxylases (PHDs) and ubiquitin E3 ligase PVH, product Hippel-Lindau (VHL) gene, when compared to the control group. Interestingly, we found that the exercise restored hypothalamic of HIF-2α expression and glucose sensitivity in obese rats.

CONCLUSIONS: Our preliminary results demonstrate that high-fat diet disrupts hypothalamic HIF-2α protein and affects the glucose sensitivity in neurons, contributing with hyperphagia. On the other hand, exercise increased HIF-2α protein levels in the hypothalamus and potentiated glucose sensitivity in obese rats, reducing the food intake.

The Effects of a Clinical Outpatient Behavioral and Nutritional Intervention Program on Body Mass

Chelsey R. Gegg¹, Kim D. Eftink², Christa R. Hudson², Candice A. O'Hare², Andrea D. Dodge², Britney L. Essary², Amanda C. Brunderman², Jason D. Wagganer¹. ¹Southwest Missouri State University, Cape Girardeau, MO. ²Saint Francis Medical Center, Cape Girardeau, MO.

(No relationships reported)

The prevalence of obesity has increased drastically over the past few decades in the United States. While a balanced nutrition and exercise program are suggested, more clinical-based treatments may be implemented (i.e., bariatric surgery and behavioral/nutritional interventions). Behavioral/nutritional intervention programs have been shown to be successful at decreasing body mass in overweight and obese individuals. However, further research needs to be conducted to determine the most successful behavioral and/or nutritional intervention for overweight and obese individuals.

PURPOSE: The purpose of this study was to assess the effects of a clinical outpatient behavioral/nutritional intervention on body mass in overweight and obese individuals.

METHODS: Forty-eight overweight (n=2) and obese (n=46) males (n=17) and females (n=29) [56 (13) yrs., height 1.70 (0.10) m., body mass 120.55 (33.83) kg, and BMI 41.45 (8.55) kg/m²] participated in this 15 week study. Participants self-selected one of two meal plans, offered through Healthy Management Resources, Decision Free or Healthy Solutions. The Decision Free meal plan required the consumption of 500-800 kilocalories per day through a minimum of five shakes or three shakes and two entrees. The Healthy Solutions meal plan required the consumption of 1,200 to 1,400 kilocalories per day through a minimum of three shakes, two entrees and five servings of fruits and vegetables. Both meal plans required regular physical activity of at least 2,000 kilocalories per week. Body mass was measured weekly. **RESULTS:** An independent samples t-test found no significant changes in body mass between the two meal plans. A paired samples t-test showed a significant decrease in the Decision Free meal plan pre- [125.71 (32.50) kg] vs. post-body mass [105.49 (27.01) kg] (t=11.688, p<.001) and the Healthy Solutions diet pre [115.40 (35.06) kg] vs. post-body mass [98.55 (29.88) kg] (t=12.452, p<.001). **CONCLUSIONS:** The results of this study support past research and suggests that behavioral and nutritional interventions are effective strategies for reducing body mass.

Do Weight Concerns Put Female Prisoners at Risk for Re-Offending?

Anne R. Lindsay, Sara C. Velasquez. *University of Nevada, Reno, Las Vegas, NV.* (Sponsor: Melinda Manore, FACSM)
Email: alindsay@unr.edu

(No relationships reported)

Incarceration and substance abuse are two of the largest public health issues in America. Substance abuse is prevalent (80%) among imprisoned women; particularly stimulant use (e.g., methamphetamine) due to its appealing side effects including weight loss and increased energy. Ironically, newly abstinent from stimulant-type drugs during incarceration, metabolic activity and appetite suppression are removed and women experience significant amounts of unwanted weight. **PURPOSE:** Examine female prisoner's body weight, perceived weight concerns, and weight loss behaviors as risk factors for re-offending. **METHODS:** Prior to participation in a health and body image program, 364 female inmates completed questionnaires to assess drug history and weight concerns/behaviors. Height, weight and body fat (4-site skinfolds) were assessed and body mass index (BMI) calculated. **RESULTS:** Prisoners were adult (age=37.8±10.2y) and 83% were overweight or obese (BMI=30±5.8 kg/m²; body fat = 30.9±5.2%). Physical activity (PA) was low, with 29% self-reporting being sedentary and 19% reporting that most days they did no PA. Use of unhealthy weight loss methods were high, with participants reporting 'sometimes', 'often' or 'very-often' to the following behaviors: tobacco smoking (43%), methamphetamine (40%), energy drinks (36%), energy supplements (36%), diet pills (32%), starvation (19%), laxative use (12%), diuretics (10%), vomiting (9%) and enemas (4%). Overall, 60% of participants were concerned about weight gain in recovery, 45% were concerned that gaining weight could trigger a relapse, and 36% were concerned about using drugs

to lose weight after leaving treatment. **CONCLUSIONS:** Female prisoners were typically overweight or obese and used risky behaviors to manage weight, which may increase their risk of re-offending. Poor weight management behaviors, combined with a lack of PA, in this vulnerable and underserved population leads to “self-medication” to lose weight, which may lead to life-threatening eating disorders and other compensatory behaviors. Health, PA, nutrition and healthy body image programs are warranted in this population.

3448 Board #353 June 2 3:30 PM - 5:00 PM

Association Between Health-related Quality Of Life And Weight Loss, Fitness, And Physical Activity

Sara J. Kovacs, Renee J. Rogers, Meghan R. McGuire, John M. Jakicic, FACSM. *University of Pittsburgh, Pittsburgh, PA.*
(Sponsor: John M Jakicic, FACSM)
Email: sjk89@pitt.edu
(No relationships reported)

Weight loss is associated with improved health-related quality of life (HRQOL); however, it is important to know whether change in physical activity or fitness that also occurs during the weight loss process influences this relationship.

Purpose: This study examined the associations between change in HRQOL and weight loss, fitness, and physical activity in response to a 12 month behavioral weight loss intervention.

Methods: Participants (N=280; Age=45.1±7.9 years, BMI=32.3±3.9 kg/m²) engaged in a 12-month behavioral weight loss intervention program. Participants were randomized to a reduced calorie diet (DIET), diet plus a moderate dose of physical activity (MOD-EX), or diet plus a high dose of physical activity (HIGH-EX). All groups received weekly in-person intervention sessions for months 1-6, with combined in-person and telephonic sessions for months 7-12. Diet was prescribed at 1200-1800 kcal/day. MOD-EX was prescribed physical activity that progressed to 150 min/wk with HIGH-EX progressed to 250 min/wk. Weight, fitness, physical activity, and HRQOL were assessed at 0 and 12 months.

Results: There was significant ($p<0.05$) weight loss at 12 months (-10.2 ± 7.9 kg; $-11.1\pm 7.8\%$), with no significant difference between intervention conditions. HRQOL, measured by the SF-36, also significantly improved across 12 months ($p<0.05$), with no significant difference between intervention conditions. Change in HRQOL was associated with change in weight ($r=-0.35$, $p<0.001$), percent weight change ($r=-0.39$, $p<0.001$), change in fitness ($r=0.29$, $p<0.001$), and change in physical activity ($r=0.21$, $p<0.001$). While somewhat diminished after controlling for change in fitness, the correlation between change in weight ($r=-0.25$, $p<0.001$) and percent change in weight ($r=-0.29$, $p<0.001$) remained significant. A similar pattern was shown when controlling for change in physical activity ($r=0.34$, $p<0.001$; $r=0.38$, $p<0.001$).

Conclusions: Weight loss across a period of 12 months is significantly associated with improved HRQOL in adults who are overweight or obese. It appears that change in fitness and physical activity partially mediate these associations. Thus, it appears that weight loss interventions should target improved fitness and physical activity to maximize improvements in HRQOL.

The Relation of Fitness and Life Stress on the Temporal Dynamics of Cognition in Older Adults: Evidence from the P3 and Lateralized Readiness Potentials

Christopher J. Brush, Brandon L. Alderman. *Rutgers University, New Brunswick, NJ.*

(No relationships reported)

A large and consistent body of evidence supports a relationship between aerobic fitness and cognitive function. Alternatively, it is well known that stress and adverse life events impact brain structure and function, and may produce enduring alterations in cognition and behavior. It remains unclear, however, whether fitness moderates the relationship between life stress and cognition. The majority of studies examining the relationship between fitness and cognitive function have relied on behavioral performance measures, while the influence of fitness on select temporal aspects of information processing remains less well known. Given the considerable variation in age-related cognitive decline, it may be important to investigate the relationship of fitness with discrete information processing stages, which may aid in future intervention development. **PURPOSE:** The purpose of this study was to examine the relationship between aerobic fitness and different stages of information processing in older adults using the P3 and lateralized readiness (LRP) event-related potentials (ERPs). A secondary aim was to determine whether fitness moderates the relationship between stressful life experiences and stimulus evaluation (P3) or motor preparation (LRP) processes. **METHODS:** 48 older adults (aged 40-70 yrs) completed an aerobic fitness test following a cognitive assessment with the recording of ERPs using electroencephalography. P3 and LRP components were elicited by a modified oddball task and were used to index stimulus evaluation and motor-preparatory cognitive processes. Measures of life stress were collected using the Holmes-Rahe and Cohen perceived stress scales. **RESULTS:** Reaction time measures and P3 difference waves support previous research indicating differences in stimulus evaluation speed between high-fit and low-fit older adults, $ps < .05$. Higher perceived stress was also associated with a reduction in P3 amplitude and a delay in P3 latency, $ps < .05$, but not moderated by fitness. **CONCLUSION:** These findings indicate that fitness is associated with preserved cognitive processing that occurs as early as stimulus evaluation. Future research may focus on earlier ERP components (e.g., sensory ERPs) to document the precise temporal relationship between fitness and cognition.

3464 June 3 9:55 AM - 10:10 AM

Effects of Exercise on Neurocardiac Responses to a Sad Mood Induction in MDD

Peter J. Ehmann, Brandon L. Alderman. *Rutgers University, New Brunswick, NJ.*

(No relationships reported)

Chronic exposure to stressful life events is known to increase vulnerability for major depressive disorder (MDD). Thus, it is critical to identify healthy lifestyle behaviors and interventions that may decrease stress and help cope with adversity, especially among those at high risk for MDD. Previous research has demonstrated that an acute bout of exercise can buffer psychological stress, as indicated by improved positive affect and attenuated cardiovascular reactivity to laboratory stressors. However, the effects of acute exercise on a sad mood induction have received less attention and the

underlying mechanisms have yet to be explored. Preliminary evidence suggests that respiratory sinus arrhythmia (RSA) responses elicited during a sad mood induction, as opposed to a more traditional laboratory stressor, predict symptomatic improvement in currently depressed individuals. **PURPOSE:** To determine the effect of a single bout of moderate-intensity aerobic exercise on affective and neurocardiac responses to a sad film induction. **METHODS:** Using a within-subjects design, 40 young adults (20.1 ± 1.8 yrs) with (or high symptoms of depression; $n=20$) and without MDD ($n=20$) completed a 30-min session of exercise or a sedentary control condition in counterbalanced order on two separate days. After a 15-min recovery period, neurocardiac function was assessed during a 3-min sad film induction. Pre-ejection period (PEP) and RSA measures were derived using impedance cardiography and served as proxies of sympathetic and parasympathetic activity, respectively. Affective valence and perceived activation were also assessed at 5-min intervals throughout each session. **RESULTS:** Individuals with MDD demonstrated more robust RSA withdrawal during the sad film following exercise relative to the control condition, $p < .05$. Importantly, RSA reactivity to the sad film following exercise was similar in individuals with MDD to typical responses among nondepressed control subjects, $p > .05$. **CONCLUSION:** These findings suggest that exercise may serve as a protective factor preceding exposure to stress in individuals at risk for MDD. Future trials investigating the antidepressant effect of exercise should aim to establish predictive biomarkers of exercise treatment response.

Effects of a Submaximal 30-Minute Run on Peak Tibial Acceleration in Novice Runners

Max R. Paquette¹, Kris Camelio¹, Douglas W. Powell¹, Allison H. Gruber². ¹University of Memphis, Memphis, TN. ²Indiana University, Bloomington, IN. (Sponsor: D.S. Blaise Williams III, FACSM)

Email: mrpquette@memphis.edu

(No relationships reported)

Peak positive tibial acceleration (PTA) immediately following foot strike during running is greater in runners with a history of tibial stress fracture. PTA does not increase over the course of a 20min run at lactate threshold pace (i.e., moderate effort) in highly trained runners. However, injury incidence in novice runners is higher, which may suggest that novice runners do not have the control strategy to prevent PTA from increasing over a prolonged run. **PURPOSE:** To assess the effects of a prolonged submaximal run on PTA in novice runners. **METHODS:** Male ($n = 2$) and female ($n = 8$) novice runners (24 ± 5 yrs; 1.69 ± 0.12 m; 70.7 ± 15.6 kg; 24.5 ± 3.8 kg/m²) who had been training for less than two years and ran on average at least 16km per week completed a 30min treadmill run at a self-selected speed equivalent to a rate of perceived exertion using the Borg scale between 10-13. A 3D accelerometer (480Hz, PCB Piezotronics, USA) used to measure PTA immediately following foot strike was attached to the distal anteromedial aspect of the right tibia along its longitudinal axis. Sagittal plane foot contact angle and ankle angle were also computed using 3D motion capture data (240Hz, Qualisys, Sweden). Data from five consecutive steps were collected after four (start), 15 (middle) and 30 min (end) of the prolonged run. A one-way repeated measures ANOVA was used to assess a main effect of time on PTA ($p \leq 0.05$). *Post-hoc* paired t-tests were used to compare mean differences among time points. Cohen's *d* effect sizes were used to assess effect magnitudes. **RESULTS:** PTA was not different among time points ($p = 0.87$). PTA was unchanged between time points during the prolonged run (start: 3.58 ± 1.43 g; middle: 3.67 ± 1.09 g; end: 3.60 ± 1.47 g). Both foot

contact angle and ankle angle at foot strike were unaffected by the run ($p > 0.05$). **CONCLUSION:** Our data suggest that PTA does not change over the course of submaximal prolonged run in novice runners. This finding is similar to unchanged PTA during a 20min moderately intense run in trained runners. These findings appear to indicate that, independent of running experience, PTA is unaffected by prolonged running. Changes in lower extremity motion and stiffness over prolonged runs of different lengths and intensities may alter active shock attenuation mechanisms and have different impacts on PTA on novice runners.

Lower Extremity Mechanical Energy Distribution Does Not Change Following A High-intensity Run
 Michael P. McNally, Margaret E. Raabe, Ajit MW Chaudhari, FACSM. *The Ohio State University Wexner Medical Center, Columbus, OH.*
 Email: michael.mcnally@osumc.edu
 (No relationships reported)

Fatigue during running decreases the body's ability to attenuate shock during impact, which may increase overuse injury risk. Muscles may assist in the attenuation of shock, and fatigue may induce redistribution in energy absorption during a single leg landing from the ankle to hip, but it is unknown whether there is a change in how joints function to dissipate energy after a high-intensity run. **PURPOSE:** To determine the effect of a high-intensity run on lower extremity energy distribution during running. **METHODS:** Ten experienced male runners, running 30+ minutes at least three times per week participated in this study. Optical motion capture was used to assess overground running mechanics at preferred running speed prior to completing a high-intensity run. A high-intensity training run was then performed at 80% of estimated $\dot{V}O_2$ max for 30 minutes, or until participants were unable to continue. Running mechanics were assessed again within 20 minutes of completing the run at the same preferred speed observed prior to the training run. Joint powers for the dominant leg hip, knee, and ankle were calculated, and net joint work and total joint work from initial contact to the end of weight acceptance were calculated and normalized to body mass. Repeated measures ANCOVA were used to assess time x joint interactions for net joint work and total joint work, with rating of perceived exertion at the end of the run included as a covariate. Statistical significance was set *a priori* at $p < 0.05$. **RESULTS:** There were no time x joint interaction effects from pre to post run in either net joint work (Hip: -0.087 vs. -0.095 J/kg; Knee: -0.384 vs. -0.366 J/kg; Ankle: -0.362 vs. -0.346 J/kg; $p = 0.198$) or total joint work (Hip: 0.175 vs. 0.160 J/kg; Knee: 0.452 vs. 0.446; Ankle: 0.365 vs. 0.348; $p = 0.282$). There were also no main effects of time for both net and total joint work ($p = 0.849$ and 0.075). **CONCLUSIONS:** No changes were observed in mechanical energy dissipation by the lower extremity joints after a 30-minute high-intensity run, indicating that lower extremity muscle function while running at a self-selected speed may not be affected by general fatigue. Self-selected running may not be intense enough to elicit changes, so further research should be performed to determine the effect of running at higher intensity on muscle function.

 Email: eric.foch@cwu.edu
 (No relationships reported)

Gluteus medius muscle activity during running may be associated with atypical hip adduction exhibited by women with previous iliotibial band syndrome (ITBS). **PURPOSE:** To determine if hip neuromechanics are different during a 30-minute run between women with and without previous ITBS. **METHODS:** Twelve women between the ages of 18 and 45 participated as part of an ongoing investigation. Women with previous ITBS ($n = 6$; age 29.8 (7.6) yrs; height 1.68 (0.07) m; mass 61.3 (7.6) kg; preferred pace 2.8 (0.5) $m \cdot s^{-1}$) were matched with controls (23.5 (5.5) yrs; 1.63 (0.07) m; 57.1 (7.6) kg; 2.7 (0.7) $m \cdot s^{-1}$). Gluteus medius muscle activity was recorded via a surface electrode during a maximal voluntary isometric contraction (MVIC). Three-dimensional marker trajectories and muscle activity were collected during a 30-minute treadmill run at preferred pace. Gluteus medius muscle activity during running was normalized to the MVIC trial for analysis. Hip angles were computed via joint coordinate systems. A moving root-mean-square created electromyography envelopes from gluteus medius muscle activity. Due to small sample size, data were analyzed using descriptive statistics with moderate effects considered clinically meaningful (≥ 0.50). **RESULTS:** Peak gluteus medius activation during the MVIC trial was less in the ITBS group compared to controls (ITBS: 0.14 (0.04) mV; Controls: 0.19 (0.10) mV; $d = 0.72$). However, women with previous ITBS had greater gluteus medius muscle activation compared to controls during the first and last minutes of the run (Table 1). Frontal plane hip kinematics were similar between groups.

Table 1: Variables of interest at minute one and minute 30 between runners with previous ITBS and controls (CON) (mean (standard deviation)); d is effect size (ES).

	Time	Group		ES
	Min	ITBS	CON	d
Peak hip adduction (degrees)	1	13.6(3.0)	13.5(2.4)	0.06
	30	14.3(3.7)	13.5(3.4)	0.23
Hip adduction excursion (degrees)	1	2.7(2.0)	3.5(1.9)	0.43
	30	3.8(3.1)	4.5(1.3)	0.32
Pre-heelstrike gluteus medius activation (%MVIC)	1	80.4(19.7)	62.0(28.4)	0.76
	30	93.9(36.9)	63.7(25.2)	0.97
Weight acceptance gluteus medius activation (%MVIC)	1	96.5(13.3)	74.6(25.6)	1.13
	30	96.4(7.7)	72.2(26.4)	1.42

CONCLUSION: Runners with previous ITBS had weak hip abductors but similar peak hip adduction angle to controls. The ITBS group activated their hip abductors more to achieve the same hip adduction angle as controls.

The Effect of Compression Tights on Muscle Vibration and Energy Expenditure during a High-Intensity Run
 Hannah Harris, Margaret E. Raabe, Michael P. McNally, Ajit M.W. Chaudhari, FACSM. *The Ohio State University, Columbus, OH.*
 Email: harris.2169@osu.edu
 (No relationships reported)

BACKGROUND: Compression garments are believed to provide performance benefits to runners. It has been shown that wearing these garments leads to reduced muscle vibrations during running and jumping. However, little research has investigated performance benefits that result from a reduction in muscle vibration. It has been proposed that the reduced muscle vibrations may lead to increased performance through a reduction in energy expenditure. **PURPOSE:** Investigate the effect of compression tights on muscle vibration and change in energy expenditure during an endurance run. **METHODS:** Twenty healthy experienced male runners participated. Participants ran at 80% $\dot{V}O_2$ max speed, previously estimated from an incremental treadmill procedure. Vibration data was collected using a passive marker motion capture system. The peak amplitude of muscle vibrations (axial direction) was calculated 150ms after foot strike for the quadriceps, hamstrings, gastrocnemius, and tibialis anterior muscles. A run was then performed on a treadmill at the same speed for 30 minutes or until voluntary exhaustion. Participants' heartrate (HR) was recorded in 5-min increments during the run and energy expenditure (EE) was estimated using the model: $EE (kcal/min) = 3.56 - 0.0136(\text{weight}) + 0.00189(\text{HR})(\text{weight})$. The percent change in EE over the course of the run was analyzed. This protocol was repeated on two separate days, one with running shorts and one with high compression tights (20-25 mmHg). The order of conditions was randomly assigned. **RESULTS:** Paired two-sided t-tests revealed significant difference in muscle vibrations between the running shorts and tights conditions (quads: 15.9±5.2 mm vs 7.6±2.5 mm, $p < 0.0001$), with significantly less muscle vibration in the tights condition for all muscle groups except for the hamstrings (7.6±3.6 mm vs 7.2±2.2 mm, $p = 0.70$). However, there was no significant difference found in the percent increase in EE (9.4±6.1% vs 10.1±5.0%, $p = 0.43$) from the start to end of the run. **CONCLUSION:** Compression tights significantly reduced muscle vibration during running but had no effect on energy expenditure during an endurance run. Future work should investigate other performance variables that may be affected by wearing compression tights to better understand possible performance benefits.

The Effect of Cushioned Insoles on Tibial Acceleration During Running
 Anisa Rohilla, Natalie Turner, Jake Glazer, Ryan Smith, Dimitrios Katsavelis. *Creighton University, Omaha, NE.*
 (Sponsor: Joan M Eckerson, FACSM)
 Email: AnisaRohilla@creighton.edu
 (No relationships reported)

Background: Running through fatigue has been found to place an excessive amount of stress to lower extremities that may increase the risk of overuse injuries. Cushioned insoles are suggested to help attenuate shock and reduce impact forces caused by running. **Purpose:** To investigate the effect of implementing cushioned insoles on subjects before and after a fatigue protocol run to determine whether the insoles significantly lessened impacts. **Methods:** Four male college students (age = 22.8± 4yr; weight = 80.2± 5kg; height = 187.3± 3cm) participated in the study. The participants

were tested three times over a period of three weeks. During the first visit, lactate threshold speed (LTS) was assessed via blood samples (7.8 ± 5 mph). During the second and third visits participants were randomly assigned to undergo incremental treadmill tests with and without insoles. The incremental runs included two rounds of seven 30-second bouts at stages -20% below to +40% above the LTS, with a 20 minute run at LTS in between the two trials. A triaxial accelerometer that was placed at each subject's dominant tibial plateau recorded acceleration before and after the 20m run. Tibial acceleration (TA), stride length and frequency were calculated through Matlab. **Results:** A two way repeated ANOVA (2 fatigue states by 2 insoles conditions) showed that there was a main effect of state ($p=0.003$) and a main effect of insole condition ($p<0.001$), as well as an interaction ($p=0.044$). Post hoc analysis revealed that TA was significantly lower during the non-fatigue control run with insoles when compared to the other conditions. Over the course of both pre- and post-fatigue incremental tests, stride length and frequency did not change. **Conclusion:** The findings indicate that insoles are an effective way to reduce tibial acceleration during running, but to a greater extent in the absence of fatigue (22% vs. 13%).

Influence Of Step Rate Control On The Metabolic Demands Of Running In A Lower-body Positive Pressure Treadmill

Brendan J. Rickert. *Sacred Heart University, Fairfield, CT.*
(Sponsor: Peter Ronai, FACSM)
Email: rickertb@sacredheart.edu
(No relationships reported)

Lower-body positive pressure treadmills (LBPP-TM) artificially reduce body weight (BW) allowing individuals to run with reduced load and metabolic demand. Previous reports document that temperospatial mechanics are significantly altered as BW levels are reduced. Specifically, step length (SL) is longer and step rate (SR) is reduced. If a runner modifies SR in the LBPP-TM they can maintain normative temperospatial mechanics, however, the influence on metabolic demand is unknown. **PURPOSE:** To investigate the relationship between the degree of unloading and oxygen consumption (VO₂) when SR is maintained. **METHODS:** Eighteen competitive runners (8M; 20.3 ± 1.8 yrs; 59.9 ± 7.8 kg) granted informed consent and completed a VO₂ peak test on the LBPP-TM and two separate trials consisting of a 30-min continuous run at 65% VO₂ peak. Each continuous run started with a 10-min familiarization segment at 100% BW before four 5-min segments at 100, 90, 80, and 70% BW. In a counter-balanced design, SR was controlled in one trial as runners matched a digital metronome (DM) set to their SR recorded during the familiarization run. VO₂ was collected over the last two-minutes of each segment. Hi-speed video (210 Hz) was recorded for each trial and SR subsequently determined. All dependent variables were compared using repeated-measures ANOVAs with Bonferonni post hoc testing (SPSS Statistics 23). **RESULTS:** There was a significant main effect of BW level ($F(2,4,41.4)=81.3, p<0.01$) and DM ($F(1,17)=45.1, p<0.01$) on SR. SR was significantly reduced at 90, 80, and 70% BW as compared to the 100% BW condition ($p<0.05$) when runners could self-select their cadence. There was a significant main effect of BW level ($F(1,3,22.9)=105.6, p<0.01$) and DM ($F(1,17)=6.6, p<0.05$) on VO₂. **CONCLUSION:** At all BW levels, runners were able to successfully match their SR with a DM set to their normal SR at 100% BW (178.1 ± 9.9 steps/min). While running with a self-selected SR at 70% BW, runners displayed both a significantly lower SR (168.5 ± 9.9 steps/min) and lower VO₂ as compared to when they were forced to match their SR to a DM. As BW level is reduced, VO₂ is significantly reduced whether SR is self-selected or matched to normal SR but the self-selected SR produced the greatest VO₂ reductions indicating that runners adjust temperospatial mechanics for improved economy.

G-15 Thematic Poster - High Intensity Training

Acute Physiological Responses of Very Short versus Standard Sprint Interval Training (SIT) protocols

Stefano Benitez Flores¹, Arilson F. M. de Sousa¹, Erick Carlos da Cunha Totó¹, Thiago Santos Rosa¹, Sebastián Del Rosso¹, Carl Foster, FACSM², Daniel Alexandre Boulosa¹. ¹*Universidade Católica de Brasília, Brasília, Brazil.* ²*University of Wisconsin - La Crosse, La Crosse, WI.*
Email: stefanobenitez@gmail.com
(No relationships reported)

Sprint Interval Training (SIT) is characterized by supramaximal "all-out" efforts of 10-30s, and promotes cardiometabolic and musculoskeletal adaptations. Given that peak power output, a key stimulus for aerobic adaptations, can be achieved during the first seconds of a sprint, it is possible that a very short SIT protocol (i.e., 5 s) can lead to similar adaptations compared to longer efforts. **PURPOSE:** To compare the physiological and mechanical responses of two different SIT protocols [(SIT with 20s efforts (SIT20s) vs. SIT with 5s efforts (SIT5s)]. **METHODS:** Eight males (VO_{2max} = 45.9 ± 3.7 mL/kg/min, age = 25.3 ± 3.6 yr) participated. VO_{2max} was measured in the 1st session. In the 2nd and 3rd sessions two different SIT protocols were completed in randomized order: SIT20s (4 × 20s with 2 min of recovery) and SIT5s (16 × 5s with 24 s of recovery). Both SIT sessions had the same load (7.5 % body mass), lasted 12 min, and had the same work-to-rest ratio. During SIT sessions, the following parameters were recorded: oxygen consumption (VO₂), heart rate (HR), respiratory exchange ratio (RER), energy expenditure (EE), post-exercise lactate (LA), peak power (PP), mean power (MP), rate of fatigue (RF), total work (TW), and OMNI-cycle scale RPE (Omni-cycle RPE). **RESULTS:** Mean VO₂, HR, and total EE were higher in SIT5s [37.61 ± 1.45 vs. 26.89 ± 1.21 mL/kg/min ($P=0.000$), 156 ± 11 vs. 141 ± 14 bpm ($P=0.021$), and 102 ± 9 vs. 73 ± 7 Kcal ($P=0.000$), respectively]. LA and RER were higher in SIT20s [16.4 ± 2.5 vs. 14.6 ± 2.6 mmol/L ($P=0.032$), 1.46 ± 0.6 vs. 1.19 ± 0.7 ($P=0.000$), respectively]. MP and TW were higher in SIT5s [735.5 ± 72.8 vs. 595.6 ± 57.4 W ($P=0.001$), and 56.6 ± 5.6 vs. 47.3 ± 4.4 kJ ($P=0.02$), respectively]. No significant differences were found between protocols in PP [911.4 ± 60.5 vs. 909.1 ± 88.5 W ($P=0.937$), for SIT5s and SIT20s, respectively]. RF was higher in SIT20s than in SIT5s [54.7 ± 5.9 vs. 39.4 ± 9 % ($P=0.001$)]. Omni-cycle RPE at 10 min recovery was lower in SIT5s [3.5 ± 1.7 vs. 4.75 ± 1.5 ($P=0.038$)]. **CONCLUSIONS:** Despite similar PP between protocols, the short SIT protocol (5s efforts) elicited greater cardiorespiratory responses, higher mechanical strain, and a lower fatigue and glycolytic activation when compared to the standard SIT protocol.

Training Status Affects The Physiological Response To A Single Bout Of High Intensity Functional Training

Yuri Feito, FACSM, Michael Giardina, Danielle Brown, Brandi Price. *Kennesaw State University, Kennesaw, GA.*
(No relationships reported)

Although the cardiometabolic effects of high intensity training are well established, little evidence surrounds physiological changes occurring as a result of a high intensity functional training (HIFT) session. Even though previous studies have linked experience with performance, experience alone does not imply greater skill. **PURPOSE:** To examine the physiological response of a HIFT workout among individuals with different competitive levels. **METHODS:** Sixty-six participants (30.8 ± 7.3 y; 172.4 ± 9.1 cm; 76.2 ± 13.6 kg) with at least six-months of HIFT experience and different levels of ability and skill were tested. Ability and skill level was determined by the benchmark workout "Fran" [Novice (Nov), N=26; Intermediate (Int), N=22; Advance (Adv), N=18]. All participants underwent aerobic capacity testing to examine peak levels of oxygen consumption (VO_{2peak}), heart rate (HR_{peak}), respiratory exchange ratio (R_{peak}), and blood lactate (Lt_{peak}). A week later, the same variables were measured (VO₂; HR; R; Lt) during a 15-min HIFT based workout. **RESULTS:** Analysis of variance revealed significant group differences in VO_{2peak} (Adv = 50.1 ± 5.4 , Int = 46.1 ± 4.9 , Nov = 43.8 ± 6.6 mL/kg/min; $p<0.001$) and Lt_{peak} (Adv = 12.6 ± 2.5 , Int = 11.5 ± 3.3 , Nov = 9.9 ± 3.2 mmol/L; $p=0.010$). Similarly, during the HIFT workout, advance athletes had the highest VO₂ of the three groups (Adv = 39.7 ± 3.1 , Int = 37.4 ± 4.1 , Nov = 35.0 ± 5.6 mL/kg/min; $p=0.006$). However, intermediate athletes had the highest Lt concentration during the HIFT workout (Adv = 9.2 ± 1.6 , Int = 11.2 ± 1.5 , Nov = 9.6 ± 2.7 mmol/L; $p=0.008$). When we compared performance of the HIFT workout, Advance athletes performed significantly better

than the Intermediate and Novice athletes (304±25, 258±26, 212±29 repetitions, respectively; $p < 0.001$). Regression analysis revealed experience was the greatest predictor of performance in this 15-min HIIT workout ($r^2 = 0.658$, $p < 0.001$).

CONCLUSIONS: These data support the notion that individuals with different training levels respond differently to a specific HIIT workout. Further studies should continue to explore these differences among athletes with different training levels.

Effects Of High-intensity Functional Circuit Training On Motor Function And Exercise Motivation: A Randomized-controlled Trial

Jan Wilke, Stefanie Kaiser, Daniel Niederer, Tobias Engeroff, Lutz Vogt, Winfried Banzer, FACSM. *Goethe University Frankfurt, Frankfurt am Main, Germany.*
 Email: wilke@sport.uni-frankfurt.de
 (No relationships reported)

PURPOSE: Only a small share of the world population meets current physical activity guidelines, which recommend regular engagement in endurance, strength, and neuromotor exercise. As lack of time has been reported to constitute a major cause of inactivity, multidimensional methods with short training duration might be a promising alternative to classical, volume-oriented approaches. This randomized-controlled trial aimed to examine the effects of a high-intensity functional circuit (HIFCT) training program on motor function and motivation to exercise in healthy, untrained adults. **METHODS:** 25 inactive participants (26±5 yrs, 9♂) were randomly allocated to two groups. The intervention group (HIFCT, $n = 15$) 3x/wk performed functional exercises incorporating complex whole-body movements (e.g. Squats, Step-Ups, Burpees) in a circuit format. The 15 min workouts were composed of repetitive 20s all-out bouts with 10s breaks. In the comparison group (moderate aerobic exercise, MAE) the participants walked 3x/wk for 50 min at moderate intensity (progressively increased from 50 to 60% of the individual heart rate reserve). Motor outcomes, measured prior to and after the six-week intervention, were cycling capacity (maximum work load), dynamic maximum strength (leg and shoulder press), postural control (force plate), and jump capacity (reactive strength index, counter-movement jump, single leg hop for distance). Motivation to exercise was assessed using the self-concordance index. Systematic group differences were detected with the Mann-Whitney-U-test ($\alpha = .05$). **RESULTS:** In comparison to MAE, HIFCT increased maximum leg strength (difference of relative median pre-post changes between groups: 6%), shoulder strength (8.4%), and cycling workload (6.5%; $p < .05$). No differences were found for postural control and jump capacity ($p > .05$). Although not statistically significant, there was a tendency for increased self-concordance following HIFCT ($p < .1$). **CONCLUSION:** Despite considerably shorter training duration, HIFCT enhances motor function in healthy untrained adults more effectively than MAE. It might moreover be better suited to motivate inactive people to engage in regular activity. Further research should thus investigate long-term adherence to the program and its effectivity in other settings.

 (No relationships reported)

Suspension Training (ST) is a form of resistance training aiming at improving strength, endurance, coordination, flexibility, power, and core stability. Although ST is thought to elicit higher muscle activations than traditional exercises, only limited information is available on its acute effects on strength and power performances. **PURPOSE:** To evaluate strength and power acute responses after group ST in relation to gender. **METHODS:** 32 college students (16 M, 16 F; Age: 25.8±3.9 years; Body Mass: 65.8±11.2 kg; Height: 166.9±8.9 cm; BMI: 23.5±2.4 kg/m²) volunteered to participate in the study. Before (PRE) and after (POST) a 45-min ST group session, Squat (SJ) and Countermovement (CMJ) Jumps were performed on a portable force plate, while lower limb Maximum Voluntary Contraction (MVC) at 90° angle isometric knee extension and grip strength (HG) were measured in preferred and non-preferred limbs through a piezoelectric force transducer and a hydraulic hand dynamometer, respectively. ANOVA for repeated measures was used to evaluate differences ($p < 0.05$) in relation to gender and experimental session. **RESULTS:** As expected, M always showed highest strength and power values ($p < 0.02$). In the POST condition, no significant improvements were found for HG, with best performances ($p < 0.02$) emerging for the preferred limb (M-PRE: 429.3±31.2N; M-POST: 445.7±30.2N; F- PRE: 254.1±12.6N;

F- POST: 256.4±13.5N) with respect to the non-preferred one (M-PRE: 399.4±16.2N; M-POST: 407.6±28.6N; F-PRE: 231.7±15.9N; F-POST: 236.1±18.1N). For MVC, only F showed differences between limbs ($p < 0.02$), with highest values in the preferred leg (PRE: 238.8±15.1N; POST: 246.9±20.1N) and lowest in the non-preferred one (PRE: 222.4±19.9N; POST=230.9±14.5 N). After the session, M only showed improvements ($p < 0.02$) in CMJ (PRE: 32.3±1.8cm; POST: 33.7±1.7cm) and MVC for the non-preferred leg (PRE: 276.1±16.6N; POST: 292.4±24.1N), while no differences emerged for SJ. **CONCLUSIONS:** Results shown that ST is a form of exercise useful to maintain and improve acute strength and power performances, in particular in male subjects. ST could be added in warm-up programs for sports where strength and power are key components.

3504 Board #5 June 3 9:00 AM - 11:00 AM
The Effects Of 4-weeks Hiit And Continuous Based Training On The Incidence Of Plateau At Vo2max And The Anaerobic Capacity

Dan A. Gordon, Viviane Merzbach, Adrian Scruton, Justin Roberts, Henry Chung. *Anglia Ruskin University, Cambridge, United Kingdom.*
 Email: dan.gordon@anglia.ac.uk
 (No relationships reported)

PURPOSE: The plateau at VO_{2max} has been attributed to the size of the finite anaerobic capacity which has previously been shown as a trainable parameter. Therefore the purpose of this study was to assess the effects of 4-weeks HiIT or continuous training on the incidence of plateau at VO_{2max} and the anaerobic capacity. **METHOD:** Following Institutional ethics approval $n = 30$ physically active adolescents agreed to participate (age, 17.2 ± 1.2 yrs; height, 173.7 ± 8.9 cm; mass, 67.7 ± 14.0 kg; VO_{2max} , 47.3 ± 7.9 ml·kg⁻¹·min⁻¹). They were assigned to 3 matched groups, high-intensity intermittent training (HiIT), continuous training (CET) and a no-training control group (CG), based on maximally accumulated oxygen deficit (MAOD) scores. HiIT completed 8 x 20s sprints at 170% W- VO_{2max} with 10s recovery 3 times a week for 4-weeks, CET completed 30min cycling at 70% W- VO_{2max} (70 rpm) 3 times per week for 4-weeks. Pre and post training VO_{2max} , MAOD, cardiac output (Q), HR were assessed using breath-by-breath analysis and exercising on an electronically controlled cycle ergometer. Additionally blood glucose, blood lactate and key haematological parameters were assessed. Plateau criteria was determined as $\Delta VO_2 \leq 1.5$ ml·kg⁻¹·min⁻¹ over the final 60s of the VO_{2max} trial. **RESULTS:** HiIT increased MAOD from 37.4 ± 10.7 to 41.9 ± 9.6 ml·kg⁻¹ ($P = 0.029$) while there was no change in either CG or CET. ΔVO_2 during final 60s of the VO_{2max} test showed no change for HiIT or CET following 4-weeks of training, while total exercise time increased by 13.2s for HiIT ($P = 0.004$) and 15.6s CET ($P = 0.036$) with no change for CG. VO_{2max} showed no change for HiIT but increased from 47.9 ± 7.7 ml·kg⁻¹·min⁻¹ to 51.5 ± 10.0 ml·kg⁻¹·min⁻¹ ($P = 0.015$). Q_{max} decreased by 2.0 ± 2.2 l·min⁻¹ following HiIT ($P = 0.019$) coupled with an increase in a- $VO_{2diffmax}$ of 2.5 3.4 ml/100ml⁻¹ ($P = 0.042$) while for CET there was no change in either Q_{max} or a- $VO_{2diffmax}$. HiIT also showed a significant increase in HCO₃⁻ post training ($P = 0.002$) with no change in either CG or CET. **CONCLUSIONS:** These data suggest that 4-weeks of HiIT training was sufficient to induce a large increase in the finite anaerobic capacity but could not show any effect on the incidence of plateau at VO_{2max} . It is thus concluded that the plateau is not simply a product of anaerobic energy provision but a more complex psychobiological component.

Sex Specific Cardiovascular And Metabolic Responses To High-intensity Exercise On An Elliptical Cross-trainer

Tony P. Nunez, Terence A. Moriarty, Kurt A. Escobar, Len Kravitz, Ann L. Gibson, FACSM. *University of New Mexico, Albuquerque, NM.* (Sponsor: Ann L. Gibson, FACSM)
 Email: tnunez12@unm.edu
 (No relationships reported)

High-intensity interval exercise (HIIT) has been shown to elicit greater cardiovascular and metabolic responses compared to moderate continuous aerobic exercise. However, the acute responses to HIIT between males and females using a novel elliptical cross-trainer have not been reported. **PURPOSE:** To investigate the cardiovascular and metabolic response of 3 HIIT protocols using a novel device. **METHODS:** Six males (M) (81.5 ± 8.1 kg; 1.79 ± 0.1 m) and six females (F) (59.6 ± 6.7 kg; 1.64 ± 0.1 m) between 19-28 years of age volunteered. Following written consent, each participant performed three different HIIT protocols in a randomized order: 10 bouts of 30/30 sec, 30/60 sec, and 30/90 sec work-to-rest ratios for a total duration of 10, 15, and 20 min, respectively. Protocols were separated by at minimum of 24 hours. Oxygen consumption (VO_2) and heart rate (HR) were collected continuously and monitored during each exercise protocol. Blood lactate (BLA), energy expenditure (EE) rating of perceived exertion (RPE), and watts (W) were also collected during the exercise

protocols. Separate 2 (sex) X 3 (protocol) repeated measures ANOVA techniques (SPSS v22; $p < 0.05$) with post hoc analysis were applied to examine differences. **RESULTS:** There was no effect of protocol. However, a significant effect of sex, although not found for BLA and $\dot{V}O_2$, was observed for RPE ($M=17 \pm 2.0$, $F=16 \pm 1.5$; $F=5.453$, $p=.034$), W ($M=165 \pm 33W$, $F=137 \pm 24W$; $F=7.519$, $p=.021$), HR ($M=168 \pm 16bpm$, $F=181 \pm 5bpm$; $F=14.218$, $p=.002$) and EE ($M=11.2 \pm 1.7kcal \cdot min^{-1}$, $F=9.0 \pm 1.5 kcal \cdot min^{-1}$; $F=11.638$, $p=.004$); peak W also differed by sex ($M=674.5 \pm 147W$, $F=420 \pm 61W$; $F=18.291$, $p=.002$). There were no sex by protocol effects. **CONCLUSION:** Our 1:1, 1:2, and 1:3 work-to-rest HIIT bouts, which held work constant at 30 sec, did not elicit a change in cardiovascular or metabolic responses. However, there were sex specific differences for 4 variables; this is most likely explained by physiological and training differences between the men and women in this study. Future studies and exercise programs should consider sex differences during HIIT training when developing exercise protocols.

The Effect of High-Intensity Interval Training and Intermittent Fasting on Body Composition in Apparently Healthy Women

Amanda Bonikowske, Cayla O'Dowd, Kira Wermuth, Devin Neilsen, Jamie Krzykowski. *Carroll University, Waukesha, WI.*
Email: bonikowske.amanda@mayo.edu
(No relationships reported)

Women are less likely to meet physical activity recommendations with a "lack of time" as the most commonly reported barrier to meeting the recommendations. High-intensity interval training (HIT; short bursts of high-intensity activity followed by low intensity rest periods) is a form of exercise that elicits similar cardiorespiratory responses as continuous training with less total energy expenditure required and a shorter time commitment. HIT has been found to increase whole-body insulin sensitivity and improve overall body composition. Alternate day fasting elicits similar improvements in body composition as HIT.

PURPOSE: To examine the effect of HIT and alternate day fasting versus HIT alone on body composition in women.

METHODS: HIT was performed 3 days per week in 20 minute sessions; one day led by an instructor; two days performed at home using the study YouTube channel. Suggested exercise intensity was determined from baseline fitness levels. Participants in the HIT only group were instructed to eat a well-balanced breakfast each morning prior to the exercise sessions. The HIT+fasting group was instructed to fast for a total of 12 hours, three days per week. The fast began 10.5 hours prior to exercise (primarily overnight) and lasted at least 30 minutes after exercise. Body composition (weight, BMI, body fat percent, waist, hip, thigh, and arm circumference) was assessed at baseline and post-intervention.

RESULTS: Hip circumference significantly reduced in the HIT+fasting group (40.5 ± 3.1 to 39.4 ± 1.3 ; $p=0.041$). Weight and waist circumference decreased non-significantly in the HIT+fasting group (158.5 ± 31.2 to 145.3 ± 13.3 , $p=0.11$; 31.6 ± 3.5 to 30.6 ± 2.1 , $p=0.402$). Body fat percent reduced non-significantly in the HIT only group (27.4 ± 4.5 to 25.5 ± 5.5 ; $p=0.461$).

CONCLUSIONS: HIT resulted in significant and non-significant beneficial body composition changes in apparently healthy women. This exercise mode provides an alternative to long duration exercise, and a way to combat the "lack of time" barrier, while still achieving similar benefits as those achieved from continuous training. The combination of HIT and alternate day fasting in women requires further investigation, specifically the metabolic and cellular effects of fasting and training in women and the resulting effects on body composition.

Psychological Impact Of 8-week CrossFit And Non-CrossFit Training Programs

April A. Wheeler, Tara M. Roelofs, Amanda L. Moelk, Jennifer L. Welch, Rebekah G. Ellerbusch, Trevor W. Frosig, Gabrielle S. Turcotte, Taylor K. Schmidt, Justin R. Geijer. *Winona State University, Winona, MN.*
(No relationships reported)

Introduction CrossFit utilizes both high-intensity aerobic training and resistance training using functional multi-joint movements such as squats, deadlifts, clean, snatch, and overhead press. There has been much debate over the safety, effectiveness and level of difficulty of CrossFit training for the general population. **Purpose** This study aimed to compare perceived difficulties of an 8-week CrossFit or non-CrossFit exercise regimen. **Methods** The non-CrossFit exercise group (N=13) participated in three days of exercise consisting of mobility and functional movements, cardiovascular endurance training and a resistance training circuit each week for eight weeks. The CrossFit exercise group (N=13) integrated cardiovascular training into their resistance training program by completing a maximum number of repetitions in a given time period. Each week an online survey was sent to each participant to complete. Mean values were calculated for each question and a paired sample t-test was used to compare the

responses between groups. **Results** Difficulty of the workouts was perceived as more difficult in the non-CrossFit group than the CrossFit group (3.22 ± 0.56 , 2.49 ± 0.51 , $p < 0.001$, respectively). CrossFit participants rated level of soreness higher than the non-CrossFit group (2.36 ± 0.37 , $p=0.002$). The CrossFit group rated better sleep quality than the non-CrossFit group (2.23 ± 0.17 , $p < 0.001$). **Discussion** A previous study found that perceived exertion and pain is more dependent on the load than the type of muscular contraction. The current study contradicted this finding as the CrossFit group used greater loads, but their perceived difficulty was less than the non-CrossFit group. The CrossFit group rated their perceived pain levels as higher than the non-CrossFit group, which supports previous research, and is possibly due to using greater loads. **Conclusion** Based on the findings of this study and findings of previous research, use of greater loads may lead to greater perceived pain levels while flexibility and mobility training may lead to greater perceived difficulty.

Mechanomyographic Responses to Blood Flow Restricted, Fatiguing Isometric Muscle Actions

Jakob J. Rosengarten, Jared W. Coburn, FACSM, Lee E. Brown, FACSM, Andrew J. Galpin. *Cal State Fullerton, Fullerton, CA.*
(Sponsor: Jared W Coburn, FACSM)
Email: jakoblpc@googlemail.com

(No relationships reported)

Blood flow restriction (BFR) during low intensity resistance exercise (LIRE) has been shown to increase activation of lower body musculature. It is unclear if this is due to increases in motor unit recruitment (MU) or firing rate. Mechanomyography (MMG) has been used to investigate motor unit recruitment (MMG amplitude) and motor unit firing rate (MMG frequency).

PURPOSE: To use MMG to investigate the neuromuscular effects of BFR in the lower body during LIRE.

METHODS: Ten males (age = $27.1 \pm 3.1y$; height = 177.6 ± 6.2 cm; mass = 86.9 ± 13.0 kg) performed 3 knee extensor maximal voluntary isometric contractions (MVIC) with the right limb. Occlusion (OCC) was then applied to the right thigh using a KAATSU master unit while two sets (set 1 = 30 ± 7.96 repetitions; set 2 = 13.7 ± 11.29 repetitions) of repeated 5-second isometric knee extensions at 30% of peak torque were performed. Each set was performed to fatigue, defined as the inability to reach 30% of MVIC torque, with 2-seconds rest between repetitions. The same procedure was repeated during a second visit without occlusion (NONOCC), while matching the number of repetitions per set to the first visit. An accelerometer was used to collect MMG data from the vastus lateralis during the MVICs and both sets. Prior to data analysis, repetitions were normalized as percentages (25%, 50%, 75% and 100%) of total repetitions completed, and MMG data were normalized to the values from MVIC testing.

RESULTS: For MMG frequency, a significant 3-way interaction between set (2), condition (2) and percent repetitions (4) ($p=0.046$) was found. Follow-up tests revealed no interaction or main effects for set 1 ($p > 0.05$), and no interactions for set 2. When collapsed across percent repetitions, MMG frequency was lower for OCC (0.837 ± 0.045) than for NONOCC (1.116 ± 0.099) during set 2 ($p=0.046$). For MMG amplitude, there was a significant condition by set interaction ($p=0.023$). MMG amplitude was higher for the OCC condition (0.754 ± 0.187) than for the NONOCC condition during set 2 (0.481 ± 0.163 ; $p=0.001$). MMG amplitude during set 1 (0.599 ± 0.179) was lower than set 2 (0.754 ± 0.187 ; $p=0.042$) for OCC.

CONCLUSION: OCC exhibited lower levels of MMG frequency and higher values for MMG amplitude. This suggests that higher MU recruitment, rather than firing rate, was responsible for increased muscle activation during BFR.

Inhibitory Feedback During Fatiguing Contractions Is Similar In Males and Females.
 Bryce Campbell, Margaret Gillespie, Alia Yasen, Anita Christie.
University of Oregon, Eugene, OR. (Sponsor: David Gabriel, FACSMM)
 (No relationships reported)

Whether an inhibitory feedback mechanism explains sex-related discrepancies in muscular fatigue is unclear. **PURPOSE** To examine sex-related differences in the influence of inhibitory sensory feedback during fatiguing contractions. **METHODS** A fatigue task was performed by 20 subjects (7 males and 13 females; 18-30 years), which consisted of 1) baseline assessments; 2) a 20-s sustained maximum voluntary contraction (MVC) while blood flow to the shank was occluded; 3) a 20-s MVC performed 3 minutes after the fatiguing task, while blood flow remained occluded; and 4) a 5-s MVC performed 3 minutes after blood flow was returned. Force of the ankle dorsiflexors and EMG of the tibialis anterior were monitored during all contractions. Maximal M-waves were recorded from the tibialis anterior via stimulation of the peroneal nerve prior to and immediately following each contraction. **RESULTS** No significant differences were observed between males and females for baseline measures of MVC ($p=0.72$), EMG ($p=0.44$), or M-wave amplitude ($p=0.40$) or latency ($p=0.37$). The 20-s contraction resulted in a significant reduction in MVC force ($p=0.001$), which was similar between males and females ($p=0.35$). MVC force remained reduced following 3 minutes of rest while blood flow was occluded, but returned to baseline when blood flow was restored ($p=0.18$). EMG amplitude remained similar at all time points of the experiment ($p=0.11$). The amplitude of the M-wave was similarly reduced ($p=0.001$) in men and women ($p=0.60$) at the end of the fatiguing contraction, increased following rest with blood flow occluded ($p=0.03$), and returned to baseline following the return of blood flow ($p=0.210$). M-wave latency did not change significantly at any time point ($p=0.11$). **CONCLUSION** These results indicate the importance of peripheral feedback during fatigue for both men and women and suggest that a potential oxidative advantage for women is eliminated during a time of high oxidative stress. Without this advantage similar feedback mechanisms are likely present during occlusion.

3511 Board #3 June 3 9:00 AM - 11:00 AM
Time-Related Changes in Firing Rate Behavior is Partially Explained by Potentiation
 Jonathan D. Miller, Trent J. Herda, Michael A. Trevino, Adam J. Sterczala, Anthony B. Ciccone. *University of Kansas, Lawrence, KS.*
 (No relationships reported)

PURPOSE: To determine the effects of age and influence of twitch force potentiation on motor unit (MU) firing rate behavior during steady force contractions. **METHODS:** Twenty young (YG) individuals (10 men and 10 women, mean \pm SD age = 22.5 ± 2.7 years, mass = 75.4 ± 16.7 kg) and 9 aged (AG) individuals (4 men and 5 women, age = 61.9 ± 2.5 years, mass = 77.8 ± 16.6 kg) participated in this study. A resting twitch was evoked immediately prior to and following a 50% maximum voluntary contraction (MVC) in which the targeted force was held for 12 s. Absolute difference scores were calculated between pre- and post-50% MVC twitch forces (ΔTF) (highest 0.005 s) and then normalized to pre-50% TF (ΔTF_{NORM}) for each subject. Mean firing rate (MFR) vs. recruitment threshold (Rec Thresh) relationships were analyzed for each subject during the first, median, and last 0.5 second of the steady force portion of the 50% MVC. The slopes and y-intercepts of these relationships were regressed against time to determine time-dependent changes in MU firing rate behavior. The slopes and y-intercepts of these relationships (MFRT_{SLOPE} and MFRT_{INT}) were used for subsequent analysis. Independent samples t-test were performed on ΔTF , MFRT_{SLOPE} and MFRT_{INT} to determine potential differences between YG and AG. Correlations were performed for MFRT_{SLOPE} and MFRT_{INT} vs. ΔTF_{NORM} . **RESULTS:** ΔTF was greater ($P < 0.001$) for YG (0.619 ± 0.258 N) than AG (0.311 ± 0.150 N). MFRT_{SLOPE} was greater ($P = 0.036$) for YG than AG (YG = 0.013 ± 0.016 pps/%MVC/s, AG = 0.003 ± 0.010 pps/%MVC/s), however, MFRT_{INT} was not significantly different between groups ($P = 0.070$). MFRT_{SLOPE} was directly correlated with ΔTF_{NORM} ($P = 0.003$, $r = 0.529$) while MFRT_{INT} was inversely correlated to ΔTF_{NORM} ($P = 0.003$, $r = -0.523$). **CONCLUSIONS:** The slopes and y-intercepts of the MFR vs. Rec Thresh relationship were changing in a time dependent manner to a greater extent for YG than AG. The slopes became less negative and the y-intercepts were reduced over time suggesting an increase in firing rates of higher-threshold MUs in conjunction with a decrease in the firing rates of lower-threshold MUs. The ΔTF_{NORM} accounted for part of the variance in these recruitment-related differences in firing rate behavior at steady force.

3512 Board #4 June 3 9:00 AM - 11:00 AM
Simultaneous Measurement of Perfusive and Diffusive Oxygen Transport During Incremental Forearm Exercise
 Shane M. Hammer, Andrew M. Alexander, Kaylin D. Didier, Joshua R. Smith, Jacob T. Caldwell, Shelbi L. Sutterfield, Carl J. Ade, Thomas J. Barstow, FACSMM. *Kansas State University, Manhattan, KS.*
 (No relationships reported)

Muscle oxygen uptake (VO_2) is comprised of perfusive and diffusive oxygen transport. Few techniques demonstrate the ability to measure both components of VO_2 simultaneously within the same volume of tissue. It has previously been shown that quadriceps microvascular blood flow during cycling exercise establishes a plateau at approximately 60% peak work rate (WR_{peak}), while muscle deoxy-[Hb+Mb] and total-[Hb+Mb] have been shown to plateau at 80-90% WR_{peak} . **PURPOSE:** The purpose of this study was to simultaneously measure perfusive and diffusive oxygen transport in the same volume of tissue during incremental forearm exercise. We hypothesized that any plateau in muscle blood flow index (BFI) would occur at the same work rate as plateaus in deoxy-[Hb+Mb] and total-[Hb+Mb]. **METHODS:** 17 subjects (age: 22.6 ± 3.1) completed an incremental handgrip exercise test to task failure. Muscle oxygenation and BFI of the flexor digitorum superficialis were measured continuously using near-infrared and diffuse correlation spectroscopy (DCS), respectively. The incremental test consisted of 2 min of baseline followed by 3 min at 1W and then a 1W increase every 2 min until task failure. During the last 10s of each stage subjects stopped exercise to obtain motion artifact-free DCS measurements. Deoxy-[Hb+Mb] and total-[Hb+Mb] were averaged over the last 10s of exercise and BFI was averaged during the subsequent 10s of rest for each stage. **RESULTS:** Deoxy-[Hb+Mb] and total-[Hb+Mb] plateaued in nearly all subjects ($n=16$; $n=15$). There was no difference between deoxy-[Hb+Mb] and total-[Hb+Mb] in the work rate at which plateaus occurred (59.8 ± 21.4 and $67.9 \pm 15.8\%$ WR_{peak} , respectively). The plateaus in deoxy-[Hb+Mb] and total-[Hb+Mb] were significantly correlated ($r=0.70$, $p<0.01$). A plateau in BFI was observed in 7 subjects ($53.1 \pm 9.3\%$ WR_{peak}), which was significantly lower than the plateaus in total-[Hb+Mb] and deoxy-[Hb+Mb] (both $p<0.05$) but was significantly correlated with the plateau in deoxy-[Hb+Mb] ($r=0.78$, $p<0.05$). 3 subjects showed a break up in BFI near end exercise; the remaining responses were approximately linear. **CONCLUSIONS:** In contrast to our hypothesis, BFI did not consistently exhibit a plateau and, when present, it occurred sooner in the incremental protocol than did the plateaus in deoxy-[Hb+Mb] and total-[Hb+Mb].

Evaluation Of ES-induced Fatigue In Relation To Muscle Size And Fiber Recruitment: A Pilot Study
 Maria Vromans, Pouran D. Faghri, FACSMM, Magdalena Wegrzyniak, Sarina Moghadam. *University of Connecticut, Storrs, CT.* (Sponsor: Pouran D. Faghri, FACSMM)
 Email: maria.vromans@uconn.edu
 (No relationships reported)

Electrical stimulation (ES) has been used to strengthen muscles in athletic training and rehabilitation programs. ES is an effective stimulus to increase muscle force by evoking contraction via the application of electrical current. However, fast neuromuscular fatigue development limits its application in the clinical setting. The rapid fatigue onset has been attributed to differences in ES parameters and motor unit (MU) recruitment pattern compared to voluntary contractions. **PURPOSE:** To evaluate the ES intensity needed to generate predetermined force in two muscles of varying size and fiber type (proportion of type I and type II fibers) during isometric contractions, as well as to investigate the fatigue characteristics and time to fatigue under these conditions. **METHODS:** ES-induced fatigue was initiated in the small, type I abductor pollicis brevis (APB) and large, type II vastus lateralis (VL) muscles of three healthy individuals (mean age: 22.33 ± 2.36 years). ES was delivered at three frequencies (10, 30, 50Hz) in randomized order, with a duty cycle of 4s on/4s off, pulse duration of 300 μ s, and stimulation intensity level required to achieve an initial tetanic force equal to 25% of the pre-fatigue MVC. ΔMVC values, required intensity, and %drop in force during ES were compared between APB and VL. **RESULTS:** ΔMVC values were relatively low, though higher in the VL with no apparent association to frequency (VL mean ΔMVC : 10Hz = 16.8N; 35Hz = 28.3N; 50Hz = 6.0N, APB mean ΔMVC : 10Hz = -4.0N; 35Hz = 0.32N; 50Hz = 2.38N). ES at 10Hz requires a higher intensity to achieve 25%MVC force than at 35Hz or 50Hz for both the APB (mean intensity: 10Hz = 20.3mA; 35Hz = 17mA; 50Hz = 15.3mA) and VL (mean intensity: 10Hz = 54mA; 35Hz = 46.7mA; 50Hz = 46.7mA). The %drop in force was greatest at 50Hz (APB = 21% drop; VL = 18% drop), then 35Hz (APB = 17.5% drop; VL = 19.9% drop), then 10Hz (APB = 14.75% drop; VL = 16.35% drop) at the first quartile of time to fatigue, while the second quartile values were consistent among frequencies.

CONCLUSIONS: Fatigue is a major limiting factor for application of ES in sports injury and rehabilitation. Muscles with different fiber type composition respond differently to stimulation frequencies and fatigue development. These differences should be considered when developing treatment plans. Supported by NSF EFRI 1332329.

High Threshold Motor Units Are Eventually Recruited During Low Force Efforts to Volitional Fatigue

Jim R. Potvin¹, Andrew J. Fuglevand². ¹McMaster University, Hamilton, ON, Canada. ²University of Arizona, Tucson, AZ. (Sponsor: Stuart Phillips, FACSM)
 Email: jim.potvin@gmail.com
 (No relationships reported)

There is disagreement in the literature regarding the magnitude of relative loads necessary to optimize muscle hypertrophy. Most recommend loads of 60-80% of 1 RM, while others demonstrate similar increases with loads as low as 30% 1 RM, as long as volitional fatigue is reached.

PURPOSE: To use a deterministic model of individual motor unit and whole muscle fatigue to evaluate MU recruitment during low and high relative force efforts to volitional fatigue.

METHODS: Our deterministic model predicts the forces and force capacities of 120 motor units, and the whole muscle, for the full range of excitations. We estimated: relative force, excitation threshold, initial firing rate, maximum firing rate and excitation adaptation of each MU. During sustained, constant force contractions, we calculated the required excitation level to meet the force demand, and monitored the instantaneous levels of each variable listed above, to determine force and force capacity changes in each active MU and the whole muscle over 0.1 s intervals. The model provided very good estimates of endurance times for intensities ranging from 15% to 90% MVC, compared to published values.

RESULTS:

The model predicted endurance times of 509.0 s and 14.4 s at 20% and 80% MVC, respectively, at which time all MUs were recruited for both intensities. The 20% MVC condition resulted in larger relative decreases in strength (i.e. 'fatigue') for all 120 MUs. At the endurance time for the 20% condition, fatigue was 6.4%, 81.8%, 7.4% and 54.3% for the lowest MU (#1), middle MU (#60), and highest threshold MU (#120) and average MU, respectively. In contrast, at the endurance time for the 80% condition, fatigue was 0.2%, 2.3%, 3.8% and 4.3% for MUs 1, 60, and 120, and average MU, respectively. Excitation adaptations resulted in decreases in firing rates for all motor units, relative to initial maximum rested values.

CONCLUSION:

The 20% MVC endurance trials resulted in the eventual recruitment of all MUs and > 10-fold greater average fatigue for the MU population compared to the 80% MVC condition. Therefore, low intensity contractions, sustained to volitional fatigue, may provide more challenge to the motor unit population, and a more profound overall stimulus for muscle hypertrophy, compared to high intensity contractions.

Reported Relationships: K.K. McCully: Intellectual Property; Infared Rx, Inc. Consulting Fee; Novartis. Ownership Interest (Stocks, Bonds); Infared Rx, Inc. Employee of an ACCME Defined Commercial Interest; Infared Rx, Inc.

Lower back pain is a common symptom that may be associated with skeletal muscle dysfunction. **PURPOSE:** This study evaluated the endurance of the lower back muscles in healthy participants using accelerometer-based Mechanomyography (aMMG). **METHODS:** Surface electrodes and a tri-axial aMMG device were placed on the belly of the erector spinae muscles along the T11-L1 vertebrae. Current levels that evoked visible and tolerable twitch contractions were used. The muscles were stimulated for 3 minutes each at 2, 4, and 6 Hz. An endurance index (EI) was calculated as the maintenance of acceleration at the end of each stage of stimulation relative to the peak acceleration. Subjects (N=7) were tested on two separate days to assess reproducibility. Muscle oxygenation (HbO₂) was measured with near infrared spectroscopy (NIRS) during stimulation and during a maximal isometric back extension to induce complete ischemia for signal calibration (N=5). EI was measured in the wrist flexor and vastus lateralis muscles for comparison. **RESULTS:** EI for the erector spinae muscles were 70.3 + 13.4%, 32.6 + 8.4%, and 19.2 + 6.2 % for 2, 4, 6 Hz, respectively. The coefficients of variation were 9.8%, 13.9%, and 20.3% for 2, 4, 6 Hz, respectively. EI values for the erector spinae were significantly lower than EI values for the arm and the leg (all comparisons, p < 0.05). HbO₂ values for the

erector spinae were 86.4 + 10.9 % at rest, and 77.2 + 15.5%, 84.3 + 14.1%, and 84.1 + 18.9% for 2, 4, 6 Hz, respectively. **CONCLUSION:** EI is a reproducible method of assessing muscle endurance of the lower back erector muscles that is not related to low oxygen levels. The erector spinae muscles have lower muscle endurance relative to limb muscles. :

Clinical Assessment Of Muscle Endurance

Thomas B. Willingham, Kevin McCully, FACSM. University of Georgia, Athens, GA. (Sponsor: Kevin McCully, FACSM)
 (No relationships reported)

Evaluation of muscle endurance is important for many clinical populations. **PURPOSE:** Evaluate the utility of a clinical assessment of muscle endurance that uses twitch electrical stimulation and accelerometer-based mechanomyography (aMMG). **METHODS:** Twenty healthy participants (9 males; 11 females) and three participants with multiple sclerosis (MS) were tested. Muscle twitch acceleration was measured using an accelerometer placed over the surface of the muscle. The relationship between acceleration and torque was measured during twitch stimulation of the vastus lateralis muscle. Muscle endurance of the forearm and gastrocnemius was measured during 9 minutes of twitch electrical stimulation, in three stages (3min/stage) of increasing frequency (2Hz, 4Hz, and 6Hz). Endurance Index (EI) was calculated as the percent of acceleration at the end of each stimulation stage relative to the peak acceleration. Oxygen saturation was measured using near-infrared spectroscopy. **RESULTS:** Acceleration correlated with torque during twitch electrical stimulation of the vastus lateralis (mean R²= 0.96±0.04; p<0.05). Measures of EI reproducibility were CV= 2.49±3.67% for the 2Hz stage, CV= 7.36±8.11% for the 4Hz stage, and CV= 4.30±3.09% for the 6Hz stage. EI was significantly higher in the gastrocnemius at the 4Hz (EI =96.1±2.9%) and 6Hz (EI =95.5±2.03%) stages compared to the forearm (4Hz: EI =87.1±9.3%; 6Hz: EI =68.3±17.6%) in healthy controls (p<0.01). Muscle oxygen saturation was not reduced during stimulation of the forearm (72.6±9.8% at 2Hz, 73.2±11.6% at 4Hz, and 71.0±12.5% at 6Hz) compared to baseline (74.3±15.1%; p>0.1). Participants with MS had significantly lower gastrocnemius muscle endurance at the 2Hz (EI =83.6±10.2%), 4Hz (EI =57.2±5.1%), and 6Hz (EI =20.6±8.7%) stages compared to healthy controls (p<0.01). **CONCLUSION:** Muscle endurance as measured by twitch electrical stimulation and aMMG has the potential to evaluate endurance in various muscles and clinical populations.

Peripheral Vascular Pulsatility in Heart Failure Patients with Continuous Flow Centrifuge and Axial Left Ventricular Assist Devices: The Effect of Pump Speed.

Jay R. Hydren, Andrew C. Kithas, Soung Hun Park, Omar Wever-Pinzon, Craig H. Selzman, William H. Perry, Camila A.S. Vargas, Stavros G. Drakos, Russell S. Richardson. University of Utah, Salt Lake City, UT.

(No relationships reported)

Current continuous flow left ventricular assist devices (LVAD) decrease peripheral vascular pulsatility, which may contribute to side effects such as bleeding, thrombotic events and orthostatic intolerance. **PURPOSE:** To investigate the impact of manipulating LVAD pump speed, documented as revolutions per minute (RPM), on peripheral (brachial artery) pulsatility index (PI) in 20 heart failure patients implanted with a HeartWare (HVAD, n = 10) or HeartMateII (HMII, n = 10) LVAD. **METHODS:** Doppler ultrasound blood velocity in the brachial artery was recorded at baseline and 3 minutes after altering RPM, at three different RPM settings above and below baseline (60 RPM increments for HVAD and 200 for HMII). Brachial PI was calculated for each cardiac cycle by dividing the difference between minimum and maximum blood velocity by the time averaged mean blood velocity. LVAD device pulsatility indices that are used clinically were also recorded: maximal blood velocity (V_{max}) and minimum blood velocity (V_{min}) (HVAD) and HMII PI (HMII). Relationships were evaluated using multilevel linear modeling with random intercepts and data are reported as mean±SE. **RESULTS:** Baseline RPMs were 2509±44 (HVAD) and 9220±75 (HMII). Brachial PI changed significantly across the range of LVAD RPM speeds tested (HVAD: 360; HMII: 1200), from 2.3±0.6 to 4.1±0.9 with the HVAD and from 1.8±0.6 to 3.6±1.0 with the HMII, with no differences in brachial PI between

device across relative pump speed stages. Specifically, a 180 RPM decrease of the HVAD resulted in a 0.9 ± 0.1 (37±4%) increase in brachial PI and a 600 RPM decrease in the HMII resulted in a 0.8 ± 0.1 (38±3%) increase. These reductions in pump speed resulted in an ~20.0% fall in LVAD power consumption and a reduction in device reported blood flow of ~9%. Brachial PI correlated with HVAD_{HW}V_{max} and HVAD_{HW}V_{min} ($r = 0.45$ and $r = -0.31$, respectively), and HMII device_{HMI}PI ($r = 0.73$), suggesting device derived indices of PI provide a fair to good linear prediction of peripheral vascular pulsatility. **CONCLUSION:** Reducing HVAD or HMII LVAD pump speed within a clinically acceptable outpatient range yields a measurable and potentially clinically and physiologically meaningful change in peripheral vascular pulsatility, accompanied by substantial power savings.

Moving from a supine to a standing position typically reduces plasma volume (PV) and while this increases the concentration of some molecules in the blood, the effect on plasma nitrate [NO₃⁻] and nitrite [NO₂⁻] has not been reported. **PURPOSE:** To determine the change (Δ) in PV, [NO₃⁻] and [NO₂⁻] while lying supine, sitting, standing, and following short-duration exercise. **METHODS:** Fourteen participants (9 male, age 27 ± 4 yr, body mass 71 ± 11 kg) completed two trials. The first was conducted with no dietary intervention (control; CON) and the second was preceded by ingestion of 3 x 70 ml of NO₃⁻-rich beetroot juice the day before and 2 x 70 ml two hours before the trial (BR; total of ~31 mmol NO₃⁻). Both trials comprised 30 min lying supine followed by 2 min of standing, 2 min of sitting, and then 5 min of cycling at 60% of the age-predicted maximal heart rate. Repeated blood samples were collected to allow measurements of haemoglobin and haematocrit in whole blood and plasma [NO₃⁻] and [NO₂⁻] by chemiluminescence. The Δ PV was calculated using the Dill and Costill formula. **RESULTS:** Following the supine phase, PV increased from baseline in both trials (CON $\Delta 12.6 \pm 10.3$ %; BR $\Delta 12.5 \pm 7$ %, both $P < 0.01$) and then decreased upon standing (CON $\Delta -5.2 \pm 3.8$ %, $P < 0.01$; BR $\Delta -4.0 \pm 3.5$ %, $P = 0.02$), sitting (CON $\Delta -10.1 \pm 3.7$ %; BR $\Delta -6.4 \pm 3.6$ %, both $P < 0.001$) and following exercise (CON $\Delta -18.1 \pm 5$ %; BR $\Delta -15.5 \pm 3.4$ %, both $P < 0.001$). Plasma [NO₃⁻] levels at baseline were 120 ± 49 nM and 357 ± 129 nM in CON and BR, respectively. Plasma [NO₃⁻] decreased from baseline after lying supine in both trials (CON 77 ± 30 nM; BR 231 ± 92 nM, both $P < 0.05$) before increasing during standing (CON 109 ± 42 nM; BR 297 ± 105 nM, both $P < 0.001$) and sitting (CON 131 ± 43 nM; BR 385 ± 125 nM, both $P < 0.002$). Plasma [NO₂⁻] remained elevated following exercise in the CON trial (125 ± 61 nM, $P < 0.05$) but was not different to the 30 min supine value in the BR trial. There were no statistical differences in [NO₃⁻] between measurement points in either condition (all $P > 0.05$). **CONCLUSIONS:** Plasma [NO₃⁻] changes in the opposite direction to PV during changes in posture, both in the presence and absence of prior dietary NO₃⁻ supplementation. Given that [NO₂⁻] offers the best approximation of nitric oxide bioavailability, researchers must be cognisant of these outcomes when designing and interpreting dietary NO₃⁻ research.

3520 Board #3 June 3 9:00 AM - 11:00 AM
Effects of Prior Aerobic Exercise on Flow Mediated Dilation Responses to Prolonged Sitting in Healthy Men

Robert M. Duguid, Craig W. Berry, Kevin D. Ballard. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)
Email: duguidrm@miamioh.edu
(No relationships reported)

Prolonged sitting is common in modern society and has recently been shown to impair vascular endothelial function (VEF) in healthy men. Conversely, a single bout of aerobic exercise improves VEF. **PURPOSE:** The objective of this study was to examine the acute effects of a single bout of aerobic exercise on VEF responses to prolonged sitting. **METHODS:** Eleven healthy men [21.2 ± 0.6 yr; BMI = 24.7 ± 1.0 kg/m²; maximal oxygen consumption (VO₂max) = 49.9 ± 5.1 ml/kg/min (mean \pm SE)] participated in two randomized 3 hours sitting trials preceded by a single bout of continuous treadmill exercise (45 min at 65% VO₂max) (EX) or 45 min of quiet rest (REST). Exercise intensity was confirmed via open-circuit spirometry during the first 15 min of exercise. Superficial femoral artery flow-mediated dilation (FMD) was measured by high-resolution ultrasonography after an overnight fast (Pre), 1 h following EX (or REST) (Post), and at 1 hour intervals during a 3 hour prolonged sitting challenge. Participants were monitored by study personnel to ensure minimal

lower extremity movement during the sitting challenge. Two-way repeated-measures ANOVA and Bonferroni post-hoc tests were used to evaluate differences within and between groups. **RESULTS:** Participants completed the 45 min of treadmill exercise at 65.6 ± 1.2 % VO₂max (range = 60.9-72.6%). Resting femoral artery diameter and FMD responses (2.7 ± 0.6 % and 2.6 ± 0.5 % for EX and REST, respectively) did not differ between trials at Pre. No time or trial effects were detected for resting arterial diameter ($P \geq 0.28$). Compared with Pre, participants' FMD responses decreased at 1, 2, and 3 hours of prolonged sitting ($P < 0.05$) when preceded by REST, whereas FMD responses were unaffected when prolonged sitting was preceded by EX ($P \geq 0.33$). In the REST trial, resting shear rate decreased at 3 hours ($P < 0.05$) relative to Pre. Resting shear rate was unaffected in the EX trial ($P \geq 0.09$). **CONCLUSION:** These preliminary findings suggest that a single bout of aerobic exercise prevents the decline in FMD induced by 3 hours of prolonged sitting in healthy men. Future studies should examine differences due to sex, age, disease status, and exercise modality on VEF responses to prolonged sitting.

3521 Board #4 June 3 9:00 AM - 11:00 AM
Comparison Of Blood Flow Characteristics Before, During, And After High-intensity Interval And Moderate-intensity Continuous Exercise

Brett B. Baughman, Stephanie D. Gagnon, Janie C. Unkefer, Kaiti A. Freeberg, Patricia Benedict, Brandon J. Sawyer. *Point Loma Nazarene University, San Diego, CA.* (Sponsor: Glenn A. Gaesser, FACSM)
Email: bbaughman1215@pointloma.edu
(No relationships reported)

PURPOSE: A comparison of blood flow characteristics in the brachial artery during high-intensity interval exercise (HIIE) and moderate-intensity continuous exercise (MOD) has not been conducted. Also, the acute effects of these exercise protocols on measures of vascular reactivity are not fully understood. **METHODS:** Sixteen healthy males (Age: 23 ± 3 years, BMI: 25.5 ± 3.0) completed HIIE (10, 1 min intervals at 90-95% of HR_{max} with 1 min of recovery between) and MOD (30 min at 70% of HR_{max}) on a cycle ergometer. Brachial artery diameter and blood flow measurements were made before, during and after exercise via high-resolution ultrasound. **RESULTS:** During exercise there were no differences in artery diameter but antegrade velocity (HIIE: 17.96 ± 6.14 cm/sec, MOD: 21.73 ± 8.11 cm/sec, $P = 0.02$) and antegrade shear rate (HIIE: 170.83 ± 55.51 sec⁻¹, MOD: 203.50 ± 76.09 sec⁻¹, $P = 0.04$) were higher during MOD compared to HIIE. Retrograde velocity (HIIE: -7.67 ± 2.79 cm/sec, MOD: -5.50 ± 2.04 cm/sec, $P < 0.01$) and retrograde shear rate (HIIE: -73.82 ± 28.37 sec⁻¹, MOD: -51.48 ± 19.77 sec⁻¹, $P < 0.01$) were of greater magnitude during HIIE compared to MOD. Baseline artery diameter decreased after HIIE ($P = 0.04$), but not after MOD ($P = 0.19$). Peak diameter after occlusion decreased with MOD ($P = 0.04$), but not with HIIE ($P = 0.80$). Minimum diameter during cuff occlusion decreased after HIIE ($P = 0.02$) and marginally decreased after MOD (Pre: $P = 0.06$). No acute changes were seen with flow-mediated dilation (FMD) or low-flow mediated constriction (L-FMC) within either group. The composite end-point of vascular reactivity (COM) increased after HIIE (Pre: 5.64 ± 3.21 , Post: 8.57 ± 3.16 %, $P < 0.01$) but not MOD ($P = 0.56$). Exercise x time interactions were observed for COM ($P = 0.02$), peak diameter ($P = 0.05$), and a trend for FMD (HIIE-Pre: 5.44 ± 4.11 , Post: 7.58 ± 5.99 % vs. MOD-Pre: 6.3 ± 2.89 , Post: 4.2 ± 5.75 %, $P = 0.09$). **CONCLUSION:** We observed more positive shear stress during MOD and more negative during HIIE. These differences in exercise shear stress during exercise may result in more vascular reactivity after HIIE compared to MOD as well as potentially explain differences observed in the chronic adaptations to these distinct exercise protocols.

3522 Board #5 June 3 9:00 AM - 11:00 AM
Eccentric Exercise And Microvascular Function: Protective Role Of Dietary Nitrate And Antioxidants?

Ryan G. Larsen¹, Jens M. Thomsen¹, Rogerio P. Hirata¹, Jens B. Frøkjær², Thomas Graven-Nielsen¹. ¹Aalborg University, Aalborg, Denmark. ²Aalborg University Hospital, Aalborg, Denmark.
Email: rl@hst.aau.dk
(No relationships reported)

Exercise involving eccentric contractions results in reduced muscle function. Blood oxygen level dependent (BOLD) MR imaging has demonstrated slowed microvascular reactivity in eccentrically exercised tibialis anterior (TA) muscle. While the mechanism is unclear, exercise-induced inflammation and oxidative stress may reduce nitric oxide (NO) bioavailability, and consequently slow microvascular reactivity. **PURPOSE:** To test the hypotheses that ingestion of dietary nitrate or antioxidants preserve microvascular reactivity following eccentric exercise. **METHODS:** Thirty young men and women were randomized into three groups, who ingested a single dose of: i) beetroot juice (BR, 8.4mmol NO₃⁻), ii) antioxidants (AO, Vitamin C and E, alpha-lipoic acid), or iii) placebo (PLA, fruit juice) at 46 hours after an exercise protocol. The

protocol consisted of eccentric contractions of the TA in one leg, while the contralateral leg served as control. At baseline, and 48h after eccentric exercise, participants were positioned in a 3T magnet, and BOLD images were acquired bilaterally in TA muscle during i) brief maximal contractions (MVC), and ii) cuff occlusion (5 min, 260mmHg) to monitor the hyperemic responses. The time-to-peak (TTP, s) of the hyperemic response was used as an index of microvascular reactivity. Data were analyzed using mixed model, three-way (Leg, Group, Session (0h, 48h)) repeated measures ANOVA. **RESULTS:** The ANOVA revealed leg-by-session interactions for TTP following brief MVCs and cuff occlusion ($P < 0.001$), with no main or interaction effects of group. Specifically, 48h after eccentric exercise, TTP (MVC) was prolonged in all groups compared with baseline (BR: 8.6 ± 1.0 vs. 10.9 ± 1.0 s; AO: 8.4 ± 0.4 vs. 10.1 ± 0.4 s, PLA: 9.0 ± 0.9 vs. 11.0 ± 0.8 s), with no changes in control leg. Similarly, 48h after eccentric exercise, TTP (cuff) was prolonged in all groups compared with baseline (BR: 45.5 ± 4.7 vs. 68.6 ± 7.7 s; AO: 36.8 ± 5.7 vs. 54.5 ± 8.5 s, PLA: 42.1 ± 6.4 vs. 68.1 ± 7.1 s), with no changes in control leg. **CONCLUSION:** Ingestion of BR and AO do not preserve microvascular reactivity after eccentric exercise, indicating that elevated oxidative stress and lower NO bioavailability do not contribute to altered microvascular function after eccentric exercise. Supported by Danish Ministry of Culture grant.

3523 Board #6 June 3 9:00 AM - 11:00 AM
Endothelium-Dependent Vasodilation following Bikram Yoga Practiced in Hot and Thermoneutral Conditions
 Stacy D. Hunter, Jitanan Laosiripisan, Ahmed Elmenshawy, Hirofumi Tanaka, FACSM. *University of Texas at Austin, Austin, TX.* (Sponsor: Hirofumi Tanaka, FACSM)
 Email: stacy.d.hunter@gmail.com
 (No relationships reported)

Bikram (hot) yoga is a style of hatha yoga practiced at 40.5°C with 40-60% relative humidity. We have previously documented improvements in endothelium-dependent vasodilation with a Bikram yoga intervention in middle-aged adults. Presently, it is not known whether the effect of hot yoga on endothelial function might be attributed to the yoga postures or the heated environment. **PURPOSE:** The purpose of this investigation was to determine the effects of Bikram yoga performed in standard heated conditions and in a thermoneutral environment on endothelium-dependent vasodilation. **METHODS:** Fifty-two sedentary but apparently healthy adults aged 40-60 years were randomly assigned to one of three groups: Bikram yoga practiced at 40.5°C ($n=19$); Bikram yoga practiced at 23°C ($n=15$); or sedentary time-control ($n=19$). The 12-week yoga intervention consisted of 3 weekly 90-minute Bikram yoga classes. The time control group was instructed to maintain current lifestyle patterns for the study duration. Body composition was determined via dual energy x-ray absorptiometry (DXA). Endothelium-dependent vasodilation was measured noninvasively using brachial artery flow-mediated dilation (FMD) after 5 minutes of blood flow occlusion. **RESULTS:** Age, anthropometric variables, lipid, glucose, and triglyceride concentrations and brachial artery FMD were not different among the three groups at baseline. Body fat percentage declined ($p < 0.01$) and LDL-cholesterol concentration tended to decline ($p = 0.09$) only in the hot (40.5°C) yoga group. Brachial artery FMD increased ($P < 0.05$) in both yoga groups. There were no significant changes in any outcome variables in the time control group. **CONCLUSIONS:** Bikram yoga practiced at hot/humid and thermoneutral conditions produced similar improvements in endothelium-dependent vasodilation in healthy, middle-aged adults. However, the addition of the heat/humidity led to further improvements in body composition. This study was funded by Pure Action, Inc. Austin, TX, USA

3524 Board #7 June 3 9:00 AM - 11:00 AM
Greater Aortic Hemodynamic Responses to Muscle Metaboreflex Activation in Older Adults with Prediabetes than Diabetes
 Arturo Figueroa, FACSM, Salvador J. Jaime, Stacey Alvarez-Alvarado, Sarah A. Johnson, Neda S. Akhavan, Negin Navaei, Shirin Pourafshar, Bahram H. Arjmandi. *Florida State University, Tallahassee, FL.*
 (No relationships reported)

PURPOSE: Wave reflection measures (augmentation pressure [AP] and index [AIx]) are similarly increased in adults with type 2 diabetes (T2D) and prediabetes (PRET2D) suggesting high cardiovascular risk. An exaggerated blood pressure (BP) response to muscle metaboreflex activation induced via post-exercise muscle ischemia (PEMI) following isometric handgrip exercise has been reported in patients with T2D. The purpose of this study was to examine the wave reflection responses to PEMI in adults with PRET2D and T2D.

METHODS: Aortic hemodynamics were obtained using pulse wave analysis at rest and during PEMI following isometric handgrip at 30% of maximal voluntary contraction in adults (age, 59.7 ± 6.3 y) with PRET2D ($n=12$) and T2D ($n=12$). **RESULTS:** Vascular parameters were similar at rest. Aortic systolic BP (PRET2D $\Delta 42 \pm 13$ mmHg vs. T2D $\Delta 31 \pm 10$ mmHg, $P < 0.001$ for both), pulse pressure (PRET2D

$\Delta 22 \pm 9$ mmHg vs. T2D $\Delta 13 \pm 10$ mmHg, $P < 0.001$ and $P < 0.01$, respectively) and AP (PRET2D $\Delta 13 \pm 5$ mmHg vs. T2D $\Delta 9 \pm 5$ mmHg, $P < 0.001$ for both) responses to PEMI were greater ($P < 0.05$) in PRET2D compared with T2D patients. The aortic diastolic BP, AIx, AIx adjusted at 75 bpm, and time to reflection responses to PEMI were similar in PRET2D and T2D.

CONCLUSIONS: Our findings show that aortic hemodynamic responses to exercise-related metabolites are exaggerated in PRET2D. These findings suggest that an increased left ventricular afterload during muscle metaboreflex activation may contribute to augment cardiovascular risk in adults with PRET2D.

Reoccurring Neck Injury in a College Football Player
 Brian Toedebusch, Brian Davis, FACSM. *University of California - Davis, Sacramento, CA.*
 (No relationships reported)

HISTORY: A 20-year-old male community college football defensive end developed left shoulder paresthesia during a game. He was tackling an opponent and his head was forced into a left lateral rotation. After this, he developed immediate paresthesia in the left upper trapezius and upper deltoid. He was evaluated on the side line by medical staff and removed from the remainder of game. Symptoms resolved within the next two days, and he returned to competition. Two weeks later, he again had his head forced into a left lateral rotation during a tackle. Paresthesia immediately returned in the left upper trapezius and upper deltoid. However, this time pain was increased and had onset of a burning sensation. After sideline evaluation, he was removed from competition. Following the game, he continued to have severe burning pain. He was sent to a local emergency department and ultimately released home. Paresthesia resolved over the next five days, but he was not cleared to return to competition.

PHYSICAL EXAMINATION: There was no deformity to the neck or upper extremity. No cervical or left shoulder tenderness to palpation. His range of motion in the left glenohumeral joint was full. Strength was full throughout the entire left upper extremity. Sensation to light touch was diminished in the left upper trapezius and upper deltoid, but normal throughout the remainder of the upper extremity. Deep tendon reflexes were 2+ in bilateral biceps, brachioradialis, and triceps. Spurling's test was positive on the left.

DIFFERENTIAL DIAGNOSIS: 1. Upper trunk brachial plexopathy 2. Cervical radiculopathy 3. Cervical stenosis **TEST AND RESULTS:** 1. Cervical spine anterior-posterior, lateral and flexion-extension radiographs: No fracture or destructive change, disc spaces preserved, no pathologic movement 2. Cervical Magnetic Resonance Imaging: Left paramedian/foraminal disc protrusion at C3-4 resulting in moderate left foraminal stenosis and displacement of left C4 nerve root. No spinal canal stenosis or ligamentous injury. **FINAL WORKING DIAGNOSIS:** Left C4 radiculopathy **TREATMENT AND OUTCOMES:** 1. Orthopaedic spine referral determined to treat with non-operative management 2. Physical therapy for cervical strengthening, flexibility, and traction 3. Currently being withheld from competition with undetermined return to play date

3529 June 3 9:20 AM - 9:40 AM
Differential Diagnosis of Quadriplegia in an Otherwise Healthy Adult Male by a Physical Therapist
 Megan Krueger, Eric Reyes. *Harris Health System, Houston, TX.*
 Email: megan.krueger@harrishealth.org
 (No relationships reported)

HISTORY: A 52-year-old male was referred to Physical Therapy (PT) by his primary care physician for progressive quadriplegia related to suspected peripheral neuropathy (PN). The patient was healthy and active until two years prior when

he began experiencing weakness and paresthesias in both hands. This progressed to his right lower extremity, then all four extremities, and by the time of the PT evaluation, the patient was no longer able to stand. He also endorsed several episodes of bladder incontinence, constipation, and painful muscle spasms. He was scheduled for imaging of the spine and a follow-up with his physician in two months. Review of the medical record revealed that the patient was evaluated by a physical therapist nine months prior. His presentation then was consistent with the working diagnosis of PN. However, a sinister diagnosis was suspected due to the involvement of all four extremities without risk factors for polyneuropathy. At that time, no further steps were taken as the patient did not follow up in clinic.

PHYSICAL EXAMINATION: The patient presented in a wheelchair, though was unable to propel or stand without assistance due to significantly worsening weakness. Neurologic exam revealed several upper motor neuron signs including hypertonicity and hyperreflexia. This presentation was no longer consistent with the working diagnosis of PN (see table).

Cognition	Normal
Cranial Nerves	Normal
Motor	Positive for proximal quadriparesis*
Sensation	Positive for impaired arms/legs/saddle distribution
Tone	Positive for hypertonicity and muscle spasms*
Reflexes	Positive for hyperreflexia and clonus*
Gait & Balance	Unable to stand/ambulate*
Coordination	Normal
* denotes red flag	

DIFFERENTIAL DIAGNOSIS:

1. Cervical spine stenosis with myelopathy
2. Space occupying lesion in cervical region
3. Progressive motor neuron disease

TESTS AND RESULTS:

Cervical/Thoracic spine MRI: 12.4 cm intradural intramedullary mass from C5 to T5, likely related to multiple tumoral cystic areas, with syrinx from T3 to T4

FINAL DIAGNOSIS:

Intradural intramedullary ependymoma extending from C5 to T5 with associated syrinx

TREATMENT AND OUTCOMES: Based on the examination and presence of multiple red flags, the physical therapist referred the patient to the Emergency Department for further evaluation.

3531 June 3 9:40 AM - 10:00 AM

17 yo Football Player with Central Cord Syndrome after Negative Initial Neck Exam

Hersch Bhatia¹, Teri McCambridge². ¹University of Maryland, Baltimore, MD. ²Towson Sports Medicine, Baltimore, MD.
(No relationships reported)

HISTORY: A 17 year old HS football receiver was injured when he sustained a hit from the opposing safety. Reported mechanism by opposing player was shoulder to head impact. He fell to the ground in the prone position. He was immediately evaluated on the field by the nearby opposing athletic trainers. He had no LOC, no neck pain on the field, and he denied tenderness to palpation. He complained of having the wind knocked out of him. He reported that he got hit in the back of the leg and it felt odd. He had an ACL brace on his right knee. Care was transitioned to his team athletic trainers. He was turned supine and his helmet was removed. Afterwards, his right arm was noted to be in an awkward position. He could not move his arms or his legs. He had good sensation but had tingling in his upper and lower extremities. He had no prior history of weakness, neck pain, or concussion. His neck was immobilized. He regained motion in the upper extremity, but continued to demonstrate weakness in grip strength. He could not move his lower extremity. On EMS arrival he was spine boarded, and then taken to the ED for further management. **PHYSICAL EXAMINATION:** He was AO x 3. He had no tenderness over the cervical spinous processes and paraspinal muscles. He had normal sensation of his bilateral extremities. After being turned supine and having his helmet removed, he developed weakness of his upper and lower extremities, but no sensory deficit. Respiratory and Cardiovascular exams were normal. **DIFFERENTIAL DIAGNOSIS:**

1. Central Cord Syndrome
 2. Anterior Cord Syndrome
 3. Posterior Cord Syndrome
 4. Brown-Sequard Syndrome
 5. Concussion
 6. Intracranial Hemorrhage
 7. Acute disk herniation
 8. Epidural Hematoma
 9. Syringomyelia
- TEST AND RESULTS:** CT Head, XR C, T, L spine: No fracture or bleed MR C-spine: Congenital stenosis of the spinal canal, with endplate osteophytes/protrusions moderately narrowing the spinal canal to 8 mm at C3-4, with expansile T2 signal suggestive of edema within the cervical spinal cord at C3-4 levels. **FINAL/WORKING DIAGNOSIS:** Traumatic Cervical Myelopathy superimposed on Congenital Stenosis of Spinal Canal **TREATMENT AND OUTCOMES:** 1. Immobilization with Miami J Collar 2. Admitted to the hospital for observation. 3. Sensory and strength deficits improved during stay. 4. Transferred to an intensive inpatient activity based rehabilitation facility.

3532 June 3 10:00 AM - 10:20 AM

Neck Injury

Özlem G. Ülger¹, Aynur Demirel¹, Mehmet Yorubulut². ¹Hacettepe University, Ankara, Turkey. ²Acibadem Hospital, Ankara, Turkey.
Email: ozlemulger@yahoo.com
(No relationships reported)

HISTORY: A 34-year-old woman has severe neck and radiating pain to left arm applied to our clinic. Two years ago she had strain and she used myorelaxative drugs and felt better. When she performing heavy weights in bench press position at the gym, she felt pain suddenly both neck and left arm.

PHYSICAL EXAMINATION: Paravertebral and shoulder muscle spasm were palpated. Cervical compression and distraction tests were positive. Vertebral artery test, Adson and Roos test were negative. There was no limitation in range of motion. There was strength (20%) and sensorial deficit (hypoesthesia in C3-C4-C5 dermatomes).

DIFFERENTIAL DIAGNOSIS

- Cervical disc herniation
- Peripheral nerve entrapment

TEST AND RESULTS

Cervical Joint T1 and T2 MRI:

- Left posterolateral foraminal extrude herniation (C5-C6 level, herniation volume decreased from 4.5 mm to 3 mm, intervertebral disc height increased from 3.6 mm to 3.9 mm. Regression was seen in this level)
- Right posterolateral protrusion (C4-C5 level, there was no change in herniation thickness and disc height)

FINAL/WORKING DIAGNOSIS:

Cervical disc herniation

TREATMENT AND OUTCOMES

- 15 sessions of Physiotherapy programme which included Non-invasive Spinal Decompression, manual therapy applied.
- Physiotherapist guided spinal stabilization exercise applied (4 months follow-up)
- After therapy strength and sensorial problems resolved.

3533 June 3 10:20 AM - 10:40 AM

Sternoclavicular Injury - Rugby Union (15-players-a-side)

Victor Lopez Jr¹, Richard Ma², Douglas E. James³, Michael S. Wilinski⁴, Answorth A. Allen⁵. ¹Rugby Research and Injury Prevention Group, Inc, Hospital for Special Surgery, New York, NY. ²Missouri Orthopaedic Institute & Thompson Laboratory for Regenerative Orthopaedics, Columbia, MO. ³State University of New York Medical Center (Downstate), Brooklyn, NY. ⁴Lake Erie College of Osteopathic Medicine, Bradenton, FL. ⁵Hospital for Special Surgery, New York, NY. (Sponsor: Robert C. Cantu, FACSM)
Email: drvictorlopezjr@gmail.com
(No relationships reported)

HISTORY: A 19-year-old men's college Rugby-15s winger collapsed during match play. The player had no impact with another player, dizziness and no loss of consciousness. A medical history revealed the player had sustained a right clavicular injury in a previous match 25 days prior to this incident. Where he complained of right shoulder pain, after impacting the ground with a multi-player tackle. The player had presented to an Urgent Care facility after that injury and provisionally diagnosed with shoulder sprain -vs- pectoralis strain, placed in arm-sling and sent home on oral analgesics. Right shoulder radiographs at Urgent Care visit were read as normal. **PHYSICAL EXAM:** Exam in ED revealed slurred speech, and complaints of localized pain and tenderness on right medial clavicle. Right sternoclavicular joint pain on palpation. Limited upper extremity range of motion secondary to pain, no facial droop, decreased left sided upper and lower extremity sensation, reflexes and strength. Symmetrical radial pulses with brisk capillary refills. **DIFFERENTIAL DIAGNOSIS** 1. Cervical Neck Injury 2. Stroke 3. Fracture Clavicle 4. Rib Fracture 5. Scapular Fracture 6. Sternal Fracture **TEST AND RESULTS:** Chest anterior-posterior radiographs: -abnormal right SCJ MRI Brain no contrast: -Large area/acute infarction. Mass effect of right lateral ventricle. No hydrocephalus. Midline shift 1-2mm. CT brain no contrast: -Right MCA infarction with right frontal/parietal lobes, insular cortex, thalamus, caudate nucleus, external/external capsule, and lentiform nucleus. -Mass-effect on the right lateral and third ventricles. Increased midline shift 8mm. No hydrocephalus. Carotid Duplex: -Arteries bilaterally, normal velocities/waveforms. CT chest: -Right clavicular head dislocated posterior to the sternum, in the superior mediastinum. Subperiosteal hematoma around proximal right clavicle. **FINAL/WORKING DIAGNOSIS:** Missed posterior sternoclavicular joint dislocation with brachiocephalic artery compromise leading to hemiparesis **TREATMENT AND OUTCOMES:** 1. Surgical Emergency. Often missed on radiograph. 2. Open repair of

brachiocephalic artery, right clavicular reduction/SCJ capsulorrhaphy with hamstring tendon allograft. 3. Patient recovered with left sided hemiparesis. No return to sport. Sponsor: NOCSAE.org

Primary Amenorrhea and High Triad Risk: The Reluctant Runner

Andrea Kussman, Aurelia Nattiv, FACSM. *University of California Los Angeles, Santa Monica, CA.* (Sponsor: Aurelia Nattiv, FACSM)
Email: akussman@mednet.ucla.edu
(No relationships reported)

History:

A 19 year-old collegiate runner presented to her pre-participation exam with primary amenorrhea and a high female athlete triad risk score placing her in the "no clearance" range for participation. She denied intentionally restricting her caloric intake, purging behaviors, or psychiatric disorders.

Physical Exam:

BMI 17.4. Blood pressure 100/60. Heart rate 56. No acne, hirsutism, or oral lesions. Lanugo present. Minimal secondary sexual development.

Differential Diagnosis:

Hypothalamic hypoestrogenic primary amenorrhea

Physiologic delay of puberty

Gonadal dysgenesis

Androgen insensitivity syndrome

Mullerian agenesis

PCOS

Isolated GnRH deficiency

Results:

-Total T3 61*

-Free T4 6.0

-LH 0.9*

-FSH 4.0*

-Estradiol <12*

-DHEA 1830

-TSH 0.57

-CMP normal

-Vitamin D 42

-Total testosterone 12

-Urine pregnancy test negative

DXA Z scores: total body 0.7, total hip 0.3, femoral 0.8, spine 0.3

*indicates abnormal

Final working diagnosis:

Female athlete triad with primary amenorrhea due to hypothalamic hypoestrogenism.

Treatment and Outcomes:

The athlete was provisionally cleared. Although very reluctant, with the support of her coach, she signed a contract which required her to meet at regular intervals with the team dietitian, physician, and psychologist, and included weekly weigh-ins. Goal and minimum weights were established, with lower weekly mileage permitted at lower body weight. She established care with a psychologist but did not engage during sessions and discontinued. Labs from the spring: estradiol <12, FSH 3.8, LH 0.9, BUN 23, AST 49, low T3, and normal prolactin, TSH, T4, and 17-alpha-OH progesterone. Transdermal hormonal treatment was considered to maintain BMD, but the patient refused. She sustained bilateral tibial stress reactions in May, 2016. She blamed her stress reactions on the weight that she had been required to gain.

Upon return in the fall, the triad risk score remained high with a further decline of BMI to 17.2, and still no menarche. The athlete was placed back on contract. She remains

resistant to meeting with the psychologist, but continues to see the dietitian and team physician. She narrowly cleared her minimum weight requirement (restricting her training to 30mi/week). Free T3 was 53.6 and total T3 was 59 suggesting ongoing low energy state. She remains provisionally cleared.

3538 June 3 9:20 AM - 9:40 AM

Proximal Muscle Weakness in 10-year-old Female Gymnast

Peter Waller, David Lessman, Philip Skiba. *Advocate Lutheran General Hospital, Park Ridge, IL.*
Email: pwaller189@gmail.com
(No relationships reported)

History:

A 10-year-old gymnast initially presented with three weeks of right hamstring pain, and was started on a home exercise program. After 4 weeks without improvement, the patient was started on a program of formal physical therapy. After ten weeks of therapy, the patient began to develop core muscle weakness and right anterior hip pain, and reported an inability to walk more than a mile without limping. She went on to develop similar pain with stair climbing, as well as activities of daily living. Shortly thereafter, the patient began to complain of quadriceps weakness and thoracic back pain.

Physical Examination:

Afebrile. Muscle strength 4/5 with bilateral shoulder elevation and abduction. Strength 5/5 with elbow flexion and extension. Bilateral hip flexor strength 3/5. Sensation intact in upper and lower extremities bilaterally. Deep tendon reflexes 2+ bilaterally. Scaly erythematous rash on each side of nose. Erythema present across knuckles bilaterally.

Differential Diagnosis:

1. Juvenile Dermatomyositis
2. Polymyositis
3. Viral myositis
4. Lupus Erythematosus

Tests and Results:

Labs: CPK: 524 H, AST: 75 H, ALT: 32 H, ESR: 18 wnl, Aldolase 11 H, CRP <0.3 wnl, LDH Total 317 H

X-Ray: 3V of bilateral hips-No acute fractures, subluxation, or dislocations.

MRI Pelvis: Diffuse intramuscular edema, predominantly involving gluteal muscles. Consistent with myositis.

Final Working Diagnosis: Juvenile Dermatomyositis

Treatment and Outcomes:

1. Patient admitted to outside hospital, and patient started on daily prednisone, weekly methotrexate, and hydroxychloroquine.
2. Patient started on IV methylprednisolone weekly, and monthly IVIG infusion by rheumatology
3. Evaluation at NIH Myositis Clinic. Recommended increasing IVIG dosing and pulse doses of IV steroid with every IVIG infusion.

3539 June 3 9:40 AM - 10:00 AM

Not All Headaches Are Concussion Related

Jennifer Oberstar. *University of Minnesota, Minneapolis, MN.*
(Sponsor: Steven Stovitz, FACSM)
Email: ober0042@umn.edu
(No relationships reported)

HISTORY: A 13-year-old soccer player was struck in the back of the head by a soccer ball. She was diagnosed with a concussion without loss of consciousness. Concussion symptoms improved over ten days, but mild headache and fatigue persisted. Her ImPACT scores were at or above baseline. She completed her soccer season. One month later, she began cross country and reported exertional headaches with running. The certified athletic trainer reduced her training to the point of exercise biking. Upon evaluation at the clinic for shortness of breath and abdominal pain, the patient was treated for exercise-induced asthma and constipation. She was started on an albuterol inhaler, polyethylene glycol, and ranitidine. At a three month follow-up, the patient reported abdominal pain despite taking ranitidine twice daily. She was diagnosed with dyspepsia and irritable bowel syndrome at gastroenterology. Ultimately, she was unable to complete her cross country season. Six months later, the patient started training for nordic skiing and now presents with escalating headaches. Her mother believes that the patient was having concussion symptoms again due to the patient's irritability, dizziness, nausea, and return of headaches upon pushing herself at a recent nordic ski meet. She was unable to get out of bed and appeared depressed. Nine months post-concussion, neurosurgery was consulted for work-up of exertional headaches. She was later evaluated by psychiatry for anxiety.

PHYSICAL EXAMINATION: Examination revealed Body Mass Index: 21.04, HEENT: PERRLA, EOMI. NECK: no masses LUNGS: clear CV: RRR GI: hard stool palpated in the LLQ

DIFFERENTIAL DIAGNOSIS:

1. Post-concussion syndrome

2. Exertional headaches
 3. Thyroid disease
TEST AND RESULTS:
 T3 TOTAL: 106
 T4 TOTAL: 4.6
 THYROID STIMULATING HORMONE: 52.57
 MRI/MRA/MRV:
 -Conspicuous enlargement of the adenohypophysis, concern for possible pituitary hyperplasia
 -No vascular abnormalities detected
FINAL/WORKING DIAGNOSIS:
 1. Hashimoto's autoimmune thyroiditis with secondary pituitary enlargement
 2. Depression and Anxiety
TREATMENT AND OUTCOMES:
 1. Evaluated by pediatric neurosurgery, endocrinology, neurology, psychiatry.
 2. Started on levothyroxine 50mcg po daily for 3 months.
 3. Three years later, the patient is enrolled in several AP courses and joined the robotics team.

3540 June 3 10:00 AM - 10:20 AM

Heat Illness- Running

José J. Correa, Anita M. Rivera-Brown, FACSM, William F. Micheo, FACSM. *University of Puerto Rico School of Medicine, San Juan, Puerto Rico.*
 Email: jjcorrea@coqui.net
 (No relationships reported)

HISTORY: A 14 year-old highly competitive runner presented to our sports medicine clinics one week after collapsing during his first 10 km race in a hot and humid climate. His goal was to achieve a time similar to adult elite runners. He felt dizzy but did not want to slow down. At 8 km he was seen disoriented and stumbling and soon after collapsed. He was taken unconscious to a local ER, where IV hydration was given. After ~25 min he regained consciousness but was disoriented and irrational. He did not remember having collapsed or transport to the ER. After ~two hours he was alert and felt better, and was discharged. Upon arrival to his home he showered with cold water. He reported a mild sore throat the day before and leg pain after the race.

PHYSICAL EXAMINATION: Normal vital signs (BP: 116/68; HR: 68 bpm), alert, does not remember details of race. Normal cardiovascular, pulmonary, musculoskeletal and neurological exam.

DIFFERENTIAL DIAGNOSIS:

1. Syncope associated to dehydration
2. Syncope associated to hypoglycemia
3. Rhabdomyolysis
4. Syncope associated to exertional heat stroke

TEST AND RESULTS:

In ER: According to the athlete's parents: his blood pressure was low, body temperature was not measured nor any blood analysis performed. He was discharged with a diagnosis of "dehydration".

Two days after discharge from ER his primary care physician ordered urinalysis and CBC: Blood and protein trace in urine; Blood glucose=84 mg/dL; Creatinine=0.94 mg/dL; Na⁺= 142 and K⁺= 4.7 mmol/L; AST: 1,923 and ALT: 1,996 U/L. CK was not ordered.

At 9 days: AST: 100 and ALT: 424 U/L; CK ordered but not done.

At 16 days: AST: 55 and ALT: 170 U/L; CK=151 U/L

Five weeks after discharge from ER: Heat Tolerance Test (running outdoors @ 12.8 to 13.8 km/hr in 32°C, 75% RH). Test stopped at 40 min when T_{re}= 39.3°C. HR=145-173 bpm. Sweat rate=1.8 L/h; Fluid replaced=16% Dehydration=1.9%; Rating of hot/overheated= 8 and thirst= 8 (0-10 scale).

FINAL/WORKING DIAGNOSIS:

Exertional heat stroke related to inadequate heat acclimatization.

TREATMENT AND OUTCOMES:

1. Allowed to swim and run in cool environment after 2 weeks at reduced pace but no running in the heat for 5 weeks.
2. Recommendations about proper hydration and gradual heat exposure to acclimatize to heat.
3. Referred to sports psychologist.
4. Repeat heat tolerance test for clearance to compete in the heat.

3541 June 3 10:20 AM - 10:40 AM

Gastrointestinal - Track and Field

Katherine Langley, Jocelyn Gravlee. *University of Florida, Gainesville, FL.*
 Email: langleykj@ufl.edu
 (No relationships reported)

HISTORY: A collegiate track athlete presented with a two-day history of nausea, non-bloody, non-bilious vomiting, bloating, inability to tolerate PO, and waves of sharp,

crampy abdominal pain. He denied fevers, chills, diarrhea, sick contacts, or recent NSAID or alcohol use. His last bowel movement was two days prior. He endorsed a history of similar symptoms due to constipation that resolved with a laxative suppository. He was evaluated the previous day and noted to have mild epigastric and RLQ tenderness. He was able tolerate PO after Zofran ODT and discharged with strict return precautions. Surgical history includes laparoscopic right sports hernia repair with mesh, open right adductor tenotomy, and umbilical hernia repair in 2014 and left adductor tenotomy in 2016.

PHYSICAL EXAMINATION:

Afebrile, normotensive, bradycardic.

Appears uncomfortable.

Abdomen soft. Bowel sounds present. Epigastric tenderness to palpation. Voluntary guarding. No rebound.

DIFFERENTIAL DIAGNOSIS:

1. Gastritis
2. Constipation
3. Ileus

TEST AND RESULTS:

Abdominal radiographs showed gaseous small bowel distension in a non-obstructive pattern with a large amount of stool in rectal vault. He received IV fluids, glycerin suppository, and a Fleet enema with no bowel movement but recurrent emesis. Repeat Fleet enema, 4 mg IV Zofran, and additional IV fluids were given. On re-examination he had worsening abdominal tenderness and guarding. He was transferred to the ED and the differential diagnosis was broadened to include small bowel obstruction and intraabdominal perforation. On arrival to the ED he was in distress with significant bilateral lower quadrant tenderness, rebound, and guarding. CT abdomen and pelvis showed a high-grade distal small bowel obstruction with moderate wall edema along distal ileum with concern for vascular compromise.

FINAL/WORKING DIAGNOSIS:

Small bowel obstruction related to prior sports hernia repair

TREATMENT AND OUTCOMES:

1. Emergently to OR for exploratory laparotomy.
2. Intraoperatively found to have herniation of distal ileum through peritoneum in RLQ inferior to prior mesh placement for sports hernia repair. Herniated loop of bowel non-viable with chronic ischemic changes and stricture requiring 30 cm resection and ileoileostomy.
3. Uneventful post-operative course.
4. Return to sport pending.

Photographic Method for Measuring Body Composition by Level of Physical Activity Level in Adults

Amber Kinsey, Howard W. Wiener, Ligaj Prahdan, Olivia Affuso, FACSM. *University of Alabama at Birmingham, Birmingham, AL.* (Sponsor: Olivia Affuso, FACSM)
 Email: akinsey@uab.edu
 (No relationships reported)

Our laboratory has previously shown that photographic methods can be used to accurately measure body composition in adults. Given the limitations of the body mass index (BMI) for assessing obesity status across different levels of physical activity (PA), we wanted to test our method to see if there were any differences in the prediction of body fatness by level of PA in a diverse sample of women and men.

PURPOSE: To examine the performance of a photographic method to estimate body composition amongst adults that differ in PA status.

METHODS: Our sample consisted of 723 black and white adults (women: n= 309, age, 39.4 ±14.4 years, height 163.2 ± 6.1 cm, weight 74.5 ± 19.5 kg, BMI 27.9 ± 7.0 kg/m²; men: n= 414, age, 40.4 ±14.6 years, height 175.8 ± 6.9 cm, weight 84.7 ± 18.0 kg, BMI 27.4 ± 5.5 kg/m²). Self-reported PA level was classified as low, moderate or high. Body fat percentage was measured with dual energy x-ray absorptiometry (%BFDXA) and predicted with digital photographic methods (%BFPHOTO). The photographic method measures pixel volume and body shape to predict body volume. The regression model to predict %BFPHOTO included age, sex, race, BMI, body volume and body shape. Pearson correlations between %BFDXA and %BFPHOTO were calculated for each level of PA.

RESULTS: There was a strong positive correlation between %BF_{DXA} and %BF_{PHOTO} for all levels of physical activity in black women (low, r = 0.89, p <0.0001; moderate: r = 0.91, p <0.0001; high: r = 0.86, p <0.0001) and white women (low, r = 0.83, p <0.0001; moderate: r = 0.82, p <0.0001; high: r = 0.71, p <0.0001). Similarly,

strong positive correlations between %BF_{DXA} and %BF_{PHOTO} at all PA levels were observed in black men (low: $r = 0.80, p < 0.0001$; mod: $r = 0.84, p < 0.0001$; high: $r = 0.79, p < 0.0001$) and white men (low: $r = 0.85, p < 0.0001$; moderate: $r = 0.80, p < 0.0001$; high: $r = 0.70, p < 0.0001$).

CONCLUSIONS: The determination of body fat percentage from digital photographs was strongly correlated with DXA measurements in black and white women and men regardless of physical activity status. Photographic methods may be a viable, cost effective alternative for the assessment of body composition.

Supported by NIH Grant R01HL107916, T32DK062710, and P30DK056336

3555 Board #2 June 3 8:00 AM - 9:30 AM

Cannabis Use And Neurological Disease: An Alternative Therapy To Improve Neurological Disability?

John Harvey Kindred¹, Kaigang Li¹, Nathaniel B. Ketelhut¹, Felix Proessl¹, Brett W. Fling¹, William R. Shaffer², Thorsten Rudroff, FACSM¹. ¹Colorado State University, Fort Collins, CO. ²Banner Health, Greeley, CO. (Sponsor: Thorsten Rudroff, FACSM)

Email: jhkindred@gmail.com

(No relationships reported)

Medicinal cannabis use has a long history. Despite this fact current federal regulations greatly restrict research into the medicinal uses of cannabis, although this sentiment is changing. **PURPOSE:** To investigate cannabis use parameters in people with neurological diseases. **METHODS:** An anonymous online survey was created using modified neurological assessment questionnaires, Guy's Neurological Disability Scale and Nottingham Health Profile, and posted to the National Multiple Sclerosis Society and Michael J. Fox Foundation websites. The survey also included measures of past/current cannabis use, fatigue (Fatigue Severity Scale), balance confidence (Activities of Balance Confidence), physical activity (International Physical Activities Questionnaire), pain (visual analogue scale), and spasticity. The survey was available online from 15 Feb 2016 to 15 Oct 2016. **RESULTS:** There were a total of 637 records with 52% (n = 326) men and 48% (n = 311) women (mean: age 57 SD 13; BMI 27 SD 5.7). Forty-three percent (n = 277) reported currently using cannabis, although 57% (n = 158) do not have a state medical marijuana card. Smoking was the most common method of use (79%, n = 213). Among the cannabis users 75% (n = 204) have been using for > 1 year and 48% (n = 131) are using 7 days a week. Most, 85% (n = 231), felt that cannabis at least moderately improved their symptoms. Medicinal purposes (74%, n = 200) were reported as the reason for use and 60% (n = 164) stated a reduction in the use of other medications due to cannabis. Of the non-users 75% (n = 265) have considered using cannabis to help manage their disease symptoms, and 97% (n = 344), said they would use cannabis if scientifically shown to help ease disease burden. There appears to be no difference in physical activity participation between the cannabis users and non-users (t-tests: $p > 0.128$). **CONCLUSIONS:** A large proportion of neurological patients are currently using cannabis to treat their disease and/or symptoms. Current medical knowledge on the benefits and consequences of both short- and long-term cannabis use are unknown in this population. It is imperative to establish the effects of cannabis so that physicians and patients can make the most informed decisions about whether adding cannabis to the current pharmacological regiment is both effective and safe.

3556 Board #3 June 3 8:00 AM - 9:30 AM

Identifying Politically Motivated Medical Withdrawals From International Competition

Peter A. Harmer, FACSM. Willamette University, Salem, OR.
Email: pharmer@willamette.edu

(No relationships reported)

The IOC and many international federations (IF) have clear regulations prohibiting participants in sanctioned events from refusing to compete against athletes from other countries for political, cultural or religious reasons. Failing to abide by these regulations can result in significant penalties for the offending athletes and their federations. However, being injured or ill provides plausible deniability for those committed to not competing for political purposes.

PURPOSE: To explore the use of quantitative analysis to uncover patterns of medical withdrawal from competitions that indicate systematic abuses of medical waivers for political purposes.

METHODS: Demographic information (number of participants, event, country) was compiled from the official entry and results lists of the Federation Internationale d'Escrime (FIE) for 1.5 competition seasons 2014-2016 for 3 countries (Iran (IRI), Kuwait (KUW), Saudi Arabia (KSA)) anecdotally reported to be systematically avoiding competing against Israel (ISR) by using medical withdrawals.

RESULTS: Athletes from the three countries had a total of 623 competition exposures during the observation period (IRI: 279 vs. other nations; 4 vs. ISR; KUW: 239 vs. other nations; 6 vs. ISR; KSA: 101 vs. other nations; 3 vs. ISR). For IRI there was

100% (279) participation against non-ISR opponents but 0% (0/4) participation against ISR athletes. KUW had 99% (233/235) participation against non-ISR athletes and 0% (0/6) against ISR. KSA had 100% (98/98) against non-ISR and 0% (0/3) for ISR.

CONCLUSIONS: Although it is not reasonable to determine the legitimacy of requests for medical withdrawal from competition on a case-by-case basis in instances where non-medical motivation may be involved, it is possible to identify systematic abuses of medical exemptions through data analyses. To reaffirm the integrity of sports competition and the independence of medical care, it is incumbent on the IOC and IFs to investigate suspect action using available entry and withdrawal data and move to hold non-conforming nations accountable.

3557 Board #4 June 3 8:00 AM - 9:30 AM

Application of Environmental Sensors to a Military Combatives Training Environment

Tyler F. Rooks, Katie P. Logsdon, B. Joseph McEntire, Valeta Carol Chancey. U.S. Army Aeromedical Research Laboratory, Fort Rucker, AL.

Email: tyler.f.rooks.civ@mail.mil

(No relationships reported)

Timely and accurate identification is important for effective concussion management and has implications for extended return-to-play/duty timelines. An environmental sensor (ES) for measuring head impact events is one method for timely identification of a potential concussion. Civilian ESs were used in the Modern Army Combatives Program (MACP). Each course has its own instructional requirements with varying levels of direct head impact or inertial loading possibilities, and protective equipment requirements. The training environment, drills, and equipment limited the ES evaluated to specific form factors including: (1) adhesive-mounted and (2) headband or skullcap worn. **PURPOSE:** Characterize ES performance in MACP. **METHODS:** Students were instrumented with multiple ES types during combatives drills to record head impact events. Human factors and environmental issues were recorded. The students were videotaped during the drills to visually identify head and body impact events. The drills were recorded from multiple views and all videos were time synchronized. **RESULTS:** The ESs used were dependent on the drill type and the required protective equipment for the drill. During a Level 1 drill, the video analysis identified 26 to 41 impacts per student with the ES recording 30 to 35 impacts. Peak linear accelerations (PLA) for all students ranged from 4.9 to 162.1 G. One student, required to wear headgear, had a maximum linear acceleration of 67.3 G (compared to 162.1 and 117.5 G for students with no headgear). For the Level 2 drills, video analysis identified between 90 to 271 impacts per student per day with the ES recording 78 to 239 impacts per student per day. PLA ranged from 4.3 to 158 G. For the Level 3 drills, video analysis identified between 10 to 76 impacts per student per day with the ES recording 44 to 191 impacts. PLA ranged from 1.6 G to 220.6 G. Human factors issues identified included sensor mounting, stability, and the need for a properly sized skullcap. For skullcap/headband use, protective headgear was required to keep the cap in place. None of the ESs evaluated were compatible with grappling drills. **CONCLUSION:** Both form factors are usable, though not perfect, in the MACP; further development is required. The ES data variance shows that ESs cannot yet be used as a diagnostic standard for likelihood of concussion.

3558 Board #5 June 3 8:00 AM - 9:30 AM

Assessment Of The Relationship Between Body Composition And Bioavailability Of Diclofenac Sodium In Healthy Volunteers

Andreia Naves¹, Valden Capistrano Júnior², Maria Elisabete Amaral de Moraes². ¹VP Research Institute, São Paulo, Brazil. ²Federal University of Ceará, Ceará, Brazil.

(No relationships reported)

PURPOSE: The objective of this study was to evaluate the relationship between body composition and pharmacokinetics of diclofenac sodium formulation in healthy volunteers.

METHODS: This was a cross-sectional study. Twenty-four healthy subjects (age range: 18-42 years) received 50 mg of sodium diclofenac single oral dose. Hematologic and biochemical analysis and body composition (bioelectrical impedance method) were obtained before and after the admission of the study. The pharmacokinetics was evaluated by high performance liquid chromatography coupled to mass spectrometry. Relationships between pharmacokinetics and body composition were assessed with simple Pearson correlations. Student's t-test was used for continuous variables and type 1 error was set at $p < 0.05$.

RESULTS: There were significant inverse correlation between area under the concentration time curve from time 0 to 24h (AUC₀₋₂₄) and lean mass ($r = -0.4917, p = 0.0147$), intracellular water ($r = -0.4406, p = 0.0312$), extracellular water ($r = -0.4964, p = 0.0136$) and basal metabolic rate ($r = -0.5033, p = 0.0122$); between area under the concentration time curve from time 0 to infinity (AUC_{inf}) and lean mass ($r = -0.4908, p = 0.0149$), intracellular water ($r = -0.4401, p = 0.0314$), extracellular water ($r = -0.4946,$

p=0,0140) and basal metabolic rate (r=-0,5023, p=0,0124); and between maximum concentration (Cmax) observed and lean mass (r=-0,7290, p<0,0001), intracellular water (r=-0,6750, p=0,0003), extracellular water (r=-0,7519, p<0,0001) and basal metabolic rate (r=-0,7505, p<0,0001).

CONCLUSIONS: The results showed that low values of AUC0-24 e AUC0inf were associated with greater values of lean mass body, intracellular water, extracellular water and basal metabolic rate. The optimization of diclofenac dose based on these parameters can avoid doses of errors in prescribing, optimization of treatment outcome and minimize side effects.

Reaction Time Assessment of Sickle Cell Anemia Children

Kellen Carvalho Visentin Marinello, Jake Carvalho Carmo, Maria Claudia Cardoso Pereira, Valdinar de Araújo Rocha Junior, Flavia Vanessa Medeiros, Flavio Junker. *Universidade de Brasília, Brasília, Brazil.*

Email: kellen.carvalho@hotmail.com

(No relationships reported)

Children with Sickle Cell Disease (SCD) may have had brain damage throughout childhood that lead in neuropsychomotor changes, such as an increase in reaction time (RT). An evaluation of RT can aid in the early detection of increased brain information processing speed. This capability is of fundamental importance for full child development and can be assessed by tests such as psychometric tests and motor skills tests or computer games. In this study, the assessment was performed using an easy to handle toy-like device, developed for this purpose in Arduino platform. **PURPOSE:** To evaluate the RT in children with sickle cell anemia (SCA), using simple reaction time (SRT) and choice reaction time (CRT) tests. **METHODS:** The 46 participants, 24 SCA group (9,41±1,97 yrs) and 22 healthy children of control group (CON) (8,33±1,54 yrs), were subject to the tests SRT and CRT developed on Arduino platform. Children had to trigger the fastest response possible button, after seeing the luminous stimulus. The Arduino was programmed to generate random light stimuli, according to the purpose of each test, as well as the capture, transfer and register the data of motor responses on the computer via Bluetooth. **RESULTS:** SRT was significantly higher (p<0.01) in children with SCA (747,80 ± 523,58 ms) when compared to CON (364,48 ± 90,66 ms). In SCA group the SRT (478,06 ± 114,03 ms) was significantly lower when compared with the CRT (747,80 ± 523,58 ms). **CONCLUSIONS:** Children with SCA have a higher CRT than children without the disease.

(No relationships reported)

The 2018 Physical Activity Guidelines Advisory Committee (PAGAC) will provide independent recommendations based on current scientific evidence to aid the federal government in the development of the second edition of the *Physical Activity Guidelines for Americans* (PAG). **PURPOSE:** To describe the analytic frameworks and systematic literature reviews used by the PAGAC to evaluate the science and develop evidence-based conclusions and recommendations for its Advisory Committee Scientific Report (Report). **METHODS:** The U.S. Department of Health and Human Services (HHS) contracted a systematic literature review to evaluate and synthesize published, peer-reviewed physical activity literature. The approach is designed to maximize transparency, minimize bias, and ensure systematic reviews are relevant, timely, and high quality. The PAGAC's first task was to develop and prioritize research questions. The highest priority questions were those with potential for the greatest public health impact (Table 1). Each question will be evaluated using de novo systematic reviews, high-quality existing systematic reviews, meta-analyses, and reports, or a combination of approaches. **RESULTS:** The output from the literature review is an evidence portfolio summarizing the findings for each question. The Committee will grade each question as strong, moderate, limited, or grade not assignable. During a series of public meetings, subcommittees will review and deliberate on their conclusions, implications, and research recommendations in order to come to consensus. Analytic frameworks and search strategies for initial questions and information discussed during the first three public meetings will be presented. **CONCLUSIONS:** HHS will use the Report, along with agency and public comments,

to develop the second edition of the PAG. This edition will provide updated science-based advice on how physical activity can help promote health and reduce the risk of chronic disease.

Subcommittee Topic	Subcommittee Lead	Priority Areas
Aging	Loretta DiPietro, PhD, MPH, FACSM	PA and risk of injury due to fall
Brain Health	Kirk Erickson, PhD	PA and brain function (cognition)
Cancer – Primary Prevention	Anne McTiernan, MD, PhD, FACSM	PA and cancer incidence
Cardiometabolic Health and Weight Management	John Jakicic, PhD	PA and weight gain prevention
Exposure	William Kraus, MD, FACSM	PA and all-cause and CVD mortality
Individuals with Chronic Conditions	David Buchner, MD, MPH, FACSM	PA and all-cause mortality in cancer survivors
Promotion of Physical Activity	Abby King, PhD	Effective PA interventions
Sedentary Behavior	Peter Katzmarzyk, PhD	Sedentary behavior and all-cause mortality

Updating The Physical Activity Guidelines For Americans: Priority Topics And Research-Related Issues

Emily Bhutiani¹, Katrina Piercy², Sarah Prowitt², Richard Troiano¹, Alison Vaux-Bjerke². ¹National Cancer Institute, Bethesda, MD. ²Office of Disease Prevention and Health Promotion, Rockville, MD. (Sponsor: Janet Fulton, FACSM)

(No relationships reported)

The U.S. Department of Health and Human Services (HHS) expects to issue a second edition of the *Physical Activity Guidelines for Americans* (PAG) in 2018 to provide updated evidence-based guidance on the types and amounts of physical activity that offer substantial health benefits. **PURPOSE:** To present the topics, priority questions, and research-related issues being reviewed by the 2018 Physical Activity Guidelines Advisory Committee (PAGAC) and to show how selected topics have evolved since 2008. **METHODS:** Seventeen nationally recognized experts were asked to review the current evidence regarding physical activity and health and provide a summary of their findings to the federal government to inform the update of the PAG. In July 2016, the PAGAC formed nine subcommittees corresponding to key topic areas to review in this process. The PAGAC has identified key research questions to be addressed through systematic reviews and will evaluate the evidence, ultimately submitting a Scientific Advisory Report to HHS. **RESULTS:** The subcommittees include: Aging, Brain Health, Cancer, Cardiometabolic Health and Weight Management, Exposure, Individuals with Chronic Conditions, Promotion of Physical Activity, Sedentary Behavior, and Youth. Similar to the 2008 PAGAC, some subcommittees will address specific health outcomes (e.g., What is the relationship between physical activity and cancer incidence?) or populations (e.g., What is the relationship between health indicators and physical activity for children younger than six years old?). Other subcommittees will explore the health impact of differing exposures such as sedentary behavior or higher intensities of physical activity. Across the topic areas the PAGAC has identified several research-related issues that require particular attention (e.g., reconciling self-report and device-measured physical activity data). **CONCLUSION:** The PAGAC is charged with reviewing the available scientific evidence, considering public comments, and ultimately submitting a comprehensive scientific report to HHS. While clear topics and questions have been established, key research issues will need to be addressed during this process in order to produce a report that best informs public health guidelines.

Promotion Of Nutrition Care By Australian Fitness Businesses: A Website Analysis

Katelyn Barnes, Lauren Ball, Ben Desbrow. *Menzies Health Institute Queensland & Griffith University, Southport, Australia.*
(Sponsor: Professor Louise Burke, FACSM)
Email: k.barnes@griffith.edu.au

(No relationships reported)

Purpose Fitness professionals are well placed to simultaneously facilitate improvements in physical activity and dietary behaviours. However, concerns regarding the competence of fitness professionals to provide nutrition care have been raised. More than 85% of fitness professionals provide nutrition care beyond the recommended scope of practice. It is currently unclear if the provision of nutrition care beyond scope of practice is intentional, or if it arises as a consequence of discussions around lifestyle modification. The aim of this study was to investigate the intention of fitness professionals to provide nutrition care, by comparing the advertised nutrition content of fitness business websites and social media pages with a national scope of practice document for fitness professionals. Fitness businesses were targeted because advertisement of a service indicates that it would be provided, and advertisements may influence public expectations of fitness professional services. **Methods** Inductive content analysis of websites and social media sites was undertaken for 36 registered fitness businesses in Queensland, Australia. This review included 8 franchise fitness businesses with more than 400 sites each across Australia and was conducted from August to October, 2014. Advertisements were considered *within scope* if they referred to national nutrition guidelines or dietetic services, *at risk* of being beyond scope if they advertised services that were not clearly in line within national nutrition guidelines, or *beyond scope* if they advertised nutrition care beyond the fitness professional scope of practice, such as personalized dietary prescription outside of national dietary guidelines. **Results** Of the businesses reviewed, 15% advertised content classed as *within scope*, 34% were *at risk*, and 51% were *beyond scope*. These included advertisements for diet planning and nutrition counselling, as well as food or nutrition claims, and recipe provision. **Conclusions** Many fitness businesses advertised nutrition care, provided by their staff members, which extended beyond the recommended scope of practice for fitness professionals. Strategies that support fitness professionals to provide nutrition care of value to clients, without extending beyond their scope of practice, are warranted.

Globalizing the ACSM Certified Personal Trainer Job Task Analysis: The Case Study of China

Melanie Poudevigne, FACSM¹, Richard Cotton², Yuri Feito, FACSM³, Rachele Kappler⁴, Chris Pitsikoulis⁵. ¹*Clayton State University, Morrow, GA.* ²*American College of Sports Medicine, Indianapolis, IN.* ³*Kennesaw State University, Kennesaw, GA.* ⁴*University of Akron, Akron, OH.* ⁵*Aurora University, Aurora, IL.*
Email: mpoudevigne@gmail.com

(No relationships reported)

China relies on foreign vendors such as the American College of Sports Medicine (ACSM) certifications and related workshops to educate its exercise specialists. **PURPOSE:** Examine the relevancy of the current ACSM Job Task Analysis (JTA) for the Certified Personal Trainer (CPT) certification in China. **METHODS:** Seventeen Chinese (including six females) and six Taiwanese (including two females) fitness professionals (age: 34.95±5.10 years) attended an ACSM CPT workshop in Shanghai, China in 2016. At the end of the workshop, U.S. presenters verbally read each JTA in English to the participants, and these were simultaneously translated verbally into Mandarin. The JTAs consist of knowledge and skills (N=191) covering four domains (D): Initial Client Consultation & Assessment (D1; N=58), Exercise Programming & Implementation (D2; N=53), Exercise Leadership & Client Education (D3; N=27), and Legal, Professional, Business & Marketing (D4; N=53). The participants were asked, "How relevant is the JTA in China?" on a scale of 1 to 3 (1: excellent, 2: somewhat relevant; 3: poor). **RESULTS:** Response rate was 87%. 67% of the participants reported that the JTAs' relevancy was excellent and 21% somewhat relevant. When individual JTAs were combined to represent their specific domain collectively, the frequency of a poor rating was 12% for D1, 5% for D2, 10% for D3, and 34% for D4. T-tests revealed that 48 JTAs were significantly ($p<0.05$) higher than the hypothesized score of 1. D4 and D1 contained the majority of these higher scores, 64% and 30% respectively (v. D2 and D3, around 10%). Specifically, the initial client consultation and interview for health appraisals, medical clearance, seeking client feedback for exercise enjoyment, dietary guidelines, liability, safety policies, professional attire, business models and plan, marketing materials and networking, copyrights and client confidentiality were significantly different. **CONCLUSIONS:** This is the first time that the ACSM CPT JTAs are investigated abroad showing an impact on their relevance for a foreign country. The desire to create a set of international JTAs outside of the U.S. should

be recommended by certified and culturally sensitive ACSM professionals. The new international JTAs should also be specific to the culture for the concerned region of the world.

Influence of Ischemic Preconditioning on Glucose Tolerance in Obese and Overweight Adults

Simon P. Fredericks. *Colorado State University, Fort Collins, CO.* (Sponsor: Raoul Reiser II, FACSM)

(No relationships reported)

The ergogenic and protective cardiovascular benefits of ischemic preconditioning (brief and repeated occlusion of blood flow) have been well described; it is unclear if ischemic preconditioning also provides metabolic benefit. **PURPOSE:** To determine the influence of lower limb ischemic preconditioning on glucose regulation in overweight and obese adult humans. **METHODS:** Following initial screening, 10 men and women (age: 45 ± 4 years; body mass index: 30.4 ± 1.2 kg/m² (mean ± SE)) visited the laboratory on 2 separate and randomly ordered occasions, separated by a minimum of 14 days. Automated pressure cuffs were inflated/deflated on alternate legs to either 20 mmHg (control condition) or 200 mmHg (ischemic preconditioning), in five-minute intervals, for a total of 40 minutes (20 minutes per leg). 15 minutes post-treatment, subjects ingested 75g of glucose dissolved in 300 ml of water; circulating glucose and insulin concentrations were measured over 180 minutes. **RESULTS:** Area under the glucose response curve was lower ($P=0.026$) after ischemic preconditioning compared with control (17,840 ± 521 vs. 17,095 ± 393). This favorable attenuation of the glucose response curve could not be attributed to a modified circulating insulin response (area under the insulin curve: 8356 ± 1807 vs. 7641 ± 1353; $P=0.33$). **CONCLUSIONS:** These preliminary data suggest that ischemic preconditioning may improve oral glucose tolerance in overweight and obese adults, without affecting the circulating insulin response. In addition to possessing ergogenic and protective cardiovascular properties, ischemic preconditioning may also provide metabolic benefit to overweight and obese adults.

Effects of a Sedentary vs. Active Lifestyle on Blood Glucose Uptake

Joohee Im, Abby Bogner, Kaitlyn Brandt, Hector Raya, Ciara Stanley, William (Turi) Braun, FACSM. *Shippensburg University, Shippensburg, PA.* (Sponsor: William A. Braun, FACSM)

Email: jooheem@yahoo.com

(No relationships reported)

It is well known that obesity, led by sedentary lifestyle, increases the risk of developing cardiovascular and metabolic disorders. However, whether leading a sedentary lifestyle alone would independently increase the risk of developing these diseases is less clear. **Purpose:** To examine the effects of sedentary (SED) vs. active (ACT) lifestyles on blood glucose (BG) uptake at rest and post exercise to identify possible predisposition for metabolic and cardiovascular diseases in young adults. **Methods:** Seven SED (age 21.0 ± 0.6 years; height 164.8 ± 6.2 cm; weight 57.9 ± 8.5 kg; % body fat 16.7 ± 5.6%) and thirteen ACT (age 20.3 ± 1.0 years; height 173.3 ± 9.5 cm; weight 66.8 ± 9.7 kg; % Body Fat 13.0 ± 6.2%) individuals participated in the study. After obtaining baseline anthropometric measures, BG was monitored at 15 minute intervals under two separate conditions; resting (R) and after exercise (E). During E, subjects cycled for 30 minutes at 60% of their estimated VO_{2max} . Before, during, and after E, subjects' heart rate (HR), blood pressure (BP), and rate of perceived exertion (RPE) were measured. Each condition was separated by a minimum of 24 hours. A 2 x 2 ANOVA was performed to make comparisons between groups (SED vs. ACT) and conditions (R vs. E). **Results:** For the baseline measure, significantly higher resting HR was seen in SED when compared to ACT (SED 95.3 ± 13.9 vs ACT 79.9 ± 14.5 bpm, $p<0.05$). Furthermore, a trend of higher BG was shown in SED throughout the hour post exercise when compared to ACT. However, these differences were not significant ($p<0.05$). Interestingly, this trend of higher BG was shown during the E condition but not during the R condition. **Conclusion:** Sedentary lifestyle in young adults may lead to early alterations in cardiovascular function. Although the difference in glucose uptake between SED and ACT groups was less clear, adapting an active lifestyle should still be considered to promote an individual's health and well-being.

3566 Board #13 June 3 8:00 AM - 9:30 AM

Multiple Short Bouts Of Walking Activity Attenuate Blood Glucose Response In Obese Women

Mynor G. Rodriguez-Hernandez, Jeffrey Martin, David D. Pascoe, FACSM, Michael D. Roberts, Danielle W. Wadsworth. *Auburn University, Auburn, AL.* (Sponsor: David D. Pascoe, FACSM)
Email: mgr0018@auburn.edu
(No relationships reported)

PURPOSE: We sought to determine the effect of 2 and 5-min multiple walking breaks interspersed during sedentary time on blood glucose responses in sedentary obese women.

METHODS: 10 obese women (age = 36.1±16.3, BMI = 38.0±5.2, Body Fat= 49.57±4.35%) participated in this crossover-design study. All participants completed three conditions in randomized order; 1) 4-h of continuous sedentary behavior (SED), 2) 4-h of sedentary behavior with 2-min of walking at a moderate intensity every 30-min (SED+2m), and 3) 4-h of sedentary behavior with 5-minutes of walking at a moderate intensity every 30 minutes (SED+5m). 48-h of 'washout' occurred between conditions. A Continuous Glucose Monitor System (CGMS) was positioned on each participant's abdomen region for the entire experiment with calibration to "finger-stick" glucose values occurring 4 times/day. Body composition was assessed with iDXA and the actigraph accelerometry was used to assess sedentary behavior and physical activity.

RESULTS: Accelerometry measured sedentary time was 99.8%, 93.7% and 84% for the SED, SED+2m and SED+5m conditions, respectively. SED+5m significantly decreased plasma glucose levels during the protocol compared to the SED condition as evidenced by a reduction in 120-min post-prandial glucose (PPG)-area under the curve (AUC) (15.9±8.8 mg/dL/min vs 22.5±13.1 mg/dL/min for SED+5m and SED respectively, p=0.031), and 180-min PPG AUC (13.2±7.8 mg/dL/min vs 20.8±13.9 mg/dL/min for SED+5m and SED respectively, p=0.006). SED+2m 60-min PPG AUC and 120-min PPG AUC values were 14.2±11.1 mg/dL/min and 13.2±7.8 mg/dL/min, respectively, but were not found to be significantly different from either the SED or SED+5m conditions.

CONCLUSIONS: Our findings show that 5 minutes of moderate intensity walking each 30 minutes to interrupt sedentary behavior can attenuate PPG excursions in sedentary obese women.

The Effects Of Malnutrition On Muscle Strength And Self Care Ability Of Elderly Living Alone In Taiwan

Hui-fen Lin, Wan-ju Liu, Mei-ju Chi, Chueh-Ho Lin. *TAIPEI MEDICAL UNIVERSITY, Taipei, Taiwan.*
Email: a0923830128@gmail.com
(No relationships reported)

The aging population has been increasing globally and raising significant concern. Research points out that the prevalence of malnutrition in community-dwelling elderly was 35% - 40%, and the risk of malnutrition of elderly living alone was 11.1 times more than non-solitary elderly. Malnutrition led to poor health, frailty, disability and death as well as other serious problems, which further reducing elderly's quality of life and at the same time increasing healthcare costs.

PURPOSE: This study aimed to investigate muscle strength and self-care ability of elderly living alone with malnutrition status.

METHODS: A total of 229 elderly individuals age 65 and above (aged 78.93 ± 7.65 years) were recruited and divided into nutrition group (MNA ≥ 12, N = 126) and malnutrition group (MNA < 12, N = 103) based on their nutritional status by mini nutritional assessment short form (MNA-SF). Muscle strength and self-care ability were measured, including maximum grip force was measured by electronic grip equipment, activities of daily living (ADL) and instrumental activities of daily living (IADL).

RESULTS: The results showed 45% elderly living alone had malnutrition. Comparing to the nutrition group, the maximum grip strength, activities of daily living and instrumental activities of daily living for elderly living alone with malnutrition were decreased by 11% ($t_{(227)} = 4.401$, $p < 0.000$), 9% ($t_{(227)} = 4.947$, $p < 0.000$) and 23% ($t_{(227)} = 5.822$, $p < 0.000$), respectively.

CONCLUSIONS: Malnutrition may reduce muscle strength and self-care ability of elderly living alone, thus it is imperative to pay attention to their food intake and conduct periodical nutritional assessment in order to early intervene malnutrition. To establish of regular exercise habits, appropriate muscle strength training, increase muscle strength and activity function.

Association Between Nutritional Risk, Physical Function, and Physical Activity in Older Adults

Randall J. Gretebeck, Wan-Chin Kuo, Carly E. Babino, Kimberlee A. Gretebeck. *University of Wisconsin-Madison, Madison, WI.*
Email: rgretebeck@wisc.edu
(No relationships reported)

Under nutrition in older adults leads to increased incidence of illness, disease, disability, slow recovery, and poor outcomes, as well as worsening of existing disease and illness. While community based exercise programs are available to help older adults improve mobility and increase physical activity (PA) levels, screening for adequate nutrition is often overlooked and may impede improvements in mobility and PA. **PURPOSE:** To examine the association between nutritional risk, physical function and PA in older adults. **METHODS:** One hundred four participants (age= 71.0 yrs±7.7); BMI=33.1±7.9) completed questionnaires related to nutritional risk (SCREEN Nutritional Risk Questionnaire) for older adults, physical function (Physical Function Questionnaire, PFQ), and physical activity (PA, CHAMPS physical activity questionnaire). Additional physical function measures included: 1) timed up and go (TUG), which involved rising from a chair, walking three meters, returning to the chair and sitting down, 2) usual gait speed (UGS) over a six-meter distance, and 3) 6-minute walk (6MW). Spearman correlation coefficients were used to examine the association between nutritional risk and the different measures of physical function and PA. **RESULTS:** In this population of community dwelling older adults, 34.4% were considered to be at risk of under nutrition. There was a significant association ($p < 0.05$) between nutritional risk and PFQ ($r = .291$), TUG ($r = -.247$) and UGS ($r = -.263$). There were also significant associations between PFQ and TUG ($r = -.508$), PFQ and UGS ($r = -.630$), and PFQ and 6MW ($r = .524$). There was not a significant association between nutritional risk and 6MW ($r = .12$). **CONCLUSIONS:** These results suggest that risk of under nutrition is prevalent in older adults living in the community. In addition, risk of undernutrition is related to objective and subjective measures of physical function. Given the association between nutritional risk and mobility, community based exercise and PA programs for older adults designed to improve mobility and physical function should include screening for nutritional risk with appropriate follow-up.

3569 Board #16 June 3 8:00 AM - 9:30 AM

Effects of A Kefir Diet on Kidney Antioxidant Enzymes of Rats Treated with Doxorubicin

Raquel B. Busekrus¹, Michael J. Capps¹, Laura K. Stewart¹, Keely O'Brien², Charles Boenke², Matthew Christensen¹, David S. Hydock¹. ¹University of Northern Colorado, Greeley, CO. ²Louisiana State University, Baton Rouge, LA.
(No relationships reported)

Doxorubicin (DOX) is a potent chemotherapy drug whose mechanisms of action includes generation of reactive oxygen species (ROS), and as such, its use as an anticancer drug is limited by toxicities in non-cancer cells. The kidney is susceptible to oxidative stress (OS), and it has been shown previously that DOX disrupts antioxidant enzyme expression. Exogenous antioxidant administration has been shown to minimize OS associated with kidney injury, and as such, interventions to protect against DOX-induced antioxidant disruption in the kidney would be of benefit. The fermented milk product kefir (K) has antioxidant properties and acts to protect against ROS-induced cell damage, but K's effect on the DOX treated kidney has yet to be explored. **PURPOSE:** To examine the expression of catalase (CAT), glutathione peroxidase (GPx) and cytosolic superoxide dismutase (SOD1) in the kidney of rats fed K prior to and during DOX treatment. **METHODS:** Male rats were randomly assigned to one of four groups: kefir+saline (K+S), kefir+DOX (K+D), milk+saline (M+S), or milk+DOX (M+D). Rats were fed either a diet supplemented with K or a milk-based control diet for 8 weeks before and after receiving 15 mg/kg DOX or saline (SAL) as a placebo. Five days after injections, kidneys were excised and Western blotting was performed to assess CAT, GPx, and SOD-1 expression. **RESULTS:** No significant drug effect ($p = 0.11$), diet effect ($p = 0.08$), or interaction ($p = 0.76$) was observed for CAT, and a 26% greater CAT expression was observed in K+D when compared to M+D. With GPx expression, no significant drug effect ($p = 0.09$), diet effect ($p = 0.11$), or interaction ($p = 0.66$) was observed, and K+D had a 32% lower GPx expression than M+D. No significant SOD-1 drug effect ($p = 0.07$), diet effect ($p = 0.61$), or interaction ($p = 0.46$) was observed, and K+D had a 27% lower SOD1 expression than M+D. **CONCLUSIONS:** DOX did not significantly alter kidney CAT, GPx, or SOD1 expression in K or M fed animals suggesting no significant protective effect of chronic K feeding on kidney antioxidant expression versus chronic M feeding. Future work, however, should include standard chow as a control diet to better elucidate the impact DOX has on kidney as it is possible that both K and M were protective against the antioxidant changes typically observed with DOX.

Pre-adolescent Cardio-metabolic Associations And Correlates: Pacmac
 Nicholas Castro¹, Paula Skidmore², Mark Weatherall³, James Faulkner⁴, Sally Lark¹, Michelle Williams⁵, Lee Stoner⁶. ¹Massey University, Wellington, New Zealand. ²University of Otago, Dunedin, New Zealand. ³University of Otago, Wellington, New Zealand. ⁴University of Winchester, Winchester, United Kingdom. ⁵Harvard University, Boston, MA. ⁶University of North Carolina, Chapel Hill, NC.
 Email: n.castro@massey.ac.nz
 (No relationships reported)

The process of atherosclerosis is increasingly frequently initiating during preadulthood. The early onset of atherosclerosis has been linked to cardiometabolic complications, including obesity, which in turn are associated with deficient lifestyle behaviors.

PURPOSE: Assess the associations between body fitness and lifestyle behaviors with cardiometabolic health in prepubescent children aged 8-10 years.

METHODS: Three hundred ninety two children aged 8-10 years (195 male, 197 female; 9.5 ± 1.1y) were recruited from three regions across New Zealand. Body composition was evaluated using anthropometric measurements (waist: hip ratio) and bio-electrical impedance analysis (body fat %). Cardio-respiratory fitness was calculated using the 20-meter shuttle run. Physical activity and sedentary behavior was estimated using the Youth Physical Activity Questionnaire. Nutritional behavior was evaluated using the New Zealand Adolescent Food Frequency Questionnaire (processed food, fruit/veg consumption, breakfast foods). Quality of sleep was assessed using the Child Sleep Habits Questionnaire (duration, habits, social jet lag). Cardiometabolic health was gauged using pulse wave analysis to assess blood pressures (diastolic, systolic, central systolic) and arterial wave reflections (augmentation pressure), and finger prick procedures to evaluate fasting blood lipids (LDL, HDL, total cholesterol, triglycerides), glucose, and glycosylated hemoglobin.

RESULTS: The cardiometabolic variables were reduced to 4 factors using principle component analysis: (blood pressure, cholesterol, vascular, carbohydrate-metabolic). Following adjustment for co-founders, body fat % associated with blood pressure and vascular factors. Cardio-respiratory fitness and strength associated with CHO-Met, whereas sedentary associated with cholesterol and vascular factors. Processed foods associated with vascular, whereas fruit/veg associated with cholesterol. Social lag associated only with cholesterol.

CONCLUSION: One common factor is unlikely to define cardiometabolic health in pre-adolescent children, and each of the underlying cardiometabolic health factors is associated with different lifestyle behaviors.

3571 Board #18 June 3 8:00 AM - 9:30 AM
Cardio-metabolic Risk Variables In Pre-adolescent Children - A Factor Analysis
 Lee Stoner, 27599-8700¹, Mark Weatherall², Nicholas Castro³, Paula SKidmore⁴, Sally Lark³, James Faulkner⁵, Michelle Williams⁶, Claudio Battaglini, FACSM¹. ¹University of North Carolina, Chapel Hill, NC. ²University of Otago, Wellington, New Zealand. ³Massey University, Wellington, New Zealand. ⁴Otago University, Dunedin, New Zealand. ⁵University of Winchester, Winchester, United Kingdom. ⁶Harvard, Boston, MA.
 (Sponsor: Claudio Battaglini, FACSM)
 Email: dr.l.stoner@gmail.com
 (No relationships reported)

BACKGROUND: Atherosclerosis begins during pre-adolescence and is occurring at an accelerated rate. This acceleration has been linked to poor lifestyle behaviors and subsequent cardio-metabolic complications. Although the clustering of cardio-metabolic risk factors has been recognized for well over two decades, previous studies in children have predominantly examined the relationships between atherosclerosis and individual cardio-metabolic risk factors, or have grouped together pre-adolescent and adolescent children. Further, no known studies have included glycosylated haemoglobin (HbA1c), or central hemodynamic measures such as central blood pressure (cSBP) and augmentation index (AIx). **PURPOSE:** In pre-adolescent children, explore the: (1) underlying factors that explain cardio-metabolic risk factors using principle components analysis; (2) unique value of HbA1c, cSBP and AIx; (3) associations between cardio-metabolic risk factors and overweight-obese status. **METHODS:** Principle component analysis was performed on 392 children (9.54 y, 50% F) from three representative sample sites across New Zealand. **RESULTS** Four factors explained 60% of the variance in the measured variables. In order of variance explained, the factors were: blood pressure (cSBP, peripheral systolic and diastolic blood pressure), adiposity (waist circumference, body mass index, HbA1c), lipids (total cholesterol, low-density lipoproteins, high-density lipoproteins) and vascular (AIx, heart rate, fasting blood glucose [FBG]). For each factor, except lipids, the overweight-obese had a small-large likelihood of having higher (worse) risk scores.

CONCLUSIONS: In accordance with previous findings in adults and adolescents, one common factor is unlikely to define cardio-metabolic health in pre-adolescent children. Each of the factors, except vascular, which was predominantly explained by AIx, are in agreement with previous findings in adolescents. An additional novel finding was that HbA1c and FBG loaded on to different factors, supporting previous work suggesting that FBG indicates short-term glycemic control whereas HbA1c reflects chronic glycemic control. Lastly, overweight-obese pre-adolescents were found to have worse scores for the adiposity, blood pressure and vascular factors.

Daily Heart Rate in Relation to Cardiorespiratory Fitness and Metabolic Syndrome in HIV+ Hispanic Adults
 Annette M. Medina-Encarnacion, Amariyls Romero-Reyes, Farah A. Ramirez-Marrero, FACSM. University of Puerto Rico, San Juan, Puerto Rico.
 Email: amme3157@gmail.com
 (No relationships reported)

Daily heart rate (HR) is usually higher among HIV+ compared with HIV- adults, a possible aspect of chronotropic incompetence (CI) in this population. Low cardiorespiratory fitness (CRF) and metabolic syndrome (MetSyn) are prevalent among HIV+ adults, possibly influencing CI. However, information regarding 24-hr HR as an index of CI, and its association with CRF and MetSyn in this population is non-existent. **PURPOSE:** To describe the association between CRF, MetSyn, and daily HR in a group of HIV+ and HIV- Hispanic adults in Puerto Rico. **METHODS:** Eighty-Nine adults (59-HIV+ and 30 HIV-) completed measurements of CRF (VO₂ peak), 24-hr blood pressure and HR, and metabolic syndrome (fasting glucose and lipid profile, resting BP, waist circumference). T-tests were used to detect differences between groups, and correlation analyses to evaluate associations between variables. **RESULTS:** The proportion of low CRF based on age and sex, and MetSyn was not different between HIV+ and HIV-participants (56 vs. 40%; and 53 vs. 37%; P=0.2, respectively). However, 24-hr HR, daytime HR, and night-time HR were all significantly higher in HIV+ compared with HIV- participants (78.3±9.4 vs. 67.4±8.4, 81.9±9.9 vs. 69.7±8.6, 70.7±9.4 vs. 62.7±9.0 bpm, respectively, P<0.05 for all). VO₂ peak was inversely correlated with 24-hr HR, daytime HR, and night-time HR in both groups (ρ = -0.40, -0.36, -0.49, P<0.05 for all). Considering CRF classification in each group, all HR measures were significantly lower among those with high CRF vs. low CRF regardless of HIV status (HIV+: 24-hr HR by CRF: low= 81.1±8.2 vs. high= 74.8±9.7 bpm, P=0.009; daytime HR: low=85.0±8.7 vs. high=78.0±10.2 bpm, P=0.006; night-time HR: low=72.8±8.7 vs. high=68.0±9.8 bpm, P=0.02) (HIV-: 24-hr HR by CRF: low= 72.1±4.4 vs. high= 64.2±9.9 bpm, P=0.009; daytime HR: low=74.1±4.9 vs. high=66.8±9.4 bpm, P=0.02; night-time HR: low=67.8±6.1 vs. high=59.2±9.1 bpm, P=0.008). No HR differences were observed by MetSyn in the HIV+ group, but HR measures in the HIV- group were lower in those without MetSyn. **CONCLUSION:** These results suggest that CRF but not MetSyn, influence daily HR in HIV+ participants, with potential impact on CI correction. Intervention studies must be conducted to confirm these results. Supported by: NIH/CTSA KL2-RR024151, NIH/NIMHHD 8U54MD 007587-03.

 (No relationships reported)

In individuals with cardiometabolic risk factors, meal timing in relation to exercise may be important for optimal metabolic control. The holistic approach of metabolic fingerprinting can provide new insights into metabolic changes due to stimuli such as exercise and meal consumption. **PURPOSE:** To investigate the effect of prior meal consumption on the serum metabolic fingerprint of exercise. **METHODS:** Eight overweight sedentary men participated in two trials: high-intensity interval exercise (HIIE) after the consumption of a standardized meal (postprandial exercise, PpEx) and HIIE in the fasted state (postabsorptive exercise, PaEx). Blood samples were collected before and immediately after exercise for targeted metabolomic analysis by liquid chromatography-mass spectrometry (HLIC-UPLC-MS/MS). Data for the 45 identified serum metabolites were subjected to univariate and multivariate analysis. **RESULTS:** A two-way repeated measures ANOVA on peak areas revealed six metabolites with significant trial x time interaction: alanine (PpEx, 11 ± 10 % change from baseline vs PaEx, 39 ± 17 %; p = 0.04), betaine (PpEx, 4 ± 1 % vs PaEx, 1 ±

8 %; $p = 0.03$), glutamate (PpEx, -23 ± 13 % vs PaEx, 2 ± 17 %; $p = 0.04$), serine (PpEx, 3 ± 9 % vs PaEx, 3 ± 16 %; $p = 0.01$), threonine (PpEx, 9 ± 13 % vs PaEx, 3 ± 21 %; $p = 0.01$), and uridine (PpEx, 1 ± 20 % vs PaEx, 20 ± 23 %; $p = 0.01$). Partial least-square discriminant analysis separated the metabolic fingerprints of PpEx and PaEx immediately after exercise ($R^2Y = 0.935$, $Q^2Y = 0.629$, $CV\text{-ANOVA} p = 0.03$). Discriminating metabolites with VIP score > 1 were: leucine-isoleucine, lysine, and tryptophan, which were higher after PpEx; and acetylcarnitine, hypoxanthine, taurine, pyruvate, and lactate, which were higher after PaEx. **CONCLUSION:** The response of the serum metabolic fingerprint to exercise in overweight sedentary men depends on the prior consumption of a meal. Our findings support the value of metabolic fingerprinting in the study of exercise metabolism.

Lipid And Glucose Profiles Of Middle-aged Male Runners After 3-week High Fat-low Carbohydrate Diet**

Ashton F. Waddell¹, Yunsuk Koh², Alexander J. Heatherly¹, Lauren G. Killen¹, Hunter S. Waldman¹, Angela Hollingsworth¹, Eric K. O'Neal¹. ¹University of North Alabama, Florence, AL. ²Baylor University, Waco, TX. (Sponsor: James Matthew Green, FACSM)
(No relationships reported)

PURPOSE: High fat-very low carbohydrate diets (HFLC) have become increasingly popular in the endurance community, but there is little data concerning the effects of HFLC on markers of cardiovascular disease risk. The aim of this study was to examine glucose and lipid marker responses following a prolonged HFLC. **METHODS:** Eight middle-aged (39.5 ± 9.9 y), trained but non-elite ($VO_{2peak} = 48.5 \pm 4.5$ ml/kg/min) runners (1.77 ± 0.08 m; 81.7 ± 7.0 kg; $19.3 \pm 6\%$ body fat) served as participants. Venous blood was drawn from an antecubital vein after an overnight fast with standardized evening fluid intake on 4 occasions. During the first phase, runners simply consumed their habitual high carbohydrate diet (HC). Blood was collected around 0600 following ~48 h of restriction from any intense exercise. A 50-min run in the heat followed by a 5-km time trial was implemented following blood collection to induce significant heat and exercise stress. A fasted blood sample was acquired the subsequent morning to further delineate the influence of exercise stress. This protocol was repeated after 3 weeks during which time runners continued normal training but consumed < 50 g of carbohydrate/day with ~70% of daily calories derived from fat. **RESULTS:** Diet intervention approached ($p = 0.07$) but did not reach significance for glucose. Triacylglycerol did not differ between treatments (pre-exercise HC = 65 ± 17 ; HFLC = 67 ± 35 mg/dL) but decreased ($p < 0.05$) for both treatments 24-h after exercise (HC = 42 ± 16 ; HFLC = 35 ± 21 mg/dL). There was a main effect for diet on HDL-C (pre-exercise: HC = 48 ± 10 and 50 ± 11 ; post-exercise: HFLC = 57 ± 13 and 60 ± 13 mg/dL). There was also a main effect ($p = 0.02$) for diet on LDL-C with HFLC exceeding HC at both collection points by ~20 mg/dL. Total cholesterol was approximately 30 mg/dL higher for HFLC both before and 24-h after exercise ($p < 0.05$). There was no change in VLDL-C and Lp(a). **CONCLUSION:** Implementing a HFLC does not appear to elicit significant negative cardiovascular disease risk in male runners 30-50 years of age with desirable pre-intervention lipid and glucose marker status.

(No relationships reported)

Low-carbohydrate high-fat (LCHF) diets are regaining popularity for improving glucose control in patients with type 2 diabetes (T2D). However, largely based on studies in rodents and findings from cell culture models, concern still remains over the possible pro-inflammatory and cardiovascular risk consequences of consuming a diet high in fat. The well-recognized anti-inflammatory and cardioprotective properties of exercise makes it a potential adjuvant to therapeutic LCHF diets. **PURPOSE:** To determine the impact of a short-term 1) LCHF diet, 2) LCHF diet with daily post-meal walking (LCHF+PW) and 3) low-fat, low glycemic index "guidelines" (G) diet on glucose control, markers of cellular inflammation, and cardiovascular risk factors in patients with T2D. **METHODS:** Nine individuals with T2D (age: 63 ± 9 , HbA1c: 6.7 ± 0.9 , means \pm SD) completed three isocaloric 4-day controlled diet conditions in a randomized crossover design. The LCHF+PW diet included three daily 15-min post meal walks at a light-to-moderate intensity. Glucose profiles were assessed by continuous glucose monitoring. Fasting blood samples were obtained before and after each intervention to measure glucose and lipids. Cellular markers implicated in the pro-inflammatory effects of excess lipids, including monocyte toll-like receptor 2 (TLR2) and 4 (TLR4) and platelet-monocyte aggregates (PMA), were measured by flow cytometry. **RESULTS:** When compared to G (7.3 ± 1.2 mmol/l), both the LCHF (6.6 ± 1.3 mmol/l) and LCHF+PW (6.4 ± 1.1 mmol/l) diets decreased the 4-day

mean glucose concentrations ($p < 0.001$). PMA count per ml increased significantly after G ($+27 \pm 16\%$, $p = 0.02$) but was not significantly altered after LCHF ($+21 \pm 68\%$, $p = 0.06$) or LCHF+PW ($-0.1 \pm 42.5\%$; $p = 0.99$). Median fluorescence intensity of TLR4 on CD16+ monocytes decreased by ~4.3% ($p = 0.05$) after the LCHF diet. No other significant changes were seen in monocyte TLR2 or TLR4 (all $p \geq 0.106$). **CONCLUSIONS:** As compared to a G diet, four days of a LCHF diet reduced hyperglycemia and improved some inflammatory markers in people with T2D. The addition of three daily post meal walks did not appear to further improve glycemic or inflammatory status. Funding from Canadian Institutes of Health Research (MSH-141980) and Medtronic Diabetes.

Subjective and Objective Measures of Physical Exertion in Adults With and Without Type 2 Diabetes**

Deirdre M. Rafferty, Rebecca L. Scalzo, Susanna Carter, Judith G. Regensteiner, Amy G. Huebschmann. University of Colorado, Aurora, CO.
(No relationships reported)

PURPOSE: Regular exercise is a cornerstone of type 2 diabetes (T2D) management because it improves cardiovascular outcomes. However, greater perceived effort at low absolute work rates remains a barrier to exercise for people with T2D. In turn, disparities in perceived effort are linked to poor adherence to regular exercise. It remains unknown if the link between T2D and greater perceived effort is due to lower peak oxygen consumption levels (VO_{2peak}). We hypothesized that exercise effort would be greater in people with T2D at relative work rates below the anaerobic threshold (AT), as compared to healthy counterparts. As T2D impacts VO_{2peak} more profoundly in women than men, we also hypothesized that sex would modify the association between T2D and exercise effort. **METHODS:** During assessment of VO_{2peak} , we measured objective (heart rate (HR)) and subjective exercise effort (Borg Rating of Perceived Exertion (RPE)) every 1 and 2 minutes, respectively. AT was identified by V-slope method. Group differences in RPE and HR were determined at 15%, 25% and 35% of VO_{2peak} . **RESULTS:** We analyzed data from 112 previous adult participants in our laboratory (Table). As compared to nondiabetic participants, we found greater effort (Table) at 25% VO_{2peak} (HR) and at 35% VO_{2peak} (RPE). We found no sex differences in the association between T2D and effort.

	Healthy men and premenopausal women (n = 55)	Men and premenopausal women with T2D (n = 57)	p-value
Age (yrs)	44.7 (6.3)	45.9 (6.1)	
BMI (kg/m ²)	29.4 (3.3)	30.9 (4.1)	
VO_{2peak} (ml/kg/min)	24.5 (6.6)	20.7 (4.5)	
Peak RER	1.22 (0.08)	1.21 (0.11)	
RPE at 15% VO_{2peak}	8.1 (1.5)	8.6 (1.7)	0.24
RPE at 25% VO_{2peak}	9.3 (1.5)	9.3 (2.0)	0.92
RPE at 35% VO_{2peak}	10.2 (1.5)	10.9 (1.6)	0.04*
HR at 15% VO_{2peak}	89.1 (11.5)	91.5 (9.5)	0.13
HR at 25% VO_{2peak}	93.2 (9.3)	96.8 (10.0)	0.02*
HR at 35% VO_{2peak}	101.4 (10.9)	104.2 (10.7)	0.11

Data presented as mean (standard deviation); * $p < 0.05$; Abbreviations: BMI, Body Mass Index; VO_{2peak} , Peak oxygen utilization; RER, Respiratory Exchange Ratio; RPE, Rating of Perceived Exertion; HR, heart rate.

CONCLUSION: T2D status conferred greater objective and subjective exercise effort at some but not all relative work rates below AT in T2D compared to nondiabetic adults. Counter to our hypothesis, there were no sex differences in the association between T2D and effort. Contradictions with our prior studies showing higher exercise effort for participants with T2D may be explained by differences in exercise test protocols and the use of relative work rates. Future research should assess if T2D status influences exercise effort during relative work rates of longer duration. Supported by ADA grants 7-02-CR-25, 1-08-CR-52, 1-12-CT-64

¹University of Texas Rio Grande Valley, Edinburg, TX. ²Texas Woman's University, Houston, TX.
 Email: lawrence.pabalinas@gmail.com
 (No relationships reported)

PURPOSE: To quantify the prevalence of prediabetes and diabetes in college-aged students 18-30 years old at a Hispanic-serving institution in south Texas.
METHODS: Fasting glucose levels and hemoglobin A1C levels, along with BMI from two hundred twenty college-aged students 18-30 years old (women: 152, men: 68) were quantitatively analyzed and compared with the American Diabetes Association's (ADA) 2015 prediabetes and diabetes criteria. An independent t-test between females and males identified the statistical significance and variance of the anthropometric measurements and blood biomarkers. These results were organized and analyzed by gender and colleges across campus.

RESULTS: Females fasting glucose (92.56±27.23 mg/dL), A1C levels (5.744±0.922%), as well as BMI (32.72±9.060) and males fasting glucose (96.25±27.52 mg/dL), A1C levels (5.772±1.050%), and BMI (32.41±9.302) were below the blood biomarker levels that define diabetes. However, students showed risk for prediabetes at this young age according to the 2015 ADA prediabetes A1C criteria (5.7-6.4%). The A1C levels across colleges ranged between 5.6% College of Health Affairs (COHA), 5.62% College of Sciences (COS), 5.7% College of Education (COE), 5.71% College of Business and Entrepreneurship (COBE), 5.8% College of Liberal Arts (COLA), 6.0% College of Fine Arts (COFA), and 6.1% College of Engineering and Computer Science (COECS). Females showed a greater prevalence in prediabetic A1C levels at 40.13% with a mean of 5.744, while males exhibited 27.94% at an average of 5.772. The t-test assessment concluded that no statistically significant differences (p<0.05) in fasting glucose levels (p=0.36), A1C levels (p=0.9), and BMI (p=0.81) between genders were found.

CONCLUSIONS: This research targets a young population where early intervention would be most effective. Results indicated that 5 out of the 7 colleges were prediabetic according to the A1C levels. Moreover, the gender comparison in prevalence proved that females were at a greater risk for prediabetes and diabetes than males. These findings suggest that surveillance and education is recommended for the prevention of chronic metabolic conditions in college-aged students at a Hispanic-serving institution.

Omega-3-Fatty Acids Hold Therapeutic Potential for the Prevention and Treatment of Diabetic Neuropathy

J. Claire Maciejewski, Matthew P. Harris, Megan L. Schaller, David S. Umbaugh, Karen E. Sandoval, Ken A. Witt, Joshua S. Wooten, Brianne L. Guilford. Southern Illinois University Edwardsville, Edwardsville, IL.
 (No relationships reported)

Mice fed a high fat diet exhibit signs of neuropathy including mechanical hindpaw hypersensitivity and neuronal inflammation, suggesting high fat diet-induced inflammation may play a role in the development of neuropathy. Omega-3 (n-3) fatty acids have anti-inflammatory properties and may hold therapeutic potential as a preventative treatment for prediabetic and diabetic patients at risk for neuropathy.
PURPOSE: Investigate the impact of diet composition on signs of neuropathy. We hypothesized that a diet rich in n-3 fatty acids would attenuate hindpaw hypersensitivity during prolonged feeding of a high fat diet. **METHODS:** C57BL/6 mice were randomized into four diet groups (n = 12/group) for 32 weeks: 10% low fat-fish oil (LFFO), 41% high fat-fish oil (HFFO), 10% low fat-lard (LFL), or 41% high fat-lard (HFL). Neuropathy was characterized at baseline and every other week thereafter using the von Frey behavioral test for hindpaw mechanical sensitivity. A glucose tolerance test was performed at end study, and total area under the curve (AUC) was calculated using the trapezoidal method. **RESULTS:** At end study, body weight was greater in HFL compared to all other groups. Body weight was also greater in HFFO compared to LFFO. Fasting glucose and glucose AUC were higher in HFL compared to LFFO and HFFO. Following the same pattern as body weight, fasting glucose was higher in HFFO compared to LFFO. Although percent paw withdrawal was greater in HFL compared to HFFO and LFFO, there were no significant differences for LF vs. HF for fish oil or lard.

End Study Values (32 wks)	Low Fat Fish Oil (LFFO)	High Fat Fish Oil (HFFO)	Low Fat Lard (LFL)	High Fat Lard (HFL)
Body weight (g)	34.3 ± 0.6	39.5 ± 1.6 ^a	37.2 ± 1.1	44.3 ± 1.7 ^{a,b,c}
Fasting glucose (mg/dl)	129.1 ± 5.6	152.0 ± 7.7 ^a	148.1 ± 5.2	158.8 ± 8.8 ^a
Glucose AUC total (mg /120 min / dl)	5368.1 ± 678.9	7282.6 ± 1144.4	7384.3 ± 685.4	9149.6 ± 1013.8 ^a
Percent paw withdrawal (%)	22.5 ± 4.5	29.2 ± 6.4	37.5 ± 7.2	54.2 ± 5.7 ^{a,b}

^aP < 0.05 vs. LFFO; ^bP < 0.05 vs. HFFO; and ^cP < 0.05 vs. LFL

CONCLUSION: A HFL diet induced signs of neuropathy including hindpaw hypersensitivity, whereas a fish oil diet was protective against hindpaw hypersensitivity. Moreover, omega-3-fatty acids may hold therapeutic potential for neuropathy prevention in nondiabetic and diabetic patients.

Muscle Specific Overexpression PGC-1α1 Promotes Exercise Adaptations During Western Diet Regardless Of Exercise Volume

Megan E. Rosa-Caldwell, Jacob L. Brown, David E. Lee, Thomas A. Blackwell, Richard A. Perry, Jr., Wesley S. Haynie, Lemuel A. Brown, Tyrone A. Washington, Nicholas P. Greene. University of Arkansas, Fayetteville, AR. (Sponsor: Dr. Stephen F. Crouse, FACSM)
 Email: mrosa@uark.edu
 (No relationships reported)

Obesity and its associated comorbidities remain the pivotal public health concern of the 21st century. One interest in the development of insulin resistance is the degeneration and dysfunction of skeletal muscle mitochondria. PGC-1α1, the principle regulator of mitochondrial biogenesis has been proposed as a possible therapeutic target to alleviate lipid overload-induced mitochondrial dysfunction. Yet current data remain controversial on the efficacy of artificially promoting PGC-1α1 as a therapeutic modality. **PURPOSE:** The purpose of this study was to investigate the efficacy of genetic overexpression of PGC-1α1 alone and in combination with physical activity as a therapeutic agent during lipid overload. **METHODS:** wild type (WT, ~20) mice and mice with muscle-specific overexpression of PGC-1α1 (MCK-PGC-1α, ~20) were given Western Diet (WD) at 8 wks of age and allowed to consume food *ad libitum* throughout the course of the study. At 12 wks of age, animals were further divided into sedentary (SED) and physical activity (voluntary wheel running [VWR]) interventions. At ages 7, 11, and 15 wks animals underwent glucose tolerance tests (GTT). At 16 wks of age animals were humanely euthanized and tissues collected for analysis. Results were analyzed by 2X2X3 repeated measures ANOVA with an α=0.05. **RESULTS:** MCK-PGC-1α animals were lighter and had less epididymal fat compared to WT (~6% and ~28% respectively). Food efficiency (weight gained:food consumed) was ~17% lower in MCK-PGC-1α animals. While there was no difference at 7 wks age, at 11 wks age MCK-PGC-1α had ~50% greater GTT integrated area under the curve (IAUC) compared to WT. Yet at 15 wks, VWR had 30% lower IAUC compared to SED, regardless of genotype. MCK-PGC-1α -VWR ran ~3X more per day compared to WT-VWR. Correlations for wheel running distance per day v. IAUC, body weight, and epididymal fat were significant and moderately strong (r=0.67-0.71) for WT-VWR, but in MCK-PGC-1α there was no correlation between these variables and wheel running distance per day (r=0.10-0.20). **CONCLUSION:** These results suggest increasing PGC-1α1 promotes exercise-induced adaptations regardless of exercise volume, but overexpression of PGC-1α1 during lipid overload without physical activity does not mitigate insulin resistance and may in fact exacerbate the condition.

Differential Metabolic Responses to Acute Fatmax and Lactate Threshold Exercise

Timothy D. Allerton¹, Kate Early², Carl Lavie, Jr³, Neil Johannsen¹. ¹Louisiana State University, Baton Rouge, LA. ²Columbus State, Columbus, GA. ³Ochsner, New Orleans, LA.
 Email: taller2@lsu.edu
 (No relationships reported)

Improvements in glucose tolerance and insulin action with aerobic exercise may be the result of increase glucose utilization and/or more complete oxidation of intramuscular triglycerides. **PURPOSE:** To investigate the effect of acute aerobic exercise at an intensity that maximizes the rate of fat oxidation (FM) on glucose tolerance, insulin action, and metabolic flexibility (MF) compared to acute aerobic exercise at lactate threshold (LT) resulting in greater carbohydrate (CHO) oxidation. **METHODS:**

Participants (aged 20.5±1.5y, BMI 29.5±4.7kg/m²) performed a VO_{2max} and baseline 2hr OGTT (n=8). Isocaloric (400 kcal) exercise sessions at FM (41±12%VO_{2max}) and LT (68±10%VO_{2max}) were performed with an OGTT ~24-hrs post-exercise. **RESULTS:** FM exercise elicited significantly (p<0.01) greater fat utilization (18.6±12.1g) than LT (10.1±20.3g) during exercise. Accordingly, LT (82.8±12.1g) exercise elicited significantly (p<0.05) greater CHO utilization than FM (62.4±20.3g) exercise. There was no significant difference in total energy expenditure between FM (416.1±11.4) and LT (422.1±10.4) exercise (p=0.2). However, AUC for glucose was significantly higher for LT exercise than baseline and FM exercise (p<0.05). MF was significantly (p<0.05) reduced post-FM (Δ120-min RER=0.04±0.03) exercise when compared to baseline (0.13±0.04). **CONCLUSION:** LT exercise appears to have deleterious effects on oral glucose tolerance acutely, however, FM exercise does not confer improved MF. These results suggest a disconnect between glucose tolerance and MF and that preferential substrate utilization does not promote comprehensive metabolic improvements acutely in young overweight men.

the final exercise session. **RESULTS:** At baseline, 2AAA and PEDF were positively correlated with HOMA-IR (r = 0.54 and 0.43, respectively) and inversely correlated with insulin sensitivity (r = -0.60 and -0.62, respectively). After the exercise program, body mass and composition were unchanged. The AIT group increased peak cycling power 11% and absolute VO_{2peak} 8% (p<0.05, effect size 0.3 for both) but the CME group did not increase aerobic fitness. HOMA-IR was unchanged in either group but insulin sensitivity during the meal was modestly increased, though only in the CME group (+5%, p<0.03, effect size 0.38). Neither PEDF (-4% overall) nor 2AAA (-12% overall) were significantly altered by the exercise, though the changes in their concentrations were positively correlated with one another (r=0.62). **CONCLUSION:** A short term exercise program has only modest effect on insulin sensitivity in habitually sedentary, overweight adolescents, and does not alter the concentration of either PEDF or 2AAA. Physical activity is important for blood glucose management in people with Type 2 diabetes (T2D). Little research has explored the relationship between sedentary behaviour and mean glucose and glucose variability in people with T2D using objective and continuous measurements. **Aims:** To explore the relationship between sedentary bout duration and mean glucose and glucose variability in people with T2D using objective continuous measurement. **Methods:** 16 participants with T2D managed with diet, Metformin or DPP4 inhibitors were recruited (mean age 64.1±10.9 yr & BMI 29.4±6.9 kg/m²). Participants completed a demographic questionnaire and wore an activPAL accelerometer and FreeStyle Libre continuous glucose monitor for 3-14 days whilst documenting sleep, food and medication. Average proportion of time spent sitting/lying, during the waking day were calculated. Bouts of wake time sedentary behaviour were identified and defined as a period of at least 30 minutes continuous, uninterrupted sitting/lying during the waking day. Correlation analysis was conducted to investigate the relationships between sedentary bout duration and mean glucose, glucose range and glucose coefficient of variation. **Results:** On average, participants spent 65% of their day sitting/lying, 76% of sedentary bouts were ≥30minutes and 29% of bouts were ≥60minutes. Mean glucose was negatively (r = -0.08, p <0.01) associated with sedentary bout duration. Glucose range (r =0.47, p <0.001) and glucose coefficient of variation (r = 0.26, p <0.001) both positively correlated with sedentary bout duration. Participant characteristics such as age, gender and BMI appear to influence the relationship between sedentary bout duration and glucose response. **Conclusions:** Results indicate increased sedentary time leads to improved mean glucose and increased glucose variability.

Physical activity is highly beneficial in patients with type 1 diabetes (T1D). The American Diabetes Association recommends at least 150min/week of moderate intensity aerobic physical activity, defined as 50–70% of maximum heart rate (HR_{max}); however, exercise intensity prescribed as percentages of HR_{max} leads to inhomogeneous cardio-respiratory acute responses when dealing with individuals with T1D where chronic stress may affect β₁-receptor sensitivity. **PURPOSE:** To determine the exercise intensity given as percentages of HR_{max} in T1D patients versus healthy controls (nT1D) related to the degree and direction of the HR performance curve (HRPC). **METHODS:** Eight male T1D patients (25±5 yrs, BMI: 24±2 kg/m², HbA1c: 7.3±0.6%, duration of diabetes: 15±9 yrs) and eight male nT1D (26±5 yrs, BMI: 23±2 kg/m²) performed an incremental exercise test (IET) until exhaustion (start 40 W; increase 20 W/min). nT1D were matched for age and maximum power output (P_{max}), respectively. The first and the second lactate turn points (LTP₁/LTP₂), as well as the direction and degree of the time course of HRPC (k_{HR}), were determined from IET and compared to 50% and 70% of HR_{max}. k_{HR}, power output (P) and HR at LTP₁ were compared between groups in relation to 50% and 70% of HR_{max}. Group differences were calculated by an ANOVA with post-hoc testing, p<0.05. **RESULTS:** No significant differences were found between both groups for HR_{max} and P_{max} (p>0.05). HR at LTP₁ vs. 50%HR_{max} and 70%HR_{max} were significantly different for both groups, except for the nT1D group at 70%HR_{max}. P at 50%HR_{max} was significantly lower than at LTP₁ in both groups; at 70%HR_{max} P was significantly higher only in T1D (p<0.05). Significant differences for P between both groups were only found at 70%HR_{max} (133±17 W vs. 91±38 W, p<0.05) 50%HR_{max} was as low as resting conditions (0 W) in 38% of the T1D group and 50% of the nT1D. k_{HR} was lower in T1D (0.21±0.30 vs. 0.39±0.27) but the difference was not statistically significant (p>0.05). **CONCLUSION:** 50%HR_{max} is clearly too low to induce any training effects even when exercising 150min/week. A lower k_{HR} for the acute HR response in T1D patients indicates a reduced β₁-receptor sensitivity, which needs to be respected for the calculation of target exercise intensities.

Several novel biomarkers of risk for diabetes in adults have been reported that have not been carefully examined in adolescents with metabolic risk factors. We previously reported that pigment epithelial derived factor (PEDF) is increased in obese adolescents and associated with insulin resistance. 2-aminoadipic acid (2AAA) was shown to predict future diabetes onset in the Framingham study, and to decline in adults following insulin sensitizer treatment. Exercise can also increase insulin sensitivity but it is unknown whether PEDF or 2AAA are altered by exercise in adolescents. **PURPOSE:** To determine whether a short-term exercise program could alter insulin sensitivity, PEDF, and 2AAA in adolescents. **METHODS:** 22 habitually inactive, overweight/obese boys and girls (15±1 y, BMI-z 1.62±0.9, BMI 94±1 %ile, 36±2% body fat) performed 2 supervised and 1 home-based exercise session per week for 5 weeks. Half of the group performed continuous moderate intensity exercise (CME; 45-min walking at 70% HRmax) while the other half performed aerobic interval training of matched total energy expenditure (AIT; 4 x 4-min at 90% HRmax with 3-min recovery intervals at 60% HRmax plus 5-min warm up and cool down). A mixed meal test with blood sampling was performed at baseline and 40 hours after

Purpose: The prevalence of type 2 diabetes mellitus (T2DM) is increasing worldwide and exercise has been shown to be a key component in the prevention of this disease. However, there is limited information comparing metabolic control in T2DM patients after high intensity interval training (HIIT). The purpose of this study was to compare body composition and metabolic changes following 16 weeks of continuous aerobic training (AT) or HIIT in T2DM patients.

Methods: Twenty-four sedentary T2DM patients (age: 46 ± 6 years, body mass index (BMI): 30 ± 5.5 kg/m², glycosylated hemoglobin (HbA1C) 6.3 ± 0.9 %) were included in this study. Maximal heart rate (HR_{max}) and oxygen consumption (VO_{2max}) were measured before and after the interventions. Participants were then randomly allocated to AT (3 times/week, 60 minutes, at 70% HR_{max}) or HIIT (3 times/week, 10 × 1:1 work-to-rest ratio, at ~85% HR_{max}) on a cycle ergometer. Anthropometrics, blood pressure, and metabolic markers (plasma glucose, HbA1c, total cholesterol, triglycerides and HDL) were obtained before and after the interventions. Data are presented as means \pm SD. Statistical analysis included repeated measured ANOVA with LSD *post hoc* analysis.

Results: No significant differences were observed between groups at baseline. Following the interventions, both groups decreased BMI (0.9 ± 0.7 kg/m², $P < 0.04$ vs. 0.03 ± 0.7 kg/m², $P < 0.01$), waist circumference (-0.4 ± 0.7 vs. 2.3 ± 4.8 , $P < 0.001$ for both) and increased VO_{2max} (7.65 ± 3.2 vs. 6.51 ± 3.6 , $P < 0.001$ for both). Although glucose significantly decreased in the HIIT group (-28 ± 46 P < 0.05), it was not significantly different compared to the no change in the AT group.

Conclusions:

Metabolic changes, aerobic fitness and measures of central adiposity were similarly improved in both groups following 16 weeks. Therefore, HIIT is an efficient alternative to continuous aerobic training for diabetic patients who enjoyed high intensity training.

Table 1. Clinical, anthropometric and metabolic characteristics

Relationship Between Mitochondrial Respiration and Glucose Tolerance in Individuals at Risk of Type 2 Diabetes

Justin J. Reid, Adam R. Konopka, William M. Castor, Jaime L. Laurin, Christopher A. Wolff, Miles T. Whedbee, Karyn L. Hamilton, FACSM, Benjamin F. Miller, FACSM. *Colorado State University, Fort Collins, CO.*

(No relationships reported)

The relationship between skeletal muscle mitochondrial respiration and development of chronic diseases is a highly contentious topic since assessment of mitochondrial function varies across studies. **PURPOSE:** To determine if ex-vivo mitochondrial respiration of permeabilized muscle fibers is related to postprandial glucose tolerance in individuals at risk of developing Type 2 Diabetes (T2D). **METHODS:** Participants (n=27; ≥ 55 yrs), with impaired fasting glucose (100-125 mg/dL), HbA1c (5.7-6.4%), impaired glucose tolerance (140-200 mg/dL) or family history of T2D twice arrived overnight fasted for an oral glucose tolerance test (OGTT) or a skeletal muscle biopsy. Glucose area under the curve (AUC) was determined after a standard 75g glucose load. Vastus lateralis skeletal muscle samples were permeabilized and evaluated by high-resolution respirometry during 2 substrate-uncoupler-inhibitor-titration (SUIT) protocols. SUIT1 evaluated NADH supported respiration during complex I-linked leak (CI_I) and maximal coupled oxidative phosphorylation (OXPHOS; CI_P) with sequential addition of fatty acid (CI&FAO_P) and complex II-linked carbohydrate substrates to determine OXPHOS (CI+CI&FAO_P) and uncoupled electron transport system (ETS) respiration. SUIT2 used an ADP titration to determine ADP sensitivity followed by evaluation of CI_P, CI+II_P, and ETS capacity. **RESULTS:** All p-values < 0.05. In SUIT1 CI_I (r=-0.45), CI+II&FAO_P (r=-0.48), and ETS (r=-0.50) were negatively correlated with glucose AUC. In SUIT2, CI_P (r=-0.60), CI+II_P (r=-0.46), and uncoupled maximal ETS (r=-0.52) were all associated with glucose AUC, as well as CI_P/CI_I (r=0.63) and CI+II&FAO_P/CI_I (r=0.63). **CONCLUSION:** In both SUIT protocols maximal mitochondrial OXPHOS and ETS were negatively correlated with glucose AUC in participants at risk for T2D. These data suggest that mitochondrial capacity is associated with impaired glucose tolerance and may contribute to the progression of T2D. Further studies will determine if there are defects in proteostatic mechanisms that impair mitochondrial function in these individuals. Funding provided by the National Dairy Council.

Neuronal Inflammation: A Potential Contributing Mechanism to High Fat Diet-Induced Neuropathy

David S. Umbaugh, J. Claire Maciejewski, Brianne L. Guilford. *Southern Illinois University Edwardsville, Edwardsville, IL.*

Email: dumbaug@siue.edu

(No relationships reported)

Neuropathy, a debilitating complication of diabetes, has primarily been attributed to poor glycemic control, but has recently been associated with obesity and the metabolic syndrome in nondiabetic individuals. A robust body of evidence indicates that a high-fat diet can induce signs of neuropathy in mice but the pathogenesis of high fat diet-induced neuropathy remains unknown.

PURPOSE: To determine if neuronal inflammation is a potential initiating mechanism for the development of mechanical hypersensitivity and nerve fiber changes (signs of neuropathy) in high fat fed mice. **METHODS:** Male C57Bl/6 mice were randomized to a standard (Std, 15% kcal from fat) or high fat diet (HF, 54% kcal from fat) for 2, 4, or 8 wks (n = 11-12 per group). Lumbar dorsal root ganglia were harvested and inflammatory mediators (IL-1 α , IL-1 β , IL-2, IL-3, IL-4, IL-5, IL-6, IL-10, IL-12p70, IL-17, MCP-1, IFN- γ , TNF- α , MIP-1 α , GM-CSF, RANTES) were quantified using a Multiplex ELISA and normalized to total protein. Neuropathy was characterized by the von Frey test for mechanical sensitivity at wk 0 and every other week thereafter. Hindpaw foot pad skin was harvested at end study and used to quantify intraepidermal nerve fiber density (IENFD) and pain-sensing (TrkA) nerve fibers via immunohistochemistry. **RESULTS:** After 8 wks, HF had greater bodyweight (33.3 ± 1.0 vs. 26.7 ± 0.5 g, p < 0.001), fasting blood glucose (160.3 ± 9.4 vs. 138.5 ± 3.4 mg/dl, p < 0.05) and insulin (3.58 ± 0.46 vs. 0.82 ± 0.14 μ g/L, p < 0.001) compared to Std. IL-1 α and IL-5 were higher in HF compared to Std after 2 wks and 4 wks, respectively (IL-1 α : 4.8 ± 1.3 vs. 2.9 ± 0.6 pg/mg, p < 0.05; IL-5: 5.8 ± 0.7 vs. 3.1 ± 0.5 pg/mg, p < 0.05). IENFD and TrkA fiber density were also higher in HF vs. Std after 4 wks (IENFD: 39.4 ± 1.2 vs. 32.2 ± 1.3 fibers/mm, p < 0.001; TrkA: 30.4 ± 1.8 vs. 22.4 ± 1.3 fibers/mm). There were no significant differences in hindpaw sensitivity for Std vs. HF at any time point. **CONCLUSION:** Increased inflammatory mediators preceded and accompanied an increase in a specific population of pain sensing nerve fibers (TrkA) in the hindpaw footpad of high fat fed mice. Diets high in fat may increase neuronal inflammation and initiate nerve fiber changes responsible for painful neuropathy in nondiabetic and diabetic individuals.

Association Between Whole-body Vo2peak And Skeletal Muscle Mitochondrial Respiration In Adults At Risk Of Diabetes

William M. Castor, Adam R. Konopka, Jaime Laurin, Christopher A. Wolff, Karyn L. Hamilton, FACSM, Benjamin F. Miller, FACSM. *Colorado State University, Fort Collins, CO.*

(No relationships reported)

Whole body oxygen consumption (VO_{2peak}) is a strong predictor of morbidity and mortality. In populations at risk for chronic disease, the relationship between skeletal muscle mitochondrial respiratory capacity and VO_{2peak} is relatively unexplored.

PURPOSE: To identify associations between VO_{2peak} and mitochondrial respiration in adults at risk for Type 2 Diabetes (T2D). **METHODS:** We enrolled 23 older adults (63+/-6yrs) at risk for T2D as defined by impaired fasting glucose (100-126mg/dL), HbA1c (5.7-6.4%), impaired glucose tolerance (140-200mg/dL), or a family history of T2D. VO_{2peak} was measured during a graded exercise test on a cycle ergometer while mitochondrial respiration was assessed in permeabilized skeletal muscle fibers obtained from muscle biopsy samples of the vastus lateralis. Two different substrate-uncoupler-inhibitor-titration (SUIT) protocols were implemented. SUIT1 evaluated carbohydrate supported respiration during complex I-linked leak (CI_I) and maximal coupled oxidative phosphorylation (OXPHOS; CI_P) with sequential addition of fatty acid (CI&FAO_P) and complex-II linked carbohydrate substrates to determine OXPHOS (CI+II&FAO_P) and uncoupled electron transport system (ETS) respiration. SUIT2 utilized an ADP titration to determine mitochondrial ADP sensitivity, as defined by apparent ADP Km, followed by OXPHOS and ETS capacity. **RESULTS:** VO_{2peak} (ml/kg/min) correlated with CI_P (r=0.687, p=0.0003) and ETS (r=0.454, p=0.047). When analyzing relative to VO_{2peak} expressed as fat free mass (FFM), these correlations were further strengthened (CI_P: r=0.694, p=0.0002; ETS: r=0.547, p=0.007). **CONCLUSIONS:** Our findings demonstrate skeletal muscle mitochondrial respiratory capacity is significantly correlated to VO_{2peak} in those at risk for T2D and is strengthened when adjusted for FFM. The data may provide a mechanistic link between mitochondrial dysfunction and the predictive value of VO_{2peak} on morbidity and mortality.

The Effect of a Western Diet on Hepatic Autophagy in Age Accelerated SAMP8 Mice
 Matthew P. Harris, Megan L. Schaller, David Umbaugh, Karin Sandoval, Ken A. Witt, Joshua S. Wooten. *Southern Illinois University Edwardsville, Edwardsville, IL.*
 Email: matthar@siue.edu
 (No relationships reported)

Non-alcoholic steatohepatitis (NASH) is characterized as a dysregulation of hepatic lipid metabolism and a chronic inflammatory state. It is hypothesized the link between lipid dysregulation and inflammation may be due in part to defective hepatic autophagy and reduced mitochondrial capacity to oxidize fatty acids. It remains to be determined; however, the effects of a Western diet on hepatic autophagy and mitochondrial function during aging. **PURPOSE:** The purpose of this study was to determine the effect of a high-fat high-fructose diet (HFF) on markers of hepatic autophagy and mitochondrial function in an age-accelerated mouse model. **METHODS:** Twenty-week old, male and female, SAMP8 mice (n=49) were randomly assigned, matching for gender, to either a standard chow (SC) or HFF (45% fat, 24% fructose) diet for 32 weeks. Liver tissue was analyzed for mRNA expression of autophagic (BNIP3, Beclin 1, p62, and Atg7) and mitochondrial (PGC-1 α and COX-IV) genes. Differences between gender and dietary groups were identified by a 2 x 2 ANOVA and statistical significance was set at p<0.05. **RESULTS:** Following 32 weeks of feeding, male mice fed the HFF diet were significantly heavier than male mice in the SC group (31.6 g vs 26.5 g; p=0.001); however, no difference was observed between diet groups for female mice. The HFF diet resulted in higher autophagic activity as observed by Beclin 1 (+36%; p=0.001) and BNIP3 (+40%; P=0.003) expression. Despite the higher autophagic activity, p62 was higher (+31%; p<0.001) in the HFF compared to the SC group, suggesting impaired autophagic flux. In addition, mitochondrial COX-IV expression was elevated (+43%; P<0.001) in the HFF group compared to the SC group suggesting increased β -oxidation. Overall, the expression of all autophagic and mitochondrial markers was higher in male compared to female mice; however, both sexes responded similarly to the HFF diet. **CONCLUSION:** Despite the higher expression of autophagic and mitochondrial genes, elevated expression of p62 suggests an impaired autophagic flux in age-accelerated mice following a Western diet.

Fish-oils Increase BAMBI Expression to Protect Against Fibrotic Activity in LPS Stimulated Hepatic Tissue
 Megan L. Schaller, Matthew P. Harris, Dakota Kamm, Kenneth A. Witt, Karin E. Sandoval, Joshua S. Wooten. *Southern Illinois University Edwardsville, Edwardsville, IL.*
 (No relationships reported)

Non-alcoholic steatohepatitis (NASH), defined as excess hepatic lipid and chronic inflammation, provides an environment prone for the development of hepatic fibrosis. Recent evidence suggests that the antifibrotic protein BAMBI (BMP-Activin membrane bound inhibitor) is downregulated in the presence of inflammation, and may be central to the development of fibrosis. Diets rich in omega-3 (ω -3) fatty acids are known to provide anti-inflammatory effects; however, the effects of ω -3 fatty acids on hepatic fibrosis are not well-established. **PURPOSE:** To determine the effects of fish-oils on the hepatic fibrosis signaling cascade, following 32-weeks of high-fat feeding in a LPS-induced model of NASH. **METHODS:** Male C57BL/6 mice were randomly assigned to one of four diets for 32 weeks (n=9/group): low-fat lard based (LFL, 10% kcal fat), low-fat fish-oil based (LFFO, 10% kcal fat), high-fat lard based (HFL, 41% kcal fat), or high-fat fish-oil based (HFFO, 41% kcal fat). Following *in situ* LPS stimulation, liver mRNA expression of CD14, TLR4, MyD88, BAMBI, and TGF- β 1 was quantified using quantitative RT-PCR. Differences between diets were identified using a one-way ANOVA with statistical significance set at p<0.05. **RESULTS:** Following LPS stimulation, CD14 was increased 2.5 fold (p=0.020) in HFFO when compared to HFL. Despite the increase in CD14, TLR4 showed no difference between groups. In contrast, MyD88 was 2.8 fold greater (p<0.001) in HFL compared to HFFO. In comparison to untreated tissue, BAMBI was 1.7 fold (p=0.017) higher in the HFFO LPS-stimulated tissue, which best explained the 1-fold (p=0.004) lower expression of TGF- β 1 in HFFO when compared to HFL post-LPS stimulation. **CONCLUSION:** Despite the increase in extracellular LPS signaling receptor CD14, the consumption of fish-oils produced a protective intracellular response as observed by an increase in BAMBI and decrease in TGF- β 1. These results suggest that a diet high in ω -3 fatty acids may protect against the development of hepatic fibrosis.

Adiposity, Physical Activity and Sedentary Time in Overweight Children With and Without Hepatic Steatosis
 María Medrano¹, Lide Arenaza¹, Beatriz Rodríguez-Vigil², Cristina Cadenas-Sánchez³, Sara Maldonado-Martín¹, Catherine L. Davis⁴, Francisco B. Ortega³, Idoia Labayen¹. ¹University of Basque Country, UPV/EHU, Vitoria-Gasteiz, Spain. ²University Hospital of Txagorritxu, Vitoria-Gasteiz, Spain. ³University of Granada, Granada, Spain. ⁴Medical College of Georgia, Augusta University, Augusta, GA.
 Email: maria.medrano@ehu.eus
 (No relationships reported)

PURPOSE: To examine differences in adiposity, physical activity (PA) and sedentary time (ST) between overweight and obese children with or without non-alcoholic fatty liver disease (NAFLD). **METHODS:** A total of 35 overweight and 54 obese (IOTF) children (46 girls) aged 8- 12y from the EFIGRO trial were included in this study. Hepatic fat content was measured by magnetic resonance imaging and body fat percent (BF%) by Dual X-ray Absorptiometry. Children were categorized into two groups according to the presence (n=41) or absence (n=48) of NAFLD (\geq 4.85% or <4.85% of hepatic fat, respectively). PA and ST were measured using accelerometers over 7 days. PA was categorized into light (LPA), moderate to vigorous (MVPA) and VPA. **RESULTS:** There were not found significant differences in BMI (26.2 \pm 0.5 vs. 25.1 \pm 0.4 kg/m², respectively, age and sex adjusted P=0.10) and obesity percentage (63.4% vs. 58.4%, respectively, adjusted P=0.60) between children having or not having NAFLD. However, BF% was higher in children with NAFLD than in those without NAFLD (41.4 \pm 0.7% vs. 38.7 \pm 0.7%, respectively, adjusted P=0.01). Children with NAFLD spent less time in VPA (6.28 \pm 0.85 vs. 8.51 \pm 0.77 min/day, respectively, P=0.06) and total PA (3517 \pm 99 vs. 3815 \pm 91 cpm, respectively; P=0.03) than those without NAFLD regardless of age, sex and accelerometer wear time, but were diminished after further adjustment for BF%. There were no significant differences in ST, LPA and MVPA between children with or without NAFLD (Ps>0.05). **CONCLUSIONS:** Overweight children with NAFLD had higher adiposity and spend less time in total PA, particularly in VPA, than their peers without NAFLD, regardless of their overweight/obesity status. These results suggest that health intervention programs should promote total PA, especially VPA, to prevent an excess of adiposity and hepatic steatosis in overweight and obese children.

Effects Of Paradoxal Sleep Deprivation On Liver Functionality Of Sedentary Rats
 Marcus L. Santos, Marcos Mónico Neto, Kil Sun Lee, Carolina Foot Moura, Daniel Araki Ribeiro, Luciana Le Sueur Maluf, Hanna Moreira Antunes. *Universidade Federal de São Paulo, São Paulo, Brazil.*
 Email: marcus.santos.nutri@gmail.com
 (No relationships reported)

PURPOSE: Evaluate the influence of PSD and sleep recovery (SR) on the integrity and functionality of liver in sedentary rats
METHODS: Thirty male Wistar rats, 3 month old, were distributed into 3 groups: Control (CTRL), submitted to PSD for 96h (PSD96), and PSD for 96h plus sleep recovery period for 96h (SR96). After the protocol, the rats were euthanized and blood sample were collected to analyze corticosterone, insulin, alanine aminotransferase (ALT) and aspartate aminotransferase (AST). A central fragment of liver was process by immunohistochemistry and the 8OHdG, TNF- α , COX-2 inflammation and oxidative stress biomarkers was performed. The data were analyzed by one-way ANOVA with Tukey *post hoc*, p<0.05. The present study was approved by ethics and research committee of Universidade Federal de São Paulo (8357240615). **RESULTS:** The corticosterone and AST concentrations increased in PSD96 and SR96 respectively compared to CTRL (148.87 \pm 71.06 vs 44.58 \pm 24.34; 95.03 \pm 18.47 vs 61.44 \pm 15.5 respectively; P<0.05) and insulin in PSD96 group decreased compared to CTRL (0.96 \pm 0.94 vs 5.72 \pm 2.88 respectively; P<0.05). The qualitative immunohistochemistry analysis showed an increase in 8OHdG and COX2 in SR96 group compared to CTRL (2.4 \pm 0.89 vs 0.66 \pm 0.51; 1.16 \pm 0.40 vs 0.33 \pm 0.51 respectively; P<0.05). No changes were seen for other variables. **CONCLUSIONS:** Hormonal and metabolic changes associated with PSD can modify parameters of inflammation and oxidative stress in the liver of sedentary rats. Physical exercise could be an important strategy to minimize the effects observed with PSD.

Asprosin, A Newly Identified Fasting-Induced Hormone Is Not Elevated In Obesity And Is Insensitive To Acute Exercise

Uwe Schumann¹, Shanhu Qiu², Katrin Enders¹, Edit Bosnyák¹, Roman Laszlo¹, Katja Machus¹, Emese Trájer¹, Sripriya Jagathan¹, Martina Zügel¹, Jürgen M. Steinacker, FACSM¹.
¹Ulm University Medical Center, Ulm, Germany. ²Zhongda Hospital, Institute of Diabetes, Southeast University, Nanjing, China. (Sponsor: Jürgen M. Steinacker, FACSM)
 (No relationships reported)

INTRODUCTION: White adipose tissue is the main source of circulating Asprosin - a newly identified protein hormone encoded by *FBN1*. It triggers hepatic glucose release into the bloodstream in order to maintain hemal energy standards between meals and is suggested to serve as target battling obesity and T2D. In obese male individuals plasma Asprosin levels were found to be increased twofold and in male Ob/Ob-mice, the *Fbn1*-mRNA expression was also elevated in skeletal muscle compared to non-obese animals (Romero et al. Cell 2016). **PURPOSE:** (i) To estimate the basal Asprosin secretion in obese women and (ii) to analyze the changes in Asprosin response after an acute bout of high intensity exercise in obese versus non-obese subjects. **METHODS:** 12 highly obese women (age 47.1±14.2; BMI 47.3±12.7) and 6 men (age 53.7±7.5; BMI 46.3±12.0) were matched to age and sex adjusted controls (age 46.1±13.6; BMI 21.6±2.2, age 52.3±5.0; BMI 23.8±1.5) and their resting serum Asprosin levels were analyzed using the human Asprosin ELISA kit from Wuhan EIAab Science, PR China. To evaluate Asprosin response to an exhaustive bout of exercise 14 obese individuals (10 women and 4 men) underwent an adapted treadmill protocol at individually adjusted speeds between 2 and 4.9 km/h constantly with increasing slopes, finishing >85% of their age-dependent maximal HR. Normal weight recreational athletes, 8 females (age 26.4±5.4; La max 9.0±1.8; HR max 190.6±8.6) and 9 males (age 25.8±6.8; La max 7.3±2.8; HR max 193.0±12.3) serving as controls performed a treadmill running test at a starting speed of 6 km/h with 2 km/h increments every 3 min accompanied by venous blood draws pre- and immediately post exercise. **RESULTS:** Resting Asprosin levels among obese women and men were comparable (19.9±36.7 and 7.1±7.5) and also similar to non-obese subjects (9.2±9.5 and 12.4±10.4) yet with huge individual variations. These results were reflected when individuals experienced acute exhaustive exercise with high interindividual distributions but low intraindividual spreadings applying to obese and lean subjects. **CONCLUSIONS:** Contrary to findings of Romero et al. we could not reproduce differences in Asprosin levels between obese and non-obese subjects. Also an acute bout of treadmill exercise did not affect Asprosin secretion in order to reflect hemal glucose status.

3593 Board #40 June 3 8:00 AM - 9:30 AM
Cross-validation Of The Developed Obesity Cut-off Points For Korean Adults

Junbae Mun¹, James L. Farnsworth², Heontae Kim¹, Minsoo Kang, FACSM¹. ¹Middle Tennessee State University, Murfreesboro, TN. ²Buena Vista University, Storm Lake, IA. (Sponsor: Minsoo Kang, FACSM)
 (No relationships reported)

PURPOSE: Establishing valid criteria for the diagnosis of obesity is important for screening and treating obesity-related disorders. Several different cut-off points (CP) have been developed for obesity to predict cardiovascular disease risk factors (CDRF) such as hypertension, dyslipidemia, and diabetes mellitus (DM) in Korean adults; however, there are no cross-validation studies for the developed obesity CP. Therefore, the aim of this study is to examine the diagnostic accuracy of obesity CP. **METHODS:** Data (9,425 adults [≥18 years], male = 4,031) from the 2008 and 2011 Korea National Health and Nutrition Examination Survey was analyzed to examine the accuracy of obesity CP developed using three obesity indices: body mass index (BMI; 23, 24, 25, & 26kg/m²), waist circumference (WC; 84, 85, & 90cm for male; 78, 80, & 85cm for female), and body fat percentage (BF%; 20, 21, & 26 for male; 36 & 37 for female). Participants with CDRF were operationally defined as having one or more of the followings; hypertension, dyslipidemia, and/or DM. CP of BMI, WC, and BF% were evaluated using Youden Index (YI; sensitivity [SE] + specificity [SP] - 1). To evaluate the CP with highest YI, adjusted odds ratios (OR) of having CDRF were calculated while controlling for age, sex, physical activity status, smoking, alcohol consumption, household income, and education level. **RESULTS:** Overall, SE and SP of the CP were low across three obesity indices (SE=29.26-75.86%, SP=46.51-85.98%). CP with highest YI were BMI of 23 (SE=69.25%, SP=53.21%), WC of 84 (SE=62.68%, SP=66.67%), and BF% of 20 (SE=75.86%, SP=46.51%) and BMI of 23 (SE=66.74%, SP=64.86%), WC of 78 (SE=69.52%, SP=67.89%), and BF% of 35 (SE=50.73%, SP=69.64%) for male and female, respectively. Obese adults were more likely to have CDRF compared to

none-obese adults (OR=2.61-2.96, 95% CI=2.19-3.63 for male; OR=2.05-3.00, 95% CI=1.69-3.60 for female, respectively). CP of WC had the highest YI and OR while the CP of BF% had the lowest for both male and female. **CONCLUSIONS:** WC of 84cm for male and 78cm for female were identified as the best obesity CP to predict CDRF for Korean adults. The overall diagnostic accuracy (i.e., SE and SP) of the obesity CP, however, was performed poorly. Therefore, caution is necessary when using the developed obesity CP.

Total Body Adiposity And Accumulated Visceral Adipose Tissue: Influence Of Age, Race/ethnicity And Sex

Philip R. Stanforth, Rachel M. Watson, Anna E. Talley. *The University of Texas at Austin, Austin, TX.* (Sponsor: Hiro Tanaka, FACSM)
 Email: p.stanforth@austin.utexas.edu
 (No relationships reported)

PURPOSE: It has been shown that visceral adipose tissue (VAT) does not increase linearly with an increase in total body fat percentage (BF%). Instead, a BF% threshold was identified above which VAT increases more rapidly. The primary purpose of this study was to investigate the effect of age, ethnicity, and sex on the BF% threshold at which the accumulation of VAT increases significantly. **METHODS:** A convenience sample of 3,211 (1,756 females and 1,455 males) participants, 18-75 years of age, who had a dual X-ray absorptiometry scan conducted at The Fitness Institute of Texas between 2008-2016, were included in this study. Self-selected ethnicities were Asian (18.1%), Black (6.7%), Hispanic (19.8%) and White (55.4%). A set of segmented linear regression models for each sex and ethnicity category were specified to estimate thresholds at which the relationship between BF% and VAT mass changed. **RESULTS:** The BF% threshold above which VAT increased more rapidly was identified and it varied between females and males and among ethnicities. The BF% threshold for females were: Asian 29.2%, Black 35.6%, Hispanic 31.7%, and White 34.2%. For males, the BF% thresholds were: Asian 25.3%, Black 23.9%, Hispanic 24.3%, and White 22.8%. There was more variability in VAT mass among participants above the BF% threshold than for those below. In order to attempt to explain this additional variability, age and ethnicity were added as covariates in multiple linear regression models applied to post-threshold participants, for both females and males separately. Post-threshold, the impact of BF% is amplified for older participants controlling for ethnicity for both females ($\beta = 0.28$, SE = .003, $p < .001$) and males ($\beta = 0.81$, SE = .006, $p < .001$), meaning that the VAT increased at a faster rate for older individuals. Controlling for age, BF% has a significantly lower impact on VAT mass for Black females compared to their White counterparts ($\beta = -3.05$, SE = 1.44, $p < .05$) and Asian males compared to their White counterparts ($\beta = -0.11$, SE = 2.3, $p < .001$), meaning that the VAT increased at a faster rate for White females and males than Black females and Asian males. **CONCLUSION:** The BF% threshold above which VAT increased more rapidly was identified and it varied by sex and ethnicity. Post threshold the increase in VAT was affected by age and ethnicity.

 (No relationships reported)

PURPOSE: Skeletal muscle dysfunction is a consequence of obesity, where changes in the extracellular matrix (ECM) and adiponectin dysregulation may play a role. To determine if an exercise regimen can prevent these changes we investigated the effect

of 10 weeks of two isocaloric training programs; moderate-intensity endurance (END) (70% of maximal running capacity (MRC)) or high intensity interval training (HIIT) (50-90% of MRC), in a mouse model of diet-induced obesity.

METHODS: Ten week-old male C57BL/6 mice were fed a high fat diet (HFD) (45% kcal from fat) *ab libitum*, and simultaneously underwent END or HIIT (3x40min sessions/week). Untrained HFD and chow-fed mice acted as controls. After 10 weeks mice were euthanased and *quadriceps* muscle was extracted for analysis.

RESULTS: END and HIIT, each with HFD, showed similar prevention in body weight (BW) gain ($p < .05$) (HFD=45±2g; END=37±2g; HIIT=36±2g), preserved fat-free mass (%FFM) (HFD=58±3; END=72±6; HIIT=72±7), and improved insulin sensitivity (blood glucose_{AUC}) during an insulin tolerance test (0.65 IU/kg*BW) (HFD=41±54; END=350±57; HIIT=320±66 A.U.). HFD induced decreases in grip strength (N) were prevented by END and HIIT similarly (HFD=1.42±0.06; END=1.53±0.10; HIIT=1.51±0.17; $P < .05$). Aerobic performance (treadmill progressive test) was higher in END and HIIT groups compared to untrained HFD, with END being superior to HIIT (2.8±0.5 and 2.2±0.3 fold-change respectively; $p < .05$). Fasting hyperglycaemia and hyperinsulinaemia found in HFD untrained mice (each $p < .05$ vs controls) were each partially prevented by END.

The higher collagen protein deposition found in HFD untrained mice, was not prevented by END nor HIIT. However, decreased collagen-I (~50% of controls; $p < .05$) and increased collagen-III (~2-fold controls; $p < .05$) seen in HFD untrained mice was prevented by both END and HIIT. Only END increased skeletal muscle adiponectin mRNA (14-fold; $p < .05$) compared to HFD untrained. Furthermore, END but not HIIT prevented the HFD downregulation in mRNA level of PGC1 α , and upregulation of UCP2 (1.5-fold; $p < .05$).

CONCLUSIONS: Whilst further research is needed to clarify the differential impact of END and HIIT in muscle function this data favour END training rather than HIIT in having muscle specific and metabolic advantages during high fat feeding.

Kefir Alters Cardiac Function and Left Ventricular Dimensions in a Model of Doxorubicin-Induced Cardiomyopathy

Peter Smoak¹, Reid Hayward¹, David Hydock¹, Keely O'Brien², Charles Boeneke², Matthew Christensen¹, Keegan Reeves¹, Jonathon Lisano¹, Laura K. Stewart¹. ¹University of Northern Colorado, Greeley, CO. ²Louisiana State University Agricultural Center, Baton Rouge, LA.
Email: petersmoak@gmail.com

(No relationships reported)

Doxorubicin (DOX), a powerful anthracycline antibiotic commonly used to treat many different forms of cancer, is associated with the production of reactive oxygen species that cause oxidative damage resulting in cardiac dysfunction. Kefir is a naturally fermented milk product containing antioxidants, probiotic bacteria and yeast.

The antioxidants contained in kefir interact with several types of reactive oxidative species, some of which act to manage oxidative stress. While recent studies suggest that consumption of kefir may have anti-tumor and antimicrobial properties, none have explored its potential for protecting against DOX-induced cardiac dysfunction.

PURPOSE: To explore the effects of dietary kefir on DOX-induced cardiotoxicity in rats. **METHODS:** Singly housed, 10 week old, male Sprague Dawley rats were placed on 1 of 2 isocaloric diets: milk control diet (CON n=24) or kefir diet (KEF, n=23) with equivalent macronutrient profiles. After 8 weeks of dietary intervention, all animals were given either a bolus injection (15 mg/kg) of DOX (CON-DOX, n=12; KEF-DOX, n=11) or saline (CON-SAL, n=12; KEF-SAL, n=12). Cardiac geometry and cardiac function were evaluated using echocardiography 5 days post injection, and data were analyzed using a 2 X 2 ANOVA. **RESULTS:** Significant effects were observed for left ventricular dimension at systole (diet $p=0.01$, drug $p=0.002$), left ventricular dimension at diastole (diet $p=0.01$ and drug $p < 0.0001$), peak mitral flow velocity (diet $p=0.02$ and drug $p < 0.001$), septal wall thickness at diastole (drug $p=0.0013$), ejection time (drug $p = 0.0039$), left ventricular mass (drug $p = 0.0085$), relative wall thickness (drug $p=0.0002$), and filling time (diet $p=0.0006$). **CONCLUSION:** Incorporation of kefir into the diet altered DOX-induced changes in rat cardiac function and morphology. We speculate that kefir may be an alternative strategy in mitigating the deleterious cardiac side effects of anthracycline chemotherapy.

Nexrutine, a Viable Exercise Mimetic for Prostate Cancer Prevention

Darpan I. Patel, Kira Pamerleau, Paul Rivas, Roble Bedolla, A. Pratap Kumar. University of Texas Health Science Center at San Antonio, San Antonio, TX.
Email: pateld7@uthscsa.edu

(No relationships reported)

Epidemiological data suggests that physical activity (PA) has the potential to decrease the risk of high-grade prostate cancer (PCa). However, for various reasons, cancer patients fail to meet minimum standards for physical activity. For this reason, efforts need to be made to discover biologics that confer the physiological benefits of exercise, serving as an "exercise mimetic." Previous work by our group has discovered that the natural product Nexrutine® (Nx), a bark extract of the *phellodendron amurense*, can inhibit tumor development in prostate, pancreatic and skin cancers. **PURPOSE:** To compare the effectiveness of Nx and exercise in modulating carcinogenesis of the prostate using the transgenic adenocarcinoma of mouse prostate (TRAMP) model. **METHODS:** 10-week old, male TRAMP mice were randomized to exercise, Nx or control groups (n=15 each). Mice randomized to the exercise group were given access to a running wheel and Nx treated mice were fed 600 mg/kg pelleted into their chow. Mice were sacrificed at weeks 4, 8, 12 and 20 weeks. Mice were monitored weekly for tumor development, activity and food consumption. Efficacy of exercise and Nexrutine was determined by histopathological evaluation of the prostate and tissue expression of pAkt and p65, key signaling proteins for carcinogenesis. One-way analysis of variance was performed with significance set at $p < 0.05$. **RESULTS:** No significant pathological changes were observed as a function of time, therefore, data were pooled for analysis. Animals on exercise intervention group ran an average of 4.4 km/day. Both exercise and Nx groups presented with palpable tumors 4 weeks later than the control group. While 100% of animals developed tumors (varying stages), Nx treated and exercising TRAMP mice had fewer poorly differentiated tumors compared to controls ($p < 0.05$). Only Nexrutine expressed lower pAkt in tumors. No differences were seen in p65 expression. **CONCLUSIONS:** Our data provides preliminary evidence that Nx can act as an exercise mimetic in protecting against tumor development in prostate cancer. Though both Nx and exercise decreased advanced stage tumors, only Nx has lower pAkt expression. Therefore, continued efforts need to be made to decipher the mechanisms by which exercise reduces tumors development.

Interfacing Continuous Glucose and Activity Measurement to Compare Glycemia after Exercise or Breaks from Sitting

Jennifer Blankenship¹, Stuart Chipkin¹, Patty Freedson, FACSM¹, John Staudenmayer¹, Barry Braun, FACSM².
¹University of Massachusetts, Amherst, MA. ²Colorado State University, Fort Collins, CO. (Sponsor: Barry Braun, FACSM, FACSM)
Email: jblanken702@gmail.com

(No relationships reported)

Physical activity is effective in the management of hyperglycemia and cardiovascular disease risk in type 2 diabetes (T2D). While light activity breaks in sitting time lower postprandial hyperglycemia in the laboratory, it is unknown whether these benefits are observed in a free living environment. **PURPOSE:** We compared the effect of increasing physical activity by breaks from sitting after meals (BR) or by a continuous morning walk (EX) on daily and postprandial glucose (PPG) concentrations (measured by continuous glucose monitoring). **METHODS:** Thirty individuals with T2D completed EX, BR and a control condition [normal behavior, (CON)] in a free-living environment, but with strict dietary control, over 7 days. Participants wore an activPAL physical activity monitor during the week and this device was used to verify compliance with experimental conditions (increase their total physical activity in EX and BR by 20, 40 or 60 minutes). Using linear mixed models with repeated measures we (1) compared PPG levels across conditions and (2) assessed the dose-response relationship between activity volume (20, 40 or 60 minutes) and glucose responses. Data are presented as mean (95% confidence interval). **RESULTS:** Compared to CON, EX significantly shortened the duration of postprandial hyperglycemia by 11.4% (7.4-15.4%) but BR was not different. In a subset of participants with high postprandial hyperglycemia at CON (n=9): (1) both EX and BR significantly shortened duration of hyperglycemia compared to CON by 23% (7.0-39.8%) and 25% (8.9-42.7%), respectively and (2) the 40 and 60-minute doses of activity significantly lowered mean PPG by a similar amount. **CONCLUSION:** A continuous walk was more effective than breaks from sitting to manage free living glycemia for the group as a whole but both were equally effective in the subset with high postprandial glycemia. The utility of post-meal breaks from sitting to manage glycemia in the latter group may be due to frequent intervals of physical activity throughout the day.

Physical Activity and Self-Efficacy in Overweight/obese Adults with Type 2 Diabetes and Concurrent Kidney Disease

Kathleen Woolf, FACSM, Lisa Ganguzza, Mary Lou Pompeii, Josh Li, David St-Jules, Ram Jagannathan, Lu Hu, Nicole Skursky, Alex Sierra, David S. Goldfarb, Stuart Katz, Aditya Mattoo, Huilin Li, Mary Ann Sevick. *New York University, New York, NY.*

 (No relationships reported)

Physical activity (PA) is an important component in the prevention and management of type 2 diabetes and chronic kidney disease (CKD). Determining current patterns and predictors of PA is essential to implement programs that encourage behavior change for patients with these diseases. **PURPOSE:** To describe self-reported PA and self-efficacy among adults with type 2 diabetes and CKD and determine predictors of overall PA patterns. **METHODS:** 76 overweight/obese participants (age: 66±8 y; body mass index [BMI]: 33.0±5.3 kg/m²; sex: 60% male; ethnicity: 91% non-Hispanic white; race: 80% white) with type 2 diabetes and CKD, participating in a technology-delivered lifestyle intervention, completed two well-validated surveys at baseline: International Physical Activity Questionnaire-Short Version and Self-Efficacy for Exercise (SEE) Scale. Biomarkers (hemoglobin A1c, glomerular filtration rate, C-reactive protein) were collected via blood draw. Multiple linear regression was performed to predict total metabolic equivalent (MET)-minutes/week of PA based on biomarkers, BMI, and SEE. Preliminary analyses were conducted to ensure no violation of the assumptions of the regression model. Statistical analyses were conducted using IBM SPSS Statistics (version 22.0). **RESULTS:** Participants self-reported completing (median [interquartile range, IQR]) 594(1435) MET-minutes/week walking intensity, 160(780) MET-minutes/week moderate intensity, 0(960) MET-minutes/week vigorous intensity, and 1431(2938) total MET-minutes/week. 40.8% of participants met the PA guidelines of 150 minutes/week (median [IQR]: 107[346] min/week). Average SEE scores were 55±22 (range 2 to 90). SEE was the only statistically significant predictor of total MET-minutes/week ($\beta=0.364$, $p=0.004$). **CONCLUSION:** Self-efficacy for exercise was a strong predictor of PA in patients with type 2 diabetes and CKD. Social cognitive theory-based programs that build self-efficacy and incorporate PA should be developed to promote risk reduction of these chronic diseases. Given the tendency to self-report higher levels of PA, future studies should include more objective measures of PA to explore these relationships. Supported by NIH Grant R01 DK100492 (PI MA Sevick)

Physical Activity Patterns and Markers of Muscle Contractile Efficiency in Male Mice

Nicole L. Stott, Luis A. Gonzalez, William T. Gaines, Madison H. Miller, S. Michaela Singletary, Taylor S. Whitsel, E. Paige Williams, Robert S. Bowen. *Truett McConnell University, Cleveland, GA.*
 (No relationships reported)

Removal of endogenous sex steroids appears to alter an organism's molecular and cellular biology resulting in immediate decreases in physical activity levels. In particular, several skeletal muscle genes have been shown to change following removal of gonadal tissues. The observed changes in expression level may be related to skeletal muscle contractile efficiency and may lead to the notable reductions in physical activity. **PURPOSE:** The purpose of this study was to evaluate changes to physical activity patterns and to quantify differences in expression in several muscle-related genes after loss of the sex hormones. **METHODS:** Physical activity patterns were observed in C57BL/6j male mice (n=28) beginning at nine weeks of age. Wheel running distance (km), duration (min), and speed (m·min⁻¹) were quantified following acclimation to wheel running use. Following acclimation, wheel running patterns were assessed under physiological (n=14, sham orchidectomy) and low circulating sex hormone conditions (n=12, bilateral orchidectomy) for ten days. End of study gastrocnemius muscle titin (Ttn; improves muscle elasticity in response to sex hormone treatment), succinate dehydrogenase (Sdhc; maintains myosin function in response to sex hormone treatment), glutathione peroxidase 3 (Gpx3; facilitates contraction by balancing oxidative stress), and mechanistic target of rapamycin (Mtor; marker for changes to protein synthesis) mRNA levels were evaluated via qPCR assays. Activity parameter and gene expression differences were determined via independent samples t-tests. **RESULTS:** Wheel running distance (sham=8.37±1.99

vs. orch=2.82±1.80; $p=0.0000001$), duration (sham=265±51 vs. orch=98±54; $p=0.00000004$), and speed (sham=31.4±2.8 vs. orch=26.1±5.4; $p=0.008$) were higher in sham treated mice than orchidectomized mice. No expression differences were identified for any of the genes of interest. **CONCLUSIONS:** The results of this study further support the notion that wheel running patterns are immediately affected by the loss of the sex hormones in male mice. Observed decrements in wheel running patterns following sex hormone loss are most likely unrelated to changes in expression of several sex hormone responsive genes in gastrocnemius tissue.

The Effect Of Grape Seed Extract On Markers Of Autophagy In Cd4+ T-lymphocytes From Hiv+ Patients

James J. McCormick¹, Cassandra G. Ulrich¹, Tamara L. Saimons², Christine M. Mermier¹. ¹University of New Mexico, Albuquerque, NM. ²Southwest CARE clinic, Albuquerque, NM. (Sponsor: Ann Gibson, FACSM)
 Email: aeneid@unm.edu
 (No relationships reported)

Autophagy is one of the most ancient and crucial cellular defense mechanisms against invading pathogens. Recently, autophagy has been shown to restrict HIV-1 infection through lysosomal degradation of the HIV-1 transactivator of transcription, a protein necessary for viral replication in CD4+ T-lymphocytes. However, as HIV-1 has evolved strategies to block the autophagic process, it is important to investigate novel approaches of autophagy upregulation. **PURPOSE:** We investigated whether grape seed extract (GSE) would induce autophagy in CD4+ T-lymphocytes from patients infected with HIV-1 when compared to rapamycin (Rapa) treatment (a known inducer of autophagy). **METHODS:** To test the concept of GSE as a novel HIV-1 treatment, CD4+ T-lymphocytes were harvested from three male HIV-1 subjects (45.7±14.2 years) and incubated at 37°C for 24 hours. The cells were then exposed to either dimethylsulfoxide (DMSO; control), bafilomycin (BAF; 100 nM; autophagy inhibitor), BAF + rapamycin, or BAF+GSE (40 µg/mL) and harvested after 2 hours to determine the efficacy of GSE when compared to Rapa (0.5 nM). Cells were then treated with GSE for 6, 24, and 48 hours and harvested for analysis. LC3-II and p62/SQSTM1 proteins and genes were analyzed via Western blot and qRT-PCR, respectively. **RESULTS:** We found no significant difference in LC3-II or SQSTM1/p62 protein responses between 2 hours Rapa (3.09±4.98RQ and 1.43±2.06RQ, respectively) and GSE treatment (2.25±3.37RQ and 1.13±1.82RQ, respectively) in HIV-1 infected CD4+ T-lymphocytes. Following 48 hours GSE exposure, an increase in both LC3-II (10.03±12.29RQ) and SQSTM1/p62 (18.22±30.23RQ) protein expression was observed, indicating increased autophagy. Expression of MAP1LC3B mRNA and SQSTM1/p62 genes increased above baseline for all measured time points, peaking at 6 hours GSE exposure (2.73±3.10RQ and 15.11±17.17RQ, respectively). **CONCLUSIONS:** Our preliminary findings suggest that GSE may be a potent inducer of autophagy in HIV-1 infected CD4+ T-lymphocytes. Further, GSE treatment resulted in elevated autophagy for up to 48 hours following GSE exposure, suggesting GSE supplementation may be beneficial when used with current antiretroviral therapies.

Lactic Acid Suppresses LPS- Induced Mast Cell Activation and Septic Shock

Heather L. Caslin, Daniel Ababayehu, Amina Abdul Qayum, L. Alexis Hoferlin, Charles E. Chalfant, John J. Ryan. *Virginia Commonwealth University, Richmond, VA.*
 (No relationships reported)

Lactic acid levels are associated with mortality in sepsis, making clearance a treatment goal. However it is unknown if lactic acid contributes to immunosuppression in the late phase of sepsis or if it is solely a consequence of bacterial infection. **PURPOSE:** To determine the effects of lactic acid on LPS-mediated mast cell activation in vitro and in a mouse model of septic shock. **METHODS:** Bone marrow derived mast cells (BMMCs) were cultured in vitro ± lactic acid for 24-hours prior to lipopolysaccharide (LPS, 1 µg/mL) activation. For the septic shock model, an intraperitoneal (IP) injection of lactic acid (80 mg/kg) or PBS was given to C57BL/6J mice 20-hours prior to an IP injection of LPS (25 mg/kg) or PBS. Cytokine production was determined via ELISA in the supernatant or plasma, respectively. **RESULTS:** In vitro, lactic acid significantly suppressed cytokine production (pg/mL ± SEM) compared to the media control: IL-6 (3438.6 ± 352.9 vs. 5734.9 ± 953.6, $p < 0.01$) at concentrations ≥ 6mM and TNF (12.2 ± 2.9 vs. 87.4 ± 16.4, $p < 0.01$) and MCP-1 (296.5 ± 47.6 vs. 717.2 ± 75.9, $p < 0.01$) at concentrations ≥ 12.5 mM. These effects are dependent upon pH, as sodium lactate had no effect on IL-6 (15391.0 ± 2541.0 vs. 17909.1 ± 1948.6, $p = .79$) and formic acid suppressed IL-6 (9797.1 ± 935.4 vs. 17909.1 ± 1948.6, $p < .01$). Additionally, lactic acid effects are transient, since activation in fresh media following a 24-hour treatment with lactic acid did not suppress IL-6 (7423.3 ± 1094.9 vs. 6975.8 ± 535.8, $p = .99$). Similar to the results in vitro, lactic acid significantly suppressed IL-6 (54, 917.6 ± 4508.0 vs. 69,451.6 ± 2283.6, $p < 0.01$) and MIP-1a (53.1 ± 9.9 vs. 149.8 ± 47.9, $p < 0.01$) levels in vivo, with a trend towards reduced TNF and MCP-1. There

was no effect of lactic acid on temperature or observational score. **CONCLUSION:** These findings suggest that elevated lactic acid levels in sepsis patients may attenuate immune cell activation. This information may improve our understanding of immunosuppression in the late phase of sepsis and could reveal new molecular targets for treatment, for which there are currently none. Supported by NIH grants: 1R01AI101153 and 2R01AI059638

The Effect of Creatine Supplementation on Upper Body Strength and Immune Function in Men

Joan M. Eckerson, FACSM¹, Lisa A. Riesberg¹, Kyle Serreyn¹, Jennifer Yee¹, Geri A. Moore¹, Dimitrios Katsavelis¹, Eric Bredahl¹, Kristen Drescher¹, David Fukuda², Laura Kurata¹, Brittany Moon¹. ¹Creighton University, Omaha, NE. ²University of Central Florida, Orlando, FL.
(No relationships reported)

PURPOSE: The purpose of this study was to examine the effect of creatine (CR) loading on upper body strength and immune system function in men. **METHODS:** Using a double-blind design, physically active males (X age \pm SD = 22 \pm 3 yr) were randomly assigned to a CR (n=22) or placebo (PL; n=22) group and were instructed to consume their respective treatments (20 g d⁻¹; CR monohydrate or maltodextrin in powder form) dissolved in water over four equal time periods for 5 d. At baseline (BL) and after the 5 d loading phase, body weight (BW) and one-repetition maximum bench press (1 RM BP) were assessed. At BL and 5 d, a 50 ml blood draw was also extracted in five EDTA tubes and one serum separation tube to obtain lymphocytes and serum. Immunomodulatory effects of CR were determined using RT-PCR to analyze the mRNA expression of pro-inflammatory cytokine tumor necrosis factor- α (TNF- α), while a creatinine assay was used to measure the amount of creatinine present in the sera. Data were analyzed using 2 x 2 (group x time) repeated measures ANOVA and statistical significance for all tests was $p < 0.05$. **RESULTS:** There were no significant interactions or treatment effects for BW or 1 RM BP, however, there was a significant main effect for time with both groups demonstrating an increase in BW (PL = 0.13 kg; CR = 0.46 kg) and 1 RM BP (PL = 1.76 kg; CR = 2.06 kg). There was a significant interaction for serum creatinine, and a significant treatment effect for TNF- α mRNA levels. Post-hoc tests revealed that the CR group demonstrated a significant increase in serum creatinine levels, and significantly lower TNF- α mRNA levels after the 5 d loading phase compared to PL. **CONCLUSIONS:** The changes in BW and serum creatinine observed in the CR group following a 5 d loading phase are consistent with previous research. However, this is one of the first studies using human subjects to show that CR significantly reduced TNF- α mRNA expression, which suggests that it may have an anti-inflammatory effect. Future studies are warranted to further define CR as an immunomodulator and should focus on determining the expression of other pro-inflammatory mediators and markers. **Acknowledgements:** Supported by LB692 and MusclePharm® (CR supplement).

Exercise During Chemotherapy May Reduce Pain By Strengthening Co-regulatory Couplings In The Cytokine Network

Ian R. Kleckner¹, Calvin Cole¹, Charles Heckler¹, Steven Rousey², Samer Kasbari³, Jessica Miller², Pavan S. Reddy⁴, Shelli Kesler², Karen Mustian¹. ¹University of Rochester Medical Center, Rochester, NY. ²Metro Minnesota NCORP, Saint Louis Park, MN. ³Southeast Clinical Oncology Research Consortium NCORP, Winston-Salem, NC. ⁴Wichita NCORP, Wichita, KS. ⁵MD Anderson Cancer Center, Houston, TX.
Email: ian_kleckner@urmc.rochester.edu
(No relationships reported)

PURPOSE: Chemotherapy is hypothesized to cause pain partly via dysregulation of the inflammatory cytokine network - namely, by weakening the normal co-regulatory couplings between concentrations of pro- and anti-inflammatory cytokines. Although research suggests that exercise reduces pain in cancer patients by favorably influencing individual markers of inflammation, no studies have examined whether exercise influences the co-regulatory couplings between concentrations of pro- and anti-inflammatory cytokines. The purposes of this study were to assess how regulation of the inflammatory cytokine network is (1) affected by exercise and (2) related to pain. **METHODS:** We performed simple network analyses (i.e., correlations matrices) on data from 348 cancer patients enrolled in a randomized trial of chemotherapy plus 6 weeks of moderate-intensity walking and resistance exercise (N = 173) vs. chemotherapy alone (N = 175) in mixed-type, early/mid-stage cancer patients (mean age = 56, 93% female). At pre- and post-intervention, patients (1) provided blood to assess concentrations of IL-1 β , IL-6, IL-8, IL-10, IFN γ , and sTNFR1 via ELISA and (2) reported pain in the last 7 days (0=not present, 10=as bad as you can imagine). **RESULTS:** Compared to chemotherapy alone, exercise plus chemotherapy strengthened the normal co-regulatory couplings between changes in concentrations of

several pro- and anti-inflammatory cytokines - specifically, between IL-6 and all other cytokines ($p < 0.05$) and between IL-10 and all other cytokines ($p < 0.05$). Among exercise participants, decreased pain was associated with strengthened co-regulatory coupling between changes in concentrations of IL-6 and IL-10 ($r = -0.18, p = 0.047$). **CONCLUSIONS:** Exercise strengthened the regulation of the inflammatory cytokine network via strengthened co-regulatory couplings between concentrations of pro- and anti-inflammatory cytokines. The strength of co-regulatory coupling between IL-6 and IL-10 may mediate the beneficial effects of exercise on pain, considering that IL-6 and IL-10 are known to contribute to the physical conditioning effects of exercise. Our novel methods to analyze cytokine data may complement traditional analytic approaches in the investigation of immune-mediated phenomena beyond this study.

The Influence of Menstrual Cycle on Salivary Antimicrobial Proteins during Endurance Exercise

Harumi Hayashida, Saori Yoshida. Tokoha university, Hamamatsu, Japan.
Email: h-hayashida@fuji.waseda.jp
(No relationships reported)

The oral-respiratory mucosal immunity is important to prevent upper respiratory tract infection after exercise for athletes. Lysozyme and lactoferrin, as salivary antimicrobial proteins, play an important role in first-line defense against invading microbials. The responses of saliva flow rate and composition during exercise are influenced by the sympathetic nervous system. Additionally, the sympathetic nervous system is affected by the menstrual cycle. However, the changes in salivary antimicrobial proteins following exercise at different phases of the menstrual cycle remains unclear. **PURPOSE:** To examine the influence of the menstrual cycle on salivary antimicrobial proteins level at rest and in response to an acute bout of endurance exercise. **METHODS:** Eight healthy recreationally active females completed a cycling exercise at 70% V(O₂)_{peak} for 45 minutes at two time points of the menstrual cycle: during the mid-follicular phase (day 8 \pm 2) and the mid-luteal phase (day 21 \pm 2). All participants have a regular menstrual cycle and have never taken oral contraceptives. Timed unstimulated saliva samples were obtained before, immediately after, and 1 hour after exercise and analyzed for salivary antimicrobial proteins. The concentrations of lysozyme and lactoferrin were measured using enzyme immunoassays. **RESULTS:** The menstrual cycle modified the resting levels of lysozyme (follicular: 23435.0 \pm 314.0 vs. luteal: 15951.7 \pm 7743.4 ng/mL, $p < 0.05$). The menstrual cycle did not significantly modify the levels of lactoferrin at rest (follicular: 4896.6 \pm 1885.0 vs. luteal: 5300.0 \pm 2488.2 ng/mL, NS). Lysozyme concentration was increased after exercise ($p < 0.01$) and lactoferrin concentration was increased immediately after exercise ($p < 0.01$) and 60 minutes after exercise ($p < 0.05$) but unaffected by the menstrual phase. Saliva flow rate was slightly reduced after exercise but not significantly altered by the menstrual cycle. **CONCLUSION:** The pattern of salivary antimicrobial protein secretion in response to endurance exercise was not influenced by the menstrual cycle. These findings indicate that the regular menstrual cycle may not need to be considered when assessing oral-respiratory mucosal immune responses to acute endurance exercise.

Post-STEMI Age-related Non-classical Monocyte CCR2 Expression Differences In Response To Stress Hormones

Anson Blanks, Charles S. Schwartz, Lauren N. Pedersen, Leo F. Buckley, Edmund O. Acevedo, FACSM, Antonio Abbate, R. Lee Franco. Virginia Commonwealth University, Richmond, VA.
Email: blanksam2@vcu.edu
(No relationships reported)

C-C chemokine receptor 2 (CCR2) plays an important inflammatory role following ST segment elevation myocardial infarction (STEMI) by regulating the chemotaxis of monocytes to damaged tissue. Circulating non-classical monocytes are responsible for debris clearance following STEMI and are positively correlated with age in healthy individuals, as well as increased plaque area in cardiovascular disease (CVD) patients. While post-STEMI non-classical composition within the monocyte population has been defined in CVD patients, age related differences in monocyte phenotypic characteristics and response to stress hormones remains unclear. Specifically, epinephrine (EPI) and cortisol (CORT), which are elevated during exercise, have been shown to both affect immune cell function and positively correlate to infarct size. **PURPOSE:** To determine the *in-vitro* effects of CORT and EPI on non-classical monocyte CCR2 expression in young and old patients post-STEMI. **METHODS:** Blood was collected from 19 volunteers 72 hours post-STEMI. Samples were grouped by age (<50 [YNG, n=7, 38.7 \pm 6.0 yrs] or \geq 50 [OLD, n=12, 61.7 \pm 6.9 yrs]). Blood was diluted to 1 x 10⁶ cells/mL and cultured for 4 hours either unstimulated, stimulated with EPI (10⁻⁸M), or CORT (10⁻⁶M). Cultures were stained against CD14, CD16, and CCR2. Flow cytometry was performed and non-classical monocytes were determined based on CD14 and CD16 expression. **RESULTS:** Unstimulated CCR2 expression

in non-classical monocytes was neither significantly different between groups (50.75 ± 22.91 [YNG] vs. 71.52 ± 28.79 [OLD], $p=0.104$), nor was there a significant correlation between age and CCR2 expression ($r=0.44$, $p=0.059$). However, there was a significant difference in non-classical monocyte CCR2 expression following EPI (47.69 ± 7.22 [YNG] vs. 80.74 ± 45.60 [OLD], $p=0.03$) and CORT (44.29 ± 21.27 [YNG] vs. 83.77 ± 30.53 [OLD], $p=0.008$). **CONCLUSION:** The results suggest an age-related difference in non-classical monocyte CCR2 expression after EPI and CORT stimulation. It is plausible that aged individuals have an increased sensitivity to EPI and CORT, which increases non-classical monocyte CCR2 expression. Post-STEMI exercise prescriptions may need to be modulated in older individuals to account for exercise induced hormonal responses. Supported by NIH Grant R34HL121402

 (No relationships reported)

Adipose tissue (AT) immunometabolic health predicts systemic metabolic health. Exercise improves metabolic function and insulin sensitivity and is thought to improve AT metabolism by reducing AT inflammation. Fibroblast growth factor 21 (FGF21) is a pleiotropic hormone-like protein that has been shown to have beneficial effects by improving glucose and lipid metabolism and may have beneficial effects on AT immunometabolic function. However, it is unknown whether exercise-induced AT adaptations are mediated through FGF21. **PURPOSE:** To determine the role of FGF21 in exercise-induced adaptations in white (W) and brown (B) AT. **METHODS:** Male FGF21 knock-out (KO) and wild type (WT) mice were fed normal chow and either exercise trained via voluntary wheel running (EX) or kept sedentary (SED) for 8 weeks. Visceral (i.e., epididymal), subcutaneous (inguinal region) WAT, and BAT (interscapular region) depots were removed, weighed and flash-frozen in liquid nitrogen. Techniques used: EchoMRI - body composition, real-time PCR - gene expression, Western blotting - protein content, and H&E staining - histology. **RESULTS:** FGF21KO mice weighed more ($p<0.05$) and had greater overall adiposity. In addition to having greater systemic insulin resistance (IR) based on HOMA-IR ($p<0.01$), AT from FGF21KO mice was more insulin resistant ($p<0.01$) based on fasting plasma insulin and free fatty acids. EX decreased AT IR ($p<0.01$) but only tended to decrease HOMA-IR ($p=0.112$). Phospho-Akt and GLUT4 proteins were increased in AT of FGF21KO mice, combined with increased IR, is suggestive of dysregulated glucose uptake. In WAT and BAT, inflammatory and oxidative stress genes (e.g., MCP-1, TNF α , CD11c, P22phox) were significantly upregulated in FGF21KO and normalized by EX. Mitochondria content, indicated by COX III and IV protein, were significantly reduced in BAT of FGF21KO. **CONCLUSION:** Absence of FGF21 increases AT IR as well as WAT and BAT inflammation; EX rescues this phenotype. Normal WAT mitochondrial adaptations to EX may be adversely affected by loss of FGF21. Metabolic dysfunction in FGF21KO appears largely due to excess AT, and is almost completely normalized by EX. Supported by grant number R25GM056901 from the NIGMS of the NIH, VA-CDA2 IK2BX001299 (RSR), and MU Research Board, Corporate Advisory Board, and Research Council.

 (No relationships reported)

PURPOSE: To examine the monocyte subset response to resistance exercise and supplementation with an aqueous proprietary polyphenol blend (PPB) sourced from *Camellia sinensis*. **METHODS:** Untrained men ($n=38$, 22.1 ± 3.1 yrs; 174.0 ± 7.9 cm; 77.8 ± 14.5 kg) were randomized to: PPB ($n=13$), placebo (PL; $n=15$) or control (CON; $n=10$). PPB and PL supplemented for 28 days prior to an acute bout of resistance exercise, consisting of 10 repetitions at 70% of 1-RM for the squat (6 sets), leg press (4 sets) and leg extension (4 sets). Blood was drawn pre (PR),

immediately (IP), 1 (1H), 5 (5H), 24 (24H) and 48 (48H) hours post exercise (PPB/PL), or rest (CON). Biopsies were obtained from the vastus lateralis at PR, 1H, 5H and 48H. Plasma and intramuscular monocyte chemoattractant protein-1 (MCP-1) was assessed by multiplex assay. Relative percent of classical (CLAS; CD14⁺⁺/CD16⁻), intermediate (INT; CD14⁺⁺/CD16⁺) and nonclassical (NC; CD14⁺/CD16⁺) monocytes were assessed via flow cytometry. Repeated measures ANOVA were applied, and non-normally distributed data were LN transformed. **RESULTS:** A group x time interaction was observed for circulating MCP-1 ($p=0.005$), which was greater at 5H in PPB (502.0 ± 154.2 pg·ml⁻¹; $p=0.001$) and PL (416.8 ± 109.9 pg·ml⁻¹; $p=0.012$) than CON (307.3 ± 142.6 pg·ml⁻¹). A time effect was observed for intramuscular MCP-1 content ($p<0.001$), with elevations observed (PR: 9.6 ± 5.0 pg·mg⁻¹; $p<0.001$) at 1H (374.2 ± 388.8 pg·ml⁻¹), 5H (595.7 ± 528.6 pg·ml⁻¹) and 48H (217.0 ± 189.1 pg·ml⁻¹). Interactions were observed for CLAS, INT and NC ($p<0.001$) populations. At IP, CLAS was reduced in PPB ($86.2 \pm 7.6\%$; $p=0.008$) and PL ($85.9 \pm 5.1\%$; $p=0.003$) versus CON ($93.8 \pm 4.3\%$). At 1H, PPB ($96.3 \pm 2.0\%$; $p=0.002$) and PL ($95.3 \pm 4.0\%$; $p=0.006$) was greater than CON ($90.8 \pm 4.3\%$). INT were greater at IP in PPB ($4.9 \pm 2.3\%$; $p=0.034$) and PL ($6.0 \pm 2.0\%$; $p=0.001$) than CON ($2.9 \pm 1.8\%$) and reduced at 1H in PPB ($1.6 \pm 1.0\%$; $p=0.003$) and PL ($2.0 \pm 1.2\%$; $p=0.008$) versus CON ($3.4 \pm 1.6\%$). PPB was greater than CON at 24H ($6.7 \pm 2.9\%$; $4.0 \pm 0.9\%$; $p=0.016$) and 48H ($7.9 \pm 3.4\%$; $4.1 \pm 1.6\%$; $p=0.007$). NC was greater at IP in PPB ($8.9 \pm 6.9\%$; $p=0.020$) and PL ($8.1 \pm 4.0\%$; $p=0.028$) than CON ($3.4 \pm 3.2\%$). **CONCLUSIONS:** Exercise resulted in increased MCP-1 and the mobilization of specific monocyte subsets. Supplementation with PPB may augment the monocyte response. Funded by Kemin Foods, L.C.

 (No relationships reported)

Exercise induces an inflammatory immune response, which is evidenced by the release of numerous cytokines. Specifically, interleukin-6 (IL-6) is of unique relevance, as exercise-induced release is mediated primarily by contracting skeletal muscle. Accordingly, elevations in IL-6 have been observed following various exercise modes, including resistance training. However, there is limited data comparing the IL-6 response between high-repetition (HR) and low-repetition (LR) resistance training programs. **PURPOSE:** To examine the effect of an acute bout of resistance training on changes in circulating IL-6 levels and to compare the response between volume-equated HR and LR training sessions. **METHODS:** Sixteen males (Age: 23 ± 3 yrs, Body Mass: 84.4 ± 12.3 kg, Body Fat Percentage: $11.7 \pm 4.7\%$) with at least two yrs. of resistance training experience were counterbalanced by relative strength and assigned to one of two groups (high repetition-HR or low repetition-LR), which performed one resistance training session of back squat and bench press: HR ($n=8$): 4 sets of 12 repetitions at 60% of one-repetition maximum (1RM) or LR ($n=8$): 8 sets of 6 repetitions at 75% of 1RM. 10ml blood was obtained from the antecubital vein 30min. prior to and immediately following the resistance training session. Samples were centrifuged and plasma was stored at -80°C until further analysis. IL-6 concentrations were analyzed in duplicate, via a commercially available enzyme linked immunosorbent assay. A 2x2 repeated measures ANOVA with a Tukey post-hoc was used to determine changes in IL-6 response. Significance was set at $p \leq 0.05$. **RESULTS:** A significant time effect was detected for IL-6 response in both groups: HR (0.71 ± 0.19 to 1.39 ± 0.18 pg/mL; $p<0.001$; $+95.77\%$) and LR (0.53 ± 0.10 to 1.27 ± 0.10 pg/mL; $p<0.001$; $+139.62\%$); however, no group differences ($p=0.46$) were observed. **CONCLUSION:** An acute resistance training bout incorporating multi-joint exercises effectively elicits a circulating IL-6 response. Further, in a trained population, this phenomenon appears to occur in a volume-dependent manner as the magnitude of IL-6 increase did not vary with repetition range.

G-29 Free Communication/Poster - Motor Control Across the Lifespan

Motor Unit Action Potential Sizes of the First Dorsal Interosseous in Young and Older Individuals

Adam J. Sterczala, Jonathan D. Miller, Anthony B. Ciccone, Michael A. Trevino, Justin X. Nicoll, Trent J. Herda. *University of Kansas, Lawrence, KS.*
Email: adam.j.sterczala@ku.edu
(No relationships reported)

Slopes from the motor unit action potential size (MUAP_{size}) vs. recruitment threshold (RT) relationships provides a non-invasive measurement of MU sizes. As such, the slopes (AP_{slopes}) may be able to quantify age-related MU atrophy. **PURPOSE:** To determine if AP_{slopes} differed between young and old individuals. **METHODS:** Twenty two young (YG, age = 22.5±2.7 yrs) and ten aged (OG, 61.0±2.0 yrs) subjects completed the investigation. Surface electromyography signals were recorded from the first dorsal interosseous (FDI) during an isometric trapezoidal muscle action with the steady force plateau set at 50% maximal voluntary contraction (MVC). The signals were decomposed to yield MUAP_{sizes} and RTs for each MU. The AP_{slopes} was calculated via the MUAP_{sizes} vs. RT relationships for MUs recruited between 10 and 50% MVC for each subject. Few MUs with RTs < 10% MVC were observed in young or old and, thus, these MUs were excluded from the slope calculation. FDI cross-sectional area (CSA) and echo intensity (EI) were quantified using ultrasonography. Possible differences in AP_{slopes}, CSA and EI between groups were examined with independent samples t-tests. **RESULTS:** OG demonstrated significantly reduced AP_{slopes} (OG: 0.033 ± 0.010; YG: 0.048 ± 0.020; p = 0.048) and greater EI (OG: 41.3 ± 7.0 AU; YG: 50.6 ± 7.5 AU; p = 0.002), however, CSA was similar between YG and OG (OG: 2.22 ± 0.47 cm²; YG: 2.09 ± 0.31 cm²; p = 0.438). **CONCLUSION:** The AP_{slopes} suggested non-uniform differences in MUAP_{sizes} in relation to RT, likely due to reduced sizes of higher threshold MUs. Higher threshold MUs have been suggested to contain a greater proportion of type II muscle fibers, which demonstrate greater age induced atrophy than type I fibers commonly associated with lower threshold MUs. As such, the difference in AP_{slopes} suggested atrophy of higher threshold MUs in OG. In addition, OG's elevated EI indicates greater infiltration of adipose and connective tissue into the muscle. Greater EI in combination with similar CSA may indicate a reduced contractile tissue volume in the OG, supporting the speculation that the AP_{slopes} differences were due to MU atrophy.

Ankle Proprioception And Soccer Skills in Youth Recreational Players

Li Li¹, Jia Han², Gordon Waddington³, Roger Adams³. ¹Teacher Training College of Yangpu District Shanghai, Shanghai, China. ²Shanghai University of Sport, Shanghai, China. ³University of Canberra, Canberra, Australia.
Email: lilee_1973@126.com
(No relationships reported)

Evidence suggests that ankle proprioceptive ability is significantly correlated with soccer performance level. It has not been determined if ankle proprioception is associated with specific soccer skills in youth recreational soccer players. **PURPOSE:** to investigate the relationship between ankle proprioception and soccer skills in youth recreational players. **METHODS:** twenty-seven youth recreational soccer player (mean 14.8 years old, range 13-17), without ankle injury during the past 3 months, participated in this study. Their passing, shooting and dribbling skills were assessed by using the reliable and valid Soccer Skill Tests (Russell et al. 2010). Ankle proprioception was measured by using the active movement extend discrimination apparatus (AMEDA) in standing. **RESULTS:** Ankle proprioceptive discrimination accuracy scores were significantly positively correlated with passing, shooting and dribbling accuracy scores (r=0.52, r=0.71, and r=0.53, respectively; all p<0.01). Further, participants who had history of ankle injury beyond 3 months performed significantly worse in both ankle proprioception and shooting accuracy tests than those who did not (F_{1,25}=5.01, p=0.03, and F_{1,25}=5.77, p=0.02, respectively). **CONCLUSION:** Findings here highlight the importance of ankle proprioception for soccer skills in youth recreational soccer players. Future research is needed to determine if there is a causal relationship between poor ankle proprioception and injury history, because this is crucial for talent identification, ankle injury prevention and rehabilitation in youth soccer players.

Force-Time Characteristics During A Reactionary Gripping Task: Effects Of A 10-Week Introductory Judo Course

Michael B. La Monica, David H. Fukuda, Tyler WD Muddle, Kyle S. Beyer, Ran Wang, Jeffrey R. Stout, FACSM, Jay R. Hoffman, FACSM. *University of Central Florida, Orlando, FL.*
(Sponsor: Jay R. Hoffman, FACSM)
(No relationships reported)

Judo is an intermittent sport associated with explosive movements reliant on static and dynamic grip strength. Analysis of force-time curves has been implemented in many judo related analyses; however, the effects of judo training in novice practitioners as an intervention is absent.

PURPOSE: To examine the effects of a 10-week introductory judo class on a reactionary gripping task.

METHODS: Sixteen healthy men (age: 22.6±3.4yr; height: 172.5±6.4cm; body mass: 78.8±13.2kg), 8 in an introductory judo class and 8 age-matched controls, were recruited. All participants performed 3, 5s maximal voluntary isometric contractions with their right hand on a handgrip dynamometer before and after the 10-week intervention. The handgrip dynamometer was connected to a data acquisition system and the force-time curve was constructed from the raw voltage data and analyzed with computer software. The variables measured were: peak force (PF), average force (AVGF), rate of force development (RFD), time to PF (TPF), force at peak RFD (F@RFD), 1s impulse (AUC1) and 2s impulse (AUC2). A 2x2 [group (judo vs. control) x time (pre vs. post)] repeated measures ANOVA was used to assess all force-time curve parameters.

RESULTS: No differences were observed between groups within any variable (Table 1). However, there was a statistically significant main effect for time (post > pre) in AUC2 (F = 5.75, p = 0.031, η² = 0.291).

CONCLUSIONS: A 10-week introductory judo class did not have an effect on handgrip performance during a reactionary gripping task. Future studies should examine longer training interventions or the force-time characteristics during gripping between novice and experienced judokas.

Table 1. Force-time curve characteristics during a reactionary gripping task before (Pre) and after (Post) the 10-week intervention

	Judo (n=8)		Controls (n=8)	
	Pre	Post	Pre	Post
PF (mV)	1.707 ± 0.240	1.773 ± 0.201	1.697 ± 0.220	1.696 ± 0.183
TPF (s)	2.539 ± 0.985	2.025 ± 0.682	2.346 ± 0.772	2.622 ± 0.510
AvgF (mV)	1.498 ± 0.215	1.551 ± 0.157	1.483 ± 0.218	1.533 ± 0.176
AUC1 (mV·s)	1.412 ± 0.206	1.454 ± 0.166	1.378 ± 0.188	1.436 ± 0.155
AUC2 (mV·s)	2.987 ± 0.472	3.162 ± 0.386*	2.965 ± 0.415	3.048 ± 0.323*
RFD (mV/s)	6.600 ± 1.260	6.182 ± 1.297	6.971 ± 1.615	6.880 ± 1.812
F@RFD (mV)	1.196 ± 0.167	1.241 ± 0.150	1.205 ± 0.129	1.243 ± 0.139

*Statistically significant from Pre (p<0.05). PF = Peak force; TPF = Time to peak force; AvgTP = Average force; AUC1 = 1s impulse; AUC2 = 2s impulse; RFD = Maximal rate of force development; F@RFD = Force at maximal rate of force development. Data presented as Mean±SD.

Differences in Mobility Among Older Adults are Associated with Motor Unit Activity and Muscle Strength

Diba Mani¹, Awad M. Almklass¹, Taian Vieira², Alberto Botter², Roger M. Enoka¹. ¹University of Colorado, Boulder, CO. ²Politecnico di Torino, Torino, Italy. (Sponsor: Robert Mazzeo, Ph.D., FACSM)
Email: manid@colorado.edu
(No relationships reported)

Advancing age is often accompanied by declines in muscle function and walking performance, which likely involve changes in the discharge characteristics of motor units in key leg muscles. **PURPOSE:** To determine the associations between the discharge characteristics of motor units in leg muscles during steady contractions and performance on functional tests of walking endurance, chair rise time, and maximal walking speed of older adults. **METHODS:** 20 healthy older adults (8 men, 72 ± 4 yrs) were recruited to participate in up to 4 experimental visits spanning ~10 wks. Motor unit characteristics were assessed by decomposing surface EMGs detected with a grid of 4x8 electrodes placed over the medial gastrocnemius (MG), lateral soleus (LS), and tibialis anterior (TA) muscles during 30 s isometric contractions with the plantarflexors (PF) or dorsiflexors (DF). The target torque was 10% or 20% of maximum. Time to walk 400 m (205 ± 43 s), time to rise and sit as quickly as possible from a chair five times (8 ± 2 s), and maximal walking speed over 10 m (2.3

± 0.5 m/s) were measured in the same visit. A best-subsets regression was performed to identify predictor variables from which the models with the lowest Bayesian Information Criterion score for each functional task was selected as the regression model. **RESULTS:** Data acquired from 70 trials were decomposed into the discharge times of single motor units, yielding data for 5,146 motor units: 1,086 from MG, 1,582 from LS, and 2,477 from TA. The mean coefficient of variation for interspike interval (ISI) during the 20% LS task ($0.47 \pm 0.2\%$) and mean ISI during the 10% LS task (150 ± 27 ms) explained 54% of the variance for 400 m walk time ($p < 0.0001$). The mean ISI during the 10% LS task, PF maximal torque (23 ± 12 N•m), and mean ISI during 10% TA task (105 ± 18 ms) explained 38% of the variance in chair rise time ($p < 0.001$). Mean ISI during the 20% MG task (145 ± 25 ms) explained 18% of the variance for 10 m walking time ($p < 0.0001$). **CONCLUSION:** Significant amounts of the variance in tests of physical function for older adults were explained by the discharge characteristics of motor units in leg muscles during steady isometric contractions and the strength of the plantarflexors. However, the predictor variables differed across the three tests of physical function.

3614 Board #61 June 3 9:30 AM - 11:00 AM
Reliability of the V-Wave during Maximal Voluntary Plantar Flexion Exercise

Alwyn T. Quarshie, Robert E. Hight III, Christopher D. Black.
University of Oklahoma, Oklahoma City, OK. (Sponsor: Pat O'Connor, FACSM)
 (No relationships reported)

An emerging technique to quantify supra-spinal contributions to neuromuscular function is the V-wave. However, little data exist regarding its day-to-day reliability in comparison to traditional measures such as MVC and motor unit recruitment assessed via twitch interpolation. **PURPOSE:** To determine the reliability of the V-wave in comparison to MVC, evoked twitches, and motor unit recruitment across 4 testing visits. **METHODS:** Eleven men and women were tested on 4 separate occasions over the course of 7-10 days. During each visit, transcutaneous electrical stimulation was applied over the tibial nerve while surface EMG recordings were obtained from the soleus muscle. Initially, single 1 ms pulses were delivered every 5 to 10 seconds in ascending increments of 5 mA until evoked M-wave amplitude peaked. Participants then performed 3, 3-second maximal voluntary isometric contractions. During each contraction, a supramaximal stimulus (150% M-max) was applied 2.5 seconds into the contraction with control twitches occurring 2 and 4 seconds following relaxation. V-wave amplitudes were determined from the peak-to-peak amplitudes of the EMG signal following the stimulation during MVC. Intra-class correlation coefficients ($ICC_{3,1}$) were calculated to determine test-retest reliability and repeated-measures ANOVAs were used evaluate the means between the 4 testing visits. **RESULTS:** No differences were observed between visits for motor unit recruitment 83 ± 19 , 89 ± 14 , 95 ± 9 , and $95 \pm 9\%$ ($p = 0.06$); twitch force 117 ± 33 , 109 ± 29 , 112 ± 28 , and 108 ± 25 N ($p = 0.61$), or the V-to-M ratio 0.42 ± 0.23 , 0.50 ± 0.28 , 0.49 ± 0.21 , and 0.48 ± 0.22 ($p = 0.65$). MVC increased across the test days ($p = 0.008$), but did not differ ($p = 0.68$) between days 3 (707 ± 220 N) and 4 (695 ± 188). Motor unit recruitment ($0.77-0.91$), twitch force ($0.86-0.91$), MVC ($0.95-0.97$), and the V-to-M ratio ($0.79-0.84$) exhibited adequate test-retest reliability that tended to improve over time. **CONCLUSIONS:** Our findings indicate the magnitude of V-wave remains stable over multiple testing days despite measured changes in motor unit recruitment and force. Indicating changes in spinal excitability and/or antagonist co-activation rather than altered supra-spinal input may underlie the changes in force and motor unit recruitment.

 (No relationships reported)

ABSTRACT. Relative, percent change differences between homologous vastus lateralis muscles across different resting muscular lengths have not previously been reported following the cessation of unilateral fatiguing aerobic exercise. **PURPOSE:** The purpose of the present study was to compare contralateral cross-over adaptations following unilateral fatiguing exercise, between different aerobically trained populations, across resting postural positions (RPPs) that incorporated different hip and knee joint angles. **METHODS:** Twenty healthy, college-aged men (mean \pm SD; age = 22.9 ± 3.5 years and 22.8 ± 2.6 years; height = 181 ± 7.5 cm and 180 ± 5.9 cm; weight = 87.2 ± 10.7 kg and 85.2 ± 10.5 kg; BMI = 26.6 ± 3 kg/m² and 26.2 ± 2.2 kg/m²; dominant thigh skinfold thickness = 15.1 ± 4.6 mm and 14.55 ± 5.3 mm; non-dominant thigh skinfold thickness = 15.55 ± 3.5 mm and 15.2 ± 3.8 mm; and VO₂ peak 25.1 ± 4.3 ml/kg/min and 44.7 ± 3.7 ml/kg/min, for the 10 novice and 10

advanced trained participants, respectively) exercised on an upright cycle ergometer, using only their dominant limb, for 30 minutes at 60% of their VO₂ peak. Resting surface electromyographic (sEMG) and mechanomyographic (MMG) signals were measured prior to and following exercise. **RESULTS:** The results indicated that the relative, percent change difference of the normalized MMG amplitude values were 7.6% and 4%; 9.1% and 7.5%; 5.7% and 3.9%; and 3.7% and 2%; while the results for the relative, percent change difference of the normalized MMG mean frequency values were 4.7% and 5.7%; 8.4% and 7.4%; 4.2% and 3.2%; and 2.7% and 3.7% (for the upright sitting position with legs extended 180° [1]; upright sitting position with legs bent 90° [2]; lying supine position with legs extended 180° [3]; and lying supine with legs bent 90° [4], respectively), for the novice and advanced groups, respectively. **CONCLUSION:** Our results provide further evidence to the concept that muscles are capable of possessing MMG activity post-exercise, despite a lack of sEMG signals. Additionally, our results suggest that there may be multiple neural and mechanical mechanisms concurrently contributing to the contralateral cross-over adaptations observed across the post-exercise recovery time course.

Is There A Cessation Of Motor Unit Remodeling As A Compensatory Strategy To Age-related Motor Unit Loss?

Kevin J. Gilmore, Eric A. Kirk, Charles L. Rice, FACSM. *The University of Western Ontario, London, ON, Canada.* (Sponsor: Dr. Charles L Rice, FACSM)
 Email: kgilmor2@uwo.ca
 (No relationships reported)

Despite the compensatory process of collateral reinnervation to counteract human age-related muscle fiber denervation, a substantial loss of functioning motor units (MUs) occurs which seems to be accelerated after the 7-8th decades of life. However, it is not known whether there is a limitation or cessation of this process in very old age because to date MU remodelling has not been explored in those above ~85 years of age. **PURPOSE:** To explore in an accessory elbow extensor muscle electrophysiological factors including, motor unit number estimations (MUNE) and measures of compensatory MU remodeling in men in their 9th and 10th decades of life. **METHODS:** A maximal compound muscle action potential (CMAP) was recorded from the anconeus in 8 healthy men aged to 82-91 years. Decomposition-enhanced spike-triggered averaging was used to collect surface and intramuscular electromyography (EMG) from the anconeus during a series of submaximal (30% and 50% of the maximal root mean squared (RMS) EMG of the anconeus) voluntary isometric elbow extensor contractions. In addition, motor unit potential (MUP) analysis was performed to provide a detailed assessment of neuromuscular status. **RESULTS:** Results were compared with a young cohort (~25y of age) published previously using the same procedures. Participants in the current study had CMAPs of ~3 mV, surface motor unit potentials (S-MUPS) of ~168 and ~232 μ V at 30 and 50% RMS, resulting in a MUNE of ~23 and ~16 at the two respective intensities. In contrast young adults had CMAPs of ~5.5 mV, but similar S-MUPS of ~155 and ~240 μ V at 30% and 50% RMS compared with the old. These values indicate a significant loss of muscle mass, but due to no difference in S-MUPS the old do not show signs of collateral reinnervation. **CONCLUSION:** Thus, compensatory remodeling may no longer be a viable process to counteract age-related loss of MUs in the very old; although this could be muscle or activity dependent.

The Difficulty Of EMG Burst Identification: Visual And Bayesian Changeoint Analysis

Matthew S. Tenan¹, Daniel Drill², Adam Fong², Victoria Voorhees², Deborah L. King². ¹US Army Research Laboratory, Aberdeen Proving Ground, MD. ²Ithaca College, Ithaca, NY.
 Email: matthew.s.tenan.civ@mail.mil
 (No relationships reported)

Surface electromyography (EMG) is commonly used to add physiologic context to observed patterns of movement. The onset of the EMG is often used to determine when a person responds to stimuli or to identify maladaptive muscle coordination strategies. Our research group has previously shown that Bayesian Changeoint Analysis (BCP) is superior to the standard linear envelope methodologies when determining a single EMG onset in a data series. **PURPOSE:** Examine the effectiveness of visual inspection and the novel BCP algorithm to detect EMG bursts in multiple muscles during complex movements. **METHODS:** Muscle activity from 10 healthy subjects was collected from the gastrocnemius, biceps femoris, and vastus lateralis muscles using surface EMG electrodes (4kHz sampling rate). Subjects completed 4 minutes of exercise on three modalities: treadmill running, ergometer cycling and stair climbing. All exercises were performed at self-selected low-to-moderate intensities. Six to ten seconds of EMG was collected at 90 and 210 seconds into the exercise. Three researchers visually identified the number of bursts in a trial twice

(randomized, double-blind methodology). The instances where all six identifications (three reviewers, twice) agreed on the number of bursts, were compared with the identification results from the BCP algorithm. **RESULTS:** While the within rater reliability (ICC: 0.85) and between rater reliability (ICC: 0.83) were good, the visual review only resulted in 111 trials (out of 180) where all raters agreed on the number of bursts (61.7% total agreement). The correlation between the number of bursts raters identified and the BCP algorithm was moderate (Pearson's R: 0.52). Furthermore, across all trials, there was a difference of 711 EMG bursts between the two methods. **CONCLUSIONS:** While visual assessment of the EMG is the "gold standard" for burst detection, its reproducibility is generally poor in dynamic tasks. Despite initial success with the BCP algorithm in determining EMG onset, the current iteration of the algorithm is insufficient for EMG burst identification in complex waveforms. This work highlights the need for a standardized algorithm of EMG burst detection, but also indicates that further work is necessary to make algorithms of sufficient accuracy and reliability.

Comparisons Between Voluntary Muscle Activation And Evoked V-wave Responses As A Function Of Torque

Robert E. Hight, Alwyn T. Quarshie, Christopher D. Black.
University of Oklahoma, Norman, OK. (Sponsor: Patrick O'Connor, FACSM)
 Email: robbyhight@ou.edu
 (No relationships reported)

The interpolated twitch technique is used to assess motor unit recruitment during voluntary actions. The V-wave is a complementary measure indicating supra-spinal contributions to force. No study has examined the relationship of these measures as a function of increasing force production. **PURPOSE:** To compare the magnitude of ITT assessed motor unit recruitment to V-wave amplitude during contractions of increasing force. **METHODS:** Thirteen men and women volunteered to participate in this study. Transcutaneous electrical stimulation was applied over the tibial nerve while surface EMG was recorded from the soleus muscle. Single 1 ms pulses were delivered every 5 to 10 seconds in ascending increments of 5 mA until the M-wave amplitude plateaued. Participants then performed 3, 3-second maximal voluntary contractions. During each contraction, a supramaximal stimulus (150% M-max) was applied 2.5 seconds into the contraction with control twitches occurring 2 and 4 seconds following relaxation. Lastly, 3 randomized series of submaximal contractions (20%, 40%, 60%, and 80% of MVC) were performed under the same stimulation conditions. Values for % recruitment and the V-to-M ratio were averaged across the 3 efforts at each force level. Repeated measures ANOVAs were conducted to examine changes in recruitment and the V-to-M ratio as a function of force. **RESULTS:** Recruitment increased as force increased ($p < 0.01$) from $6 \pm 14\%$ to $51 \pm 18\%$ to $82 \pm 13\%$ to $94 \pm 11\%$ to $95 \pm 8\%$ at 20%, 40%, 60%, 80%, and 100% of MVC, respectively. All values differed from each other ($p < 0.05$) except for values from 80% and 100% of MVC ($p = .75$). Similarly, the V-to-M ratio also increased ($p < .01$) as force was increased—with values increasing from $5 \pm 3\%$ to $13 \pm 8\%$ to $23 \pm 7\%$ to $38 \pm 18\%$ to $48 \pm 20\%$ at 20%, 40%, 60%, 80%, and 100% of MVC, respectively. Unlike recruitment all values for the V-to-M ratio differed from each other ($p < 0.05$). The increase in recruitment as a function of force was modeled with a polynomial equation ($R^2 = 0.99$) while a linear model better fit the relative V-to-M ratio ($R^2 = 0.97$). **CONCLUSION:** As the demand for force production increases, supra-spinal output increases in a linear manner while recruitment plateaus around 80% of MVC. As recruitment plateaus, the increased supra-spinal input likely increases rate coding to augment force production.

Exploring Bilateral Handgrip Forces Control During Inter-limb Coordination Task After Hemiparetic Stroke: A Preliminary Study

Chueh-Ho Lin¹, Liang-Hsuan Lu², Shang-Lin Chiang³, Chien-Hung Lai¹. ¹Taipei Medical University, Taipei, Taiwan. ²Tri-Service General Hospital, Taipei, Taiwan. ³Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.
 Email: chueh.ho@gmail.com
 (No relationships reported)

Interhemisphere cooperation plays an important role in daily living because the most functional performances of daily activities require the participation of bilateral hands simultaneously. However, the influence of stroke-related impairments on bilateral handgrip forces control between hands was still unclear. Therefore, it is necessary to develop a quantitative method to directly evaluate the coordination performances of two hands in stroke patients. **PURPOSE:** The purpose of this preliminary study was to investigate interhemisphere cooperation by analyzing inter-limb force control and coordination during inter-limb coordination tasks. **METHODS:** Seven stroke participants (Brunnstrom motor recovery stage III recovery or beyond, mean age = 57.0 ± 7.8 y/o) were recruited and asked to execute maximal voluntary contraction

(MVC) tests and inter-limb coordination tasks with reciprocal grasping, holding, and releasing of a dynamometer of two hands at two target force levels (20% and 40% MCV of paretic hand). The force outputs of the participant's hands were recorded and the alternating time of cross point (from non-paretic to paretic hand and paretic to non-paretic) in force generation was calculated and identified for the evaluation of bimanual coordination in both hands. Differences in non-paretic and paretic grip force and changes in hand-grip performance at two targeted force levels were determined using paired samples t-test and two-way ANOVA. **RESULTS:** The results demonstrated that the alternating time in non-paretic to paretic hand was longer than in paretic to non-paretic hand condition at 20% ($41.3 \pm 15.6\%$ vs. $23.7 \pm 12.0\%$, $p = .006$) and 40% ($52.8 \pm 19.4\%$ vs. $26.0 \pm 14.6\%$, $p = .004$) inter-limb coordination tasks. No significant changes in the force modulation timing between the non-paretic and paretic hand at different force levels were found ($F = .608$, $p = .443$). **CONCLUSION:** This is the first study to directly evaluate the capacity and quality of coordination control via the grip force between two hands and demonstrate the non-hemiparetic brain controlling non-paretic hand has greater coordination control ability than hemiparetic brain during bilateral force modulation for stroke patients, which may provide useful information on developing effective exercise interventions in stroke rehabilitation.

Inter-individual Variability In The Mechanomyographic Frequency Response During A Sustained Isometric Force Task

Joshua C. Carr. *The University of Oklahoma, Norman, OK.*

 (No relationships reported)

Inter-individual variability in the mechanomyographic frequency response during a sustained isometric force task.

Joshua C. Carr, Travis W. Beck, Xin Ye, Nathan P. Wages, and Hayden M. Tharp
 The University of Oklahoma, Norman, OK.

There is recent evidence that suggests a relationship exists between the frequency content of the mechanomyographic signal (MMG MNF) and motor unit activity. The fatigue-based changes that occur in the MMG MNF during a sustained force task may provide insight regarding the alterations in motor control that lead to task failure. **PURPOSE:** To examine the individual patterns of response for MMG MNF during a sustained submaximal isometric force task to failure. **METHODS:** Twenty males (mean \pm SD: age = 24 ± 3 years) volunteered for this investigation and were familiarized with the procedures prior to testing. Before the fatigue test, the subjects maximal voluntary contraction force (MVC_0) of their dominant elbow flexors was established. The subjects then performed a sustained submaximal isometric force task (60% MVC_0) for as long as possible. A piezoelectric accelerometer was used to detect the MMG signal from the biceps brachii. Polynomial regression was used to determine the relationships for MMG MNF versus time for each subject. **RESULTS:** The results indicated significant ($p < 0.05$) relationships for MMG MNF versus time for all subjects, and that the majority of subjects demonstrated curvilinear reductions in MMG MNF during the fatigue task. Specifically, the relationships were fit with linear (4 of 20, $R^2 = 0.72$), quadratic (12 of 20, $R^2 = 0.49$), and cubic (4 of 20, $R^2 = 0.86$) models. **CONCLUSIONS:** These results demonstrated that the MMG MNF response was capable of monitoring the fatigue-based changes in muscle function that progressed to task failure. The consistent declines exhibited for MMG MNF during the sustained isometric force task likely reflects alterations in the twitch properties of the contributing motor units. The inter-individual variability in the patterns of response may be due to differences in training status, muscle fiber type composition, or subject-specific motor control strategies related to the demands of the fatigue task.

An Examination of Patellar Tendon Reflex Pre-Motor Conduction Velocity across the Adult Lifespan

Alejandra Barrera-Curiel, Ryan J. Colquhoun, Zachary K. Pope, Jason M. DeFreitas. *Oklahoma State University, Stillwater, OK.*
 Email: ale.barrera_curiel@okstate.edu
 (No relationships reported)

It is known that aging is accompanied by a loss in muscle mass and motor units. However, the direct cause for the loss of motor units has not been identified. One possible mechanism could be related to changes in the sensory input motor neurons receive. Therefore, it is important to find objective measures to quantify sensory function that are sensitive to changes with aging. **PURPOSE:** To determine if the conduction velocity of a patellar tendon reflex is sensitive to aging. **METHODS:** One hundred and one volunteers participated in this study. Tendon taps were delivered to the patellar tendon of each subject while surface electromyographic (EMG) signals were recorded from the rectus femoris. The pre-motor reflex latency was calculated as the time from the onset of the hammer-strike to the onset of EMG activity. This latency (s) was adjusted for femur length (m) to instead provide a pre-motor conduction velocity (CV; m/s). The subjects were then grouped and averaged into intervals based on age as follows: 18 - 29 yrs. ($n = 50$), 30 - 39 ($n = 10$), 40 - 49 ($n = 6$), 50 - 59 ($n =$

16), 60 - 69 (n = 13) and > 70 (n = 6). Linear regression was applied across the mean age and pre-motor CV from each interval. **RESULTS:** Pre-motor CV was negatively related to age ($r = -0.799$; $p = 0.028$). The resulting regression equation was $y = -0.1113x + 24.216$. The group averaged data as well as the line of best fit are shown in the figure below. **CONCLUSION:** Our findings show that the conduction velocity of a patellar tendon reflex is significantly related to age. Therefore, this variable may be useful in future studies that wish to track changes in sensory function across age.

Motor Execution And Imagery With Greater Task Difficulty Increases Corticospinal Excitability

Hironori Watanabe, Sohei Washino, Hiroaki Kanehisa, Yasuhide Yoshitake. *National Institute of Fitness and Sports in Kanoya, Kanoya, Japan.*

Email: m157010@sky.nifs-k.ac.jp

(No relationships reported)

PURPOSE: To elucidate the influence of task difficulty during actual and imaginary force control by the unilateral first dorsal interosseous muscle (FDI) on the corticospinal excitability of 1) the contracting and contralateral resting hands and 2) the resting hand, respectively. **METHODS:** Seventeen young adults were asked to perform isometric abduction with their left index fingers (contracting hand) at 5 and 15% of maximal voluntary contraction (MVC) with visual guidance in actual force control task and to imagine isometric abduction at 15% MVC in imaginary force control task with the same procedure to actual force control task. Task difficulty was adjusted by the size of range about target force displayed on the computer monitor, which was defined by upper and lower lines, i.e., $\pm 7\%$ of target force between lines as 'easy' task and 0% of target force between lines as 'difficult' task. Subjects actually or imaginarily attempted to match their abduction force within the target range as steady as possible. In each task, transcranial magnetic stimulation was applied twenty times to the optimal scalp position for eliciting the motor evoked potential (MEP) in FDI overlying right or left motor cortex. The averaged MEP was normalized by the maximal motor response (% Mmax) that was obtained during supramaximal electrical stimulation to the ulnar nerve. **RESULTS:** In actual force control task, the MEP of the contracting hand was significantly larger ($P < 0.05$) during difficult task (24.8% Mmax) compared with easy task (22.3% Mmax) when collapsed across force levels. The MEP of the resting hand was also significantly larger ($P < 0.05$) in difficult task (12.3% Mmax) than in easy task (9.5% Mmax) when collapsed across force levels. In imaginary force control task, the MEP for difficult task (11.0% Mmax) was significantly larger ($P < 0.05$) compared with that for easy task (8.1% Mmax) in the resting hand. **CONCLUSION:** These results indicate that 1) actual force control task with greater task difficulty increases corticospinal excitability of the contracting hand, and 2) corticospinal excitability of the resting hand is enhanced when subjects actually and imaginarily perform force control task with greater task difficulty by the unilateral hand.

Bilateral Arthrogenic Muscle Inhibition in the Soleus Muscle Following Acute Ankle Sprain

Kyung-Min Kim, Joo-Sung Kim. *University of Miami, Miami, FL.* (Sponsor: Arlette Perry, FACSM)

Email: kmk154@miami.edu

(No relationships reported)

Arthrogenic muscle inhibition (AMI) is characterized by decreased spinal excitability, and has been suggested to be one of the neurophysiological mechanisms responsible for muscle dysfunction following joint injury. AMI has been found in individuals with chronic ankle instability, yet it is unclear whether AMI is present in patients with acute ankle sprain (AAS). **PURPOSE:** To determine the effects of AAS on spinal excitability in lower leg muscles. **METHODS:** Nineteen subjects with AAS within 72 hours of the injury onset (10 females; age=21 \pm 2.7 years; height=173.2 \pm 9.2cm; weight=71.7 \pm 11.7kg) and 19 healthy controls without any history of ankle sprain (10 females; age=22 \pm 2.2 years; height=170.8 \pm 9.2cm; mass=68.9 \pm 14.2kg) participated.

Hoffman reflex (H-reflex) was used to quantify AMI. H-reflex tests of the soleus, fibularis longus, and tibialis anterior were performed bilaterally in the prone position. Maximum peak-to-peak amplitudes of H-reflexes (H-max) and motor waves (M-max) were recorded. Since H-max significantly varies between individuals, it was normalized to M-max to obtain a $H_{max}:M_{max}$ ratio for each muscle. Separate two-way ANOVAs with repeated measures were performed to compare groups (AAS, control) and limbs (injured, uninjured) for each of the muscles. The alpha level was set at <0.05 . **RESULTS:** There were no significant group-by-limb interactions for all muscles: the soleus ($F_{(1,34)}=1.763$, $P=0.19$), fibularis longus ($F_{(1,32)}=1.194$, $P=0.28$) and tibialis anterior ($F_{(1,32)}=0.887$, $P=0.35$). However, there was a significant group main effect for the soleus ($F_{(1,34)}=5.219$, $P=0.029$). The $H_{max}:M_{max}$ ratio in the AAS group (0.56 \pm 0.04) was significantly lower than in the healthy control group (0.68 \pm 0.04). No significant main effects were found in the fibularis longus ($F_{(1,31)}=0.084$, $P=0.77$) and tibialis anterior ($F_{(1,32)}=1.255$, $P=0.27$). **CONCLUSION:** AMI in the soleus muscle was present bilaterally in patients with AAS, which provides insight into neurophysiological mechanisms responsible for bilateral muscle dysfunction following the unilateral acute injury.

Changes In Motor Unit Recruitment And De-recruitment Strategies Are Not Associated With The Repeated-bout Effect

Jessica Peterson, 73019, Robert Hight, Cameron Lohman, Christopher Black. *University Of Oklahoma, Norman, OK.* (Sponsor: Kevin McCully, FACSM)

Email: jessica.a.peterson-1@ou.edu

(No relationships reported)

The "repeated bout effect" (RBE) is an adaption that attenuates muscle damage following eccentric exercise. Several neural adaptations have been proposed to underlie the RBE. **PURPOSE:** This study used decomposition of surface EMG signals (dEMG) to examine the relationship between recruitment (RT) and de-recruitment thresholds (DRT) and changes in firing rates or motor units during recruitment and de-recruitment prior to and following eccentric exercise resulting in the RBE. **METHODS:** Nine participants performed 5 sub-maximal isometric trapezoid contractions at force levels corresponding to 50% and 80% of maximal isometric strength (MVC). Eccentric exercise was then performed until biceps brachii MVC had decreased by ~40%. MVC, range-of-motion (ROM), and delayed onset muscle soreness (DOMS) were measured 24-hours, 72-hours, and 1-week following eccentric exercise. Three weeks later all procedures were repeated. EMG signals of the biceps brachii were decomposed into individual motor-unit action potential trains. The relationship between RT and DT was examined using linear regression. The slope of the change in mean firing rate (MFR) during the ramp-up and ramp-down phase of the trapezoid contraction was also examined. **RESULTS:** No changes were found in the slope of the RT vs DT relationship for 50% MVC (1.13 \pm 0.17 vs 1.29 \pm 0.43; $p=0.42$) and 80% MVC (1.09 \pm 0.18 vs 1.25 \pm 0.41; $p=0.25$). There were also no changes in the y-intercept of the RT vs DT relationship at 50% (-13.79 \pm 6.77 vs -15.37 \pm 17.07; $p=0.80$) and at 80% (-9.29 \pm 10.71 vs -23.07 \pm 20.28; $p=0.06$) of MVC. The mean slope of the increase in firing rate during recruitment did not change between bouts 10.2 \pm 1.8 vs 10.5 \pm 2.2 pps/s ($p=0.77$) and 8.4 \pm 0.7 vs 9.0 \pm 1.6 pps/s ($p=0.28$) for 50% and 80% of MVC, respectively. The slope of the decrease in firing rate during de-recruitment did not differ at 50% of MVC -9.7 \pm 1.5 vs -10.2 \pm 1.8 pps/s ($p=0.48$), but became steeper during contractions at 80% of MVC -7.3 \pm 0.9 vs -8.7 \pm 1.7 pps/s ($p=0.04$). However, no relationship was observed between the change in DT slope and the magnitude of the RBE. **CONCLUSION:** A bout of eccentric exercise conferred protection from a subsequent identical bout. Few changes in motor-unit recruitment and de-recruitment behavior were observed suggesting changes in these parameters are not responsible for the RBE.

Myosin Heavy Chain Influences Firing Rate Behavior from Moderate to High Intensity Targeted Forces

Michael A. Trevino, Philip Michael Gallagher, Andrew C. Fry, Jonathan D. Miller, Adam J. Sterczala, Trent J. Herda. *University of Kansas, Lawrence, KS.*

Email: mtrevino@ku.edu

(No relationships reported)

PURPOSE: It is suggested the ratio of myosin heavy chain (MHC) isoforms and their influence on twitch forces and fatigability effect motor unit (MU) behavior. However, no study has correlated changes in MU firing rates among moderate- to high-intensity contractions with MHC area *in vivo*.

METHODS: Twelve individuals (age=20.89 \pm 2.52 yrs, weight=72.03 \pm 14.02 kg) performed 3 isometric maximal voluntary contractions (MVC) of the leg extensors on an isokinetic dynamometer followed by randomly ordered isometric muscle actions at 50, 70, and 90% MVC. An electromyographic (EMG) sensor was placed over the

VL. EMG signals were decomposed to extract action potentials and firing events of single MUs. Only MUs with > 90% accuracy were used for analysis. Recruitment thresholds (REC Thresh) and mean firing rates (MFR) were calculated for each MU. MFR was calculated as the average value of the MFR trajectory during steady force. Subjects gave a muscle biopsy of the VL. Type I %MHC area was determined by SDS-PAGE. Linear regressions were performed for the 50% MVC, whereas inverse exponential regressions were performed on the 70% and 90% MVC to determine the slopes and y-intercepts for the MFR vs REC Thresh relationships. Predicted firing rates at target force were calculated from the regression equations for each subject for MUs with a REC threshold of 5-45% MVC in 5% increments. To examine changes in MU firing rates in relation to REC Thresh, predicted firing rates from the 70% and 90% MVC were normalized to the predicted firing rate value for the 50% MVC. For each REC Thresh, linear regressions were performed on the normalized firing rate values vs contraction intensity. Pearson's product moment correlations were calculated comparing the slopes and type I %MHC area. Alpha was set at 0.05.

RESULTS: Pearson's product moment correlations were significant among type I %MHC area and the slopes of the change in predicted firing rates vs contraction intensity for MUs with a REC thresh of 35, 40, and 45% MVC ($P < 0.05$; $R = -0.754$ to -0.669).

CONCLUSIONS: Individuals with lower percentages of type I MHC area had greater increases in MU firing rates with increments in targeted forces for MUs with REC Thresh of 35 - 45% MVC. This may indicate that MU firing rate and recruitment patterns differ as a function of MHC area.

Fatiguing Knee Extensors Has Differential Effects on Contralateral Homologous and Non-Related Heterogenous Muscles

Xin Ye¹, Travis W. Beck², Nathan P. Wages², Joshua C. Carr², Hayden M. Tharp², Michael G. Bembem, FACSM², Rebecca D. Larson², Carr J. Ade³. ¹University of Mississippi, University, MS. ²University of Oklahoma, Norman, OK. ³Kansas State University, Manhattan, KS.
Email: xye1@olemiss.edu
(No relationships reported)

Non-local muscle fatigue (NLMF), defined as a temporary motor performance deficit in a non-exercised muscle group following a fatiguing protocol on a different muscle group, has been gaining attention in the recent decade.

PURPOSE: To examine the possible NLMF-induced changes in isometric strength and surface electromyographic (EMG) of both the contralateral homologous and non-related heterogenous muscles after fatiguing the unilateral knee extensor (KE) muscle group.

METHODS: Ten men (27 ± 3 years) and five women (27 ± 2 years) participated in a 3-visit investigation which consisted of a familiarization visit and 2 separate randomly sequenced experimental visits. During the experimental visits, the same fatiguing intervention (six sets of 30-second maximal isometric KE contractions, with 30-second rest interval between sets) were applied. Before and after the fatiguing intervention, the maximal isometric strength and the corresponding surface EMG amplitude were measured on the non-exercised left elbow flexors (EF) or KE. Separate paired sample t-tests were used to examine the potential changes in the dependent variables described above.

RESULTS: After the fatiguing intervention, there was a significant decrement in isometric strength for the non-exercised EF (Pre- vs. Post-fatigue = 382.06 ± 34.28 vs. 354.20 ± 120.76 N, $t = 3.676$, $p = 0.001$), but not for the non-exercised KE. For the non-exercised EF, there was also a decreased normalized EMG amplitude in the biceps brachii (Pre- vs. Post-fatigue = $100.0 \pm 0.0\%$ vs. $86.5 \pm 6.6\%$, $t = 2.049$, $p = 0.03$). However, the normalized EMG amplitude did not change in the non-exercised vastus lateralis (VL).

CONCLUSIONS: Fatiguing the unilateral KE did induce the NLMF in the non-related heterogenous upper body muscle group (the EF), which was possibly due to the fatigue-induced decreased voluntary drive. However, for its contralateral homologous muscle group (non-exercised KE), the NLMF effect on isometric strength was absent, which could be explained by the unaltered maximal muscle activation level in the non-exercised VL. Therefore, fatiguing unilateral KE has differential effects on contralateral homologous and non-related heterogenous muscles.

Recruitment Properties In Vastus Medialis And Vastus Medialis Oblique In Individuals With Patellofemoral Pain Syndrome

Yi-Ling Peng¹, Matthew S. Tenan², Lisa Griffin¹. ¹UT Austin, Austin, TX. ²US Army Research Laboratory, Aberdeen Proving Ground, MD.
Email: elena.peng@utexas.edu
(No relationships reported)

Patellofemoral pain syndrome (PFPS) is a commonly diagnosed knee pathology that is twice as prevalent in women. Sports medicine clinicians commonly use exercises to attempt to preferentially activate the vastus medialis oblique (VMO) to enhance medially vectored forces on the patella. Recently, our group confirmed clinical theory that the VMO is neurologically distinct from the vastus medialis (VM). However, the ability to voluntarily activate these muscle sub-sections is still disputed. **Purpose:** To determine how PFPS affects neuromuscular control of VM/VMO and examine if hip rotation during a straight leg raise (SLR) modifies motor patterns. **Methods:** Thirteen healthy women and four women with PFPS performed isometric SLR in neutral hip rotation (SLR-NR) and during 30 degrees hip lateral rotation (SLR-LR). Participants performed ramp contractions by tracing a line on a screen with a rate of rise of 7.5% maximal voluntary contraction (MVC) per second up to 75% MVC. Bipolar intramuscular fine-wire electrodes were inserted into the VM and VMO. Initial motor unit firing rates (IFR) and recruitment threshold (RT) forces were measured. Generalized linear mixed models and Tukey post hoc tests were used to assess significant differences. The recruitment thresholds were log-transformed to meet the assumptions of normality of residuals and constant variance within each level. **Results:** A total of 420 motor units were analyzed. There was a significant interaction effect for Muscle \times Group for RT ($p=0.02$), demonstrating that women with PFPS activated their VMO later ($20.4 \pm 2.5\%$ MVC) than healthy women ($11.2 \pm 1.5\%$ MVC; $p=0.01$). The Group \times Hip Position interaction effect was also significant for RT ($p=0.02$). Healthy women activated their VMO earlier during SLR-NR ($9.9 \pm 1.5\%$ MVC) than during SLR-LR ($14.9 \pm 1.5\%$ MVC; $p=0.02$). Women with PFPS had a delayed VMO onset time ($19.1 \pm 2.5\%$ MVC) compared to healthy women ($9.9 \pm 1.5\%$ MVC) in SLR-NR ($p=0.02$). There was no significant difference in IFR between muscles or hip positions between groups. **Conclusions:** Targeted strengthening of the VMO in SLR with a neutral hip rotation is a more effective training position for women with PFPS than using lateral hip rotation.

(No relationships reported)

Non-contact anterior cruciate ligament (ACL) injury is associated with motor coordination errors leading to comprised knee positioning and resultant knee loads that exceed ligament structural integrity. The nature of the ACL injury event (non-contact) and typical occurrence during high neurocognitive demand situations indicate a nervous system mechanism underlying the inciting event associated with injury. A better understanding of the neural contribution to ACL injury prevention training may enhance the ability to target the underlying mechanisms associated with injury risk. However, it is unknown what neuroplastic mechanisms contribute to the improved motor control documented after neuromuscular training.

Purpose: To compare the knee sensorimotor cortex activation level before and after neuromuscular control training.

Methods: Ten high school female soccer participants from the local community (age: 15.7 ± 0.95 years; height: 168.4 ± 4.60 cm; mass: 59.91 ± 5.62 kg.) were included in the analysis. fMRI data were collected during performance of a unilateral knee motor task of the left knee consisting of repeated cycles of extension-flexion before and after neuromuscular training. The activation level (blood oxygen level dependent signal) was calculated within the sensorimotor cortex as the primary region of interest. The neuromuscular training program consisted of 6 weeks of standardized ACL injury prevention training augmented with real time feedback designed to reduce movement related knee injury risk factors.

Results: Sensorimotor cortex activation increased after training (cluster data: voxels: 1120; $p < 0.0001$; z -max: 8.55; MNI coordinate peak voxel: 12, -26, 80; %signal difference: 0.37 ± 0.81) relative to pre-training.

Conclusions: The sensorimotor increased activation associated with neuromuscular training is similar to motor recovery after injury and after long-duration (weeks) motor skill training. The increased sensorimotor cortex activation indicates the cortical representation may be functionally increased for knee motor control after the focused intervention. Future work with expanded sample sizes will map whole brain connectivity and other brain region activation changes associated with neuromuscular training.

Exploring Relations Between Gross Motor Skills, Attention, and Inhibition in Adolescents

Jonathan Rivard, Julie Bouchard, Annie Gagné, Linda Paquette, Jacinthe Dion, Tommy Chevrette. *UQAC, Chicoutimi, QC, Canada.*

Email: jonathan.c.rivard@gmail.com

(No relationships reported)

PURPOSE: Scientific literature addressing the association between Gross Motor Skills (GMS), attention, and inhibition is scarce. Studying these relations helps better understand the interactions and their behavioral repercussions. The aim of this study is to search for relations between gross motor skills, attention, and inhibition. **METHODS:** GMS of adolescents ($n=220$, range=13-17; mean 15.0 ± 1.4 yrs) were assessed using protocols from UQAC-UQAM research team. Measures included: Arm and Leg Limb Speed, Agility, Coordination, Balance and Simple Reaction Time. Attention and inhibition measurements were collected using a Continuous Performance Test (CPT) protocol. Reaction times, number of errors, types of errors and derived measures from the CPT were used. Statistical analysis includes Spearman correlation test and Kruskal Wallis ANOVA. Both parents and adolescents gave their written consents. **RESULTS:** Reaction Time was in relation with all agility measurements (Circle Run: $r = .19$, $p < .01$; Shuttle Run: $r = .17$, $p = .01$; Slalom Run: $r = .17$, $p = .01$), but also with Limb Speed measures ($r = -.21$, $p < .01$). Variability of Reaction Time was correlated with Agility (Circle Run test: $r = .16$, $p < .05$), (Slalom Run test: $r = .15$, $p < .05$), Limb Speed ($r = .24$, $p < .01$) and Balance ($r = .15$, $p < .05$). Girls showed more correlations between GMS and neuropsychological measures. **CONCLUSIONS:** Some neuropsychological measures obtained with CPT protocol were related to Limb Speed, Agility, Balance and Reaction Time in adolescents. This conclusion suggests that motor and psychomotor development may play a role in helping adolescents to better perform in attention and inhibition ability. The relations between functions were affected by gender. Future research is needed to better understand the role of motor and psychomotor development program on psychological measurements.

Gaze Stability of Visually Trained and Non-Visually Trained Athletes During a Sport-Like Postural Task

Brian Szekely¹, Megan Mormile¹, Peter Chrysoferidis¹, Katelyn Grimes¹, Brian Mizeski¹, Barry Munkasy¹, Douglas Powell², Nicholas Murray¹. ¹Georgia Southern University, Statesboro, GA. ²University of Memphis, Memphis, TN.

(No relationships reported)

During object tracking, reflexive eye movements away from the target object or directional errors occur in order to capture visual field information. These 'off-target' visual data aid the brain in determining the velocity, location, and orientation of the objects in motion. However, an excessive amount of movement is classified as pro-saccade errors and can disrupt gaze stability. Little is known about how these errors differentiate between athletes who participate in object tracking sports versus those that do not in object tracking sports. **PURPOSE:** The aim of this study was to compare gaze stability of athletes who train and perform in visually (VT) and non-visually (NVT) rich environments during a sport-like postural anti-saccade task, the Wii Fit Soccer Heading Game (WFS). **METHODS:** 12 NCAA Division I VT (17.91 ± 0.51 years of age) and 12 matched (NVT) athletes (18.08 ± 0.51 years of age) wore a monocular eye tracker (240 Hz) while participating in two WFS trials of approximately 60 s. Athletes were instructed to maintain their gaze on the center of the screen during play. Motion capture was synced during the postural task to determine instantaneous gaze coordinates. Multivariate ANOVAs assessed gaze by direction (horizontal and vertical) for excursion and peak velocity, while an independent t-test assessed pro-saccade errors. **RESULTS:** A significant group difference was observed in vertical gaze ($p < .05$). Follow up assessments indicated greater gaze excursions (VT = 871.74 ± 446.23 pixels; NVT = 554.79 ± 220.54 pixels; $p = 0.038$) and vertical peak velocities (VT = 1660.25 ± 860.78 pixels/s; NVT = 711.01 ± 551.45 pixels/s; $p = 0.004$). No significant differences were observed in the horizontal direction. There were no significant differences in pro-saccade errors between the groups ($p = 0.96$; VT SE = 2.64; NVT SE = 1.63). **CONCLUSION:** These results suggest that VT athletes' gaze moved more and had greater velocity in the vertical direction when compared to NVT. This could indicate that VT use a vertical scanning visual strategy to locate and determine

velocity of the object during a sport-like anti-saccade postural task. This could suggest that VT use different motor control strategies to maintain gaze stability during anti-saccade task than NVT.

The Effect of Different Cognitive Tasks on Motor Output in Young Adults

Amanda Morris, David Gallacher, Anita Christie. *University of Oregon, Eugene, OR.* (Sponsor: David Gabriel, FACSM)

Email: amorris8@uoregon.edu

(No relationships reported)

Performance of a cognitive task can alter performance on a simultaneous motor task. The underlying mechanisms leading to these changes are unknown. **PURPOSE:** To determine the effects of a simple and complex cognitive task on motor cortex excitability and inhibition. **METHODS:** Transcranial magnetic stimulation of the motor cortex was performed on 11 participants (21.2 ± 0.9 years; 6 females) to measure motor evoked potentials (MEP), an assessment of cortical excitability, and cortical silent periods (CSP), an assessment of cortical inhibition, from the first dorsal interosseous muscle. MEP and CSP were obtained during: (1) baseline with no cognitive task, (2) a simple cognitive task, and (3) a complex cognitive task. The simple cognitive task consisted of counting from 1 to 10 and the complex task consisted of counting down from a large number by smaller numbers (e.g. count backward from 97 by 6). **RESULTS:** MEP amplitude was similarly increased during the simple ($1.38 + 1.23$ mV) and complex tasks ($1.34 + 1.1$ mV), compared to baseline ($0.68 + 0.38$ mV) ($p = 0.01$). CSP duration was $114.65 + 58.64$ ms at baseline and did not change significantly with either the simple ($117.07 + 53.27$ ms) or complex ($113.93 + 50.71$ ms) task ($p = 0.93$). There was no significant difference in accuracy ($p = 0.89$) or time to complete ($p = 0.95$) the complex task at any time point. **CONCLUSION:** These results indicate that there was no effect of cognitive task on cortical inhibition. Further, the act of talking, rather than the act of thinking, is likely responsible for the increase in cortical excitability.

Quadriceps Torque During High- And Low-frequency Neuromuscular Electrical Stimulation

Dillon M. Magee¹, Joni A. Mettler¹, Barbara M. Doucet². ¹Texas State University, San Marcos, TX. ²Louisiana State University Health Sciences Center, New Orleans, LA. (Sponsor: Tinker D. Murray, FACSM)

Email: dm1441@txstate.edu

(No relationships reported)

Neuromuscular electrical stimulation (NMES) is often used to artificially generate muscle contraction; however, the stimulation parameters that optimally modulate torque output during prolonged stimulation protocols are not well-established. **PURPOSE:** To compare torque output between low-frequency and high-frequency NMES protocols with increasing stimulation intensity throughout the protocol to achieve a constant submaximal torque output. **METHODS:** Ten healthy individuals (age, 24.8 ± 1.2 yrs) participated in the study. This study employed a quasi-experimental crossover design in which each subject received a low-frequency (20 Hz) and a high-frequency (60 Hz) NMES intervention on different days. Repetitive, intermittent stimulation of 10 seconds on and 15 seconds off was applied for 60 min over the quadriceps muscles. Stimulation intensity was increased every 5 min throughout the course of the intervention to achieve a target torque of 15% maximal voluntary contraction (MVC). Mean torque and peak torque were measured for each contraction, were normalized to MVC, and the overall mean for all contractions was used for comparison. Force-time integral (FTI) was also measured for each contraction and the sum of all contractions was compared between protocols. Frequency was compared using paired *t*-tests. **RESULTS:** The 20 Hz protocol compared to the 60 Hz protocol produced a higher overall mean torque ($11.2 \pm 0.5\%$ MVC vs. $8.0 \pm 0.6\%$ MVC, $p < 0.01$) and FTI sum ($38,030.0 \pm 1724.9$ Nm·s vs. $32,128.0 \pm 1668.0$ Nm·s, $p < 0.01$). There was no difference between frequencies for peak torque ($14.0 \pm 0.6\%$ MVC vs. $12.3 \pm 0.7\%$ MVC) or stimulation intensity required to achieve 15% MVC during the first 5 mins (80.2 ± 3.8 mA vs. $120.7 \pm 8.0\%$ mA) or during the last 5 mins of the NMES protocol (74.7 ± 5.0 mA vs. 120.8 ± 10.6 mA, $p > 0.05$) for 20 Hz and 60 Hz, respectively. **CONCLUSION:** Torque maintenance was greater during a low-frequency compared to a high-frequency NMES protocol when stimulation intensity was increased to achieve a constant submaximal torque output. When the goal is to optimize torque output during functional electrical stimulation, low frequency stimulation may be preferred.

Identification of Latent Variables Underlying Manual Dexterity in Middle-aged and Old Adults
 Landon D. Hamilton¹, Ewan Thomas², Roger M. Enoka¹.
¹University of Colorado Boulder, Boulder, CO. ²Università degli Studi di Palermo, Palermo, Italy.
 Email: laha3107@colorado.edu
 (No relationships reported)

As a biomarker of neurologic health and function, manual dexterity quantifies the ability to coordinate and manipulate objects in a timely manner. The NIH Toolbox measure of manual dexterity is the Rolyan 9-hole pegboard test with the Lafayette 25-hole grooved pegboard test provided as a supplement.

PURPOSE: To identify latent variables associated with pegboard times in middle-aged and old adults. We hypothesized that pegboard times would be slower for old adults and that latent variables would differ for the two groups.

METHODS: Middle-aged (MA, 40-60 yrs; n=25) and old adults (OA, 65-89 yrs; n=28) performed the 9-hole pegboard test (9HPT) and the grooved pegboard test (GPT), as well as tests of maximal grip strength, tactile discrimination, force steadiness, and the NIH Toolbox cognition battery. Latent variables were identified using Independent Component Analysis from significant Spearman's rank correlation coefficients between pegboard times and secondary measures.

RESULTS: MA adults (51±7 yrs) performed significantly faster than OA (72±5 yrs) on both the 9HPT (18±3 s and 20±3 s, $p<0.01$) and GPT (60±9 s and 78±16 s, $p<0.01$). MA adults also had superior tactile discrimination (95±11 au and 72±20 au, $p<0.01$). The latent variables influencing manual dexterity differed for the two tests and age groups: (1) 9HPT - MA times were negatively correlated ($r = -0.84$) with the first Independent Component (IC), which explained 37.8% of the covariance and included the 10% double-action pinch force error as the second largest contributor ($r = 0.45$; scaled $r = 0.54$); OA times were positively correlated ($r = 0.60$) with the first IC, which explained 24.4% of the covariance and included wrist extension strength the second largest contributor ($r = 0.52$; scaled $r = 0.88$); (2) GPT - MA times were positively correlated ($r = 0.71$) with the first IC, which explained 44.7% of the covariance and included index finger abduction strength as the second largest contributor ($r = -0.42$; scaled $r = -0.59$); OA times were negatively correlated ($r = -0.90$) with the first IC, which explained 73.6% of the covariance and included age as the second largest contributor ($r = -0.44$; scaled $r = -0.49$). **CONCLUSIONS:** 9HPT times were explained by accuracy to reach a force target and strength for MA and OA respectively, whereas GPT times were explained by strength and age.

Effect Of Knee Joint Angle On Force Accuracy And Neuromuscular Activation During Force Tracking Task.
 Aya TOMITA, Hiroshi AKIMA. Nagoya University, Nagoya, Japan. (Sponsor: Katsumi ASANO, FACSM)
 Email: to-mi-ta@nagoya-u.jp
 (No relationships reported)

Force steadiness and neuromuscular activities during isometric knee extension have been investigated in a condition of only one joint angle, e.g. 90°. Muscle length may modify force steadiness by change in neuromuscular activation patterns of working muscles; however, it have not been well understood. In terms of the quadriceps femoris muscle (QF), muscle activation differs dependent upon knee joint angle (i.e. muscle length), and its magnitude of difference is muscle dependent during knee extension force exertion. Therefore, there is a possibility that knee joint angle affects to the force accuracy (FA) and neuromuscular activation during force tracking task. **PURPOSE:** The purpose of this study was to examine FA and neuromuscular activity of QF during isometric knee extension force tracking task for 3 knee joint angles.

METHODS: Thirteen healthy men and women (23 ± 4 years) performed force tracking task during isometric knee extension to match a given a constant force signal on a computer monitor. This task was lasted 30 seconds. The force level of the task was 6% of maximal voluntary contraction (MVC). The tasks were performed in 70°, 110° and 150° of knee joint angle (180° = full knee extension). During the tasks, surface electromyogram (EMG) was recorded from 4 QF muscles. We calculated FA as follows: (produced force - target force) / target force*100. The root mean square (RMS) of EMG signals of each muscle was calculated in the middle of 10 seconds during 30 seconds task. The RMS of the individual muscles was normalized by that of the MVC.

RESULTS: There was significant difference in FA between knee joint angles. FA at a knee joint angle of 70° was significantly greater than that at knee joint angle of 110° and 150° ($p = 0.026$ and 0.028). RMS of vastus intermedius (VI) was smaller at 70° than 110° ($p = 0.005$). On the other hands, RMS of vastus lateralis, vastus medialis, and rectus femoris did not differ between knee joint angles ($p > 0.05$).

CONCLUSIONS: The FA of the QF was worse at a flexed knee joint position than other extended knee joint positions. Furthermore, neuromuscular activation pattern of VI was different depend on knee joint angles, whilst that of other muscles was similar. That result suggests that force control strategy may be modified by neuromuscular activation of VI with respect to knee joint angle (i.e. muscle length).

Locomotor Training with Adjuvant Testosterone Promotes Activity-Mediated Neuromuscular Plasticity in Spinal Cord Injured Rats

Joshua F. Yarrow. VA Medical Center, Gainesville, FL.
 Email: jfyarrow@ufl.edu
 (No relationships reported)

Testosterone (T) treatment preserves motor neuron survival and dendritic morphology after spinal cord injury (SCI), but produces only minimal neuromuscular recovery in the absence of locomotor activity. **PURPOSE:** To determine whether a multimodal strategy involving T treatment with partial body weight supported quadrupedal treadmill (TM) training produces neuromuscular benefit in a rodent severe contusion SCI model. **METHODS:** 16-week old male Sprague-Dawley rats (n = 8-11/group) received: 1) SHAM surgery (T9 laminectomy), 2) severe (250 kdne) contusion SCI, 3) SCI+T (7.0 mg/week, i.m.), or 4) SCI+T+TM. Manually assisted TM training was initiated one-week post-SCI and consisted of two 20 min bouts/day, performed 5 days/week. **RESULTS:** After surgery, all SCI animals exhibited a near-complete absence of hindlimb locomotor function [BBB score < 1 (scale 0-21); $p < 0.01$ vs SHAM]. SCI and SCI+T regained minimal voluntary locomotor function, with BBB scores progressing to 4 ± 1 and 6 ± 1, respectively, over the 8 week intervention. At sacrifice, SCI animals exhibited 42% lower soleus mass ($p \leq 0.001$) and altered *in vitro* force mechanics, characterized by 35% lower maximal tetanic force ($p \leq 0.001$), 8% faster time to peak tension (TPT, $p \leq 0.001$), and 50% faster half-relaxation time (half RT, $p \leq 0.01$) vs SHAM; effects that were not prevented by T treatment-alone. BBB hindlimb locomotor scores were higher in SCI+T+TM vs SCI and SCI+T groups from weeks 2-8 ($p < 0.01$ at all time points), reaching a value of 10 ± 1 by week 8. At sacrifice, 7 of 8 SCI+T+TM animals exhibited unassisted/voluntary weight supported stepping (BBB score ≥ 9), in comparison with 0 of 11 SCI animals and 2 of 10 SCI+T animals ($p \leq 0.001$). In addition, T+TM ameliorated muscle loss and produced a near-complete preservation of muscle mechanical properties, exemplified by 33-40% higher soleus mass ($p \leq 0.001$), 35% higher maximal tetanic force ($p \leq 0.001$ vs SCI-only), 9-11% slower TPT ($p \leq 0.001$), and 130% slower half RT ($p \leq 0.001$) vs SCI and SCI+T groups. **CONCLUSION:** TM training with adjuvant T accelerated hindlimb locomotor recovery after severe contusion SCI and mitigated the loss of soleus muscle mass and muscle function, suggesting that this combinatory strategy promotes activity-mediated neuromuscular plasticity.

Relationship Between Body Composition And The Autonomic Nervous System Behavior At Rest

Henry H. León-Ariza¹, Daniel A. Botero-Rosas¹, Alejandra I. Silva-Urribé¹, Gabriela Sánchez-Tangredi¹, Victoria I. Morales-González¹, Aura C. Zea-Robles². ¹La Sabana University, Chia, Colombia. ²Santo Tomas University, Bogotá, Colombia.
 Email: henrylear@clinicaunisabana.edu.co
 (No relationships reported)

In recent years, the assessment of body composition (BC) has been reframed by the hormonal effect that skeletal muscle and adipose tissue have in the body, including the autonomic nervous system (ANS). **PURPOSE:** To determine the relationship between the BC and ANS response in a population of individuals with different levels of physical activity. **METHODS:** 63 individuals (31 men 19.9 ± 2.4 years and 19.6 ± 32 women 2.0 years) were evaluated on their body composition (bioimpedance and anthropometry) and the ANS activity at rest through the Heart Rate Variability. **RESULTS:** In men a directly proportional relationship between the percentage of muscle mass (evaluated for both methods) and indicators of parasympathetic activity was found: The Root Mean Square Successive Differences RMSSD ($r=0.40$; $p<0.05$), the deviation of the scattergram plot in the "short" direction SD1 ($r=0.40$; $p<0.05$), and Vagal Cardiac index VCI ($r=0.46$, $p<0.05$), while body fat was associated with sympathetic indicators as the ratio Low Frequency / High Frequency ($r=0.36$; $p<0.05$) and sympathetic cardiac index SCI ($r=0.36$, $p<0.05$), the SCI was inversely proportional to muscle mass too ($r=-0.41$ $p<0.05$). In women only heart rate was directly related to adipose tissue ($r=0.35$; $p<0.05$) and inversely with muscle mass ($r=-0.42$; $p<0.05$). **CONCLUSIONS:** The muscle mass has an influence on the ANS by increasing parasympathetic activity and reducing the sympathetic activity, the evidence suggests that there are some hormones produced by the muscles (myokines) like the Fibroblast Growth Factor 21 or the Brain Derivate neurotrophic Factor that produce

this effect. For the other hand, some adipokines like the Tumoral Necrosis Factor alpha and the leptin contribute to have greater sympathetic and lower parasympathetic activity.

The Effects of Short-Term Resistance Training with & without Blood Flow Restriction on Neuromuscular Adaptations

Gabriela A. Soto, Roberto Osornio IV, Danny Dominguez, Delisha Horne, Ashley Taylor, Pedro Vasquez, Hugo Santana, Murat Karabulut. *University of Texas Rio Grande Valley, Brownsville, TX.*
 Email: gabriela.soto01@utrgv.edu
 (No relationships reported)

PURPOSE: To investigate the neuromuscular adaptations in quadriceps muscles after short-term resistance training with and without blood flow restriction (BFR). **METHODS:** Twelve males (age = 27.4 ± 6.3 years; height = 171 ± 7 cm; weight = 79.8 ± 13.2 kg) volunteered to participate in this study. Subjects had their legs randomly assigned to two training conditions that differed in contraction intensity. One leg was trained with blood flow restriction (BFR) at an intensity of 20% of their one repetition maximum (1RM) for a total of four sets (30, 15, 15, 15 repetitions) and the contralateral leg was trained without BFR (non-BFR) at an intensity of 70% 1RM for two sets of 11 repetitions. Subjects performed unilateral knee extensions and trained each leg with their assigned training protocol for 2 weeks, 3 times/wk. Pre, and post 1RM tests were performed for each leg on a dynamic constant external resistance machine and an isokinetic exercise machine was used to determine maximal voluntary contraction (MVC) and isokinetic exercises at two speeds of 60°/s and 180°/s. Additionally, heart rate (HR) and rating of perceived exertion (RPE) were recorded after the completion of each set. **RESULTS:** No condition*time interaction or condition main effect for 1RM strength test was detected, but there was a significant time main effect for 1RM strength from pre to post values (p=0.01). There were significant condition*time, condition*day, and day*time interactions and condition (HR was higher for non-BFR and RPE for BFR), day, and time main effects for HR and RPE values (set 3 and 4 for BFR vs. set 1 and 2 for non-BFR) (p<0.05). There were no significant condition*time interaction, condition main effect, or time main effect for MVC and isokinetic strength at 180°/s and 60°/s (p>0.05). **CONCLUSION:** The findings indicate that both training conditions resulted in similar dynamic strength gains suggesting that low-intensity BFR training is as effective as high-intensity training in neuromuscular adaptation following short-term resistance training. The results also suggest that non-BFR condition placed an increased demand on the cardiovascular system, but subjects experienced higher perceived exertion during BFR.

3638 Board #85 June 3 8:00 AM - 9:30 AM
Validation of the Neuromuscular Fatigue Threshold Treadmill Test

Chelsea Hahn, Benjamin Hendrickson, Rachel Davis, Cole Monson, Clayton Camic. *University of Wisconsin-La Crosse, La Crosse, WI.*
 Email: hahn.chelsea@uwlax.edu
 (No relationships reported)

PURPOSE: To examine the validity of the physical working capacity at the fatigue threshold (PWC_{FT}) model as a neuromuscular fatigue-threshold during incremental treadmill running. **METHODS:** Twelve aerobically-trained individuals [(mean ± SD) 24.0 ± 14.8 yr, 73.1 ± 13.1 kg, 178.8 ± 9.1 cm] volunteered to perform a treadmill test to exhaustion on four separate visits with electromyographic (EMG) signals recorded from the vastus lateralis. The first visit required each subject to complete an incremental treadmill test to exhaustion that started at 9.0 km·hr⁻¹ and increased 1 km·hr⁻¹ (1% constant grade) every two minutes for determination of their PWC_{FT}. During the second, third, and fourth visits, the subjects completed constant-velocity treadmill runs to exhaustion at 90, 100, or 110% PWC_{FT} in random order. Each laboratory visit was separated by at least 48 hours. **RESULTS:** Mean ± SD values were calculated for the running velocities associated with 90% (11.6 ± 1.5 km·hr⁻¹), 100% (13.0 ± 1.6 km·hr⁻¹), and 110% (14.3 ± 1.8 km·hr⁻¹) PWC_{FT}. The one-way ANOVA with repeated measures and post-hoc analyses indicated that the time to exhaustion (TTE) at the constant velocity of 110% PWC_{FT} (19.44 ± 10.26

min) was significantly less than at 90% PWC_{FT} (60.00 ± 0.00 min) and 100% PWC_{FT} (48.86 ± 14.59 min). Individually, ten of the subjects (83.3%) were able to maintain the running velocity associated with 100% of their PWC_{FT} for at least 40 minutes, whereas only one of the subjects (8.33%) was able to maintain 110% PWC_{FT} for more than 30 minutes. All subjects maintained 90% PWC_{FT} for 60 minutes. Furthermore, the normalized EMG amplitude values increased across time (R² = 0.98, p < 0.001) during the 110% PWC_{FT} run to exhaustion, but resulted in no change during the 90% PWC_{FT} (R² = 0.23, p = 0.16) and 100% PWC_{FT} (R² = 0.03, p = 0.64) runs to exhaustion. **CONCLUSIONS:** The findings of the present study indicated that the PWC_{FT} treadmill test was able to accurately estimate the fastest running velocity that could be maintained for an extended period of time (i.e. ≥ 40 min) without evidence of neuromuscular fatigue (i.e. slope coefficient of zero for the EMG amplitude versus time relationship).

Correlation Between Muscle Strength And Vagal Cardiac Autonomic Modulation In Healthy Men

Giliard L. Garcia, Keila E. Fontana, Carlos J. G. da Cruz, Edgard M. K. V. K. Soares, Luiz G. G. Porto, Luiz F. Junqueira Jr, Guilherme E. Molina. *University of Brasilia, Brasilia, Brazil.*
 Email: giliardlgarcia@gmail.com
 (No relationships reported)

Unsatisfactory muscle strength (MS) and low degree of cardiac autonomic modulation (CAM) at rest are related to higher morbidity and mortality in apparently healthy men. However, the association between MS and CAM at rest in this population is still unclear. **Purpose:** We aim to correlate the muscle strength with resting and responsiveness vagal CAM in healthy men. **Methods:** We evaluated 14 clinically normal men, aged 24.1 ± 5.6 years showing BMI = 24.9 ± 1.9 kg/m². MS was assessed by isokinetic dynamometer Biodex during knee extension with 60°/s in 2 sets of 4 maximum repetitions and 60s between them. The highest peak torque (PT), absolute and relative, was adopted as the maximum MS value. CAM was assessed by 5-min heart rate variability (HRV) at rest, supine and orthostatic postures by the time-domain rMSSD and Poincaré plot SD1 vagal indexes, using the Polar RS800® to RR-interval acquisition and the Kubios software for analyses. CAM responsiveness was estimated by the absolute variation (Δabs) of rMSSD and SD1 from supine to orthostatic postures. Due to non-normal distribution of variables (*Shapiro-Wilk test*) we used the Spearman correlation at the 5% level of significance. **Results:** We observed a positive correlation between rMSSD and SD1 in supine position with relative PT and a positive correlation between the Δabs of rMSSD and SD1 with PT absolute and relative, as shown in Table 1.

variables	r-MSSD sup	r-MSSD ort	Δabs r-MSSD	SD1sup	SD1ort	ΔabsSD1
PT(N-M)	r _s = 0.27 (p = 0.17)	r _s = 0.09 (p = 0.36)	r _s = 0.45 (p = 0.05)*	r _s = 0.27 (p = 0.17)	r _s = 0.09 (p = 0.36)	r _s = 0.45 (p = 0.05)*
PT (%)	r _s = 0.51 (p = 0.03)*	r _s = 0.32 (p = 0.12)	r _s = 0.51 (p = 0.03)*	r _s = 0.51 (p = 0.03)*	r _s = 0.32 (p = 0.12)	r _s = 0.51 (p = 0.03)*

PT: peak torque; (N-M): newton-meters; %: relative; sup: supine; ort: orthostatic; Δabs: absolute variation; * *Spearman correlation test* (p ≤ 0.05).

Conclusion: We found significant positive correlation between relative MS with resting vagal CAM on supine position and significant positive correlation between absolute and relative MS with vagal responsiveness (withdrawn) after active orthostatic stress. Our results demonstrate that the higher is the MS the higher is the tonic (resting supine) and phasic (withdrawn on standing up) vagal modulation.

Sport Events, Task Motivation Climate and Motivation in Physical Education Learning

Yu Su¹, Xiang-yang Fan². ¹*Dalian Maritime University, Dalian, China.* ²*Dalian Education Bureau, Dalian, China.*
 Email: 1760902161@qq.com
 (No relationships reported)

The impact of differences in sport events on the motivation of Physical Education Learning (PEL) has rarely been investigated although it has been reported that task

motivation climate is beneficial to the improvement of PEL. PURPOSE: To investigate the impact of differences in sport events (individual event and group event) and three types of needs (competence, autonomy and relatedness) on motivation and further to explore the causes for the lack of motivation. METHODS: The present study combines experiment and questionnaire. With 65 male students randomly selected from a high school in Dalian as subjects (age: M=16.1, SD=3.4; height: M=176.4cm, SD=9.2; weight: M=69.7kg, SD=7.5), an 8-week experiment was conducted. All the subjects were divided into two groups, 31 of which were allocated to a roller-skating class, the others to a basketball class. In order to control the variable of task motivation climate, the same teacher completed the tasks of teaching in both classes. Before the experiment, a pretest was conducted based on the Sport Situational Motivation Scale and a post-test was carried out based on the Post-Experimental Intrinsic Motivation Inventory when the experiment was completed. RESULT: The task motivation climate helped students to improve the intrinsic motivation in PEL (P>0.05). The satisfaction of competence needs is more important in the environment of autonomous learning (Motivation: $F_{intrinsic}=5.147, P<0.05$; $F_{autonomy}=5.013, P<0.05$; Interests: $F=7.808, P<0.01$; Efforts: $F=12.090, P<0.01$). The needs of autonomy, relatedness and competence are the intermediary variables which influenced the motivation level, interests and efforts in PEL. Relatedness is an important factor to account for the effects on motivation and efforts in PEL ($T_{Relatedness}=-3.995, P<0.01$). CONCLUSION: In physical education teaching, creating task motivation climate is conducive to improve the students' intrinsic motivation in PEL. The factor of sport events has no significant effect on motivation in PEL. The satisfaction of competence needs is more important in the autonomic learning environment and the group event is helpful to improve the students' relatedness.

Perceived Impact Of Restorative Flow Movement Patterns On NCAA Division II Football Athletes

Justin R. Geijer, Connie A. Mettillie. *Winona State University, Winona, MN.*
Email: jgeijer@winona.edu
(No relationships reported)

The Restorative Flow Movement Patterns are a combination of yoga principles, functional movements, and various other training principles. The traditional yoga movements are essentially modified to improve function, recovery, mobility, and stability. The goal of the Restorative Flow Movement Pattern sessions was to improve recovery, prevent injury, and improve symmetry, which is acquired through improved mobility, stability, and functionality. Previous research has indicated a significant decrease in games missed due to injury after implementation of the Restorative Flow Movement Patterns injury prevention program.

PURPOSE: The purpose of this investigation was to determine the perceived effectiveness of the injury prevention program implemented for an NCAA Division II football program, as measured by a qualitative, online survey of the student-athletes.

METHODS: A newly developed injury prevention program (Restorative Flow Movement Patterns) was implemented prior to the 2014 football season. Athletes participated in a modified yoga flow, which combined functional movement patterns with yoga movements, twice a week for the duration of the pre-season, regular season, and spring season. Online survey data was collected after the 2015 football season. Likert scales were used for all questions on the survey. Means and standard deviations were calculated for all question responses.

RESULTS: Thirty-six student-athletes responded to the survey. Participants self-reported decreased muscular soreness after games and workout sessions (1-10 scale, 5.47±2.48), improvements in flexibility (1-10 scale, 6.53±2.24) and overall well-being (1-10 scale, 5.94±1.91) as a result of the injury prevention program. Of the 36 respondents, 14 (39%) claimed the program was a useful addition to their training regimen, and 12 (33%) reported that the program improved their physical health and recovery, and another 12 (33%) reported that the program actually improved their physical health and recovery.

CONCLUSIONS: NCAA Division II football student-athletes perceive that the combination of functional movements and yoga movements can be useful in improving flexibility, decreasing muscular soreness, and improving overall well-being.

Is Vo2max Related To Rating Of Perceived Capacity (RPC) And What Is Vo2max At Onset Of Training?

Christina Gjestvang, Lene Annette Hagen Haakstad, Trine Stensrud. *Norwegian School of Sports Sciences, Oslo, Norway.*
Email: christina.gjestvang@nih.no
(No relationships reported)

ABSTRACT

Objective: To examine how maximal oxygen uptake (VO_{2max}) is related to rating of perceived capacity (RPC) and evaluate VO_{2max} at onset of training in healthy untrained adults.

Methods: In this methodological comparison study, 125 newly registered members, equally males and females, at 25 fitness centers answered an electronic questionnaire including the RPC scale and performed measurements of VO_{2max} . Eligible criteria was <4 weeks of fitness center membership, ≥18 years, and not pregnant. The RPC is a one-page scale based on metabolic equivalents task (MET), where the individual choose the most strenuous activity that can be sustained for at least 30 minutes, rated from 1 to 20. RPC was answered before measurement of VO_{2max} (using a stepwise modified Balke-protocol until exhaustion) at the laboratory. The strength of agreement between the two methods was analyzed by Bland-Altman plot, as well as Pearson correlation coefficient to enable comparison of these results with other studies. VO_{2max} at onset of training is presented as means with standard deviations (SD).

Results: Agreement as seen in Bland-Altman plot demonstrated a tendency of overestimation, meaning that the participants ranked their own aerobic capacity estimated from the RPC scale higher than objectively measured values of VO_{2max} . The mean differences between the two methods were + 0.98 (± 1.96) and + 1.31 (± 1.96) METs, with 95 % confidence limits of agreement varying from + 4.57 to - 2.60 and + 5.35 to - 2.72 METs, in men (n = 62) and women (n = 63), respectively. The Pearson correlation coefficient were moderate, with $r = 0.426$ ($p < 0.01$). VO_{2max} was mean (± SD); 37.7 (± 7.2) ml·min⁻¹·kg⁻¹, with 40.5 (± 7.2) for men and 35.0 (± 6.0) ml·min⁻¹·kg⁻¹ for women.

Conclusions: The RPC scale may be useful in large scale studies of healthy untrained individuals, but may overestimate VO_{2max} individually.

Key words: Rating of perceived capacity, RPC scale, VO_{2max} , METs

Can Rate Of Perceived Exertion Be Used To Estimate Muscle Activation?

Daniela Schäfer Olstad¹, Per-Ludvik Kjendlie², Jan Cabri², Bjørn Harald Olstad². ¹*Polar Electro Oy, Kempele, Finland.* ²*Norwegian School of Sport Sciences, Oslo, Norway.*
(No relationships reported)

Rate of perceived exertion (RPE) has been shown to be highly correlated with heart rate based training load calculations. However, there is limited information whether RPE can also be used to estimate muscle activation during exercise.

PURPOSE: Therefore, we aimed to assess the relationship between integrated electromyography (iEMG) and RPE in breaststroke swimming.

METHODS: Nine elite breaststroke swimmers (4 male and 5 female, 24 ± 7 years, BMI 23 ± 2 kg/m²) swam 25 m breaststroke at 60% (Borg RPE scale 11), 80% (Borg RPE scale 15) and 100% of maximal effort simulating the 200, 100 and 50 m breaststroke events paces. IEMG was measured from upper body muscles (UBM) including m. triceps brachii, m. biceps brachii, m. trapezius and m. pectoralis major and lower body muscles (LBM) including m. gastrocnemius, m. tibialis anterior, m. biceps femoris and m. rectus femoris. EMG was sampled at 1000 Hz and iEMG was amplitude normalized to the relative maximal voluntary contraction. Relative iEMG was expressed as % of iEMG measured at 100%. The average relative iEMG of UBM, LBM and total measured muscles (TBM). Wilcoxon signed ranks test were used to compare relative iEMG with RPE. Sex differences were assessed with Mann-Whitney U tests.

RESULTS: Relative iEMG for breaststroke was [mean ± standard deviation (SD)] 74 ± 14 for UBM, 64 ± 13 for LBM and 69 ± 13 for TBM for breaststroke at RPE 60% and 89 ± 9 (UBM), 80 ± 8 (LBM) and 85 ± 8 (TBM) for breaststroke at RPE 80%. iEMG from UBM was significantly different from RPE for RPE 60% and RPE 80% ($p=0.015$ and $p=0.038$, respectively) while TBM and LBM were similar ($p>0.05$). M. biceps femoris showed the most similar values compared to RPE (64 ± 15 for RPE 60% and 82 ± 14 for RPE 80%). There were no sex differences in relative iEMG at RPE 60% or RPE 80% ($p>0.05$).

CONCLUSION: The similar results for relative iEMG and RPE for LBM and TBM suggests that RPE can be used to estimate muscle activation of muscles generating the highest propulsive forces in breaststroke swimming. RPE may therefore also be used to optimize training load calculations from breaststroke sessions with high speeds of short duration (e.g. 50-200 m event paces) where quantifying training load from heart rate has its limitations.

Efficacy Of The Repetitions In Reserve-based Rating Of Perceived Exertion For The Bench Press In Experienced And Novice Benchers

Joseph P. Carzoli¹, Alex Klemp¹, Brittany Allman¹, Michael C. Zourdos², Jeong-Su Kim, FACSM¹, Lynn B. Panton, FACSM¹, Michael J. Ormsbee¹. ¹*Florida State University, Tallahassee, FL.* ²*Florida Atlantic University, Boca Raton, FL.*
Email: jcarzoli2016@fau.edu
(No relationships reported)

Autoregulation (AR) is the practice of adjusting training variables in response to athlete feedback. One strategy to implement AR is to utilize the resistance training-

specific rating of perceived exertion (RPE) scale measuring repetitions in reserve (RIR). **PURPOSE:** The purpose of this study was to examine the efficacy of this method using the bench press exercise. **METHODS:** Twenty-seven college aged men were assigned to one of two groups based upon training age: experience benchers (EB) (n=14, 4.7±2.0 yrs of training) and novice benchers (NB) (n=13, 1.1±0.6 yrs of training). Subjects performed a one-repetition maximum (1RM) followed by single-repetition sets at 60, 75, and 90% of 1RM and finally an 8-repetition set at 70% 1RM. Subjects reported RIR-based RPEs following every set. Average concentric velocity (ACV) was recorded via the TENDO Weightlifting Analyzer during the 1RM and all single repetitions sets, along with the first and last repetitions of the 8-repetition set. Pearson product moment correlations were used to assess relationships between RPE and velocity, while two-tail independent-sample t-tests examined differences in RPE and velocity between EB and NB. **RESULTS:** ACV at 100% of 1RM in EB was slower (0.14±0.04 m·s⁻¹) compared to NB (0.20±0.05 m·s⁻¹) (p<0.001). EB recorded greater RPE than NB at 100% of 1RM (EB: 9.86±0.14 vs. NB: 9.35±0.36) (p=0.011). No between-group differences existed for average velocity or RPE at any other intensity. Both EB (r=0.85, p<0.001) and NB (r=0.85, p<0.001) had strong inverse significant correlations between average velocity and RPE at all intensities. **CONCLUSION:** Our findings suggest that the RIR-based RPE scale may be an efficacious approach for AR of bench press training load and volume in EB and NB; however, EB may record more accurate RPEs at near maximal loads.

 (No relationships reported)

Half of all young adults between the ages of 18 and 24 yrs have at least one coronary heart disease risk (CHD) factor significantly increasing their risk for heart disease¹. Health-related fitness components are used to measure physical fitness and may facilitate in determining one's risk for CHD and other hypokinetic diseases. **PURPOSE:** The purpose of this study was to compare college students' perceived health-related fitness and their measured health-related fitness. **METHODS:** Health related fitness assessments for flexibility, body composition, cardiovascular fitness, muscular strength, and muscular endurance were selected from ACSM's Guidelines for Exercise Testing and Prescription (8th ed). Participants (n=100; 54 males and 46 females) were asked to complete an electronic questionnaire in which they selected a perceived category for each of the health-related fitness components. Participants then performed the health-related fitness assessments and categorical values were assigned to their fitness test scores. Crosstabs were used to compare actual versus perceived categories of fitness for each assessment and approximate significance was tested using Kendall's tau-b. **RESULTS:** There were significant differences (p= .05) between self-perceived and measured categories of fitness for all health-related fitness components. The area with the least amount of agreement between perceived and actual fitness was cardiovascular fitness where only 6% of participants accurately identified their fitness category. Percent body fat and muscular endurance (curl-up test) also had low levels of agreement with only 19% of participants accurately identifying their body fat category and muscular endurance category. Flexibility was the category with the highest level of agreement (33%) between actual and perceived category. **CONCLUSION:** The results of this study suggest that college students do not accurately perceive their actual health-related fitness compared to their measured fitness. Thinking one is more fit than one is could impact behaviors such as food choice and exercise that increases one's risk of hypokinetic diseases. 1. Arts, J., Fernandez, M. L., & Lofgren, I. E. (2014). Coronary heart disease risk factors in college students. *Advances in Nutrition: An International Review Journal*, 5(2), 177-187.

Physiological, Gait, and Perceptual Responses At 5-km Race Pace On Motorized Vs. Non-motorized Treadmills

Emily P. Kennedy, Chandon L. Hines, Hunter S. Waldman, Alex J. Heatherly, Gavin W. Hall, Eric K. O'Neal. *University of North Alabama, Florence, AL.* (Sponsor: Matt Green, FACSM)
 Email: ekennedy1@una.edu
 (No relationships reported)

PURPOSE: This study examined physiological, gait, and perceptual differences of running at 5-km race pace on a non-motorized (NMT) versus a traditional motorized treadmill (MT). **METHODS:** Trained (VO₂max = 53.0 ± 6.8 ml/kg/min) male runners (n = 11) of varying skill level and age (30 ± 10 y) completed 3, 5-km time trials on a NMT. During a later session, the average finishing time of the trials was used as the goal pace to maintain during a 5 min run on the NMT. Participants also ran at their personal best 5-km race pace within the last 6 months on a MT for 5 min with a

10 min rest period between bouts (counter-balanced crossover design). **RESULTS:** NMT resulted in a slower pace (10.6 ± 1.5 vs 13.9 ± 2.6 km/h; p < 0.001), shorter stride length (1.02 ± 0.10 vs 1.27 ± 0.18 m; p < 0.001), and decreased cadence (175 ± 12 vs 181 ± 13 steps/min; p = 0.01). However, VO₂ (NMT = 3.4 ± 0.4; MT = 3.4 ± 0.5 L/min), RER (NMT = 0.96 ± 0.04; MT = 0.96 ± 0.04), lactate at 3 min into recovery (NMT = 6.9 ± 3.7; MT = 5.7 ± 3.4 mmol), and heart rate at the end of each trial (NMT = 172 ± 10; MT = 170 ± 10 bpm) did not differ significantly. Likewise, RPE for legs, breathing, and overall did not differ significantly between treatments. **CONCLUSION:** Although gait and pace were altered significantly, physiological and perceptual responses between the MT and NMT were similar. NMT time trial testing can be expected to elicit similar endurance exercise stresses when a more "free" running task is desired, but interpretation of results need to be made with the consideration that performance is expected to decline by ~25% or more likely due to excess resistance from the NMT belt.

Training and Chronological Age Effect Repetitions in Reserve-based Rating of Perceived Exertion Accuracy

Michael H. Haischer¹, Jacob A. Goldsmith¹, Daniel M. Cooke¹, Ryan K. Byrnes¹, Jared H. Perlmutter¹, Jose C. Velazquez¹, Adam Sayih¹, Eric R. Helms¹, Chad Dolan², Michael C. Zourdos¹. ¹Florida Atlantic University, Boca Raton, FL. ²University of Houston, Houston, TX. (Sponsor: Michael Whitehurst, FACSM)
 Email: mhaischer2015@fau.edu
 (No relationships reported)

PURPOSE: The purpose of this study was to examine the relationship between training age (TA) and chronological age (CA) on the accuracy of intra-set recorded rating of perceived exertion (RPE) values on the repetitions in reserve (RIR)-based RPE scale. **METHODS:** Twenty-five college-aged and resistance trained men (Body Mass: 88.95±14.72kg, squat one-repetition maximum-1RM: 175.76±34.68kg) performed a 1RM back squat followed by one set of maximum repetitions at 70% of 1RM. Subjects were blinded to the load during the 70% set via an opaque trash bag covering the weight discs. During the 70% set subjects verbally called a 5RPE (i.e. 5RIR), 7RPE (i.e. 3RIR), and 9RPE (i.e. 1RIR) when the subject believed he was at the respective threshold. Pearson correlations were used to assess relationships between total repetitions performed and the absolute RIR difference from the actual RIR when each RPE was verbally called. For example, if a subject completed 15 total repetitions and called a 5RPE after 7 repetitions then the RIR difference would equal 3. **RESULTS:** Average TA was 4.7±3yrs and CA was 25±3yrs. There were moderate inverse correlations approaching significance between TA and the RIR difference at the called 5RPE (r=-0.35, p=0.094) and 7RPE (r=-0.34, p=0.096), however no relationship for TA at the called 9RPE (r=-0.23, p=0.32). Regarding CA, no difference existed with the RIR difference at 5RPE (r=-0.27, p=0.20), however, CA had a moderate inverse relationship with RIR difference at a 7RPE (r=-0.36, p=0.07), and a moderate significant correlation with a 9RPE (r=-0.50, p=0.021). **CONCLUSION:** Our findings suggest that a lower TA is related to increased difficulty of RIR assessment when 3 or more RIR exist. However, TA was not related to RIR accuracy close to failure (i.e. 9RPE). Interestingly, greater CA is associated with more accurately assessing RIR closer to failure.

 (No relationships reported)

The resistance training-specific rating of perceived exertion (RPE) scale measuring repetitions in reserve (RIR) has been validated to gauge effort per set in resistance exercise. However, it is unknown what descriptive factors of the lifter influence RPE/RIR accuracy. **PURPOSE:** The purpose of this study was to examine the relationship between total repetitions per set and the accuracy of intra-set RPEs of 5, 7, and 9 on the 1-10 RIR-based RPE scale. **METHODS:** Twenty-five college-aged and resistance trained men (Age: 25±3yrs, Body Mass: 88.95±14.72kg) performed a one-repetition maximum (1RM) back squat followed by one set of maximum repetitions at 70% of 1RM. Subjects were blinded to the load during the 70% set via an opaque trash bag covering the weight discs. During the 70% set subjects verbally called a 5RPE (i.e. 5RIR), 7RPE (i.e. 3RIR), and 9RPE (i.e. 1RIR) when the subject believed he was at the respective threshold. Pearson product moment correlations were used to assess relationships between total repetitions performed and the absolute RIR difference

from the actual RIR when each RPE was verbally called. For example, if a subject completed 15 total repetitions and called a 5RPE after 7 repetitions then the RIR difference would equal 3. **RESULTS:** Average squat 1RM was 175.76±34.68kg and the mean number of repetitions performed at 70% of 1RM was 16±4. There were moderate and significant correlations between total repetitions performed and the RIR difference at the called 5RPE ($r=0.64, p=0.01$) and 7RPE ($r=0.56, p=0.004$), however no relationship between total repetitions and the RIR difference existed at the called 9RPE ($r=0.01, p=0.97$). **CONCLUSION:** Our findings suggest that the greater amount of repetitions performed per set is related to increased difficulty to accurately gauge RIR further from failure. However, total repetitions per set do not seem to effect RIR accuracy when close to failure (i.e. 9RPE).

The Role of the Rating of Perceived Exertion Template in Pacing

Jos J. de Koning, FACSM¹, Wouter Schallig¹, Tim Veneman¹, Dionne A. Noordhof¹, José A. Rodriguez-Marroyo², John P. Porcari, FACSM³, Carl Foster, FACSM³, ¹Vrije Universiteit, Amsterdam, Netherlands. ²University of León, León, Spain. ³University of Wisconsin - La Crosse, La Crosse, WI.
 Email: j.j.de.koning@vu.nl
 (No relationships reported)

The Rating of Perceived Exertion (RPE) template is thought to regulate pacing and has been shown to be very robust in different circumstances. **Purpose:** The primary purpose was to investigate whether the RPE template can be manipulated by changing the anticipated race distance during the course of a time trial. The secondary purpose was to study how athletes cope with this manipulation, especially in terms of the RPE template. **Method:** Trained male cyclists (N=10) performed three cycling time trials: a 10 km (TT10), a 15 km (TT15) and a manipulated 15 km (TTman). During the TTman, subjects started the time trial believing that they were going to perform a 10-km time trial. However, at 7.5 km they were told that it was a 15-km time trial. **Results:** A significant main effect of time-trial condition on RPE scores until kilometer 7.5 was found ($P=0.016$). Post-hoc comparisons showed that the RPE values of the TT15 were lower than the RPE values of the TT10 (Diff:0.60; CI:0.11, 1.0) and TTman (Diff:0.73; CI:0.004, 1.5). After the 7.5 km, a transition phase occurs, in which an interaction effect is present ($P=0.011$). After this transition phase, the RPE values of TTman and TT15 did not statistically differ ($P=1.00$). **Conclusions:** This novel distance-endpoint manipulation demonstrates that it is possible to switch between RPE templates. A clear shift in RPE during the TTman is present between the RPE template of the TT10 and TT15. The shift strongly supports suggestions that pacing is regulated using a RPE template.

Perceived Exertion Compared to Physiological Exertion over the course of Two Different Exercise Interventions

Adam C. Lowe¹, Neil M. Johannsen¹, Conrad P. Earnest, FACSM², Catrine Tudor-Locke, FACSM³, Melissa Harris⁴, Timothy S. Church⁴, Corby K. Martin⁴. ¹Louisiana State University, Baton Rouge, LA. ²Texas A&M University, College Station, TX. ³University of Massachusetts, Amherst, MA. ⁴Pennington Biomedical Research Center, Baton Rouge, LA.
 (Sponsor: Catrine Tudor-Locke, FACSM)
 (No relationships reported)

PURPOSE: To evaluate the differences in perceived exertion (RPE) and cardiovascular intensity (%HRmax), and to determine the differences in metabolic stress (RER) during two exercise interventions following guidelines for (1) general health and (2) weight loss. **METHODS:** Sedentary, overweight or obese men and women (N=133; age 47.68, range 21-65 y) were randomly assigned to one of two

intervention groups for 24wks. Exercise for general health and weight loss was prescribed at 8 and 20 kcal/kg body weight per week. Exercise was performed at a target HR associated with 65% and 85% of peak oxygen consumption (average HR% = 76.6±6.3%). HR and RPE were recorded every 5min during exercise. Respiratory values (VO₂, VCO₂, and RER) were measured at the start of exercise at BL and periodically during training (weeks 2, 4, 6, 8, 12, 16, 20, and 24) to determine energy expenditure and RER. Data were analyzed using a group by time analysis. **RESULTS:** RPE (mean±SD, 12.10±0.13 vs. 12.18±0.13, resp, treatment $p=0.67$, interaction $p=0.14$) and HR (133.96±1.69 vs. 135.48±1.68, resp, treatment $p=0.53$, interaction $p=0.62$) were not different between healthy exercise and weight loss groups. HR plateaued by week 8 for both the healthy exercise and weight loss groups (treatment $p=0.53$; 134.7±1.9 vs. 136.2±1.9, resp). %HRmax was not different between the healthy exercise and weight loss groups at any time point (treatment $p=0.59$, interaction $p=0.58$). RER was significantly different between groups at Week 8 (0.93, 95% CI [0.91, 0.94]; 0.89, 95%CI [0.87, 0.91], resp, $p=.001$) and Week 12 (0.93, 95% CI [0.91, 0.95]; 0.89, 95% CI [0.87, 0.91], resp, $p=0.0003$). **CONCLUSIONS:** Despite no difference in perceived exertion or cardiovascular intensity, exercise for general health seemed have a higher RER compared to exercise for weight loss. Physiological adaptations seemed to plateau at a similar time point between groups; however the increased caloric expenditure of weight loss may have induced metabolic adaptations at a faster rate compared to general health. Exercise for weight loss could induce metabolic adaptations without greater perceived or cardiovascular stress.

 (No relationships reported)

INTRODUCTION: Exercise capacity, assessed by peak oxygen uptake (VO₂ peak), has been shown to predict mortality in patients with cystic fibrosis (CF), independent of lung function. Systemic chronic inflammation is a common phenotype in patients with CF characterized by an excessive production of circulating inflammatory mediators. Inflammation contributes to dysfunctional mitochondria, which in turn contributes to exercise intolerance. The link between inflammation and exercise capacity, however, has yet to be investigated in patients with CF. **PURPOSE:** This study sought to test the hypothesis that 1) C-reactive protein (CRP) is related to exercise capacity and 2) changes in CRP are related to changes in exercise capacity. **METHODS:** A prospective longitudinal cohort study was completed in 33 patients with CF (18 males and 15 females; age 20±10 yrs) involving a total of 127 visits over a 4 year period (average 4±2 visits per subject). At every visit, anthropometrics, pulmonary function test, exercise capacity, and circulating levels of CRP were evaluated. **RESULTS:** Overall, a significant inverse relationship was identified between VO₂ peak and circulating concentrations of CRP ($r=-0.389, p<0.001$). Longitudinal changes in VO₂ peak were negatively associated with changes in CRP ($r=-0.336, p=0.004$) and remained significant when either FEV₁ (% predicted) ($r=-0.345, p=0.004$), or BMI ($r=-0.281, p=0.018$) were considered. In addition, changes in VO₂ peak were also significantly associated with changes in CRP ($r=-0.248, p=0.041$) after controlling for FEV₁ (% predicted), BMI, and sex. Longitudinal changes in VO₂ (% predicted) were also correlated with changes in CRP ($r=-0.248, p=0.043$) even after controlling for FEV₁ (% predicted) ($r=-0.263, p=0.039$) or BMI ($r=-0.237, p=0.046$). **CONCLUSION:** Circulating CRP is inversely related to exercise capacity in patients with CF. Additionally, for the first time in CF, we have documented that the changes in CRP over time may predict meaningful changes in exercise capacity. These findings support the use of CRP to provide prognostic information into exercise capacity in patients with CF. Supported in part by NIH/NIDDK R21DK100783 and Vertex Pharmaceuticals IIS (RAH).

Prevalence of Asthma and Exercise-induced Bronchoconstriction In College Wrestlers

Steve Burns¹, Brian Hughes¹, Mathew J. Garver¹, David Glover¹, Taylor Dinyer¹, Alex Rickard¹, Molly Jennings¹, Dustin Davis¹, Adrianna Blazer¹, Jenna Carducci¹, Laura Miller¹, Justin Colf¹, Dave Burnett², Michael Godard, FACSM¹. ¹University of Central Missouri, Warrensburg, MO. ²Kansas University School of Medicine, Kansas City, MO. (Sponsor: Michael Godard, FACSM)
Email: sburns@ucmo.edu
(No relationships reported)

Exercise-Induced Bronchoconstriction (EIB), a transient narrowing of the airways, is activated by vigorous exercise in approximately 10% of the general population. Published articles indicate in college athletic populations, EIB is identified in between 3% and 42% of the tested population. **PURPOSE:** The purpose of this study was to identify the prevalence of asthma and EIB in college wrestlers. **METHODS:** Participants were 33 student-athletes (wrestlers). Athletes underwent baseline spirometry following American Thoracic Society (ATS) guidelines, to determine each athlete's individual baseline FEV₁. Each individual's FEV₁ was used to calculate 50-60% of exercise target ventilation (VE) (35*FEV₁*0.5 and 35*FEV₁*0.6). After the baseline spirometry was obtained the athlete performed exercise on a treadmill at 80-90% of their age predicted maximum heart rate or 40-60% of their maximal ventilation for at least 4 minutes. After exercise the athlete repeated maximum spirometry efforts at 2, 5, 10, 15, and 20-min. A fall in FEV₁ > 10% from baseline was considered positive for EIB. **RESULTS:** Thirty-three wrestlers volunteered for the testing. Three (9.09%) having been previously diagnosed with asthma were excluded. Two of the subjects (6.06%) failed to obtain a minimum of 70% of predicted FEV₁ at pre-test were also excluded. Of the 28 subjects completing the protocol, 4 (12.1%) failed to obtain 90% of their pre-exercise FEV₁ (mean FEV₁ drop post-exercise 12.8±2.2%) indicating EIB. In total, undiagnosed asthma (n=2) and EIB (n=4) were present in 18.8% of the college wrestlers who were unaware of their condition. **CONCLUSION:** Results of this study are important for raising awareness and potentially improving performance due to unknown pulmonary conditions in college wrestlers.

Asthma, Undiagnosed Asthma, And Exercise-Induced Bronchoconstriction In Collegiate Men's Basketball

Matthew J. Garver¹, Steve Burns¹, Brian J. Hughes¹, David Glover¹, Taylor K. Dinyer¹, Alex Rickard¹, Molly A. Jennings¹, Laura A. Wilson¹, Thomas Lewis¹, William Miller¹, Rachel K. Brown¹, Dave M. Burnett², Michael P. Godard, FACSM¹. ¹University of Central Missouri, Warrensburg, MO. ²University of Kansas Medical Center, Kansas City, KS.
Email: garver@ucmo.edu
(No relationships reported)

Asthma and Exercise-Induced Bronchoconstriction (EIB) are pulmonary conditions associated with narrowing of the airways, one chronically and the other activated by exercise. Screening in college athletes is valuable, as there is a dearth of evidence and great variability (range 3-42%) among the prevalence rates published. **PURPOSE:** The purpose of this ongoing analysis is to systematically investigate these pulmonary conditions in athletes across the University-affiliated athletics program. **METHODS:** The current focus was on men's basketball players. The EIB protocol commenced with spirometry. Participants were encouraged to expire as forcefully as possible (and achieve a six second plateau). Values were collected in duplicate, with readings ideally within 150ml. Subjects with asthma and those failing to achieve a forced expiratory volume (FEV₁) of at least 70% of the predicted value were removed from ongoing testing. After the baseline spirometry was evaluated, the athletes performed a single-bout of exercise, intensifying to 80-90% of age predicted maximal heart rate (HR). Once at target HR, the stage was held for 4 minutes. Confirmation of an appropriate exercise intensity was established by confirming that 40-60% of the maximal ventilation was achieved (35*FEV₁*0.5 and 35*FEV₁*0.6). Post exercise, participants repeated the spirometry efforts at 2, 5, 10, 15, and 20-min time points. A fall in FEV₁ > 10% from baseline was considered positive for EIB. Values were reviewed by a registered respiratory therapist. **RESULTS:** Fifteen student-athletes volunteered for testing, as 1 (6.67%) had been previously diagnosed with asthma, he was excluded from ongoing testing. In the cohort tested, all athlete's obtained a minimum of 70% of predicted FEV₁ at pre-test. Of the 14 subjects completing the protocol, 2 (13.3%) failed to obtain 90% of their pre-exercise FEV₁ (mean drop 11.6±1.2%) at one of the post-test time points; an indication of EIB. In one subject (6.67%), results were not conclusive. **CONCLUSIONS:** There is value in raising awareness of these pulmonary conditions in athletes. Also, future research should simultaneously consider the divergent physiological, environmental, and bioenergetic demands placed on the athlete to investigate the prevalence rates from a more comprehensive view.

Muscle Oxidative Capacity Is Low In The Upper And Lower Limbs Of COPD Patients

Alessandra Adami, Rogerio B. Corvino, Richard Casaburi, Robert V. Cao, Robert A. Calmelat, Janos Porszasz, Harry B. Rossiter, FACSM. Los Angeles Biomedical Research Institute at Harbor-UCLA, TORRANCE, CA. (Sponsor: Harry B. Rossiter, FACSM)
Email: aadami@labiomed.org
(No relationships reported)

Muscle atrophy, weakness and fatigability are characteristic of patients with chronic obstructive pulmonary disease (COPD), which contribute to dyspnea, exercise intolerance and morbidity. Comparisons between upper and lower limb performance suggests intrinsic differences in muscular adaptations between leg and arm muscles, with preserved *biceps brachii* endurance in COPD (Franssen et al. *MSSE* 37:2-9, 2005). We were therefore interested whether loss of muscle oxidative capacity was different between upper and lower limbs in COPD.

PURPOSE: To compare muscle oxidative capacity in the upper and lower limbs between smokers with or without COPD.

METHODS: 19 COPD patients (GOLD 2/3/4, n=7/6/6; FEV₁%pred 44.1±18.7; M/F=14/5) and 18 smokers with normal spirometry (CON; M/F=14/4) volunteered. Non-dominant medial forearm and medial *gastrocnemius* oxidative capacity was assessed from the O₂ consumption recovery rate constant (*k*) following brief muscle contractions using near-infrared spectroscopy with intermittent vascular occlusion. *k* was estimated from the mean of two repetitions. Differences were determined by 2-way ANOVA (group x limb).

RESULTS: There was a significant main effect of group on muscle oxidative capacity (F=11.7, $\eta_p^2=0.14$, p<0.001): COPD patients had significantly lower *k* in both upper and lower limb muscles (upper 1.01±0.17, lower 1.05±0.24 min⁻¹) compared with CON (1.27±0.49, 1.49±0.67 min⁻¹). However, there was no effect of limb (F=1.8, $\eta_p^2=0.03$, p=0.18) and no group x limb interaction.

CONCLUSION: We found that muscle oxidative capacity is lower in COPD than controls in both upper and lower limbs. Although, when compared to age- and sex-matched smokers with normal spirometry, *k* tended to be more reduced in the *gastrocnemius* (-30%) than the forearm (-20%) of COPD patients, this difference was not significant. Unlike previous findings, these data suggest that muscle mitochondrial function is systemically impaired in COPD patients, and not simply the result of inactivity-induced deconditioning; which is expected to manifest as greater impairments in lower limb than upper limb. The variables contributing to systemic deficiency in muscle oxidative capacity in COPD warrant further study. Supported by SNSF P300PB_167767; PERF; ATS Foundation/Breathe California of Los Angeles

Prevalence of Exercise Induced Bronchoconstriction in Puerto Rican Athletes with Respiratory Symptoms during Exercise

Anita M. Rivera-Brown, FACSM, Claudia Jiménez. University of Puerto Rico School of Medicine, San Juan, Puerto Rico.
Email: aniriver.brown@gmail.com
(No relationships reported)

Athletes in endurance sports such as running, swimming and cycling, are at increased risk for exercise-induced bronchoconstriction (EIB). Exercise hyperventilation and frequent exposure to allergens and bronchial irritants, such as chlorine by-products in swimming pools, have been implicated in bronchial hyperresponsiveness, especially in those with a history of asthma. There is a high prevalence (~11%) of asthma in the general population of Puerto Rico and asthmatic athletes may be at risk of severe asthma exacerbations precipitated by exercise. **PURPOSE:** We examined the prevalence of EIB in athletes with respiratory symptoms during exercise, which underwent an exercise challenge test in our Center. **METHODS:** 54 athletes (14 adults, 40 adolescents; 25 females, 29 males) in 16 sport events classified as either low (skill, sprint/power, multiple events; N=18), medium (team, combat; N=12), or high (endurance; N=24) risk for EIB were examined. They completed an exercise challenge test, either running, cycling, or swimming at an intensity of 70-95% of estimated maximal heart rate for at least 7 to 15 min. Spirometry was measured pre-exercise and at 2, 5, 8, 11, and 15 min post-exercise. A fall in forced expiratory volume in 1 second (FEV₁) >10% was considered positive for EIB. **RESULTS:** Of the 54 athletes, 17 (31.5%) were positive for EIB. The prevalence among female and male athletes was 20% and 41%, respectively. 15/17 EIB positive athletes were adolescents, including 8 swimmers. Half of the EIB positive athletes were from events classified as high risk for EIB such as: long distance running (n=2) and swimming (n=4), road cycling (n=1), and triathlon (n=1). Eleven of the EIB positive athletes (65%) had a previous diagnosis of asthma, and 7 of those also had allergic rhinitis. Two of EIB positive athletes had allergic rhinitis only. Swimmers had an EIB prevalence of 53% (8/15). **CONCLUSION:** Results indicate that EIB may affect 1 in 3 athletes who

report respiratory symptoms during exercise. The prevalence is highest in swimmers suggesting airway hyperresponsiveness that may be associated to a previous history of asthma, allergic rhinitis, and/or exposure to chlorinated irritants. Athletes with previous diagnosis of asthma and/or respiratory symptoms should be screened with a challenge test so EIB can be detected and prevented.

Relationship between Vascular Health and Maximal Exercise Capacity Following Sildenafil Treatment in Cystic Fibrosis

Matthew A. Tucker, Nicole Seigler, Kathleen T. McKie, Caralee Forseen, Reva H. Crandall, Ryan A. Harris, FACSM. *Augusta University, Augusta, GA.* (Sponsor: Ryan A. Harris, FACSM)
Email: matttucker@augusta.edu
(No relationships reported)

Patients with cystic fibrosis (CF) have compromised exercise capacity (VO_2 peak) and impaired vascular health. Sildenafil, a phosphodiesterase type 5 inhibitor, has not only been shown to improve vascular health, but also improve maximal exercise capacity in various patient populations. However, it is unknown if improvements in vascular health contribute to improvements in exercise capacity in CF. **PURPOSE:** To investigate the relationship between the change in vascular health and the change in VO_2 peak following sub-acute treatment with sildenafil in patients with CF. **METHODS:** 14 patients with CF (age 9-43 y, BMI = 20.7 ± 4.1 kg/m²) participated in this study. At baseline and 4 weeks following sildenafil treatment (20 mg thrice daily), vascular health was assessed via flow-mediated dilation (FMD) and pulse wave velocity (PWV) to determine endothelial function and arterial stiffness, respectively. In addition, forced expiratory flow in 1 second (FEV_1) was assessed via spirometry as an index of disease severity, and VO_2 peak was determined on a cycle ergometer using the Godfrey protocol. Pearson correlations were used to investigate associations between changes (Δ) in VO_2 peak, FMD, and PWV while controlling for potentially confounding variables. **RESULTS:** VO_2 peak increased from 44.4 ± 8.7 to 46.6 ± 10.0 ml/kgFFM/min ($p = 0.010$) after controlling for baseline disease severity (FEV_1). FMD increased from 8.3 ± 5.2 to 9.3 ± 3.6 % ($p = 0.07$). There was a significant relationship between ΔVO_2 peak and ΔFMD ($r = 0.636$, $p = 0.035$) when controlling for age, BMI, and baseline FMD. PWV tended to decrease following treatment (5.4 ± 0.9 to 5.3 ± 0.9 m/s, $p = 0.077$); however, the change was not associated with ΔVO_2 peak ($r = 0.400$, $p = 0.373$) or ΔFMD ($r = 0.063$, $p = 0.894$) when controlling for age and baseline values. **CONCLUSIONS:** These data suggest that improvements in maximal exercise capacity can, in part, be explained by concomitant increases in FMD following 4 weeks of sildenafil treatment in patients with CF.

(No relationships reported)

The Chronic Obstructive Pulmonary Disease (COPD) is a lung disease with a significant deterioration of the quality of life, functional capacity, and important morbidity. However, exercise can improve fitness and functional capacity, linked with a better quality of life for these patients. **PURPOSE:** Motion capture devices with a high intensity interval training active video game never been tried with COPD patients. Thus, the objective was to observe the feasibility of using this device safely and easily with COPD patients. **METHODS:** A total of 14 patients (8 men 69±6 years, 6 women, 74±6 years), with a moderate to severe COPD diagnostic (FEV_1 % predicted: 44.0 ± 14.8 %, FEV_1/VC (%): 43.8 ± 15.2 % and FEV_1 : 1.12 ± 0.38 L, without a significant difference between the genders $F(1)=3.307$, $p=0.096$) performed 4 mini-games (Shape-Up, Ubisoft) adapted for their condition. During the games, the oxygen uptake, ventilation, heart rate and saturation was taken with a portable metabolic analyser (Metamax, Cortex Medical, Germany). Gaming sessions of 10 to 15 min duration were composed of 4 games of about 1.5 min separated with rest. **RESULTS:** The average and peak minute ventilation, and the METs peak were respectively: Stunt Run game (lifting knees on the spot) 25.3 ± 6.8 , 33.5 ± 8.2 L/min, and 4.2 ± 1.5 METs; Arctic Punch (punching targets): 23.1 ± 5.6 , 31.8 ± 9.8 L/min, and 3.7 ± 1.2 METs; To the Core (Core twist), 22.2 ± 7.3 , 29.2 ± 9.9 L/min, and 3.3 ± 1.1 METs, and Squat me to the Moon (sitting to standing from a chair), 27.8 ± 6.7 , 36.8 ± 11.1 L/min, and 4.4 ± 1.1 METs. No important desaturation was observed during the training. **CONCLUSION:** The safety, the pleasure/motivation reported by the participants and, the ability to use it with assistance seems that the game can be a good tool for maintaining physical activity at home for COPD patients. However, further investigation needs to be completed in order to observe the benefits in comparison to a traditional training program and to observe the utilisation at home.

The Acute Response to Sprint Interval Exercise in Adults With and Without Confirmed Airway Hyper-responsiveness

Joshua Good¹, Kirsten A. Burgomaster², Shilpa Dogra¹.
¹University of Ontario Institute of Technology, Oshawa, ON, Canada. ²Lakeridge Health, Oshawa, ON, Canada.
(No relationships reported)

Among those with airway hyper-responsiveness (AHR), acute bronchoconstriction typically follows an acute bout of moderate intensity continuous exercise (MICE) due to an increase in ventilation. Similar to high intensity interval exercise, sprint interval exercise (SIE) may reduce the risk of bronchoconstriction due to the recovery periods between sprints. **Purpose:** To compare changes in lung function following a SIE and a MICE session in those with and without confirmed AHR. **Methods:** Participants completed four sessions. Session 1 was to confirm AHR using a $\geq 15\%$ decline in forced expiratory volume in 1 second (FEV_1) following a eucapnic voluntary hyperpnea challenge. In session 2, participants completed a maximal exercise test to determine maximal O_2 uptake and peak power output (PPO). Participants then completed SIE (4 x 30 second sprints at 0.075kg/kg bodyweight, separated by 4.5 minutes of unloaded cycling) and MICE (65% PPO for 20 minutes) sessions in random order separated by at least 72 hours. All exercise sessions were completed on a cycle ergometer. Lung function was assessed pre and post exercise (1, 5, 10, 15, and 20 mins post) as well as at 3.5, 8.5, 13.5 and 18.5 minutes during exercise to coincide with time points post-sprint. Expired O_2 and CO_2 were collected breath-by-breath, and deoxygenated hemoglobin (HHb) was continuously monitored throughout exercise using near-infrared spectroscopy. **Results:** No statistically significant difference was observed for FEV_1 when comparing SIE and MICE ($8.56 \pm 7.07\%$ vs. $8.48 \pm 3.09\%$, respectively, $p=0.98$) among those with AHR. One participant with AHR experienced a $\geq 10\%$ decline in FEV_1 following SIE and another participant experience a clinically relevant decline following MICE. In participants with AHR, no statistically significant differences were observed in average ventilation during MICE compared to SIE (66.97 ± 10.69 vs. 64.20 ± 9.89 , $p=0.35$). Peak ventilation was greater during SIE (108.27 ± 17.00) compared to MICE (87.66 ± 13.88 , $p<0.05$). In participants with AHR, maximum ΔHHb was not significantly different when comparing SIE and MICE (5.03 ± 3.73 vs. 5.79 ± 2.67 , respectively, $p=0.43$). **Conclusion:** SIE and MICE lead to similar post-exercise declines in lung function. This may be due to the similar average ventilation observed in both sessions.

Abnormal Gas Exchange in Dyspneic Veterans with Normal Spirometry

Jacquelyn C. Klein, Anays Sotolongo, Duncan Ndirangu, Omowunmi Y. Osinubi, Drew A. Helmer, Lydia Patrick-DeLuca, Nancy Eager, Michael J. Falvo. *Department of Veterans Affairs, NJ Health Care System, East Orange, NJ.*
Email: jacquelyn.klein@va.gov
(No relationships reported)

Over the last two decades, more than 3 million veterans have experienced at least one combat deployment to the Middle East. Some Veterans present with respiratory complaints that began after deployment and frequently attribute these symptoms to deployment-related airborne hazards exposure (e.g., sand and dust, burn pits), but spirometry is often within normal limits. **PURPOSE:** To compare cardiopulmonary exercise responses in veterans reporting frequent (High Sx) and infrequent respiratory symptoms (Low Sx) who have normal spirometry. **METHODS:** 28 veterans were referred to our post-deployment tertiary care clinic for a dyspnea evaluation. 15 veterans (45.3±11.6 years) reported ≥ 2 lower respiratory symptoms on a bi-weekly basis over the preceding 6 months (High Sx), and 13 (46.5±8.5 years) reported ≤ 1 lower respiratory symptom at least bi-weekly. All veterans underwent complete pulmonary function testing and cardiopulmonary exercise testing (CPX). **RESULTS:** Forced vital capacity (High Sx, Low Sx: 99.9 ± 10.8 , 98.0 ± 12.8 %predicted) and forced expiratory volume in 1 second (99.5 ± 12.5 , 97.0 ± 14.7 %predicted) were similar between groups. On CPX, veterans in the High Sx group had lower peak oxygen consumption (VO_2) relative to body mass (22.6 ± 7.2 , 27.8 ± 6.0 ml/kg/min, $p=0.05$); though both groups achieved ventilatory threshold at an acceptable level of exercise (52.5 ± 15.9 , 51.7 ± 11.1 % peak VO_2). High Sx veterans had a significantly higher ventilatory equivalent for carbon dioxide (VE/VCO_2) slope (34.7 ± 11.4 , 27.0 ± 3.2 , $p<0.05$), and revealed significantly lower end-tidal carbon dioxide ($PetCO_2$) levels at ventilatory threshold (36.6 ± 7.3 , 41.4 ± 3.2 mmHg, $p<0.05$). **CONCLUSIONS:** Despite similar resting lung function, veterans who reported more frequent lower respiratory symptoms had reduced exercise capacity and poorer gas-exchange in comparison to their less symptomatic counterparts. These findings may suggest an underlying gas exchange pathology that is not yet detectable at rest. Therefore, CPX should be considered when evaluating deployed veterans with respiratory complaints; especially when resting measures of pulmonary function are normal.

3660 Board #107 June 3 8:00 AM - 9:30 AM
Postoperative Complications After Surgical Treatment For Exercised Induced Laryngeal Obstruction

Magnus Hilland¹, Ingvild Engesaeter¹, Astrid Sandnes², Lorentz Sandvik¹, Ola Røksund¹, John-Helge Heimdal¹, Thomas Halvorsen², Hege H. Clemm¹. ¹Haukeland University Hospital, Bergen, Norway. ²University of Bergen, Bergen, Norway.
 (No relationships reported)

PURPOSE: Exercised induced laryngeal obstruction (EILO) is a situation in which an apparently normal larynx instead of opening fully during exercise adducts, and thus represents an obstruction to free airflow. In principle, EILO can be primarily glottic or supraglottic. Surgery has been suggested as treatment for highly motivated patients suffering from severe forms of the latter. We would like to report on complications after surgical treatment for supraglottic EILO.

METHODS: During 2010-2015, 66 patients underwent laser supraglottoplasty due to a primary severe supraglottic EILO verified using continuous laryngoscopy during exercise. The surgical procedure was performed in general anaesthesia by one of three surgeons. Care was taken to avoid patients with glottic EILO or other upper airway malformations.

RESULTS: Of 66 patients operated at mean age 15.8 (range 5-26) years, 43 (65%) were females, three (4.5 %) required two surgical procedures, and 63 (95 %) met for a postoperative follow-up exercise laryngoscopy (mean interval 5.8 months). Complications were reported for two patients: (A) Male, 15 years at surgery, diagnosed with postoperative left recurrent laryngeal nerve palsy. Injury caused by intubation or a direct complication from surgery were possible explanations. A mediastinal mass discovered on chest x-ray and a concomitant Epstein-Barr infection, prompted comprehensive work-up; however, with no conclusive findings. At a second follow-up 1.5 year later, the patient had nearly fully recovered and had no problems performing daily activities. (B) Male, 13 years at surgery, diagnosed with postoperative extensive scarring needing a re-operation. Fifteen months after the last surgery, he still had breathing problems during heavy exercise, but reported no problems performing daily activities. Exercise laryngoscopy performed at that time indicated better laryngeal opening when compared to the findings before the first surgery, despite the postoperative scarring.

CONCLUSIONS: Complications were experienced by 2/66 (3%) highly motivated patients operated with supraglottoplasty for severe supraglottic EILO. At follow-up approximately 1.5 years after last surgery, none had symptoms influencing their daily activities.

3661 Board #108 June 3 8:00 AM - 9:30 AM
Influence of Respiratory Limitation on Exercise Capacity with Potential Implication of Ventilatory Muscle Fatigue

Monira I. Aldhahi, Liana C. Wooten, Randall E. Keyser, FACSM. *George Mason University, Fairfax, VA.*
 (No relationships reported)

Introduction: It is known that respiratory muscles are prone to fatigue in women with systemic lupus erythematosus (SLE) but the extent to which this limits their cardiorespiratory capacity is yet unclear. **Purpose:** This study characterized the ventilatory response during maximal exercise testing in women with SLE, examining the potential contribution of respiratory muscle fatigue to diminished cardiorespiratory fitness. **Methods:** Fifteen women participated in the study (control: n=7, age= 36±8 yr, SLE: n=8, age=37±9 yr). Each subject performed a modified Bruce treadmill exercise test to volitional exhaustion. The ventilatory response was characterized by measures of expired minute volume (Ve), tidal volume (Vt), respiratory rate, expiratory time (T_e), ventilatory quotients for O₂ and CO₂ and ventilation-perfusion matching using expired gas analysis and exponential rise CO₂ rebreathing methods. **Results:** Women with SLE had lower Vt (1449±83 vs 1795±124 ml; p=0.04) and Ve (61±6.7 vs 71.4±4.1, Cohen's ES=0.70) and prolonged T_e (42±2.5 vs 32±2.3 ms, p=0.03) compared to the control group. Significant differences of the other cardiorespiratory measures were not observed. The time to exhaustion during the exercise test (13±0.70 vs 17±0.46 min; p=0.02) and peak VO₂ (21±1 vs 29±2 ml/kg/min p= 0.01) were significantly diminished in those with SLE. **Conclusion:** Poor cardiorespiratory endurance has been reported in women with SLE. In the current study, group similarity in ventilatory efficiency and ventilation-perfusion matching eliminate the observation of any impairment of ventilatory drive. Conversely, the decline in Ve and Vt, and an increase in T_e coupled with a decreased time to exhaustion suggest that respiratory muscle fatigue may have contributed to low cardiorespiratory fitness and endurance in these subjects.

Health Related Quality of Life in COPD Patients Completing Aerobic and Resistance Training

Michael J. Berry, FACSM, Katherine Shields, Jordan Irwin. *Wake Forest University, Winston-Salem, NC.*
 Email: berry@wfu.edu
 (No relationships reported)

Both aerobic and strength training have been found to improve health related quality of life in chronic obstructive pulmonary disease (COPD) patients. However, these findings are not unequivocal, and there has been no direct comparison between the two training methods. **PURPOSE:** To compare improvements in health related quality of life in a group of COPD patients completing both an aerobic and strength training program. **METHODS:** Eleven mildly diseased patients completed a 3 month aerobic training program and, approximately 5 years later, a 3 month strength training program. Differences between 3 month and baseline scores were examined for the 4 domains of the Chronic Respiratory Disease Questionnaire (CRDQ) - a disease specific measure (dyspnea, fatigue, emotional function, mastery) and the 2 summary measures (physical (PCS) and mental (MCS)) component scales of a generic survey (SF-36) and the physical function subscale of the SF-36. **RESULTS:** Fatigue scores improved by 0.9 ± 0.3 units (p = 0.02) for the aerobic group and 0.8 ± 0.4 units (p = 0.07) for the strength training group. These differences were not significantly different from one another. No other domains of the CRDQ were found to increase significantly in either group. PCS scores improved by 5.7 ± 2.5 units (p = 0.05) in the aerobic training group, but only by 0.7 ± 2.9 units (p = 0.82) in the strength training group. MCS scores did not improve significantly for either group. Physical function scores improved by 3.3 ± 1.4 units (p = 0.04) in the aerobic training group, but only by 0.5 ± 1.2 units (p = 0.70) in the strength training group. **CONCLUSIONS:** These results suggest that an aerobic training program may be a better training modality to improve health related quality of life in patients with COPD.

Supplemental Oxygen Enhances the Effects of Interval Training On Exercise Capacity in Cystic Fibrosis

Ronen Reuveny¹, Cedric Gunaratnam², Gerry McElvaney², David Susta³, Fred DiMenna⁴, Niall Moyna⁵. ¹University of Haifa, Haifa, Israel. ²Beaumont Hospital, Dublin, Ireland. ³Dublin City University, Dublin, Ireland. ⁴Columbia University, New York, NY. ⁵Dublin City University, Dublin, Ireland.
 Email: ronen.reuveny@sheba.health.gov.il
 (No relationships reported)

PURPOSE: to examine the effect of interval exercise training with supplemental O₂ on VO₂ kinetics and endurance time in individuals with cystic fibrosis (CF).

METHODS: Using a single blind design, adults with different severities of CF were randomly assigned to a room-air group (n=4, FEV₁ = 43(31-109) % of predicted) or supplemental O₂ group (n=5, FEV₁ = 45(31-86) % of predicted). The training program consisted of interval training on a cycle ergometer, 2 days a week for 8 weeks at an intensity of 30% and 75% of the initial peak work rate (WR). All subjects performed a pulmonary function test, incremental symptom-limited cardiopulmonary exercise test on a cycle ergometer, and a submaximal constant WR exercise test at 30% and 70% of the initial peak WR. VO₂ kinetics assessed by mean response time (MRT) and physiological responses during low and high constant exercise were assessed before and after the exercise program. Within each group, data were compared using the Wilcoxon sign rank test.

RESULTS: Breathing supplemental O₂ during the training program improved the total duration of high intensity interval training by 93% (p<0.05) in the supplemental O₂ group between week 1 and week 8 (15±3 vs. 29±2 min, p<0.05), with no change in the room-air group (17±4 vs. 25±9 min). The improved in VO₂ kinetics (MRT) was significantly greater in the supplemental O₂ group than the room-air group following exercise training, 40(36-58) to 32(26-53) versus 42(28-67) to 36(26-58) min, respectively, p<0.05. Endurance time to exhaustion in high intensity constant load exercise improved following exercise training in the supplemental O₂ group [11 (11-14) vs. 27 (14-30) min, p<0.05], and did not change in the room-air group [10 (7-20) versus 18 (8-27) min].

CONCLUSIONS: The provision of supplemental O₂ during exercise training yields higher training volume and improves VO₂ kinetics and endurance capacity in CF patients. Supported by the Cystic Fibrosis Hopesource Foundation in Ireland

Relationship between Body Weight and Youth Fitness Tests with Absolute and Relative Load
 Weimo Zhu, FACSM, Hai Yan. *University of Illinois at Urbana-Champaign, Urbana, IL.*
 Email: weimozhu@uiuc.edu
 (No relationships reported)

A physical fitness test gets its information by test takers performing under a load, e.g., carrying one's own body while running, lifting a weight, and using a handgrip device. The load of one's own body weight (BW) varies from person to person and the loads of weights or devices are constant. Therefore, the former can be called a "relative load" and the latter can be called an "absolute load." The relationship of these loads in regards to test takers' weight in youth fitness testing have not been carefully examined.

Purpose: To examine the role of BW in the youth physical fitness tests with absolute and relative load.

Method: A subset of raw data from the 2012 National Youth Fitness Survey were used for the study, in which a total of 1,640 children and youth (M±SD: Age = 9.07±3.70 yr.; height = 136.98±22.90 cm; weight = 39.55±20.68 kg; BMI = 19.58±5.04) were tested for two sets of tests with body weight as the load (relative load), consisting of maximal endurance time on a treadmill test, modified pull-up, and plank, and without body weight as the load (absolute load), using handgrip strength and leg extension (combined). After analyzing the data using descriptive statistics by age and sex, the correlations between BW and absolute and relative load tests were computed.

Results: Descriptive statistics (M±SD) of the tests and their correlations (r) with BW were summarized below:

	Endurance Time (sec)	Pull-up (#)	Plank (sec)	Handgrip (kg)	Leg extension (pounds)
Male	663.30±152.44	6.32±6.38	63.86±49.58	45.8463±21.42	113.88±65.16
Female	636.83±122.74	3.56±4.15	58.08±40.92	39.3208±14.33	104.25±50.67
Total	649.52±138.31	4.94±5.55	60.96±45.52	42.57±18.49	109.02±58.47
Male	-.49	.12	.22	.79	.70
Female	-.47	-.21	.12	.79	.67
Total	-.47	-.01	-.18	.78	.69

Conclusion: BW has a negative correlation with relative load fitness tests and has a positive relationship with absolute load fitness tests. The question then is which load should be used in physical fitness testing, absolute or relative one? While more studies are needed to answer this question, it seems that absolute load is more appropriate for performance-related fitness since the best performance in a sport competition is the key interest while relative load is more appropriate health-related fitness since one's own health is the main focus.

The Importance Of Accurate Measurements In Voluntary Wheel Running In Mice
 Ayland C. Letsinger¹, Jorge Z. Granados¹, Heather L. Vellers¹, Victor A. Garcia¹, Jeremiah D. Velasco¹, Nick R. Walker¹, Madison Spier², Isabel Lambert², Robin Fuchs-Young², J. Timothy Lightfoot, FACSM¹. ¹Texas A&M University, College Station, TX. ²Texas A&M Health Science Center, College Station, TX. (Sponsor: J. Timothy Lightfoot, FACSM)
 Email: aylandletsinger@gmail.com
 (No relationships reported)

PURPOSE: Accuracy of data collection is essential in reducing variability in voluntary wheel running which could potentially hide statistically significant results. When measuring physical activity in rodents, a large portion of each collection period is unobserved and thus, systematic checks to reassure functionality must be a priority. The purpose of this study was to create a procedure that would determine if a running wheel was accurately functioning based on the measured data.

METHODS: The TAMU IACUC approved all procedures. SENCAR breeder pairs were mated and at 3 weeks of age, the female pups were co-caged. At 4 weeks of age, two running wheels were mounted in each cage, with an odometer attached to the top of the cage to record daily distance (km/day), duration (mins/day), and to calculate speed (m/min). At 14 weeks of age, the number of manual rotations required to reach a 0.01 km change on the odometer was determined with the number of rotations averaged across three trials. Each wheel's position in relation to the computer pick-

up was then adjusted until the total spins to reach a 0.01 km odometer change were as close to 61 (calculated to be the true distance of 0.01 km) as possible. Resulting average daily distance, duration, and speed were compared to the amount of rotations before and after adjustment using a one-way ANOVA.

RESULTS: Wheel rotations needed to reach 0.01 km before adjustments to the wheel were significantly higher (p=0.002) than after adjustments (74.7±15.3 vs. 64.5±6.6 rotations, respectively). Before adjustments, rotations had varying correlations with distance (R²=0.080; p=0.18), duration (R²=0.027; p=0.44), and speed (R²=0.50; p<0.0001). After adjustments, all correlations were lower and insignificant with distance (R²=0.0034; p=0.79), duration (R²=0.0032; p=0.51), and speed (R²=0.0091; p=0.66). **CONCLUSIONS:** Completing ongoing and regular manual checks on the functionality of running wheels will allow for higher accuracy and lower variance in data, especially running speed, which could otherwise hide significant differences between treatment groups.

 (No relationships reported)

Vienna CPX-tool is newly developed software that evaluates cardiopulmonary exercise test by assessing the transitions (T) between 3 phases of energy supply, i.e., T1 and T2. We integrated 3 calculation methods (angle, regression and error variance). Each allows for estimation of threshold indicators (IND) of blood lactate turn point 1 (LTP₁), first ventilatory threshold 1 (VT₁) and ventilatory equivalent of oxygen (V_E/V_{O₂}) for T1 and LTP₂, VT₂, V_E/V_{CO₂}, and heart rate turn point (HRTP) for T2. Since each T is based on a common physiological mechanism, we assume that an accurate calculation method would yield a small range of power output (PO) estimates IND within each T. **PURPOSE:** The aim of the present study was to compare the 3 methods via the Vienna CPX-tool. **METHODS:** Sixty-five incremental cardiopulmonary exercise tests were analyzed for PO estimates of LTP₂, VT₂, lowest turn point of V_E/V_{CO₂} and the HRTP with any of the three calculation methods. To compare the results with the PO at the maximal lactate steady state (MLSS), the following criterion was used: a valid MLSS prediction was provided if the difference between the PO estimate and the PO at the MLSS was within a range of ± 4% from the maximum PO resulting from the incremental test. Pearson's chi-square was used to test for the effects. To determine the association between the variables, pairwise comparisons were calculated via Bonferroni-Holm tests. **RESULTS:** Prediction frequencies were only significantly different between the angle and regression for LTP₂, as well as the angle and regression and regression and error variance in VT₂. **CONCLUSION:** The implemented calculation methods had a prediction accuracy of ~75-80% using a ± 4% criterion. Based on the present results it is not possible to identify a single best method whereby angle seems to be the most robust variable. To improve calculations and estimations of the above listed variables should be the leading priority for future research endeavors.

Effect Of Neighborhood-unit Definition On The Relationship Between Physical Activity And The Built Environment
 Deborah Salvo¹, Casey P. Durand², Alexandra E. Evans¹, Adriana Perez¹, Harold W. Kohl III, FACSM¹. ¹The University of Texas Health Science Center at Houston - School of Public Health (Austin), Austin, TX. ²The University of Texas Health Science Center at Houston - School of Public Health (Houston), Houston, TX.
 (No relationships reported)

PURPOSE: Substantial evidence demonstrates that built environment features, like density, connectivity, land-use, pedestrian/transit infrastructure, and recreational facilities, can influence physical activity. However, inconsistent findings remain in terms of significance, direction and strength. The purpose of this paper was to determine if the lack of a standardized definition for a neighborhood unit contributes towards these inconsistencies. **METHODS:** Published literature (PUBMED & SCOPUS) was abstracted to identify studies examining the relation between physical activity and Geographic Information Systems (GIS)-based built environment measures. Data were abstracted to determine the various definitions of neighborhood units used for GIS built environment measures. Each tested association was coded per the presence or absence of a significant finding. Logistic regression was used to estimate the odds of reporting a significant association (p<0.05) between GIS built environment measures and physical activity outcomes, by neighborhood unit definition. Models adjusted for study sample size. **RESULTS:** Among 165 articles (published articles since Jan 2013), 26.8% used Euclidean buffers of varying radii (400-3000m) to

define neighborhoods, 28.4% used network buffers, and 44.8% used administrative units of different shapes and sizes (e.g., census tracts). Relative to studies using large administrative units to represent a neighborhood, those using buffers of 400-500m (OR: 3.2, 95% CI: 1.4, 5.8), and 800-1000m (OR: 2.9, CI: 1.3, 7.1), had greater odds of reporting a significant association between GIS built environment measures and physical activity outcomes. Among those using buffers, no significant differences were found between Euclidean vs. network buffers (OR: 1.07, 95% CI: 0.46, 4.29). **CONCLUSIONS:** Researchers aiming to accurately estimate the effect of the neighborhood built environment on physical activity should consider using 400-1000m buffer-based GIS indicators. Using network vs. Euclidean buffers may not be essential for characterizing the neighborhood environment for physical activity research. Future analyses should examine differences by physical activity measures (objective vs. subjective) and by built environment constructs. Supported by NIH R01DK101593

Validation Of A Multi-electrode Bioelectrical Impedance Analyzer With A Dual-energy X-ray Absorptiometer

Nathan Meier¹, Yang Bai², Duck-chul Lee, FACSM¹. ¹Iowa State University, Ames, IA. ²University of Vermont, Burlington, VT. (Sponsor: Duck-chul Lee, FACSM)
Email: nfmeier@iastate.edu

Reported Relationships: N. Meier: Contracted Research - Including Principle Investigator; Biospace Co, Ltd.

Sarcopenia, the loss of muscle mass, strength, and function due to ageing, is a major health concern for the growing older adult population. One challenge for prevention, diagnosis, and treatment of sarcopenia is the need for a dual-energy X-ray absorptiometry (DXA) analyzer to measure appendicular lean mass (ALM). DXA is the recommended measurement of muscle mass for sarcopenia, but is expensive and exposes subjects to radiation. Therefore, inexpensive, safe, and widely available alternative measurements, such as bioelectrical impedance analysis (BIA), need to be identified and validated to be practically utilized in clinical settings. **PURPOSE:** The purpose of this study is to validate the multi-frequency BIA with 8 tactile electrodes (InBody 720) with the gold-standard DXA scan (Hologic Horizon W). **METHODS:** Participants were 277 older adults from 65 to 96 years old without history of cancer and severe medical or mental conditions. Individuals completed a 12-hour fast, refrained from activity that morning and wore scrubs. BIA and DXA analyses were taken immediately after each other. **RESULTS:** Correlation between the two methods for fat free mass (FFM), ALM, and percent body fat (PBF) were 0.93, 0.86 and 0.92, respectively, after adjusting for age and sex. Mean Percent Error (MPE) (DXA - InBody) and Mean Absolute Percent Error (MAPE), measures of prediction accuracy, were -13% and 13% for FFM, -12% and 13% for ALM, and 16% and 17% for PBF. Prediction equations were developed for improved estimation, in which age was coded in years and sex was coded as 1 for male and 0 for female:

DXA FFM = 0.83 (BIA FFM) + 0.025 (Age) + 2.0 (Sex) + 0.36 (R²=0.96)

DXA ALM = 0.74 (BIA ALM) - 0.025 (Age) + 1.84 (Sex) + 4.15 (R²=0.92)

DXA PBF = 0.71 (BIA PBF) - 0.089 (Age) - 3.3 (Sex) + 23.5 (R²=0.91)

DISCUSSION: The BIA body composition variables are highly correlated with DXA variables. However, we found consistent overestimation of FFM and ALM and underestimation of PBF in BIA compared to DXA based on MPE and MAPE analyses, which were incorporated in the development of FFM, ALM, and PBF estimation equations.

A Useful Equation For Predicting Visceral Adipose Tissue Volume From Anthropometric Measurements

RINA SO¹, Tomoaki Matsuo¹, Kiyoji Tanaka, FACSM². ¹National Institute of Occupational Safety and Health, Japan, Kawasaki, Japan. ²Faculty of Health and Sport Sciences, University of Tsukuba, Tsukuba, Japan. (Sponsor: Kiyoji Tanaka, FACSM)
Email: sorina@jhiat.com

(No relationships reported)

Abdominal circumference (AC) at the umbilical region is used to define metabolic syndrome (MS) in Japan. The AC is based on a cross section of the abdominal visceral adipose tissue (VAT) area. However, recent studies indicate that using a single-slice image may lead to an erroneous conclusion as to individuals' VAT accumulation levels. Therefore, relying only on AC may be an inadequate method for evaluating individual VAT accumulation levels and defining MS. **Purpose:** To develop a new equation model for predicting VAT volume using anthropometric values and to clarify the association between metabolic risk factors and actual and predicted VAT volume values. **Methods:** The cross-sectional data of 214 participants (derivation group) were used to develop an equation model for VAT volume, and data from 66 of the participants (validation group) were used to validate this anthropometric model for predicting VAT volume.

We collected anthropometric measurements and measured metabolic risk factors: blood pressure, HDL cholesterol, triglyceride and fasting glucose. VAT volume was determined by continuous T1-weighted abdominal magnetic resonance images. **Results:** Using multiple regression analyses, we determined the best prediction equation for abdominal VAT volume with a VAT variance of 47% as follows: VAT volume (cm³) = (74.18×AC) + (47.03×age) + (117.79×BMI) - 8792.733. In our validation group, the correlation coefficient between the predicted and actual VAT was 0.71 (P < 0.01). Also, the predicted VAT volume correlated significantly with blood pressure and fasting glucose, even though we did not observe significant correlations between AC and these risk factors. **Conclusions:** The predicted VAT volume from our equation model was significantly related to metabolic risk factors. This study suggests that the equation model has potential to assess VAT accumulation levels in the field and in clinical settings where CT or MRI is not available.

Data Imputation Improves Sedentary Behavior and Physical Activity Estimates in Low Wear Time Accelerometer Data

David R. Paul¹, Brenda M. Vincent², Chantal A. Vella, FACSM¹, Philip W. Scraggs¹, Ryan P. McGrath³. ¹University of Idaho, Moscow, ID. ²VA Ann Arbor Health System, Ann Arbor, MI. ³University of Michigan Medical School, Ann Arbor, MI.
Email: dpaul@uidaho.edu

(No relationships reported)

Missing accelerometer data from low participant wear time underestimates sedentary behavior (SB) and physical activity (PA) measurements. Yet, it remains unclear if imputing data for low participant wear time improves SB and PA estimates.

PURPOSE: To determine if a data imputation technique improves SB and PA estimates in accelerometer data with low participant wear time. **METHODS:** One-hundred participants wore an accelerometer at the hip for ≥22.0 hours/day, at least 4 days including 1 weekend day, to capture habitual SB, light physical activity (LPA), and moderate-to-vigorous physical activity (MVPA) levels. After removing sleep time (RAW; 15.9±3.5 hours/day), random 60-minute blocks of data were removed from the RAW data set until participants had a unique data set with wear time adherence at 10 hours/day. A minute-by-minute, mean data imputation technique was used to impute estimates of SB, LPA, and MVPA in place of the missing data for the 10-hour adherence level. A series of paired t-tests with a Bonferroni correction (alpha level=0.006) compared the estimates of SB, LPA, and MVPA to the RAW data set at the 10-hour adherence level. Similarly, imputed estimates of SB, LPA, and MVPA were compared to the RAW data set at the 10-hour adherence level. **RESULTS:** SB, LPA, and MVPA were underestimated by 163.7 (95% confidence intervals [CI]: 156.0, 171.5; p<0.0001), 138.4 (CI: 129.1, 147.9; p<0.0001), and 27.2 (CI: 24.3, 30.1; p<0.0001) minutes/day at 10-hours of wear compared to the RAW data set, respectively. When utilizing the data imputation technique at the 10-hour adherence level, SB and MVPA were underestimated by 16.8 (CI: 8.7, 24.9; p<0.0001) and 17.1 (CI: 14.5, 19.6; p<0.0001) minutes/day compared to the RAW data set, respectively. LPA at the 10-hour adherence level was overestimated by 33.9 (CI: 25.9, 41.9; p<0.0001) minutes/day compared to the RAW data set after utilizing the data imputation technique. **CONCLUSION:** A minute-by-minute, mean data imputation technique improved SB, LPA, and MVPA estimates in accelerometer data with low wear time adherence. Future studies should examine the impact of data imputation techniques on accelerometer data with low participant wear time.

Effects Of Different Pull Up Training Strategies On Pull Up Scores

Eric Martin, George Beckham. California State University Monterey Bay, Seaside, CA. (Sponsor: Kent Adams, FACSM)
Email: ermartin@csumb.edu

(No relationships reported)

PURPOSE: The ability to perform pull ups is important for improving mission readiness and for career advancement and retention for tactical athletes such as military, fire, and police. The purpose of this study was to investigate different strategies for improving pull ups. **METHODS:** Healthy adults were recruited via the internet and randomized into one of four training groups: traditional (5 sets of repetitions to failure, n=17), additional

loading (5 sets of repetitions to failure with additional 10% body weight, $n=7$), eccentric-only (5 sets of 6-second-eccentric-phase-only repetitions to failure, $n=6$), and control (no pull up training, $n=9$). Participants assessed pull ups at baseline, week 6, and week 12. Over 12 weeks, participants followed general training guidelines and performed pull up specific training twice per week. Changes in number of pull ups were compared with ANCOVAs, using body mass as the covariate.

RESULTS: There were no differences between training groups on changes in pull ups at any point. All intervention groups improved significantly more than the control group from baseline to week 12 ($p < 0.05$). On average, intervention participants improved from 9.3 (+ 5.7) repetitions at baseline to 12.9 (+ 7.0) repetitions at week 6, to 15.3 (+ 8.4) repetitions at week 12. The eccentric training group had the highest drop-out rate and required the greatest time commitment.

CONCLUSIONS: On average for all intervention participants, the improvements in pull ups were large, with a 39% improvement by week 6 and a total of 65% improvement over baseline at week 12. Eccentric training requires more time to complete and potentially decreases adherence to a training program and thus may be a less efficient training program. Any mode of pull up training, performed twice per week, using the basic structure of five sets of maximal repetitions, is effective at improving pull up performance.

Continuous Maximal Vertical Jumping Until Exhaustion Negatively Affects Landing Impact Severity: Effective Duration Measure

Chad A. Sutherland¹, Paul Leuty², Joel A. Cort², Jim R. Potvin¹.
¹McMaster University, Hamilton, ON, Canada. ²University of Windsor, Windsor, ON, Canada.

Email: sutherca@mcmaster.ca

(No relationships reported)

Non-contact ACL injuries account for ~75% of all knee injuries. Landing criteria have been recommended as a prevention strategy: proper knee and hip flexion angles, minimize knee abduction and land softly on both feet simultaneously. However, when fatigued, individuals have been shown to adopt higher risk landing strategies.

PURPOSE: Evaluate landing impacts during maximal vertical jumping (MVJ) until exhaustion using a novel measurement method. **METHODS:** 14 male and 14 female, recreational athletes performed a MVJ every 5 s until exhaustion. We monitored 3D lower limb kinematics and vertical ground reaction forces (VGF) with parallel force plates. Effective duration (ED) is calculated as the VGF impulse during landing (first ground contact to the bottom of crouch when vertical velocity becomes zero) divided by the peak VGF, and represents the magnitude of the peak force relative to the downward momentum that was arrested during the landing. A decreasing ED would be associated with less hip, knee and/or ankle flexion during a landing and would pose a higher risk for instability and injury at the knee. For example, a peak GRF of 1779.9 N would need to be exerted for 0.122 s (ED), to equal the total impulse (217.4 Ns) of the entire landing curve. Jump height was also recorded and normalized to body mass and time was expressed as a percent of trial duration (%trial = 0, 20, 40, 60, 80, and 100%).

RESULTS: There was a main effect of time and gender on both jump height and ED. Males jumped 53% higher than females but both genders had a significant decrease in jump height with fatigue. Females maintained an ED that was an average of 14.5% longer than males, but both demonstrated progressive and significant decreases in ED in response to fatigue (18% decrease by the end of the trial). **CONCLUSION:** This measure was found to provide an excellent representation of the impact severity, independent of the height jumped, so it was an effective single measure that could monitor the adverse effects of fatigue on the risk of knee joint injury over the course of the trials. Effective duration shows promise for instantaneous feedback of landing impact injury risk so that athletes at risk can be identified and trained to maintain safe landing mechanics in the face of fatigue.

11-wk Preparation With Polarized Compared To Pyramidal Intensity Distribution Is Not Superior In Sub-Elite Rowers

Gunnar Treff¹, Kay Winkert¹, Jürgen M. Steinacker, FACSM¹, Mahdi Sareban², Martin Becker³, Billy Sperlich³. ¹University of Ulm, Ulm, Germany. ²Paracelsus Medical University, Salzburg, Austria. ³University of Würzburg, Würzburg, Germany.

Email: gunnar.treff@uni-ulm.de

(No relationships reported)

Polarized intensity distribution (POL) is discussed to be superior to pyramidal distribution (PYR) in high performance endurance sports. POL is characterized by relatively high training volume performed in zone (Z) 1 (low intensity; < 2 mmol/L blood lactate) and Z3 (high intensity; > 4 mmol/L blood lactate), with far less volume in Z2 (close to lactate threshold). PYR is characterized by greater volume in Z2 than in Z3, albeit similar total volume. **Purpose:** The aim of this prospective study was to evaluate whether the gains in performance was superior with POL when compared to

traditional PYR in sub-elite rowers during the final 11 weeks of a preparation period.

Methods: Fourteen internationally competing German male rowers participated in the 11-wk intervention and pre-post testing (age: 20 ± 2 y, VO_{2max} : 66 ± 5 mL/min/kg). The sample was split into a PYR and a POL group by varying the percentage spent in Z2 and Z3 and matched for overall training and rowing volume including strength, unspecific endurance and other training (e.g. stretching). The actual training and intensity distributions were calculated from all athletes' official training diaries and heart rate. To quantify the level of polarization, an index was calculated as follows: Pol-Index = $\log(Z1/Z2*Z3)$. Main outcome variable was average power in 2000 m ergometer test (P2k) (Concept 2). **Results:** PYR and POL did not significantly differ regarding specific training volume (1334 ± 67 km and 1255 ± 264 km) or total volume (5953 ± 315 min and 5919 ± 1216 min), but POL had a significantly higher percentage of Z3 intensities ($6 \pm 3\%$ vs. $2 \pm 1\%$; $p < .005$) and lower amount of Z2 ($1 \pm 1\%$ vs. $3 \pm 2\%$; $p < .05$) than PYR while Z1 was similar ($94 \pm 3\%$ vs. $93 \pm 2\%$, $p = .37$). P2k significantly improved from 443 ± 30 W to 445 ± 26 W ($p = .023$), but no changes were found between groups or between measurements within groups. 6/7 (86%) of the rowers with a Pol-Index > 2 improved P2k by more than 1.3%, being the estimated error of measurement for this specific test. **Conclusion:** POL was not significantly superior to PYR during 11 wk of preparation in 14 rowers. However, results suggest that POL could be beneficial and advantageous, if it is particularly pronounced.

A Study of Sling Exercise Training for Judo Athlete to Improve Technique of Seoi-nage

Shan-Shan MAO. Beijing Sport University, Beijing, China.

(No relationships reported)

Purpose: As an important and the most frequently used Judo skill, the technique of Seoi-nage requires Judo athlete to disturb the balance of the opponent, and maintain his own stability and balance at the same time. This lies on the strong support of core muscles. As we known, sling exercise training (SET) is an effective method for core stability training, which can enhance core strength and stability and improve the ability of balance control. However, very few studies are found about the application of SET in the Judo training. The purpose of the study is to investigate how SET affects the technique of Seoi-nage for Judo athletes.

Methods: A total of 14 health male Judo athletes has participated in the study. They are all athletes of National Rank 2 from a sports university. They are randomly divided into two groups, the SET group (S, $n=7$) and the control group (C, $n=7$). The S group use the SET program particularly designed for them, while the C group take only conventional free-hand training, which has the comparable load as the S group. They take the training for 6 weeks, three times per week, and each time lasting 15-20 minutes. Before and after the training, technical specifications of Seoi-nage are recorded and analyzed by the video analytical system. The kinematical parameters include the level of the trunk maximum flexion angle (TMFA), maximum angular velocity (MAV), the leg speed in stage of the entering, and the time to finish Seoi-nage. The quality score and the number of Seoi-nage performed within 30 seconds are also measured. The data are processed by the SPSS 13.0. One-way ANOVA is used.

Results: After 6w training, we got the following results. (1) The S group has significant increases ($P < 0.05$) in the averaged TMFA from 20.1° to 28.4° and the MAV from $177.1^\circ/\text{sec}$ to $197.0^\circ/\text{sec}$. (2) The mean speed of leg in stage of the entering is 0.12 sec, significantly improved ($P < 0.05$) compared with the group C, which is 0.15 sec. (3) Both the averaged quality score and number of Seoi-nage completed within 30 seconds are very significantly improved ($P < 0.01$), from 3.1 to 3.6, and from 10.4 to 12.5, respectively.

Conclusion: 6w- SET can improve the kinematical parameters and performance of Seoi-nage for male Judo athletes. It seems that SET is a useful exercise for training of Judo athletes.

Effectiveness and Feasibility of Integrating Video Feedback into Practice to Improve the Collegiate Softball Hit

Erin H. Hartigan, Stacey Howard, Katherine Michelsen, Morgan Wilson. University of New England, Portland, ME.

Email: ehartigan@une.edu

(No relationships reported)

Feedback about performance is standard coaching practice to improve acquisition of an athletic skill. Video feedback improves performance during golf and tennis swings; thus may improve performance during softball swings. Still shots with written instructions (task cards) guide peer assessment; yet the benefits for self-assessment are unknown. **Purpose:** To determine if self-assessment of performance using task cards and video feedback will improve hitting mechanics in collegiate softball players more than standard coaching alone.

Methods: Nineteen collegiate DIII softball players (age 19.6 ± 1.3 years; years of experience 12.5 ± 2.3) were randomized into a control or intervention group. The intervention group used task cards and delayed video feedback of their at bats during each hitting practice for four weeks. The control group received standard coaching

only. Data were collected at: pre-intervention (T1), immediate post-intervention (T2), and delayed post-intervention (T3). Five random hits were coded as “met=1” or “not met=0”. Met was defined as: weight centered between feet during each phase of swing and 1) pre-swing: chin on front shoulder, hands at back armpit, 2) contact: lead with knob of bat, strong lead leg, 3) follow-through: chin on front shoulder. The phase of the hit was coded as “not met” if all criteria were not achieved.

RESULTS: A main effect of time was found for pre-swing (P=0.014), with improvements occurring between T1 and T3 (P=0.009). No other main effects or interaction effects were found for hitting. (Table 1)

CONCLUSIONS: Task cards and delayed video feedback did not improve hitting mechanics more than standard coaching. Regardless of group assignment, all players improved in the pre-swing phase by the end of regular season games. The improvement in pre-swing suggests an improved ability to make contact with the ball because the batters’ pre-swing stance puts them at an advantage to reach a variety of pitches (i.e. inside, outside, high, low).

	T1	T2	T3
Pre-swing	.30 (.37)	.51 (.45)	.59 (.43)
Contact	.85 (.30)	.76 (.41)	.87 (.19)
Follow-through	.90 (.23)	.83 (.23)	.87 (.20)

3676 Board #123 June 3 9:30 AM - 11:00 AM
Effects Of Aerobic Exercise Using Swiss-ball Or Chair Compared With Walking.

Toshihiro Wakimoto¹, Tatsuya Saitou¹, Tomomi Monri¹, Yoshiyuki Yamanaka², Souhachi Fujimoto², Toshihiro Takao².
¹Kawasaki University of Medical Welfare, Kurashiki, Japan.
²Kawasaki Medical School, Kurashiki, Japan.
 Email: wakimoto@med.kawasaki-m.ac.jp
 (No relationships reported)

PURPOSE: To clarify the physiological effectiveness of various movement on aerobic exercise using Swiss-ball (SB) or chair, we compared the exercise intensity between walking and aerobic exercise using SB or chair.

METHODS: Nine healthy men performed walking and aerobic exercise using SB or chair. Respiratory metabolism and heart rate were measured during walking and aerobic exercise using BB. Subjects walked at 4 speeds (4 km/h, 5 km/h, 6 km/h and 7 km/h) on treadmill ergometer. During aerobic exercise using SB, subject was sitting on the SB and bouncing with upper and lower limb movements. During aerobic exercise using chair, subject was sitting on the chair and exercising with upper and lower limb movements. The movements consisted of four patterns of upper and lower limb movements.

RESULTS: The exercise intensity during aerobic exercise using SB (4.8±0.6 Mets) was significantly higher (p<0.001) compared with aerobic exercise using chair (3.6±1.1 Mets). There was no difference between aerobic exercise using SB and chair on the heart rate (SB: 118±12 beats/min, Chair: 110±14 beats/min). The exercise intensity in aerobic exercise using SB were nearly identical with walking at 6 km/h (4.5±0.4 Mets). In contrast, the exercise intensity and heart rate in aerobic exercise using chair were nearly same as walking at 4-5 km/h (3.3±0.4 Mets - 3.8±0.5 Mets).

CONCLUSIONS: The exercise intensity and heart rate during aerobic exercise using SB or chair was nearly identical with moderate-intensity walking. The aerobic exercise using SB or chair can be alternative to walking for people who cannot walk.

Time Course for Physiological Adaptations with Hypobaric Exposure: A Research-Pedagogical Project

Frank B. Wyatt, Carpenter B. Wyatt, Elizabeth Wilson, Kayla Nelson, Kristin Russell, Destiny Zynda, Lucas Veitenheimer, Nicole Cochran. *Midwestern State University, Wichita Falls, TX.*
 Email: frank.wyatt@mwsu.edu
 (No relationships reported)

PURPOSE: The purposes were: 1) determine physiological change following a brief sojourn training period at altitude; 2) through pedagogy, facilitate student proficiency in methods of testing and interpretation in determining rate of change in adaptation. **METHODS:** A pre-post testing measurement design utilizing twelve (n=12) volunteers from the Midwestern State University Cycling Team was used. Subjects signed an Informed Consent, approved by the Institutional Review Board for Humans as Subjects at Midwestern State University. Measures were sub-categorized into Resting and Exercise. A Repeated Measures ANOVA determined differences between pre and post-tests. Alpha was set *a priori* at p < 0.05. **RESULTS-Physiological:** Subject means and standard deviation (SD) for descriptive measures were: age, 21.56 (2.83) y; height, 161.83 (34.68) cm; weight, 69.36 (8.37) kg; body fat, 6.6 (1.98) %; maximal oxygen consumption, 70.41 (8.61) ml*kg⁻¹*min⁻¹; peak lactate, 14.25 (2.56) mM; maximal power, 372.22 (55.12) watts. Significant (p<0.05)

changes in baseline vs. altitude exposure were seen in average heart rate, 164 vs 162 (b*min⁻¹), respectively and average blood lactate 6.01 vs 5.83 (mM) respectively, across the workload continuum. Maximal oxygen consumption (Max VO₂) and time to exhaustion (TE) after altitude exposure improved (increase and decrease, respectively) over baseline. Hematocrit, hydration status via urine specific gravity (USG), fasting blood glucose (mg*dL⁻¹) and kilocalorie (Kcal) consumption were not significantly altered during five days of altitude exposure. **RESULTS-Pedagogical:** Students showed proficiency in the following: anthropometry, blood pressure, electrocardiograph (ECG), urine specific gravity (USG), blood glucose, blood lactate, Max VO₂. In addition, students were involved in research literature review and article summation. Following the research data collection, the students were shown statistical procedures for research analysis. **CONCLUSION:** This project involved a research component and a pedagogical component. Physiologically, exposure to altitude showed trends toward positive performance measures after five days of exposure. Pedagogically, this project allowed for experiential learning for undergraduate students and involvement in research.

3678 Board #125 June 3 9:30 AM - 11:00 AM
Velocity-based Training: Exploring The Potential Implications Of Training With Absolute Versus Relative Velocities

Steven M. Hirsch, David M. Frost. *University of Toronto, Toronto, ON, Canada.*
 Email: steven.hirsch@mail.utoronto.ca
 (No relationships reported)

Although training intensity is commonly adapted by modifying the *relative* load (e.g. % 1RM), *absolute* velocities are also targeted to facilitate speed- and power-oriented training objectives. **PURPOSE:** Examine the variation in *relative* loads and *relative* velocities used to perform a bench press at 6 *absolute* velocities. **METHODS:** Thirty men completed three bench press tests: 1RM, max velocity with 2.5kg bar, and 6 sets of 4 reps with loads of 15-90% 1RM. Participants were instructed to lower and lift the bar as fast as possible. Mean and peak concentric barbell velocity was computed via a linear position transducer. The average mean velocity of each 4-rep set and the relative load lifted were used to create participant-specific regression equations that would capture each individual’s load-velocity relationship. These equations were then used to estimate the % 1RM that would have been used to move the bar with the group’s mean velocity with loads of 15-90% 1RM). These “target” velocities were also expressed as a relative percentage of the maximum velocity (% Vmax) achieved by each participant during the 2.5kg test. The variation in %1RM for each velocity was described by the standard deviation and range amongst participants. A similar approach was used to estimate the % Vmax that would have been achieved using a range of loads (15-100% 1RM). **RESULTS:** Lower % 1RM and higher mean velocities were associated with the largest variation in training intensity across participants (Table 1). **CONCLUSION:** Using specific *absolute* mean velocities as “targets” could result in substantial variation to the corresponding % 1RM and % Vmax across a group of athletes. To accommodate the abilities of each performer, it may be important to use *relative* velocity targets.

Absolute Velocity (m/s)	Estimated %1RM			Relative Load (%1RM)	Estimated %VMax		
	Mean	SD	Range		Mean	SD	Range
1.70	11	11	-32-27	15	42	6	33-57
1.30	33	8	-1-45	30	32	5	25-44
1.00	49	7	23-58	45	25	4	19-35
0.75	62	5	43-71	60	18	4	13-27
0.50	76	4	63-83	75	12	3	6-19
0.25	87	4	82-96	90	6	3	1-12

Does Time of Day in Which Exercise Training is Performed Alter Fitness and Health Outcomes in Women?

Stephen J. Ives, Nathaniel Robinson, Daniela Escudero, Jake Robinson, Kayla Rose, Olivia Minicucci, Gabriel O'Brien, Kathryn Curran, Maia Paul, Caitlin Sheridan, Paul J. Arciero, FACSM. *Skidmore College, Saratoga Springs, NY.* (Sponsor: Paul Arciero, FACSM)
Email: sives@skidmore.edu

(No relationships reported)

While there is much anecdotal evidence suggesting the importance of time of day (TOD) in which exercise training is performed, there is a paucity of controlled comprehensive studies examining the influence of TOD on training-induced adaptations. **PURPOSE:** to determine the effect of TOD on mediating training-induced changes in exercise performance, cardio-metabolic health, and body composition in active normal weight women. **METHODS:** 27 healthy active females (BMI = 24 ± 3 kg/m²; 42 ± 8 yrs) were recruited for this study and randomized to either exercise training in morning (AM) or evening (PM) for 12 weeks. In following recent ACSM guidelines, we employed a multimodal training paradigm (Resistance, Interval, Stretching, and Endurance, RISE). Baseline exercise performance was assessed via abdominal, upper and lower body muscular strength (situps, pushups, 1 RM bench and leg presses), power (jump squats and bench throws), aerobic power (5km cycling time trial), flexibility (sit and reach), and balance (stork stand), cardiovascular health (blood pressure, and augmentation index (AIx)), body composition (DEXA: Fat free mass, fat mass, abdominal/visceral fat, %body fat), hunger/satiety ratings (visual analog scales), and cardio-metabolic profile (energy expenditure, fasting lipids, glucose, insulin). **RESULTS:** At baseline, no differences existed between groups in any variable. Training resulted in significant ($p < 0.05$) improvements in exercise performance, cardio-metabolic health, and body composition. However, there were significant interactions ($p < 0.05$) of TOD x training for DBP (-10 ± 1 v. -5 ± 5 mmHg), RMR (-130 ± 65 v. -12 ± 36 kcal/d), FM (-1.0 ± 0.2 vs. -0.3 ± 0.2 Δkg), Abfat (-2.6 ± 0.3 v. -0.9 ± 0.5 Δkg), 1RM BP (8 ± 2 v. 12 ± 2 Δlb), Pushups (9 ± 1 v. 13 ± 2 Δreps), BT power (10 ± 6 v. 45 ± 28 Δwatts), SJ power (135 ± 6 v. 39 ± 8 Δwatts), AM vs. PM, respectively. **CONCLUSIONS:** The multimodal RISE protocol improved performance, cardiovascular health, and body composition, with the TOD altering the magnitude of exercise training-induced adaptations. Specifically, training in the AM resulted in greater improvements in diastolic blood pressure, fat mass, abdominal fat mass, and lower body peak power. Whereas, training in the PM resulted in greater gains in upper body muscle strength, endurance, and power. Support: Isagenix.

Differences in Physiological Responses Between Traditional and 3v3 Game Sessions Among Elite Developmental Ice-hockey Players

Ken Martel, Andrea Workman, Davor Stojanov. *Eastern Michigan University, Ypsilanti, MI.* (Sponsor: Andrew Coggan, FACSM)

(No relationships reported)

Small sided games are commonly used in team sports to incorporate live play and high repetition skill execution. There is little data with regard to the physiological requirements of small sided vs. traditional game format in ice-hockey. **PURPOSE:** Use player mounted sensors (PMS) to compare the accelerations (ACC) and heart rate (HR) between traditional (TRAD) and 3v3 cross-ice games among elite, national-level youth ice-hockey players. **METHODS:** 29 elite ice hockey players (15.2 yrs \pm .27, 177.4 cm \pm 7.1, 72.9 Kg \pm 10.7) who participated in USA Hockey National Player Development Camp consented to procedures approved by the EMU human subjects committee. Players wore Zephyr Bioharness-3 (Zephyr, MD) PMS across their chest. The PMS recorded HR and ACC at 10 Hz over the seven on ice sessions of the five-day camp. This included three practice sessions, three games (G1, G2 and G3) and one 3v3 training session. PMS were downloaded to Omnisense software (Zephyr, MD) and data was exported from Omnisense to WKO4 (Peakware, CO) for storage and analysis. Peak ACC across multiple time frames (5, 10, 20, 30, 45, 60 sec, 5, 10, 20, 40 min) were quantified. Heart rate was quantified and used in conjunction with ACC to determine exertion profiles for each on-ice session. MANOVAs for peak ACC and HR at each time point across games and 3v3 with magnitude and time as main effects were performed using SPSS 23.0 (IBM, NY). **RESULTS:** No differences were observed between sessions for 5 sec, but 10 sec ACC was lower for 3v3 vs G1 and G2 ($p < .05$), but not G3. No sig differences were observed for 20-60 sec ACC ($p > .05$), but small effects were present at all time frames ($\eta^2 = 0.021 - 0.077$). No sig differences were observed for 5 min ACC, but 10, 20 and 40 min, were all significantly higher for 3v3 than G1, G2 or G3 ($p < .05$). For HR, no sig differences or effects ($\eta^2 < .01$) were present for any time frame less than 5 min. HR was higher for 5, 10, 20 ($p < .05$) but not 40 min, for 3v3 vs G1, G2 and G3. **CONCLUSIONS:** Reduced 10 sec ACC for 3v3 indicates a reduced reliance on phosphagen system vs TRAD games while

higher ACC and HR for 10, 20 and 40 min indicates that 3v3 is more reliant on aerobic systems than TRAD games. Insignificant differences, with small effects, for 20 - 60 sec between TRAD games and 3v3 indicate there may be practical differences that are less distinct than for other time frames.

3681 Board #128 June 3 9:30 AM - 11:00 AM

Three Weeks of CrossFit Training Does Not Contribute To Overtraining Syndrome in Recreationally Trained Males: A Pilot Study

Derek Crawford. *Pittsburg State University, Pittsburg, KS.*
Email: dcrawford@pittstate.edu

(No relationships reported)

CrossFit® (CF) is currently one of the most popular health and fitness activities. However, CF faces strong opposition and criticism claiming it causes injury. **PURPOSE:** The purpose of this study was to investigate if CF participation contributes to overtraining syndrome. A secondary purpose was to determine if there are differences between CF original methodologies and real-world practice. **METHODS:** Six recreationally trained males (height, 182.8 ± 8.6 cm; weight, 84.3 ± 12.4 kg, and age, 25.0 ± 5.4 years) were randomized into two groups, theoretical (TH) or real-world (RW) prior to the intervention. Both groups completed pre-testing assessment of body composition, physiological, biochemical, psychological, and performance-based data. Both groups participated in CF training 5 days/week. The TH group completed training designed to follow original CF methodology while the RW group followed programming designed by a randomly selected CF affiliate. Prior to and at the end of each week blood was collected for serum analyses and select joint range-of-motions (ROM) were measured. Additionally, prior to each training session, resting heart rate (RHR), blood pressure (BP), muscle soreness (DOMS), and select training variables were collected. Following the completion of each training session, HR and perceived exertion (RPE) were collected. **RESULTS:** There are no significant differences in physiological, biochemical, immunological, psychological, or performance outcome variables assessed in this study for both between groups and pre-post testing (all $p > .05$). However, there are differences in intervention programming between TR and RW groups. In practice, there were significantly less element priority sessions in practice compared to what is recommended (40% vs 0%; $\chi^2 = 8.25$; $p = .016$). Element priority sessions had significantly lower associated training heart rates (127.4 vs 167.0 , 172.4 bpm; $F = 8.63$; $p = .001$) and ratings of perceived exertions (9.4 vs 14.8 , 14.7 ; $F = 15.26$; $p = .000$) than other session designs common in CF. **CONCLUSION:** These data suggest that short-term CF participation does not contribute to the development of overtraining syndrome in recreationally trained males.

3682 Board #129 June 3 9:30 AM - 11:00 AM

The First Twenty Exercise Training Program and Fire Academy Recruits' Fitness and Health

Brittany S. Hollerbach¹, Sara A. Jahnke², Thomas J. Barstow, FACSM¹, Craig A. Harms, FACSM¹, Katie M. Heinrich¹.
¹Kansas State University, Manhattan, KS. ²National Development and Research Institutes, Leawood, KS. (Sponsor: Craig Harms, FACSM)

(No relationships reported)

PURPOSE: To examine the effects of a novel high-intensity training program on fire academy recruits' health, fitness, and performance. **METHODS:** 13 participants were recruited from a fire academy and were randomly assigned to the control (CG, n=6) or intervention group (IG, n=7). Due to attrition 10 male recruits (23.8 ± 2.7 years) completed the study (CG, n=3, IG, n=7). The CG was asked to continue their current exercise habits. The IG was provided a 10-week online-based periodized training program developed by firefighters specifically for firefighters that included nutritional and mental readiness education. Participants completed pre/post-intervention assessments including a timed simulated fireground test (SFGT). A feasibility analysis was also completed for the IG. Due to the small sample size and group differences at baseline, descriptive statistics were calculated and each participant was reviewed as an individual case study. The Wilcoxon Signed Rank Test was used to compare pre- and post- changes among groups. **RESULTS:** The IG showed marked improvement on SFGT performance (40% to 86% passing); four improved their passing time. The IG significantly increased estimated VO_{2max} ($p = 0.028$), improved body composition (decreased fat mass and body fat %, $p = 0.028$), and increased grip strength ($p = 0.018$). With a small sample size we were unable to discern if the intervention improved recruit fitness and performance compared to the control group or other covariates, however, the CG showed no statistically significant changes. Though the IG completed ~75% of the assigned workouts, there may be a better way to implement this intervention. Participants mentioned they'd like group workouts led by a certified strength and conditioning coach/peer fitness trainer as opposed to workouts completed on their own. **CONCLUSIONS:** This study showed that a high-intensity training program improved fireground performance, aerobic fitness, body composition, strength, and agility among fire academy recruits. A larger randomized controlled trial is necessary to further investigate program effects among this population.

Abstracts were prepared by the authors and printed as submitted.

Effect Of An Eighteen-week Cessation Of Physical Training On Army Rotc Cadets

Ryan G. Kunkle, 96816. *University of Hawaii at Manoa, Honolulu, HI.* (Sponsor: Ronald K. Hetzler, FACSM)
 (No relationships reported)

During summer break, ROTC cadets are not required to participate in mandatory physical training. **PURPOSE:** To investigate the effect of an eighteen-week cessation in regimented physical training on body composition measurements and cardiorespiratory endurance in a cohort of Army ROTC cadets. **METHODS:** Two testing sessions were completed in the spring and fall, by 35 cadets (males n=29, age=22.9±3.8 vs. 23.1±4.0yrs, height=175.1±5.9 vs. 175.0±5.9cm, weight=76.5±9.7 vs. 77.7±9.1kg and females n=6, 21.4±1.5 vs. 21.6±1.5yrs, 162.7±5.6 vs. 162.5±5.9cm, 63.0±5.4 vs. 64.1±5.6kg, for the spring and fall respectively). Body composition was assessed using circumference and 3-site skinfold measurements. Percent body fat (%BF) was calculated using Brozak formula. Cardiorespiratory endurance was assessed by completion of maximal oxygen uptake ($\dot{V}O_{2max}$) test on a motorized treadmill using a modified Åstrand protocol. **RESULTS:** Body mass was significantly increased in both male (spring: 76.5±9.7kg vs. fall: 77.8±9.1kg; p<0.05, Δ=1.3kg) and female (spring: 63.0±5.5 kg vs. fall: 64.1±5.7kg; p<0.05, Δ=1.1kg) cadets. There was a significant increase in the sum of three skinfolds and %BF in male cadets (spring: 43.0±13.3mm & 12.4±3.8% vs. fall: 49.8±11.8mm & 14.3±3.3%; Δs =6.8mm & 1.9%, respectively, p<0.05), but not in female cadets. Lean body mass remained unchanged from spring to fall testing sessions (p>0.05). Body Mass Index was significantly increased in male (spring: 24.9±2.7 vs. fall: 25.3±2.4; p<0.05) and female cadets (spring: 23.7±1.5 vs. fall: 24.2±1.9, p<0.05). Time on treadmill decreased significantly in male cadets (spring: 12.3±1.3min vs. fall: 11.5±1.5min; p<0.05). Significant declines in relative $\dot{V}O_{2max}$ results were seen in male cadets (spring: 51.1±4.2 vs. fall: 49.4±3.3ml/kg/min; p>0.05, Δ=1.8ml/kg/min). There were no significant changes for time on treadmill or relative $\dot{V}O_{2max}$ for female cadets. There was a significant interaction for post-test blood lactate with the female cadets increasing from 7.7±2.1 to 9.7±1.5mmol and male cadets decreasing from 10.6±2.0 to 9.0±2.6mmol.

CONCLUSION: An eighteen-week training cessation from physical training negatively effected body composition in both male and female Army ROTC cadets and cardiorespiratory endurance in male cadets.

3684 Board #131 June 3 9:30 AM - 11:00 AM
Training Unloading During Winter Break Improves Fitness in Male Rugby Players

J. Mark VanNess, Jeremy McConnell, Derek Gleason, Courtney Jensen. *University of the Pacific, Stockton, CA.*
 Email: mvanness@pacific.edu
 (No relationships reported)

When athletes experience training distress, a break in training may facilitate recovery and improve performance. Conversely, when team training is interrupted, such as occurs during winter break in collegiate athletes, deconditioning may result. In the current study, physiological responses to exercise were made before and after an unstructured winter break in male collegiate rugby players. **PURPOSE:** The purpose of the study was to examine detraining effects that occurred when structured training was interrupted for four weeks. **METHODS:** Fourteen (n=14) male club rugby players underwent exercise testing to assess aerobic capacity ($\dot{V}O_{2max}$), strength (maximal bench press and leg squat), speed (10 yd dash), power (vertical jump), and body composition (body weight and % body fat by underwater weighing). A subject orientation of the testing was performed for all tests, and the treatment data were collected just prior to, and after the winter school break. T-tests were performed on pre- and post-winter break values. **RESULTS:** There was no evidence of detraining after four weeks of unstructured training. No changes were observed in bench press strength (183 versus 188.6 lbs) or speed (1.69 versus 1.69 seconds) across the break. However, performance measures for aerobic capacity (45.45 versus 47.70 ml/kg/min), squat strength (269.6 versus 308.2 lbs) and vertical jump (22.52 versus 23.94 inches) all showed significant improvements following the break. Additionally, there were significant increases in body weight (176.96 versus 178.63 lbs) and percent fat (12.76 versus 15.27% fat). **CONCLUSION:** Four weeks of unstructured training over the winter school break appears to have provided a recovery period that allowed for increases in physiological function despite increases in body fat.

3685 Board #132 June 3 9:30 AM - 11:00 AM
No Acute Effect of Sled Towing on Sprint Acceleration or Maximum Speed

Megan A. Wong, Casey M. Watkins, Ian J. Dobbs, Saldiam R. Barillas, Anne Lin, David C. Archer, Jared W. Coburn, FACSM, Robert G. Lockie, Lee E. Brown, FACSM. *California State University, Fullerton, Fullerton, CA.*
 (No relationships reported)

Sled towing is a popular method of overload training in many field sports. The initial acceleration and top speed phases are components in developing peak velocity in athletes. Acute training may lead to postactivation potentiation (PAP), which occurs when subsequent muscle performance is enhanced following a preload stimulus. However, this is highly dependent on rest time. **PURPOSE:** To investigate acute sprinting in the acceleration and maximum speed phases following different rest periods after sled towing. **METHODS:** Eleven male field sport athletes (age=23.00±2.79yrs, height=177.45±6.34cm, mass=82.52±8.79kg) completed a standardized warm-up then performed a baseline 30 meter (m) sprint (measured with acceleration and maximum speed splits). They were then attached to a waist harness and towed a sled equal to 30% of their bodyweight for 30m with maximal effort. Following a random rest period (2, 4, 6, 8, or 12min), they performed another maximal effort bodyweight sprint without the sled. **RESULTS:** A 4x6 (split x condition) ANOVA revealed that baseline split times (split 0-5m 1.14±0.05s, split 5-10m 0.77±0.04s, split 10-20m 1.30±0.06s, split 20-30m 1.25±0.07s) were not different than split times for any rest condition (collapsed across rest conditions, split 0-5m 1.14±0.75s, split 5-10m 0.78±0.03s, split 10-20m 1.33±0.07s, split 20-30m 1.27±0.07s). **CONCLUSIONS:** Sled towing did not increase or decrease acute maximal effort bodyweight acceleration or maximum speed sprint times. The different rest periods did not elicit a PAP effect, which may be attributed to less than optimal loading.

The Effect of Reduced Training Volume during Tapering on Kicking Response in Taekwondo Competitors

Pedro J. Carazo-Vargas, José Moncada-Jiménez. *University of Costa Rica, San José, Costa Rica.*
 Email: pcarazov@hotmail.com
 (No relationships reported)

PURPOSE: The purpose of the study was to evaluate the effect of training volume during tapering on kicking performance in college Taekwondo competitors trained under a periodization block model. **METHODS:** Participants were eight men and four women of the taekwondo team at the University of Costa Rica. All individuals completed a 13-week macrocycle loading phase (10 weeks of load and 3 weeks of taper). Following the loading phase, participants were paired by gender and randomly assigned to either a condition in which they kept the same training volume or a condition where training volume was reduced by 50% using a linear pattern. Kicking motion time was measured by instructing individuals to perform a circular kick to a target located at 1.10m high followed by another kick to a target located at 1.60m high. Kicking time response was obtained by recording the time required to kick a random sequence of 10 targets. The "Fitlight Trainer system" was used to time both dependent variables. Measurements were recorded at the beginning of the loading phase, the sixth week of the load period and twice a week during each of the three weeks of the tapering phase. Effect sizes (ES) were computed and analysis of variance (ANOVA) tests were used to detect significant interactions. **RESULTS:** No significant interactions were found on kicking motion-time (Pre = 1.39 ± 0.09s vs. Post = 1.26 ± 0.06s) and kicking time response times (Pre = 9.63 ± 1.01s vs. Post = 8.47 ± 0.51s) in the group following the same training volume and the group with reduced training volume (Pre = 1.35 ± 0.10s vs. Post = 1.26 ± 0.11; Pre = 9.42 ± 1.52s vs. Post = 9.57 ± 1.78s, respectively). ANOVA results showed that regardless of the training volume, during the tapering phase improvements were observed on kicking motion time (p = 0.03) and kicking time response (p = 0.04), with the best performance observed at the end of the third week of the tapering phase. The 50% training volume reduction produced a higher ES on kicking motion time (1.50) and kicking time response (3.32) compared to no reduction in training volume (0.86 and 0.04, respectively). **CONCLUSIONS:** The reduction of volume training during tapering under a periodization block model improved kicking performance on taekwondo competitors. In the analyzed conditions, tapering must extend at least three weeks.

Effects of a 3-week Core Training Program on Different Unstable Platforms

Alexa J. Chandler¹, Sebastian Harenberg², Joseph DiSalvo², John Fausold², Larissa Melendez², Rachel Simkins², Collin Gill², Victor Lopez-Carmen², Thomas Swensen². ¹Rutgers, The State University of New Jersey, New Brunswick, NJ. ²Ithaca College, Ithaca, NY. (Sponsor: Shawn Arent, FACSM)
 (No relationships reported)

The untested InertiaCore Balance Trainer (ICT) is designed to improve core function. Users engage the core musculature to maintain balance on the unstable device; its stability is adjusted by adding weight. This flexibility makes the ICT appropriate for all fitness levels. **PURPOSE:** To compare the effects of a 3 wk core-training program completed on the ICT or a stability ball (SB). **METHODS:** Thirty-one active college age students (19.4 ± 1.4 y and 65.2 ± 11.0 kg) were divided into the ICT and SB groups, each of which completed various medicine ball throws, crunches, and Russian twists. Subjects trained 3 d·wk⁻¹ for 3 wk; medicine ball weight and repetitions increased during the program's midpoint. Changes in core power and strength were measured across time with the Front Abdominal Power Throw (FAPT) and a Cybex dynamometer. Data were analyzed using repeated measures ANOVAs. Dependent t-tests were used to examine changes across time within groups. **RESULTS:** The ANOVAs revealed no significant main effects between the time points or groups for any dependent variable. The dependent t-tests revealed that SB training significantly increased Cybex flexion and extension power by 2.2% (138.3 ± 38.1 to 141.4 ± 37.6; p=0.047) and 5.6%; (118.3 ± 49.2 to 124.9 ± 50.8; p=0.018), respectively, while ICT training produced no significant changes. A significant interaction was found for flexion power (p=0.036), indicating opposing trends between the two groups across time. A similar relationship was found for flexion work, but the interaction only approached significance (p=0.059). **CONCLUSION:** The ICT did not improve core function relative to the SB. This study focused on unstable training, but using more weight on the device, thereby increasing stability and resistance, may alter outcomes.

Effects Of An Eight-week Swingfit Training Program On Balance, Muscular Strength, And Muscular Endurance.

James Schoffstall, FACSM, Chris Carver, Jon Houck, Andy Bosak, Chelsea Page. *Liberty University, Lynchburg, VA.*
 Email: jeschoffstall@liberty.edu
 (No relationships reported)

PURPOSE: The purpose of this study was to determine the impact of an eight-week SwingFit training program on balance and strength. **METHODS:** Twelve active, low-risk stratified individuals were recruited as subjects. The experimental group consisted of seven females (25 ± 11yrs; 163.4 ± 6.5cm; 62.9 ± 7.8kg) and five males (29 ± 14yrs; 175.9 ± 4.4cm; 75.3 ± 5.4kg). Pre- and post-training assessments were completed for balance, strength and muscular endurance. Balance was assessed using the Biodex Balance System SD using the static balance assessment. Grip strength was assessed using the Takei hand dynamometer. Hip/leg strength was assessed using a Takei back & leg dynamometer. Muscular endurance was measured using a SwingFit® seated pullup test. **RESULTS:** Overall stability improved significantly (p<0.05) from 1.03 ± 0.49 to 0.74 ± 0.13. Muscular endurance improved significantly (p<0.05) from 27.2 ± 7.7 reps to 35.5 ± 0.3 reps on the SwingFit seated pullup test. Hip & Leg strength increased significantly (p<0.05) from 69.6 ± 30.7 kg to 78.1 ± 32.4 kg. The combined grip strength (right hand + left hand) increased significantly (p<0.01) from 61.2 ± 19.1 kg to 70.8 ± 22.3 kg. **CONCLUSIONS:** The SwingFit training program has been demonstrated to be an effective option for improving balance, as well as muscular strength and endurance in an eight-week training program. Future research may examine the impact of longer duration training programs and/or comparing the SwingFit program to other more established methods of training.

Changes In Heart Rate Variability And Training Load In Elite Football Players

Bryna C. Christmas¹, Lee Taylor², Graham Stark³. ¹Qatar University, Doha, Qatar. ²Aspetar Orthopaedic and Sports Medicine Hospital, Doha, Qatar. ³University of Bedfordshire, Bedford, United Kingdom.
 Email: bchristmas@qu.edu.qa
 (No relationships reported)

Heart rate variability (HRV) is a popular and accessible monitoring tool utilized ubiquitously in the field to measure autonomic nervous system activity, readiness to train, and training adaptations. Acquisition of this information is essential for coaches,

practitioners and athletes in order to effectively monitor positive training adaptations, nonfunctional over-reaching, injury and illness risk. However, longitudinal data assessing HRV changes with respect to training load in elite football is lacking. **PURPOSE:** To investigate changes in HRV and training load across several weekly training blocks in elite football. **METHODS:** Six male professional footballers (three defenders, three midfielders) from an English Premier League squad agreed to participate in this study. HRV was assessed with the ithlete application (HRV Fit Ltd, UK) using an Apple iPad2 (Apple Inc, CA), and a Polar T31 heart rate monitor (Polar Electro Ltd, Finland). HRV was calculated for each participant prior to the daily training session. Physical training load was monitored using a Global Positioning System (GPS) to quantify total distance (TD), high speed distance (HSD), training load (TL), impacts, maximum speed (MS), accelerations and decelerations, and energy expenditure (EE). Training sessions were separated into five equal training blocks (weeks 1 - 3, weeks 4 - 6, weeks 7 - 9, weeks 10 - 12 and weeks 13 - 15). **RESULTS:** There was a significant decrease in TD, HSD, TL, impacts and EE and a significant increase in MS, accelerations and decelerations across the five training blocks (p ≤ 0.03). However, there was no significant change in HRV (p = 0.27). **CONCLUSION:** The significant change in TL across the 15 week training period, despite no change in HRV may be due to the heterogeneity that exists in elite football players, where some athletes show smaller reductions in HRV in response to training compared to others. Subsequently it is important that individual changes in HRV are interpreted alongside additional monitoring methods (e.g. wellness, training load) to ensure that quantification of training adaptation, readiness to train and overreaching is accurate.

Acute Effects of Plyometric Exercise on Blood Glucose

Saldiam R. Barillas, Casey M. Watkins, Megan A. Wong, Ian J. Dobbs, David C. Archer, Cameron N. Munger, Andrew J. Galpin, Jared W. Coburn, FACSM, Lee E. Brown, FACSM.
California State University, Fullerton, Fullerton, CA.
 (No relationships reported)

Short duration, high intensity exercise has been implemented in various weight-loss programs. Although traditional plyometric training is not commonly prescribed for weight loss, exercises such as jumping are popular in commercial exercise programs. However, the effect of plyometric exercise on blood glucose levels is unknown. **PURPOSE:** To investigate the effect of relatively high intensity plyometric exercise on glycemic control. **METHODS:** Thirteen subjects (6 females age=21.8 ± 1.0yrs; height=163.7 ± 7.8cm; mass=60.8 ± 6.7kg and 7 males age=22.0 ± 2.6yrs; height=182.3 ± 3.6cm; mass=87.4 ± 12.5kg) volunteered to participate. Inclusion criteria was the ability to achieve 80% of their age predicted max heart rate (APMHR) following the plyometric exercise. Subjects wore a heart rate monitor and completed two random conditions on two separate days, consisting of either five sets of 10 maximal effort countermovement squat jumps (SJ) with 50 seconds rest between sets or quiet sitting (SIT) for the time equated to the SJ duration (~4min). Immediately after each condition, subjects drank 75g of anhydrous glucose in 100ml of water. Blood glucose measurements were taken via finger prick and analyzed by an Accu-Chek Performa device pre and immediately post SJ or SIT, and 5, 15, 30, and 60 min post. **RESULTS:** A 2x6 (condition x time) ANOVA revealed a significant interaction where SJ blood glucose levels were lower at 15 (114.0 ± 14.6mg/dl) and 30 (142.1 ± 22.5mg/dl) min post compared to SIT (15min 130.8 ± 14.0mg/dl & 30min 159.3 ± 21.0mg/dl). Pairwise comparisons revealed that 5 (106.1 ± 9.5mg/dl), 15 (114 ± 14.6mg/dl), 30 (142.1 ± 22.5mg/dl), and 60 (146.5 ± 34.1mg/dl) min were significantly greater than baseline (93.8 ± 8.8mg/dl) for SJ and for SIT 5 (106.1 ± 12.8mg/dl), 15 (130.8 ± 14mg/dl), 30 (159.3 ± 21mg/dl), and 60 (144.6 ± 19.1mg/dl) min baseline (94.7 ± 8.1mg/dl). **CONCLUSIONS:** The current plyometric protocol attenuated post-exercise blood glucose levels at 15 and 30 minutes post SJ at 80% APMHR when compared to SIT. This may be due to increased physiological stress applied to the muscles, thus increasing muscular glucose uptake. Reaching 80% APMHR might be the desired physiological stress level to stimulate a change in glycemic control.

Effects Of Lifestyle Modifications On Serum Testosterone Levels In Overweight And Obese Men

Hiroshi Kumagai, Toru Yoshikawa, Kanae Myoenzono, Tomoko Kaneko, Takehiko Tsujimoto, Kiyoji Tanaka, Seiji Maeda.
University of Tsukuba, Tsukuba, Japan.
 (No relationships reported)

PURPOSE: Testosterone is associated with lots of physiological functions in men. Obesity results in reduced serum testosterone levels in men. Previously, we demonstrated that combination of dietary modification and regular aerobic exercise increased serum testosterone levels in overweight/obese men. However, the differences in the effects on serum testosterone levels between dietary modification and regular aerobic exercise are unknown. The aim of this study was to compare the effects of dietary modification and regular aerobic exercise on serum testosterone levels in overweight/obese men.

METHODS: Twenty-four overweight/obese men completed 12-week dietary modification class (well balanced 1680 kcal/day diet: diet group) and twenty-seven overweight/obese men completed 12-week regular aerobic exercise intervention (1-3 days/week, 40-60 min/day: exercise group). Before and after the intervention, we measured serum testosterone levels in overweight/obese men.

RESULTS: At baseline, there were no significant differences in all parameters between both groups. Body mass was significantly decreased in both groups (both $P < 0.01$), and the magnitude of weight loss was greater in diet group than exercise group ($-7.8 \pm 2.0\%$ vs. $-2.1 \pm 0.6\%$, $P < 0.01$). While, serum testosterone levels were significantly increased only in exercise group, and we found a significant difference in the percentage change in serum testosterone level (diet group: $-0.3 \pm 8.6\%$, exercise group: $11.6 \pm 3.1\%$, $P < 0.01$). Moreover, in diet group, we found a significant correlation between percentage change in body mass and that in serum testosterone levels ($r = -0.77$, $P < 0.001$), but not in exercise group ($r = -0.16$, n.s.).

CONCLUSIONS: We demonstrated regular aerobic exercise significantly increased serum testosterone levels, while dietary modification did not change serum testosterone levels in overweight/obese men. Moreover, percentage change in serum testosterone levels did not correlate to that in body mass in exercise group. Thus, these results suggest that regular aerobic exercise increases serum testosterone levels independent of the change in body mass in overweight/obese men. These findings may provide a new insight into the role of regular aerobic exercise for prevention and/or treatment of obesity-induced health disorders.

Comparison Of HR And BP Among A Non-exercise Session And Before HIIE And MICE Sessions

Katherine E. Miller, Charles E. Robison, Devon B. Grassi, Jatin P. Ambegaonkar. *George Mason University, Manassas, VA.*
 (No relationships reported)

Understanding changes in cardiovascular post-exercise values requires the accurate measurement of pre-exercise values. Exercise anticipation can elevate heart rate (HR) and blood pressure (BP). However, no study has compared these variables among a non-exercise session and before high intensity interval exercise (HIIE) and moderate intensity continuous exercise (MICE) with equivalent workloads. The development and implementation of a pre-exercise HR and BP measurement protocol that controls for the anticipatory response could provide a more precise understanding of acute HR and BP responses to exercises of different intensities. **PURPOSE:** To compare HR and BP among a non-exercise session and immediately before HIIE and MICE sessions. **METHODS:** Healthy participants ($n = 14$, 21.5 ± 2.1 yrs, 171.0 ± 9.4 cm, 72.6 ± 11.4 kg) reported to the laboratory on four occasions. Session 1 included HR and BP assessment, session 2 consisted of a maximal exercise test, and sessions 3 and 4 consisted of HR and BP assessments before either HIIE or MICE in a random order. Participants were previously informed that HIIE and MICE would be equivalent in total workload. HR and BP were measured using an oscillometric automated device (Omron 10 series, Illinois, USA) after 10 minutes of rest. The average of three readings taken 60 seconds apart was used for all measurements. **RESULTS:** Repeated measures ANOVAs compared HR and BP among sessions ($p < .05$). Systolic blood pressure was not significantly different among baseline (111.6 ± 8.6 mm Hg), HIIE (108.9 ± 7.4 mm Hg) or MICE (111.3 ± 8.0 mm Hg) ($F_{(2,26)} = 1.15$, $p = .33$). Diastolic blood pressure was not significantly different among baseline (74.4 ± 6.8 mm Hg), HIIE (71.7 ± 6.6 mm Hg), or MICE (72.7 ± 4.5 mm Hg) ($F_{(2,26)} = 1.55$, $p = .23$). Mean arterial pressure was not significantly different among baseline (86.8 ± 6.9 mm Hg), HIIE (84.1 ± 6.1 mm Hg) or MICE (85.6 ± 4.9 mm Hg) ($F_{(2,26)} = 1.66$, $p = .21$). HR was not significantly different among (70.6 ± 11.0 bpm), HIIE (68.6 ± 12.5 bpm) or MICE (70.4 ± 12.6) ($F_{(2,26)} = 0.39$, $p = .68$). **CONCLUSION:** This study demonstrates that non-exercise associated HR and BP can be similar to pre-HIIE and pre-MICE HR and BP with equivalent workloads. Study findings indicate that using a protocol similar to ours may account for exercise anticipation before exercise sessions.

Sprint Interval Training and Associated Improvements in VO2max Amongst College Age Women

Leigha Embertson, Sophie Olson, Jenna Thompson, Mark Blegen, 55105, FACSM. *St. Catherine University, St. Paul, MN.*
 (Sponsor: Mark Blegen, FACSM)
 (No relationships reported)

Aerobic exercise has been shown to induce positive physiological outcomes. Research into the effects of high intensity interval training (HIIT) is rapidly growing, with specific interest in sprint interval training (SIT). Current research on SIT emphasizes its applications to young, recreationally active males. **PURPOSE:** The present investigation focuses on SIT in college age, recreationally active females thus addressing the dearth of research in women. **METHODS:** Participants ($n=11$) were randomly assigned into one of three groups: two intervals (2INT), three intervals (3INT), or endurance group (END). All groups cycled three times a week for eight weeks for a total of 24 sessions. 2INT sprinted two 20 second bouts and cycled five

minutes total. 3INT sprinted three 20 second bouts and cycled ten minutes total. END cycled for 20 minutes at 60% of their VO_{2max} . VO_{2max} was measured pre and post intervention. **RESULTS:** While there were no significant differences in VO_{2max} within or between groups (2INT 43.3 ± 1.2 v. $46. \pm 0.9$ ml $kg^{-1}min^{-1}$, 3INT 43.1 ± 5.6 v. 44.6 ± 6.3 ml $kg^{-1}min^{-1}$, END 37.0 ± 6.9 v. 37.4 ± 7.7 ml $kg^{-1}min^{-1}$), it is important to note that the 2INT group improved their VO_{2max} by an average of 8% and the 3INT group by 2.3%. The END group remained unchanged. **CONCLUSIONS:** The findings of this study suggest that women engaging in SIT have the potential to increase their VO_{2max} in a time efficient manner.

Comparison Between Unilateral and Bilateral Plyometric Training on Single and Double Leg Jumping Performance

Gregory C. Bogdanis¹, Olga Kaloheri¹, Athanasios Tsoukos¹, Gerasimos Terzis¹, Panagiotis Veligeas¹, Lee E. Brown, FACSM². ¹National and Kapodistrian University of Athens, Athens, Greece. ²California State University, Fullerton, CA.
 Email: gbogdanis@phed.uoa.gr
 (No relationships reported)

The phenomenon of bilateral deficit in jumping implies that greater muscle power can be developed when performing maximal single leg jumps, compared with two-leg jumps. Thus, it may be hypothesized that training with single leg plyometric exercises would be more effective compared to an equivalent volume of double leg plyometric training. **PURPOSE:** To compare the effects of unilateral and bilateral plyometric training on single and double leg jumping performance. **METHODS:** Fifteen moderately trained subjects (age: 19.6 ± 2.1 yrs, height: 172 ± 9 cm, body mass: 65.6 ± 10.6 kg) were randomly assigned to either a unilateral (U, $n=7$) or a bilateral group (B, $n=8$). Both groups performed maximal effort plyometric leg exercises two times per week for 6 weeks (6 exercises per session, 3 sets of 10 repetitions per exercise), as well as 3 sets of knee extensions and flexions at 70%-90% of their 1 repetition maximum. The U group performed all plyometric and knee flexion/extension exercises with both legs, while the B group performed half the repetitions with each leg, so that the total exercise volume was the same. Jumping performance was assessed by double and single leg countermovement jumps (CMJ) and drop jumps (DJ) from 30 cm, measured using an optical measurement system (Optojump). Reactive strength index (RSI) was calculated from DJ data (jump height and ground contact time). Results were analyzed using a 2 x 2 ANOVA with repeated measures in one factor and Tukey's post-hoc test. **RESULTS:** CMJ with both legs significantly improved equally in the U and B groups by $12.1 \pm 7.2\%$ and $11.0 \pm 5.5\%$ ($p < 0.001$), respectively. However, single-leg CMJ, quantified as the sum of dominant and non-dominant single leg CMJ, only improved in the U group ($19.0 \pm 7.1\%$, $p < 0.001$) and was unchanged in the B group ($3.4 \pm 8.4\%$, $p = 0.80$). Similarly, RSI for single leg only improved in the U group (from 0.95 ± 0.21 to 1.17 ± 0.25 m s^{-1} , $p = 0.002$), but not in the B group. **CONCLUSIONS:** Plyometric training with single leg exercises was more effective in increasing both single and double-leg jumping performance, compared to bilateral training.

An Integrated Perspective on Firefighter Recruit Academies: Examining the Sustainability of Fitness Gains

Stacy L. Gnacinski, Kyle T. Ebersole, David J. Cornell, Barbara B. Meyer. *University of Wisconsin-Milwaukee, Milwaukee, WI.*
 (Sponsor: Terry J. Housh, FACSM)
 Email: gnacins4@uwm.edu
 (No relationships reported)

Research indicates that 16-week firefighter recruit academies yield pre-post program fitness gains. However, timelines of academy training protocols have been questioned, as the majority of fitness gains are observed after the first eight weeks of the program. Further, no research has examined the effect of recruit academies through an integrated lens, with physiological and psychological variables assessed concurrently. **PURPOSE:** To examine the effect of a firefighter recruit academy on measures of fitness and stress-recovery state. **METHODS:** Recruits enrolled in a Midwest region academy program ($N = 15$; 2 females; 29.0 ± 4.6 yrs; 181.7 ± 7.2 cm; 86.8 ± 11.5 kg) completed all measures at three time points throughout the 16-week academy: week 1 (T1), week 8 (T2), week 16 (T3). To assess fitness (i.e., muscular strength, estimated VO_{2max} , body fat percentage [%]), recruits completed handgrip dynamometry, Forestry Step Test, and skinfold measurements. To assess stress-recovery state, recruits completed a 52-item questionnaire on perceptions of stress and recovery (RESTQ-Sport). Repeated measures multivariate analysis of variance (RM MANOVA) tests were conducted to examine the effect of time on fitness (3 levels) and stress-recovery state (2 levels). An alpha of .05 was used to determine statistical significance. **RESULTS:** The RM MANOVA test for the effect of time on fitness was significant ($F_{(2,12)} = 6.438$, $p = .013$, $\lambda = .482$). *Post hoc* pairwise comparisons demonstrated a

significant increase in fitness between T1 and T2 ($p = .005$), and a significant decrease in fitness between T2 and T3 ($p = .020$). In addition, the RM MANOVA test for the effect of time on stress-recovery state was not significant ($F_{2,12} = 1.884, p = .194, \lambda = .761$). **CONCLUSIONS:** Results of the study indicate that current firefighter recruit academies may not generate sustainable fitness gains from onset to graduation. This conclusion is supported by the non-significant stress-recovery state results, as previous research has established a dose-response relationship between acute training load and stress-recovery state. Thus, the periodization of firefighter recruit academies may need careful examination to ensure a progressive physiological and psychological training stimulus is applied throughout the program to achieve sustainable outcomes.

Relationship between Training Volume and Dietary Status in Triathletes A Preliminary Study

Barbara S. McClanahan¹, Christopher Vukadinovich², Michelle Stockton¹, Kenneth Ward¹, Deborah Slawson³. ¹University of Memphis, Memphis, TN. ²St. Jude Children's Research Hospital, Memphis, TN. ³East Tennessee State University, Johnson City, TN. (Sponsor: Lawrence Weiss, FACSM)

Email: bmcclnln@memphis.edu

(No relationships reported)

PURPOSE: Optimal sports training, especially for long endurance athletes, is dependent on favorable genetic, environmental and behavioral profiles. Dietary intake is central to and interacts with each of these domains. Therefore, the purpose of this preliminary study was to explore potential relationships between dietary intake and training volume in triathletes over a competitive season. **METHODS:** Participants were 18 male (36.6 ± 10.7 years old) and 19 female triathletes (31.8 ± 6.8 years old). Body fat percent, determined through dual-energy x-ray absorptiometry, for male and female triathletes was $12.5\% (\pm 4.5\%)$ and $21.3\% (\pm 5.0\%)$ respectively. Training volume was determined by exercise duration and intensity over 24 weeks. Nutrient intake was assessed through a seven-day dietary recall. **RESULTS:** Average daily energy intake for males was $2776 (\pm 774)$ kcals and $1987 (\pm 386)$ kcals for females. Relative contribution to total energy intake of fat was 25% for males and 28% for females, protein was 19% for males and 16% for females, and carbohydrates was 52% for males and 53% for females. For males, bivariate correlations revealed that total kcals ($r = 0.81$), protein ($r = 0.86$), and carbohydrates ($r = 0.72$) were significantly associated with total training volume. For females, only protein had a significant association ($r = 0.62$). Preliminary analyses using multiple linear regression indicated that for males the independent variables (kcals, protein, carbohydrates, fat) explained 79% of the variance in total training volume ($p = .045$) while controlling for age. However, none of the predictors were significant at a univariate level. The multiple regression for females indicated that the independent variables (kcals, protein, carbohydrates, fat) explained 82% of the variance in total training volume ($p = .015$) while controlling for age. Protein was the only significant predictor of total training volume for females ($\beta = .860; t = 3.18; p = 0.02$). **CONCLUSIONS:** Given the high training volumes associated with triathlon training it is important to consider the potential relationships among energy and nutrient intake and training volume. Further studies are required to better understand the potential influence energy and nutrient intake may have on triathlete performance.

3697 Board #144 June 3 9:30 AM - 11:00 AM

Relationship Between Fatigue Index And Obla Before And After Muscular Endurance Training

Daniel Blackwood, John W. Farrell, III, David J. Lantis, Gregory S. Cantrell, Debra A. Bemben, FACSM, Rebecca D. Larson.

University of Oklahoma, Norman, OK. (Sponsor: Dr. Debra A. Bemben, FACSM)

Email: dblackwood@ou.edu

(No relationships reported)

The Thorstenson test has been well established as a valid assessment of fatigability by providing a Fatigue Index (FI) of the knee extensors. The Onset of Blood Lactate Accumulation (OBLA) has also been shown to have a significant influence on the development of fatigue during high intensity exercise bouts. Improvements in OBLA have been seen during muscular endurance resistance (MER) training resulting in enhanced exercise performance. However, the relationship between OBLA and FI remains unclear. **PURPOSE:** The purpose of the current study was to investigate the relationship between OBLA and FI as well as examine if improvements in FI could be achieved through MER training. **METHODS:** 17 endurance trained males (age: 23.4 ± 4.92 years and BMI: 23.5 ± 3.11) were recruited to participate in a 6 week study. Subjects were randomly assigned to either an experimental (EX) or control (CON) group: 9 EX and 8 CON. Both groups continued their current aerobic training for the duration of the study. Baseline measures included OBLA, using a cycle ergometer, 1 repetition maximum (1RM) for: leg press (LP), leg curl (LC), and leg extension (LE). The Thorstenson protocol was also performed using a dynamometer. In addition, the EX group performed supervised MER training (12 to 15 repetitions for

4 sets for LP, LC, and LE) for four weeks. T-test were used to determine if between group differences existed using delta scores (post-pre). Pearson's correlation was used to assess the relationship between OBLA and FI. **RESULTS:** No significant group differences were observed in all baseline measurements ($p > 0.05$). There were no significant group differences for OBLA (mmol/L) (EX: -7.24 ± 12.09 vs. CON: 3.54 ± 9.21) and FI (%) (EX: -0.06 ± 17.62 vs. CON: 1.68 ± 10.97) ($p > 0.05$). Pearson's correlation revealed no significant relationship ($p > 0.05, r = < 0.01$) exists between FI and OBLA. **CONCLUSIONS:** Four weeks of MER training was unable to improve both OBLA and FI. It was also observed that no significant relationship existed between OBLA and FI. It can be speculated that the physiological stress associated with the Thorstenson protocol is only sufficient enough to require energy contributed from the phosphocreatine system and not the glycolytic system. Thus improvements in OBLA will have no effect on FI as it was assessed in this study.

Effect of Ankle Exercise on Ankle Isokinetic Strength: A Meta-Analysis

Han-Joon Lee¹, Minsoo Kang, FACSM², Hyung-Kyu Kim¹, Kyun-Sang Yoon¹, Sung-Jin Hong¹, Hee-Bok Song¹. ¹University of Ulsan, Ulsan, Korea, Republic of. ²Middle Tennessee State University, Murfreesboro, TN. (Sponsor: Minsoo, Kang, FACSM)

Email: hanjoon@ulsan.ac.kr

(No relationships reported)

Ankle injury is one of the most common injuries that occur during sports activities in Korea. Ankle strengthening exercise (ASE) is often used in the rehabilitation of ankle injuries; however, the degree of ASE effect and the effect of moderating variables are not known. **PURPOSE:** The purpose of this study was using meta-analysis to determine the effectiveness of ASE on ankle isokinetic strength. **METHODS:** Articles were searched from 1998 to 2015 using online database: RISS, NDSL and NAL (National Assembly Library in Korea). Search terms included phrases such as "ankle", "exercise", and "ankle strength", "ankle rehabilitation", "ankle isokinetic". Comprehensive Meta-Analysis version 2 software was used to calculate the weighted mean effect sizes (ES) and 95% CI and to conduct moderator analyses. ES calculations were based on a comparison of change scores from control and intervention groups using a random effects model. Cochran's Q statistic and I² were used to assess heterogeneity of ESs. Moderator variables included participants' sex, age, type of exercise, intervention duration, and ankle action. **RESULTS:** Overall, 111 ESs were calculated from 29 studies. The results showed a large and positive weighted mean ES of 0.78 (95% CI = 0.64, 0.92). The ESs were heterogeneous, $Q = 309.62, df = 110, p < .001, I^2 = 64.47$, which supported a further examination of moderator variables. Intervention duration (Qbetween = 8.68, $df = 2, p = .013$) and sex (Qbetween = 10.30, $df = 2, p = .006$) influenced the overall ES. Duration of 12 weeks (ES = 1.36) had a higher ES than other durations (.60 and .78 for 8 weeks and 6 weeks, respectively). There were larger effects on studies with only females (1.18) than studies with only males (0.76) and both males and females combined (.46). Age, type of exercise, and ankle action did not influence the overall ES. **CONCLUSIONS:** ASE was determined to be an effective training method to enhance ankle strength with a greater effect from studies with longer interventions and females.

3699 Board #146 June 3 9:30 AM - 11:00 AM

Impact of a Firefighter Recruit Training Academy on Movement Quality & Balance Ability

Kyle T. Ebersole, David J. Cornell, Stacy L. Gnacinski.

University of Wisconsin-Milwaukee, Milwaukee, WI. (Sponsor: Terry J Housh, FACSM)

Email: ebersole@uwm.edu

(No relationships reported)

Approximately 55% of the annual injuries to firefighters are classified as sprains and strains and may be related to movement quality and/or balance ability. The Functional Movement Screen™ (FMS™) and Y-Balance Test (YBT) have previously been associated with musculoskeletal injury risk among athletic populations. Although research has reported fitness-related changes in firefighter recruits during a 16-week training academy, the responses of the FMS™ and YBT are unclear. Whether any changes in movement quality and balance are retained after a 22 week, post-academy probation period are unknown. **PURPOSE:** To determine the changes in FMS™ and YBT during a 16-week recruit academy and subsequent 22-week active-duty probationary period. **METHODS:** Twenty-seven male firefighter recruits volunteered to participate (29.3 ± 4.1 yrs, 179.8 ± 4.6 cm, 87.2 ± 9.7 kg). FMS™ and YBT measures were collected at start and end of the 16-week recruit training program and again at week 38. The FMS™ was scored on a 0–21 scale. The YBT scores for each limb were formed by normalizing the reach distances to limb length, summing these distances in each direction, and dividing by three. The scores for right and left limbs were then averaged to create a composite score (%). Two separate (FMS™ and YBT) repeated measures ANOVAs and follow-up pairwise analyses were used to identify

significant differences across weeks. An alpha of $p < 0.05$ determined statistical significance for all analyses. **RESULTS:** Significant main effects were identified for both FMS™ ($F_{2,55} = 44.9, p < 0.001$) and YBT ($F_{2,55} = 276.9, p < 0.001$). Pairwise analyses indicated that FMS™ significantly increased from week 1 to 16 ($p < 0.001$; 11.93 ± 1.8 vs. 13.7 ± 1.5) and from week 16 to 38 ($p = 0.002$; 13.7 ± 1.5 vs. 14.4 ± 1.3). There was not a significant change in YBT from week 1 to 16 ($p = 0.539$; $97.8\% \pm 5.7\%$ vs. $97.1\% \pm 3.8\%$), but YBT did significantly decrease from week 16 to 38 ($p < 0.001$; $97.1\% \pm 3.8\%$ vs. $91.9\% \pm 3.7\%$). **CONCLUSIONS:** Firefighter recruits exhibited better movement quality, but decreased balance after 38 weeks. The work of a firefighter may prompt a loss in balance ability, perhaps serving as a key risk factor slips, trips, and falls. Future research should examine longitudinal changes in other measures of fitness to elucidate the underlying mechanism(s) in decreased balance ability.

Effects Of Rock Climbing Exercise On Physical Fitness Among College Students: A Meta-Analysis

Lun Li¹, An Ru², Ting Liao³, Shisi Zou¹, XiaoHong Niu¹, Yong Tai Wang, FACSM⁴. ¹China University of Geosciences, Wuhan, China. ²Shandong Sport University, Jinan, China. ³Wuhan Sport University, Wuhan, China. ⁴The University of Texas at Tyler, Tyler, TX. (Sponsor: Yong Tai Wang, FACSM)
 Email: lilun1020@163.com
 (No relationships reported)

Nowadays, the sedentary lifestyle and lack of interest in participating in physical activity among the college students in China result in the declining their health and physical fitness. Rock climbing is a newly growing physical exercise which provides excitations and challenges and is attracting more college students to participate in this physical exercise in China. **PURPOSE:** The purpose of this meta-analysis was to determine the effects of rock climbing on the physical fitness among college students. **METHODS:** Conducting a thorough electronic search and selection, nine studies were included in this meta-analysis, and the rock climbing intervention periods ranged from 4 to 24 weeks (3-6 times/week and 60-120 minutes each time). Ten variables included in this meta-analysis were: Body fat percentage, VO_2 max, Heart rate, Hand grip strength, Lower limb pedaling power, Vertical jump, Push-ups, Pull-ups, Sit-ups and Sit-and-reach. The effect sizes (ES) and forest plots of these ten variables were calculated ($p < .05$) and generated, respectively.

RESULTS: Eight variables (Hand grip strength, ES = .81; Lower limb pedaling power, ES = .36; Vertical jump, ES = .73; Push-ups, ES = .84; Pull-ups, ES = 1.09; Sit-ups, ES = 1.16; Sit-and-reach, ES = 1.15; and VO_2 max, ES = .76) out of ten were significantly improved after rock climbing intervention, while ES values of Heart rate and Body fat percentage did not show significant improvement after the intervention.

CONCLUSIONS: Rock climbing as one of fast-growing exercises has some positive effects on the physical fitness among college students, and might be more effective if the college students engage in rock climbing in a longer term.

3701 Board #148 June 3 9:30 AM - 11:00 AM
Short and Long Term Effects of a Simulated Mixed Martial Arts Competition

Montassar Tabben¹, Nihel Ghoul², Jeremy B Coquart³, Claire Tourny³, Karim Chamari⁴. ¹ASPREV, ASPETAR, Orthopedic and Sports Medicine Hospital, Doha, Qatar. ²Laboratoire Mobilité, vieillissement et exercice (MOVE) - EA 6314, Poitiers, France. ³CETAPS, University of Rouen, Rouen, France. ⁴Athlete Health and Performance Research Center, ASPETAR, Orthopedic and Sports Medicine Hospital, Doha, Qatar.
 (No relationships reported)

PURPOSE: Investigate the short (immediately and 30 min post-competition) and the long-term effects (24h post-competition) of passive rest on physical parameters, metabolic, hormonal and inflammatory responses following Mixed Martial Arts (MMA) competition.

METHODS: Twelve male mixed martial artists participated in three rounds of 3 min of MMA competition separated by 1 min of passive rest. Passive recovery was monitored for 24h post-competition. Blood samples, physical measures, arterial blood pressure, perceptual measures, lactate and heart rate (HR) were measured pre-competition, immediately, 30 min and 24h post-competition. During the period rest between rounds, perceptual measures, lactate and HR were recorded.

RESULTS: Blood lactate, HR were affected by the moment ($P < 0.001$), with lower values pre and 24h post-competition compared to post-1, 2 and 3 rounds. Systolic blood pressure changed across the moments with higher values at post-competition compared to 30 min and 24h recoveries. White blood cells count was affected by moments with higher values at post-competition compared to pre-competition, 30 min and 24h post-competition ($P < 0.001$) and higher values at 30 min compared to 24h recovery. Hemoglobin was also affected with higher values post-competition compared to pre, 30 min and 24h post-competition ($P < 0.001$) and higher values at pre compared

to 24h post-competition. Uric acid was affected across time with higher values at 30 min recovery compared to all other moments ($P < 0.001$). Cholesterol, glycemia, proteids, cortisol and testosterone were also affected by moment with higher values at post-competition compared to all other moments. No change in creatine kinase was detected but lactate dehydrogenase changed with lower values at pre compared to post-competition, 30 min and 24h recovery. CounterMovement Jump and Hand Grip were affected by the moment with lower values at post-competition compared to pre and 24h post-competition. Rating of Perceived Exertion was affected by the moment, with lower values at post-1 compared to post-2 and post-3 and lower values at post-2 compared to post-3.

CONCLUSIONS: Long-term recovery appears to promote better restoration of physiological changes (alterations), physical performance and psychometric measures than short-term rest.

3702 Board #149 June 3 9:30 AM - 11:00 AM
Effect of Plyometric Training on Explosive Strength And Sprint on Team Sports: A Meta-analysis

Denis Alfaro-Jiménez, Alejandro Salicetti-Fonseca. *University of Costa Rica, San José, Costa Rica.*
 Email: denis.alfarojimenez@ucr.ac.cr
 (No relationships reported)

Plyometric training (PT) has shown to improve vertical jump height in athletes. However, little is known about its effectiveness for improving strength and speed performance in team sports. **PURPOSE:** To determine the effect of PT on explosive strength and sprint performance in team sports. **METHODS:** The search for information was conducted in the following electronic databases: Ovid, SportDiscus, Medline, Academic Search, Pubmed, ProQuest, Science Direct and Springer Link. Studies employing a PT intervention and containing data necessary to calculate effect sizes (ES) were included in the analysis. Hedge's standardized mean difference effect size (ES) was calculated and ESs pooled using random-effects models. Non-overlapping 95% confidence intervals ($CI_{95\%}$) were considered statistically significant. Heterogeneity was assessed using Q and I^2 . **RESULTS:** A total of 31 studies with total of 50 ESs met the inclusion criteria for explosive strength and 18 studies with a total of 43 ESs for sprint performance. PT improved explosive strength (ES = 0.98, $CI_{95\%} = 0.77, 1.20, Q = 174.51, I^2 = 71.95$) in team sports and sprint performance (ES = -0.30, $CI_{95\%} = -0.59, -0.00, Q = 237.60, I^2 = 82.32$) only in soccer. The improvement occurred regardless of the training season and protocol used. Analysis of moderator variables demonstrated that the strategies to maximize the probability of obtaining significant ($p < 0.05$) improvements in explosive strength included a training volume > 9 weeks, at least 27 sessions, 3 to 6 exercises, 20 to 32 repetitions per exercise, 4 to 6 series, 4-min rest between sets, 50 to 150 vertical jumps, and a session duration of approximately 30-min. To improve sprint performance in soccer, moderator variables included training 8 to 10 weeks, 2 times a week, 4 to 6 exercises, 2 to 4 series, 5 to 10 repetitions, 1-min rest between sets, 50 to 200 vertical jumps per session, and a session duration of about 40-min. **CONCLUSIONS:** PT enhanced explosive strength in team sports and sprint performance in soccer. Post meta-analytical studies on a variety of sports are warranted to confirm the validity of the results of the present study. The findings of this meta-analysis suggest that PT should be considered by coaches to optimize explosive strength and speed performance in team sports athletes.

A Comparison of Resisted and Assisted Sprint Training in Collegiate Sprinters

Jeramie Murray¹, Chad Harris, FACSM², Kent J. Adams, FACSM³, Joseph Berning, FACSM⁴, Mark DeBeliso, FACSM⁵. ¹Utah State University, Logan, UT. ²Metropolitan State University of Denver, Denver, CO. ³California State University Monterey Bay, Seaside, CA. ⁴New Mexico State University, Las Cruces, NM. ⁵Southern Utah University, Cedar City, UT.
 (Sponsor: Mark DeBeliso, FACSM)
 (No relationships reported)

Sprint time (ST) is the product of stride length (SL) and stride frequency (SF). Increases in either of these variables results in speed improvement. **PURPOSE:** To compare resisted (RST) and assisted sprint training (AST) on sprint performance. **METHODS:** Twenty (10 male, 10 female) collegiate sprinters and hurdlers were randomly divided into two training groups: RST (age: 21.8 ± 1.8 yrs, Ht: 1.73 ± 0.10 m, BM: 69.5 ± 12.8 kg) and AST (age: 22.2 ± 2.4 yrs, Ht: 1.76 ± 0.10 m, BM: 69.1 ± 9.9 kg). Each group trained 3 day/wk for 6 weeks. The RST group used a combination of weighted sled pulls, uphill sprinting and depth jumps. The AST group combined downhill running, towing, sprint ladders and single leg bounds. Prior to and following the training interventions SL and ST (10 meter sprint time) were recorded at sprint distances of 30m, 60m, and 120m during the last 10 meters of each sprint distance. Pre-post training ST and SL were compared within training groups at each sprint distance using paired t-tests. Additionally, a gain score was calculated by taking the difference between the post and pre test scores. The gain scores for SL and ST were

compared between training groups via independent t-tests at each sprint distance. RESULTS: For the RST 30m, ST (1.18±0.08s vs 1.14±0.08s, p<0.01) and SL (2.06±0.08m vs 2.09±1.14m, p<0.01) were significantly improved. For the AST, 30m ST (1.19±0.08s vs. 1.18±0.08s, p<0.01) and SL (2.10±0.13m vs. 2.11±0.13, p=0.04) were significantly improved. No improvements in ST or SL were detected for either the RST or AST groups at the 60m sprint distance. For the RST 120m, ST (1.13±0.07s vs. 1.12±0.08s, p<0.01) was significantly improved. For the AST 120m, ST (1.12±0.07s vs. 1.11±0.07s, p<0.01) and SL (2.30±0.08 vs. 2.33±0.08, p<0.01) were significantly improved. At the 30M interval, the RST demonstrated significant improvements in SL and ST as compared to the AST (p<0.01). However, at the 120M interval, the AST demonstrated a significant improvement in SL as compared to the RST (p<0.01). CONCLUSION: Within the parameters of this study, RST and AST methods have proven effective at improving sprint performance. It appears that RST protocols may be of greatest benefit for improving sprint performance at shorter distances, while AST protocols may be of greater benefit at longer sprinting distances.

Head Accelerations Associated with Six Standard Judo Throws and Break Falls

Tyler K. Florentin, Casey Snodgrass, Shawn O. Henry. *Pacific University, Forest Grove, OR.*
 Email: flor0760@pacificu.edu
 (No relationships reported)

The contact sport of judo involves throwing an opponent in a variety of ways, with potential risk of concussive head impacts. When being thrown, a judo practitioner executes a break fall, theoretically protecting the head from injury. However, little research has directly measured head accelerations of a person executing a break fall in response to various throws in judo. PURPOSE: Quantify and compare head accelerations associated with six standard judo throws and corresponding break falls. METHODS: In random and repeated design, 14 judo martial artists (13 male, 1 female; age = 28 ± 9 yrs; stature = 177 ± 6.7 cm; mass = 80.3 ± 9.4 kg; rank = brown or black belt) performed five sets of six standard judo throws & corresponding break falls. The six throws were layback throw (tomoe-nage), hand throw (tai-otoshi), leg sweep (harai-tsuri-komi-ashi), shoulder throw (seoi-nage), forward leg sweep (deashi-braai), and thigh throw (uchi-mata). The participant being thrown wore a headband-mounted tri-axial accelerometer, measuring linear (g) and rotational accelerations (krad·s⁻²) of the head when performing a break fall corresponding with one of the six throws. Minimum threshold for registering acceleration was 16 g. RESULTS: Repeated measures one-way ANOVA and post hoc compared magnitude and frequency of accelerations of the head when performing a break fall corresponding with each of the six throws. When utilizing the linear acceleration criterion >80 g for risk of concussion, as suggested by some experts, none of the six judo throw/break fall combinations resulted in a significant head impact (incidence rate = 0%). However, when comparing all registered accelerations above 16 g threshold, hand throw (1 impact, 1.4 % incidence rate, 27.94 g, 2.8 krad·s⁻²), forward leg sweep (1 impact, 1.4 % incidence rate, 20.58 g, 1.59 krad·s⁻²), and thigh throw (7 impacts, 10% incidence rate, 28.16 ± 4.92 g, 3.94 ± 1.83 krad·s⁻²) had higher frequency of occurrence and magnitude of acceleration than other throws (p<0.01). Thigh throw had highest incidence rate of any throw (p<0.01). CONCLUSION: The judo thigh throw (and break fall) had the highest incidence of sub-concussive head accelerations in the category of 20-40 g. However, none of the judo throws and associated break falls resulted in any impact considered high risk for concussion.

3705 Board #152 June 3 9:30 AM - 11:00 AM
Impact of Percentage-based Versus Autoregulated-based Load Prescription on Maximal Strength

Daniel M. Cooke¹, Eric R. Helms², Ryan K. Byrnes¹, Michael H. Haischer¹, Trevor K. Johnson¹, Jose C. Velazquez¹, Joseph P. Carzoli¹, John B. Cronin², Adam G. Storey², Michael C. Zourdos¹. ¹Florida Atlantic University, Boca Raton, FL. ²Auckland University of Technology, Auckland, New Zealand. (Sponsor: Michael Whitehurst, FACSM)
 Email: dcooke2014@fau.edu
 (No relationships reported)

Researchers and practitioners use the resistance training-specific rating of perceived exertion (RPE) scale for individualization of training load prescription. However, an intervention to compare traditional percentage-based load prescription versus RPE-based loading for strength adaptations has not been conducted. PURPOSE: To compare changes in one-repetition maximum (1RM) strength of the back squat and bench press between percentage-based training (PBT) and autoregulated-based training (ABT) via RPE. METHODS: Eleven males (age: 23±4 yrs, body mass: 77.4±7.7 kg, body fat: 9.5±3.8%) with at least two yrs. of training experience and a minimum 1RM of 1.5 and 1.25x bodyweight on the squat and bench press respectively, were assigned to one of two groups: PBT (n=6) or ABT (n=5) for 8 weeks. Forty eight hours following pre-testing 1RM both groups performed the squat and bench press 3x/

wk. on non-consecutive days (i.e. Mon., Wed., Fri.) using the same number of sets and repetitions following an undulating resistance training program, which linearly increased load and decreased repetitions throughout. Weeks 1-3 consisted of 8, 6, and 4 repetitions on Mon., Wed., and Fri., while weeks 4-5 consisted of 7, 5, and 3 repetitions during the week, with 6, 4, and 2 repetitions being performed during weeks 6-7. Week 8 served as a taper with 4 and 3 repetition days on Mon. and Wed. and post-testing on Fri. Load increased during each week in PBT from 65, 70, and 75% in week 1 to 82.5-92.5% of 1RM in week 7. In ABT there was no prescribed load but subjects were instructed to select a load, in which the set ended with a 5-7RPE in week 1 and progressing to an 8-10RPE in week 7. A 2x2 repeated measures ANOVA was used with significance set at p≤0.05. RESULTS: There was a time effect (p<0.01) for 1RM squat (141.00±22.49 to 153.75±20.40kg; +9.46%), bench press (109.08±15.89 to 116.67±14.61kg; +7.22%), and total strength-TS (250.08±32.30 to 270.42±29.62kg; +8.39%) in PBT, and for 1RM squat (152.20±21.65 to 171.30±24.97kg; +12.52%), bench press (123.00±11.31 to 133.70±14.82kg; +8.58%), and TS (275.20±30.24kg to 305.00±37.61kg; +10.71%) in ABT. However, no significant group differences existed for squat (p=0.31), bench (p=0.11) or TS (p=0.16). CONCLUSION: Our findings indicate that both PBT and ABT are equally effective at increasing maximal strength.

3706 Board #153 June 3 9:30 AM - 11:00 AM
Greater Ankle Strength and Anaerobic Capacity in Female Marines Who Completed Military Occupational Specialty School

Erin R. Pletcher¹, Karen Keenan¹, Mita Lovalekar¹, Bradley Nindl, FACSM¹, Lawrence C. Coleman², Katelyn Allison¹. ¹University of Pittsburgh, Pittsburgh, PA. ²United States Marine Corps, Quantico, VA. (Sponsor: Bradley C. Nindl, FACSM)
 (No relationships reported)

Female Marines can now serve in all military occupational specialty (MOS). A cohort of female Marines participated in ground combat MOS schools as part of the Ground Combat Element Integrated Task Force (GCE ITF), which studied the integration of women into combat arms. It is important to identify characteristics of female Marines who successfully graduated from ground combat MOS schools.

PURPOSE: To explore physical and physiological differences between female Marines who did or did not successfully complete MOS school. METHODS: Female GCE ITF Marines (N=62, 22±3yrs, 163±6cm, 63±7kg) underwent the following assessments prior to ground combat MOS school: anthropometric, strength (average peak torque % body weight) with an isokinetic dynamometer (knee, shoulder, trunk) or hand-held dynamometer (ankle), maximal oxygen uptake (VO₂)/ lactate threshold (LT) during an incremental ramped protocol to exhaustion, and anaerobic power (AP)/capacity (AC) during a 30-second cycling protocol. Subjects were classified as graduated (N=45) or did not graduate MOS school, due to failed fitness testing or injury (N=16). Statistical significance was set a priori at alpha of 0.05. Between group differences were assessed with an independent t-test or Mann Whitney U test, as appropriate.

RESULTS: : Despite no significant anthropometric differences between groups, significant differences were found in right/left ankle evertor strength, right ankle invertor strength, AC, VO₂ max and VO₂ at LT (all p<0.05 - Table 1). CONCLUSIONS: Higher ankle strength and anaerobic capacity were observed in female ground combat MOS school graduates. These results may help female Marines optimize physical readiness for ground combat.

Table 1. Strength and physiology comparison of female Marines who did and did not graduate from MOS school

Effects Of Speed- And Circuit-based High-intensity Interval Training Excess Post-exercise Oxygen Consumption
 Jeffrey M. Janot, Lindey Schleppebach, Andreas Ezer, Sarah Gronemus, Katelyn Widenski, Saori Braun. *University of Wisconsin-Eau Claire, Eau Claire, WI.* (Sponsor: Mark Blegen, FACSM)
 (No relationships reported)

In the United States, there remains interest in developing efficient, effective ways for individuals to increase energy expenditure for weight management. Research has shown that high-intensity exercise elicits a higher excess post-exercise oxygen consumption (EPOC) throughout the day compared to steady-state exercise. Currently, there is no single research study that examines the differences in EPOC resulting from high-intensity interval training (HIIT) modalities. **PURPOSE:** The purpose of this study is to review the impact of circuit training (CT) and speed interval training (SIT) on EPOC in individuals who regularly exercise or are sedentary. **METHODS:** Twenty-six participants were recruited and divided into active and sedentary groups according to self-reported exercise participation status. Oxygen consumption (VO_2) was measured during and after two HIIT sessions and was used to estimate caloric expenditure. Mean VO_2 and caloric expenditure responses during and after exercise were then compared across modality and activity status using a 2-way RM ANOVA. **RESULTS:** There was no significant difference ($p > .05$) in caloric expenditure during exercise between active (83.52 ± 26.1) and sedentary (83.84 ± 31.9) individuals. There was also no significant difference ($p > .05$) in EPOC between sedentary (67.43 ± 29.6) and active (69.1 ± 32.8) individuals or between modalities for both groups (Active: 73.49 ± 21.2 SIT vs 64.68 ± 44.4 CT; Sedentary: 67.52 ± 31.6 SIT vs 67.33 ± 27.5 CT). However, there was a significantly higher ($p < .05$) caloric expenditure during exercise between modalities in both groups (Active: 98.79 ± 25.6 SIT vs 68.25 ± 26.5 CT; Sedentary: 89.57 ± 33.8 SIT vs 78.1 ± 30.1 CT). **CONCLUSION:** Regarding maximizing EPOC, individuals can choose either method of HIIT since both had similar effects on overall energy expenditure following exercise. However, it is recommended that individuals engage in SIT routines versus CT if the goal is to maximize overall caloric expenditure.

The Effect Of Morning Or Evening Exercise On Cardiovascular Fitness And Body Weight
 James D. LeCheminant, FACSM, Jessica Davies, Alyssa Evans, Kaylie Carbine, Michael J. Larson. *Brigham Young University, Provo, UT.*
 (No relationships reported)

PURPOSE: To compare the effect of 8 weeks of morning exercise or evening exercise on cardiovascular fitness and body composition in healthy women. **METHODS:** Fifty-five participants were randomized to either a morning exercise group (AM) (25.3 ± 4.1 yrs; 25.2 ± 4.7 kg/m²; 37.9 ± 7.6 %BF) or an evening exercise group (PM) (25.4 ± 6.7 yrs; 23.5 ± 3.9 kg/m²; 34.1 ± 6.1 %BF). The AM group completed exercise between 6:30-9:30am and the PM group between 6:30-9:30pm, both for 4 days per week (3 days supervised), 45 minutes per session, and for 8 weeks. All participants followed an exercise program of moderate-intensity treadmill walking (40-59% heart rate reserve [HRR]) and progressed to include vigorous-intensity exercise (60-89% HRR). Cardiovascular fitness was determined using a maximal treadmill protocol and indirect calorimetry. Body weight/composition was determined using a digital scale and dual-energy x-ray absorptiometry (DXA). **RESULTS:** Eighty-two percent of participants completed the study; 21 (78%) from the AM group and 25 (86%) from the PM group, with 94.75% of the prescribed exercise sessions completed. Using intent-to-treat analysis, there was not a group*period interaction for VO_2 peak or time-to-completion during the treadmill test ($ps > .05$); however, with groups combined, time-to-completion during the fitness test significantly improved ($F = 6.66$; $p = 0.013$). For completers in the AM group, 76% gained weight while 36% gained weight in the PM group. For completers, body weight increased by 0.79 ± 1.16 kg in the AM group ($F = 5.05$; $p = 0.0361$) and decreased by 0.21 ± 1.46 kg in the PM group. Intent-to-treat analysis showed a significant group*period interaction ($F = 5.12$; $p = 0.029$). This trend persisted with control of baseline body weight ($F = 5.02$; $p = 0.0301$). However, there was not a significant group*period interaction for total body fat (g) or fat-free mass (g) ($ps > 0.05$). **CONCLUSIONS:** Eight weeks of exercise may improve exercise performance but does not appear to be a function of time of day of exercise. However, these results suggest the possibility that evening exercise may be slightly superior for body weight maintenance. As these differences are small and body composition did not differ between groups, caution should be used when interpreting these data; however, additional research may be warranted.

Improvements In Recruit Fitness During A 6-week Firefighter Training Academy
 Kathryn Rougeau¹, Annmarie Chizewski¹, Tina A. Greenlee², Daniel R. Greene¹, Denise L. Smith, FACSM³, Steven J. Petruzzello, FACSM¹. ¹University of Illinois at Urbana-Champaign, Urbana, IL. ²Center for the Intrepid, Fort Sam Houston, TX. ³Skidmore College, Saratoga Springs, NY.
 (Sponsor: Steven J. Petruzzello, FACSM)
 Email: kmrougeau@gmail.com
 (No relationships reported)

Firefighting is a unique and dangerous career in that, unlike some sports and careers that primarily focus on one training goal, firefighters (FFs) must train both aerobic and anaerobic systems. The leading cause for death of on-duty FFs is sudden cardiac events. Emphasizing physical training early in a firefighters career (academy training) has the potential to impact fitness and perceptions of the importance of fitness, and hence to decrease the risk of sudden cardiac events. **PURPOSE:** Examine physical fitness parameters, assessed during the first and last week of a 6-wk firefighter (FF) training academy, in male recruit FFs from 2004 through 2016 to establish the effectiveness of the training regimen employed by the Illinois Fire Service Institute (IFSI). **METHODS:** Participants were male FF recruits ($N = 383$; 26.2 ± 4.2 yrs, $M \pm SD$) from the IFSI who completed baseline fitness measures including measures of weight, estimated $\text{VO}_{2\text{max}}$ (1.5-mi run), muscular endurance (60-s sit-ups, 60-s push-ups, bench press), and flexibility (sit and reach). Following the 6-wk fire academy, which included daily physical training, recruit FFs repeated the fitness test battery. **RESULTS:** Results indicated significant improvements ($M_{\text{diff}} \pm SE$; all $P_s < 0.001$) for weight (1.12 ± 0.14 kg, Cohen's $d = 0.08$), 1.5-mile run (0.92 ± 0.04 min, $d = 0.57$), 60-s sit-ups (5.11 ± 0.25 reps, $d = 0.60$), 60-s push-ups (13.21 ± 0.38 reps, $d = 1.08$), bench press [i.e., 38.6 kg; 2.56 ± 0.26 reps, $d = 0.23$], and flexibility (2.15 ± 0.19 cm, $d = 0.28$). **CONCLUSIONS:** Following a 6-wk training academy, including daily physical training, recruit FFs made significant improvements in weight, BMI, estimated $\text{VO}_{2\text{max}}$, three measures of muscular endurance, and flexibility. Since the majority of on-duty deaths can be attributed to stress or overexertion-related cardiac events, it is important to recognize the importance of a varied fitness regimen for FFs' health as well as performance. All areas of fitness need to be examined with training modalities and performance goals that are consistent with the physical demands of firefighting.

The Effect of Time of Day of Training on Health and Fitness Outcomes in Men
 Sarah L. Herrick, Stephen J. Ives, Chelsea Norton, Nathaniel Robinson, Daniela Escudero, Jake Robinson, Kayla Rose, Olivia Miniucci, Gabe O'Brien, Kathryn Curran, Maia Paul, Caitlin Sheridan, Paul J. Arciero, FACSM. *Skidmore College, Saratoga Springs, NY.* (Sponsor: Paul J. Arciero, FACSM)
 Email: sherrick@skidmore.edu
 (No relationships reported)

As subjective evidence continues to suggest a link between time of day (TOD) of exercise training and potential health and fitness outcomes, it is essential to explore this prospective influence in controlled comprehensive studies. **PURPOSE:** To determine the effect of TOD on mediating training-induced changes in exercise performance, cardio-metabolic health, and body composition in active normal weight men. **METHODS:** 26 healthy active males ($\text{BMI} = 26 \pm 3$ kg/m²; 44 ± 8 yrs) were recruited for this study and randomized to either exercise training in morning (AM) or evening (PM) for 12 weeks. Following current ACSM guidelines, a multimodal training paradigm was used (Resistance, Interval, Stretching, and Endurance, RISE). Baseline exercise performance was assessed via abdominal, upper and lower body muscular strength (situps, pushups, 1 RM bench and leg presses), power (jump squats and bench throws), aerobic power (5km cycling time trial), flexibility (sit and reach), and balance (stork stand), cardiovascular health (blood pressure, and augmentation index (AIx)), body composition (iDEXA: Fat free mass, fat mass, abdominal/visceral fat, %body fat), hunger/satiety ratings (visual analog scales), and cardio-metabolic profile (energy expenditure, fasting lipids, glucose, insulin). **RESULTS:** At baseline, no differences existed between groups in any variable. Training resulted in significant ($p < 0.05$) improvements in exercise performance, cardio-metabolic health, and body composition. Furthermore, there were significant interactions ($p < 0.05$) of TOD x training for fasting glucose (1.83 ± 2.05 v. 1.75 ± 1.48 Amg/dL), LDL-C (6.50 ± 5.78 v. -3.57 ± 2.80 Amg/dL), and total cholesterol (4.17 ± 0.88 v. -3.26 ± 2.86 Amg/dL) levels, AM vs. PM, respectively. In addition, non-significant trends were found for resting metabolic rate (increase in AM, $p = 0.07$) and fasting triglycerides (lower in PM, $p = 0.06$). **CONCLUSION:** The multimodal RISE protocol improved performance, cardiovascular health, and body composition, with the TOD altering the magnitude of cardio-metabolic training-induced adaptations. Specifically, training in the AM

exhibited a trend of increasing RMR, while training in the PM resulted in greater improvements in fasting total cholesterol, LDL-C, and triglycerides in healthy men. Supported by Isagenix.

Personalized Exercise Training Maximizes Comprehensive Training Responsiveness in Adults At-Risk for Cardiovascular Disease
 Chantelle A. Robitaille, Thomas F. Cuddy, Abigail L. Owen, Christina A. Buchanan, Lance C. Dalleck. *Western State Colorado University, Gunnison, CO.*
 Email: chantelle.robitaille@western.edu
 (No relationships reported)

PURPOSE: Previous research has identified considerable variability in training responsiveness among individuals exposed to regular exercise. While examining the considerable heterogeneity in exercise-induced changes in cardiorespiratory fitness and common cardiometabolic risk factors, it has been identified that an individualized and evidence-based approach to exercise prescription may be necessary to optimize training efficacy and reduce training unresponsiveness. The purpose of this study was to compare comprehensive training responsiveness between two exercise training programs: personalized vs. standardized. **METHODS:** Sedentary men and women (n=46, ages 44 to 83 yrs) were randomized into a non-exercising control group or one of two exercise training treatment groups: 1) standardized group (exercise intensity prescribed according to heart rate reserve) or 2) personalized group (exercise intensity prescribed according to ventilatory thresholds). Exercise training was performed 60-75 min/day on 3 days/wk for 13wk. Maximum oxygen uptake, systolic blood pressure, HDL cholesterol, triglycerides, and blood glucose were measured pre/post intervention, and percent change for each measure was calculated. Based on percent change for each measure, participants were assigned scores (responder: 1, non-responder: 0), and a comprehensive response to training score (scale 0-5) was determined. **RESULTS:** Training responsiveness as evidenced by the responder composite score was greater (p<0.05) in the personalized treatment group (4.71 ±0.47) when compared to the standardized treatment group (2.86 ±0.66). There were similar (p>0.05) responder composite scores across men and women for both the personalized (men=4.75; women=4.67) and standardized (men=2.75; women=3.00) treatment groups. Training responsiveness was also similar (p>0.05) across age for both treatment groups. **CONCLUSION:** Our findings demonstrate that personalized exercise training maximizes comprehensive training responsiveness. These preliminary results are promising for exercise physiologists and other health professionals who prescribe exercise for populations at-risk for cardiovascular disease and other chronic conditions.

The Influence of Foam Rolling on Recovery From Exercise Induced Muscle Damage
 Anthony D'Amico, Jason Gillis. *Salem State University, Salem, MA.*
 Email: adamico@salemstate.edu
 (No relationships reported)

With the increased popularity of foam rolling (FR) as a recovery tool, it is important to establish the exact manner in which the practice is useful. **PURPOSE:** The purpose of this study was to examine the impact of FR on recovery from exercise-induced muscle damage. **METHODS:** In a between-group design, 37 males performed 40x15m sprints, inducing muscle damage. Immediately following sprinting and in the four days following, perceived muscle soreness, hip ROM, vertical jump, and agility measures were recorded. 18 subjects (mean±sd; age 22.4±2.0 yrs; BMI 26.9±4.2 kg m⁻²) foam rolled prior to testing each day (FR), while 19 (mean±sd; age 23.2±3.2 yrs; BMI 26.3±4.0 kg m⁻²) served as a non-foam rolling control (CON). Measurements recorded during the five days of recovery from the repeated sprint protocol were compared to those obtained during three baseline days of familiarization the prior week. The area under the curve (AUC) was calculated by summing all five scores and these data were compared by condition using a two-tailed Mann-Whitney U test (alpha level = 0.05). **RESULTS:** Perceived soreness, hip ROM, and vertical jump were not significantly different between groups (p>0.05). Agility, specifically the difference in time from baseline to complete the agility T test, was significantly lower in the foam rolling condition (p<0.05). AUC was higher in CON (2.88 s±2.45) than FR (0.33 s±2.16). Mean values for agility changes from baseline in CON were 0.52 s, 0.82 s, 0.78 s, 0.45 s, and 0.32 s on the day muscle damage was induced, and then the four days following, respectively. Mean values for agility changes from baseline in FR on those days were 0.11 s, 0.17 s, 0.06 s, 0.12 s, and -0.13 s. **CONCLUSIONS:** FR expedites recovery of agility following exercise-induced muscle damage instigated by a repeated sprint protocol. FR may be useful for athletes requiring adequate agility who need to recover quickly from intensive bouts of exercise. Supported by: Performance Health (Hygienic Corporation, Akron, Ohio) supported this project with donations of foam rollers.

Cold-water Immersion During Halftime Does Not Affect Second-half Physical Performance In A Football Match
 Sungwan Kim, Jihyeon Park, Daeho Kim, Jihong Park. *Kyung Hee University, Yongin, Korea, Republic of.*
 Email: ksw9354@naver.com
 (No relationships reported)

In football matches, cold-water immersion (CWI) is often practiced during halftime to recover from fatigue and maintain performance in the second-half. **PURPOSE:** To develop and validate a 90-min long simulated football match using a football simulated protocol (FSP) and to observe performance changes in the second-half responding to an application of a 5-min CWI during halftime. **METHODS:** Twenty male elite footballers (athletic career: 9 ± 1 years) visited a regular outside natural-grass football pitch three separate days. On the first day, baseline values of two-legged maximal vertical jump, 20-m sprint, arrowhead agility test, and accuracy scores of short-pass and long-kick were assessed. On the second and the third days, participants performed nine repetitions of a 5-min long FSP, consisted of football related activities (walking, jogging, sprinting, cutting, jumping, side-stepping, and kicking) to complete the first- and second-half. On the second and third days, calorie expenditure and heart rate (HR) were also recorded. During halftime, participants were received one of conditions (CWI: bare feet immersed up to 8 cm below from the tibial tuberosity at 7.5 °C or control: sitting on a bench: in a counterbalanced order) for 5-min. To test condition effects over time, time points were divided as T1 (first 15-min of the first-half) through T6 (last 15-min of the second-half), thus 2 × 6 mixed model ANCOVAs (covariate: baseline values) and Tukey-Kramer post hoc tests were performed (p<0.05). **RESULTS:** A total value of calorie expenditure (1,245 Cal) and an average value of HR at a time point (163 bpm) in our study were similar to typical football matches. Participants spent less calories during T1 (186 Cal) and T4 (191 Cal) than to T2 (213 Cal) or T3 (224 Cal), and T4 (212 Cal) or T5 (219 Cal), respectively. An application of CWI during halftime did not change any performance in the second-half (maximal vertical jump: F_{5,209}=0.44, p=0.82; 20-m sprint: F_{5,209}=0.6, p=0.7; arrowhead agility test: F_{5,209}=0.26, p=0.93; short-pass: F_{5,209}=1.75, p=0.12; long-kick: F_{5,209}=1.19, p=0.31). **CONCLUSIONS:** Our football simulated match can be used as experimental or practical purposes. Halftime CWI does not affect performance in the second-half. Water temperature or duration of application may explain the ineffectiveness of CWI.

3714 Board #161 June 3 9:30 AM - 11:00 AM
Effects of External Counter Pulsation (ECP) on Physical Recovery after Strenuous Exercise
 Steven Tally, Naomi Hillery, Merissa Kado. *UC San Diego, La Jolla, CA.*
 Email: stally@ucsd.edu
 (No relationships reported)

External Counter Pulsation (ECP) therapy is a non-invasive treatment that enhances blood flow and delivers oxygenated blood to the extremities through the sequential compression of the lower limbs during diastole. While ECP has been used to treat patients with chronic angina pectoris/congestive heart failure, there has been little research on the impact of ECP on healthy individuals. **PURPOSE:** To determine if ECP therapy impacts recovery and ability to perform after strenuous exercise. **METHODS:** Fifty-seven amateur athletes, 27 males and 30 females, aged 38.9 ± 11.6 years, participated in three two-hour study visits over three consecutive days. During each study visit subjects engaged in a 20 min lower-body exercise circuit while wearing a weighted vest containing 12-15% of their body weight and then completed a 10k time trial using an indoor cycling trainer. Balance and jump tests were conducted both before the exercise circuit (PRE) and following the cycling time trial (POST). Balance was the amount of postural sway over 20 sec for both right and left leg, measured using a force plate. Jump explosiveness was ground time between consecutive jumps, measured using a contact mat. Subjects who were randomly assigned to the treatment condition then received 30 min of ECP therapy, while control subjects passively recovered for 30 min while wearing thigh and calf cuffs from the ECP machine. Repeated measures ANOVA was used to examine within group differences. **RESULTS:** Average cycling time significantly decreased from visit 1 to visit 3 for the ECP group compared with the control group (1,524 to 1,432 vs. 1,499 to 1,479 sec; p<0.05). Although balance for both groups improved, the ECP group significantly improved their balance as compared to the control group from POST visit 1 to PRE visit 2 (74.8 to 67.9 vs. 75.2 to 73.6; p<0.05). Jump explosiveness was maintained from POST visit 1 to PRE visit 2 for the ECP group, while performance on this test decreased significantly for the control group over the same period (.403 to .404 vs. .363 to .393; p<0.05). **CONCLUSION:** ECP therapy after strenuous exercise improved cycling time trial performance, improved balance, and maintained jump explosiveness. Mechanisms through which ECP impacts performance are possibly enhanced recovery by means of vasodilation and increased blood flow.

3715 Board #162 June 3 9:30 AM - 11:00 AM
Does Foam Rolling Increase Pressure Pain Threshold Of Ipsilateral Lower Extremity Antagonist And Contralateral Muscles?
 Scott W. Cheatham¹, Morey J. Kolber², Willam J. Hanney³.
¹California State University Dominguez Hills, Carson, CA.
²Nova Southeastern University, Fort Lauderdale, FL. ³University of Central Florida, Orlando, FL.
 (No relationships reported)

Sports medicine professionals often prescribe foam rolling as an intervention to treat myofascial restrictions. Of particular interest, is the effect foam rolling has on the ipsilateral antagonist muscle and contralateral muscles. Recent research has observed ROM changes in these muscles after a foam rolling intervention. To date, no studies have examined how foam rolling effects the pressure pain threshold (PPT) levels of the ipsilateral antagonist and contralateral muscles. **PURPOSE:** To examine the acute effects of a foam rolling intervention on ipsilateral antagonist and contralateral muscle group PPT levels. **METHODS:** Twenty-one healthy participants (mean age 27.52±8.9 years) (M=13, F=8) were recruited for this study and signed an IRB consent. Participants underwent pretest and immediate posttest PPT measures after a 2-minute video-guided foam roll intervention to the left quadriceps. PPTs were measured using a digital algometer to the ipsilateral left hamstrings and right quadriceps. Pretest and posttest measures were calculated using the paired *t*-test. Statistical significance was considered *p*< 0.05 using a two-tailed test. **RESULTS:** A significant difference was found between pretest to posttest measures for the ipsilateral hamstrings (*t* (20) = -6.2, *p*<0.001) and contralateral quadriceps (*t* (20) = -9.1, *p*<0.001) suggesting an increase in PPT. **CONCLUSIONS:** These findings suggest that foam rolling of the quadriceps musculature may have an acute effect on the PPT of the ipsilateral hamstrings and contralateral quadriceps muscles. Individual may feel less discomfort due to a higher PPT. The ipsilateral decrease in hamstring PPT may have occurred through reciprocal inhibition and agonist pain perception from rolling on the left quadriceps. The cross-over effect of decreased right quadriceps PPT may have been from a more global neurophysiological response. Clinicians must consider these results to be exploratory and future investigations examining this intervention on PPT is warranted.

3716 Board #163 June 3 9:30 AM - 11:00 AM
Downhill Running Followed by Foam Rolling Has No Effect on the Cost of Running
 Emma J. Lee, Christopher J. Lundstrom, Eric M. Snyder.
 University of Minnesota, Minneapolis, MN. (Sponsor: Thomas Olson, FACSM)
 Email: leex4357@umn.edu
 (No relationships reported)

Purpose: Downhill running (DHR) causes muscle soreness that may affect running performance. Foam rolling (FR) is a potential recovery tool for reducing soreness and attenuating performance decrements. Running economy (RE), which quantifies the efficiency of running, is a key factor in distance running ability. It is unclear whether DHR affects RE in trained runners and whether FR is an effective recovery method for DHR-induced soreness. Furthermore, RE may be assessed in several ways, including O₂ cost (VO₂) and energy cost (EC, kcal*kg⁻¹*min⁻¹). These measures may be more accurate with allometric scaling of body weight (alloVO₂ and alloEC; body weight in kg^{0.66}). Thus, our purpose was to evaluate changes in RE with DHR and FR or placebo using 4 definitions of RE.

Methods: Subjects did submaximal running to assess RE 2-4 days before (SUBMAX1) and 48 hours after (SUBMAX2) DHR. Immediately after DHR, they performed FR or placebo (sham compression tights [T]). In a randomized crossover design, subjects repeated these tests 2-4 weeks later. RE during SUBMAX was calculated as VO₂, alloVO₂, EC, and alloEC. Muscle soreness was measured on a 0-10 verbal scale before DHR and SUBMAX2.

Results: Eight trained runners completed the study (VO_{2max} 57±7 ml*kg⁻¹*min⁻¹, age 30.6±7 years, 4 females). Soreness at SUBMAX2 was greater than at SUBMAX1, showing that DHR induced soreness in all subjects (*p* = 0.012). Subjects had lower soreness at SUBMAX2 with FR than T (*p* = 0.025). However, there were no significant effects of time or treatment on VO₂, alloVO₂, EC, or alloEC (*p* > 0.05 for all comparisons).

Conclusion: Downhill running causes muscle soreness but does not affect running performance as evaluated through RE. FR reduces DHR-induced soreness compared to a placebo. While allometric scaling and energy cost definitions of RE may be better indicators of running performance than the traditional VO₂, none of the measures of RE are affected by DHR-induced muscle soreness.

3717 Board #164 June 3 9:30 AM - 11:00 AM
An Examination of Self-Myofascial Release vs. Instrument Assisted Soft Tissue Mobilization Techniques on Vertical and Horizontal Power in Recreational Athletes
 Debra Stroiney¹, Rebecca Mokris¹, John Ranney¹, Gary Hanna².
¹Gannon University, Erie, PA. ²Edinboro University, Edinboro, PA.
 Email: stroiney001@gannon.edu
 (No relationships reported)

Self-Myofascial Release (SMR) and Instrument Assisted Soft Tissue Mobilization (IASTM) both relieve adhesions and restrictions in muscle tissue. These tools are popular however there is limited research as to their efficacy on improving athletic performance.

PURPOSE: The objective of this study was to determine if using pre-exercise SMR or IASTM would improve performance on measures of vertical and horizontal power. The researchers also examined if any differences in perceived pain existed between the two manual therapy interventions. **METHODS:** A total of 29 male and 22 female college students volunteered to participate in the study. Subjects were required to meet the American College of Sports Medicine recommendations for physical activity. Subjects were randomly assigned to receive either IASTM via Tecnica Gavilan or SMR via The Stick. Vertical power was assessed by a vertical jump test and horizontal power was measured by a 40 yd sprint. In the first session, body fat percentage and baseline measurements for the vertical jump and 40 yd sprint were collected. During the second session, the subjects received either SMR or IASTM prior to their vertical jump test and 40 yd sprint. Subjects were asked to rate the level of pain they perceived after the massage intervention using a visual analog scale. Subjects then repeated the vertical jump and 40 yd sprint tests. A dependent *t*-test was used to determine differences in pain between the two massage interventions. A 2 x 2 ANCOVA was used to determine if differences existed between genders and the two types of manual therapy. **RESULTS:** There was no interaction (*p* > .05) between the massage intervention and gender for both the vertical jump and 40 yd sprint tests. There was a significant main effect for vertical jump and SMR (*p* = .04). Gender also had a significant main effect for both the vertical jump (*p* = .04) and the 40 yd sprint (*p* = .02). There were no significant differences between massage interventions for the 40 yd sprint times (*p* = .73). There were no significant differences in perceived pain between the massage interventions (*t* (49) = -1.60, *p* > .05). **CONCLUSION:** The use of SMR prior to exercise may be beneficial in improving vertical power in recreational athletes, and was not perceived to be more painful than IASTM. However, neither SMR nor IASTM improved horizontal power.

3718 Board #165 June 3 9:30 AM - 11:00 AM
The Impact of a 30 vs. 60 Second Passive Recovery Period on Vertical Jump Performance
 Andy Bosak, Austin Smith, Christopher Carver, Matthew Sokoloski, Jon Houck, Jared Feister, Robert Sanders. Liberty University, Lynchburg, VA. (Sponsor: James Schoffstall, FACSM)
 Email: ambosak@liberty.edu
 (No relationships reported)

The vertical jump (VJ) test is commonly utilized to determine how high a person can jump and what their resulting power will be. Thus, it is important that the VJ test is administered correctly for a person to jump as high as possible. The standard time between subsequent jumps is usually 30 seconds (secs) with a completion of 3-6 jumps. But, if an individual is not fully recovered before their next jump, it is possible that jump may be lower vs. the first or earlier jumps. If a longer recovery period is granted between each jump, the individual may potentially jump as high as or even higher than their previous attempts. However, to the best of the researchers' knowledge, the impact of a 30 vs. 60 secs passive recovery period on VJ performance has not been assessed. **PURPOSE:** To investigate the potential differences between a 30 vs. 60 secs passive recovery period on VJ performance in no less than average fit college-age males. **METHODS:** After having descriptive data (ie. Ht., Wt., BF%, age) recorded, 31 average fit college-age males had their reach height measured and then participated in an 8 min dynamic warm-up. Subjects were then given a 4 minute passive recovery (PR) period after the warm-up and then completed 4 familiarization jumps (ie. trials) using a VJ measurement device. After another 4 min PR period, subjects completed 2 series of jumps (ie. 4 trials apiece) in a counterbalanced order with either 30 (THIR) or 60 (SIXT) secs of PR between each jump. The THIR and SIXT jump series were separated by 4 min of PR. Excluding the first jump/trial for each series, the highest jump for THIR vs SIXT were compared using Paired-Samples *t*-Tests with significant differences occurring at *p* < 0.05. **RESULTS:** No significant differences (*p* = 0.44) occurred between SIXT (70.01 + 10.36 cm) and THIR (69.97 + 9.86 cm). **CONCLUSION:** The current results suggest that 30 or 60 secs of passive recovery between jumps is optimal recovery for peak performance to occur during the vertical jump test using average fit college-age males. However, further research may

be necessary to assess the impact of 30 vs. 60 sec passive recovery on vertical jump performance using averagely fit college-age females. Also, future studies may need to examine the effects of a shorter recovery period vs 30 or 60 seconds on vertical jump performance in male and female athletes.

Effects Of Manual Inter-structural Release For Posterior Shoulder Tightness On The Humeral Head Position

Koki Hamada¹, Masashi Sadakiyo¹, Kazuyoshi Gamada².
¹Sadamatsu Hospital, omura, Japan. ²Hiroshima International University, Higashihiroshima, Japan.
 (No relationships reported)

PURPOSE: The aims of this study were to determine if inter-structural release for posterior shoulder tightness on the position of the humeral head with respect to the center of the glenoid cavity. **METHODS:** Twenty-four healthy adult males participated in this IRB-approved study. Inclusion criteria were; age between 18 and 50 years old, and Japanese males. Exclusion criteria were; a history of surgery on the glenohumeral joint, and current pain in the glenohumeral joint. The subjects were allocated randomly to (1) stretch (S) group who performed the sleeper and cross body stretch, (2) combined stretch and manual release (R) group who performed the same stretch and received manual release to the posterior deltoid, or (3) control (C) group. An intervention period was set at four weeks. The manual release technique was intended to release loose connective tissue between the structures, e.g. the posterior deltoid and infraspinatus, was performed to achieve complete superior gliding of the posterior deltoid. We expect that normal alignment of the humeral head relative to the glenoid and normal end feel in maximal glenohumeral internal rotation at 90 degrees abduction can be achieved. The main outcome measures included range of motion in flexion, horizontal adduction, internal and external rotation at 90 degrees abduction. Secondary outcome was the alignment of the humeral head relative to the glenoid cavity and the distance between the acromion and humeral head. Statistical analyses included two-way analysis of variance and Bonferroni method as a post hoc test. The level of significance was set at $\alpha=.05$. **RESULTS:** The R group showed significant improvements in flexion by 17.2 ± 9.5 ($P=0.043$) and in total arc by 16.4 ± 9.5 ($P=0.038$). The R group (10.1 ± 7.7) showed significant improvements than the C group (0.1 ± 5.0) in horizontal flexion ($P=0.041$). No significant differences were observed between the S and R groups. **CONCLUSION:** Limitations of this study were small sample size and reproducibility of the manual technique. To conclude, the shoulder range of motion and the humeral head position had no correlations.

The Effect Of Between Innings Cooling Or Compression On Baseball Pitching During Competitive Game

Kristin J. Heumann, PhD, CSCS, c-EP, Michael Reeder, DO, Nathaniel Snyder, Shelby Kasch, Jeremy Hawkins, PhD, ATC.
 Colorado Mesa University, Grand Junction, CO.
 Email: kheumann@coloradomesa.edu
 (No relationships reported)

In baseball, pitching effectiveness is critical for team success. Previous research has identified that short-duration cooling in between simulated innings was effective for maintaining velocity and improved perceptions of recovery. This combination is thought to improve overall pitching effectiveness. **PURPOSE:** A pilot study to assess the effect of short-term, between innings, cryotherapy and/or compression on perceived exertion and recovery of pitchers during a live college baseball game. **METHODS:** NCAA Division II baseball pitchers were studied during Fall season scrimmages. Participants were familiarized with the Rating of Perceived Exertion (RPE) and Perceived Recovery Scale (PRS) prior to game play. Participants dressed in game day attire and warmed up in their usual manner. After each inning, RPE was recorded upon entering the dugout. Between innings, participants received one of two treatments: 1) cryotherapy and compression or 2) compression alone (of the equal weight to the cryotherapy and compression) applied to his shoulder and elbow for four minutes, regardless of the length of time between innings (unless this time was less than four minutes). Each pitcher indicated his PRS before re-entering the game to pitch. Time of each inning pitched from warm up pitch to last pitch, rest time, and total pitches thrown were recorded. RPE was measured following the final inning pitched as well as 3 days later prior to throwing the next bullpen. Repeated measures ANOVA were used to determine if RPE or PRS were significantly different between innings. **RESULTS:** Five players participated. One player was excluded because he did not pitch more than one inning. There were no significant differences between RPE or PRS between treatment conditions. Individual RPE values remained constant or declined in subsequent innings with treatment in four of the five players. PRS improved in subsequent innings during the cold treatment. **CONCLUSIONS:** Sample size was likely too small to detect differences. This pilot study may indicate that with more subjects and/or innings pitched, cold and/or compression could be effective modalities

for improving perceived exertion and recovery during a collegiate game. Further studies need to be conducted during the competitive season to include a greater number of players and innings pitched.

The Effects of a Protein and Carbohydrate Recovery Beverage on Muscle Protein Accretion in Trained Weightlifters

Christopher B. Taber. Sacred Heart University, Fairfield, CT.
 Email: taberc@sacredheart.edu
 (No relationships reported)

Human skeletal muscle expresses significant plasticity of phenotype in response to an applied stimulus. Skeletal muscle in response to a resistance training stimulus undergoes a transformative process where cellular signaling pathways lead to increases in contractile proteins that overtime express themselves in muscular hypertrophy. Diametrically opposed to these anabolic signaling pathways are the cellular survival and homeostatic regulatory pathways that are integrated with energy availability and balance. Attempting to shift the balance between the anabolic and catabolic pathways is the basis for adaptation-recovery and can be altered via training and the use of recovery methods including nutritional interventions.

Purpose: To examine the effects of a recovery supplement containing protein and carbohydrate given immediately after each training session on muscle protein accretion in trained weightlifters.

Methods: 10 trained male weightlifters completed a 12-week training protocol implementing block periodization. A double blind placebo protocol was utilized to compare effects between treatment and placebo groups. The treatment group received a protein and carbohydrate recovery beverage and the placebo group received a calorie free beverage. Muscle biopsies were obtained pre and post the 12 week training intervention training and samples were analyzed for the specific muscle proteins (mTOR, AMPK, pmTOR, pAMPK) and gene expression of myosin heavy chains 1, 6 and 7.

Results: Pre and post increases were found for total mTOR ($p=0.044$) for the treatment group but not for pmTOR ($p=0.385$), AMPK ($p=0.159$), and pAMPK ($p=0.430$). No statistical difference was found pre and post for gene expression of myosin heavy chain 1 ($p=0.08$), 6 ($p=0.08$) or 7 ($p=0.37$) for the treatment group.

Conclusion: These findings indicate that a protein supplementation has positive effects on total mTOR accretion and was trending towards a positive effects on myosin heavy chains 1 and 6 in trained weightlifters. This data indicates a potential acute anabolic effect from the consumption of a protein and carbohydrate recovery beverage following training in trained male weightlifters.

Effect Of Recovery Methods On Blood Lactate Clearance After Strenuous Exercise On Brazilian Jiu-jitsu Athletes

Judy R. Wilson, FACSM, Jordan A. Shepler. University of Texas at Arlington, Arlington, TX.
 Email: jrwilson@uta.edu
 (No relationships reported)

Introduction: Blood lactate (BLa) is a frequently measured parameter during performance testing and is produced by high intensity exercise. High levels are associated with impaired muscle function and reduced exercise performance. Previous studies showed that active recovery (A), performing low intensity aerobic exercise post exercise, is more effective at clearing lactate than rest/passive recovery (P). Whole-body Cryotherapy (WBC) has recently gained popularity for improving recovery after strenuous exercise as an alternative to traditional ice-water therapy. Subjects enter a specially designed cabin in which liquid nitrogen lowers the temperature of the air (-110 to -140°C) for a short period of time, usually 3 min. **Purpose:** Our purpose was to determine which recovery, A, P, or WBC, was most effective at reducing BLa in Brazilian Jiu-Jitsu athletes. **Methods:** Five males (37.8 ± 3.82 yrs) participated in this study. Baseline BLA, heart rate (HR), rate of perceived exertion (RPE) and measures of pain were recorded before, during and after the workout. A 5 min dynamic warm-up preceded the circuit: 8 power clean and press with 95 lbs x 8 reps; 10 pull-ups; box jumps for 30 seconds; renegade row for 30 sec; full squat with 95 lbs x 10 reps; inverted row, 10 reps; medicine ball slam 30 sec; treadmill run 7 mph, 15% incline, 1 min. After the circuit, subjects sat for 5 min to allow BLa to peak, then it was measured using a finger prick and results recorded. Subjects randomly performed one of three recovery methods: 1) P - sit - 15 min; 2) A - 15 min cycling 40% HRmax; or 3) WBC - stood in Cryochamber 3 min. Blood lactate was obtained every five min for 15 min. Data were analyzed using SPSS 19.0. **Results:** Mean values for BLA (mmol/L) at 5 min ($P=16.52\pm 2.10$; $A=13.2\pm 2.29$; $WBC=16.78\pm 2.72$). BLa for A recovery was significantly less than P or WBC ($p=0.003$). At 10 min ($P=16.76\pm 0.68$; $A=11.74\pm 2.72$; $WBC=11.62\pm 1.48$) and 15 min ($P=16.34\pm 4.0$; $A=11.62\pm 1.48$; $WBC=8.98\pm 2.73$) BLa levels were significantly less for A and WBC than P ($p=0.003$). There was no significant difference ($p > 0.05$) between A and WBC recovery

for 10 and 15 min. **Conclusion:** The results of this study indicate that initially, A recovery was the most effective in clearing blood lactate, but WBC was as effective as A at 10 and 15 min, and A and WBC were more effective than P at 10 and 15 min of recovery.

Effects of Acute Foam Rolling on Quadriceps Performance and Short-term Recovery from Fatigue

Jolene Lim¹, Govindasamy Balasekaran, FACSM¹, Visvasuresh Victor Govindaswamy², Wayne Foo¹, Yew Cheo Ng¹, Peggy Boey¹. ¹Nanyang Technological University, Singapore, Singapore. ²Concordia University Chicago, Chicago, IL.
 (No relationships reported)

Foam rolling is a common technique among fitness professionals and athletes. However, the effect of this technique on performance and short-term recovery remains unclear. **PURPOSE:** To examine the effects of acute foam rolling on quadriceps performance and short-term recovery from exercise-induced fatigue. **METHODS:** 10 recreationally active, right leg dominant, male university students (height: 173 ± 0.70cm, mass: 70.81 ± 1.33kg, age: 23.9 ± 0.28yrs) participated in a randomized, counterbalanced, crossover study that was held over three weeks. Maximal Voluntary Contraction (MVC) pre-test, fatigue-inducing protocol and MVC post-tests were conducted. Foam rolling (FR) and Control (CON) intervention took place before each MVC test. In FR, the hamstrings, iliotibial band, and quadriceps muscles were rolled for 1 minute per set, twice, with a 30 second rest between sets and muscle groups. **RESULTS:** No significant differences were found between FR and CON for concentric (FR: 219.250 ± 11.18, CON: 220.90 ± 11.18, p=0.918) and eccentric (FR: 238.40 ± 16.61, CON: 254.00 ± 16.61, p=0.515) MVC, as well as between pre and post-MVC for concentric (Pre: 221.70 ± 8.34, Post: 218.45 ± 7.75, p=0.307) and eccentric (Pre: 249.05 ± 12.00, CON: 243.35 ± 12.20, p=0.337). No significant interaction was found between conditions and time for MVC performances (concentric: p=0.987; eccentric: p=0.646). Post-test MVC decreased by 1.49% (concentric) and 3.46% (eccentric) in FR, and 1.43% (concentric) and 1.17% (eccentric) in CON. No significant differences were found between FR and CON for muscle soreness (MS), fatigue, and rate of perceived exertion (RPE) during MVC pre-test (MS: FR: 17.3 ± 11.53, CON: 22.8 ± 14.41, p=0.358; Fatigue: FR: 2.8 ± 1.55, CON: 2.6 ± 1.07, p=0.741; RPE: FR: 3.0 ± 1.41, CON: 3.2 ± 1.62, p=0.772), after fatigue protocol (MS: FR: 75.3 ± 23.51, CON: 78.7 ± 21.55, p=0.945; Fatigue: FR: 8.3 ± 1.70, CON: 7.7 ± 1.89, p=0.501; RPE: FR: 8.3 ± 1.70, CON: 8.1 ± 1.85, p=0.801), and during MVC post-test (MS: FR: 38.3 ± 21.77, CON: 36.2 ± 18.08, p=0.817; Fatigue: FR: 4.4 ± 1.35, CON: 4.2 ± 1.55, p=0.762; RPE: FR: 4.9 ± 0.88, CON: 4.7 ± 1.34, p=0.853). **CONCLUSION:** Results indicated that acute foam rolling do not significantly affect isokinetic MVC performance or improve short-term recovery of fatigue-induced quadriceps.

The Effectiveness of Compression Socks on Recovery from Maximal Aerobic Exercise

Haylee Schiltz, Joceyln P. Awe, Magdalena Saenz Ruiz, Elaina Biechler. *Loras College, Dubuque, IA.* (Sponsor: Vincent Paolone, FACSM)
 Email: haylee.schiltz@loras.edu
 (No relationships reported)

PURPOSE: The purpose of the present investigation was to determine the effect of compression socks on recovery from maximal aerobic running for college aged subjects.

METHODS: Moderately fit college aged student subjects (N=16) were recruited to participate in the present study. Specific anthropometric measurements were first recorded, including appropriate fitting for compression socks. Subjects completed two sets of maximal graded treadmill exercise tests to exhaustion using the McConnell Treadmill Protocol including a control phase and a compression phase. During the control phase, two treadmill maximal tests were conducted with 24 hours of recovery separating them. During the compression phase, subjects completed two treadmill maximal tests, wearing compression socks during their 24 hours of recovery. At least 7 days separated the compression and control phases, and a cross over design was utilized. During each treadmill test, heart rate, RPE, and Vo₂ were recorded at baseline and every three minutes. Blood lactate values were measured before and after each exercise session.

RESULTS: Blood lactate levels measured 24 hours following a maximal exercise bout were significantly lower (p < .05) when compression socks were worn for the 24 hours when compared to a control phase (2.31 mmol/L; 3.59 mmol/L, respectively). Blood lactate levels 20 minutes following the maximal exercise bout were not significantly different (p > .05) when wearing the compression socks compared to the control phase (5.51 mmol/L; 5.77 mmol/L, respectively).

CONCLUSIONS: Pre-exercise lactate levels were significantly lower while wearing compression socks, which indicated an improvement in short-term (24 hour) aerobic exercise recovery. Compression socks have a positive effect on short term recovery from maximal aerobic exercise for moderately fit college aged individuals.

Pilot Study: The Influence Of Menthol On Recovery From Exercise-induced Muscle Damage.

D. Jason Gillis, Aurora Vellante, Joseph Gallo. *Salem State University, Salem, MA.*
 Email: jason.gillis@salemstate.edu
 (No relationships reported)

PURPOSE: Menthol is a cold receptor agonist found in various products claiming to relieve muscle soreness, but menthol's influence on recovery from exercise-induced muscle damage requires clarification. The purpose of this study was to compare serial measures of muscle soreness and performance following exercise-induced muscle damage between a Menthol (M), Placebo (P) and Control (CON) condition. It was hypothesized dependent variables would not differ between conditions (null hypothesis).

METHODS: 38 males with a mean (SD) age, weight and height of 24.0 (4.0) yrs, 79.5 (16.1) kg and 1.74 (0.12) m were randomized to M (n=11), P (n=8), and CON (n=19). Participants were familiarized with a testing battery (TB) including: perception of lower body muscle soreness; 0-10 pain response to 30N of pressure applied to right quadriceps/hamstrings/calf; hip flexion/abduction range of motion; vertical jump; Agility T-test. Muscle damage was induced on Monday using 40x15m sprints with a 5m deceleration zone. Participants in M applied Biofreeze™ (4% menthol gel) twice daily to the lower body, whilst P applied a gel that smelled like Biofreeze™ but contained no menthol. CON did not undergo any intervention. Participants completed TB daily from Monday to Friday. Dependent variables were calculated as they changed from baseline and the area under the curve was then calculated by summing Monday to Friday scores. The area under the curve values were then compared by condition using the Kruskal Wallis test (alpha level = 0.05).

RESULTS: A significant difference in agility time (s) was observed by condition (p=0.0044) and Dunn's post-hoc test indicated that menthol caused less decrement in agility performance following exercise-induced muscle damage compared to both CON and P (p<0.05). No other significant differences were observed between conditions.

CONCLUSIONS: Menthol application may help to preserve agility performance after exercise-induced muscle damage, however the mechanism of action is not clear. Further data collection is required to strengthen Monday to Friday comparisons and observe the time-course of recovery by condition. *Performance Health (Hygienic Corporation, Akron, Ohio) supported this project with donations of Biofreeze and Placebo gel.*

Comparison Of Recovery Measures Following Cardiorespiratory Fitness Testing In Young Children

Shannon E. Vinci, Michael C. Taylor, Jr, Justin M. Thomas, Cassandra M. Blase, Rosie K. LaCoe, Jody L. Clasey, FACSM. *University of Kentucky, Lexington, KY.* (Sponsor: Jody L. Clasey, FACSM)
 (No relationships reported)

Post exercise heart rate recovery measures have been used as a predictor of fitness and mortality in adult populations. Less is known about the predictive value of oxygen consumption and heart recovery responses to clinical and field cardiorespiratory fitness testing in young children. **PURPOSE:** To compare oxygen uptake (VO₂; ml·kg⁻¹·min⁻¹) and heart rate (HR; beats·min⁻¹) recovery responses (mean ± SD) from the FitnessGram Progressive Aerobic Cardiovascular Endurance Run (PACER) test to recovery measures from a progressive maximal graded exercise test (GXT; treadmill) in 17 (9 boys) young (10-11 yr old) children. **METHODS:** Subjects completed the PACER and GXT in a randomized order 1 week apart while wearing a HR monitor and portable oxygen analyzer. VO₂ and HR recovery measures were determined at 1, 3 and 5 mins post completion of the PACER and GXT. **RESULTS:** There were no significant mean VO₂ measures between the PACER and GXT VO₂ at 1 min (14.5 ± 3.1 vs 16.1 ± 3.6), 3 min (8.0 ± 1.4 vs 7.9 ± 1.3), or 5 min (7.3 ± 1.4 vs 7.2 ± 1.6) of recovery. The GXT recovery HR (149.0 ± 31.0) recovery was significantly (p < 0.05) greater at 1 minute than the PACER recovery HR (136.0 ± 17.0), however there was no significance between the GXT and PACER HR at 3 min (115.2 ± 9.1 vs 110.8 ± 11.7) or at 5 min (108.5 ± 7.7 vs 107.1 ± 10.0) of recovery. **CONCLUSIONS:** The PACER resulted in similar absolute cardiorespiratory recovery responses in young children when compared with a criterion fitness test.

Supported by the University of Kentucky Pediatric Exercise Physiology Laboratory Endowment

Chronic Effects of Cupping Therapy on Balance, Flexibility and Muscular Power
 John W. Wygand, FACSM, Shelby Stoner, John Petrizzo, Robert M. Otto, FACSM. *Adelphi University, Garden City, NY.*
 Email: wygand@adelphi.edu
(No relationships reported)

Cupping is an alternative therapy used by athletes to purportedly improve performance or enhance recovery. Bell shaped cups are placed on the skin (above a targeted muscle) and air is withdrawn to create a vacuum against the skin surface. Blood flow is expected to improve under the cup area during the application and impact somatosensory integrity and performance. **PURPOSE:** To determine the effect of chronic Cupping Therapy (CUP) on unilateral hip flexibility, balance, and muscular power, 12 subjects (age 21.4± 1.2, ht. 167.6 ± 8.4 cm, and body mass 71.6 ± 18.2 kg, 7♀) participated. **METHODS:** Familiarization trials ensured reliability. Testing was conducted within 15 minutes after CUP for four consecutive days (1-4) with CUP randomly assigned to either leg on day one. Single foot balance was obtained with a sway index (SI) on the Biodex Balance System with unilateral trials for 20 seconds and 10 sec recovery repeated twice. Each test consisted of two measures of unilateral passive hip range of motion (degrees) obtained by goniometer with the subject in the prone (hip extension [HE]) and supine (straight leg raise test of hamstring [HF]) positions. Unilateral hamstring/quadriceps muscle power (MP) testing was conducted with a Biodex Isokinetic dynamometer (Watts = W) including five repetitions @ 60°/sec warm-up and 10 maximal repetitions at 120°/sec for the trial. CUP required the application of 6 plastic cups applied at -14 PSI bilaterally for 10 minutes at 30 mm lateral of the vertical midline of the posterior thigh above the hamstring muscle group. **RESULTS:** Statistical analysis by ANOVA (p<.05) with repeated measures revealed no significant difference among matched variables including: SI: .89, .99, .74, & .86 and 1.07, .78, .84 & 1.01; HE(degrees): 13.4, 14.3, 13.6, & 13.3, and 12.7, 14, 13.8 & 13.6; HF(degrees): 66.6, 62, 61, & 62.4 and 65.1, 62, 61, & 62; MP(W): 94, 53.4, 68.7, & 61.2 and 82.1, 40, 66.3, & 65.9 for CUP and No CUP treatments on days 1, 2, 3, and 4, respectively. **CONCLUSION:** The application of cupping therapy on four consecutive days with six treatment cups applied for ten minutes at a modest negative pressure provided no alteration in balance, flexibility or muscular power compared to no treatment over four days. The efficacy of cupping for enhancement of performance related measures is not supported by this study.

The Effects of Acute Cupping Therapy on Balance, Flexibility and Muscular Power
 Shelby Stoner, John Petrizzo, John W. Wygand, FACSM, Robert M. Otto, FACSM. *Adelphi University, Garden City, NY.*
 (Sponsor: Robert M. Otto, FACSM)
 Email: sstoner@adelphi.edu
(No relationships reported)

In the recent Rio Olympics, spectators witnessed round circles across the upper back of swimmer Michael Phelps and others. These circles were as the result of cupping therapy (CUP) received prior to competitive performances and drew widespread publicity, despite little scientific evidence to support the practice. **PURPOSE:** To evaluate the impact of acute CUP on muscular power, balance and flexibility, 12 subjects (age 21.4± 1.2, ht. 167.6 ± 8.4 cm, and body mass 71.6 ± 18.2 kg, 7♀) volunteered. **METHODS:** Familiarization trials preceded CUP by 48 hrs and included all of the following tests: single foot balance with a sway index (SI) on the Biodex Balance System with unilateral trials for 20 seconds and 10 sec recovery repeated twice. Flexibility included two measures of unilateral passive hip range of motion by goniometer with the subject in the prone (hip extension [HE]) and supine (straight leg raise test of hamstring [HF]) positions. Hamstring/quadriceps unilateral muscle power (MP) testing was conducted with a Biodex Isokinetic dynamometer (Watts = W) including five repetitions @ 60°/sec warm-up and 10 maximal repetitions at 120°/sec for the trial. Assessments were conducted within 15 minutes of CUP (PreC), as well as within 15 minutes post (Post15) and 60 minutes post (Post 60) CUP. CUP required the application of 6 plastic cups applied at -14 PSI bilaterally for 10 minutes at 30 mm lateral of the vertical midline of the posterior thigh above the hamstring muscle group. **RESULTS:** Statistical analysis by ANOVA (p<.05) with repeated measures revealed no significant differences among matched variables including: MP(W): 64, 62, & 59.4, and 63.8, 58.7, & 56.3; HED(degrees): 13.3, 13.4 & 13.8, and 12.3, 13.2, & 12; HF(degrees): 67.4, 65.8, & 63.8, and 66.5, 63.8, & 64.3 and SI: .94, .83, & .95 and 1.17, .96, & .76, for CUP and No CUP treatments, respectively. **CONCLUSION:** A single application of CUP did not yield changes in muscular power, flexibility or balance when assessed within 60 minutes of the treatment. These data fail to support the practice of cupping for improved strength, flexibility or balance.

3729 Board #176 June 3 9:30 AM - 11:00 AM
The Effect Of Foam Rolling On Exercise induced Muscle Fatigue
 Yuanpeng Liao, Wanliang Yu. *ChengDu Sports Institute, ChengDu, China.* (Sponsor: Tongjian You, FACSM)
 Email: lyppericy@163.com
(No relationships reported)

PURPOSE: To evaluate the effectiveness of foam rolling (FR) on the rehabilitation of exercise-induced muscle fatigue (EIMF). **Methods:** Forty-two male college students (age: 24.5±2.5 yrs) were randomly divided into two groups: a control group (n=21) and a FR group (n=21) group. All subjects performed a bout of bottom-up squats for obtaining EIMF. All subjects were measured for peak torque (PT), peak torque/body weight (PT/BW), average peak torque (APT) and total work (TW) by using an isokinetic test system before, and 0.5h, 24h, and 48h after the squats. The only difference between two groups was that the FR group performed a 6-min FR exercise protocol before each post-EIMF protocol measurement (at 0.5h, 24h, and 48h). The data was analyzed by one-way ANOVAs with LSD post-hoc tests, and independent t-tests. **Results:** See below table for all results. At 0.5h after the EIMF protocol, PT, PT/BW, APT and TW significantly decreased in FR group and control group (all p<0.05), and there were no significant group differences in these variables. At 24h after the EIMF protocol, T, PT/BW, APT and TW tended to be higher in the FR group than in the control group, although there were no significant group differences. At 48h after the EIMF protocol, PT, PT/BW, APT and TW were significantly higher in the FR group than in the control group (all p<0.05), and nearly reached the pre-EIMF protocol values. **Conclusion:** Foam rolling resulted in a faster recovery in muscle strength and muscle work following a bout of bottom-up squats. The potential mechanism needs to be further investigated.

The Change of PT, PT/BW, And APT TW Between Control Group And FR Group

Stretching Techniques and Their Effects on Sprint Speed for Wheelchair Athletes
 Laura J. Newsome, J.P. Barfield. *Radford University, Radford, VA.* (Sponsor: Dr. Trent Hargens, FACSM)
(No relationships reported)

Flexibility is an important health- and motor-fitness variable as it improves and maintains range of motion, reduces joint stiffness, reduces soreness, reduces the risk of injury, and improves mobility (Peck, 2014). Recent research has examined the effects of varied stretching modes on athletic performance in able-bodied populations but fewer empirical studies have been conducted on athletic performance in disability populations. **Purpose:** The purpose of this research project was to examine the effect of stretching mode on sprint speed among competitive wheelchair athletes. **Method:** Wheelchair rugby players with tetraplegia (N = 32.4±9.8 yrs, 76.78±13.8 kg, 161.2±17.2 cm, 13.1±9.5 yrs post injury) were randomly assigned to one of three different stretching techniques [proprioceptive neuromuscular facilitation stretching (PNF), static stretching, (SS) or dynamic stretching (DS)] on three testing dates. Timing gates (Brower TC Motion Start, Knoxville, TN) were used to assess sprint speed before warm-up, after warm-up (which included the assigned stretching mode, and after 75 minutes of rugby play. The best of the two sprint times was used to compare pre- and post- warm-up speeds as well as pre- and post-practice speeds. **Results:** Sprint speed improved from pre- to post-warm-up across each stretch condition. PNF yielded the greatest improvement (-0.10±0.22 s). As expected, sprint scores declined from pre- to post-practice with DS yielding the least change (0.02±0.19 s). **Conclusion** Regardless of stretch mode, short term performance can be improved

by PNF, SS, or DS stretching modes. Flexibility training may also help to offset fatigue in athletes during regular practice sessions. With the concern that increased fatigue could interrupt proper mechanics, these findings are applicable to both performance training and injury prevention.

Effect Of Branched-chain Amino Acids, β -hydroxy- β -methylbutyrate, And Glutamine On Recovery From Resistance Exercise
 Sara A. Baggett¹, Ludmila M. Cosio-Lima¹, Phillip A. Bishop².
¹The University of West Florida, Pensacola, FL. ²Liberty University, Lynchburg, VA.
 Email: sbaggett@uwf.edu
 (No relationships reported)

Adequate training recovery is essential for optimization of muscle performance, injury prevention, and avoiding overtraining. Consequently, athletes may benefit from interventions that accelerate recovery processes. **PURPOSE:** To evaluate the effects of concurrent supplementation with branched-chain amino acids (BCAA), β -hydroxy- β -methylbutyrate (HMB), and glutamine on recovery from weightlifting. **METHODS:** Fourteen trained participants (mean \pm SD: age = 21 \pm 2 y) completed two protocols (treatment and placebo), each consisting of two resistance bouts separated by 24 h rest. Sessions consisted of three sets to failure at an 8 - 12 repetition maximum load for six exercises. Muscle pain and ratings of perceived exertion (RPE) were assessed after each set using a 100-mm visual analog scale (VAS). Residual pain and ratings of perceived recovery (RPR) were assessed 24 h after initial workouts. Treatment included one 6-g BCAA plus glutamine (BCAA + G) supplement (Leucine, 2.5 g; Valine, 1.5 g; Isoleucine, 1 g; Glutamine, 1 g) and one 1-g dose of HMB respectively consumed 1 h or 30 min before exercise, and another BCAA + G immediately after exercise. An additional HMB supplement was ingested after 2 h and 6 h of recovery. Sugar pills replaced supplements as a placebo, and the order was randomized, counter-balanced, and double-blind. **RESULTS:** Treatment enhanced second-day performance for the leg extension (11 \pm 1 vs. 10 \pm 3; $p = .03$), latissimus pull-down (11 \pm 2 vs. 10 \pm 1; $p = .02$), and total repetitions (62 \pm 5 vs. 59 \pm 7; $p = .03$). Reduced residual pain (29 \pm 19 vs. 40 \pm 23; $p = .01$) and pain during the leg press (37 \pm 14 vs. 45 \pm 21; $p = .04$) and shoulder press (39 \pm 17 vs. 47 \pm 24; $p = .04$) were observed with treatment. RPE on the second day was reduced under the treatment for the leg press (55 \pm 20 vs. 62 \pm 16; $p = .02$) and leg extension (53 \pm 20 vs. 61 \pm 19; $p = .03$) exercises. RPR were similar between conditions ($p > .05$). **CONCLUSIONS:** Combined ingestion of BCAA, HMB, and glutamine may enhance muscle recovery 24 h after an exhaustive resistance bout. Reduced muscle pain and RPE under the treatment may have attributed to enhanced performance during subsequent workouts. Additional research is necessary to understand the effects of chronic supplementation and the mechanisms associated with individual supplements.

3732 Board #179 June 3 9:30 AM - 11:00 AM
Influence of Interval vs Continuous Exercise on Markers of Metabolic Rate During Exercise and Recovery
 Robert Buresh, Brian Kliszczewicz. *Kennesaw State University, Kennesaw, GA.*
 (No relationships reported)

Studies have shown that improvements in body composition after interval training are equivalent or superior to those resulting from continuous, moderate-intensity exercise training, although time and energy expenditure associated with interval training is lower. **PURPOSE:** To compare exercise and 3-hour recovery VO_2 , energy expenditure (EE), core temperature, and heart rate (HR), associated with 40 minutes of continuous, moderate-intensity exercise (50-60% of heart rate reserve [HRR]) (CON) with those associated with three models of interval training: 4 (I-4), 7 (I-7), and 10 (I-10), one-minute bouts of exercise at ~90% of maximal heart rate alternated with 1-minute recovery bouts at ~50-60% of HRR. **METHODS:** Nine healthy adults (5 females, 4 males, 23.8 \pm 2.8 years, 75.0 \pm 9.9 kg) underwent a submaximal exercise test to determine estimated VO_2 max. Exercise sessions were then completed in random sequence at least one week apart. **RESULTS:** Exercise VO_2 was 66.0 \pm 12.2 L for CON, 17.0 \pm 2.9 L for I-4, 30.4 \pm 6.9 L for I-7, and 44.3 \pm 10.4 L for I-10. EE for each exercise session was 323.5 \pm 60.1 kcal for CON, 84.2 \pm 19.5 kcal for I-4, 151.0 \pm 33.7 kcal for I-7, and 219.5 \pm 51.4 kcal for I-10. Average exercise HR was 133.8 \pm 4.1 for CON, 142.2 \pm 8.2 for I-4, 152.4 \pm 5.8 for I-7, and 152.4 \pm 5.7 for I-10. Recovery HR in first hour after exercise was higher after I-10 (82.3 \pm 6.4 beats/min) than after CON (75.4 \pm 8.4 beats \cdot min⁻¹) and I-4 (76.8 \pm 7.3 beats \cdot min⁻¹). Recovery HR in 2nd hour after exercise was higher after I-10 (70.8 \pm 8.1 beats \cdot min⁻¹) than after CON (66.7 \pm 6.7 beats \cdot min⁻¹) or I-4 (67.7 \pm 6.9 beats \cdot min⁻¹). Rate of EE was lower in 2nd hour after exercise for CON (1.04 \pm 0.15 kcal \cdot min⁻¹) than after I-10 (1.10 \pm 0.15 kcal \cdot min⁻¹) or I-4 (1.11 \pm 0.18 kcal \cdot min⁻¹). **CONCLUSIONS:** Though exercise VO_2 and EE associated with CON were significantly higher than those associated with any of the interval training sessions,

several markers of metabolic rate (HR, EE) were higher during recovery after I-10 than after CON. Differences in the recovery periods after interval training vs CON may partially explain reports that interval training results in similar or greater improvements in body composition when compared with continuous exercise, even with significantly lower exercise energy expenditure.

The Effects of Various Methods of Self Myofascial Release on Muscular Power
 Paul Weber, Robert M. Otto, FACSM, John Petrizzo, John W. Wygand, FACSM. *Adelphi University, Garden City, NY.*
 (Sponsor: Robert M. Otto, FACSM)
 Email: paulweber@mail.adelphi.edu
 (No relationships reported)

Myofascial release (MR) is purported to reduce friction between muscle and fascia, thus relaxing a muscle, improving local circulation, and stimulating the stretch reflex. Various forms of MR, including Self Myofascial Release (SMR) have evolved in an effort to improve function and performance. **PURPOSE:** The purpose of this study was to evaluate the effect of three different forms of SMR on muscular power. **METHODS:** 15 physically active adults (age: 27 \pm 4.4 yr., ht: 176.6 \pm 9.1 cm, body mass: 83.1 \pm 13.1 kg, 13 ♂) participated in a familiarization trial following informed consent. Familiarization consisted of proper methods of using 3 different modalities of SMR; foam rollers (FR), Myoballs (MB), and Tiger Tails (TT). Subjects performed the proper mechanics and execution of four tests of muscular power (MP): vertical jump (VJ), broad jump (Broad), right and left leg lateral bounds (LBR/LBL), and an 18.3 meter sprint (S). Subjects participated in four randomly assigned, crossover trials that were preceded by one minute of SMR with TT, MB, or FR on the quadriceps, IT Bands, gluteals, hamstrings, and calves. A control (C) trial was conducted with no SMR prior to the MP testing. Trials were separated by at least 48 hrs. Sprint time was recorded with concurrent, independent timing devices. For each MP test, 3 attempts were provided with the best score recorded for the trial. A recovery period of 15 seconds was given between each attempt, and 2 minutes were allowed between each test. One way ANOVA ($p < .05$) was applied to the data. **RESULTS:** VJ(cm): 51.8 \pm 8.3, 54.8 \pm 8.8, 55.3 \pm 8.6, and 54.3 \pm 10.4; Broad(cm): 215.9 \pm 29.9, 218.4 \pm 28.7, 221.7 \pm 28.9, and 218.9 \pm 28.4; LBR(cm): 176.5 \pm 21, 176.7 \pm 18, 178.3 \pm 18.7, and 176.5 \pm 17.2; LBL(cm): 173.4 \pm 12.1, 175.7 \pm 13.2, 177.2 \pm 14.4, and 177.2 \pm 16.5, and S(sec): 2.8 \pm .17, 2.8 \pm .12, 2.8 \pm .16, and 2.8 \pm .14 for C, FR, MB, and TT trials, respectively. Statistical analysis revealed no significant difference in MP among modalities. **CONCLUSION:** Although SMR did not improve measures of muscular power performance, it was not deleterious and may be considered a viable pre-activity preparation. Any potential benefits associated with SMR are subjective in nature and may be related to the relief of tension and DOMS.

Cold Water Immersions For Recovery In Young Female Handball Players
 Braulio Sánchez-Ureña¹, Ismael Martínez-Guardado², Marta Camacho-Cardeñosa², Alba Camacho-Cardeñosa², Rafael Timón², Guillermo Olcina², Jeffrey M. Mjaanes, FACSM³.
¹National University of Costa Rica, Heredia, Costa Rica. ²University of Extremadura, Cáceres, Spain. ³Northwestern University, Evanston, IL.
 Email: brau09@hotmail.com
 (No relationships reported)

Cold water immersion (CWI) is a recovery method used frequently in sport. Multiple studies indicate a potential role for CWI after training and competition in various sports. However, a critical review of the medical literature reveals a paucity of studies regarding use of CWI specifically in team handball. As a high intensity sport, handball is characterized by significant eccentric loading of the lower extremity musculature and therefore requires effective post-competitive recover strategies. **PURPOSE:** To compare the effect of two CWI protocols on markers of recovery in female handball players. **METHOD:** Twelve female handball players (Age: 14 \pm 0.7 years, body mass: 58.44 \pm 7.8 kg, Height: 161 \pm 7.1 cm, fat %: 21.5 \pm 3) were involved in a "cross-over" experimental design. After three game training sessions (Avg Heart Rate 183 \pm 9, 180 \pm 8 and 180 \pm 8 bpm respectively), participants were enrolled into either a CnCWI protocol (n=12), (12 min water temperature 14 \pm 0.5°C), InCWI protocol (n=11), (4x 2 min water temperature 14 \pm 0.5°C+1min out of water) or a control group (CG) with passive recovery (n=9) (sit in the room). Counter-movement Jump test (CMJ), Visual Analog Scale (VAS-Pain) and thigh volume were measured pre- and post-training, post-immersion, as well as 24 hours and 48 hours after training + recovery protocol. **RESULTS:** Statistically significant differences were found in DOMS ($F(4,116) = 6.84$, $P < 0.001$, $\omega^2: 0.32$) in post-immersion CnCWI vs. CG (5.08 \pm 0.8 vs. 6.6 \pm 0.86, $P < 0.001$) and InCWI vs. CG (5 \pm 0.76 vs. 6.66 \pm 0.86, $P < 0.001$). In the post 24h CnCWI vs. CG (5.08 \pm 0.81 vs. 7.22 \pm 0.97, $P < 0.001$) and InCWI vs. CG (4.72 \pm 0.81 vs. 7.22 \pm 0.97, $P < 0.001$). In post 48h CnCWI vs. CG (3.83 \pm 0.7 vs. 7.22 \pm 0.83, $P <$

0.001) and InCWI vs. CG (3.90 ± 0.92 vs. 7.22 ± 0.83 , $P < 0.001$). With regards to the percentage of change in CMJ and thigh volume, no statistically significant changes were seen in any of the times of measurement. **CONCLUSION:** Both CWI protocols appear effective in reducing delayed onset muscle soreness at all times post-training in female handball players. CWI should be included after training sessions to enhance players' recovery for the next training day. CWI protocol could be used according to individual preferences as both protocols used in this study demonstrated similar effects on psychological indicators of recovery, such as pain.

Effects Of A Short Intervention Of AIS And PNF On College Students' Shoulder Flexibility

Chunmei Cao¹, Chongyao Xiao¹, Jingmin Liu¹, Yu Liu², Weimo Zhu, FACSM³. ¹Tsinghua University, Beijing, China. ²Peking University, Beijing, China. ³University of Illinois at Urbana-Champaign, Urbana, IL. (Sponsor: Weimo Zhu, FACSM)
(No relationships reported)

(No relationships reported)
Both Proprioceptive Neuromuscular Facilitation (PNF) and Active Isolated Stretching (AIS) are widely used stretching techniques, but their difference in improving shoulder flexibility has not been evaluated.
PURPOSE: To compare the effects of a 2-wk AIS and PNF intervention on the flexibility of shoulder joints.
METHODS: Twenty male college physical education students (21.46 ± 1.18 yr., height: 172.91 ± 4.48 cm, mass: 74.37 ± 6.34 kg) without shoulder injury volunteered for the study. They were randomly divided into two intervention groups, one AIS and the other PNF intervention, with both met 5 times a week, 15 minutes each, for two weeks. Joint mobility (flexion and stretch) was measured by F-JDC type joint measurement scale before and after the intervention. Paired *t*-test and effect size (ES, Cohen's *d*) were calculated to determine the difference between AIS and PNF.
RESULTS: There was no statistical significant difference between the groups before the intervention. There were significant improvements in both groups ($P < 0.01$), but greater improvement was found in the post-intervention AIS group (flexion: 4.1 ± 0.86 ; stretch: 1.96 ± 0.003 ; $P < 0.001$).

Table: The change of shoulder flexibility before and after AIS and PNF

		Before	After	Difference	ES	P-value
AIS	flexion	$157.42 \pm 2.83^\circ$	$164.51 \pm 2.24^\circ$	$9.77 \pm 1.96^\circ$	2.78	<0.001
	Stretch	$34.37 \pm 1.44^\circ$	$37.91 \pm 0.92^\circ$	$5.72 \pm 0.56^\circ$	2.93	<0.001
PNF	flexion	$156.28 \pm 2.49^\circ$	$159.85 \pm 2.24^\circ$	$5.67 \pm 2.36^\circ$	1.51	0.003
	Stretch	$34.17 \pm 0.73^\circ$	$36.22 \pm 0.77^\circ$	$3.78 \pm 0.56^\circ$	2.73	<0.001

CONCLUSIONS: Both of the methods can improve the flexibility of the shoulder joints, but AIS shows more effective.

The Influence of Post-Exercise Cryotherapy on Circulating Testosterone

Andrew D. Sherman¹, Disa L. Hatfield¹, David R. Healy¹, William J. Kraemer, FACSM², Jacob E. Earp¹. ¹University of Rhode Island, Kingston, RI. ²Ohio State University, Columbus, OH. (Sponsor: William J. Kraemer, FACSM)
Email: Shermadr@uri.edu
(No relationships reported)

Cryotherapy is commonly used to improve muscle recovery from exercised induced damage. Recent studies have shown that use of post exercise cryotherapy can blunt adaptations in muscle hypertrophy and strength but the mechanism as to why is unclear. **PURPOSE:** To examine the effects of post-exercise cold water immersion (CWI) on free circulating testosterone (T). **METHODS:** Ten well-trained men [one repetition maximum (1RM) to body mass ratio: 1.65 ± 0.15], completed two resistance training sessions (6 sets of 10 repetitions at 80% of their 1RM for a smith machine squat) separated by 72 hrs. After each session subjects were given one of two recovery interventions prescribed in a randomized and counterbalanced order. These interventions were 1) 60 min of seated passive recovery (CON) or 2) 15 min of lower body cold water immersion (15°C) followed by 45 min of seated passive recovery (CWI). Venous blood samples were taken pre (PR) and immediately post (IP) and at 15, 30, and 60 min post exercise and an ELISA was used to measure T. Hormone levels were compared between interventions across all time points using a mixed model MANOVA with Bonferroni post hoc test ($p < 0.05$). **RESULTS:** No significant differences in T were found between the CWI or CON at any time point: PR (15.24 ± 7.64 ; 14.25 ± 8.95 ; $p = 0.374$), IP (CWI = 20.45 ± 13.11 ; CON = 22.75 ± 22.22 ; $p = 0.514$), 15 min (CWI = 18.03 ± 9.33 ; CON = 20.21 ± 18.20 ; $p = 0.556$), 30 min

(CWI = 17.10 ± 11.75 ; CON = 16.42 ± 11.34 ; $p = 0.662$) and 60 min (CWI = 13.70 ± 7.82 ; CON = 16.55 ± 15.16 ; $p = 0.321$). Additionally, no significant differences were found between recovery interventions in T area under the curve (CWI = 1014; CON = 1091 $p = 0.588$). **CONCLUSIONS:** Post exercise T showed no significant differences after CWI, suggesting that diminished T response from CWI is not responsible for the mitigation of hypertrophy observed from chronic use of cryotherapy previously observed. Rather, changes in inflammatory markers or immune response post CWI may be the cause of this reduced hypertrophic responses. Future research exploring the relationship between cryotherapy and testosterone may benefit from investigating colder water temperatures or other forms of cryotherapy.

Pneumatic Compression Device Speeds Recovery from DOMS in Comparison to Compression Sleeve

Molly R. Winke, Shelby Williamson. Hanover College, Hanover, IN. (Sponsor: Bryant Stamford, FACSM)
Email: winke@hanover.edu
(No relationships reported)

Delayed onset muscle soreness (DOMS) is known to decrease range of motion (ROM), increase muscle swelling, and increase perception of pain in the affected muscle. Wearing compression garments during recovery from DOMS has been demonstrated to reduce both the recovery time and the peak disturbance in these variables when compared to no treatment. **PURPOSE:** To determine the effects of a pneumatic compression device (PCD) compared to a compression sleeve (CS) during a 5-day recovery period from DOMS of the elbow flexors. **METHODS:** Eight college-aged students participated in this crossover design study. Upper and lower arm circumference were measured to determine muscle swelling; pain during elbow flexion and elbow extension was measured using a 0 - 100mm visual analog scale to determine muscle soreness; flexion and extension ROM were measured to determine joint mobility. The muscle-damage protocol consisted of 4 sets of 25 repetitions of isokinetic concentric elbow flexion followed by eccentric elbow extension. Immediately following the muscle-damage protocol, subjects either wore a CS continually for five days or completed daily, 20-minute PCD treatments for 5 days. Swelling, ROM, and pain were measured pre- and post-exercise, and daily during the 5-day recovery period. Subjects rested for 7 days before completing another muscle-damage protocol and the remaining treatment. Repeated measures ANOVA was used to determine differences between treatments. **RESULTS:** PCD significantly reduced increases in upper arm circumference (1.7 vs. 2.0 cm), flexion pain (24.4 vs. 34.3mm), extension pain (30.8 vs. 41.4mm), and minimized reductions in flexion ROM (15.9 vs. 25 degrees) and extension ROM (2.5 vs. 4.1 degrees). There were no differences in lower arm circumference. Non-significant interaction effects between time and treatment suggest that the time course of DOMS recovery was similar between trials. However, because the PCD disturbances from baseline were lower, measurements returned to baseline earlier in the PCD trial. **CONCLUSIONS:** These findings suggest that daily treatments using a PCD further reduce peak disturbance and recovery time from DOMS of the elbow flexors when compared to a continuously-worn CS.

Effects of Compression Socks on Muscle Recovery in Competitive Masters Endurance Athletes

Brittany M. Steers, John Farmer, IV, Jennifer Kirk-Sorrow, C. Matthew Lee, PhD, Marialice Kern, PhD, FACSM, James R. Bagley, PhD. San Francisco State University, San Francisco, CA. (Sponsor: Marialice Kern, PhD, FACSM)
Email: bsteers@mail.sfsu.edu
(No relationships reported)

Purpose: Compression socks are a popular recovery modality in endurance sports. We investigated the efficacy of compression (COM) vs placebo (PLA) socks on perception of muscle fatigue/soreness and functional recovery in Masters athletes. **Methods:** Four competitive male triathletes participated (age: 49 ± 8 yr; height: 176 ± 14 cm; mass: 83.0 ± 13.3 kg; body fat: $23 \pm 7\%$; ≥ 18 mo run training, ~ 2.3 h/day, ~ 5.5 day/wk). During Visit 1, participants underwent calf circumferences (CIR) and dorsiflexion range of motion (ROM) measures, completed fatigue/soreness surveys, and performed a timed 1-mile run. Then, participants completed a fatiguing protocol (6 sets, weighted calf raises to failure) and were randomly assigned to wear either COM or PLA socks for 48-h. Visit 2 (48-h post) consisted of CIR/ROM measures, surveys, and 1-mile run. Participants were assigned the sock type not previously given and completed the same protocols during Visits 3-4. T-tests determined differences 48-h after fatigue with COM and PLA socks ($p \leq 0.05$). **Results:** Perception of muscle fatigue and soreness [scores: 1 (least)-10 (most); taken pre-, 24-h, and 48-h post] tended to increase 24-h [vs pre (fatigue: PLA: $+1.00$; COM: $+1.75$ points)(soreness: PLA: $+1.00$; COM: $+2.25$ points)] and 48-h [vs pre (fatigue: PLA: $+2.50$; COM: $+2.75$ points)(soreness: PLA: $+2.75$; COM: $+2.75$ points)] after the fatiguing protocol, but no significant differences existed between sock types ($p > 0.05$). Compared to pre-fatigue, calf CIR was similar (48-h post) with both socks

($p > 0.05$). Dorsiflexion ROM tended to decrease 48-h post-fatigue using both socks, but was not statistically significant [right (PLA: $p = 0.22$; COM: $p = 0.24$); left (PLA: $p = 0.06$; COM: $p = 0.19$)]. Additionally, 1-mile run time was not affected by COM (pre: 8.5 ± 1.9 min; 48-h: 8.5 ± 2.0 min; $p = 0.24$) or PLA socks (pre: 8.7 ± 2.0 min; 48-h: 8.3 ± 1.7 min; $p = 0.07$).

Conclusion: COM had no significant effects on objective and subjective measures of recovery after a fatiguing exercise. Interestingly, 50% participants reported "feeling like" COM helped them recover (vs. PLA). Large interindividual differences in perception of soreness existed among participants, highlighting the importance of collecting more data on Masters athletes to make conclusive recommendations on the use of these popular recovery modalities.

Acute Effects of Two Different Foam Rollers on Range of Motion

Isaac D. Henry, Jacilyn Olson, Melissa Powers, Jill Robinson, Ed Cunliff. *University of Central Oklahoma, Edmond, OK.*
 Email: ihenry@uco.edu

(No relationships reported)

Self-myofascial release via foam rolling does not yield significant acute effects on muscular performance, but it can yield benefits to range of motion (ROM) similar to static stretching, without the negative effects to muscular performance. Additionally, exercising through larger ROM during resistance training will produce superior chronic benefits. **PURPOSE:** Therefore, the aim of this study was to determine if differences existed between the acute effects two different foam rollers had on hip and shoulder ROM. **METHODS:** Ten college students participated in a random cross over design study. Participants' hip and shoulder ROM were measured with a goniometer pre and post three different conditions: control, supernova (SN), and grid. The first session consisted of taking pre ROM measurements followed by 10 minutes of rest and post ROM measurements (control). Then the participants were familiarized with the foam rolling procedures that were used for the next two sessions. During the next two sessions the control trial procedures were repeated, except instead of resting between pre and post testing the participants foam rolled using one of the foam rollers. **RESULTS:** Repeated measures ANOVA followed by protected dependent t tests revealed that significant ($p < .05$) differences existed between control and SN, control and grid, but not between SN and grid ($p > .05$). Effect sizes revealed that when comparing mean differences from pre to post for SN and grid: a large effect was seen for shoulder extension ($d = -.80$) in favor of SN, moderate effects were observed for shoulder flexion ($d = -.50$) in favor of SN, hip flexion ($d = -.62$) in favor of SN, and hip abduction ($d = .57$) in favor of grid. **CONCLUSION:** Both foam rollers produced similar acute improvements to hip and shoulder ROM, which were significantly better than the control condition. When improvements to ROM are desired prior to resistance training, the use of either foam roller in this study would be preferred over static stretching or no mobility exercises.

Effect of Cooling on Postmatch Recovery in Elite Volleyball Players in Warm Conditions

Nihel GHOUL¹, Montassar TABBEN², Karim CHAMARI³, Claire TOURNAY⁴. ¹Faculty of Sport Sciences, Laboratoire MOVE (EA 6413), Poitiers, France. ²ASPREV, ASPETAR, Orthopedic and Sports Medicine Hospital, Doha, Qatar. ³Athlete Health and Performance Research Center ASPETAR, Orthopedic and Sports Medicine Hospital, Doha, Qatar. ⁴Faculty of Sport Sciences, CETAPS EA 3832, Rouen, France.

(No relationships reported)

PURPOSE: The purpose of this study was to determine the effect of a single 14 min of contrast water therapy (CWT) or cold shower (CS) on recovery postmatch in elite volleyball players performed in warm conditions

METHODS: Ten volleyball players completed a 60 min simulated match play in the heat followed randomly by 1 of 3 recovery modalities: (a) CWT consisted of alternating cold (12°C) and hot (38°C) water immersion, (b) CS (20°C), and (c) Passive recovery (PAS; ambient temperature). Blood plasma markers levels (Lactate, Glucose, Fatty acids, Triglycerides, Total cholesterol, Urea, Apolipoproteins: apoB, apoA-I), inflammatory proteins (C-reactive protein, Orosomucoid, Albumin and Haptoglobin) were collected pre-match and immediately after recovery. Vertical jump, agility and speed performances, body temperature and perceived fatigue were also measured pre-match, and immediately after each recovery modality

RESULTS: Plasma concentrations of physiological biomarkers showed a significant changes after all recovery modalities, while concentration of Albumin remained unchanged in passive recovery compared to CWT and CS. After CWT, a significant improvement in lower-limbs power was observed during squat jump and agility performance ($p < 0.05$). Conversely, the CS resulted in a decrease of the lower-limbs power during counter-movement jump but improved start sprint speed. There was a

significant ($p < 0.05$) attenuation in RPE and perceived leg fatigue for all groups with CWT and CS being more successful than PAS (2 ± 0.9 ; 2 ± 1.0 ; 4 ± 1.9). However body temperature was significantly lower (-0.58°C) after CS compared with CWT and PAS modalities

CONCLUSIONS: There is no evidence that cold and contrast water immersions appear to promote better physiological responses. However the observed positive effect on perceived leg fatigue and temperature suggest that cold and contrast water therapy may be effective for players performing in the heat

Decrease muscle soreness by medical tape is supported by the literature. Subjects: Twenty normal subjects ranging in age from 18 to 55 with no history of previous skin allergy and do not have any upper body injuries participated.

PURPOSE: To assess the efficacy of the cross tapes in muscle soreness.

METHODS: Subjects will perform the lowering phase of a bicep curl exercise using a dumbbell consisting of 3 sets 25 repetition, followed 90 seconds rest between each set. A grid shaped adhesive, a little larger than a stamp, called a cross tapes will be applied in the bicep of the dominant hand and the other hand as control for one week. The range of motion and pain for both arms will be measured before and after applied the tape.

RESULTS: The study findings show that there were statically significant difference between the ROM and the pain (pre, post) when the procedure is carried out over a period of two consecutive weeks (1 day per week) with large effect size (0.2) and strong power (0.96). However; there were no significant differences between the two groups (right, left arms) with medium effect size (0.1) and weak power (0.33).

CONCLUSIONS: Therefore, this study suggest that cross tapes may reduce delayed onset muscle soreness, however more research is needed. Future studies should include a larger number of subjects, more diverse cohort, an exercise that applies a greater intensity, and expands the time of research. CT is an advisable method to decrease DOMS and improved functional performance.

Combined Effects of Cold Water Immersion and Compression Garment after Exercise on Muscle Damage Markers

Maruyama Tatsuhiro, Sahiro Mizuno, Kazushige Goto. *Ritsumeikan University, Kusatsu, Japan.* (Sponsor: ROobert R. Kraemer, FACSM)

Email: maruyama.t.route@gmail.com

(No relationships reported)

Cold water immersion (CWI) and compression garment (CG) are popular post-exercise treatments for reducing exercise-induced muscle damage. Although efficacy of CWI and CG has been already reported, combined effect of these post-exercise treatments remains unclear. **PURPOSE:** To investigate the effect of combined treatment of CWI and wearing CG after maximal eccentric exercise on recovery of muscular strength and indirect muscle damage markers. **METHODS:** Six males performed two trials (TRE, CON) in random order. In the TRE trial, the subjects performed 15min of cold water immersion (15°C) followed by wearing a lower body CG for 24 h after the exercise, whereas no post-exercise treatment was conducted in the CON trial. The exercise consisted of 10×6 maximal isokinetic (60°/s) eccentric knee extension using unilateral leg, and exercised leg was randomly selected in each trial to avoid repeated bout effect for the same muscle groups. Time course changes in maximal voluntary contraction (MVC) and isokinetic (60°/s) strength for knee extension, score of muscle soreness, muscle thickness of quadriceps femoris were evaluated before exercise and post-exercise period. Blood sample was drawn to investigate blood glucose and lactate, serum creatine kinase (CK) and myoglobin (Mb) concentrations before exercise, 3 h and 24 h after exercise. **RESULTS:** Total work volume during eccentric exercise did not significantly differ between the two trials ($P > 0.05$). MVC and maximal isokinetic strength were markedly decreased during post-exercise period in both trials ($P < 0.05$), and these responses were not significantly different between the trials. Serum CK and Mb concentrations were significantly elevated during post-exercise period in both trials ($P < 0.05$). However, area under the curve for Mb concentration during exercise and 3 h of post-exercise period significantly lowered in the TRE trial (196 ± 31 ng/ml) compared with the CON trial (260 ± 50 ng/ml) ($P = 0.04$). No significant difference was observed between trials for time-course changes in other variables.

CONCLUSION: CWI followed by wearing CG after maximal eccentric exercise did not facilitate recovery of muscular strength. However, exercise-induced increase in Mb was significantly attenuated when the combined treatment of CWI and CG was applied.

scale of 5 (best) to 1 (worst). **Results:** Twenty eight female soccer players (14.3-17.9 years) and 23 female basketball players (12.6-16.0 years) were included. Average VO_{2peak} was 48 and 47.9 ml/kg/min, respectively. Forward soccer players had a better VO_{2peak} comparing to other positions (goalkeepers=42.2, defenders=48.4, midfield=47.3, forwards=54.7 ml/kg/min). Soccer coach playing ability (average=4.21) and fitness estimation (average=3.96) did not correlate with VO_{2peak} results (Correlation Coefficient= 0.292, $p=0.13$ and 0.257, $p=0.18$ respectively). Center basketball players had the lowest and point guards the highest average VO_{2peak} (centers=34.2, forwards=44.6, guards=50.5 and point guard=53.1 ml/kg/min). Basketball coach playing ability (average=3.14) and fitness estimation (average=2.86) correlate with VO_{2peak} results (Correlation Coefficient= 0.464, $p=0.03$ and 0.547, $p=0.008$ respectively). **Conclusions:** Adolescent female soccer and basketball players at different playing positions exhibited different VO_{2peak} values as reported in the literature. Basketball coaches' estimation of aerobic fitness and general playing ability were associated with VO_{2peak} results whereas soccer coaches' estimation did not. VO_{2peak} may be considered as a parameter for team selection of ball game players game players, however in light of the inconclusive results, further research is required.

Association Between Genu Valgus And Physical Activity, Adjusted To Chronological Age In Brazilian Males Adolescent

Andrea Cassimiro de Oliveira, Rafael Benito Mancini, João Pedro da Silva Junior, Luis Carlos de Oliveira, Timoteo Leandro de Araujo, Victor Matsudo. *CELAFISCS, SÃO CAETANO DO SUL, Brazil.*

(No relationships reported)

PURPOSE: Genu valgus interferes negatively in physical activities of moderate and moderate to vigorous intensity among Brazilian females adolescent students, which may be a negative factor for an active lifestyle. **Objective:** To analyze the association between genu valgus and physical activity level (PAL), categorized in: total, light, moderate, vigorous and moderate to vigorous intensity, adjusted to chronological age in male adolescent students.

METHODS: sample comprised 270 male students, 30 boys in each age group, aged 10-18 years (14.0 ± 2.6), and living in the city of Ilhabela, Brazil. Genu valgus was evaluated using a goniometer, measuring the intermalleolar distance (cm). Physical activity behavior in different intensities (minutes per week) was assessed by the International Physical Activity Questionnaire (IPAQ). Statistical analysis has used multiple linear regression adjusted to chronological age.

RESULTS: There was no association ($p>.05$) between intermalleolar distance and total ($\beta=.475$), light ($\beta=4.843$), moderate ($\beta=2.012$), vigorous ($\beta=.412$) and moderate to vigorous ($\beta=2.423$) physical activity level.

CONCLUSIONS: Genu valgus does not interfere in different levels of physical activity (total, light, moderate, vigorous and moderate to vigorous) among males adolescent students.

The association between genu valgus and physical activity level, adjusted to the chronological age in Brazilian males adolescent students

Males (n=270)				
IM: 3.15 ± 1.80 cm				
Variables	B	p	R ²	IC 95%
Total PA (min/w)	.475	.917	.014	-5.542; 9.493
Light PA (min/w)	4.843	.223	.05	-2.964; 12.65
Moderate PA (min/w)	2.012	.577	.005	-5.078; 9.101
Vigorous PA (min/w)	.412	.73	.007	-1.932; 2.755
MV PA (min/w)	2.423	.52	.005	-4.989; 9.836

$p < .05$; association between genu valgus and level of physical activity (PAL). IM: Intermalleolar distance; PAL: physical activity level; min/w: minutes per week; MV: moderate to vigorous.

Association Between Waist-to-Height Ratio And Fitnessgram® BMI Classification In Sixth-grade Children

John L. Walker, FACSM¹, Tinker D. Murray, FACSM¹, James Eldridge, FACSM², William G. Squires, Jr., FACSM³. ¹Texas State University, San Marcos, TX. ²University of Texas of the Permian Basin, Odessa, TX. ³Texas Lutheran University, Seguin, TX.

Email: jw18@txstate.edu

(No relationships reported)

FITNESSGRAM has established criterion standards for body composition and body mass index (BMI) according to gender and age in children. Standards for aerobic capacity (AC) have also been established to assess cardiorespiratory function. Waist-to-Height ratio (WHtR) has been shown to be a strong indicator of metabolic syndrome in youth. **PURPOSE:** The purpose of this study was to determine the association between WHtR and FITNESSGRAM BMI classification in sixth-grade children. **METHODS:** Subjects were 528 sixth-grade boys and girls, ages 11-13,

who completed each of the FITNESSGRAM components as a part of their yearly assessment. In addition to height and weight, subjects were also measured for waist circumference. AC was determined from one-mile run/walk times, age, gender and BMI. The percent of these students classified within the Healthy Fitness Zone (HFZ) were 46% for BMI, and 52% for AC. The percent of these students classified as High Risk were 43% for BMI, and 31% for AC. **RESULTS:** The correlation between WHtR and BMI was .92, and the correlation between BMI and AC was -.75. The correlation between WHtR and AC was -.70. Receiver Operating Characteristic (ROC) analysis indicated that a WHtR of 0.451 represents the best cut-off score for classifying girls within the HFZ for BMI, with 91% classified correctly, and AUC = .96. Also, a WHtR of 0.475 represents the best cut-off score for classifying boys within the HFZ for BMI, with 90% classified correctly, and AUC = .95. For determining High Risk classification for BMI, a WHtR of 0.476 represents the best cut-off score for classifying girls as High Risk for BMI, with 90% classified correctly, and AUC = .96. Also, a WHtR of 0.484 represents the best cut-off score for classifying boys as High Risk for BMI, with 94% classified correctly, and AUC = .97. **CONCLUSIONS:** WHtR is strongly associated with classification according to FITNESSGRAM BMI standards in sixth-grade children. These data suggest that a WHtR of .451 for girls and .475 for boys are the best criteria for HFZ classification for FITNESSGRAM BMI. Also, a WHtR of .476 for girls and .484 for boys are the best criteria for High Risk classification for FITNESSGRAM BMI. Reduction of WHtR may provide important benefits since children in the High Risk category are most likely to develop problems related to metabolic syndrome as adults.

Correlation Between Varying Back Squat Depths On Speed And Vertical Jump Performance In North American High School Football Players

Nicholas Farrell¹, Kent J. Adams, FACSM², Joseph Berning, FACSM³, Mark DeBeliso, FACSM¹. ¹Southern Utah University, Cedar City, UT. ²California State University Monterey Bay, Seaside, CA. ³New Mexico State University, Las Cruces, NM.

(Sponsor: Mark DeBeliso, FACSM)

Email: nicholasfarrell@suemail.net

(No relationships reported)

The back squat exercise is perhaps the most popular and most effective exercise for developing lower body musculature. Development of the lower body musculature is paramount for increasing ground reaction forces which in turn can translate to increased explosiveness in movements such as sprinting or vertical jumping (VJ). For athletes in particular, developing lower body strength can be of utmost importance. There is however dispute over which back squat depth is most optimal. **PURPOSE:** This study attempted to determine which of two back squat depths (90 degree knee flexion or 45 degree knee flexion) would correlate with superior sprint times and VJ performance. **METHODS:** Participants were high school aged males on a North American football team (age: 15.1 ± 0.9 yrs, mass: 77.0 ± 13.2 kgs). Twenty three athletes performed the 36.6 meter (36.6M) sprint and VJ tests along with performing a 3RM back squat at 90 and 45 degrees of knee flexion on randomized separate days. A Pearson Correlation Coefficient (r) test was used to compare the squat scores with sprint times and VJ performance. **RESULTS:** Variable measures were 36.6M: 5.23 ± 0.26 secs, VJ: 59.6 ± 6.6 cms, 90° 3RM squat: 116.1 ± 21.0 kgs, and 45° 3RM squat: 132.1 ± 22.2 kgs. Low correlations were found at both knee flexion angles: 90° 3RM squat ($36.6M_r = -0.32$, $VJ_r = 0.33$, $p < 0.01$), and 45° 3RM squat ($36.6M_r = -0.31$, $VJ_r = -0.33$, $p < 0.01$). However, moderate correlations were revealed when comparing the 3RM back squat/body mass ratio with the participant's 36.6M sprint times ($90_r = -0.46$, $45_r = -0.46$, $p < 0.01$). **CONCLUSIONS:** Within the parameters of this study, low to moderate correlations were determined between back squat strength and sprint speed as well as VJ at both 90 and 45 degrees of knee flexion.

Metabolic Cost of Battling Rope Exercise in Children

Avery D. Faigenbaum, FACSM, Jie Kang, FACSM, Anne Farrell, Nicholas A. Ratamess, Stephanie Golda, Andrew Stranieri, Jordan Coe, Jill A. Bush, FACSM. *The College of New Jersey, Ewing, NJ.*

Email: faigenba@tcnj.edu

(No relationships reported)

Battling ropes (BR) are an effective mode of conditioning for adults, but the efficacy of BR exercise for children is unknown. **PURPOSE:** To examine the acute metabolic cost of BR exercise in children. **METHODS:** 15 boys (10.6 ± 1.4 yr) were tested for peak oxygen uptake (VO_{2peak}) on a treadmill and subsequently (≥ 48 hours later) performed a progressive 10 min BR protocol of 5 exercises (EX#: repetitions): standing side to side wave (EX1; 30), seated alternating wave (EX2; 60), standing alternating wave (EX3; 60), jumping jacks (EX4; 20) and double arm slams (EX5; 20). Each BR exercise was performed twice for 30 sec with a 30 sec rest interval between sets and exercises while connected to a metabolic system. A metronome was used to standardize cadence

and a 12.8 m rope (4.1 kg) was used for all trials. Comparisons between exercises were made using one-way ANOVA with repeated measures. **RESULTS:** Peak values for VO₂ and HR during the treadmill test were 47.4 ± 8.8 ml/kg/min and 195.1 ± 6.6 bpm, respectively. Mean HR and VO₂ values for both sets of each exercise during the BR protocol were 52.7% to 84.1% and 21.5% to 60.1% of HR_{peak} and VO_{2peak}, respectively. During the BR protocol, there were progressive increases in VO₂ and HR from EX1 to EX5. Results of pairwise comparisons of VO₂ and HR among five BR exercises are below (mean ± SD):

	EX1	EX2	EX3	EX4	EX5
HR (bpm)	103.3 ± 11	124.1 ± 15 ¹	148 ± 16 ^{1,2}	147 ± 14 ^{1,2}	164 ± 11 ^{1,2,3,4}
VO ₂ (ml/kg/min)	10.2 ± 2	12.7 ± 3 ¹	18.1 ± 3 ^{1,2}	23.1 ± 3 ^{1,2,3}	28.5 ± 3 ^{1,2,3,4}

p<0.05 ¹vs EX1; ²vs EX2; ³vs EX3; ⁴vs EX4

CONCLUSION: These data indicate that BR exercise can pose a moderate to vigorous metabolic and cardiovascular stimulus in children with the mean effects augmented with the use of exercises requiring greater muscle mass.

Changes in VO₂max are Not Associated with Ventricular Morphology or Function in Female Youth Athletes
 Carol Coutinho, Andrew Watson, Stacey Brickson. *University of Wisconsin-Madison, Madison, WI.*
(No relationships reported)

While the relationship between fitness changes and ventricular morphology and function has been studied in adults and in cross-sectional studies with children, we are aware of no prior research which has evaluated this relationship in female youth athletes longitudinally.

PURPOSE: To determine if changes in maximal aerobic capacity are associated with changes in ventricular morphology or systolic function in female youth athletes.

METHODS: 26 female soccer athletes (ages 13-18) underwent resting 2-D echocardiography and maximal aerobic testing at two time points 7 months apart to determine, maximal aerobic capacity (VO_{2max}), left ventricular (LV) end-diastolic diameter (LVEDD), right ventricular (RV) end-diastolic diameter (RVEDD), LV mass (LVM), RV area in diastole (RVAD), RV area in systole (RVAS), LV shortening fraction (LVSF), RV fractional area change (RVFAC), interventricular septal wall thickness (IVWT), and LV posterior wall thickness (LVPWT). Echocardiographic and fitness variables were compared at the two time points using paired Wilcoxon tests and Cohen's d. Linear regression models were used to predict changes in VO_{2max} using changes in echocardiographic variables as predictors.

RESULTS: During the study period, no significant change in VO_{2max} was identified (2.61 ± 32% v 2.62 ± 32%, p = 0.75, d=0.05). A significant decrease was identified in RVFAC (44 ± 10% v 36 ± 5%, p = 0.02, d=-0.61). No significant differences were identified in any other echocardiographic or fitness variables (p>0.05 for all). None of the changes in echocardiographic variables were significant predictors of change in VO_{2max} (β=-0.33 to 0.50, p>0.05 for all)

CONCLUSION: During the 7 month study period, no changes were identified in VO_{2max} or ventricular size. The reason for the significant decrease of RVFAC is unclear but could be due to increased afterload or decreased RV contractility. Also, none of the echocardiographic variables were significant predictors of change in VO_{2max} during the study period. While this suggests that changes in aerobic capacity may not be related to changes in ventricular size or function, it is also possible that the changes in these variables during the study period were not large enough to demonstrate meaningful relationships between them.

3752 Board #199 June 3 8:00 AM - 9:30 AM
Muscle Strength Thresholds For The Detection Of Cardiometabolic Risk Among Colombian Children And Adolescents: The Fuprecol Study
 Jhonatan Camilo Peña-Ibagon¹, Felipe Lobelo², Antonio García-Hermoso³, Daniel H. Prieto-Benavidez¹, Jorge E. Correa-Bautista¹, Robinson Ramírez-Vélez¹. ¹Centro de Estudios para la Medición de la Actividad Física «CEMA». *Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá D.C, Co, Bogota, Colombia.* ²Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA. ³Laboratorio de Ciencias de la Actividad Física, el Deporte y la Salud, Universidad de Santiago de Chile, Santiago, Chile.
 Email: robin640@hotmail.com
(No relationships reported)

PURPOSE: Evidence shows an association between muscular strength (MS) and health among youth, however low muscular strength cut-points for the detection of

high metabolic risk in Latin-American populations are scarce. The aim of this study was two-fold: to explore potential age- and sex-specific thresholds of MS, for optimal cardiometabolic risk categorization among Colombian children and adolescents; and to investigate if cardiometabolic risk differed by MS group by applying the receiver operating characteristic curve (ROC) cut point.

METHODS: MS was estimated by a handle dynamometer on 1,950 children and adolescents from Colombia, using the MS relative to weight (handgrip strength/body mass). A metabolic risk score was computed from the following components: waist circumference, triglycerides, HDL-c, glucose, systolic and diastolic blood pressure. ROC analysis showed a significant discriminatory accuracy of MS in identifying the low/high metabolic risk in children and adolescents and both gender.

RESULTS: ROC analyses showed a significant discriminatory accuracy for the identifying the low/high CMRI in both gender and age group (AUC=0.83 (95%CI: 0.71-0.95), p< 0.001; boys AUC= 0.84 (95%CI: 0.74-0.94), p< 0.001; adolescents girls AUC=0.79 (95%CI: 0.70-0.89), p< 0.001; boys AUC= 0.88 (95%CI: 0.68-0.92), p< 0.001). In children (9 to 12.9 years old), handgrip strength (kg)/body mass (kg) values at these points were 0.359 and 0.376 in girls and boys, respectively. In adolescents (13.0 to 17.9 years old), these points were 0.440 and 0.447 in girls and boys, respectively

CONCLUSIONS: In conclusion, the results suggest a hypothetical MS level relative to weight for having a low metabolic risk, which could be used to identify youths at risk.

3753 Board #200 June 3 8:00 AM - 9:30 AM
Maximal Oxygen Uptake Equations To Discriminate The Cardiometabolic Risk In Colombian Children And Adolescents: The Fuprecol Study
 Jorge E. Correa-Bautista¹, Andres Vivas², Jorge Mota³, Antonio Garcia-Hermoso⁴, Daniel H. Prieto-Benavidez¹, Robinson Ramirez-Vélez¹. ¹Centro de Estudios para la Medición de la Actividad Física «CEMA». *Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá D.C, Co, Bogota, Colombia.* ²Grupo de Investigación en Ejercicio Físico y Deporte. *Vicerrectoría de Investigación, Universidad Manuela Beltrán, Bogotá, D.C, Colombia, Bogota, Colombia.* ³Research Centre in Physical Activity, Health and Leisure, Faculty of Sport, University of Porto, Porto, Portugal. ⁴Laboratorio de Ciencias de la Actividad Física, el Deporte y la Salud, Universidad de Santiago de Chile, Santiago, Chile.
 Email: robin640@hotmail.com
(No relationships reported)

PURPOSE: Associations between maximal rate of oxygen uptake (VO_{2max}) and cardiometabolic risk have not been adequately studied in Colombian children and adolescents. The aim of the present study was two-fold: (i) to determine the ability of eight different VO_{2max} equations to discriminate between low and high cardiometabolic risk; and (ii) to determine cardiorespiratory fitness (CRF) thresholds associated with a more favourable cardiovascular health profile in Colombian children and adolescents.

METHODS: CRF was estimated by the 20 m shuttle run test on 2,870 schoolchildren (54.5% girls) from Bogota (Colombia). We computed a metabolic syndrome score (MetScore) as the sum of the age-sex standardized scores of waist circumference, triglycerides, HDL-c, glucose, systolic and diastolic blood pressure.

RESULTS: Linear regression analyses showed that the Barnett et al. (b) and Mahar equations were negatively associated to MetScore showing the highest discriminatory accuracy for identifying the low/high cardiometabolic risk in both sexes and age group (9-12 and 13-17 years old). Therefore, we are proposing to use Barnett et al. (b) equation [Boys and girls: VO_{2max} = 25.8 x 6 x G + 1 x 0.2 x body mass + 3.2 x final speed] in Colombian youths to classify youths at metabolic risk.

CONCLUSIONS: The CRF cutoffs can be used as a quantitative marker of healthier cardiovascular profile Colombian in children and adolescents.

Maturational Timing and Adolescent Swim Performance
 Sierra L. Wagner¹, Andrew Cornett¹, Alan Duski¹, Brian Wright², Joel Stager, FACSM³. ¹Eastern Michigan University, Ypsilanti, MI. ²DePauw University, Greencastle, IN. ³Indiana University, Bloomington, IN. (Sponsor: Joel Stager, FACSM)
 Email: swagne11@emich.edu
(No relationships reported)

Beunen et al. (1978) found that the early maturers in their sample of non-athletic girls performed better on simple motor tasks than the late maturers early in adolescence, but that the late maturers performed better than the early maturers late in adolescence. Purpose: To determine if the same relationship between maturational timing and

performance exists when high-level athletes execute complex motor tasks. Methods: NCAA women swimmers (N = 254) completed an online questionnaire in which they provided age, height, weight, swimming history, and age at menarche (AaM). We divided the sample into early-, average-, and late-maturing groups using AaM. We utilized the USA Swimming (USAS) performance database to identify individual performances for each swimmer at three adolescent phases: (1) early adolescence (12 years old), (2) middle adolescence (15 years old), and (3) late adolescence (18 years old). Each performance in the USAS database equates to a standardized score called a Power Point Score (PPS). We selected the highest PPS for each swimmer at the three adolescent phases. We analyzed the data using a Two-way Mixed Design ANOVA. Results: Mean AaM values for the early-, average-, and late-maturing groups were 12.0 years (95% CI, 11.8 to 12.2), 13.4 years (95% CI, 13.3 to 13.5), and 15.4 years (95% CI, 15.2 to 15.6). We identified performances for 173 of the 254 respondents (68.1%) in the USAS database at all three adolescent phases. We detected a significant two-way interaction ($F_{4,334} = 5.8, P < 0.001$), which indicated that the effect of maturational timing on swim performance differed by adolescent phase. Mean PPS for the early, average, and late maturers during early adolescence was 496.4, 494.8, and 480.0, whereas mean PPS during middle adolescence was 664.4, 683.1, and 721.3. Thus, the late maturers improved more (62.6%) from early to middle adolescence than the average (47.0%) and early (45.2%) maturers. In contrast, swim performance improved to a similar extent for the three groups from middle to late adolescence. Conclusion: Our results extend Beunen et al.'s findings by showing that early-maturing swimmers have a performance advantage over late-maturing swimmers during early adolescence. But by middle adolescence, the late maturers have a performance advantage that is maintained into late adolescence.

Which One Is The Decisive Factor To Cognition Performance In Preschool Children Aged 3.5 To 4.5 Years Old, Aerobic Fitness Or Agility?: A Cross-sectional Study In Shanghai, China

Ru Wang, female¹, Pengcheng Xun, male², Guoyuan Huang, male³, Tang Zhou, female¹, Minghui Quan, male¹, Hui Fang, female¹, Xueqiang Wang, male¹, Weihua Xiao, male¹, Jian Liu, male², Jiayi Zhang, female¹, Hanbin Zhang, male¹, Guanggao Zhao¹, Ying Zhang, female¹, Liping Lu, female¹, Zhenbo Cao, male¹, Yu Liu, male¹, Ka He, male², Peijie Chen, male¹.
¹Shanghai University of Sport, Shanghai, China. ²Indiana University, Bloomington, IN. ³University of Southern Indiana, Evansville, IN.
Email: wangru0612@163.com
(No relationships reported)

Purpose: This cross-sectional study was to compare the associations of aerobic fitness and agility with cognition performance in preschool children. **Methods:** A total of 346 preschool children (age 3.5-5.5 yr old) with 201 boys and 145 girls were recruited from eight preschools in Yangpu, Shanghai, China. After enrolled in this study (Trial Registration: clinicaltrials.gov NCT00674544), the young children were asked to perform a comprehensive package of tests including physical fitness and cognitive function. Children's scores on the tests of 10-m Shuttle Run (time; this test can be used to determine speed and agility performance, and elite players will use less time than the subelite participants) and 20-m Shuttle Run (laps; this test can be used to determine aerobic fitness performance, and elite players will have more laps than the subelite participants), Verbal Intelligence Quotient (VIQ), Performance Intelligence Quotient (PIQ), and Full Intelligence Quotient (FIQ) were assessed. Correlation coefficients were determined by conducting Pearson product-moment and Spearman's rho analyses. Linear regression analyses were used to examine the associations of cognitive performance with aerobic fitness and agility in a sequential manner. Descriptive data were reported as mean±SD. Statistical significance was set at a p-value < 0.05. **Results:** After adjustment for age, gender, BMI, physical activity, nutrition status, sleep habits, and education, a negative relationship ($P < 0.001$) was found between the change in the 10-m Shuttle Run Test (times) and the change in PIQ, VIQ and FIQ, whereas a positive association ($P < 0.01$) was observed between the change in the 20-m Shuttle Run Test and the change in PIQ, VIQ and FIQ. However, after the 10m and 20-m Shuttle Run Tests were mutually adjusted with covariates to control the confound variables, only the negative association still remained in the changes between the 10m Shuttle Run Test and PIQ, VIQ and FIQ ($P < 0.001$), respectively. **Conclusions:** Compared with aerobic fitness, a high level of the agility fitness may be associated more with a high cognition performance (performance of the PIQ, VIQ, and FIQ). Further research is needed to examine the effect of the aerobic and agility fitness related interventions on the cognitive parameters in this population.

Effects of Self-Regulation at Ventilatory Breakpoint on Children's Running Fitness during Physical Education Pedagogical Strategies

Peggy Boey¹, Govindasamy Balasekaran, FACSM¹, Dianna Thor¹, Visvasuresh Victor Govindaswamy², Yew Cheo Ng¹, Jolene Lim¹. ¹Nanyang Technological University, Singapore, Singapore. ²Concordia University Chicago, Chicago, IL.
Email: peggy_boey@hotmail.com
(No relationships reported)

Introduction: Exercising at ventilatory breakpoint (Vpt) with the use of Rate of Perceived Exertion (RPE) scale has been used widely in children but its effect on running fitness during Games Concept Approach (GCA) or Skill-based Approach (SA) pedagogical strategies during physical education lesson is unknown. **Purpose:** To investigate the effects of running fitness of exercising within the range of Vpt (RPE 4-6) via self-regulation by children during GCA and SA pedagogical strategies. **Methods:** 18 healthy children, 9 boys (age: 10years old, height: 138 ± 5.94cm, weight: 34.56 ± 7.3kg) and 9 girls (age: 10 ± 0.5years old, height: 135 ± 8cm, weight: 33 ± 10.45kg) were recruited. The intervention was conducted in a school for 12 sessions over a period of 6 weeks. Students were split into GCA or SA group. Two sessions were held in a week and each lasted for 45 minutes (5 minutes warm up, 15 minutes GCA or SA activities, 5 minutes break, 15 minutes GCA or SA activities and 5 minutes cool down). RPE and Heart Rate (HR) were recorded during the sessions. Physical activity was kept similar throughout the intervention period. The students ran a 1.6km before and after the intervention. **Results:** Paired-t test showed significant difference between pre and post 1.6km run test for GCA (pre: 693.67 ± 98.03 seconds, post: 614.89 ± 74.18 seconds, $p = 0.001$) and SA (pre: 817.11 ± 92.98 seconds, post: 712 ± 68.51 seconds, $p < 0.0005$). Independent-t test showed significant difference between GCA and SA in the 1.6km post run ($p = 0.011$) and HR (GCA: 159.03 ± 12.22, SA: 129.99 ± 17.23, $p = 0.001$) but not in RPE (GCA: 4.30 ± 1.16, SA: 3.73 ± 1.72, $p = 0.426$). Maximum HR (HR_{max}) percentage was higher in GCA (75.73% of HR_{max}) than SA (61.9% of HR_{max}). **Conclusion:** Faster timings in the 1.6km post run test results showed improvement in cardiovascular fitness for both pedagogical approaches, which may have been attained with sustained exercise intensity within 60-75% of HR_{max} and RPE of 4-6. A higher improvement from the GCA group suggests that GCA is a better pedagogical approach as it is fun for children. Self-regulation of exercise intensity using the OMNI RPE scale during both GCA and SA improved fitness and may be a safe way to exercise as the students are not exercising at high RPE (8-10) which may induce injuries.

Nine-year Longitudinal Study Of Obesity In Japanese Young Children

Kazuo Oguri¹, Kosho Kasuga², Takahiro Nakano³, Tomoaki Sakai³. ¹Gifu shotoku Gakuin University, Gifu, Japan. ²Gifu University, Gifu, Japan. ³Nagoya Gakuin University, Aichi, Japan. (Sponsor: Kiyoji Tanaka, FACSM)
Email: oguri@gifu.shotoku.ac.jp
(No relationships reported)

PURPOSE: Childhood obesity is increasing worldwide. Tracking, or the tendency for an individual to maintain his/her disease risk factor rank level relative to his/her peers through time, leading to adolescence and adult obesity is observed even in early childhood. Childhood obesity is associated with increased risk of mortality due to cardiovascular diseases in adulthood, independent of adult weight. Therefore, intervention, and prevention of obesity in young children is important in reducing the risks of obesity and cardiovascular disease in adulthood. However, little is known about the process and tracking of obesity during the years of young childhood because of a lack of longitudinal studies. Consequently, prevention and treatment of obesity in the young childhood has made little progress. The purpose of this study is to investigate the trends in degree and tracking of obesity in young children over nine years. **METHODS:** The subjects were 58 young children (22 boys and 36 girls). They were followed up for height, weight, and obesity index from 3 to 11 years old. Obesity index ((actual weight - standard weight) / standard weight × 100) was calculated using the standard weight for Japanese children, which was determined according to the formula: Male $y = 1.83 \times 10^{-3}x^2 - 0.071x + 4.43$, female $y = 2.34 \times 10^{-3}x^2 - 0.157x + 7.71$ (y: standard weight, x: height). Obese was defined as having an obesity index of more than +15%. Pearson's correlation coefficients and χ^2 test were used to estimate the effects of age on frequency trend and tracking of obesity. Statistical significance was $p < 0.05$. **RESULTS:** The prevalence of obesity was 17.2% (n=10) in 3-year-old children and 20.7% (n=12) in the same children at 11-years-old. There were no age-related differences in frequency of obesity. The obesity index at 3-years old was significantly correlated with that at 4-years-old ($r=0.861$), 5-years-old ($r=0.774$), 8-years-old

($r=0.630$), 9-years-old ($r=0.548$), 10-years-old ($r=0.559$), 11-years-old ($r=0.512$). Among 10 young children who were obese at 3-years-old, 3 showed tracking of obesity from 11-years-old.

CONCLUSIONS: The status of many obese young children is likely to track, but the chance of a decrease in obesity over nine years is not small in young childhood.

3758 Board #205 June 3 8:00 AM - 9:30 AM
Relationships Between Young Children's Physical Activity And Guardians' Consciousness Regarding It
 Takahiro Nakano¹, Kosho Kasuga², Tomoaki Sakai¹, Kazuo Oguri³. ¹Nagoya Gakuin University, Nagoya, Japan. ²Gifu University, Gifu, Japan. ³Gifu Shotoku Gakuen University, Gifu, Japan. (Sponsor: Kiyoji Tanaka, FACSM)
 Email: taka@ngu.ac.jp
 (No relationships reported)

Young children's acquisition of the habit of engaging in physical activity (PA) and having a positive attitude to PA are very important to improve children's physical fitness. The acquisition of the habit of engaging in PA translates into an increase in the amount of PA. It is also expected that the improvement of physical fitness supports the development of a positive attitude to PA. However, the amount of PA is changed according to influence of daily lifestyle and guardians' consciousness of children's PA. **PURPOSE:** The purpose of this study was to examine the relationships between young children's PA and guardians' consciousness regarding the same. This study specifically focused on the change in the longitudinal relationships. **METHODS:** The subjects of this study were 77 young children. Data included their PA, daily lifestyle, and guardians' consciousness of children's PA. The amount of PA was measured on all days of a week. The data on 18 items related to daily lifestyle and guardians' consciousness of children's PA were collected using a questionnaire. These data were collected when the children were aged 3 and 5 years, using the same protocol. The subjects were divided into 2 groups, the improvement group and maintain or no-improvement group, based on the change in guardians' consciousness of children's PA. The difference in the amount of PA between these groups was examined using an independent t-test. **RESULTS:** The amount of PA increased on weekdays and decreased on weekends from 3 years old to 5 years old. The amount of PA increased significantly in the improvement group based on the consciousness that "playing outside, exercise, and sports are very important" and "the guardian sometimes takes a walk with the child". Regarding daily lifestyle items, "the frequency of playing using the whole body" was the only item that showed a significant difference in PA. Although statistical significance was not confirmed, PA increased in the improvement group based on "the duration of watching TV/videos" and "duration of playing video games". **CONCLUSIONS:** It was suggested that guardians' consciousness regarding playing outdoors, and engaging in exercise and sports is very important for children's PA. Further, it is necessary to control the duration of watching TV/videos and of playing video games in order to increase children's PA.

Vertical Jump Performance Predicts Selection Of Young Talented Volleyball Players For the Junior National Team
 Athanasios Tsoukos, Sotirios Drikos, Panagiotis Veligeas, Gregory C. Bogdanis. School of P.E and Sports Science, National & Kapodistrian University of Athens, Greece, Athens, Greece.
 Email: atsoukos@phed.uoa.gr
 (No relationships reported)

PURPOSE: To determine whether anthropometric measurements and fitness test results can discriminate between selected and non-selected junior volleyball players. **METHODS:** Forty three male junior volleyball players (age: 15.0±0.7 yrs) took part in training camp and underwent a selection procedure by coaches of the junior national team. Anthropometric data (body height, body mass and body height with extended arm) and fitness tests results (countermovement jump (CMJ), block jump, spike jump, 10m sprint and 505 agility test) were obtained. Four expert volleyball coaches of the national team evaluated and graded the players in a scale from 0 to 100 during their participation in a volleyball tournament. The coaches selected the best 23 players on the basis of their score (selected players; n=23, height: 186±5 cm, body mass: 72±10 kg) (non-selected; n=20, height: 188±3 cm, body mass: 69.5±7.5 kg). A linear discriminant analysis was conducted on the selected and non-selected groups to determine if the anthropometric and fitness test data could predict the coaches' selection. Anthropometric and fitness test data of the two groups were compared using independent samples t-tests. Statistical significance was set at p<0.05. **RESULTS:** Selected players had higher coaches' scores compared to the non-selected (83.9±7.2 vs. 65.3±7.5, p<0.05). There were significant differences between selected and non-selected in only in vertical jumps (CMJ: 40.5±6.7 vs. 34.4±3.6 cm, block jump: 43.6±6.9 vs. 36.9±3.5 cm, spike jump: 72.8±10.3 vs. 63.4±3.8 cm, all p<0.05), but not in any other anthropometric or fitness test parameter. The multivariate analysis yielded

a discriminant function (Wilk's lambda= 0.69, $\chi^2= 15.12$, p=0.001, $\eta^2=0.12$). CMJ was the main test result that highly loaded the discriminant function ($r=0.85$). Cross validation results showed that selection was correctly predicted in 31 out of the 43 selected athletes (predictive accuracy: 72.1%).

CONCLUSIONS: Vertical jumping ability may be used as an important parameter that largely determines success, since it may discriminate between selected and non-selected junior volleyball players.

Comparison Of Cardiorespiratory Fitness Testing Measures In Young Children
 Michael C. Taylor, Jr, Shannon E. Vinci, Justin M. Thomas, Cassandra M. Blase, Rosie K. LaCoe, Jody L. Clasey, FACSM. University of Kentucky, Lexington, KY. (Sponsor: Jody L. Clasey, FACSM)
 (No relationships reported)

Laboratory and field methods of assessing cardiorespiratory fitness in young children provides valuable information to assess the effectiveness of intervention strategies designed to improve overall health outcomes. **PURPOSE:** To compare peak oxygen uptake (VO₂peak; ml·kg⁻¹·min⁻¹) and maximal heart rate (MHR; beats·min⁻¹), from the FitnessGram Progressive Aerobic Cardiovascular Endurance Run (PACER) test to a maximal graded exercise test (GXT; treadmill) in 17 (9 boys) young (10-11 yr old) children. In addition, VO₂peak from the PACER test was compared (mean ± SD) to the estimated VO₂peak using the Topend Sports Beep Test Score Calculator (Topend) equation. **METHODS:** Subjects completed the PACER and GXT in a randomized order 1 week apart while wearing a heart rate monitor and a portable oxygen analyzer. **RESULTS:** The PACER test VO₂peak (30.4 ± 4.6) was not significantly different from the GXT VO₂peak (32.1 ± 5.5) however, MHR GXT (194.8 ± 9.4) and MHR PACER (173.7 ± 20.9) were significantly (p < 0.05) different. Topend VO₂peak (23.8 ± 2.9) was significantly (p < 0.05) lower than the PACER VO₂peak. Both the GXT and the Topend VO₂peak were significantly (p < 0.05) correlated with the PACER ($r=0.75$ and 0.62, respectively). There was no significant correlation between the PACER and GXT MHR ($r=0.40$). **CONCLUSIONS:** The PACER elicits a similar VO₂peak response, however the Topend estimation equation should be used with great caution to estimate the cardiorespiratory fitness of young children.  (No relationships reported)

Physical fitness encompasses health-related fitness (HRF) variables such as cardiovascular fitness (CF), lumbar and lower limb flexibility (LLLF), muscular strength (MS) and body fat percentage (BF%). To date, no large study has been conducted on HRF variables among Singaporean youths. **PURPOSE:** To compare HRF variables between male and female Singaporean youths. **METHODS:** One thousand four hundred and fifty-six youths (762 males: age: 13.63 ± 1.35 years, height: 158.36 ± 8.75 cm, weight: 53.82 ± 14.39 kg, BF%: 17.64 ± 10.73 %; and 694 females: age: 13.34 ± 1.21 years, height: 160.73 ± 8.68 cm, weight: 48.82 ± 10.9 kg, BF%: 25.74 ± 7.87 %) from Singapore schools participated in this study. Body Mass Index (BMI) was calculated using standard methods and BF% was measured with a Tanita BC-581 FitPlus Innerscan Scale and Body Composition Monitor. CF, LLLF, and MS were tested using the 15m youth Progressive Aerobic Cardiovascular Endurance Run test (PACER), one-legged sit-and-reach test (SRT), handgrip strength test (HS), and 1-minute sit-up test (SUT) respectively. **RESULTS:** 76.65% of the youths (males: 77.82%, females: 82.56%) were in the healthy BMI range according to the Health Promotion Board of Singapore. Significant differences were found between males and females for all variables (BF %: Males: 17.64 ± 10.73 %, Females: 25.74 ± 7.87 %, p < 0.005; SRT: Males: 52.97 ± 10.04 cm, Females: 55.53 ± 10.03 cm, p < 0.005; HS: Males: 28.35 ± 7.98 kg, Females: 20.77 ± 4.11 kg, p < 0.005; SUT: Males: 43.26 ± 11.29, Females: 33.24 ± 9.16, p < 0.005; PACER: Males: 48.79 ± 24.93 stages, Females: 29.41 ± 12.9 stages, p < 0.005). Males were significantly stronger than females, whereas females were significantly more flexible than males. **CONCLUSIONS:** Generally, youths in Singapore are aerobically fit, with a healthy BF% indicating low obesity rates. If these results of HRF variables are maintained throughout their lifetime, there may be low risk of cardiovascular diseases in Singapore in the future.

Abstracts were prepared by the authors and printed as submitted.

Effects of Backward Walking on Balance in Children
 Lang Qin, Yuanpeng Liao. *Chengdu Sport University, Chengdu, China.* (Sponsor: Tongjian You, FACSM)
 Email: 250990326@qq.com
 (No relationships reported)

Injuries caused by falls account for 25% to 40% in morbidity and mortality of children worldwide. Therefore, it is important to identify effective interventions to prevent falls.

Purpose: To investigate the effects of backward walking on balance and fall risk in children.

Methods: Twenty eight healthy boys (6.2±0.5 yrs) were randomly assigned into a control group (n=14) and an intervention group (n=14). Boys in the control group participated in a conventional physical activity program, and those in the intervention group received conventional physical activity plus balance training with backward walking. The programs were provided 30 min/day, 3 days/week for 12 weeks. Balance at baseline and post-intervention was evaluated by using a dynamic training system BTA-200DP which includes anterior/posterior balance index (API), medial/lateral balance index (MLI), and overall balance index (OBI), as well as kinematic parameters in lower extremities. Independent t-tests were performed for group comparisons. Results: There were no significant differences between the control group and the intervention group in each of the parameters before treatment. After 12 weeks of training, the intervention group was significantly better than the control group in API (0.69±0.18 vs. 1.66±0.71, p<0.01), MLI (0.61±0.23 vs. 1.08±0.41, p<0.01), and OBI (0.82±0.15 vs 1.85±0.36, p<0.01). There were no significant group differences in kinematic gait parameters in backward and forward walking between control and intervention group after 12 weeks of training, however, compared with the control group, the intervention group had significantly higher support phase time (0.83±0.07 sec vs. 0.69±0.05 sec, P<0.01), swing time (53.58±11.01 sec vs. 73.77±62.46 sec, P<0.01), step length (53.58±11.01 cm vs 73.77±62.46 cm, P<0.01), step speed (6.19±1.26 m/s vs 8.57±1.74m/s, P<0.01).

Conclusions: Backward walking training improved dynamic balance and motion control ability in children.

Test-retest Reliability Of The 40-yd Dash And Vertical Jump Assessments In Youth Athletes

Brianna D. McKay¹, Amelia A. Miramonti¹, Nathaniel D.M. Jenkins², Zachary Gillen¹, Todd J. Leutzinger¹. ¹University of Nebraska - Lincoln, Lincoln, NE. ²Oklahoma State University, Stillwater, OK. (Sponsor: Dr. Joel Cramer, FACSM)
 Email: bdmckay10@gmail.com
 (No relationships reported)

Introduction: Limited data exist on the reliability and sensitivity of the 40-yard dash (40-yd) and vertical jump (VJ) tests in youth athletes, which are popular combine performance assessments. **Purpose:** To examine the test-retest reliability for the 40-yd and VJ in youth athletes. **Methods:** Seventy-seven 5-15 year-old athletes (mean height ± SD = 153.0 cm ± 14.9; weight = 45.8 kg ± 16.3) volunteered for the performance assessments during two visits separated by 24-72 hours. Athletes were divided into three age groups (5 - 9, 10 - 11, and 12 - 15 years old). The 40-yd was assessed in seconds (s) with a digital timing gate, and the VJ was assessed in centimeters (cm) with a vertec, both performed on indoor field turf. Intra-class correlation coefficients (ICC) with corresponding 95% confidence intervals, standard errors of measurement (SEM), coefficients of variation (CV), and minimum detectable changes (MDC) were calculated from the repeated measures analysis of variance (ANOVA) from test 1 to test 2 for both assessments. **Results:** There were systematic decreases in 40-yd times from test 1 to test 2 for the 12 - 15 year-old group, but there was no other detectable systematic variability for any other variable. The ICCs ranged from 0.78 to 0.96, which were greater than zero. MDCs (calculated from SEMs) for the 5 - 9, 10 - 11, and 12 - 15 age groups were 0.49, 0.70, and 0.38 s for the 40-yd, and 6.7, 4.3, and 13.7 cm for the VJ, respectively. **Conclusions:** Twelve to fifteen year olds may need a familiarization trial (i.e., test run) for the 40-yd. Based on the age of the athlete, 0.4 - 0.7 s and 4 - 14 cm changes in the 40-yd and VJ, respectively, may be necessary for individual youth athletes to consider their improvements real beyond the errors of the measurements.

3764 Board #211 June 3 8:00 AM - 9:30 AM
Research On The Influence Of Exercise On Brain Structure And Brain Function In The Resting State Of Children With Febrile Convulsion
 zhiping zhen¹, Hanran Li², chao luo¹, liangyi hu¹. ¹Beijing normal university, beijing, China. ²China University of Mining and Technology (Beijing), beijing, China.
 Email: zzpxt@bnu.edu.cn
 (No relationships reported)

PURPOSE: Using the complex brain function and brain structure as an entry point in the resting-state, the research explored the central mechanisms of febrile convulsion, aiming to improve the condition of impaired brain function and the level of physical ability of FC children. **METHODS:** We chose 10 children (group A) and 10 FC children (group B). The group B was intervened by the sensory integration training, which was based on balance and flexibility and coordination. The intervention lasted for 6 months. Adopting BOLD-fMRI technology, regional homogeneity was observed. Based on VBM measurement technology, Cerebral gray matter concentration was measured. The dynamic change of regional homogeneity and gray matter concentration of the whole brain for both A and B group has been observed before and after exercise intervene. **RESULTS:** 1. Compared with group A, the abnormality of regional homogeneity occurred in many encephalic regions for group B. 2. After intervene, group B's regional homogeneity signal changed obviously in SG (P<0.05; P<0.01) and cerebellum (P<0.05; P<0.01), MI (P<0.05; P<0.05), PMA (P<0.05; P<0.05), SMA (P<0.05; P<0.01) and IPL (P<0.05; P<0.05). 3. The gray matter of group B occurred in such encephalic regions as precentral gyrus (BA 4), inferior parietal lobule (BA 40), cuneus (BA 18), precuneus (BA 7), cingulate gyrus (BA 24, 32) encephalic regions improved. 4. Sit and reach (flexibility, P<0.01), walking balance beam (balance ability, P<0.01), cross jump (coordination ability, P<0.05), two feet continuous jump (jump ability, P<0.01) significantly increased for group B. **CONCLUSIONS:** 1. SG was the main encephalic region which resulted in FC children motor function injuries. So it was the main intervene target. 2. MI, PMA, SMA and IPL were the critical regions for FC children to accomplish reorganization and compensation of the brain function in the resting-state. They were the important focus for exercise intervene. 3. the abnormal alteration of ray matter concentration was the main difference among group A and B children' brain structure. It became the material basis of the abnormality of brain function. 4. Sensory integration training and exercise intervene based on the development of balance and coordination ability had the significant effect on improving FC children's physical ability .

Activity and Fitness in Recreational and Competitive Youth Rock Climbers.
 Shannon R. Siegel, FACSM¹, Martin R. Lindley². ¹University of San Francisco, San Francisco, CA. ²Loughborough University, Loughborough, United Kingdom.
 Email: ssiegel@usfca.edu
 (No relationships reported)

In the search to find activities youth enjoy and to which they will adhere, rock climbing has become increasingly popular; youth climbing teams/programs exist all over the United States (US) and United Kingdom (UK). The US has over 800 climbing gyms, with almost 400 in the UK. From a health-related fitness perspective, climbing appears to be a good option for decreasing sedentary behavior and keeping youth active.

PURPOSE: 1) To determine if recreational (REC) and elite/competitive (EC) youth climbers meet US DHHS (2008) physical activity guidelines during their climbing gym sessions, and 2) to determine if REC and EC youth climbers differ in estimated energy expenditure (EE), fitness, and body composition. **METHODS:** Data were collected between 2009-2013 in the US and UK. Thirteen REC (mean age: 10.7 ± 3.3 yrs) and 18 EC (13.8 ± 2.3 yrs) female climbers were assessed; 17 REC (10.6 ± 1.7 yrs) and 22 EC (13.9 ± 1.9 yrs) males were assessed. Heart rate (HR) monitors were used to collect time of activity (mins), average heart rate (AHR), and peak heart rate (PHR) in beats per minute (bpm) during climbing. Energy expended (kcal) during climbing was estimated from the HR data. Health-related fitness was measured via sit and reach (flexibility), pushups (muscular endurance), and right and left grip strength (muscular strength). Body composition (%fat) was calculated from skinfolds using standardized equations. Differences between groups were tested using ANCOVAs, controlling for age. **RESULTS:** In the REC and EC groups, climbers spent between 73 and 85 mins being active during climbing sessions; the groups did not significantly differ. However, female and male EC climbers, respectively, had higher estimated EE (5.4 ± 1.3 and 6.7 ± 1.7 kcal/min) than female and male REC climbers (3.5 ± 1.4 and 4.3 ± 1.4 kcal/min; p<0.05). Female EC climbers were also stronger than female REC climbers in both right and left grip strength (p<0.01). Once adjusted for age, few other differences existed between REC and EC. **CONCLUSION:** For all groups, AHR ranged between 120-158 bpm, and the exercise intensity approached moderate levels. REC and EC climbers did not differ on most physical or fitness parameters. Additionally, climbers met US DHHS recommendations for duration of cardiorespiratory activity, but intensity did not consistently meet moderate levels.

Effect of Modified Tai Chi Exercise on Physical Function among Chinese High School Students

lulu gao¹, Wei Sun², Nan Ye³. ¹Capital University of Physical Education and Sports, Beijing, China. ²Shandong Institute of Sports Science and Technology, Jinan, China. ³Beijing Sports University, Beijing, China. (Sponsor: Yong Tai Wang, FACSM)
Email: 271585838@qq.com
(No relationships reported)

PURPOSE: The physical function of high school students has been declined in the last decade. The purpose of this study was to investigate the effect of a modified Tai Chi intervention on physical function among high school students.

METHODS: One hundred-twenty healthy high school students (60 boys & 60 girls aged 16-18 years) volunteered for the Tai Chi intervention. The participants were randomly assigned to four groups (30/group): the boys experimental group (BEG); girls experimental group (GEG); boys control group (BCG) and girls control group (GCG). The experimental groups received the Tai Chi intervention for 20 weeks, 5 days a week and 40 minutes/day. The control groups did not do any exercises. The selected physical function variables: resting heart rate (RHR), vital capacity (VC) and single leg standing with eyes closed balance (SLSECB) were measured at the beginning, and at the end of 10th week and end of 20th week. One-way ANOVA was performed to determine the differences ($p < .05$) between four groups, and repeated ANOVA was employed to examine the differences within the groups over the course of the intervention ($p < .05$).

RESULTS: The results demonstrated that by the end of 20th week, the BEG had a significantly lower RHR than the BCG did (62.06 ± 0.75 vs 69.97 ± 2.89 beats/min), and the similar trend of the RHR was discovered between the GEG and GCG; the BEG had significantly greater improvement in VC than the BCG did ($4,230 \pm 224$ vs $2,865 \pm 143$ ml), and the similar trend was found between the GEG and the GCG. On the SLSECB, the BEG showed significant longer standing time than the BCG did (22.00 ± 1.75 vs 12.04 ± 0.67 s) and the similar trend was observed between the GEG and GCG.

CONCLUSIONS: The modified Tai Chi exercises may improve high school students' physical function in terms of resting heart rate, vital capacity and balance. This modified Tai Chi exercise may be used as an optional exercise for promoting physical function for high school students in China.

3767 Board #214 June 3 8:00 AM - 9:30 AM

Longitudinal Changes in Physical Fitness and Physical Activity in Childhood

Tomoaki Sakai¹, Takahiro Nakano¹, Kosho Kasuga², Kazuo Oguri³. ¹Nagoya Gakuin University, Seto, Aichi, Japan. ²Gifu University, Gifu, Japan. ³Gifu Shotoku Gakuen University, Gifu, Japan. (Sponsor: Kiyoji TANAKA, FACSM)
Email: tsakai@ngu.ac.jp
(No relationships reported)

PURPOSE: The purpose of this study was to examine longitudinal changes in infants' physical fitness and physical activity.

METHODS: The participants were 66 three-year-old children (38 boys and 28 girls) attending daycare centers in 2012. For all participants, we made longitudinal measurements of physical fitness and physical activity over three years between the ages of three and five. Physical fitness and physical activity were measured every year in November and December. We evaluated participants' performance with the standing long jump, upright hand standing time, sitting trunk flexion, 25 m dash, ball throwing, side-step, and hand grip, calculating changes through the year. Additionally, participants were given an accelerometer for one week, and we evaluated the number of steps on weekdays and weekends.

RESULTS: On weekdays, the number of steps by five-year-old boys was significantly higher than for boys of other ages (three-year-old: 12848 ± 2330 steps, four-year-old: 12820 ± 2905 steps, five-year-old: 14274 ± 2871 steps, $p < 0.05$), but for the girls, there were no significant differences among all ages. In all test items except the side-step and the sitting trunk flexion, we found significant improvements in physical fitness scores every year. There were significant improvements in the side-step only in the span of three and four years of age (6.3 ± 0.3 , 9.2 ± 0.3 and 9.7 ± 0.3 times/5 sec, $p < 0.05$). No significant changes were observed in sitting trunk flexion. The amount of change between three and four years of age for the 25 m dash and side-step was significantly greater than that between four and five years of age. On the other hand, changes in upright hand standing time, ball throwing, and hand grip were significantly greater between four and five years of age than between three and four years of age. For the amount of change in physical fitness between three and four years of age and between four and five years of age, a negative correlation was observed both for boys in sitting trunk flexion ($r = -0.42$), ball throwing ($r = -0.41$), and side-step ($r = -0.63$) and for girls in sitting trunk flexion ($r = -0.73$), ball throwing ($r = -0.58$), and hand grip ($r = -0.48$).

CONCLUSIONS: Our study suggests that there are distinctive characteristics pertaining to every factor in the improvements observed in physical fitness in childhood.

Salivary Cortisol Responses After A Tennis Match In Adolescent Athletes

Maria Maridaki¹, Argyro Papadopetraki², Athanasios Moustogiannis², Loukas Kollias², Panagiotis Kostopoulos², Anastassios Philippou². ¹Faculty of Physical Education and Sport Science, National and Kapodistrian University of Athens, Dafni-Athens, Greece. ²Medical School, National and Kapodistrian University of Athens, Goudi-Athens, Greece.
Email: mmarida@phed.uoa.gr
(No relationships reported)

Cortisol can negatively affect athletic performance, potentially causing fatigue and inflammation, while high levels of this hormone have been associated with impaired performance in elite athletes. Monitoring hormones in saliva has distinct advantages over doing it in other biological fluids. However, little is known about the salivary cortisol responses in adolescent athlete, particularly after a tennis match. **PURPOSE:** The purpose of this study was to examine the salivary cortisol responses in elite (finalists of national competition playoffs) adolescent tennis players after a tennis match. **METHODS:** Thirty-two tennis athletes (20 females: age 14 ± 0.5 yrs, height 165 ± 7 cm, mass 52.2 ± 7.6 kg, BMI 19.0 ± 1.6 , and 12 males: 14 ± 0.5 yrs, height 173 ± 10 cm, mass 60.0 ± 8.2 kg, BMI 19.9 ± 1.2) participated in the study. Mean match duration for all participants was 77.5 ± 13.6 min. Unstimulated mixed saliva samples were collected in salivate swabs 15 minutes prior to and 15 minutes after the end of the tennis match. Specifically, the swab was placed in the mouth for one minute, then it was transferred into plastic tubes, centrifuged and the resulted saliva sample was analyzed. Saliva samples were assayed in duplicate using a commercially available ELISA kit for cortisol. Differences between the cortisol levels before and after the match were analyzed using student's T-test. **RESULTS:** Salivary cortisol levels were significantly higher after the completion of the tennis match compared to the baseline levels (4478.9 ± 598.3 pg/ml vs. $976.1 \pm 143.143.7$ pg/ml; $p < 0.001$). No significant differences were found between the mean cortisol responses in males and females ($p > 0.05$). **CONCLUSION:** The findings of the present study suggest that monitoring cortisol in saliva can be a useful, non-invasive and sensitive method to assess this hormonal response in adolescent athletes after a tennis match. Moreover, in contrast to findings of previous studies in adult tennis players, the increased cortisol levels in the adolescent athletes of this study found to be independent of their gender. The possible negative effects of these cortisol responses on the adolescent elite athlete's performance needs to be further investigated.

Physical Exercise Program To Improve The Sport Performance On Speed Skating In Children

Susana Paz-Viteri¹, Emilio Villa-González¹, Vinicio Sandoval¹, Julio Mocha-Bonilla², Yaira Barranco-Ruiz¹. ¹National University of Chimborazo, Riobamba, Ecuador. ²Technical University of Ambato, Ambato, Ecuador.
Email: suzypaz19@gmail.com
(No relationships reported)

PURPOSE: To investigate the effects of physical exercise program on sport performance of children speed skaters. **METHODS:** A total of 52 children speed skaters (aged=9.09±0.27; 69.2% girls) from Ecuador participated in the study. The ALPHA-Fitness battery was used to analyze the body composition and physical fitness: muscular fitness (hand-grip strength and standing long jump test), speed-agility (4x10-m shuttle run test), and cardiovascular fitness (20-m shuttle run test). Sport performance was measured by the time-marks of the different modalities of the speed skating (combined test, time trial, sprint and hare test). All participants were evaluated before and after 10-weeks of intervention based on a physical exercise program (90-min/ session, 4-days/week). A mixed factorial ANOVA was used to analyze effects and interactions of the study factors age (<10-y and >10-y), sex (boys and girls), and measure moments (baseline and post-intervention) on body composition, physical fitness, and sport performance. **RESULTS:** Post-intervention compared with baseline, weight was lower in girls <10-yr (MD=-0.66±0.30 Kg, $p=0.033$), fat mass was lower in girls <10-yr and >10-yr (MD= 7.37±1.21 Kg, $p<0.001$; MD=7.71±1.71 Kg, $p<0.001$), muscle mass was lower in boys >10-yr (MD=-0.13±0.06 Kg, $p<0.035$) and bone mass was higher in girls <10-yr (MD=0.28±0.09, $p=0.03$). The muscular fitness of upper limbs was higher post-intervention compared with baseline in boys <10-yr (DM=1.55±0.57, $p=0.010$) and girls <10-yr (MD=1.58±0.35, $p<0.01$). For lower limbs, muscular fitness post-intervention was higher in girls <10-yr (MD=5.20±2.28, $p=0.02$). The cardiovascular fitness was higher post-intervention in girls <10-yr (MD=0.65±0.20, $p=0.002$) compared with baseline. The time marks of the combined test post-intervention was lower in boys >10-yr (MD=6.06±2.00, $p=0.004$, in time

trial the time-mark was lower in boys <10-yr (MD=0.71±0.19, p=0.001), girls <10-yr (MD=0.52±0.12, p<0.001) and in girls >10-yr (MD=0.38±0.17 p=0.027) compared with baseline. The time-mark in sprint was lower for girls <10-yr (MD=2.39±1.02, p=0.023) post-intervention. **CONCLUSION:** A 10-weeks physical exercise intervention improves sport performance in children speed skaters, what are directly related with sex and age.

Reliability of the Neuromuscular Fatigue Threshold Measurement across Maturity Status in Boys

Jeffrey R. Stout, FACSM, Kyle Beyer, David Fukuda, Michael Redd, Kayla Baker, Jay Hoffman, FACSM. *University of Central Florida, Orlando, FL.*

Email: jeffrey.stout@ucf.edu

(No relationships reported)

Several studies in adult men and women have demonstrated excellent reliability and sensitivity when measuring neuromuscular fatigue threshold (NFT) during an incremental cycle ergometer test. Recently, the ability to estimate NFT in young boys (11.1±1.1yrs) was demonstrated, which may provide a new noninvasive method to examine training interventions as well as the effect of maturation on changes in motor unit recruitment strategies. However, to date, no one has examined the reliability of estimating NFT in boys. **PURPOSE:** To determine the reliability of estimating the onset of neuromuscular fatigue in boys across maturity status. **METHODS:** Twenty-four boys (age 11 to 17yrs) volunteered with parental consent to complete two graded exercise test (GXT) on a cycle ergometer separated by at least 48 hours. The NFT was estimated during the GXT by way of the maximal distance method using electromyographic amplitude values from the right vastus lateralis vs power output (W). All participants were separated according to their number of years from peak height velocity (PHV), an estimation of somatic maturity status, into PRE- (-1yr), PERI- (between -1 to +1yr) and POST- (+1yr) PHV groups. Test-retest reliability was calculated for PRE-, PERI-, POST-PHV as well as the combined group. Intraclass correlation coefficient (ICC_{2,1}), standard error of the measurement (SEM) and minimum detectable change (MDC) were calculated using a custom written Excel spreadsheet. **RESULTS:** Table 1 summarizes the results. Every group independently and combined demonstrated excellent reliability (ICC>0.75) **CONCLUSIONS:** The current results described in Table 1 are similar to other studies that have reported ICC (0.85 to 0.95), SEM (6W to 14.6W) and MDC (17W to 34W) in adult men. The estimation of NFT, therefore, is reliable in boys regardless of maturity status.

Table 1. Summary of the reliability data

Group	NFT-Trial 1 (w)	NFT-Trial 2 (w)	ICC	SEM (w)	MDC (w)
All (n=24)	161.7+38.0	163.1+39.0	0.96	10.4	23.3
PRE (11.6+0.7yrs; n=6)	123.7+46.0	122.0+48.2	0.99	6.1	14.5
PERI (14.2+1.0yrs; n=7)	157.7+18.4	157.1+12.7	0.80	10.0	23.3
POST (17.0+0.8yrs; n=11)	185.1+24.2	189.4+21.1	0.85	12.5	29.2

(No relationships reported)

PURPOSE: The recreational and competitive practice of acrobatic sports, that is, trampoline, is growing rapidly around the world. The trampoline is a gymnastic implement used for learning acrobatic skills in children's gymnastics. However, few studies investigating its application for the development of the power of lower limbs. Thus, the aim of this study was to analyze the effect of an intervention program based on trampoline training on lower limbs in children's gymnasts.

METHODS: A total of 20 gymnasts children (age: 8.00±1.71 years) participated in the study. The power of lower limbs was evaluated before and after an intervention of 8 weeks (3 days/week, 1 h/session) based on training trampoline. Leg power was assessed by Bosco test with the battery Squat Jump (SJ) and Countermovement jump (CMJ) by jumping platform (Axon Jump, software 4.0). The jump time, jump height and speed takeoff were evaluated for both batteries jump. The technical implementation of vertical jump in trampoline was evaluated by scoring code of the International Federation of Trampoline (range of score from 0 to 10). The weight, height and the attendance during the intervention were also analyzed. Paired-samples

Student t-test was used for comparing the means of the normal study variables pre and post intervention. Wilcoxon test was used for non-normal variables. Statistical analysis was performed using SPSS (v.22, IBM, USA). The value of significance was p <0.05.

RESULTS: Post-intervention, SJ significantly increased the flight time (MD=39.2±17.19 ms; p<0.001) and the jump height (MD=4.22±1.88 cm, p<0.001). However, there were no significant differences post-intervention in the variable speed off in SJ. In the CMJ, the time of flight and jump height significantly increased (MD=41.8±25.97 ms; p<0.001; MD=4.88±3.13 cm; p<0.001, respectively). Moreover, the takeoff speed decreased significantly (MD=0.73±0.93 ms, p<0.01). There were no significant differences in the technical implementation of vertical jump in trampoline. **CONCLUSIONS:** An 8-weeks of trampoline training improved the power of the lower limbs in gymnasts children increasing the time of flight, height of jump in SJ, and all the variables studied in CMJ.

(No relationships reported)

The maximal oxygen consumption (VO_{2max}) and Wingate test are two of the most popular assessments for aerobic and anaerobic power, strongly associated with overall performance in athletes. **PURPOSE:** To assess differences by sport in VO_{2max} and Wingate peak power weight (WPPW) in middle and high school athletes of five team sports in South Korea. **METHODS:** The maximal oxygen consumption (ml·kg⁻¹·min⁻¹) and the anaerobic PPW (watts·kg) were evaluated in 163 players of swimming, track & field, shooting, golf, and wrestling (Age = 16.9 ± 1.2 years, BMI = 21.7 ± 1.9 kg·m⁻²; mean ±SD). All participants performed a treadmill maximal test using the Bruce protocol and the 30 second Wingate test using Inbar Wingate test protocol. Differences in VO_{2max} and WPPW among the sports were tested through one-way ANOVAs. Post-hoc multiple comparisons were made using Bonferroni tests. Linear associations of VO_{2max} and WPPW with age were also inspected by computing Pearson correlation coefficients. Statistical significance was determined at p<0.05. **RESULTS:** ANOVA showed statistically significant differences among the sports for WPPW and VO_{2max} (respectively: F(4, 158) = 3.25, p<0.013; F(4, 158) = 14.91, p < 0.001). In WPPW, multiple comparisons among the means showed three homogeneous subsets; 1) swimming (13.7 watts·kg) and Shooting (13.9 watts·kg), 2) Golf (14.7 watts·kg) and Track & Field (14.5 watts·kg), and 3) Wrestling (16.7 watts·kg). In VO_{2max}, multiple comparisons among the means also exposed three homogeneous subsets; 1) Track & Field (56.1 ml·kg⁻¹·min⁻¹) and Wrestling (56.9 ml·kg⁻¹·min⁻¹), 2) Golfer (44.6 ml·kg⁻¹·min⁻¹) and Shooting (46.7 ml·kg⁻¹·min⁻¹), and 3) Swimming (51.6 ml·kg⁻¹·min⁻¹). No correlations were found between Age and VO_{2max} and between Age and WPPW (respectively: -0.083, p=0.293; 0.52, p=0.513). **CONCLUSIONS:** The comparisons between sports that reached statistical significance evidenced differences was observed in several groups on VO_{2max}: 1) Wrestling and Golf (p=.001), 2) Wrestling and Shooting (p=.005), 3) Swimming and Golf (p=.001), 4) Shooting & Track & field (p=.001), 5) Track & field and Golf (p=.001). A similar tendency was observed in WPPW, except for the comparison between swimming and Wrestling. Age was poorly correlated to VO_{2max} and WPPW.

Effect of Modified Tai Chi Exercise on Lower Extremity Muscle Strength and Proprioception among Chinese High School Students

Nan Ye¹, Wei Sun², Lulu Gao³. *¹Beijing Sports University, Beijing, China. ²Shandong Institute of Sports Science and Technology, Shandong, China. ³Capital University of Physical Education and Sports, Beijing, China.* (Sponsor: Yong Tai Wang, FACSM)

Email: okok_ok@qq.com

(No relationships reported)

PURPOSE: The effect of Tai Chi exercise on muscle strength and proprioception among high school students has been well documented. The purpose of this study was to investigate the effect of a modified Tai Chi intervention on lower extremity muscle strength and proprioception among high school students.

METHODS: Sixth male and sixty female healthy high school students aged 16-18 years participated in the Tai Chi intervention. The participants were randomly assigned to four groups with 30 per group: the male experimental group (MEG); female experimental group (FEG); male control group (MCG) and female control group (FCG). The experimental groups received the Tai Chi intervention for 20 weeks, 5

days a week and 40 minutes/day. The control groups did not do any exercises. Lower extremity muscle strength (LEMS) of squat, proprioception of ankle inversion (PAI), proprioception of ankle eversion (PAE), proprioception of knee flexion (PKF) and proprioception of knee extension (PKE) were measured at the beginning, at the end of 10th week and the end of 20th week. The proprioception reflected the sensitivity of joint angle changed. One-way ANOVA was used to determine the differences ($p < .05$) between four groups, and repeated ANOVA was employed to examine the differences within the groups over the course of the intervention ($p < .05$).

RESULTS: The results indicated that at the end of 20th week, the MEG had a significantly more increment than MCG did in LEMS (62.12 ± 5.11 vs 53.15 ± 5.78 kg, $p < .05$), and the similar trend was found between the FEG and the FCG on LEMS; the MEG had a significantly better proprioception (PAI & PAE) than the MCG did (PAI: 2.93 ± 0.92 vs 5.81 ± 0.99 deg, $p < .05$; PAE: 2.98 ± 1.04 vs 5.70 ± 1.01 deg, $p < .05$), and the similar trend was observed between FEG and FCG on PAI and PAE; the MEG also showed a significantly better proprioception (PKF & PKE) than the MCG did (PKF: 0.99 ± 0.49 vs 2.69 ± 0.51 deg, $p < .01$; PKE: 0.75 ± 0.51 vs 2.05 ± 0.51 deg, $p < .05$), and the similar trend was discovered between the FEG and FCG on PKF and PKE.

CONCLUSIONS: The modified Tai Chi exercises may improve high school students' lower extremity muscle strength and proprioception at the ankle and knee joints. This modified Tai Chi exercise may be used as an optional exercise for high school students in China.

3774 Board #221 June 3 9:30 AM - 11:00 AM The Effects Of Myplate And Paleolithic-based Diets Recommendations, With And Without Exercise, In Women.

Collin Popp, Michelle Bohan Brown, William Bridges, Elliot Jesch. *Clemson University, Clemson, SC.*

(No relationships reported)

A Randomized Clinical Trial on the Effects of MyPlate and Paleolithic-based Diet Recommendations, Both with and without Exercise, on Aerobic Fitness, Muscular Strength and Anaerobic Power in Young, Healthy Women.

Collin Popp¹, Michelle Bohan Brown¹, William C Bridges², Elliot D Jesch¹

¹Clemson University, Department of Food, Nutrition and Packaging Sciences, College of Agriculture, Forestry & Life Sciences, Clemson, SC, USA

²Clemson University, Department of Mathematical Sciences, College of Engineering and Science, Clemson, SC, USA

Objective: To determine and compare the effects of MyPlate and Paleolithic-based diet recommendations when combined with and without exercise on aerobic fitness, strength and anaerobic power in healthy, adult women over 8 weeks.

Methods: Participants ($n=20$) were randomized to one of four groups, (1) a MyPlate (MP) diet, (2) Paleolithic-based diet (PD), (3) MyPlate and exercise (MP + Ex) and (4) Paleolithic-based diet and exercise (PD + Ex). The unsupervised exercise recommendation included two days of aerobic exercise and two days of resistance exercise every week at the university recreation center. At baseline and final a graded treadmill test was performed to determine absolute and relative peak oxygen consumption ($\text{abs}\dot{V}O_{2p}$ and $\text{rel}\dot{V}O_{2p}$) and Wingate test were used to determine peak power (PP) and relative peak power (RPP). Leg press and chest press machines were used to estimate upper body (CP1RM), and lower body (LP1RM) strength. Data were analyzed using repeated measures two-way analysis of variance.

Results: The ANOVA indicated that there was no significant interaction between time point (TP)*diet (D)*exercise (Ex) for $\text{abs}\dot{V}O_{2p}$ ($p = 0.093$), strength (CP1RM ($p = 0.753$), LP1RM ($p = 0.427$), PP ($p = 0.732$), RPP ($p = 0.498$)). Based on the ANOVA there was a significant three-way interaction of TP*D*Ex for $\Delta\text{rel}\dot{V}O_{2p}$ ($p = 0.016$) as the MP + Ex group ($\Delta + 4.4 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) had a greater change from baseline compared to the MP group ($\Delta - 2.7 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$, ($p = 0.002$)), and PD + Ex group ($\Delta - 0.3 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$, ($p = 0.03$)).

Conclusions: MP recommendations when combined with two days of aerobic and two days of resistance exercise are effective at improving aerobic fitness when compared to PD recommendations in young, sedentary women.

3775 Board #222 June 3 9:30 AM - 11:00 AM

Asymmetries In Slowed On-transient \dot{V}_{E-} and $\dot{V}O_{2-}$ Kinetics Are Not A Consequence Of Age In HFpEF

Erik H. Van Iterson, Hector R. Villarraga, Lara F. Nhola, Carolyn M. Larsen, Benjamin S. Simmons, Eric J. Bruhn, Thomas P. Olson, FACSM. *Mayo Clinic, Rochester, MN.*

(No relationships reported)

PURPOSE: Aging, increased ventilation (\dot{V}_{E-}), and reduced pulmonary oxygen uptake ($\dot{V}O_{2-}$) during exercise are hallmark features of heart failure with preserved ejection fraction (HFpEF). The pathophysiology of increased \dot{V}_{E-} and reduced $\dot{V}O_{2-}$ linked to exercise intolerance remains unclear in HFpEF. Aging is associated with prolonged exercise on-transient \dot{V}_{E-} and $\dot{V}O_{2-}$ kinetics suggesting abnormal integrated cardiopulmonary and skeletal muscle function. This study aimed to test whether the continuous effect of age explains on-transient \dot{V}_{E-} and $\dot{V}O_{2-}$ kinetics in HFpEF during submaximal ergometry.

METHODS: Sixteen HFpEF (age: mean = 69 ± 7 , range = 55-83 years; BMI = 30 ± 4 kg/m²) performed 2 transients of 6 min fixed-load (20 W) square-wave ergometry at 65 rpm transitioning from rest. Breath-by-breath \dot{V}_{E-} and $\dot{V}O_{2-}$ were measured via open-circuit metabolic system. Raw data were linear interpolated to 1 s intervals and time-aligned for ensemble averaging across transients into 10 s bins for analyses. Excluding the cardiodynamic phase (35 s), Phase II on-transient \dot{V}_{E-} and $\dot{V}O_{2-}$ kinetics were assessed via single exponential models as, $Y_{b+A_1}[1 - e^{-(t-TD)^{\tau}}]$, where, Y_b = rest; A_1 = steady-state increase in \dot{V}_{E-} or $\dot{V}O_{2-}$ above rest; TD = time delay; τ = time constant.

RESULTS: Resting \dot{V}_{E-} and $\dot{V}O_{2-}$ were 12 ± 1 and 0.36 ± 0.06 L/min, respectively. Phase II $\tau\dot{V}_{E-}$ and $\tau\dot{V}O_{2-}$ were 81 ± 40 and 49 ± 23 s, respectively, whereas TD were -4 ± 23 and 23 ± 6 s, respectively. A_1 for \dot{V}_{E-} and $\dot{V}O_{2-}$ were 13 ± 2 and 0.46 ± 0.08 L/min, respectively. Linear regressions (R^2) between age and $\tau\dot{V}_{E-}$ or $\tau\dot{V}O_{2-}$ were 0.01 and 0.12, respectively (both $P > 0.05$). In contrast, R^2 between $\tau\dot{V}_{E-}$ or $\tau\dot{V}O_{2-}$ with A_1 for \dot{V}_{E-} or $\dot{V}O_{2-}$ were 0.38 ($P = 0.02$) or 0.02 ($P = 0.66$), respectively. Lastly, R^2 between $\tau\dot{V}_{E-}$ and $\tau\dot{V}O_{2-}$ was 0.28 ($P = 0.04$).

CONCLUSIONS: These data suggest that the continuous effects of aging cannot explain prolonged on-transient \dot{V}_{E-} and $\dot{V}O_{2-}$ kinetics in HFpEF. However, unique to on-transient \dot{V}_{E-} kinetics, prolonged $\tau\dot{V}_{E-}$ explained the variance in slowed $\tau\dot{V}O_{2-}$ and the increased rise in A_1 for \dot{V}_{E-} . These interactions between on-transient \dot{V}_{E-} and $\dot{V}O_{2-}$ kinetics suggest calibration between pathophysiology at both skeletal muscle and cardiopulmonary levels contributing to exercise intolerance in HFpEF.

Effect Of Ankle Plantar Flexion On ACL Strain During Landing From A Jump

Cameron Trepeck, Weston Kirschbaum, Mark P. Diroma, Oren Masory, Javad Hashemi. *Florida Atlantic University, Boca Raton, FL.*

(No relationships reported)

Injuries to the Anterior Cruciate Ligament (ACL) are one of the most common injuries in athletic activities. Landing from a jump is one of the leading athletic activities associated with ACL injuries. Researchers have postulated that landing flat footed (hill contact) is a more detrimental landing posture to ACL health than landing on toes (or ball of foot). In this research, a novel hybrid robotic system utilizing cadaveric legs (six inches above the knee joint to the toes) was designed to simulate lower extremity biomechanics. The robotic system has the ability to raise a cadaveric leg with pre-applied muscle forces and instrumented ACL to a desired height and drop it onto a force plate. Because we have full access to the foot and ankle joint, tests were performed to determine the impact of flat footed versus plantar flexed landing at various hip and knee flexion angles. **PURPOSE:** To compare the strain of the ACL during a one inch jump landing with foot in a toe down, plantar flexion position versus flat footed, with foot parallel to contact surface. **METHODS:** Four cadaveric knees were tested using a hybrid biomechanical device designed to simulate athletic activities such as landing from a jump, or a plant and cut movement. The cadaveric knees were attached to the device by insertion of a threaded rod implanted into the femur. Quadriceps and Hamstring (Q/H) forces were applied by the use of linear pull cables attached to the associated muscle group. Hip flexion angle was controlled allowing comparison of ACL strain at different degrees of hip flexion during flat-footed and plantar flexed landing scenarios. ACL deformation, Ground Reaction Force (GRF), Q/H forces, and Hip Flexion/Extension were measured across all tests. Data was post-processed using MATLAB to find maximum GRF, ACL deformation during impact, and associated muscle forces. T tests were performed comparing ACL strain of flat-footed vs. plantar-flexed landings. **RESULTS:** ACL strain of flat footed landings at all hip flexion angles were significantly higher than the plantar flexed tests ($p = 0.0019$). **CONCLUSION:** Our results indicate that landing from a jump with the foot plantar flexed lowers the strain on the ACL compared to a flat footed jump landing. The main reason for this could be the shock absorbing role of the ankle and foot ligaments during the plantar flexed landings.

Acute Aerobic Exercise Stimulates ATP Production Rate Similarly in Subsarcolemmal and Intermembranar Muscle Mitochondria in Humans

Christos S. Katsanos¹, Katon Kras¹, Wayne T. Willis¹, Lori Roust². ¹Arizona State University / Mayo Clinic in Arizona, Scottsdale, AZ. ²Mayo Clinic in Arizona, Scottsdale, AZ.
 (No relationships reported)

Purpose: Mitochondria (MITO) in skeletal muscle are organized in reticulum extending from the subsarcolemmal region (SS MITO) to the intermembranar region (IMF MITO). Animal studies suggest that SS MITO are more responsive to physiological stimuli. The purpose of these studies was to assess whether similar responses are observed in humans that vary in age and obesity status, and specifically with respect to maximal ATP production rate (MAPR).

Methods: Twelve healthy subjects (gender, 7M/5F; age, 19-50 years; BMI, 19-40 kg/m², body fat, 12-42%) had muscle biopsies performed before and 3 hours after 45 min of cycling at 65% VO₂max. SS and IMF MITO were isolated using standard procedures. MAPR in the isolated mitochondria was measured by firefly-luciferase assay, and using the following substrates: Malate+Pyruvate+Glutamate (MPG; complex I activity), Succinate (complex II activity), malate-palmitoyl carnitine (M+PC; fat substrate). Insulin sensitivity of the subjects was evaluated from an oral glucose tolerance test (i.e., Matsuda index), and body composition was determined by bioelectrical impedance analysis.

Results: Insulin sensitivity index ranged from 2.7 to 29.0, and did not correlate with either SS or IMF MAPR ($P > 0.05$). MAPR increased after exercise in both SS MITO (MPG substrate: 322±38 vs 449±40; nmol ATP/min/mg protein) and IMF MITO (MPG substrate: 259±44 vs 427±61; nmol ATP/min/mg protein) (for both $P < 0.05$), and the exercise-induced delta change in MAPR was not different between SS MITO and IMF MITO ($P > 0.05$). Similar results were obtained with the other two substrates. The change in MAPR did not correlate with age, percent body fat, or insulin sensitivity in either SS or IMF MITO ($P > 0.05$). However, this change in MAPR with exercise was inversely correlated with the basal MAPR in the SS MITO for both the MPG (Pearson's $r = -0.60$; $P < 0.05$) and Succinate (Pearson's $r = -0.76$; $P < 0.01$) substrates, but not the M+PC substrate. No such correlations were observed in the IMF MITO ($P > 0.05$).

Conclusions: Acute aerobic exercise stimulates both SS and IMF MITO MAPR in humans. The improvement in mitochondria function is not lower in relation to older age or obesity status. However, the magnitude of the stimulation of MAPR by exercise is lower in SS MITO exhibiting the greatest MAPR prior to the exercise stimulus.

Acute Exercise Increases STARS mRNA in Human Skeletal Muscle

Stefan Reitzner, Eva-Karin Gidlund, Carl Johan Sundberg.
 Karolinska Institutet, Stockholm, Sweden.
 (No relationships reported)

Striated Activator of Rho Signaling (STARS) has recently been proposed as link between external stimuli and cellular responses in the adaptation to physical activity. This actin-binding protein is localized in the sarcomere and has been previously shown to modulate Serum Response Factor (SRF) activity which activates transcription of factors important in muscle growth and metabolism. STARS has also been linked to PGC-1 α and ERR α gene expression changes and protein interactions. However, the context and regulation of STARS is still unclear. **Purpose:** To determine how a single bout of physical activity influences STARS mRNA expression over a 24-hour time course. **Methods:** 20 untrained subjects (male and female; aged 20-35) were randomized to either 60 minutes of endurance exercise on a cycle ergometer (20 min at 50% VO₂max + 40 minutes at 65% VO₂max) or no exercise. Muscle biopsies were taken from *M. vastus lateralis* at rest and 30 minutes, 2h, 6h and 24hrs after the end of exercise. cDNA was extracted and gene expression analysed. Fold induction was statistically analysed by ANOVA. **Results:** Exercise induced a significantly higher STARS gene expression increase compared to control ($p=0.048$). Furthermore, after an initial upregulation at 30 minutes (2.8-fold ± 0.5), a time-dependent decrease in expression could be observed at 2h (2.1-fold ± 0.34), 6h (1.4-fold ± 0.38) until baseline was reached after 24hrs. **Conclusion:** Acute endurance exercise upregulates STARS mRNA expression in a time-dependent manner. These data strengthen the possible role of STARS as an important player in the regulation of muscle growth and metabolism.

Occupational And Leisure-time Physical Activity And Risk Of Disability Pension: Prospective Data From The Hunt Study, Norway

Marius S. Fimland¹, Gunnhild Vie¹, Andreas Holtermann², Steinar Krokstad¹, Tom IL Nilsen¹. ¹Norwegian University of Science and Technology, Trondheim, Norway. ²National Research Centre for the Working Environment, Copenhagen, Denmark.
 (No relationships reported)

PURPOSE: To prospectively investigate 1) the association between occupational physical activity (OPA) and disability pension, and 2) the combined association of OPA and leisure-time physical activity (LTPA) with disability pension in a large population-based cohort. **METHODS:** Data on 32 362 persons aged 20-65 years in the Norwegian HUNT2 study (1995-1997) were linked to the National insurance database. To reduce possible reverse causality, we excluded the two first years of follow-up. Cox regression with 95% confidence intervals (CI) were estimated.

RESULTS: Throughout a median follow-up period of 9.3 years and 265 592 person years, a total of 1 574 men (10%) and 2 263 women (13%) received disability pension. Both men and women who reported much walking in their jobs had increased risk of disability pension (adjusted hazard ratio [HR] for men: 1.26, 95% CI 1.09-1.45; women: 1.27, 95% CI 1.13-1.42). The risks were even higher for men and women who performed much walking and lifting (men: 1.46, 95% CI 1.26-1.70; women: 1.41, 95% CI 1.26-1.58) or had heavy physical work (men: 1.48, 95% CI 1.28-1.70; women: 1.42, 95% CI 1.13-1.77). Relative to the reference group with sedentary OPA and were active during leisure-time, all other groups had higher risk of disability pension. The combination of high OPA and being inactive during leisure-time was associated with the highest risk of disability pension (HR: 1.77, 95% CI 1.58-1.98). Several sensitivity analyses corroborated the results.

CONCLUSIONS: We observed a strong positive association between OPA and risk of disability pension, whereas physical activity during leisure-time reduced some, but not all of the unfavorable effect of physically demanding work on risk of disability pension. It could be useful to incorporate policies to reduce the negative health impact of occupational physical activity, as well as encouraging leisure-time physical activity, to reduce work disability.

Physical Activity Level and Androgen Concentrations are Independently and Additively Associated with Cardiovascular Disease Risk in Men.

Lauren C. Chasland¹, Matthew W. Knuiam¹, Mark L. Divitini¹, Yi X. Chan², David J. Handelsman³, Louise H. Naylor¹, Bu B. Yeap², Daniel J. Green¹. ¹University of Western Australia, Perth, Australia. ²Fiona Stanley Hospital, Perth, Australia. ³ANZAC Research Institute, Sydney, Australia.
 (No relationships reported)

Purpose

Male ageing is associated with increased incidence of cardiovascular disease (CVD) and lower circulating testosterone (T). However, whether physical activity (PA) interacts with hormones to modify CVD risk is unclear. We assessed whether PA and sex hormone concentrations were independently associated with measures of CVD risk in 1649 men.

Methods

Leisure, home, work and total PA were ascertained via questionnaire. At baseline, serum T, dihydrotestosterone (DHT) and estradiol (E2) were assayed. Men were stratified into high PA+high hormone (H/H); low PA+high hormone (L/H); high PA+low hormone (H/L) and low PA+low hormone (L/L) groups.

Results

Mean age was 49.8 years at outset with 415 CVD events and 127 CVD deaths occurring during 20-year follow-up. Men with higher PA and higher T or DHT had lower odds of metabolic syndrome (leisure H/H vs L/L odds ratio [OR] 0.17 $p < 0.001$ for T, 0.26 $p < 0.001$ for DHT). Men with higher PA and E2 had lower risk of metabolic syndrome (leisure PA H/H vs L/L OR 0.51, $p = 0.001$). Men with higher leisure PA and higher DHT had the lowest risk of CVD events (H/H hazard ratio [HR] 0.72 vs L/L, $p = 0.016$) and CVD death (H/H HR 0.52 vs L/L, $p = 0.015$). Men with low leisure PA and higher E2 were at greater risk of CVD death (L/H vs L/L HR 1.67, $p = 0.022$).

Conclusions

Considering PA levels in the context of T, DHT and E2 better informs consideration of cardiovascular risk. A 2x2 factorial RCT assessing PA and T would illuminate the scope for preventing CVD in men.

Building Healthy Communities: A Comprehensive School Health Program to Prevent Chronic Disease
 Erin E. Centeio¹, Nate McCaughtry¹, Whitney Moore¹, Alex Garn², Mariane Fahlman, FACSM¹, Jeffrey Martin¹, Noel Kulik¹. ¹Wayne State University, Detroit, MI. ²Louisiana State University, Baton Rouge, LA.
 (No relationships reported)

INTRODUCTION: Obesity among children is highly prevalent and can lead to risk factors for chronic disease in adulthood. The Institute of Medicine and Centers for Disease Control and Prevention have called on schools to play a larger role by increasing children's physical activity (PA) and nutrition by adopting an overall culture of health.

PURPOSE: This study examined the impact of a socioecological theory driven school-wide nutrition and PA intervention on 5th graders' central adiposity as a primary predictor of chronic disease.

METHODS: Four treatment and two control schools, including 628 (377 treatment, 251 control) 5th grade children participated in the study. Over eight months, children in the treatment schools participated in a comprehensive healthy school transformation program consisting of six components: 1) principal messaging and engagement, 2) classroom nutrition and physical activity lessons, 3) active recess, 4) quality physical education, 5) student leadership teams, and 6) after-school healthy kids clubs. Trained research assistants privately measured height, body weight, and waist circumference. Waist-to-Height Ratio (WHtR) was calculated and used as the measure of obesity. Missingness of data ranged from 0.40% to 15.40%. To reduce parameter estimate bias, as well as improve generalizability and power (Enders, 2010) the full pre-post dataset was imputed ($m = 100$) at the item level.

RESULTS: An ANCOVA controlled for differences between the treatment and control groups at time one. While controlling for age, gender, and race, the ANCOVA revealed a significant difference in WHtR among treatment and control groups at time two (T2) $F_{M1}(24.61, 63.08) = 4.59, p < .001, R^2_{\text{Treatment}} = 0.01$. There were no significant differences in T2 WHtR based on age $F_{M1}(0.02, 63.08) = 0.44, p > .05$, gender $F_{M1}(0.03, 63.08) = 0.001, p > .05$, and race $F_{M1}(0.15, 63.08) = 0.02, p > .05$. A total of 64% of T2 WHtR variance was accounted for by this model.

CONCLUSIONS: The healthy school intervention led to significant differences in central adiposity (obesity) levels, regardless of age, gender, or race, across the 8-month program between 5th grade children in treatment and non-treatment schools. This supports the ability of schoolwide programs to significantly and positively impact student health and chronic disease prevention.

Effects Of Exercise Training And Increasing Non-exercise Physical Activity On Cardiometabolic Risk Factors: Results From The I-can Study
 Damon L. Swift¹, Lesley D. Lutes², Tyara R. Nevels¹, Patricia M. Brophy¹, Chelsey A. Solar¹, Joeseeph D. Houmar, FACSM¹. ¹East Carolina University, Greenville, NC. ²University of British Columbia Okanagan, Kelowna, BC, Canada.
 (No relationships reported)

PURPOSE: Exercise training has known cardiovascular benefits, however little data exists on the potential additive effects of exercise training combined with increasing non-exercise physical activity on cardiometabolic risk factors, especially in a long duration intervention. **METHODS:** We randomized obese adults (N=45) to one of 3 groups: 1) aerobic training (AERO); 2) aerobic training and increasing non-exercise physical activity (AERO-PA) or; 3) a control group for 6 months. Both the AERO and AERO-PA groups participated in aerobic training at 50-75% $\dot{V}O_2$ max at a dose of 12 kcal/kg/week. In addition to exercise training, the AERO-PA group participated in behavioral coaching sessions to determine strategies to increase non-exercise physical activity levels (measured via accelerometer) by 3,000 steps/day. The main outcome of the trial was waist circumference. Secondary outcomes included fitness ($\dot{V}O_2$ max), body composition (dual-energy X-ray absorptiometry), and insulin action (oral glucose tolerance test). **RESULTS:** The study population had a mean (SD) age of 52.6 (7.6) yrs., body mass index of 36.0 kg/m² (4.8) and a physical activity level of 4635.6 (1242.7) steps/day at baseline. A significant higher steps/day was observed in the AERO-PA group (7216.6) compared to the AERO (5662.3, $p=0.007$) or CON (5330.3, $p=0.029$). Intent to treat analyses revealed significant changes in absolute $\dot{V}O_2$ max (0.28 vs. 0.09 L/min), relative $\dot{V}O_2$ max (3.8 vs. 0.91 ml/kg/min) and estimated maximal METs (Est METs) (1.2 vs. 0.52 METs) in the AERO-PA compared to the AERO group (all $p < 0.05$). No effects were observed for waist circumference, body mass, body composition, or insulin action variables. Person correlations showed that change in steps during the intervention in exercisers were associated with improvements in Est METs ($r=0.54, p=0.007$), body weight ($r=-0.43, p=0.03$), waist circumference ($r=-0.54, p=0.005$) and approached significance for body fat ($r=-0.40, p=0.054$). **CONCLUSIONS:** Exercise training and increasing non-exercise physical activity resulted in a greater improvement in fitness compared to aerobic training alone

($\Delta 0.71$ METs), which may be clinically important based on epidemiological data. In addition, higher step levels outside of exercise are supportive for improvements in body composition.

Winning off the Field: The Role of High School Sports Participation in College Physical Activity
 Fiona M. Asigbee¹, LaShaune P. Johnson², Jaimie N. Davis¹. ¹University of Texas at Austin, Austin, TX. ²Creighton University, Omaha, NE.
 (No relationships reported)

PURPOSE: To examine the role of High School (HS) sport participation and specific HS sport involvement on college physical activity (PA) levels.

METHODS: A cross-sectional cohort of 1,339 traditional, full-time degree seeking undergraduate students completed *The High School Physical Activity and College Health Behaviors Survey* (HSPA & CB) survey, consisting of 80-items, to assess health behaviors, including PA levels and HS sport participation. The relationship between HS sport participation (grouped as quintiles) and the likelihood of meeting the Centers for Disease Control and Prevention (CDC) recommendations for PA—number of days of aerobic activity and strength activity—was accessed using logistic regression. ANCOVAs were used to determine if the number of HS sport (in quintiles) was related to the number of days involved in aerobic and strengthening activities.

RESULTS: Results showed that the sum of all sports for all four years of HS was a significant predictor of the likelihood of meeting the CDC recommendations for number of days involved in aerobic (OR=1.08; 95%CI 1.04-1.13; $p < 0.001$), and strength (OR=1.11; 95%CI 1.07-1.16; $p < 0.001$) activities as college adults. Findings were also significant for the number of days involved in aerobic and strength activities for specific HS sports. When compared to other HS sports (competitive dance: 3.04 \pm 0.20 days, cross country: 3.49 \pm 0.31 days, football: 3.06 \pm 0.22 days, soccer: 2.90 \pm 0.17 days, and group "other": 3.48 \pm 0.40 days), HS cheerleaders (1.83 \pm 0.22 days) had lower aerobic and strength activity in college. HS volleyball and softball players (0.88 \pm 0.8 days; 0.86 \pm 0.11 days) had less strength activity in college, compared to other HS sports (baseball: 1.44 \pm 0.11 days, hockey and field hockey: 1.51 \pm 0.14 days, football: 1.52 \pm 0.09 days, and the group "other": 1.59 \pm 0.17 days).

CONCLUSION: Current findings support a strong connection between HS sport involvement and its lasting effects on college PA levels.

There is an association between agility and some neuromuscular functions such as perception capability and decision making. The maintenance of agility across the longevity process will increase the functional independence in old people over 65 years.

PURPOSE: To test the evolution of agility capability across the aging process in seniors aged over 65 years. **METHODS:** In this longitudinal study 152 participants (32 men and 120 women; 70.9 ± 4.5 years) were evaluated in Aragon (Spain) within the framework of the *elderly EXERNET* multi-center study. Agility was measured in all participants using the 8-foot up-and-go test (Senior Fitness Test Battery). The time (seconds) required to get up from a seated position, walk 2.45 m, turn and return to a seated position was registered. The test was performed twice, with at least one minute of rest between repetitions. The best result was recorded. The measurements were registered in 2008-2009 and eight years later, in 2016-2017. A 2-way repeated measures ANOVA test was used to evaluate the changes in this parameter. The sample was divided into three groups (group 1: ≤ 74 years old; group 2: 75-84 years old; group 3: ≥ 85 years old) to observe if there were differences between ages. As no sex-by-time interactions were found, analyses were performed including men and women as a whole group. **RESULTS:** Significant decreases in agility between both measures (5.1 ± 1.9 s vs. 6.4 ± 0.9 s; $p < 0.001$) were found. The average percentage of change during the follow-up was 24%. However, the oldest group showed a larger increase in agility in the 8-year follow-up than the younger groups (12%, 23%, 50%, groups 1, 2 and 3, respectively; $p < 0.001$ between youngest and oldest group). **CONCLUSION:** Agility constantly decreases across the aging process, being this decrease more pronounced after the age of 85. Physical fitness interventions for elderly people should include aspects of agility training in order to increase functional independence and quality of life.

Supported by Ministerio de Trabajo y Asuntos Sociales (104/07), University of Zaragoza (UZ 2008-BIO-01), Centro Universitario de la Defensa (UZCUD2016-BIO-01), Ministerio de Economía y Competitividad (DEP 2016-78309-R) and FEDER funds.

Physical Activity among Navajo Cancer Survivors: A Qualitative Study

Luis Valdez¹, Hendrik de Heer², Anna Schwartz², Brian Kinslow², Etta Yazzie¹, Mark C. Lee¹, Pearl Nez², Shelby Delgai², Jennifer W. Bea¹. ¹University of Arizona, Tucson, AZ. ²Northern Arizona University, Flagstaff, AZ.

(No relationships reported)

PURPOSE: Physical activity (PA) may improve quality of life and survival among cancer survivors, however, little is known about Navajo cancer survivor PA. We sought to understand Navajo cancer survivor PA habits, perceptions, barriers, and preferences. **METHODS:** Focus groups (N=5 groups, 19 individuals) and individual interviews (N=13) were conducted by a bilingual facilitator using a standardized guide. Discussions were recorded, transcribed and translated. NVivo software was used to summarize major themes. **RESULTS:** Participants were male (N=13) and female (N=19) Navajo cancer survivors (31% breast, 31% colorectal, or other). Treatment side effects reduced PA during and after treatment. However, most reported at least one mode of current PA (N=24; 71% walking). Work and homestead related PA was a common necessity (46%). Cancer survivor PA recommendations were largely unknown, though many survivors understood the benefits of PA and valued resilience, social support, movement, and life balance. Limited access to recreational PA opportunities was cited as a barrier. Fear of "over doing it" and family/friends encouraging rest also limited PA. Preferences for PA programming varied by individual. **CONCLUSION:** In this first qualitative inquiry of PA among Navajo cancer survivors we found that PA education is needed and varied PA opportunities are desired.

3786 Board #233 June 3 9:30 AM - 11:00 AM

The Association Of Leptin With Unique Measures Of Body Composition Distribution In Exercising Women

Kristen J. Koltun, Heather C.M. Allaway, Nancy I. Williams, FACSM, Mary Jane De Souza, FACSM. Penn State University, State College, PA.

(No relationships reported)

Women with functional hypothalamic amenorrhea (FHA) present with suppressed systemic leptin, a signal of nutritional status. Unique measures of regional body composition that reflect subcutaneous (leg and gynoid) versus visceral (trunk and android) fat have varying impacts on leptin. The relationship between leptin and these unique measures has not yet been explored in exercising women with varying menstrual status.

ACSM May 30 – June 3, 2017

Purpose: To examine the relationship between systemic leptin concentration and unique measures of body composition distribution in exercising women with FHA and ovulatory menstrual cycles.

Methods: Leptin and body composition were assessed in exercising women with ovulatory cycles (OV, n=22) and with FHA (AMEN, n=17). Leptin was measured by immunoassay and trunk, leg, android, and gynoid percent fat were measured by DXA with the ratios of trunk/leg (T/L%R) and android/gynoid (A/G%R) fat % calculated. Student t-tests were used to compare demographics. Pearson and Spearman correlations were used to determine associations between leptin and unique body composition variables.

Results: There were no differences between the groups with respect to age, height, weight, BMI, or body fat % ($p > 0.05$). Log leptin was significantly correlated with leg (OV: $r = 0.794$, $p < 0.001$; AMEN: $r = 0.647$, $p = 0.005$), trunk (OV: $r = 0.679$, $p = 0.001$; AMEN: $r = 0.757$, $p < 0.001$), android (OV: $r = 0.673$, $p = 0.001$; AMEN: $r = 0.779$, $p < 0.001$), and gynoid (OV: $r = 0.822$, $p < 0.001$; AMEN: $r = 0.617$, $p = 0.008$) % fat in both groups. AMEN log leptin was significantly correlated with T/L%R ($r = 0.490$, $p = 0.046$) and A/G%R ($r = 0.735$, $p = 0.001$). The regions of strongest association differed between OV and AMEN with a stronger relationship in OV between log leptin and leg and gynoid % fat, whereas in AMEN log leptin was more strongly related to trunk and android % fat.

Conclusion: Ratios of T/L%R and A/G%R were significantly related to leptin concentration in AMEN and body fat distribution measures were related in both groups. Regions of body composition reflecting subcutaneous fat have a greater influence on systemic leptin concentration than regions reflecting visceral fat indicating that the site distribution of adiposity may be more important for systemic leptin than traditional measures of total fat mass and the association may reflect menstrual status.

Dietary Nitrate and Muscle Power with Aging

Andrew R. Coggan, FACSM¹, Joshua L. Leibowitz², Deana Mikhalkova², Dakkota Thies², Seth R. Broadstreet¹, Suzanne Waller², Linda R. Peterson². ¹Indiana University Purdue University Indianapolis, Indianapolis, IN. ²Washington University School of Medicine, St. Louis, MO.

(No relationships reported)

Reductions in muscle speed and power are highly predictive of disability, institutionalization, and mortality in the elderly. We have recently demonstrated that ingestion of dietary nitrate (NO_3^-), a source of nitric oxide (NO), increases maximal muscle speed and hence power in healthy younger individuals, in athletes, and especially in patients with heart failure (HF). **PURPOSE** The purpose of the present study was to determine whether dietary NO_3^- improves muscle contractile function in older people, another population (like HF patients) in whom NO production is reduced. **METHODS** Six healthy older subjects (5 men, 1 woman; age 73 ± 6 y, height 1.74 ± 0.10 m, mass 82.4 ± 12.1 kg) were studied using a randomized, double-blind, placebo-controlled, crossover design. On one occasion, subjects were tested 2 h after ingesting a concentrated beetroot juice (BRJ) supplement containing 11.2 mmol NO_3^- . On another, they were tested 2 h after ingesting BRJ depleted of NO_3^- (placebo). Breath NO was measured periodically, and maximal knee extensor force (torque), speed, and power were assessed using a Biodex 4 isokinetic dynamometer. **RESULTS** Dietary NO_3^- ingestion increased breath NO levels, a marker of whole-body NO bioavailability, from 27 ± 10 to 51 ± 26 ppb ($P < 0.05$). On average, this resulted in an increase in the maximal velocity of knee extension of 10% (i.e., from 9.81 ± 1.38 to 10.75 ± 2.42 rad/s), but this difference only approached statistical significance (i.e., $P = 0.13$). On the other hand, maximal knee extensor power did not differ between the NO_3^- and placebo trials (i.e., 4.16 ± 1.18 vs. 4.08 ± 1.22 W/kg; $P = 0.47$). This lack of difference, however, seemed to be due to an inadequate dose of NO_3^- in some subjects, as the relative increase in maximal power was correlated (i.e., $r = 0.78$; $P < 0.05$) with the amount of NO_3^- ingested per kilogram of body mass. In keeping with this conclusion, maximal power increased ($P < 0.05$) by $6.4 \pm 3.9\%$ in the four subjects who ingested > 125 mmol/kg of NO_3^- , but did not improve in the two subjects who ingested less. **CONCLUSION** Acute dietary NO_3^- supplementation appears to improve muscle contractile function in healthy elderly individuals, but only when provided at a dose of > 125 mmol/kg of NO_3^- . The optimal dose of dietary NO_3^- for improving muscle speed and power in older (or younger) persons remains to be determined.

Effect Of Dietary Nitrate Supplementation On The Development Of Neuromuscular Fatigue During Whole Body Exercise

Taylor S. Thurston, Thomas J. Hureau, Joshua C. Weavil, Jayson R. Gifford, Hsuan-Yu Wan, David T. La Salle, Russell S. Richardson, Markus Amann. University of Utah, Salt Lake City, UT.

(No relationships reported)

PURPOSE: To investigate the effect of dietary nitrate supplementation on the development of neuromuscular fatigue during whole body exercise. **METHODS:**

Denver, Colorado

Three healthy, recreationally active males (30 ± 1 yrs) performed fatiguing, constant-load cycling exercise ($80\% W_{peak}$, 243 ± 12 W) following three days of dietary nitrate supplementation (DNS) or a nitrate-stripped placebo (PLA). PLA exercise was performed to task failure, with DNS exercise time matched to that which was achieved during PLA exercise. General quadriceps fatigue was quantified as the pre- to post-exercise decrement in maximal voluntary contraction torque (ΔMVC). Peripheral and central fatigue were quantified as the pre- to post-exercise changes in quadriceps twitch torque (ΔQ_{tw} ; supramaximal electrical femoral nerve stimulation) and voluntary activation (ΔVA), respectively. Prior to each trial, femoral arterial blood flow (Doppler ultrasound, common femoral artery) was quantified during cycling exercise at 50, 75, and 100 W (4 min each). Heart rate, ventilation, and pulmonary gas exchange were recorded throughout exercise. **RESULTS:** Femoral arterial blood flow was similar between conditions at baseline (~ 0.3 L \cdot min $^{-1}$) and all 3 workloads (~ 1.9 , ~ 2.4 , ~ 2.8 L \cdot min $^{-1}$ during cycling exercise at 50, 75, and 100 W, respectively). Furthermore, heart rate (~ 185 BPM), minute ventilation (~ 146 L \cdot min $^{-1}$), O_2 consumption (~ 3.1 L \cdot min $^{-1}$), and CO_2 production (~ 3.4 L \cdot min $^{-1}$) during the final minute of exercise were similar between trials. While nitrate supplementation had no effect on ΔMVC ($\sim 14\%$) and ΔVA ($\sim 4\%$), ΔQ_{tw} was significantly lower in DNS compared to PLA ($-35 \pm 2\%$ vs $-41 \pm 7\%$, respectively). **CONCLUSION:** Dietary nitrate supplementation attenuates the development of peripheral fatigue during whole body exercise. As the treatment did not alter the cardiopulmonary response and bulk locomotor muscle blood flow during cycling exercise, this ergogenic effect is likely determined by intramuscular and/or intracellular mechanisms. Finally, the observed attenuation of peripheral fatigue during endurance exercise might contribute to the documented performance enhancement previously reported with DNS.

Efficacy of a Personalized Hydration Plan on Repeated Countermovement Jump Performance after Exercise-Heat Stress

Stephen A. Wolf, Riana R. Pryor, Bhupinder Singh, J Luke Pryor. *California State University, Fresno, CA.*
 (No relationships reported)

Exercise-induced hyperthermia, dehydration, and fatigue independently impair anaerobic power production, but any synergistic effect on anaerobic power is less known. Further, the efficacy of a personalized hydration plan in maintaining anaerobic power after exercise-heat stress is unclear.

Purpose: To evaluate the effect of exercise-induced hyperthermia, dehydration, and fatigue on anaerobic power during a 20-second repeated countermovement jump (CMJ). Secondly, to assess the efficacy of a personalized hydration plan in maintaining anaerobic power during CMJ after exercise-heat stress. **Methods:** Five males (age: 25.4 ± 5.7 y; height: 175.4 ± 8.2 cm; weight: 78.7 ± 16.8 kg; VO_{2max} : 60.1 ± 6.1 mL \cdot kg $^{-1}\cdot$ min $^{-1}$) completed 50-90 min of exercise in warm conditions (wet bulb globe temperature: $27.0 \pm 2.24^\circ C$) with (EXP) and without (CON) fluid replacement equal to sweat rate in a counterbalanced, randomized, cross-over fashion. Gastrointestinal temperature (T_{gi}) and fatigue (scale of 0-10) were measured throughout exercise. Dehydration was determined by percent body mass loss (BML). Peak power (PP), mean peak power (MPP), and heart rate (HR) were measured during CMJ pre- and post-exercise using dual force plates and a HR strap. Dependent t-tests evaluated post-exercise T_{gi} , fatigue, and BML between groups. Separate two-way repeated measures ANOVA evaluated differences in PP, MPP, and HR with $\alpha=0.05$. **Results:** Subjects achieved $2.59 \pm 0.52\%$ BML in CON and $0.92 \pm 0.41\%$ in EXP ($p < 0.001$). Post-exercise T_{gi} (39.29 ± 0.31 , $39.03 \pm 0.61^\circ C$, $p=0.425$) and fatigue (9 ± 1 , 9 ± 2 ; $p=0.424$) were similar between CON and EXP, respectively. HR response during post-exercise CMJ was greater in CON than EXP (174 ± 7 , 161 ± 11 , $p=0.040$). No differences ($p > 0.05$) were seen in PP or MPP pre-exercise (PP: 53.80 ± 10.78 , 55.80 ± 11.63 ; MPP: 45.20 ± 8.26 , 45.80 ± 8.14) to post-exercise (PP: 52.80 ± 12.05 , 52.20 ± 8.17 ; MPP: 46.40 ± 7.83 ; 44.20 ± 7.29) for EXP and CON, respectively. **Conclusion:** Exercise-induced hyperthermia, dehydration, and fatigue to the levels achieved in this study did not affect anaerobic power. Fluid replacement reduced cardiovascular strain but did not affect anaerobic power during CMJ, likely due to the mild hyperthermia and $< 3\%$ dehydration in CON.

Alaska Mountain Wilderness Ski Classic: Alterations in Body Composition

Kenneth J. Shin, Michelle Johannsen, Karolina Priebe, Robert H. Coker, FACSM. *University of Alaska, Fairbanks, Fairbanks, AK.*
 (No relationships reported)

* **PURPOSE:** The Alaska Mountain Wilderness Ski Classic (AMWSC) is considered to be one of the most challenging endurance events in the world. It has endured for more than 2 decades and various courses have traversed the Wrangell St. Elias, Chugach, Brooks and Alaska mountain ranges. There are no food drops, rest stations,

or marked trails as skiers are free to pick the best route (i.e. 100-150 miles) through the mountainous and remote Alaskan backcountry. Given the combined challenges of chronic activity, mental stress and cold exposure on physiological resilience, the purpose of this study was to evaluate the influence of the 2016 AMWSC that was staged in the Brooks Range on energy expenditure and body composition. A two-tailed paired t-test was used to compare pre- and post-event alterations in lean body mass, fat mass and bone mineral density.

* **METHODS:** 15 male and female skiers (mean \pm SEM; Age = 31.4 ± 0.7 , BMI = 23.7 ± 0.6) were recruited for the study. Lean body mass, total fat mass, and bone mineral density were measured using a General Electric iDXA pre- and post-event. In order to estimate total and daily energy expenditure, all participants wore a Actigraph wGT3X-BT monitor throughout the event.

* **RESULTS:** The first finishing group completed the event in 100 hours and 25 min, and the last individual completed the event at 121 hours and 7 min setting a course record for the closest time range within the finishing groups. Lean body mass and the relative skeletal muscle index (RSMI) increased by 1.7 ± 0.3 kg and 0.22 ± 0.05 kg/m 2 , respectively. While there was a significant reduction (Δ of -1.3 ± 0.2 kg) in total fat mass, there was no change in bone mineral density (Δ of 0.0044 ± 0.0085 g/cm 3). Including a correction for pack weight, daily energy expenditure was 5084 ± 244 , 7314 ± 332 , 7492 ± 422 , 7505 ± 307 , 6538 ± 376 , 3843 ± 592 , 5889 ± 859 kcal, respectively over the course of the event. Total energy expenditure was $37,162 \pm 2174$ kcal.

* **CONCLUSION:** Lean body mass and RSMI increased in all athletes. Previous work using isotopic methodologies during acute exercise showed that urea reincorporation into protein increased during exercise. Future studies are planned with this cohort that will utilize isotopic methodology to measure changes in protein synthesis and skeletal muscle for evaluating the impact of cold exposure on physiological resilience.

Influence of Physical Activity Patterns and Age on Acute Mountain Sickness Incidence during Mt. Kilimanjaro Trek

Girish Pathangey¹, Courtney M. Wheatley¹, Alex R. Carson², Glenn M. Stewart², Kirsten E. Coffman², Amine N. Issa², Norman D. Morris³, Jan Stepanek¹, Bruce D. Johnson². ¹Mayo Clinic, Scottsdale, AZ. ²Mayo Clinic, Rochester, MN. ³Griffith University, Gold Coast, Australia.
 (No relationships reported)

PURPOSE: Physical activity is often noted as a risk factor for the development of AMS. We sought to explore the interaction between age and physical activity patterns on the development of AMS in a group of 27 individuals during a gradual ascent of Mt. Kilimanjaro (19,341 ft).

METHODS: 27 adults (44 ± 15 yrs; 24.45 ± 3.90 BMI; $n=11/27$ Female) climbed over an 11-day period. Use of acetazolamide and NSAIDs were minimized but remained optionally taken as necessary during the ascent. Physical activity was monitored using BodyMedia activity monitors; heart rate and oxygen saturation were monitored with Biovotion devices; AMS incidence was classified from the Lake Louise Questionnaire; and total symptoms were scored from the questionnaire's original five symptoms plus an additional five symptoms. Groups were divided based on age (group 1: 28 ± 2 yrs, 2: 44 ± 8 yrs, and 3: 58 ± 10 yrs). Comparisons were made using ANOVA and independent T-tests, and post hoc analyses were made using Tukey's method.

RESULTS: Throughout the trek, 59% ($n=16/27$) of subjects displayed AMS at least for one day during the climb. Average total symptom scores were 4.2 ± 2.9 , 2.2 ± 1.9 , 3.3 ± 1.5 for group 1 vs. 2 vs. 3 respectively. Focusing on the summit push (day 10), AMS incidence was highest in group 1 (87.5%; $n=7/8$) compared to group 2 (33%; $n=3/9$) and group 3 (25%; $n=2/8$) with an ANOVA statistical significance of $p < 0.05$. Moreover, percentage of climb spent in moderate to vigorous activity (MVPA), hiking speed (KPH), and steps taken per minute were highest for group 1 (MVPA: $65\% \pm 14\%$ vs. $54\% \pm 19\%$ vs. $52\% \pm 14\%$; KPH: 1 ± 0.1 vs. 0.91 ± 0.09 vs. 0.85 ± 0.06 ; Steps/min: 23 ± 5 vs. 22 ± 5 vs. 14 ± 2 ; ANOVA $p < 0.05$ for KPH, steps/min). Average heart rate and SpO2 was higher for group 1 during the climb to summit (HR: 109 ± 13 bpm vs. 88 ± 14 bpm vs. 87 ± 8 bpm; SPO2: $85.5 \pm 5.5\%$ vs. $83.2 \pm 9.4\%$ vs. $81.9 \pm 8.0\%$; $p < 0.05$ for HR). Post hoc analyses depicted a significant difference between group 1 and group 3 in AMS incidence, KPH and steps/min, and a significant difference in HR between group 1 and the rest.

CONCLUSIONS: In this study, the youngest group averaged a higher total symptom score throughout the trek, and exerted greater physical intensity, hiking speed, and activity on summit day. It was found that AMS was more common in young adults, which may be due to being more active and adventurous than older individuals.

3792 Board #239 June 3 9:30 AM - 11:00 AM
The Response Of Plasma Hypoxia-inducible Factor-1 Alpha, Serum Erythropoietin And Plasma Vascular Endothelial Growth Factor During Acute Exposure To Altitude (4300 M)

Roy Salgado, Beth Beidleman. *United States Army Research Institute of Environmental Medicine, Natick, MA.*
 (No relationships reported)

The response of plasma hypoxia-inducible factor-1 alpha, serum erythropoietin and plasma vascular endothelial growth factor during acute exposure to altitude (4300 m) Salgado, R.M.¹ and Beidleman, B.A.² ¹Thermal and Mountain Medicine Division, US Army Research Institute of Environmental Medicine, Natick, MA ²Biophysics and Biomedical Modeling Division, US Army Research Institute of Environmental Medicine, Natick, MA Intracellular hypoxia-inducible factor-1 alpha (HIF-1 α) increases in response to hypoxia and regulates erythropoietin (EPO) and vascular endothelial growth factor (VEGF) expression. However, the response of extracellular HIF-1 α (i.e. plasma HIF-1 α) to acute hypobaric hypoxia (HH) exposure is unclear. **PURPOSE:** To determine whether plasma HIF-1 α and downstream targets such as serum EPO and plasma VEGF increase from sea level (SL) to acute HH. **METHODS:** Venous blood samples from 14 SL residents (M = 10, F = 4, age = 23 \pm 7 years, ht: 179 \pm 10 cm, wt: 74 \pm 12 kg, 46 \pm 6 ml/kg/min; mean \pm SD) were collected after ~20 min of seated rest at SL (~50 m, Natick, MA) and after ~19 hrs of exposure to HH (4300 m, Pikes Peak, CO). Plasma HIF-1 α , serum EPO, and plasma VEGF were measured via ELISA assay. **RESULTS:** From SL to HH, plasma HIF-1 α (SL: 287 \pm 108 pg/mL vs HH: 264 \pm 128 pg/mL, p = 0.51) and plasma VEGF (SL: 74 \pm 55 pg/mL vs HH: 100 \pm 87 pg/mL, p = 0.23) did not change. From SL to HH, serum EPO increased (SL: 14 \pm 15 mIU/mL vs HH: 62 \pm 42 mIU/mL, p < 0.0001). **CONCLUSION:** During the first ~19 hrs of HH exposure plasma HIF-1 α and plasma VEGF do not increase, while serum EPO does increase. While we were the first to measure plasma HIF-1 α during an acute exposure to HH, our results indicate that extracellular HIF-1 α may not represent intracellular HIF-1 α response to HH. Disclaimer: Author's views are not official U.S. Army or DoD policy.

Stress And Well-Being Of Correctional Officers

Kerry S. Kuehl, Diane L. Elliot, FACSM. *Oregon Health & Science University, Portland, OR.*
 (No relationships reported)

Working as a correctional officer (CO) in the U.S. leads to a lower life expectancy than the average U.S. adult, but little research has been done to understand factors leading to these high health risks. **PURPOSE:** To assess mental and physical health characteristics of CO's working in minimum security level prisons as compared to CO's working in maximum security level prisons. **METHODS:** 210 CO's from the Oregon Department of Corrections were assessed by physical measures and survey. Survey included validated measures of stress, diet, physical activity, sleep, pain, disability and injury data, tobacco and alcohol use. Physical measures included fasting lipid and blood glucose, blood pressure, body weight, body composition, waist and hip circumference, flexibility and grip strength. Independent two sample t-tests or chi-square tests were used to assess differences among CO's working in minimum versus maximum security prisons. **RESULTS:** 87% of CO's were overweight or obese and 52% had metabolic syndrome. While years on the job were similar (13 years), CO's working at maximum security prisons reported significantly higher work stress (p=.013) and higher alcohol consumption (p=.040) compared to CO's working at a minimum security level prison. Maximum security level CO's reported greater missed days of work compared to CO's working at a minimum security prison and correlated with increased work stress (p<0.001), less sleep, unhealthy eating habits, and not exercising (p<0.01 for each). **CONCLUSION:** Corrections work is regarded as one of the most difficult and stressful occupations with high morbidity and mortality rates. Our findings indicate CO's working in maximum security prisons have higher mental and physical health risks as compared to minimum security CO's. Specific wellness interventions are needed to improve the well-being of these vulnerable workers. Encouraging Exercise In The Palmetto State: A Descriptive Analysis Of Hiit And Its' Associated Injuries

Brian J. Schutzbach¹, William N. Gasque², Allyson L. Hale¹, Joseph A. Ewing¹, Michael W. Wiederman¹, Andrew W. Albano¹. ¹Greenville Health System, Greenville, SC. ²University of South Carolina School of Medicine-Greenville, Greenville, SC.
 (No relationships reported)

The Exercise Is Medicine® initiative has increased the focus on exercise and its impact on health and wellness. High intensity interval training (HIIT) is an exercise modality that is reported to be gaining popularity. Because physicians, and other medical professionals, are often tasked with encouraging exercise as part of a patient's medical therapy, it is important to understand the risks associated with HIIT so as to provide the best guidance and care possible. **Purpose:** The aim of this study was to describe the HIIT population and their HIIT-related injuries, including incidence, location, duration, and management. **Methods:** A multi-item survey was distributed to various facilities throughout the state of South Carolina promoting and instructing HIIT. Survey results were analyzed using students t-test and Chi-squared tests. **Results:** Sixty-six people met the inclusion criterion of participation in HIIT. The majority were male (56%), in their mid-thirties (33.9 \pm 8.1), with a mean BMI of 25.6 (\pm 4.1). Most reported participation in a beginner's HIIT training program (71%), prior weight lifting training (64%), and some level of previous athletic experience (91%). From these 66 individuals, 70% said they do HIIT \geq 4 times a week, and approximately 44% (n=29) reported at least one HIIT-related injury. Fifty-three total injuries were reported; the most common being shoulder (19%) and lower back (19%). Approximately 38% sustained their injury within 6 months of starting HIIT and 55% within the first year. Most people (62%) self-diagnosed their injury, and 52% did not seek professional treatment. The majority of those injured said they recovered from their injuries within 2 months (83%) following rest (38%) and/or a decrease in exercise intensity (41%). **Conclusions:** Despite introductory training programs and prior athletic and weight lifting experience, approximately half of HIIT participants experienced a HIIT-related injury. Individuals with HIIT-related injuries are most likely to self-diagnose, and/or self-adjust their exercise program prior to resuming HIIT.

Development Of A Novel Grading Scale Based On The ULNT1 And BPTT

Mark W. Butler¹, Mary Lou Galantino², M. Alysia Mastrangelo, FACSM². ¹Nova Care Rehabilitation, Medford, NJ. ²Stockton University, Galloway, NJ.
 (No relationships reported)

Purpose: Upper Limb Neurodynamic Tests assess for mechanosensitivity, with moderate degrees of reliability and validity. The purpose of this study was to assess inter and intra-rater accuracy of a novel standardized grading scale based on neurodynamic tests demonstrated to bias the median nerve and brachial plexus. **Methods:** Participants attending lectures on neural mobilization were instructed in a novel grading scale based on the Upper Limb Neurodynamic Test 1 and Brachial Plexus Tension Test. At least one hour after instruction, participants were shown 7 different videos of a possible 14 test positions in random order and asked to score the tests on a data collection sheet. To determine accuracy in Phase II, at least one month after participating in Phase I, nine of the 307 clinicians were re-tested by again viewing the 7 videos and scoring the tests. **Results:** In Phase I, SPSS 22.1 was used for descriptive statistics and ANOVA data analysis. Fifty eight percent achieved the correct response for all 7 positions, 23.5% for six positions, and 12.1% for five positions 4.6% for 4 positions and less than 2% accurate for 3 or less test positions. Of note, clinicians with 1 – 5 years of experience scored significantly better than clinicians with 15+ years of experience (p<.002). There were no significant differences in accuracy between groups of clinicians based on area of specialty or location. In Phase II a similar analysis included 9 participants, 89% achieved the correct response for all 7 positions, with 100% achieving a correct response to 6 or more positions. **Conclusion:** Previous authors have identified the value of neural mobility testing but have not utilized a specific grading scale. This study is the first step to identifying and testing a clinical scale that may have utility in the clinic. Our results demonstrate good accuracy of responses among all clinicians in their ability to correctly identify test positions in this grading scale. However, there was a significant difference in accuracy between clinicians with 1 – 5 years of experience vs. clinicians with 15+ years of experience. This grading system may provide quantified outcome in neural mobility scoring for clinical utility. Further testing is needed to ascertain why differences exist in two levels of years of experience.

3796 Board #243 June 3 9:30 AM - 11:00 AM
Impact of Attention Deficit Hyperactivity Disorder on Athletes
 Timothy M. Dekker. *Mayo Clinic, Jacksonville, FL.*
(No relationships reported)

Impact of Attention Deficit Hyperactivity Disorder on Athletes
 Timothy Dekker, George G.A. Pujalte, Jennifer R. Maynard, McKennan J. Thurston, Walter C. Taylor, and Mohit Chauhan
Purpose: This systematic review was done to try to uncover Attention deficit hyperactivity disorder's (ADHD) impact on athletics, treatment effects on sports participation, basis for regulation by sports organizations, and approaches to conditions occurring with ADHD.
Methods: A systemic review was done using specific keywords, gathering articles from MEDLINE, Embase, PsycINFO, Cochrane Database of Systemic Reviews and Ovid Interface.
Results: ADHD is a common neurobehavioral disorder, reported as affecting 11% of children, with symptoms persisting into adulthood in up to 15% of individuals. ADHD has been shown to have both beneficial and detrimental effects on athletic performance. Advantages include: Impulsivity, increased aggressiveness, improved pain tolerance, and decreased fatigue. Conversely, children with ADHD were found to have lower total motor composite ($t=-9.32$, $p<.001$) with Bruininks-Oseretsky Motor Performance Test. Sports and exercise have numerous positive effects on those with ADHD, for example, an increase in Dupaul ADHD rating scores of 4.53($p=.04$) were found after a 6 week aerobics program. Stimulants combined with behavioral techniques are known to be superior to behavioral management alone. Return to play is also different in athletes with pre-existing ADHD, especially with concussions due to more persistent memory issues, decreased focus and brain fog after injury. Sport organizations regulate stimulants due to presumed advantages and side effects: Increased thermogenic effects of stimulants, MI, CVA, psychosis, seizures, and even death have been recorded.
Conclusions: Athletes with ADHD should be recognized and managed appropriately. Sports performance can be positively and negatively affected by ADHD, which individual athletes and organizations need to consider. More research is needed to determine how ADHD and medications used affect specific sports.

Understanding Injury and Injury Prevention in Paralympic Sport
 Marcus Fearing¹, Shana Harrington². ¹*Creighton University School of Medicine, Omaha, NE.* ²*University of South Carolina, Columbia, SC.*
(No relationships reported)

PURPOSE: Adaptive equipment technologic advances and increased media attention to the Paralympic Games have led to an increasing number of athletes with disabilities participating in Para sports. Still, little is known about common injuries that occur in Para sport athletes. Even less is known about whether these athletes are currently participating in injury prevention programs. The purpose of this study was to survey swimming, cycling and athletic Para sport athletes to better understand common injuries and whether injury prevention programs were being performed.
METHODS: An electronic survey was created using Qualtrics consisting of 28 questions and emailed to 364 athletes who competed in the US Para Swimming, Cycling and Athletic Trials in Charlotte, NC -July 2016. The following information was collected from the survey: average number of hours trained, number of cross training hours performed each week, descriptive information regarding sport related injuries, pain, and whether athletes received treatment for injuries and descriptive information regarding whether the athletes had participated in an injury prevention program.
RESULTS: A total of 137 surveys were completed. Males represented 58% of respondents and females 42%. Swimming represented 29% of the respondents, cycling 26% and athletics 51%. Over 70% of respondents trained ≥ 11 hours/week; and 45% of athletes reported spending ≥ 6 hours per week cross-training. Forty-two percent of athletes revealed they have current pain, and 34% had missed a competition because of injury. Sixty-two percent reported receiving physical therapy relating to sports injuries and 13% required surgeries for the sports-related injury. Only 24% of athletes participated in an injury prevention program.
CONCLUSIONS: A large percentage of Para sport athletes report injuries and often have to miss training and competition due to these injuries. Despite this, only 24% report participating in an injury prevention program. Results from this study emphasize the need to develop and implement injury prevention programs in para sport athletes to help diminish the impact these injuries have on training and competition.

Minute Porosity of 3D Printed Splints and Casts May Allow Water Entry
 Diana Hall¹, Frank Roquemore¹, Jay Townsend², Bill Bentley³, David Atkins⁴, Lex Schultheis³. ¹*ActivArmor, Pueblo, CO.* ²*Department of Corrections, State of Colorado, Canon City, CO.* ³*Robert E. Fischell Medical Device Institute, College Park, MD.* ⁴*Dept. of Aerospace Engineering, Clarke School of Engineering, University of Maryland, College Park, MD.*
Reported Relationships: D. Hall: *Intellectual Property; Patent holder for ActivArmor technology. Ownership Interest (Stocks, Bonds); Owner of ActivArmor.*

MINUTE POROSITY OF 3D PRINTED SPLINTS/CASTS MAY ALLOW WATER ENTRY
 Acknowledgements: Jorge Hernandez, James Coburn, FDA, Center for Devices and Radiation Health, Office of Science and Engineering Laboratories
PURPOSE: Optical scanning and additive manufacturing of immobilizing devices allow for custom fit without padding, allowing patients to return to wet/athletic activity during recovery. However, no studies have evaluated waterproofing of 3D printed immobilization devices. We hypothesized that water may enter the interior of these devices unless strict manufacturing process controls are followed and claims of waterproofing are verified. **METHODS:** Patient specific ABS polymer casts manufactured using fused filament methods by ActivArmor were evaluated for water penetration and retention. Manufacturing parameters were evaluated. Finished devices with visually smooth unbroken surfaces were immersed in fresh water in depths from 1 to 25 feet for periods ranging from 5 to 30 minutes. Change in gross weight was used to determine the quantity of water retained. Examination of surface features was evaluated by digital optical microscopy and internal structure by micro computed tomography. **RESULTS:** Some casts that appeared completely sealed admitted water at depths as little as one foot, increasing up to 16% of dry weight at depths of 25 feet. Small changes in manufacturing reduced water entry to 3% of dry weight, while increasing extrusion diameter completely waterproofed prints. Optical microscopy revealed fenestrations in lamination at acute angles in geometry of prints in prints that retained water. Micro computed tomography was notable for 17 micron gaps in smooth straight sections of water absorbing prints. **CONCLUSIONS:** Visual inspection of 3D printed devices is not sufficient to verify watertight integrity. Retained water inside devices may support bacterial colonization. However, application of appropriate manufacturing process controls and verification procedures enable custom 3D printed devices support claims of improved hygiene and waterproofing. Supported by FDA, Office of Regulatory Science and Innovation, University of Maryland Center for Regulatory Science Initiative

Creatine Kinase, Glomerular Filtration Rate and Military Physical Activity during 2012 Comandos Course
 NILTON G. ROLIM FILHO. *EB/CNPq/FADEUP, Porto, Portugal.*
(No relationships reported)

Exercise rises muscle serum parameters and thus their interpretation could be helpful in monitoring recovery from acute overload or from muscular trauma. Our understanding of these relationships among Special Operations students is limited. **PURPOSE:** This study aimed evaluate effects of repeated sessions of military training exercises during 2012 Comandos Course on muscle damage (CK, LDH, and AST), renal function (creatinine, urea and estimate glomerular filtration-eGFR) and body composition (skeletal muscle mass, visceral fat area and extracellular water). **METHODS:** Biomarkers from 19 Brazilian Army students (age=28.26 \pm 3.91) were analyzed, once a week, during 14 weeks. Serum CK, LDH, AST, creatinine and urea levels by dry-chemistry method. The eGFR by CKD-EPI, expressed as ml/min/1.73m². The BIA evaluation carried out with *InBody720*. Data analyzed to evaluate the baseline and post-training differences were determined by paired sample t test and their effect size (ES) by Cohen's d. **RESULTS:** The presented results of the paired sample t test were significant ($p<0.05$). In extracellular water $t(18)=10.07$, $ES=3.36$ were a huge increase from the baseline ($M=18.37\pm 2.18$) at the 4th week ($M=19.53, \pm 2.4$), this huge effect also occurs with skeletal muscle mass $t(18)=-12.67$, $ES=4.22$ from baseline ($M=38.42, \pm 4.13$) to $M=40.65 \pm 4.61$. The results demonstrated a huge decrease in visceral fat area $t(18)=12.26$, $ES=4.09$ / baseline ($M=47.61\pm 13.18$) to the 5th week ($M=25.53\pm 9.7$), as well as eGFR $t(18)=4.51$, $ES=1.5$ with baseline ($M=128.18\pm 15.07$) to $M=111.16\pm 20.54$. The eGFR $t(17)=-4.59$, $ES=1.58$ were significant increase from baseline ($M=129.62\pm 14.12$) to 11th week ($M=138.77\pm 10.87$). What concerns creatinine different trends were found with a very large increase $t(18)=-4.05$, $ES=1.35$ from baseline ($M=0.93\pm 0.12$) to 5th week ($M=1.06\pm 0.18$), otherwise creatinine $t(17)=4.99$, $ES=1.71$ had a huge decrease at the 11th week ($M=0.82\pm 0.9$). Significant increase occurs in urea $t(18)=-10.99$, $ES=3.66$ from baseline ($M=32.75\pm 4.37$) to the 5th week ($MD=63.89\pm 13.08$), even as were found a huge effect on CK $t(14)=-6.33$,

ES=2.39 concerning baseline (M=123.13±36.05) to 5th week (M=777.87±408.41).

CONCLUSION: Our results support a significant effect of military physical intervention in muscular protein, eGFR and body composition markers.

Resistance Training Versus General Exercise In Multidisciplinary Rehabilitation Of Low Back Pain: A Randomized Trial

vegard M. Iversen, Ottar Vasseljen, Paul Jarle Mork, Øyvind Salvosen, Marius S. Fimland. *Norwegian University of Science and Technology, Trondheim, Norway.*
(No relationships reported)

PURPOSE: Chronic low back pain (CLBP) is commonly managed through multidisciplinary rehabilitation (MDR). We aimed to assess if the effectiveness of MDR could be improved by replacing general exercise (GE) with progressive resistance training (PRT) with high intensity using elastic bands. **METHODS:** Consenting adults (n=99) with moderate to severe non-specific CLBP were randomized to an intervention (PRT) or a comparative group (GE). Both groups received 3-weeks MDR with either GE or PRT (squats, stiff-legged deadlifts, flies, unilateral rows, reversed flies, lateral shoulder raises and lateral pulldown performed 3 times per week with resistance varying from 15-20 to 8-10 repetitions). Both groups were instructed to continue their respective exercise program for 9 weeks after completing the MDR, in which time participants were offered up to three supervised booster sessions. Researchers were blinded during data collection and analyses. The difference in change between groups at 12-weeks in pain-related disability (Oswestry disability index; ODI: 0-100) was the primary outcome. Secondary outcomes were pain (numerical pain rating scale), limitations in important activities (patient-specific functioning scale; PSFS: 0-10), health related quality of life, work ability, global perceived change, fear-avoidance beliefs and back-extension strength were secondary outcomes. **RESULTS:** Baseline data were missing for 25 patients due to early dropouts. Thus, data from 74 participants (mean age: 45 years, 57% women, mean ODI: 30.4) were obtained at baseline and included in the analyses. Forty-six persons participated at the 12-week follow-up test. There were no difference in change in ODI score between groups at 12 weeks (mean difference 1.6, 95% CI: -3.9-7.0, p=0.570, in favor of GE). The improvement in PSFS was larger in the GE group than in the PRT group (mean difference 1.4, 95% CI: 0.1-2.7, p=0.033). No significant differences between the groups were observed for the other secondary outcomes (p≥0.11). **CONCLUSIONS:** This study provided no evidence in support of replacing GE with PRT in MDR for CLBP. In fact, GE might be slightly more beneficial than PRT in reducing limitations in important activities.

At present, the prevention of disability in the elderly is a priority in research topic because it affects the functionality and consequently the quality of life. Determine which process is toward disability a person is crucial to prevent the advanced stage of the loss of functionality; this loss can be detected clinically by the decline or lack of autonomy and emergence of dependence.

PURPOSE: To determine the features and functionality of the free-living older adults of 60 years and over in the metropolitan area of Nuevo León. **METHODS:** In this study, descriptive and cross-sectional study of 367 adults aged 60 years and over different club houses in the metropolitan area of Nuevo León, was applied an anamnesis, anthropometric measurements such as weight and height and the battery short of physical activity (SPPB) that consists in the realization of three tests of balance (feet together, semitandem and tandem), speed (4 meters, up and sit in a chair five times, the battery allows you to assess the risk of disability, with a total score that ranges between 0 and 12, a score below 10 can determine a high risk of disability. For the statistical analysis we used the SPSS version 21.0, using descriptive statistics mean, median and standard deviation. **RESULTS:** In older adults the average age is 72 ±7.28 years of age, with an average schooling of 5 years, 98% with cognitive ability to answer your interviews, 50.8% are widowed, 55.7% is devoted to the home, 24.2% are pensioners, who are economically dependent on someone are 53.9% situation related to the 70.1% who referred to live together, the most outstanding is the hypertension with 51.3%, according to diabetes mellitus in 31.5% and high cholesterol in a 29.2 %;

the SPPB showed a 12.1% with low performance of physical capacity, 47.3% risk of disability. **CONCLUSION:** In the characterization predominantly female, in a state of widowhood with household activities, presenting an economic dependence, the main pathology is hypertension and there is a significant percentage of risk of disability in this population.

Effect Of Stretching On Intracerebral Oxygen Dynamics And Calculation Capability

Wakako Tsuchida¹, Shigeyuki Suzuki², Shingo Matsuo¹, Sena Wakano¹, Mayu Asakawa¹, Taizan Fukaya², Eiji Yamanaka², Yuji Asai¹. *¹Nihon Fukushi University, Handa, Aichi, Japan. ²Nagoya University, Nagoya, Aichi, Japan.*
(No relationships reported)

Low- to moderate-intensity exercise enhances nerve activity in the prefrontal cortex, thereby improving cognitive function (Byun et al., 2014; Chang et al., 2012). However, few studies have investigated the effects of stretching on cognitive function.

PURPOSE: We examined the effect of stretching on cognitive function using a simple calculation task. We also measured brain oxygenation kinetics using near-infrared spectroscopy (NIRS).

METHODS: Participants were 16 healthy students (8 males, 8 females, average age: 20.3 ± 1.4 years). Participants sat on an isokinetic exercise machine and kept their knee joints at the maximum extension position (hamstring stretch) for 5 minutes (Primus RS, BTE). We used NIRS to analyze brain oxygenation kinetics while participants completed a simple calculation task before, during, and after stretching. We measured oxygenated hemoglobin (oxy-Hb) and deoxygenated hemoglobin (deoxy-Hb) in the bilateral prefrontal cortex, motor area, and somatosensory area, as well as the ratio of oxygenated hemoglobin contained in tissue (TOI).

RESULTS: We observed a significant increase in oxy-Hb in the motor and somatosensory areas during stretching compared with measured values at rest (p<0.05). Although we found no significant differences in the rate of correct answers before vs. after stretching, participants took less time to solve the computational task after vs. before stretching (p<0.05). We found no significant differences in Δoxy-Hb, Δdeoxy-Hb, or ΔTOI in the prefrontal cortex, motor area, or somatosensory area before vs. after stretching.

CONCLUSIONS: Stretching affects brain oxygenation dynamics. Specifically, oxy-Hb increased during stretching in the motor and somatosensory areas. The computation time was shorter after stretching, but stretching did not influence brain oxygenation dynamics during the calculation task. Future work will benefit from the use of neuroimaging methods to investigate the effects of stretching on brain function.

Feasibility and Efficacy of Aerobic Exercise Training in Cognitively Impaired Older Adults

Marcel Turner¹, Takashi Tarumi², Jonathan Riley¹, Justin Repshas¹, Candace Hill¹, Tammy Lewis¹, Rong Zhang².
¹*Institute for Exercise and Environmental Medicine, Dallas, TX.*
²*University of Texas Southwestern Medical Center, Dallas, TX.*
(No relationships reported)

Advanced age is a significant risk factor associated with brain structural damage, cognitive impairment, and dementia. Regular aerobic exercise potentially protects the brain from structural and functional damage related to age. Therefore, it is important to investigate whether cognitively impaired individuals adhere and respond to exercise training in a similar manner to their cognitively healthy counterparts.

PURPOSE: To test the hypothesis that cognitively impaired individuals respond to structured, supervised exercise regimentation in a similar manner to healthy controls.

METHODS: 73 sedentary, cognitively normal adults (CN) and 68 sedentary adults diagnosed with mild cognitive impairment (MCI) participated in the study. All participants were assigned to one of the two 1-year intervention groups: a moderate-intensity aerobic exercise training regimen or a low-intensity stretching/toning control group. The exercise regimen mandated a progressive increase in duration and frequency over the course of the first 6 months, followed by a maintenance phase over the second half of the intervention. **RESULTS:** MCI patients were slightly younger (MCI 65 ± 6 years vs. CN 68 ± 5 years, P<0.01) than CN adults. At baseline, MCI patients and CN adults in the exercise and stretching group were not different in terms of maximal oxygen uptake (VO₂max: MCI 22.9 ± 5.4 ml/kg/min vs. CN 22.3 ± 3.7 ml/kg/min, P=0.44). Aerobic exercise training improved VO₂max in both CN and MCI groups (P=0.001 for time x treatment), and the magnitude of improvement was similar in both groups (MCI 11%±15% vs. CN 10%±12%). With adjustment for age, the exercise-related improvement in VO₂max remained significant in both groups. Cognitively normal exercise trained adults showed similar compliance to MCI patients (MCI 75% ± 24% vs. CN 81% ± 14%, P>0.05) and similar dropout rates (MCI 37% vs. CN 26% within treatment). **CONCLUSIONS:** MCI patients showed a similar improvement in VO₂max and compliance to exercise training when compared to their

cognitively normal counterparts. This suggests that aerobic exercise training may be a feasible method for combating further cognitive decline in older adults. Funded by National Institutes of Health.

Recent Illness but Not Prior Heat Injury Affects the Rate of Cooling Following Exertional Heat Stroke

Michelle A. King, Matthew Ward, Bruce Adams, Lisa Leon.
United States Army Research Institute of Environmental Medicine, Natick, MA.
(No relationships reported)

PURPOSE: Anecdotal evidence suggests that certain risk factors may impact the severity of exertional heat injury/stroke (EHI/S) and alter the rates of cooling during treatment.

METHODS: In order to examine this hypothesis we performed a clinical records review of heat casualty reports for 215 cases of EHI/S at Marine Corps Base Quantico, VA from 2012-2015. Documentation included information pertaining to the EHI/S episode and treatment. Treatment for EHI/S consisted of a standardized cooling protocol where individuals were continuously doused with ice water and actively rubbed with ice bags, while receiving a normal saline solution of IV fluid.

RESULTS: The majority of patients that underwent the emergent cooling protocol were male, 23 years of age, and had a body mass index (BMI) of 24.5 kg/m². Patients presented on their 28th day of training with a maximal core temperature (T_c max) of 104°F, pulse rate of 111 beats per minute, blood pressure of 122/63 mmHg, and a respiration rate of 22 breaths per minute. *Rates of cooling:* Individuals with a recent or concurrent illness were cooled faster than those without (P=0.016), even though this group presented with a higher core temperature (T_c) at the initiation of cooling (P=0.034). Duration of cooling (minutes) was not different between these two groups (P=0.0945). Previous EHI/S had no effect on the rate of cooling (P=0.413). Further, BMI did not affect the rate of cooling nor was it predictive of T_c max. *Indicators of severity:* Upon admission blood glucose and pulse rate appeared to be indicators of EHI/S severity. Higher T_c max was positively correlated with both higher blood glucose values (P= 0.027, r = 0.195) and pulse rates (P=0.013, r= 0.176). In this population, restrictions on sleep, diet, or water intake did not affect T_c max. *Return to duty:* T_c max did not correlate with the number of rest days prescribed following injury (P=0.119). Further, those experiencing prior EHI/S or recent illness were prescribed the same amount of rest days as those without (P=0.103 and P=0.156 respectively). **CONCLUSIONS:** Contrary to our hypothesis, individuals with recent illness cooled faster, while prior heat injury had no effect on the rate of cooling. Author view not official US ARMY or DoD policy.

Do Female Gymnasts Experience Catch-up Growth During Periods of Rest Following Injury?

Katherine V. Yao, Dai Sugimoto, Nathalie Slick, Cynthia Stein.
Boston Children's Hospital, Boston, MA.
(No relationships reported)

PURPOSE: Several studies report delayed growth and hormonal changes during high intensity training in gymnasts, yet no studies specifically investigate the growth rate of gymnasts during periods of rest. The purpose of this investigation is to determine if an increased growth rate, or "catch-up growth", exists in high level female gymnasts during periods of rest following injury.

METHODS: A 5-year retrospective chart review was conducted at a large pediatric hospital. A search of medical records (1/1/2010-12/31/2015) identified female gymnasts 10-16 years old, training ≥10 hours/week or Junior Olympic level ≥7 who suffered an anterior cruciate ligament (ACL) tear requiring at least 6 months (m) recovery time out of training (Gym-ACL). The 6m growth rate of this group (n=23) was compared to female non-gymnast athletes with ACL injury and similar competitive level (Non-gym-ACL, n=29) and high level gymnasts training with minor injuries (Gym-min, n=27). One-way ANOVA with post-hoc correction was used to analyze the 6m rate of change in height, weight, and BMI of the 3 groups.

RESULTS: There were no differences in mean ages (Gym-ACL: 14.8±1.8; Non-gym-ACL: 14.6±1.2; Gym-min: 13.9±2.0), nor significant differences in 6m changes in weight or BMI among the 3 groups. However, there was significant differences in the 6m height change among the 3 groups (p=0.024). A significantly greater height increase was observed in Gym-ACL (+1.40±2.16cm) compared to Non-gym-ACL (+0.02±1.72cm) groups (p=0.047), but no significant differences were

found between the Gym-min (+1.32±2.27cm) and Non-gym-ACL (p=0.051) groups. **CONCLUSIONS:** The 6m growth rate of high level female gymnasts during periods of rest is greater than non-gymnast athletes, suggesting that catch-up growth does occur during periods of rest for highly active gymnasts. This evidence may help us better understand how growth is affected by training load and timing and help develop future training protocols and growth predictions.

Helmet Design And Hits To The Head: Analysis Of NFL Tackling 1951-present

Kevin N. Blythe¹, David Wang², Taylor Polk¹, Douglass Johnson¹, Jordan Murphy¹, Brian McCormick¹, Alex Webb¹, Andrew Horn¹, David Milzman¹. ¹*MedStar Georgetown University Hospital, Washington, DC.* ²*Georgetown University School of Medicine, Washington, DC.*
(No relationships reported)

PURPOSE: Many anecdotal statements attribute NFL helmet design to changing tackling styles and thus, an increase of helmet to helmet hits and subsequent concussive injury. There are no current studies reviewing changes of tackling style over time in the NFL. This study will examine whether the advent of newer helmet technology has led to an increase in the number of tackles involving the helmet in the NFL. **METHODS:** In this preliminary study, investigators were trained in the NFL definition of a "hit," and 2-3 investigators independently reviewed the TV broadcast or game film of each championship game from seven different decades, (1951-2016). Hits were classified based on the involvement of the helmet of both the offensive player and defensive player. A point-system was developed and mean values were collected for each game and open access sources were used to confirm number of head, neck injuries. Additionally, players' behavior in the aftermath of a helmet hit was determined as "concussive" as defined by a neurotrauma trained emergency physician based on delay in getting up and steadiness of gait. **Results:** Helmet to helmet hits occurred on just 1.28% of hits in the 50s compared to 6.97% of hits in the 10s, a 5.44 fold increase. Such hits have increased every decade, with statistically significant (p<0.05, t-test) after the 1960s and again after the 1980s. These changes correspond with the introduction of energy absorbing plastic helmets in the 1970s and the introduction of molded polycarbonate helmets in the late 1980s. These two helmet changes represent the most significant helmet technology changes in the time period studied. Overall hits involving the helmet of at least one player have increased at a similar rate, indicating a more dangerous tackling style. Additionally, the number of players that were judged to exhibit concussive symptoms after a hit significantly (p<0.05, t-test) increased after the 1980s.

CONCLUSIONS: Helmet-helmet hits have had the greatest jumps in frequency corresponding with helmet innovation in the NFL, with the largest jump occurring in the last three decades. That newer helmets with better technology has potentially led to more dangerous hits suggests that helmets designed to withstand greater impact may actually be a detriment to player safety.

Does CTHRC1 Affect Serum Lipid Profiles in Adults?

James Alex¹, William Dexter, FACSM¹, Christina Holt¹, Amy Haskins¹, Volkhard Lindner². ¹*Maine Medical Center, Portland, ME.* ²*Maine Medical Center Research Institute, Scarborough, ME.* (Sponsor: William Dexter, MD, FACSM)
(No relationships reported)

Purpose: Obesity has become a global public health concern as evidence mounts that it is related to a large variety of life threatening diseases from diabetes to heart disease. The biochemical links between body composition and hypercholesterolemia are a target of ongoing research. The hormone collagen triple helix repeat containing 1 (CTHRC1) has been shown to play an important role in the regulation of body composition in mouse models. This study aimed to compare CTHRC1 and serum lipid panels in human adults. We hypothesized that higher CTHRC1 levels would be associated with both decreased cholesterol and triglycerides (TG).

Methods: This study was done in collaboration with researchers at the University of South Carolina who completed the Energy Balance Study (EBS) on 430 adult subjects age 21-35, with BMI ranging from 20-35. Deidentified baseline plasma samples from the EBS subjects were analyzed with enzymatic calorimetric testing and ELISA to measure lipid panels (total cholesterol, HDL, LDL, triglycerides) and CTHRC1 concentrations respectively. Statistical analysis software was used to compare the data both generally and within clinically accepted subgroups of lipid concentrations.

Results: Of the 430 samples from the EBS subjects, 310 contained sufficient plasma for both CTHRC1 and lipid panel testing. No statistically significant difference in lipid concentrations was found between detectable and undetectable CTHRC1 groups (p=0.17-0.99). Stratification of CTHRC1 into undetectable, middle 75% and top 25% also showed no significant difference in lipid concentrations (p=0.32-0.79), nor did stratification of lipid panel components into clinically relevant subgroups (total

cholesterol $</>200$, HDL $</>40$, LDL $</>100$, TG $</>150$, $p=0.12-0.94$). Lastly, linear regression models showed no correlation between CTHRC1 and lipid concentrations ($p=0.21-0.93$).

Conclusion: This study demonstrates no association between CTHRC1 and lipid concentrations in a sample of relatively healthy human adults. Further research is required to better understand the temporal variation of CTHRC1 levels in vivo and thus, better time the collection of samples from subjects. Furthermore, a broader range of body composition among future subjects will help to better generalize data to the adult population.

3808 Board #255 June 3 9:30 AM - 11:00 AM
Use Of FEV1/FVC For Diagnosis Of Exercise-induced Bronchoconstriction (EIB) in Adolescents
 Rebecca Breslow, Kathryn Ackerman, FACSM, Carter Petty, Katherine Cooper, Dawn Ericson. *Boston Children's Hospital, Boston, MA.* (Sponsor: Kathryn Ackerman, FACSM)
(No relationships reported)

Purpose: Standard asthma therapies must be used judiciously in adolescent athletes to minimize side effects and costs. Current diagnostic criteria for EIB, $\geq 10\%$ decline in forced expiratory volume in the 1st second (FEV1) after exercise challenge, does not predict significant response to bronchodilator after challenge. This suggests some patients diagnosed with EIB may not benefit from standard treatment. We sought to determine if the ratio of forced vital capacity (FVC) to FEV1 could be used as a clinical indicator to help guide management decisions in adolescent patients presenting with EIB.

Methods: Using retrospective chart review, we examined valid EIB-protocol challenges performed by patients 13-18 years old in our Pulmonary Function Test lab between 6/1/11 and 5/30/16. We collected demographic data including age, height, weight, body mass index (BMI), gender, and ethnicity. We calculated maximal % decline in FEV1 and % decline in FEV1/FVC for all tests in which patients received albuterol ($n=139$). We examined % change and volume increase in FEV1 after bronchodilator. We used the standard definition of bronchodilator reversibility, $\geq 12\%$ and/or 0.2L increase in FEV1, to signify a positive response. We used two-sample t-tests and logistic regression to compare patients who did and did not exhibit bronchodilator reversibility.

Results: 84/139 (60.4%) patients met current diagnostic criteria for EIB. The mean % decline in FEV1/FVC was 9.6% (SD=9.0). Within this group, 55/84 (65.5%) displayed a positive bronchodilator response. None of the demographics we looked at were associated with reversibility. The mean % decline in FEV1/FVC in those who did not exhibit bronchodilator reversibility was significantly less than the mean % decline in FEV1/FVC for those who did: 6.2% (SD 5.5%) vs. 11.4% (SD 9.9%), $p=0.01$. Each 10% decline in FEV1/FVC was associated with a 3.36 fold increased odds of bronchodilator reversibility (95% CI 1.28-8.78, $p=0.01$). None of the demographics we examined modified this relationship.

Conclusions: Percent decline in FEV1/FVC may predict a positive response to bronchodilator in adolescent patients presenting for EIB evaluation. This finding may help identify individuals who will respond well to use of standard asthma therapies for this condition.

3809 Board #256 June 3 9:30 AM - 11:00 AM
Joint Injection Teaching of Internal Medicine Residents
 Michael Seifert. *Maine Medical Center, Portland, ME.* (Sponsor: Heather Gillespie, FACSM)
(No relationships reported)

Previous studies have shown that Internal Medicine (IM) residents lack confidence in performing joint injections. They report lack of training as the primary cause for low confidence. We developed a teaching session to see if hands-on teaching of IM residents and faculty would help residents make durable confidence gains in performing joint injections of the knee and shoulder. **PURPOSE:** To assess whether a teaching intervention, performed early in the training year for IM residents, would improve resident confidence in their knowledge of and ability to perform joint injections.

METHODS: A 90 minute resident joint injection workshop occurred in September 2016. Residents were given a pre-course questionnaire to measure their confidence with knee and shoulder injection indications, techniques, and risks and benefits as measured in a five-point Likert scale (1 is low, 5 is high). Following a brief lecture reviewing these topics, the residents then practiced on simulation models. A post-course questionnaire given afterwards assessed whether there was an increase in confidence of knowledge in these procedural skills. The IM faculty were given the same lecture and opportunity to practice on models in October 2016. The longer-term effect of the teaching intervention was measured by re-administering the post-course questionnaire four months later via Survey Monkey®.

RESULTS: 18 IM residents completed the workshop. Confidence for performing knee injections increased from a mean of 2.22 to a mean of 3.78; for shoulder injections the mean increased from 1.61 to 3.78. Confidence in knowledge of the risks and benefits,

supplies needed, and indications increased similarly. Statistically paired t-tests of all measured items showed significant increases. Four months post-workshop, confidence levels were sustained above the pre-testing levels for all areas studied (again $p < 0.001$). Finally, residents indicated they were more likely to perform these injections even after four months.

CONCLUSIONS: Based on this study, our workshop-style teaching session for residents and supervising faculty led to significant and durable increases in resident's confidence of their knowledge and ability to perform two common joints injections. Further development of this model may increase clinical performance and practice confidence.

3810 Board #257 June 3 9:30 AM - 11:00 AM
Athlete Risk Correlation Study: Psychosocial Determinants Of Musculoskeletal Injury Risk
 Vicki Nelson¹, Christina Thompson², Christopher Tangen².
¹Greenville Health System, Greenville, SC. ²University Hospitals Cleveland, Cleveland, OH. (Sponsor: Kyle Cassas, FACSM)
(No relationships reported)

PURPOSE: Several modifiable factors are linked to athletic injury including disordered eating, sleep, team climate, anxiety and life stressors. We hypothesize that characterization of psychosocial factors could help identify at-risk athletes and areas for possible intervention.

METHODS: High school student-athletes aged 14-18 participating in school sponsored athletics were provided with a 31-question survey including perception of athletic pressures, diet and weight, family and personal relationships, academics and sleep. 156 athletes were surveyed with 144 athletes participating (92% response rate). Each athlete indicated whether they had sustained a musculoskeletal injury or concussion requiring time away from sport. Athletes who reported musculoskeletal injury were compared to non-injured peers using fisher's exact test for significance.

RESULTS: Significant association was seen between musculoskeletal injury and a perceived competitive athletic environment including playing multiple sports (82% of injured vs 55% of well athletes, $p < 0.001$), belief that the team depends on them to do well (92% v 77%, $p < 0.02$), and deriving most personal friendships from among teammates (85% v 63%, $p < 0.005$). Injured female athletes were additionally more likely to identify feeling pressure to perform well in their sport and plans to pursue collegiate athletics. Self-identified change in school grades was protective (53% vs 71%, $p < 0.03$), with decreased injury in these students. Additionally, feeling tired upon waking (91 v 77%, $p < 0.02$) and occupation with weight (30 v 15%, $p < 0.04$) correlated with increased injury. This association between injury and occupation with weight was enhanced among female athletes. None of the significant associations were seen among athletes reporting concussion.

CONCLUSIONS: In a cohort of high school athletes screened for psychosocial and behavioral determinants, a more competitive athlete environment, fatigue and preoccupation with weight were found to increase the risk of musculoskeletal injury. The significant survey responses support the hypothesis that psychosocial factors contribute to risk of injury and further studies are warranted.

3811 Board #258 June 3 9:30 AM - 11:00 AM
Preliminary Results from a Prospective Study Using the Female Athlete Triad Cumulative Risk Assessment
 Emily Kraus¹, Aurelia Nattiv, FACSM², Adam Tenforde³, Andrea Kussman², Michelle Barrack⁴, Brian Kim⁵, Megan Deakins-Roche¹, Nikita Mistra¹, Sonal Singh², Michael Fredericson, FACSM¹. ¹Stanford Hospital and Clinics, Redwood City, CA. ²University of California - Los Angeles, Los Angeles, CA. ³Spaulding National Running Center, Boston, MA. ⁴California State University - Long Beach, Long Beach, CA. ⁵University of California - Irvine, Irvine, CA.
(No relationships reported)

Purpose: Bone stress injuries (BSIs) are a common overuse injury in running athletes. The purpose of this study is to determine whether a nutrition intervention targeting at risk athletes using the Female Athlete Triad Cumulative Risk Assessment (TRIAD R-A) would result in changes in bone health and reduce incidence of BSIs. **Methods and Study Design:** One hundred fifty-five (76 male, 69 female) middle and long-distance runners at two NCAA Division I programs were followed prospectively over four years. The TRIAD R-A was used to identify at risk athletes pre-season followed by nutrition interventions based on these assessments. Running-related BSIs were diagnosed by a physician and confirmed radiographically. **Results:** A subset of twelve returning female athletes with consecutive DXA scans were evaluated at the same program. Five females had $> 2\%$ improvement in L1-L4 DXA BMD (two females with $> 5\%$). Of this same subset over the same year, the number of females identified as high to moderate risk for amenorrhea/oligomenorrhea decreased from nine to six and number of BSI's decreased from four (three high risk) to three (one high risk).

Conclusions: This is the first prospective outcome study using the TRIAD R-A and a nutrition intervention tailored to an athlete's risk. Based on these preliminary

results, use of the TRIAD R-A in conjunction with a nutrition intervention focused on optimizing energy availability led to improvements in bone health and reductions in incidence of BSI. Further research is needed to evaluate the significance and impact of these trends. **Acknowledgements:** The authors would like to thank AMSSM and Pac-12 for helping fund this study.

3812 Board #259 June 3 9:30 AM - 11:00 AM
Improving Prp Production In An Outpatient Sports Medicine Office: A Qi Project

William L. Patterson Jr., William Dexter, FACSM, Christina Holt, Amy Haskins. *Maine Medical Center, Portland, ME.*
(No relationships reported)

PURPOSE: Platelet rich plasma (PRP) is a clinically current topic in sports medicine and orthopedics, and is used for various orthopedic pathologies. Prior studies show that commercial kits consistently yield platelet concentrations of approximately $1,000 \times 10^3$ platelets/ μL , but are prohibitively expensive to most patients. Studies comparing these "kits" vs in-office "do-it-yourself" protocols have found that a desktop centrifuge and phlebotomy tubes can produce similar elevated platelet concentrations. Our office had been using a protocol that had not yet been internally validated. We desired to identify and assess an optimal in office, high quality, accessible protocol to make PRP.

METHODS: We compared whole blood and preparations from 3 separate "in-house" protocols to isolate PRP and quantified amount of platelets in each sample. For protocol 1 (our previous in-office standard protocol) we drew 16.2ml of blood, spun this at 1318g for 10 minutes, and manually removed the buffy coat layer for analysis. For protocol 2 we drew 16.2ml of blood, spun this at 900g for 5 minutes, and manually removed the buffy coat layer for analysis. For protocol 3 we drew 16.2ml of blood, spun this at 900g for 5 minutes, and manually removed the entire supernatant layer including the buffy coat, spun this solution at 1500g's for 15 minutes, discarded the top 2/3rd of the supernatant, resuspended the remaining sample, and sent these samples for analysis. We used T tests to compare means between each method and in comparison to whole blood.

RESULTS: 31 specimens were obtained and put through the 3 protocols above. Whole blood (WB) yielded a mean of 257.1×10^3 platelets/ μL (95%CI 240-274). Protocol 1 yielded a mean of 648.4×10^3 platelets/ μL (95%CI 581-714) (2.5x WB concentration). Protocol 2 yielded a mean of 464.4×10^3 platelets/ μL (95%CI 424-504) (1.8x WB concentration). Protocol 3 yielded a mean of 974.1×10^3 platelets/ μL (95%CI 850-1097) (3.8x WB concentration). All pairwise comparisons of means were highly statistically significant ($p < 0.0001$).

CONCLUSIONS: Highly concentrated platelet rich plasma (PRP) can be consistently obtained using common in-office centrifuges and phlebotomy tubes following protocols, comparable to concentration data previously reported from using professional kits.

3813 Board #260 June 3 9:30 AM - 11:00 AM
Utilization of Emergency Department Services: A Comparison of High Schools With and Without Athletic Trainers

Christine Bender, William W. Dexter, FACSM, Amy Haskins, Christina Holt. *Maine Medical Center, Portland, ME.* (Sponsor: William W. Dexter, FACSM)
(No relationships reported)

Purpose:

The primary aim of this study is to compare utilization of ED services in Maine between students in areas of public high schools with certified athletic trainers (AT) and those without by looking at three common athletic injuries in the high school population of teens aged 14-18.

Methods:

Using 2013 Maine All Claims data, we obtained aggregated counts of ED visits categorized by zip code for three injuries (ankle sprain, concussion, and fracture) based on their respective diagnosis codes. Each zip code was attributed to a high school in Maine. Each high school was contacted directly to determine AT status, number of students, number of athletes, and types of sports. We then calculated the rates of each of the three types of ED visits in schools with and without AT. Chi-square tests were used to compare the ED utilization for each type of injury among high schools with and without ATs.

Results:

The 2013 Maine All Claims Data includes injury data for 346 Maine zip codes. There were a total of 1114 fractures, 826 sprains, and 538 concussions. Preliminary results were obtained from 185 (53.5%) zip codes, representing a total of 620 (55.6%) fractures, 427 (51.7%) sprains, and 305 (56.7%) concussions. These 185 zip codes represent 31992 students, 56.2% of the estimated 56,924 public high school student population in 2013-2014.

In HS w/ AT, the cumulative student population was 28270 and there were 536 fractures, 339 ankle sprains, and 266 concussions. In HS w/o AT the cumulative student population was 3722 and there were 84 fractures, 88 ankle sprains, and 39

concussions. Rates were calculated by injury type per student population for schools w/ and w/o AT and reported per 100 person-time units. Fractures had rates of 1.90 and 2.26 for HS w/ AT and HS w/o AT, respectively, with a p value of 0.1423. Sprains had rates of 1.20 and 2.37 for HS w/ AT and HS w/o AT, respectively, with a p value of < 0.0001 . Concussions had rates of 0.94 and 1.05 for HS w/ AT and HS w/o AT, respectively, with a p value of 0.5223.

Conclusion:

Although data analysis is not yet complete, our preliminary investigation reveals a significant difference in the rates of utilization of ED services for sprains when comparing schools with and without ATs. There was no statistically significant difference found for similar comparisons of fractures and concussions.

Opioid Prescription Practices for Pediatric Musculoskeletal Injuries

Erin Moix Grieb, Jane Gralla, Ariel Kiyomi Daoud, Julie Wilson, Christopher Hoyte. *University of Colorado, Denver, CO.* (Sponsor: John Hill, FACSM)
(No relationships reported)

PURPOSE: Prescriptions of controlled substances for youth, including opioids, nearly doubled from 1994-2007. Previous studies have shown that for patients aged 10-19 years, dentists were the main prescribers, followed by primary care and emergency medicine physicians; however, analgesic prescribing practices among sports medicine and orthopedic providers are unknown. The purpose of this study is to determine opioid prescribing patterns to youth with musculoskeletal (MSK) injuries in various clinical settings.

METHODS: This retrospective case series reviewed patients aged 10-18 years, evaluated within the network of care of a local pediatric hospital, for known or suspected musculoskeletal injury from October 2014 to September 2016. Data was extracted from electronic medical records based on inclusion query terms. 14,172 initial visit records with complete data for provider (Physician, Physician Assistant - PA, Nurse Practitioner - NP), department (ED, Orthopedics which includes Sports Medicine, Primary Care - PC), diagnosis (fracture, no fracture), location of injury (upper extremity - UE, lower extremity - LE), prior opioid prescription, age and sex were included. Data were analyzed using multivariable logistic regression.

RESULTS: Mean age was 13 years. Opioid prescribing was more common for male patients (odds ratio (OR) 1.3, 95% CI 1.1-1.5), fractures (OR 7.1, 95% CI 5.8-8.7), and ED visits (ED vs PC OR 10.3, 95% CI 4.6-23.4; ED vs Ortho OR 8.7, 95% CI 7.2-10.6). Opioids were prescribed in 5.9% of UE injuries, 3.6% of LE injuries, 9.4% of fractures and 1.9% of non-fracture injuries. ED providers ordered 68.9% of opioid prescriptions in the study, and saw 27.7% of patients with MSK injuries. NPs were less likely to prescribe opioids than physicians (OR 0.5, CI 0.4-0.6) and PAs (OR 0.5, CI 0.4-0.7) and there were more NPs in the ED (27.0%) than Ortho (2.2%) or PC (13.0%). Of those patients who received an opioid prescription, 68.3% did not have any prior MSK injury.

CONCLUSIONS: For pediatric patients with MSK injuries, most opioid prescriptions originated from an ED visit. Injury type and provider type also impacted opioid prescribing patterns.
