Young Children assessed preschoolers' PPC. The Bruininks-Oseretsky Test of Motor Proficiency, Second Edition (BOT-2) subtests for balance, running speed and agility (locomotor), upper-limb coordination (ball skills) and strength assessed children's actual FMS. Spearman's rho correlations were used to assess the relationships between PPC and each BOT-2 subtest. Hierarchical linear regression analyses were conducted for each of the four BOT-2 subtests to investigate the amount of variance in FMS explained by PPC (overall model controlled for age, sex, ethnicity, and BMI z-score). **Results:** Spearman's rho correlations showed significant correlations between PPC and FMS when data were examined separately by sex and/or ethnicity. There were significant positive correlations between PPC and ball skills for males ($r=0.20$, $p<0.05$) and non-Hispanic preschoolers ($r=0.18$, $p<0.05$). There was a significant negative correlation between PPC and balance in Hispanic females ($r=-0.31$, $p<0.05$). Regression analyses showed PPC was significantly related to locomotor scores ($\beta=14$, $t=2.19$, $p<0.05$) with the overall model accounting for 16% of the variance in locomotor scores, $F(5,219)=8.43$, $p<0.05$. Further, PPC was significantly related to strength scores ($\beta=12$, $t=1.97$, $p<0.05$) with the overall model accounting for 20% of the variance in strength scores, $F(5,216)=10.48$, $p<0.05$. **Conclusions:** The correlation between PPC and FMS in preschoolers varies by sex and ethnicity in LEAP study participants. Moreover, PPC is significantly related to locomotor and strength skills. Promoting FMS development in preschoolers could potentially influence their movement competence or confidence, thus enhancing their physical literacy and ultimately physical activity engagement.

2030 Board #43 June 1 2:00 PM - 3:30 PM
Types Of Leisure, Leisure Motivation, And Well-being In University Students With An Emphasis On Physical Activity
 Jong-Ho Kim¹, Stephen Brown², Heewon Yang³. ¹Temple University, Philadelphia, PA. ²Sam Huston State University, Huntsville, TX. ³California State University, University Long Beach, CA.
 Email: jong-ho.kim@temple.edu
 (No relationships reported)

It is well-documented that leisure is conducive to psychological well-being for a variety of population. However, a scarcity of research on types of leisure influenced by individual attributes and health status as well as contributing factors for leisure satisfaction. **PURPOSE:** The research aims to investigate the types of leisure influenced by individual attributes and health status as well as the contributing factors for leisure satisfaction. **METHODS:** Cross sectional data were collected by administering Leisure Satisfaction Scale (LSS), Leisure Motivation Scale (LMS), Types of Leisure Scale, Perceived Stress Scale (PSS), Health Risk Survey, and Demographic Survey including Body Mass Index (BMI) to 199 university students. **RESULTS:** Leisure satisfaction was inversely correlated with perceived stress ($r = -.21$, $p < .01$) and amotivation ($r = -.23$, $p = .01$). Perceived stress was positively associated with amotivation ($r = .23$, $p < .05$). Stepwise multiple regression shows that intrinsic leisure motivation was a single strong predictor for leisure satisfaction even after controlling for elementary school leisure, high school leisure, extrinsic leisure motivation, and perceived stress [$b = .83$, $\beta = .71$, $t = 4.72$, $p < .01$]. Interaction analyses in multiple regression demonstrate that there was a significant interaction between BMI and social support, which indicates that the impact of BMI on active leisure differs depending on levels of social support ($\Delta R^2 = .048$, $F [1, 138] = 7.02$, $p = .009$). There was a significant interaction between BMI and perceived stress, indicating the impact of BMI on passive leisure differs depending on perceived stress ($\Delta R^2 = .034$, $F [1, 148] = 5.23$, $p < .05$). **CONCLUSION:** Intrinsic leisure motivation appears to influence leisure satisfaction, which may lead to lowered levels of stress. Conversely, leisure apathy (amotivation) may lead to elevated levels of perceived stress. University students with high BMI do not tend to engage in physically active leisure in the presence of high perceived social support. Also, university students with high BMI were more likely to engage in passive leisure in the presence of low stress levels. These findings could shed light on the motivational strategies health care providers can use to support health-promoting leisure activities such as physical activity.

2031 Board #44 June 1 2:00 PM - 3:30 PM
Affective Associations as Predictors of Physical Activity in Cancer Survivors
 Jeanna Tran¹, Emily Van Wasshenova¹, Ashley Murray¹, Adrienne Boczar¹, Debra Boardley¹, Andrew Geers¹, Rachel Mahas², Ryan Schropp¹, Jessica Maras¹. ¹University of Toledo, Toledo, OH. ²Madonna University, Livonia, MI.
 (No relationships reported)

Traditional physical activity promotion programs have focused on changing cognitions with the belief that physical activity decisions are made by weighing the benefits and costs of performing the behavior. However, recent research reveals that affective associations with physical activity (e.g. positive feelings about exercise) can also

predict physical activity behavior. These findings suggest that cognitive measures and feeling measures may both be important predictors of participation in physical activity. **PURPOSE:** The objective of the study was to use psychosocial factors, including affective associations, to predict physical activity intentions and physical activity behavior in cancer survivors. **METHODS:** A convenience sample of cancer survivors ($n=122$) were recruited for the study. Participants completed a survey which included questions on demographics, current physical activity, survivorship, cognitive measures, affective associations, and implicit measures. Multiple regressions were run to predict intentions and physical activity behavior. **RESULTS:** Majority of the participants were Caucasian (83%), and breast cancer survivors (62%) out of treatment with a mean BMI of 30 kg/m². Results show physical activity intentions were significantly predicted by cognitive measures ($p<0.01$). In contrast, positive affective associations ($p<0.01$), worry about physical activity ($p<0.01$) and implicit measures ($p<0.05$) were the only significant predictors of physical activity behavior. Affective measures predicted physical activity behavior approximately 2 weeks later, even when intentions were included in the regression model ($p<0.05$). **CONCLUSIONS:** The current study suggests cognitive beliefs predict physical activity intentions and affective measures separately predict physical activity behavior in cancer survivors. These findings could be implemented into physical activity programs focusing on both increasing cognitive beliefs about physical activity and increasing positive feelings towards physical activity.

2032 Board #45 June 1 2:00 PM - 3:30 PM
Weight Training and Self Determined Motivation: A Longitudinal Analysis of Previously Untrained, Sedentary Women

Jacob Havenar. *University of San Francisco, San Francisco, CA.*
 Email: jmhavenar@usfca.edu
 (No relationships reported)

PURPOSE: To examine the impact of weight training on autonomy, competency, relatedness, and self determined motivation over a period of 28 months. We hypothesized that women who participated in a 12 week weight training program would exhibit significant increases in autonomy, competency and self determined motivation over time. In addition, we hypothesized that the treatment group would exhibit a more self determined motivational profile than the control group. **METHODS:** The sample consisted of 44 sedentary women with no prior weight training experience. The mean age was 22 years (range 18 - 29) and BMI's ranging from 19.3 to 46.7 ($M=27.0$). Upon random group assignment, psychosocial and anthropomorphic data were collected from all participants at baseline. The treatment group training protocol consisted of three 45-60 minute sessions/week. The treatment group also received a training manual and supervision from certified personal trainers for 14 of their 36 total sessions. The control group received the manual after post testing (week 13) and instructions on how to perform the exercises. Follow up assessment of all psychosocial variables was conducted at 28 months post baseline. **RESULTS:** Psychosocial and anthropomorphic data did not significantly differ across groups at baseline. A between group effect was present $F(1, 39) = 4.332, p < .05$ at three months with the treatment group ($4.61 + .65$) displayed a higher level of competence ($t(22) = 4.33, p = .05$) than the control group ($3.72 + .63$). Repeated measures ANOVA indicated a significant increase in Autonomy ($p = .032$) and Competency ($p = .002$) for the treatment group from baseline to 28 months. **CONCLUSIONS:** An exercise intervention typified primarily by free weight exercises over 28 months is more efficacious than a weight training instruction booklet alone for increasing women's feelings of autonomy and competence. Future analyses inclusive of a post intervention follow up period would test lend further insight by assessing both groups during a time exclusive of any supervised training.

2033 Board #46 June 1 2:00 PM - 3:30 PM
Effects of External Stimuli on Exercise Engagement in College Females
 Adam Lomenick. *Baker University, Baldwin City, KS.*
 (No relationships reported)

Important to the promotion of physical activity is the assessment of the psychological effects that occur when trying to adhere to exercise regimens. By measuring the effects of exercise on mood, enjoyment, and perceived exertion it allows for the ability to evaluate engagement in one's program and provides a means to measure and potentially predict their continuance in the exercise. **PURPOSE:** To examine the effects of external stimuli on mood, enjoyment, and perceived exertion in college females. **METHODS:** 18 college female subjects (age: 19 ± 1 years) completed 4 separate trials of treadmill walking with a different intervention for each trial. The conditions being tested: no external stimuli (NES), self-selected music (MU), self-selected video with sound (VS), and self-selected video without sound but with captions (VC). Every 3 minutes throughout the 30-minute session, the subjects rated perceived exertion and mood with the Borg rate of perceived exertion (RPE) scale and the Fast Assessment of Children's Emotion scale (ES). At the end of each

session, the participants evaluated their enjoyment of the exercise using the Physical Activity Enjoyment Scale (PACES). Statistical comparisons on each condition were determined as well as any correlations between having stimuli (MU, VS, and VC) vs no stimuli using a single factor ANOVA, contrast, and Bonferroni statistical analysis. **RESULTS:** We found when comparing no stimuli to all external stimuli collectively, PACES ($F=6.08, p < 0.05$) and ES ratings ($F=2.66, p < 0.05$) were significantly different. Specific to the PACES scale, we found significance when comparing NES to MU ($t=2.90, p < 0.05$), NES to VC ($t=3.11, p < 0.05$), and NES to VS ($t=4.03, p < 0.05$). RPE was not statistically significant in any condition ($F=0.01, p > 0.05$). **CONCLUSION:** Greater levels of overall enjoyment and increased mood were seen when an external stimuli was used as compared to exercising with no stimuli. No changes in perceived exertion were seen whether a stimulus was used or not. For best adherence to an exercise program use of external stimuli is recommended.

2034 Board #47 June 1 2:00 PM - 3:30 PM
Sustainable Healthy Commuting: Environmental Factors Associated With Bicycling And Walking Among Danish Students.

Oline Anita Bjørkelund¹, Fredrik N. Christiansen¹, Anders K. Jensen¹, Christian J. Cass¹, Catrine R. Andersen¹, Maiken Bille¹, Elling Bere². ¹Aalborg University, Aalborg, Denmark. ²University of Agder, Kristiansand, Norway.
 Email: oline@hst.aau.dk
 (No relationships reported)

Cycling and brisk-walking to university, leisure-time activities and part-time jobs represents an opportunity to incorporate sustainable transport related moderate- to-vigorous physical activity (MVPA) and exercise into daily routine among students, and thus, may make an important contribution to health. Denmark has a strong and well-developed cycling culture with good walkable paths and cycle lanes, infrastructure and traffic. Still, a large proportion of commuters choose to use other means of transport when cycling and walking would be a highly appropriate transport mode.

Purpose: The aim of this study was therefore to investigate the associations between commuting mode and environmental factors in a group of young students in Aalborg municipality in Denmark.

Methods: In an internet survey gathered data about students' commuting behaviour and their perception of the influence of environmental factors. Comparisons were made using cross tabulation and chi-square statistical tests ($p<0.05$).

Results: In total, 348 students, mean age 23 ± 2.1 years, responded to the questionnaire, of which 80.5 % were categorised as active commuters (walkers and cyclists) and 19.5 % were categorised as passive commuters (car and public transporters). The mean commuting distance for the active commuters were $3.0 \text{ km} \pm 1.4$ and $2.9 \text{ km} \pm 1.6$ for the passive commuters when summarizing all localisations (part-time job, leisure-time activities and university location). The passive commuters perceived the traffic as more unsafe than the active commuters when commuting to part-time job (31.4% vs. 11.5%, $p<0.05$) and leisure time activities (69.6% vs. 52.8%, $p<0.05$). Those students who were categorized as active commuters more likely to go by bike to their university location than those categorized as passive commuters (37.9% vs 19.1%, $p<0.05$) if they perceived the cycling paths as well maintained.

Conclusion: Those categorised as active commuters perceived the environment as more comprehensive for active commuting than those categorised as passive commuters.

 (No relationships reported)

Physical exercise can be an effective intervention, with a positive effect on health and improving quality of life. However, studies show that 50% of persons starting an exercise program will drop out within the first 6 months. Thus, most people does not the chronicles benefits provide by regular physical exercise. **Purpose:** To determine exercise behavior (personality and level of motivation) of participants during a 1 year exercise program. **Methods:** 29 volunteers (17 women's) Age (years) 34.97 ± 9.51 , BMI (kg/m²) 26.47 ± 4.36 and attendance (months) 8.1 ± 3.45 , were grouped by adherent (Adh) and non-adherent (NAdh). Personality and level of motivation were assessed via translated version of the BREQ-2 (Markland D, Tobin VA, 2004) and IMPRAF-54 (Barbosa MLL, Balbinotti AAM., 2006) and attendance during 1-year exercise program were assessed too. A Mann Whitney U. Test, Spearman correlation and

Logistic regression are used. **Results:** Considering attendance in months, Spearman correlations were made with sociodemographic measures and scales scores IMPRAF, BREQ and NEOPIR. Correlations were found in attendance with the IMPRAF sociability ($\rho = 0.4$) and NEOPIR extraversion ($\rho = -0.43$). These variables were adjusted in a linear regression model ($R^2 = 0.53$) and they had coefficients significantly different from zero (IMPRAF sociability $B = 0.29$, $t = 2.158$ $p = 0.04$ and $B = -0$ NEOPIR extraversion, $38 t = -2.24$ $p = 0.03$). Finally, considering Adh ($N = 6$) or NAdh ($N = 23$) group, there are significant only for NEOPIR extroversion ($U = 31.5$, $p = 0.04$), where the Adh (119.0) has a median less than the NAdh (106.5). **Conclusion:** In this study, the longer training produced greater sociability (need basic psychological issues related to acceptance and gaining new friends, self-esteem and motivation for physical activity practitioners) and lower extraversion (possibly due to a structured that exercise was offered). CEPE, CEMSA, CNPq, CAPES, AFIP.

2036 Board #49 June 1 2:00 PM - 3:30 PM
Physical Strength by Mental Health Profile in School-Aged Boys and Girls
 Armando Cocca, Francisco Daniel Espino Verdugo, Michaela Cocca. *Autonomous University of Nuevo León, San Nicolás de los Garza, Mexico.*
 Email: armando.cocca@gmail.com
 (No relationships reported)

Mental health can play an important role in the development of a good health-related physical fitness, especially during physical education (PE) classes. In fact, kids with low self-esteem and psychological wellness are often inclined to avoid carrying out physical assignments in front of their peers due to the fear to be ridiculed. Similar psychological processes occur in children with high stress and anxiety associated to exercising. This could have a negative impact on the development of an appropriate level of strength, which is considered an important indicator of wellbeing at all ages. **PURPOSE:** To assess primary school boys' and girls' physical strength associated to mental health profiles. **METHODS:** A sample of 189 children (88 boys, 101 girls) aged 10-11 participated in the study. Physical strength measurements were carried out according to EUROFIT protocol, and included 30-sec sit-ups (SU), standing broad jump (SBJ), bent arm hang (BAH), and handgrip (HG) tests. In addition, participants were asked to fill self-esteem, psychological wellbeing, anxiety, and stress questionnaires. **RESULTS:** Cluster analyses evidenced two main profiles in boys: "partial psychopathology" (PP) and "partial mental health" (PMH). Participants showing the former profile had lower scores in SU (PP: 13.09; PMH: 17.89), SBJ (PP: 96.89; PMH: 123.57), BAH (PP: 3.91; PMH: 8.74), and HG (PP: 12.15; PMH: 14.60). Both profiles had low scores in relation with cut-off points for their age. Girls only belonged to PP, also showing lower results than expected at their age (SU = 15.22; SBJ = 111.59; BAH = 7.27; HG = 12.25). **CONCLUSIONS.** Partial mental health is not a sufficient condition for triggering the development of healthy physical strength. PE teachers need to create the proper conditions for children to reach full mental wellbeing, which may increase their chances to achieve beneficial levels of physical fitness.

2037 Board #50 June 1 2:00 PM - 3:30 PM
Relation between Body Composition, Physical Fitness, and Mental Health in Primary School Students
 Michaela Cocca, Francisco Daniel Espino Verdugo, Armando Cocca. *Autonomous University of Monterrey, San Nicolás de los Garza, Mexico.*
 Email: michaela.cocca@gmail.com
 (No relationships reported)

According to the World Health Organization, the fulfillment of a complete health state implies balance between physical and mental condition. Physical fitness (PF), comprised of health-related strength, endurance, and flexibility, is an essential indicator of physical condition. Good levels of PF have been linked to lower risk of injuries and chronic diseases. In addition, body composition (BC) is an indicator of health, the accumulation of abdominal body fat having being associated to higher cardio-metabolic risk. However, mental state can negatively affect individuals' overall health regardless of their physical condition. For instance, research has demonstrated that high anxiety in athletes may not only increase the risk of psychological diseases, but also activate unhealthy physiological processes. **PURPOSE:** To assess the relation between body composition, physical condition, and mental health in primary school students. **METHODS:** A sample of 339 children aged 10-11 were asked to fill self-esteem, psychological wellbeing, anxiety, and stress questionnaires. Measurements of PF comprised handgrip (HG), standing long jump (SLJ), 30-second sit-ups (SU), sit-and-reach (SR), and course navette (CN) tests. Body composition was assessed by means of waist circumference (WC). **RESULTS:** Outcomes showed a significant negative correlation of WC with CN ($r = -.509$; $p < .001$), and SLJ ($r = -.175$; $p = .033$). However, WC was positively correlated with HG ($r = .355$; $p < .001$). No significant correlations were found between the elements

of mental health, PF, and BC. **CONCLUSIONS.** Both mental health and physical condition must be taken into account if we aim to increase people's overall health state. Despite previous literature suggests a connection between these two spheres of health, our outcomes seem to hint at isolated approaches, implying the implementation of different strategies to enhance physical condition and mental state simultaneously, though separately.

2038 Board #51 June 1 2:00 PM - 3:30 PM
Auditory Discrimination and Short Term Memory are Preserved during Simulated Altitude and Moderate Intensity Exercise.
 Sarah Kamakawiwo'ole, Laura Q. Jimenez, Brian Arwari, Arlette C. Perry, FACSM, Joseph F. Signorile, FACSM, Soyeon Ahn, Kevin A. Jacobs, FACSM. *University of Miami, Coral Gables, FL.* (Sponsor: Dr. Kevin Allen Jacobs, FACSM)
 Email: s.kamakawiwoole@umiami.edu
 (No relationships reported)

PURPOSE: This study was conducted to examine the cognitive and neurophysiological effects of acute exposure to simulated moderate and high altitudes at rest and during exercise to examine whether short term memory or auditory oddball task performance were affected beyond a certain threshold of simulated altitude and whether exercise improves or worsens cognitive function during these conditions. **METHODS:** Fourteen recreationally active college students (M=9, F=5) aged 18-35 participated in this study, which consisted of six experimental days, with three simulated altitude conditions: sea level (SL), simulated moderate altitude (MA; 15.4% F_{O_2} , ~2400 m) or simulated high altitude (HA; 12.8% F_{O_2} , ~3900 m); and two exercise conditions: rest or moderate intensity cycling exercise at 60% altitude-specific peak power output, in a randomized-order, crossover design. Accuracy and reaction time on an auditory oddball task and a Sternberg memory task were assessed, alongside the amplitudes and latencies of their associated event-related potentials. **RESULTS:** Exercise improved auditory reaction time, regardless of altitude ($p < 0.01$), though task accuracy was not affected under any condition. In addition, simulated altitude induced lower P300 amplitudes and slower latencies during the auditory oddball task ($p < 0.01$), while exercise improved latencies at HA and SL, but not at MA ($p = 0.03$). Sternberg memory task behavioral performance was not affected by either simulated altitude or exercise. However, P200 latency was slowed during exercise trials ($p = 0.02$) as well as during MA trials ($p < 0.01$). **CONCLUSIONS:** Acute exposure to simulated moderate and high altitudes may not significantly impact short term memory and auditory discrimination. On the other hand, an acute bout of moderate intensity cycling exercise may improve reaction time on oddball tasks, even though it does not seem to benefit short term memory. It is possible that these cognitive modalities were negatively affected by simulated altitude, as evidenced by some altered event-related potentials, but that these effects were either too small to translate into performance deficits or that there are as yet unknown compensatory mechanisms at work that preserve performance as one ascends to altitude, at least until 3900 m.

2039 Board #52 June 1 2:00 PM - 3:30 PM
Impact of Biological Attractiveness on Exercise Motivation and Physical Activity in Female College Students
 Elizabeth A. Easley, Mary N. Fargalla, Sarah H. Sellhorst, William F. Riner, FACSM. *University of South Carolina Lancaster, Lancaster, SC.*
 Email: easleyea@mailbox.sc.edu
 (No relationships reported)

Waist-to-hip ratio (WHR) has been used as an indicator of biological attractiveness, which has been associated with reproductive potential, health, and youthfulness. Previous reports have shown that women with a WHR closer to 0.70 than 0.80 are found more biologically attractive (BA). Considering the potential health implications of biological attractiveness, exercise motivations in women may vary based on WHR. **PURPOSE:** To determine if differences existed in health pressure and appearance-related exercise motivations and physical activity between the BA group (WHR ≤ 0.74) and less biologically attractive group (LBA, WHR ≥ 0.75). **METHODS:** Full-time female college students (19.26 ± 1.37 yr) completed the Exercise Motivation Inventory-2 (EMI-2). Following the survey, waist and hip circumferences were measured, and WHR was calculated. Participants then wore an Actigraph accelerometer (GT3X, Pensacola FL) for seven consecutive days. A one-way MANOVA was used to determine if differences existed in exercise motivations and physical activity between groups. **RESULTS:** There was a significant multivariate main effect for biological attractiveness, Wilks' lambda = .815, $F(3, 43) = 3.247$, $p = .031$. Closer examination of the univariate results demonstrated a significant difference in health pressure-related motivation to exercise $F(1, 45) = 8.592$, $p = .005$ between BA ($n = 23$, 1.48 ± 1.34) and LBA ($n = 24$, 2.53 ± 1.41). There were no differences in appearance-related motivation (BA, $3.27 \pm .91$ vs. LBA, $3.76 \pm .93$) or physical

activity measured in average steps between groups (BA, 6437.64 ± 2633.76 steps/day vs. 6486.39 ± 3026.91 steps/day). **CONCLUSIONS:** Although the health pressure-related score was higher in the LBA group, it was not a strong enough motivator to result in greater physical activity in this group. This suggests that health pressures are not a major motivator for exercise in female college students regardless of WHR and BA group. Appearance-related motivation was scored similarly between groups and despite higher scores than health pressure-related motivation in both groups, both categories of women were classified as low-active based on their average daily step counts. More research is needed regarding motivating factors for exercise in traditional-age female college students.

2040 Board #53 June 1 2:00 PM - 3:30 PM
Reasons Why College-aged Women Perform Resistance Training

Sydney R. Makela, David Q. Thomas, FACSM, Brianna Ackerman. *Illinois State University, Normal, IL.* (Sponsor: David Q. Thomas, FACSM)
 Email: srmakel@ilstu.edu
 (No relationships reported)

Resistance training itself has many far-reaching benefits in regards to muscular strength and endurance, bone health, and metabolism. However, despite its importance women tend to participate in resistance training at an alarmingly lower rate than men. Previous research on resistance training participation focused primarily on male subjects. Limited research is available on the resistance training practices of both sexes. **PURPOSE:** To determine the reasons why college-aged women perform resistance training. **METHODS:** Thirty-seven college-aged women (18-24 yrs. old) participated in this study by completing an online survey. Means, standard deviations, and frequencies were calculated for all questions. **RESULTS:** Women perform strength training for a variety of reasons. Over 95% agreed that resistance training gives them a sense of accomplishment and they enjoy how it makes them feel. Ninety-four percent agreed that resistance training will make them healthier. The results showed that 90.91% agreed that resistance training relieves stress. Over 90% agreed that they resistance train with the goal of improving muscular strength and endurance. Maintaining body weight is why 69.69% of the respondent's resistance train. Half of the respondents (50%) resistance train because they have someone willing to do it with them. In regards to appearance, 84.38% resistance train because they feel that it will make them more attractive. Of the women who responded 65.65% resistance train because they know it won't make them bulk up. Approximately 84.38% resistance train because it makes them happy. In order to improve bone health 62.5% of the respondents said that they resistance train. In order to cope with depression 53.13% of respondents said they resistance train. Coping with stress and anxiety is one reason why 75.51% resistance train. **CONCLUSIONS:** These findings suggest that females who participate in resistance training are health and fitness focused. These findings also suggest that resistance training helps college-aged women improve mental, physical, and emotional health overall.

Predicting Affective Responses To, And Enjoyment Of, High-intensity Interval Exercise: Comparison Of Two Tolerance Measures

Raja Amjod¹, Daniel R. Greene¹, Tina A. Greenlee², Kathryn Rougeau¹, Annmarie Chizewski¹, Steven J. Petruzzello, FACSM¹. ¹University of Illinois at Urbana-Champaign, Urbana, IL. ²Center for the Intrepid, Fort Sam Houston, TX. (Sponsor: Steven J. Petruzzello, FACSM)
 Email: ramjod0934@gmail.com
 (No relationships reported)

Individual differences have been explored with respect to predicting affective responses to exercise. As such, new measures are developed to further understand these relationships and old measures are constantly updated to be more accurate. **PURPOSE:** Compare two measures of exercise tolerance. **METHODS:** Participants ($N=268$; 154 f; 20.72 ± 1.33 yrs, $M \pm SD$) completed the Preference for and Tolerance of Exercise Intensity Questionnaire (PRETIE-Q) and the Physical Activity Acceptance Questionnaire (PAAQ) and then a 15-min high-intensity interval exercise (HIIE) session. Affective valence (Feeling Scale; FS) was assessed every 3-min during (average FS during used in analyses) and enjoyment (Physical Activity Enjoyment Scale; PACES) was assessed post exercise. **RESULTS:** A moderate relationship existed between the PAAQ and PRETIE-Q Tolerance (Tol; $r=0.45$; $P<0.001$). PAAQ was related to enjoyment ($r=0.21$; $P=0.001$), but not FS ($r=0.11$; $P=0.09$). Tol was related to both enjoyment ($r=0.31$; $P<0.001$) and FS ($r=0.22$; $P=.001$). Using hierarchical regression, PAAQ accounted for 3.8% unique variance in enjoyment ($\beta=0.199$, $P=0.003$), after accounting for age, sex and BMI; the addition of Tol explained an additional 6.8% unique variance in enjoyment ($\beta=0.297$, $P<0.001$). In a separate regression, Tol explained 10.0% unique variance in enjoyment ($\beta=0.332$, $P<0.001$), after accounting for age, sex and BMI; the addition of PAAQ did

not explain any additional variance ($\beta=0.088$, $P=0.21$). The PAAQ did not account for any variance in FS ($\beta=0.074$, $P=0.28$); Tol explained 4.2% unique variance in FS ($\beta=0.215$, $P=0.002$), after accounting for age, sex and BMI. **CONCLUSION:** Comparison of Tol and PAAQ with respect to explaining affective responses revealed a modest relationship. While both explained affective responses, Tol accounted for more variability in such responses. Further, Tol accounted for all variance explained by the PAAQ, while the PAAQ accounted for roughly one third of the variance explained by Tol; with respect to enjoyment. In order to maximize benefits and minimize adverse affective responses to exercise, understanding individual difference factors is crucial. As such, the PRETIE-Q appears to predict affective outcomes of HIIE to a greater extent than the PAAQ.

2042 Board #55 June 1 2:00 PM - 3:30 PM
Cognitive Processes Of The Stages of Changes for Healthy Exercise Practice According To The ACSM

SAMANTHA MEDINA-VILLANUEVA¹, JORGE ZAMARRIPA¹, MARIA MARENTES-CASTILLO¹, MANUEL DE LA CRUZ², HECTOR DUARTE². ¹Universidad Autónoma de Nuevo León, Nuevo León, Mexico. ²Universidad Estatal de Sonora, Sonora, Mexico.
 Email: samantha.medinavl@uanl.edu.mx
 (No relationships reported)

Within the Transtheoretical Model, the stages explain *when* and the process *how* the people change his problematic conducts. The stages involve the pre-contemplation (PC= inactive without any intention to change), contemplation (C= inactive with intention to change), preparation (P= active but not fulfilling the recommendations of the American College of Sports Medicine [ACSM]), action (A= has complied with the recommendations of the ACSM but for less than six months) and maintenance (M= has complied with the recommendations ACSM for more than six months). Meanwhile, the cognitive processes involve Increasing Knowledge (IK), Being Aware of Risks (BAR), Caring About Consequences to Others (CACO), Comprehending Benefits (CB) and Increasing Healthy Opportunities (IHO). **PURPOSE:** To analyze which cognitive process are most commonly used in the different stages to fulfill with the recommendations of physical exercise healthy of the ACSM. **METHODS:** A total of 533 subjects (48% female and 51.8% male; 33.22 ± 15.27 ; range = 11-76). A Mexican Spanish version of the Stages of Change Questionnaire, as well as items on cognitive processes from the Processes of Change Questionnaire, were applied. **RESULTS:** The internal consistency of the different CP ranged from .65 to .81. The results of One-Way ANOVA revealed significant differences in IK, BAR, CACO, CB and IHO in different stages ($F_{(4,525)} = 7.844 - 25.761$, $p < .001$). Tukey HSD post hoc indicated that the use of IK (PC<C, P<A, M), CACO (PC<P<A, C, M), CB (PC<A<C, P, M) and IHO (PC<C, P<A, M) increases through the stages, except the BAR process (PC<P, A, M, C) which was more emphasized in the use in C. **CONCLUSION:** All the CP contribute to the achievement of the recommendations of the ACSM, however, the BAR process had more relevance to generate the intention of being physically active.

Motivators for Physical Activity in Older Latino Caregivers

Guilherme M. Balbim, Isabela G. Marques, Melissa Magallanes, Judith S. Rocha, David X. Marquez, FACSM. *University of Illinois at Chicago, Chicago, IL.* (Sponsor: David X. Marquez, FACSM)
 Email: gbalbi2@uic.edu
 (No relationships reported)

Alzheimer's disease (AD) and related dementia may affect 1.3 million people by 2050, and nearly 70% of people with AD live at home. Caregivers face challenging responsibilities, and experiences of enduring stress and frustration are common among family members caring for people with dementia. Physical activity (PA) can lead to reducing burden and stress, and a positive impact on well-being and quality of life in caregivers. **PURPOSE:** To determine the motivators for PA in older Latino caregivers. **METHODS:** Participants were 16 Latino caregivers, aged 50 years and older, who had been caring for a relative ($N=6$ for the mother, 4 for a husband, 3 for the wife, 2 for father, and 1 for both parents) with AD or related disorder for at least 6 months. The majority of caregivers were female (12). Interviews were conducted in English and Spanish about the caregiver role, family, and social support, coping strategies and PA. For the purposes of this study answers regarding PA were analyzed. **RESULTS:** Six caregivers (4 female and 2 male) did not mention motivators for PA. Of those who stated motivators for PA, the remaining two men indicated staying healthy and fit as primary motivators to exercise, as well as receiving social encouragement from their wives. Women stated the motivation for PA as resulting from social support (7), especially from their sons, daughters, brothers, friends and boss. The importance of facilities available for engagement in PA was also noted. Parks were the most cited environmental factors to motivate PA (3). **CONCLUSIONS:** A significant number of older Latino caregivers did not stress any motivators for PA. Men cited health-

related outcomes as their PA motivation. Among women, receiving support from family members was demonstrated as a relevant promoter of PA. Social support was a great motivating source for PA among older Latino caregivers. Future research and interventions should take into consideration the importance of social support to increase PA in this population. Funded by the Department of Kinesiology and Nutrition of UIC.

Association between Baseline Fitness and Exercise Adherence during a 26-Week Supervised Exercise Program
 Danielle M. Ostendorf¹, Zhaoxing Pan¹, Seth A. Creasy¹, Emmanuel Seyoum², Kristen Bing¹, Liza Wayland¹, Edward L. Melanson, FACSM¹, Victoria A. Catenacci¹. ¹University of Colorado, Anschutz Medical Campus, Aurora, CO. ²University of Colorado, Denver Campus, Denver, CO. (Sponsor: Edward L. Melanson, FACSM)
 Email: danielle.ostendorf@ucdenver.edu
 (No relationships reported)

Few studies have examined the relationship between baseline fitness and exercise adherence in adults with overweight/obesity during a comprehensive behavioral weight loss program (BWLP). Differentiating individuals who adhere to an exercise prescription based on fitness level may improve future intervention approaches. **PURPOSE:** To examine the association between baseline fitness and exercise adherence during a 26-week supervised exercise program. **METHODS:** Data from participants enrolled in an 18-month BWLP combining a calorie-restricted diet and supervised exercise were used in this analysis. The 26-week supervised exercise intervention consisted of moderate intensity exercise (65-75% max HR), three supervised sessions/week, progressing from 20 to 60 min/session by week 13. Baseline fitness (VO₂ max) was categorized based on published age and sex norms. Logistic regression was used to examine the association between baseline fitness and a) attrition and b) exercise adherence (attended ≥80% of supervised sessions). The association with adherence was assessed over the entire program (weeks 1-26) and during discrete intervals (weeks 1-4, 5-8, 9-14, 15-20, and 21-26). **RESULTS:** 69 participants (age 41±9.7 kg/m², BMI 34±3.8 years, 87% female) were enrolled in the BWLP. Participants were classified based on baseline fitness level: 29% very poor (VO₂ max 21.8±4.2 mL/kg/min), 48% poor (24.2±3.1 mL/kg/min), 19% fair (26.4±2.4 mL/kg/min), 3% good (32.2±3.8 mL/kg/min), and 1% superior (38.2 mL/kg/min). 78% (n=54) completed the 26-week supervised exercise intervention. Baseline fitness category was not associated with attrition, nor was it associated with adherence over the entire program (weeks 1-26) or at weeks 1-4, 5-8, 9-14, and 15-20. However there was a positive association between baseline fitness category and adherence during weeks 21-26. Participants categorized as poor or above were 9.4 times more likely to attend ≥80% supervised sessions as compared to those categorized as very poor (95%CI: 1.1-78.5; p=0.039). **CONCLUSION:** Baseline fitness levels in our study population were surprisingly low. Those starting an exercise program with very poor fitness may struggle with adherence over time as the exercise volume reaches higher levels and may require more coaching during this phase of the program.

Relationships between Physical Activity and Motivation in Early Secondary School Adolescents in Scotland
 Lauren McMichan, Ann-Marie Gibson, David A. Rowe, FACSM. University of Strathclyde, Glasgow, United Kingdom. (Sponsor: David A. Rowe, FACSM)
 Email: lauren.mcmichan@strath.ac.uk
 (No relationships reported)

PURPOSE: High prevalence of physical inactivity and sedentary behaviour (SB) in adolescents is a global issue with as few as 18% of adolescents meeting physical activity (PA) guidelines. Research has suggested that higher intrinsic motivation is positively related with higher levels of PA. The purpose of this study was to test this relationship in early secondary school adolescents. **METHODS:** PA/SB was measured using an adapted version of the survey used in the Health Behaviour in School Children study and motivation was measured using the BREQ-3 questionnaire (Mark & Tobin, 2004; Wilson, Rodgers, Loitz & Schime, 2006). Questionnaires were completed during class time by students aged 11-14 years. The Relative Autonomy Index (RAI) was calculated using the weightings provided for each subscale. Spearman's Rho was used to determine the relationship between number of days active and each subscale of the BREQ-3, as well as the RAI. **RESULTS:** Participants' (N = 94) mean age was 12.79 ± 0.95 yr and 55.3% of the sample were male (n = 52). Based on 7-day recall, participants spent an average of 3.77 ± 2.05 days active. Correlations between the BREQ-3 and number of days active were: amotivation (r_s = -.12, p = .27); external regulation (r_s = .27, p = .01);

introjected regulation (r_s = .01, p = .95); identified regulation (r_s = .17, p < .01); integrated regulation (r_s = .35, p < .01); intrinsic motivation (r_s = .35, p < .01). These results suggest there is no relationship between introjected regulation and PA in early adolescents. Total RAI scores were significantly positively correlated with days active (r_s = .25, p = .02). **CONCLUSIONS:** The strongest positive relationships with PA are for external regulation, integrated regulation and intrinsic motivation. The patterns of these correlations appear to support the sub-theory of Self-Determination Theory - Organismic Integration - that adolescents further along the continuum towards the intrinsic motivation end are likely to engage in more PA compared to those who are towards the amotivated end of the continuum. However, in this study, external regulation appears to have a stronger relationship than introjected or identified regulation. Overall, the total RAI indicates a positive relationship between autonomous motivation and PA.

The Influence Of Attentional Focus Cueing On Jump-and-reach Performance
 Rajab Intair, Justin Usher, Dimitri Castro, Evranjeet Brar, Julio Gomez, Vanessa Yingling, FACSM, Jenny O, FACSM. California State University, East-Bay, Hayward, CA.
 Email: rajabintairkupt@gmail.com
 (No relationships reported)

Movement cueing involves the provision of verbal instructions to performers prior to movement execution. Research literature examining attentional focus cueing has clearly documented the performance advantages of adopting an external focus (e.g., focusing on the center of a basketball hoop) over an internal focus (e.g., focusing on flicking the wrist; Al-Abood et al., 2002; Wulf et al., 1999; Zachry et al., 2005). Most commonly, deviation from a target has been employed as the measure of objective success, across a variety of specialized sport skills (for a review, see Wulf, 2013). **PURPOSE:** Consistent with this body of research, it is reasonable to hypothesize that when cueing individuals performing a vertical jump-and-reach task, an external focusing cue would lead to a superior task performance compared to an internal focusing cue. Preliminary research has provided support for this assertion (i.e., Wulf & Dufek, 2009; Wulf et al., 2007); however, these preliminary quasi-experiments employed relatively small sample sizes (i.e., ns = 8-12 participants). The current experiment examined the effect of attentional focus cueing on performance of a vertical jump-and-reach task. **METHODS:** Sixty-five college-aged participants were randomly assigned to one of three cueing conditions: control (n = 21), external focus (n = 22), or internal focus (n = 22). A Vertec™ measurement device was used to measure jump height. **RESULTS:** Interestingly, and contrary to the attentional focus literature, results demonstrated similar jump-and-reach performances between the external- (Mexternal = 19.97in.; SD = 5.38) and internal-focus groups (Minternal = 18.91in.; SD = 5.31; p > 0.05), as well as similar performances between the external focus and control groups (Mcontrol = 21.55in.; SD = 4.88; p > 0.05). **CONCLUSIONS:** These findings question the applicability of the external focus effect on the performance of less complex motor skills, however, other possible explanations for the current results and future research suggestions are also offered.

Validity Of The Multidimensional Outcome Expectations For Exercise Scale In Young Adults
 Gene L. Farren, Paul E. Yeatts, Tsz Lun Chu, Tao Zhang, Scott B. Martin, FACSM, Mitch Barton. University of North Texas, Denton, TX.
 Email: gene.farren@unt.edu
 (No relationships reported)

Though outcome expectation is considered an important element of the social cognitive theory (Bandura, 1977, 1986), it has received little attention in physical activity research, especially in younger populations (Hellsten & Rogers, 2009). Moreover, when measured, this construct is often unidimensional. **PURPOSE:** To determine the psychometric properties of the 3-factor (physical, social, and self-evaluative) 15-item Multidimensional Outcome Expectations for Exercise Scale (MOEES; Wójcicki, White, & McAuley, 2009) in a sample of young adult college students enrolled in a health-related fitness course. **METHODS:** Confirmatory factor analysis was used to examine the 3-factor MOEES model in 346 young adults (52% female, M_{age} = 20.59 ± 4.79) from a public university located in the Southwest United States. Participants completed questionnaires assessing physical, social, and self-evaluative outcome expectations, barrier self-efficacy (Dwyer et al., 2012), and self-esteem (Robins et al., 2001), as well as the FITNESSGRAM® health-related fitness assessment to measure their cardiorespiratory fitness, muscular strength and endurance, and body composition (Cooper Institute, 2013). **RESULTS:** Analyses supported the 3-factor measurement model of the MOEES in young adults, χ²(81) = 312.11, p < .01, RMSEA = .09, CFI = .95, SRMR = .04 (Hu

& Bentler, 1999). Using structural equation modeling, construct validity was further demonstrated by significant path coefficients from barrier self-efficacy and self-esteem to the outcome expectations, as well as significant variance explained by 3-factor MOEES model in cardiorespiratory fitness ($r^2 = .18, p < .01$), muscular strength and endurance ($r^2 = .09, p < .01$), and body composition ($r^2 = .10, p < .01$). **CONCLUSION:** The MOEES appears to be a reliable and valid measure of outcome expectations for exercise in this limited sample of young adult college students enrolled in a health-related fitness course. Further validation in alternative young adult and adolescent samples is warranted.

The Relationship between Cell Phone Use, Physical Activity, and Sedentary Behavior In Adults above College-age

Curtis Fennell¹, Ellen L. Glickman, FACSM², Andrew Lepp², J. Derek Kingsley², Jacob E. Barkley². ¹University of Montevallo, Montevallo, AL. ²Kent State University, Kent, OH.
 Email: cfennell@montevallo.edu
 (No relationships reported)

While there is evidence of a positive relationship between cellular telephone (cell phone) use and sedentary behavior, but not physical activity in college-aged individuals (18-29 years old), these relationships have not been tested in individuals older than college age (≥ 30 years old). This research is warranted as cell phone use is inversely associated with age; thus these relationships may be different in older individuals. **PURPOSE:** To assess the relationship between cell phone use, physical activity and sedentary behavior in adults older than college age (≥ 30 years old). **METHODS:** Adults aged 30-63 years ($N = 69, 51 \pm 8$ years old) wore physical activity monitors (accelerometers) for seven days and completed surveys assessing daily cell phone use, physical activity, and sedentary behavior. Pearson's correlation analyses were performed to assess relationships between cell phone use and age, physical activity, and sedentary behavior. Participants were then split into tertiles based on total cell phone use (low, moderate, and high) and a MANCOVA (sex and age as covariates) was used to determine if there were group differences in physical activity and sedentary behavior. **RESULTS:** Cell phone use ($= 125.2 \pm 146.8$ minutes per day) was inversely associated with age ($r = -0.3, p = 0.005$). Cell phone use was not associated with objectively- or subjectively-measured physical activity or sedentary behavior ($r \leq 0.1, p \geq 0.3$ for all). There were also no significant differences in physical activity or sedentary behavior between the low, moderate, and high cell phone user groups ($F \leq 2.0, p \geq 0.12$ for all). **CONCLUSION:** Consistent with previous research, there was an inverse relationship between cell phone use and age. Unlike what has been reported in college-aged individuals, cell phone use was not associated with sedentary behavior in adults older than college age. Because younger individuals are "digital natives" who have been raised with near-constant access to cell phones this may be their sedentary activity of choice. Conversely, adults who are older may prefer other, more traditional forms of sedentary activities such as watching television and using a desktop computer. This may explain the lack of a relationship between cell phone use and sedentary behavior in adults beyond college age.

Understanding Active Behaviors Among Insufficiently Active Adults During Experimental Studies: A Descriptive Analysis

Paula-Marie M. Ferrara¹, Brittany S. Overstreet¹, Kelley Strohacker², David R. Bassett, FACSM². ¹University of Delaware, Newark, DE. ²University of Tennessee, Knoxville, TN.
 Email: pferrara@udel.edu
 (No relationships reported)

A recent study examined the impact of TV viewing during exercise on observable volitional behavior (i.e. treadmill endurance time) among insufficiently active adults (46 ± 15 years, 31 ± 5 kg/m²; 68% women). Participants completed two visits in a randomized order, with >48H separating them. Participants could sit or walk on the treadmill (moderate intensity) as desired within a 60-minute time frame. During one visit, participants were able to view TV during exercise and while sitting. During the other, TV viewing was allowed only when seated. Despite the average participant accumulating 63±58 minutes of moderate-to- vigorous physical activity (MVPA) per week, 24% of participants walked continuously for 60-min at both visits. **PURPOSE:** Determine differences in relevant physical, psychological, and behavioral characteristics between participants who walked 60-min in both conditions (WALK, n=6) compared to those who did not (WALK/SIT, n=19). **METHODS:** T-tests were used to compare physiological (BMI, %body fat, estimated VO₂max), psychological (preference for and tolerance of exercise, intrinsic and extrinsic motivation), and behavioral (MVPA/week) factors. **RESULTS:** Tolerance for exercise intensity was significantly higher in WALK relative to WALK/SIT (3.2 vs. 2.5 $p=0.04$). No other significant differences were observed (>0.05) between WALK and WALK/SIT, respectively (BMI=29.8 m/kg² vs. 31.6 m/kg², %body fat=34.0% vs. 36.0%,

estimated VO₂max =29.4ml/kg/min to 26.6ml/kg/min, intrinsic motivation=2.1 vs. 2.0, extrinsic motivation=1.04 vs.1.07, preference for exercise intensity= 2.6 vs. 2.6. Although not significantly different, WALK reported nearly twice the average minutes of MPVA (83.3 vs. 48.9 min/week, $p=0.20$). Anecdotally, several participants indicated that, because it was already scheduled, they used this time to exercise regardless of condition. **CONCLUSION:** The ceiling effect in volitional walking time noted for 24% of participants warrants further investigation. Preliminary descriptive analyses suggest that tolerance of exercise intensity may play a role, while anecdotal data indicate additional motivational factors (i.e. "making use" of experimental visits) should be accounted for. Future studies may consider implementing experimental time frames greater than 60 minutes.

2050 Board #63 June 1 2:00 PM - 3:30 PM
Competence Beliefs Mediate the Relation between Physical Activity and Motor Competence in Elementary School Children

Tao Zhang, Xiangli Gu, Allen Jackson, FACSM. University of North Texas, Denton, TX.
 Email: TAO.ZHANG@UNT.EDU
 (No relationships reported)

PURPOSE: Recent research has proposed that a lack of motor competence (MC) leads to physical inactivity during childhood as children lack the competence beliefs to participate in physical activities. Stodden and colleagues' conceptual model suggested children's physical activity (PA) will drive the development of MC during childhood, but this assumption has not been tested in the pediatric literature. This study, therefore, aimed to examine whether the changes of PA after an 8-week pedometer-based intervention would cause the changes of MC through competence beliefs in physical education (PE). **METHODS:** A pretest-posttest comparison group design was used with an 8-week pedometer-based intervention combined with a goal setting strategy (3 days/week for 24 sessions). Elementary school children were randomly allocated to three conditions: 1) an intervention group with a personalized pedometer weekly target, 2) an intervention group with the fixed pedometer target range, or 3) a control group. Children's PA in PE (steps/class), competency beliefs in PE, and MC (PE Metrics™) were measured at baseline and follow up after the 8-week intervention. Of 273 original participants, 259 (Mean_{age} = 10.88; boys = 131, girls = 128) were in the final data analyses. **RESULTS:** AMOS 22.0 was employed to assess the hypothesized mediation model using structural equation modeling (SEM). The model represented an acceptable fit ($\chi^2/df = 11.51/6$, RMSEA = 0.06, CFI = 0.98, NFI = 0.96). Standardized path coefficients indicated competence beliefs fully mediated the relationships between PA ($\gamma = .26$) and MC ($\gamma = .33$). The model accounted for 39% of the variance in MC. We then inspected the path coefficients between the same outcome variables across times. The magnitude of the path coefficients across intervention ranged between 0.14 and 0.56. Hence, there were some degrees of change in the relative rank ordering of participants on scores from the measures through the intervention. **CONCLUSION:** This study provided evidence from a randomized controlled intervention to test Stodden et al.'s conceptual model. The results supported that PA intervention results in increased MC through competency beliefs in PE, which highlighted the mediation role of competence beliefs in PA interventions designed to increase MC among elementary children.

2051 Board #64 June 1 2:00 PM - 3:30 PM
Is Playing Pokémon Go Associated With Increased Walking Behavior?

Zi Yan, Kayla Breton, Kevin Finn, Rachel Millerick. Merrimack College, North Andover, MA. (Sponsor: Kyle McInnis, FACSM)
 Email: yanz@merrimack.edu
 (No relationships reported)

PURPOSE: One of the latest advancements in the video gaming industry is the location-based, augmented, reality, mobile games (e.g., Pokémon GO). Different from other exergames, the location-based augmented reality games utilize GPS and camera compatible devices to create a fantasy setting in which the games take place. The users need to physically walk in the real world to participate in the game. It is expected that playing the Pokémon GO game will promote walking behavior by the users. The current study compared the walking behavior of the Pokémon GO users to the non-users. **METHODS:** 393 college students (Female=175, age M=19.03, SD=2.04) from a medium size college in the Northeast took an online survey that measured their user activity (how much time they played the APP in the last 7 days), whether they agree the APP makes them walk more (Likert scale from 1 strongly disagree to 5 strongly agree), as well as their walking behavior (recall their total walking time in the last 7 days). Based on the responses, 105 athletes were excluded from the study. The rest of participants were classified as non-users (n=227, 79.1%), regular-users (i.e., playing less than 30 min a day, n=24, 8.4%), and active-users (i.e., playing more than 30 min a day, n=36, 12.5%).

RESULTS: 25.6% of regular-users and 75.7% of the active-users strongly agreed or agreed that playing the APP made them walk more. Different from the hypothesis, ANOVA and Post Hoc analysis showed that regular-users and active-users walked significantly less than non-users, $M=4.73\text{hr/w}$ $SD=3.76$, $M=4.65\text{hr/w}$ $SD=3.67$, and $M=6.96\text{hr/w}$ $SD=4.76$, respectively, $F(2,247)=4.78$, $p<.001$.

CONCLUSIONS: Although most Pokémon GO players believed that playing the APP made them walk more, they still walked less than non-players in general. There may be pre-existing differences in the walking behaviors between players and non-players. There can be an assumption that video game users are more sedentary than non-users and therefore this is why there are differences in walking behaviors between the two groups. However, future studies would need to investigate this.

2052 Board #67 June 1 2:00 PM - 3:30 PM
Comparative Influence of Exercise Self-efficacy and Physical Activity on Depression in Older Adults

Lindsay M. Tyree, Kelsey D. Loss, Kelsey L. Owens, Victoria E. Warren, Thelma S. Horn, Kyle L. Timmerman. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)
 Email: tyreelm@miamioh.edu
 (No relationships reported)

There is currently research that suggests that physical activity level is a significant positive predictor of satisfaction with life (SWL) as well as a significant negative predictor of depression in older adults. The belief that an individual holds regarding their physical activity capabilities (exercise self-efficacy) has also been found to serve as a predictor of SWL and depression. It's currently unknown which of these two variables (physical activity or self-efficacy) is the better predictor of satisfaction with life and depressive symptoms in older adults. Thus, the **PURPOSE** of this study was to examine the relationships among physical activity level, exercise self-efficacy, age, SWL, and depressive symptoms in this population. We hypothesized that exercise self-efficacy would be the better predictor of SWL and depressive symptoms than physical activity level in older adults. **METHODS:** In 68 older adults (78.3±7.8y) we assessed depression (Geriatric Depression Scale, GDS), well-being (Satisfaction with Life Scale, SWLS), moderate-to-vigorous physical activity (MVPA, Community Healthy Activities Model Program for Seniors questionnaire), and exercise self-efficacy (SEFF). Hierarchical linear regression analyses were utilized to assess the predictive value of MVPA, SEFF, and Age for SWLS and GDS using two models (Model 1: Age and MVPA; Model 2: Age, MVPA, and SEFF). Significance was set to $p<0.05$. **RESULTS:** Only age was a significant predictor of GDS in model 1. In model 2, only SEFF was a significant predictor of GDS ($\beta=-0.34$, $p<0.01$). Neither age nor MVPA were significant predictors of SWLS in Models 1 and 2. SEFF was a significant predictor of SWLS in model 2 ($\beta=-0.33$, $p<0.05$). **CONCLUSIONS:** These preliminary data show that exercise self-efficacy is a stronger predictor of depressive symptoms and satisfaction with life compared to age and MVPA in older adults.

2053 Board #66 June 1 2:00 PM - 3:30 PM
Perceived Barriers to Physical Activity among Latino Caregivers

Isabela G. Marques, Guilherme M. Balbim, Melissa Magallanes, Judith S. Rocha, David X. Marquez, FACSM. *University of Illinois at Chicago, Chicago, IL.* (Sponsor: David X. Marquez, FACSM)
 (No relationships reported)

The older Latino population will increase rapidly over the next four decades, from 7.3% in 2012 to a projected 18.4% by 2050. Latinos have twice the incidence of Alzheimer's disease (AD) compared to Non-Latino Whites. Caregivers face challenging responsibilities, stress and frustration are commonly experienced among family members caring for people with dementia. Physical activity (PA) can reduce familial caregiving burden and stress; however, caregivers often report barriers to being physically active. **PURPOSE:** To identify older Latino caregivers' barriers to engage in PA. **METHODS:** Interviews were conducted with Latino caregivers (N=16, 12 females; 4 males), 50 years and older, caring for a relative with AD or related dementia for a minimum of 4 hours daily, for the past 6 months. Eight interviews were conducted in Spanish and eight in English about the caregiver role, family, and social support, coping strategies and PA. For the purposes of this study only responses regarding barriers that prevent PA were analyzed. Interviews were recorded, transcribed, translated and coded according to directed content analysis. **RESULTS:** Fifteen caregivers cited many barriers that prevent them from participating in PA, and only one reported no barrier. Most obstacles cited involved the care recipient. The necessity to stay at home caring for the relative was the main barrier mentioned (8). Interestingly, this barrier was only mentioned by female caregivers. Women also reported laziness, lack of time due to work, illness, and necessity to take care of grandchildren as other barriers. Males pointed out the lack of time because of work, disability, and laziness as barriers. The most relevant barrier for PA was the impossibility of leaving the care recipient by him/herself or with other temporary

caregivers; however, this barrier did not seem to prevent males to engage in PA. **CONCLUSIONS:** Older Latino caregivers cited caring for the family member as the main obstacle to engage in PA. Gender differences seem important, as males are still able to participate in PA despite of caregiving. Future research and interventions should considerate the need of offering an alternative type of assistance to the primary caregiver to allow extra time to PA participation. Funded by the Department of Kinesiology and Nutrition of UIC.

2054 Board #67 June 1 2:00 PM - 3:30 PM
Exercise Preference Mode Related to Trait Anxiety in College Students

Kaitlyn E. Carmichael¹, Gene L. Farren¹, Paul E. Yeatts¹, Tsz Lun Chu¹, Mitch Barton², Scott B. Martin, FACSM¹. ¹*University of North Texas, Denton, TX.* ²*Dallas Independent School District, Dallas, TX.* (Sponsor: Scott B. Martin, PhD, FACSM)
 (No relationships reported)

Previous research has indicated that exercisers report lower levels of trait anxiety than non-exercisers regardless of age and gender (De Moor et al., 2006). Significant reductions in trait anxiety occur when aerobic exercise interventions exceed 10 weeks (Petruzzello et al., 1991). However, there is limited research examining the relations between trait anxiety and preferred mode of exercise in both population studies and exercise interventions. **PURPOSE:** To examine the association between trait anxiety and preferred mode of exercise during leisure time in health-conscious young adults. **METHODS:** Participants included 770 college students from 14 health-related fitness courses (416 male, 354 female, $M_{\text{age}} = 20.64 \pm 3.16$) who completed a measure of trait anxiety (Spielberger, 1983) and an item that assessed preferred mode of exercise during leisure time (i.e., no exercise, playing sports, strength training, aerobic training, or multiple modes). **RESULTS:** Descriptive statistics revealed 88 students preferred no exercise during their leisure time, whereas 140 students preferred playing sports, 158 preferred strength training, 129 preferred aerobic training, and 255 students preferred multiple modes of exercise during their leisure time. One-way ANOVA indicated there was a significant main effect for preferred mode of exercise on trait anxiety levels, $F(4,765) = 25.00$, $p < .01$, $r^2 = .12$, $\omega^2 = .11$. Hochberg's GT2 post hoc tests indicated that mean trait anxiety scores for students who preferred no exercise during their leisure time were significantly higher than students who preferred playing sports ($d = 0.86$), strength training ($d = 0.92$), aerobic training ($d = 0.84$), and multiple modes ($d = 1.16$). In addition, students who preferred multiple modes had a significantly lower mean trait anxiety scores than students who preferred playing sports ($d = 0.31$) and aerobic training ($d = 0.38$). **CONCLUSION:** These findings indicate that exercise preferences relate to trait anxiety in a collegiate sample. Specifically, participants that did not prefer to participate in any mode of exercise reported the highest levels of anxiety. These results are consistent with previous research indicating that exercise, in general, may lead to reductions in trait anxiety (Petruzzello et al., 1991).

The Relationship Between Motivational Factors And High Intensity Functional Training (HIFT)

Angelina Micalizzi¹, Ashton Matson¹, Allyson Box¹, Chris Brown¹, Katie Heinrich², Yuri Feito, FACSM¹. ¹*Kennesaw State University, Kennesaw, GA.* ²*Kansas State University, Manhattan, KS.* (Sponsor: Yuri Feito, FACSM)
 (No relationships reported)

INTRODUCTION: High Intensity Functional Training (HIFT) is characterized by varied weight training, gymnastic, and body weight movements performed at high intensity. HIFT presents participants with the opportunity to improve factors related to physiological and psychological health. Considering its global growth, it is important to recognize the motivational factors behind participation in this training modality. **PURPOSE:** We sought to examine what motivational factors were most important among participants engaging in HIFT at different frequencies throughout a week. **METHODS:** 732 adults (32.4 ± 8.2 years) with more than three-months of HIFT experience (<3 d/wk, N = 114; 3-5 d/wk, N = 413; >5 d/wk = 205) completed an online version of the Exercise Motivation Inventory (EMI-2) survey. **RESULTS:** Significant Spearman rho (ρ) correlations were seen between HIFT frequency and all EMI variables (p<0.01) except those related to health pressures (ρ = -0.036; p = 0.331), ill health avoidance (ρ = 0.011; p = 0.774), and appearance (ρ = -0.025; p = 0.506). Kurskal-Wallis H test and post-hoc comparisons showed that individuals training 3-5 and >5 d/wk scored higher in factors related to enjoyment, affiliation, and competition (p<0.001) compared to those training <3d/wk. Also, those training >5 d/wk scored higher in factors related to challenge, social recognition, strength and endurance, and nimbleness (p<0.001), and lower in factors related to weight management (p<0.001) than the other two groups. **CONCLUSIONS:** This is the first study to express differentiation of motivational factors in HIFT participants based on their weekly training frequency. Considering its growth and expansion, it is important to understand the psychological motives to successfully implement programs targeted towards an

individual's motivation. Future studies should look at how these motivational factors impact adherence based on the workout frequency, age of the participants, and number of years training.

Correlates of Chinese College Student's Physical Activity Behavior: A Social Ecological Model Perspective
 Meirong Huang¹, Haichun Sun². ¹China University of Mining and Technology, xuzhou, China. ²University of South Florida, Tampa, FL. (Sponsor: Zan Gao, FACSM)
 Email: 411462089@qq.com
 (No relationships reported)

Purpose: A recent report indicated that the number of Chinese college students reached 37 million in 2015, representing the world's largest college student population. Despite the well-known health benefits of regular physical activity (PA) participation, Chinese college students are less likely to engage in PA as compared to their counterparts in Western countries. Understanding the factors that relate to Chinese college students' PA would provide valuable insights for future PA interventions. Guided by the Social Ecological Model, this study examined the associations among personal, social, and environmental correlates of PA participation among Chinese college students. **Methods:** Chinese college students (N = 741) were recruited from East region of China. Demographic information was collected, and PA and Social Ecological Model-based correlates (values, efficacy, social support, media and social media, weather, and facilities) were measured via a previously validated questionnaire for Chinese college students. Multiple regression analysis was conducted using gender and social ecological factors as independent variables and PA as the dependent variable. **Results:** Regression analysis suggested that gender was a significant predictor ($\beta = .17, p < .01$) with male students being more physically active. For the social ecological factors, values ($\beta = .071, p = .03$), efficacy ($\beta = .40, p < .01$), social support ($\beta = .20, p < .01$), and weather ($\beta = -.18, p < .01$) emerged as significant predictors; while media and social media ($\beta = -.057, p = .083$) and facilities ($\beta = -.003, p = .913$) were not found to be significant predictors for college students' PA. The model accounted for 42.6% of the variances in college students PA participation. **Conclusions:** Strategies and interventions are needed to promote female college students' PA. Programs that specifically designed to develop or enhance college students' efficacies and values toward PA and to encourage social interaction among peers might be helpful for PA participation.

Does Experience Matter? Enjoyment Of High Intensity Interval Exercise With Respect To Exercise History
 Daniel R. Greene, Steven J. Petruzzello, FACSM. *University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Steven J. Petruzzello, FACSM)
 Email: dgreene2@illinois.edu
 (No relationships reported)

While post exercise enjoyment and affective responses to aerobic exercise are fairly well documented, only recently have they been investigated within high-intensity interval exercise protocols. Further, little is known regarding how exercisers compare to non-exercisers with respect to affective responses during, and enjoyment following, high-intensity interval exercise (HIIE). **PURPOSE:** With respect to individual exercise history, evaluate affect during and enjoyment post: (a) continuous moderate intensity aerobic exercise (MIA); (b) high-intensity interval exercise (HIIE); and (c) a sedentary control condition (SED). **METHODS:** Participants (N=269; 156 ♀; 20.60 ± 1.20 yrs, M±SD) were divided into "regular exercisers" (n = 194; 102 ♀) and "non-exercisers" (n = 75; 54 ♀) based on self-reported exercise history. All participants completed each of the randomly ordered 15-min conditions: MIA (walking), SED (quiet reading), and HIIE (2 min activity, 1 min recovery). Enjoyment (Physical Activity Enjoyment Scale) was measured post condition; affective valence (Feeling Scale; FS) was assessed pre and every 3 min during each condition. **RESULTS:** Regular exercisers reported greater enjoyment following HIIE [$M_{diff} \pm SE = 10.40 \pm 2.40; P < 0.001$] and reported more positively valenced affect during HIIE [$M_{diff} \pm SE = 0.96 \pm .26; P < 0.001$] relative to non-exercisers. Additionally, regular exercisers enjoyed HIIE more than the MIA condition [$M_{diff} \pm SE = 6.12 \pm 1.46; P < 0.001$], while non-exercisers showed no difference in enjoyment between the two active conditions [$M_{diff} \pm SE = 3.43 \pm 2.35; P = 0.15$]. No differences were observed in enjoyment post or affect during the MIA condition between regular and non-exercisers. **CONCLUSION:** This believed to be the first study comparing regular exercisers to non-exercisers with respect to enjoyment and affective responses to HIIE. These findings both extend previous research by adding to the limited work on affective responses to HIIE and highlight the importance of exercise experience with respect to HIIE. In order to maximize exercise enjoyment and affective responses, especially when prescribing exercise, more attention needs to be given to exercise history.

The Physical, Psychological, and Behavioral Impact of Undergraduate Physical Education Courses Varies by Course Content

Zack Papalia, Melissa Bopp, FACSM, Michele Duffey. *Pennsylvania State University, University Park, PA.* (Sponsor: Melissa Bopp, PhD, FACSM)
 Email: zvp5003@psu.edu
 (No relationships reported)

BACKGROUND: Physical Activity (PA) rates are declining in college students, though many universities are moving to eliminate any Physical Education (PE) course requirements for undergraduates. Examining the impact and aspects of collegiate PE courses on health behaviors is crucial for the future implementation and support of collegiate PA. **PURPOSE:** To evaluate the impact collegiate PE classes have on undergraduate student's physical, psychological, and behavioral outcomes. **METHODS:** Participants, a volunteer sample of students enrolled in PE class at a large northeastern USA university, were asked to take an online survey at the beginning and end of their PE course. The survey examined current PA level, goal setting behaviors, self-efficacy, PA enjoyment, opinion of PE course, (whether) and demographic factors. Basic frequencies and descriptives described the sample. Independent sample T-Tests and One Way ANOVAs with Tukey's post-hoc were used to examine differences in end-of-semester and change-over-the-semester findings. **RESULTS:** The final sample (n=431) was 56.6% women, 83% Non-Hispanic White with an average age of 21.1±1.7y. PE Course was divided into seven types: Aerobic, Strength, Yoga, General Sport, Dance, and Aerobic/Strength with Lecture. There were significant differences between types for course impression (F=9.16, p=0.00), BMI Change (F=2.77, p=0.02), PA Enjoyment (F=2.33, p=0.04), PA Goal Setting Behavior (F=2.78, p=0.02). Additionally, positive course impression was significantly correlated (p<0.05) with increases in goal setting behavior (r=.36), self efficacy (r=0.21), and Vigorous PA (r=0.10). Higher goal setting behavior at the end of the semester was correlated with a pre-to-post increase in PA enjoyment (r=0.36) and self-efficacy (r=0.14). **CONCLUSIONS:** The current study offered insight on the impact and effectiveness of different types of collegiate PE courses. The differences found between sections and the relationships between certain behavior changes and health outcomes may prove very useful in determining how future PE course offerings and resource allocation may be optimized.

Relations between Basic Psychological Needs and Health-Related Fitness Measures in Male and Female College Students
 Veera H. Korjala, Paul E. Yates, Tsz Lun Chu, Gene L. Farren, Scott B. Martin, FACSM. *University of North Texas, Denton, TX.* (Sponsor: Dr. Scott B. Martin, FACSM)
 Email: veera.korjala@unt.edu
 (No relationships reported)

INTRODUCTION: Self-determination theory (SDT; Deci & Ryan, 1985) is a prominent theoretical framework applied to assess exercise participation (Kirkland et al., 2011). SDT holds that satisfying the three basic psychological needs (BPNs; autonomy, competence, and relatedness) fosters self-determined motivation, personal growth, and psychosocial well-being (Deci & Ryan, 1985). Relations between BPNs and exercise participation may vary between sexes (Martinez et al., 2013). Given that exercise participation is highly related to health-related fitness (Blair et al., 2001) investigating whether the relations between BPNs and fitness outcomes also vary between sexes is warranted. **PURPOSE:** To investigate the relations between BPNs and fitness outcomes in male and female college students. **METHOD:** Participants were 564 male and 503 female college students ($M_{age} = 20.57 \pm 3.82$ years) enrolled in a health and wellness course. Students completed a survey assessing the BPNs (Vlachopoulos & Michailidou, 2006), as well as the FITNESSGRAM® test battery (Cooper Institute, 2013), which includes measures of cardiorespiratory fitness (Progressive Aerobic Cardiovascular Endurance Run [PACER]), muscular strength and endurance (curl-up and push-up), and body composition (body fat %). Correlation analyses were conducted by sex to examine bivariate relationships between BPN and fitness outcomes. **RESULTS:** Analyses revealed that BPNs were significantly correlated with each fitness outcome (p < .05). Correlation magnitudes were not statistically different between males and females based on Fisher's z tests (p > .05). In both genders, competence had significantly higher correlations with the fitness outcomes (excluding PACER) when compared to relatedness (p < .05), but did not significantly differ from autonomy (p > .05). **CONCLUSION:** Results indicated that all three BSNs related to components of physical fitness in men and women enrolled in a health and wellness course. Interestingly, competence had the strongest relationships with fitness outcomes. Based on this study and previous research, fitness instructors may want to promote competence by providing social support and constructive individualized feedback, believing in participants' abilities, acknowledging their improvements and successful experiences.

Comparing Bmi With Health Related Quality Of Life In College Freshman: The Herd Study
 Lauren Bartoldson, *Marshall University, Martinsburg, WV.*
 Email: laurbartoldson@outlook.com
(No relationships reported)

Obesity in the United States is significantly higher than it was in the previous generation. West Virginia's obesity rate currently exceeds 30% of its population. Previous literature has demonstrated an inverse relationship between BMI (body mass index) and health-related quality of life, however these associations rarely include college-aged adults. **PURPOSE:** To examine the relationship between BMI and health related quality of life in college aged freshman enrolled in the HERD (Higher Education Reducing Diabetes) Study at Marshall University in Huntington, West Virginia. **METHODS:** The HERD Study is a 4 year longitudinal, randomized study examining the effects of a freshman year, healthy lifestyle intervention on the reduction of student's risk factors for developing type 2 diabetes and cardiometabolic disease. Freshmen were recruited during the Fall 2016 Freshman Week of Welcome at Marshall University. Quality of Life was assessed at baseline using the Short Form-12 Questionnaire. The SF-12 is a 12 item, validated survey assessing participant's physical and mental quality of life.

RESULTS: To date, 76 freshman have enrolled into the HERD study [age= 18.5±2.36 years; female=60.5% (n=46); 85.5% Caucasian (n=65); BMI= 26.5±5.85 kg/m². Fifty-three percent (n=40) of the students were deemed overweight or obese (BMI > 25 kg/m²). Students with a BMI ≥ 25 kg/m² were significantly less likely to record their health as very good or excellent compared to those with a BMI < 25 kg/m² (p=0.002). Students with a BMI ≥ 25 kg/m² were more likely to record that over the past four weeks, their emotional health caused them to accomplish less than usual (p=0.017). Also, students with a BMI ≥ 25 were more likely to record that their health (physical and emotional) interfered with social activities (p=0.004).

CONCLUSIONS: The BMI of college-aged freshman appears to have an impact on health related quality of life with higher BMI contributing to reduced health quality, productivity and social factors. Future efforts will examine strategies for decreasing BMI to improve the physical and mental health of young adults.

Cancer Survivors' Experiences Of Physical Activity: Exercise As A Vehicle For Recovery?
 Mairéad Cooney¹, Niall Moyna¹, Deirdre Walsh¹, Bróna Furlong¹, Lisa Loughney¹, Lorraine Boran¹, Sinead Smyth¹, Catherine Woods². ¹*Dublin City University, Dublin 9, Ireland.* ²*University of Limerick, Limerick, Ireland.*
 Email: mairread.cooney4@mail.dcu.ie
(No relationships reported)

Physical activity (PA) can have benefits for individuals at each stage of the cancer journey, including improved fitness and quality of life. However, many cancer survivors are not meeting the physical activity recommendations.

PURPOSE: The aim of this study was to explore cancer survivors' experiences of PA across the cancer journey.

METHODS: Participants were recruited from a cancer support centre and a community-based exercise programme that caters for cancer survivors. To ensure that a variety of opinions and experiences of PA across the cancer journey were captured, purposive sampling methods were used to recruit male and female cancer survivors of all ages who were either currently active or inactive. The focus group discussions were transcribed verbatim and were analysed using a thematic analysis approach.

RESULTS: 7 focus groups were conducted with 41 cancer survivors. Each group consisted of 4-8 participants. Most cancer survivors reported a decrease in their PA levels during treatment which was commonly attributed to treatment-related side effects. Participants reported that a period of isolation and a decrease in wellbeing can be experienced after treatment completion. Participants identified the lack of PA advice and services throughout the cancer journey and the need for a holistic approach to rehabilitation. Many viewed exercise as a vehicle for recovery as it facilitates 'self-power' - taking ownership and control of one's PA to increase wellbeing. Some participants reported that engagement in PA after treatment was empowering and that it increased their self-confidence and belief in their physical capabilities. Other participants reported that PA was difficult to initiate and maintain for a number of reasons, including the negative impact of treatment-related side effects on the physical ability to be active. Individuals reported that exercising with other cancer survivors created an accepting and supportive environment for exercise.

CONCLUSIONS: These findings suggest that there is a gap in the cancer care pathway post-treatment completion. An exercise rehabilitation programme at this time could support cancer survivors to increase their physical and psychological well-being.

Effects of Beetroot Juice Supplementation and Hypoxia on Time Trial Performance in Well-Trained Cyclists

Torben Rokkedal Lausch, Ryan Godsk Larsen, Mathias Krogh Poulsen, Dan Karbing, Lars Pilegaard Thomsen, Jesper Franch. *Aalborg University, Aalborg, Denmark.*
 Email: Torben@hst.aau.dk
(No relationships reported)

Beetroot juice supplementation is known to improve endurance performance in untrained and moderately trained subjects. In well-trained subjects beneficial effects of supplementation are questionable in normoxia but may be promising in hypoxia. Therefore, effects on maximal and submaximal performance during normoxia and normobaric hypoxia should be further investigated. **PURPOSE:** To examine the effects of beetroot juice (BR) supplementation on cycling performance in well-trained cyclists during normoxia and normobaric hypoxia (15% O₂). **METHODS:** Five well-trained male cyclists (VO_{2max}, 69.1 ± 5.2 ml·min⁻¹·kg⁻¹, W_{max} 5.7 ± 0.3 W/kg) completed four exercise trials. Subjects consumed 140 ml BR (equivalent to 12.4 mmol nitrate) or placebo (PLA) (nitrate-depleted BR) for seven days in a double-blind, randomized crossover design. On day four and seven, subjects completed 3x6-min submaximal cycling at 70% lactate threshold and a 10-km time trial (TT) in either normoxia or hypoxia. Inspiratory conditions were randomized and single blinded.

RESULTS: BR did not affect TT performance in either hypoxia (BR: 253.8 ± 35.6; PLA: 252.8 ± 32.3 Watt; P=0.65) or normoxia (BR: 296.8 ± 45.4; PLA: 297.4 ± 44.8 Watt; P=0.83). However, average power output during the TT was higher in normoxia than in hypoxia (297.1 ± 45 vs. 253.3 ± 33.9 Watt; P=0.003). Average oxygen uptake during the TT was higher in normoxia than hypoxia (4411.4 ± 462.9 vs. 3959.0 ± 368.7 ml·min⁻¹; P=0.008). Similarly, peak oxygen uptake during the TT was higher in normoxia than hypoxia (4885.9 ± 483.9 vs. 4204 ± 395.3 ml·min⁻¹; P=0.003). During submaximal cycling BR did not affect average steady state oxygen uptake in neither hypoxic (BR: 3239.8 ± 320.5; PLA: 3158.8 ± 406.1 ml·min⁻¹; P=0.28) nor normoxic conditions (BR: 3167.7 ± 312.5; PLA: 3069.7 ± 249.3 ml·min⁻¹; P=0.55). Further, oxygen uptake during submaximal cycling was similar in hypoxic and normoxic conditions (HYP: 3199.3 ± 360.5; NORM: 3118.7 ± 241.2 ml·min⁻¹; P=0.47).

CONCLUSIONS: These preliminary results suggest that seven days of high dose BR supplementation do not enhance cycling performance in normoxia or moderate hypoxia in well-trained cyclists.

2063 Board #76 June 1 3:30 PM - 5:00 PM
A Single Night of Sleep Restriction Following Heavy Exercise Impairs Next-Morning 3-km Cycling Performance

John D. Chase, Paul A. Roberson, Michael J. Saunders, Trent A. Hargens, FACSM, Christopher J. Womack, FACSM, Nicholas D. Luden. *James Madison University, Harrisonburg, VA.*
(No relationships reported)

Sufficient sleep (7-9 hr) is necessary for proper physiological function. Athletes are susceptible to sleep loss due to the physical demands of heavy training and the emotional stress of competition. A single night of sleep restriction does not appear to negatively impact next-morning performance. However, this has only been assessed with subjects in a well-rested training state. **PURPOSE:** The primary goal of this project was to examine recovery from of a single night of sleep restriction following heavy exercise on cycling time trial performance (TT) and skeletal muscle function in the morning. **METHODS:** Seven recreational cyclists (age, 24 ± 7 yr; VO_{2max}, 62 ± 4 ml/kg/min) completed two phases, each consisting of an evening (EX1) and next-morning (EX2) exercise session. EX1 and EX2 were separated by an assigned sleep condition; a full night of rest (SLP+, 7.1 ± 0.3 hr of sleep) or sleep restriction through early waking (SLP-, 2.4 ± 0.2 hr). EX1 consisted of baseline testing (muscle soreness, peak isokinetic torque at 120 deg/sec, a 20 min cycle ergometer warm-up, and subsequent 3-km TT performance) followed by heavy exercise that included 60 min of high intensity cycling intervals and resistance exercise. EX2 was performed to assess recovery from EX1, and included all baseline measures. Magnitude-based inferences were used to evaluate the effects of sleep condition on these measures.

RESULTS: SLP- had a 'very likely' negative impact (96% likelihood) on the change in 3-km TT performance compared to SLP+. Specifically, 3-km TT performance was 'very likely' (99% LH) slower during EX2 compared to EX1 following SLP- (-4.0%), whereas TT performance was 'possibly' (54% LH) slower during EX2 (vs. EX1)

following *SLP+*. Sleep condition did not influence the change in peak torque, as peak torque during EX2 was 'likely' lower than EX1 with both *SLP+* (89% LH) and *SLP-* (80% LH). Likewise, sleep condition did not impact the change in muscle soreness, as muscle soreness 'very likely' increased from EX1 to EX2 with both *SLP+* (97% LH) and *SLP-* (99% LH). **CONCLUSION:** A single night of sleep restriction following heavy exercise had marked consequences on 3-km TT performance the next morning. Strategies to ameliorate the consequences that sleep loss have on performance should be investigated.

2064 Board #77 June 1 3:30 PM - 5:00 PM
Validity of a Novel Staged Exercise Test for Measuring Maximal Steady State Lactate In Recreational Cyclist Using the Lactate Plus Analyzer(R)
 Jacob Harp, Max Sanderford, Joe Gillespie, Jennifer Blevins-McNaughton. *Tarleton State University, Stephenville, TX.*
 Email: jblevins@tarleton.edu
 (No relationships reported)

Several types of lactate threshold (T_{inc}) protocols have been developed over the years to maximize accuracy and reliability while maintaining ease of measurement and application to training and performance. **PURPOSE:** The purpose of this study was to determine the validity of a novel staged maximal lactate steady state exercise test (sMLSS) in predicting the MLSS using the Lactate Plus® (Nova Biomedical, Waltham, MA) analyzer. **METHODS:** Blood lactate concentration (BLC) was measured in duplicate for all tests. Seven trained cyclists (20 miles per week) performed a VO_{2max} test starting at 100W and increasing by 30W every three minutes until volitional fatigue. Lactate threshold was defined as the previous workload to a 2 mmol/L increase in BLC. Next, the sMLSS test was performed starting at the T_{inc} workload, determined previously, then increasing 10W every 15 minutes for a total of three stages. BLC was measured every 3 minutes. MLSS was predicted by visual inspection and defined as < 1.0 mmol/L increase in the final 6 minutes of the stage. Finally, cyclists then performed two to six MLSS exercise tests, adjusting by 5W depending on lactate response, to validate the sMLSS. MLSS was determined at the maximal workload with < 1 mmol/L increase in BLC in the final 20 minutes. Dependent t-test and Pearson correlation analysis was used to determine reliability between lactate trials. Bland-Altman plots, One-way ANOVA, and regression analyses were used to analyze differences between the types of exercise tests. **RESULTS:** There were no significant differences for duplicate BLC trials for all tests ($p=0.21$; $r=0.982$). Ninety-five percent confidence intervals for the sMLSS and MLSS were significantly correlated with the MLSS workload and percentage of max workload ($r=0.997$; $p=0.001$, $r=0.978$, $p=0.01$), respectively. There was no bias noted between sMLSS and MLSS protocols for predicting lactate accumulation. **CONCLUSION:** In conclusion, the sMLSS was a valid and reliable predictor of MLSS in trained cyclists.

2065 Board #78 June 1 3:30 PM - 5:00 PM
High-intensity Cycling Intervals Are Prescribed Accurately Using The 3-min All-out Exercise Test
 Nathan D. Dicks¹, Zachery A. Roloff², Luke M. Krynski², Robert W. Pettitt, FACSM². ¹North Dakota State University, Fargo, ND. ²Minnesota State University, Mankato, Mankato, MN. (Sponsor: Robert Pettitt, FACSM)
 Email: nathan.dicks@ndsu.edu
 (No relationships reported)

High-intensity interval training (HIIT) has been used to enhance critical power (CP) and the finite capacity for work (W'); yet, research on prescriptions using the CP concept is warranted. **PURPOSE:** We investigated the validity of interval prescriptions derived using CP and W' measures acquired from a 3-min all-out exercise test (3 MT). **METHODS:** Eight competitive cyclists completed a 3 MT, verification bout for determining peak oxygen uptake (VO_{2peak}), and subsequent HIIT bouts, noted numerically using the number of bouts by duration and % W' depletion riding on a cycle affixed to a CompuTrainer. Using expired gas exchange data, VO_{2peak} values from a verification bout subsequent to a 3 MT were compared with end-exercise values of HIIT schemes using 60 and 80% W' depletion for 180 and 300 s for each condition. The HIIT schemes were counterbalanced to avoid an order-effect. **RESULTS:** VO_{2peak} ($ml\ kg^{-1}\ min^{-1}$) values from the verification bout (58.7 ± 6.9), 4 X 180 s 60% W' scheme (57.4 ± 8.2), 3 X 180 s 80% W' scheme (58.3 ± 5.7), 4 X 300 s 60% W' scheme (54.3 ± 8.0), and the 3 X 300 s 80% W' scheme (55.7 ± 7.4) did not differ ($F=2.10$, $p=0.25$). Strong measurement agreement was observed for VO_{2peak} between measures (ICC = 0.85, typical error = 2.37 $ml\ kg^{-1}\ min^{-1}$, coefficient of variation = 4.6%). **CONCLUSION:** The 60% and 80% W' HIIT schemes for either 180 or 300 s durations evoked VO_{2peak} consistently, providing empirical support for the CP concept to standardize HIIT.

Difference Of Anaerobic Capacity, Muscle Activity Of Lower Extremities In Win-gate Test According To Events Of Cyclists
 Da-Woon Park, Moo-Yeop Ji, Shun-Zhe Piao, Dong-Woo Kim, Tae-Yeon Kim, Deuk-Su Park, Hyeong-Jun Park, Jae-Keun Oh. *Korea National Sport University, Seoul, Korea, Republic of.*
 (No relationships reported)

PURPOSE: This study examined anaerobic capacity, muscle activity of dominant lower extremities Gluteus maximus(Gmax), Rectus femoris(RF), Long head of biceps femoris(LBF), Tibialis anterior(TA), Gastrocnemius medialis(GM) with Standing start 10sec(SS-10sec) and Rolling start 30sec(RS-30sec) Wingate test between short distance cyclist group(SDC, 20±1 yrs) and long distance cyclist group(LDC, 21±2 yrs) total 12 elite cyclists to develop baseline data which can provide proper training program for each event through comparison and analysis of this experiment.
METHODS: Independent t-test was conducted to verify the differences of anaerobic capacity, lower extremities muscle activity, isokinetic muscle strength, and paired t-test was executed to verify anaerobic capacity, muscle activity differences within each group. All the statistical significance level was set as $\alpha=0.05$.

RESULTS:
 1. SDC group was identified as significant higher Peak/kg than LDC group during SS-10sec wingate test between the groups($p<0.05$).
 2. SS-10sec was identified as significantly higher than RS-30sec in Peak power and Peak/kg between SS-10sec and RS-30sec wingate test within SDC group($p<0.01$, $p<0.01$). SS-10sec was identified as significantly higher Peak power and Peak/kg than RS-30sec, within LDC group($p<0.05$, $p<0.05$), for Mean power and Mean power and Mean/kg, RS-30sec was identified as significantly higher result than SS-10sec($p<0.001$, $p<0.001$).
 3. SS-10sec was identified as significantly higher Peak and Mean muscle activity than RS-30sec in long head of biceps femoris during wingate test within SDC group($p<0.05$, $p<0.01$). Peak muscle activity within LDL group was identified as no significant difference between SS-10sec and RS-30sec in Peak muscle activity, for Mean muscle activity, SS-10sec was identified as significantly higher muscle activity than RE-30sec in tibialis anterior and gastrocnemius medialis($p<0.01$, $p<0.05$).

CONCLUSION: With the above results, it is identified anaerobic capacity and activated muscle groups during pedalling according to cycling events. Therefore, in the future study, it is considered that specialized training program application for specific event based on the current study could improve athletic performances.

2067 Board #80 June 1 3:30 PM - 5:00 PM
Preliminary Examination Of Stamina Sensor Device With Laboratory Testing Measures In Recreationally Trained Cyclists
 Robert Blaisdell, Nicholas Fiolo, Kimitake Sato. *East Tennessee State University, Johnson City, TN.*
 Email: blaisdell@etsu.edu
 (No relationships reported)

The availability of app based fitness technology has led users to a wide selection of devices to aid in their training regimes, however some do not accurately represent individual physiological characteristics. With an ever growing base of device choices, selecting a highly reliable and valid unit should be of utmost importance to the attentive athlete. **PURPOSE:** To determine the relationship of a stamina sensor device with traditional laboratory cardiorespiratory testing protocols to evaluate inter-individual physiological characteristics in trained cyclists. **METHODS:** Recreationally trained cyclists ($n=6$) completed a successive fixed work rate incremental cycle ergometer test to exhaustion. The testing protocol began at 85 W and increased by 15 W every 5 minutes. Inspired and expired gases were continuously recorded using a metabolic cart, heart rate (HR) using a stamina sensor device app; blood lactate levels utilizing a using a finger stick capillary sample (0.7 microliter (μL)) and a blood lactate analyzer and rate of perceived exertion (RPE) were obtained during the final 30 seconds of each stage. Individual physiological data were assessed to determine heart rate (HR), lactate threshold (LT), ventilator threshold (VT), and RPE responses between athletes. Delta values were calculated per dependent variable to assess the relationship between changes in physiological response to changes in the stamina levels. **RESULTS:** The stamina sensor device displaying stamina percentage, aerobic percentage, and anaerobic percentage has shown low correlation with laboratory testing measures such as VO_2 and blood lactate values. When correlations were run on VO_2 and stamina % change, stamina value, aerobic, and anaerobic values it produced r values of 0.616, -0.743, -0.861 and -0.664 respectively. When correlations were run on blood lactate values and stamina % change, stamina value, aerobic, and anaerobic values it produced r values of 0.509, -0.817, -0.914 and -0.761 respectively.

CONCLUSION: Though the stamina sensor device is not a direct replacement of laboratory testing to measure performance, the stamina sensor does appear to accurately represent the subjective output (RPE) of the individual athlete.

The Impact of Cycling Cadence On Oxygen Consumption During Maximal & Submaximal Exercise

Enda E. Murphy, Javier J. Monedero, Donal J. O'Gorman. *Dublin City University, Dublin, Ireland.*

Email: enda.murphy@dcu.ie

(No relationships reported)

The impact of cycling cadence on oxygen consumption has not been studied in detail but previous reports describe increased oxygen consumption at higher rates of muscle contraction, even when external work is similar. The majority of studies were performed during incremental exercise to exhaustion and there is little data on sub-maximal responses. One of the challenges is to determine the relative intensity to compare different cycling cadences during submax exercise as %VO_{2peak} will be influenced by the cadence during VO_{2peak} testing. **PURPOSE:** The purpose of this study was to determine if peak power output (PPO) could be used to compare the metabolic responses during submaximal exercise at different cycling rates. **METHODS:** Eleven young (21±1 yr) recreationally active males completed a continuous incremental exercise test to exhaustion (VO_{2peak}) on an electrically braked cycle ergometer at 65rpm and 95rpm. The power output corresponding to 55% PPO was calculated for each cycling cadence and, on two further occasions, participants cycled for 1-hr at 65-rpm and 95-rpm. Indirect calorimetry was used to monitor a number of metabolic variables during exercise. In addition, heart rate and blood lactate was measured during all trials. **RESULTS:** At VO_{2peak}, oxygen consumption (3182±230 vs 3348±318 ml/min, p=0.002), total ventilation, respiratory rate, heart rate and lactate were all significantly greater following the 95-rpm trial (p<0.05). There were no significant differences in peak power output or ventilatory threshold between trials. During sub-maximal exercise, VO₂ (2012±194 vs 2371±218 ml/min, p<0.001) and all other parameters were significantly greater at 95-rpm (p<0.05). **CONCLUSIONS:** As PPO does not change during maximal exercise it can be used to control external work and compare the metabolic responses while cycling at differences cadences. The mechanisms underpinning the increased metabolic demand at higher rates of muscle contraction need further examination.

Adding Video Games or Music Videos to Stationary Cycling: Effects on Exercise Enjoyment.

Shawn R. Reich, James R. Whitehead, FACSM, John S. Fitzgerald, Tanis J. Hastmann-Walch. *The University of North Dakota, Grand Forks, ND.* (Sponsor: Dr. James R. Whitehead, FACSM)

Email: shawn.reich@ad.ndus.edu

(No relationships reported)

Various strategies designed to promote physical activity participation and enjoyment have been researched, but few studies have focused on exercising while playing video games. **PURPOSE:** To investigate whether playing a video game, or watching music videos while working out on an exercise cycle increases exercise enjoyment, decreases perceived exertion, and increases work output. **METHODS:** Using a randomized order within-subjects experimental design, college-aged males (n=24) participated in three conditions: cycling while playing an Xbox@ 360 video game console (VG), cycling while watching music videos (MV), and cycling with no external media (NM). Dependent measures were exercise enjoyment (PACES), perceived exertion (RPE), heart rate (HR), and total work output (kJ). Data were analyzed using paired t-tests with Holm's Sequential Bonferroni adjustments (SPSS v21). **RESULTS:** VG and MV PACES scores were statistically similar, but both were significantly higher than NM (NM: M = 3.33, SD = .85. VG: M = 4.31, SD = .44, p < .001, d = 1.14. MV: M = 4.32, SD = .56, p < .001, d = 1.15). RPE was significantly lower in the VG condition (M = 13.21, SD = 1.56) than both the MV (M = 14.46, SD = 1.71, p < .005, d = .73) and NM conditions (M = 14.25, SD = 1.62, p < .001, d = .64). A significantly higher total work output (in kJ) was observed in the MV condition over the VG condition and NM over the VG condition (VG: M = 113.12, SD = 29.21; MV: M = 128.11, SD = 30.17, p < .001, d = .51 and VG: M = 113.12, SD = 29.21; NM: M = 122.75, SD = 33.30, p < .005, d = .33). There were no statistically significant differences in HR between the three conditions. **CONCLUSION:** While there were moderate statistical differences in work output and RPE, the practical significance of these results may be most related to the large effect on exercise enjoyment in the VG and MV conditions compared to NM. With less than half of the US adult population currently meeting the 2008 Physical Activity Guidelines, an intervention that can make an exercise modality significantly more enjoyable may have important potential public health benefits via improved physical activity participation levels. Future research might investigate if these laboratory-based results can translate into improved volitional physical activity levels in free living adults.

The Effect of Typical Power Variation on Cycle Time-trial Performance

Marc S. Wells, Simon Marwood. *Liverpool Hope University, Liverpool, United Kingdom.*

Email: wellsm@hope.ac.uk

(No relationships reported)

The manner in which power output is distributed during a time-trial (TT) can affect performance. However, previous studies that have compared the effect of constant and variable power outputs on performance have failed to consider the typical amplitude and period of power variations that competitive cyclists undertake. **PURPOSE:** To compare the time required to complete an indoor, self-paced 4 km TT following a 12 km constant and variable power "pre-load". **METHODS:** Eleven competitive cyclists (32 ± 10 years, 181 ± 4 cm, 78 ± 9 kg, VO_{2peak} 4.2 ± 0.7 L·min⁻¹) initially completed a self-paced 16.1-km TT. Participants then undertook two 16.1-km experimental TT whereby the initial 10 km was either at a constant (CT) or variable (VT) power output. Mean power (MP) during this time was equivalent to the mean power from the initial 16.1-km TT but in VT, power was varied in accordance with a previously determined template which was based on the typical power variation of competitive cyclists. For each trial, a 2 km normalisation period at MP preceded a maximal, self-paced final 4 km. **RESULTS:** There was no difference in the time to complete the final 4-km (CT: 362 ± 39 vs VT: 348 ± 43 s, t₁₀ = -1.38, P = 0.20) or average power (275 ± 42 vs. 287 ± 57 W, t₁₀ = 1.29, P = 0.23) between trials. Power output increased during the final 4 km compared to 12 km (P < 0.05); the increase in power during the final 4 km was accompanied by an increase in oxygen uptake which at 16.1 km (3.7 ± 0.5 L·min⁻¹) was greater (P = 0.05) than that at 12 km (3.6 ± 0.5 L·min⁻¹). Heart rate also increased continuously throughout the final 4 km (P < 0.001), though was not different between trials. **CONCLUSIONS:** In using the typically displayed amplitudes and periods of variation in power output that competitive cyclists undergo during TTs in order to define VT, this study sought to replicate the typical variations which are apparent during self-paced TT. The results of the present study suggest that this typical power variation does not adversely affect performance, at least during a 16.1-km TT. The similar performance was accompanied by similar physiological responses during the final 4 km of the trial.

2071 Board #84 June 1 3:30 PM - 5:00 PM

Relationships Between A Smartphone Stamina App With The Performance And Physiological Responses To Cycling

Nicholas Fiolo, Robert Blaisdell, Kimitake Sato. *East Tennessee State University, Johnson City, TN.*

Email: fiolon@etsu.edu

(No relationships reported)

In order to complete an event as fast as possible an endurance athlete must select a work rate that maximizes intensity and optimizes the rate of fatigue. This pacing strategy ensures a true maximal effort without premature exhaustion and can be conceptualized as an allocation of the athlete's stamina resources. The relationship between intensity and time to exhaustion is curvilinear and dependent upon the athlete's individual fitness characteristics and current fatigue state. Therefore, an athlete's stamina level and rate of allocation should be influenced by exercise intensity, duration, and individual fitness characteristics. **PURPOSE:** To determine the relationships between smartphone stamina sensor device and the performance and physiological responses to an incremental cycling test to exhaustion in trained cyclists. **METHODS:** 6 trained cyclists completed a successive, fixed work rate incremental cycle ergometer test to exhaustion. Testing began at 85 W and increased by 15 W every 5 minutes. Inspired and expired gases were continuously recoded using a metabolic cart and HR using the smartphone app. RPE was obtained during the final 30 seconds of each stage. Individual physiological data were assessed to determine the individual VO₂ and metabolic cost per stage and the ventilatory thresholds. Bivariate correlations were conducted between the following variable: stamina and total mechanical work (J), stamina percent change and stage RPE, stamina and energy expenditure (kcal.), and stamina and percentage of total kcal. to exhaustion. **RESULTS:** Stamina had statistically significant correlations with J, r(140) = -.81, p < .01, RPE, r(140) = -.62, p < .01, kcal., r(140) = -.79, p < .01, and percentage of kcal. to exhaustion, r(140) = -.83, p < .01. **CONCLUSIONS:** The stamina variable is highly related to performance and physiological responses to an incremental cycling test to exhaustion. Stamina is able to respond to the dynamic nature of exercise to exhaustion and may prove to be a valid variable to assess endurance performance.

2072 Board #85 June 1 3:30 PM - 5:00 PM
Time Deception Affects Performance But Not Metabolic Variables In Cyclists

Mateus Leite¹, Joelma Donadio², Alexander J Koch³, Dailson Paulucio⁴, Marco Machado⁵. ¹Laboratory of Physiology and Biokinetics, UNIG Campus V, Itaperuna, RJ, Brazil. ²Laboratory of Physiology and Biokinetics, UNIG Campus V, Itaperuna, RJ, Brazil. ³Exercise Physiology Laboratory, Lenoir-Rhyne University, Hickory, NC. ⁴Laboratory of Biometry, Federal University of Rio de Janeiro, Rio de Janeiro, RJ, Brazil. ⁵Human Movement Laboratory Studies, FUNITA, Itaperuna, RJ, Brazil. (No relationships reported)

PURPOSE: Previous investigations have found that various types of deception (ie. unknown task endpoint) could alter perception and consequently affect performance. We investigated whether time deception influenced performance and metabolic variables in cyclists. **METHODS:** Ten semi-professional male cyclists (age 36±5, years; height 173±6 cm; weight 76.7±265 kg; with 2 years of experience) completed three 60 min cycling time trials (roller trainer) after 2 familiarization sessions. Visual feedback of elapsed time was provided, but the chronometer was manipulated to display either real (NOR), 10% slower (SLO) or 10% faster time lapse (RAP). Total distance covered and heart rate (HR) were recorded at each 10 min interval. Ratings of perceived exertion (RPE) were assessed with the 20-point Borg scale. Blood samples were collected before and immediately after each time trial, and analyzed for blood glucose, serum creatinine, serum urea, and serum urate. Data were analyzed with repeated measures ANOVA. Significant main effects were further analyzed using pairwise comparisons with Bonferroni post hoc tests. Statistical significance was set at the p ≤ 0.05 level of confidence. Statistical analysis was completed using SPSS v20.0 for Windows (LEAD Technologies). **RESULTS:** Distance completed at any 10 min time point was similar between conditions, but total distance covered over the 60 min differed among conditions (NOR = 20.7±4.1; SLO = 25.7±7.1; RAP = 23.7±5.2 Km) (p < 0.05). Post-hoc analyses indicated that both RAP (p = 0.001) and SLO (p = 0.027) covered a greater total distance than NOR, with no difference in distance covered between SLO and RAP (p=0.458). RPE (NOR = 17±3; SLO = 16±4; RAP = 18±1) and HR (NOR = 171±12; SLO = 172±17; RAP = 180±12 bpm) were similar (p = 0.145) among conditions. Blood glucose increased during the time trial for all conditions, however increases in blood glucose (NOR = 7.4±10.7; SLO = 5.2±8.6; RAP = 6.8±13.3 mg·dl⁻¹) were similar among all conditions. Serum creatinine, serum urea and serum urate were stable and did not differ among conditions. **CONCLUSION:** These results indicate that deception (±10%) consisting of either a slower or more rapid perception of elapsed time can increase performance in a time trial, but does not affect RPE nor the measured metabolic variables in semi-professional cyclists.

2073 Board #86 June 1 3:30 PM - 5:00 PM
The Effect Of Acute Versus Accumulated Soccer Training On Postprandial Dysmetabolism

Darren J. Paul¹, George P. Nassiss¹, Jens Bangsbo². ¹Aspetar Sports Medicine and Orthopaedic Hospital, Doha, Qatar. ²University of Copenhagen, Copenhagen, Denmark. (No relationships reported)

Playing soccer has shown to have short and long term health benefits. Whether a dose response relationship exists for soccer training over a short period (1 week) is unknown. **PURPOSE:** The aim of the present study was to examine the effects of acute versus accumulated soccer match play on postprandial dysmetabolism in recreational players. **METHODS:** Fifteen participants were recruited and preliminary data was collected for body composition and cardiorespiratory fitness. There was no significant difference between the groups at baseline and the groups did not differ in their pre intervention triglyceride (TG) incremental area under the curve (iAUC) response to the fat load meal. On day 1, pre intervention (control(C)) blood samples were collected at 0 (fasted) and 0.75, 2, 4, 6hrs post a high fat load. Participants were randomly allocated to an experimental group (soccer (S)) of 1xpw or 3xpw small sided games training over a week period. The final session for the 3xpw was on the same day as the 1xpw training. Participants returned the next day, after completing the S, to the laboratory for post intervention blood samples. Repeated measures ANCOVA was used to compare differences and iAUC/AUC, confidence intervals (CI) and effect sizes (ES) were calculated. **RESULTS:** TG iAUC was significantly lower in the 1xpw from pre to post measures (p=0.04; 95%CI=-3.45 to -0.04; ES=-1.02), but not in the 3xpw. The average TG response was lower at all time points for the S compared to the C for both groups. There was no significant delta change for 2hrs insulin iAUC in both groups. **CONCLUSION:** Playing soccer can improve the PP TG response compared to no exercise but 3 consecutive days will not attenuate the response more than 1 session per week.

2074 Board #87 June 1 3:30 PM - 5:00 PM
Iron Deficiency And Physical Performance In Elite Female Soccer Players

Claudia A. Pérez. Centro de alto rendimiento de Chile. Hospital de Carabineros de Chile, Santiago, Chile. (Sponsor: Stella Volpe, FACSM)
 Email: claudiaperezlmd@gmail.com
 (No relationships reported)

Introduction: Iron deficiency is a prevalent condition among athletes especially in women. Iron is a key element for biological functions including oxygen carrying and oxidative phosphorylation among others. This has led to the idea that its deficit may impact physical performance. In Chile approximately 5% women have Anemia and over 10 % may have iron deficiency without anemia. There is ongoing research about this subject but none of it has been conducted on Chilean female athletes. **Purpose:** to determine the prevalence of iron deficiency with and without anemia in Chilean elite female soccer players and to evaluate if there is an association between iron deficiency and VO2 max or anaerobic power and fatigability. **Subjects and methods:** Twenty five female athletes from the Chilean National Soccer team where included in this study. After informed consent, blood samples to determine Hemoglobin and Ferritin levels were taken from them. They participated in a clinical evaluation, ergo spirometry to determine VO2 max, and RAST test for anaerobic capacity and fatigability. Data were analyzed with Pearson correlation, ANOVA and Kruskal-Wallis tests. **Results:** No cases of anemia were detected. Among these athletes, 25% had Ferritin levels over 50 mcg/ml and 28% under 15 mcg/ml. No correlation or association was found between hematological variables and VO2max, maximal anaerobic capacity or fatigue index. **Conclusion:** The prevalence of iron deficiency was high in Chilean female elite soccer players as compared to the Chilean female population, and most participants of this study had ferritin levels that would prompt supplementation in our center. In this group we found no impact of iron deficiency or ferritin level in physical performance. This results may have been influenced by different training levels of the participants prior to participating on this study. More research is needed in this area to determine the influence of iron in performance in female athletes.

2075 Board #88 June 1 3:30 PM - 5:00 PM
Regulatory Fit: Impact On Anxiety, Arousal, And Performance In College-level Soccer Players

Brianna Leitzelar, Lindsey Blom, Jocelyn Bolin, Justin Guilkey, Anthony Mahon. Ball State University, Muncie, IN. (No relationships reported)

Sport behavior may be regulated through a desire to win (promotion) or a desire to avoid losing (prevention), which differentially impacts cognitive tasks. Performance facilitation may also stem from a match between an individual's self-regulatory focus and her chronic regulatory strategy, possibly due to "feeling right". This notion of regulatory fit may impact pre-performance anxiety and arousal which may impact sport performance. **PURPOSE:** To determine the impact of regulatory fit on anxiety, arousal, and performance of college soccer players. **METHODS:** Twenty-five female soccer players were randomly assigned to a regulatory match (M) or mismatch (MM) condition. Participants received a task-framing phrase in which their performance goal either matched (M) or mismatched (MM) their chronic regulatory strategy. Anxiety, measured by the Competitive State Anxiety Inventory-2 Revised (CSAI-2R) and arousal, measured by pre-ejection period (PEP), heart rate (HR), and heart rate variability (e.g. high frequency variability (HF), and the square root of the mean squared differences of successive NN intervals (RMSSD)) were determined pre- and post-manipulation. Performance, the number of successful penalty kicks out of 10, was measured post-manipulation. The impact of regulatory fit on performance and on anxiety and arousal variables were determined by ANOVA and RM ANOVA, respectively. **RESULTS:** There was no difference between M (3.0 + .95) and MM (2.5 + 1.8) on performance (p>0.05). Pre (32.6 + 4.8) to post (34.5 + 5.4) CSAI-2R for M was not different than MM pre (35.0 + 4.6) to post (35.4 + 6.3) (p>0.05). Arousal variables ln HF, HR, and ln RMSSD in M were not significantly different pre (6.2 + .99; 76.4 + 15.0 bpm; 3.6 + .54) to post (6.3 + .99; 75.1 + 17.5 bpm; 3.6 + .53) compared to MM pre (6.6 + 1.0; 75.3 + 12.3; 3.8 + .49) to post (6.9 + .85; 74.6 + 10.5; 4.0 + .36), respectively (p>0.05). There was an interaction effect for PEP (p<0.05). Post-hoc testing indicated M post (0.14 + 0.01 msec) was greater than pre (0.13 + 0.01 msec) (p<0.05) but MM did not change pre (0.15 + 0.02 msec) to post (0.15 + 0.02 msec) (p<0.05). **CONCLUSION:** PEP is an indicator of the sympathetic nervous system (SNS), thus regulatory fit may impact pre-performance arousal through SNS activation. Supported by a Hollis Grant, ASPiRE program, Ball State University.

2076 Board #89 June 1 3:30 PM - 5:00 PM
Readiness To Perform, Sprint Ability, and Reaction Time Following A 2-hour Nap In Soccer Players.

Georgia Romyn¹, Michele Lastella¹, Nathan G. Versey², Gregory D. Roach¹, Charli Sargent¹. ¹Central Queensland University, Adelaide, Australia. ²Australian Institute of Sport, Bruce, Australia.

Email: Georgia.Romyn@ausport.gov.au

(No relationships reported)

Athletes' performance may improve by increasing their sleep duration. This would typically be achieved by increasing time in bed at night, but this may not always be possible. One potential solution is to nap during the day, however the time taken to reach optimal performance after waking from a nap is not known. **PURPOSE:** To examine readiness to perform, sprint ability, and reaction time 30, 60, 90 and 120 min after waking from a daytime nap. **METHODS:** Twelve soccer players (18.3±1.0 yrs) completed two conditions in a randomised order. In one condition, participants had 9 hours time in bed (22:00-07:00h) without napping the next day and in the other condition, participants had 7 hours time in bed (00:00-07:00h) with a 2-h nap the next day (14:00-16:00h). Sleep was assessed using polysomnography. Each day, participants completed four 30-min test sessions (every 30 min starting at 16:15h) that included a visual analogue scale for readiness to perform, a 7-min warm up, two 10-m sprints, and a 90-s reaction time task. Total sleep time was compared between conditions using a paired t-test. The effect of condition (no nap vs. nap) and test session (30, 60, 90, 120 min) on readiness to perform, fastest 10-m sprint, and mean reaction time were assessed by separate repeated ANOVAs. **RESULTS:** Total sleep time was similar between conditions (no nap 8.1±0.7 h vs. nap 8.0±1.0 h, p=0.87). There were main effects of condition (p<0.01) and test session (p<0.05) on readiness to perform, but no interaction between condition and session (p=0.09). Readiness to perform was lower in the nap condition (68.2±20.1) vs. the no nap condition (82.4±15.4), and at 30 min (68.0±20.8) vs. both 60 min (80.0±15.3, p=0.01) and 90 min (77.8±17.9, p=0.03). There was a main effect of test session (p=0.02) on reaction time, but no effect of condition (p=0.84) and no interaction between condition and session (p=0.26). Reaction time was faster at 120 min (211.3±20.0 ms) vs. 30 min (219.5±20.5 ms, p=0.01) and 60 min (219.8±20.8 ms, p=0.01). There were no main effects of condition (p=0.17) or time (p=0.37), and no interaction between condition and session (p=0.84) on sprint ability. **CONCLUSIONS:** The findings suggest that a daytime nap will not affect subsequent sprint ability or reaction time. However, athletes may feel less ready to perform after napping compared with not napping.

2077 Board #90 June 1 3:30 PM - 5:00 PM
Physiological Variables to Detect Training Distress in Collegiate Soccer Players

Haylee Bettencourt, Courtney Jensen, Ryan Jorden, J. Mark VanNess. University of the Pacific, Stockton, CA.

Email: h_bettencourt@u.pacific.edu

(No relationships reported)

Non-invasive and measureable techniques to identify training distress may be useful to adjust training volume. Traditionally, questionnaire data examining psychological domains have been relied on to detect training distress. **PURPOSE:** To examine running performance (shuttle run), resting heart rate and heart rate recovery throughout a soccer season to determine if these physiological parameters can be used to detect training distress in collegiate soccer players. **METHODS:** 26 women and 17 men were enrolled in the study. Data were collected at four time points throughout the season (beginning, twice during season and during post-season play). Shuttle run time, heart rate recovery time, resting heart rate values, and multi-component training distress scale (MTDS) questionnaire at each time point. Multivariate analyses were performed with the dependent variable, with time, grade in school and gender as independent variable. **RESULTS:** Shuttle run times were prolonged in the beginning and end of season compared to the two mid-season tests (p<0.001); heart rate recovery improved throughout the season (p=0.003); freshmen deviation from baseline MTDS was greater compared to all other grades (p=0.001). Although not statistically significant, resting heart rate values trended up at the end of the season for both genders. MTDS correlated most with shuttle run time and resting heart rate. **CONCLUSIONS:** Shuttle run time and resting heart rate appear to be possible variables that could serve as physiological measures for training distress, although it appears higher physical fitness serves as a protective effect against training distress.

Workload, Energy Expenditure, and Biomarker Differences in Division I Male and Female Soccer Players

Alan J. Walker, 08901, Bridget A. McFadden, David J. Sanders, Morgan L. Hofacker, Marissa L. Bello, Anthony N. Poysyck, Nick S. Mackowski, Chris E. Ordway, Brittany N. Bozzini, Shawn M. Arent, FACSM. Rutgers University, New Brunswick, NJ. (Sponsor: Shawn Arent, FACSM)

Email: alanwalk12@gmail.com

(No relationships reported)

Differential physical demands and physiological responses between males and females in the same sport have rarely been explored. **PURPOSE:** To compare work load and biomarker changes in male and female Division I college soccer players through preseason and the first half of the competitive season. **METHODS:** Male (N=24; M_{age} = 19 ± 1.1 yrs; M_{%BF} = 11.9 ± 3.2 %) and female (N=26; M_{age} = 19 ± 1.3 yrs; M_{%BF} = 20.9 ± 3.4 %) DI college soccer players participated in blood draws prior to preseason (T1), two weeks into the regular season (T2) and at season's midpoint (T3). The athletes arrived fasted in the morning. T2 and T3 draws occurred ~18 h after a game. Creatine kinase (CK), free cortisol (FC), total cortisol (TC), iron (Fe), growth hormone (GH), and IGF-1 were assessed. Workload (km and kcal/kg) was monitored using the Polar Pro system. **RESULTS:** There were no significant changes in TC over time. FC increased from T1 to T2 (Δ FC = 0.34 + 0.1 mcg/dL, P<.05) and remained elevated, particularly for females. There were significant Time x Sex interactions for Fe, GH, and IGF-1 (P<.05). Fe decreased from T1 to T2 (Δ Fe = -29.6 + 7.8 mcg/dL, P<.05) before returning to baseline at T3 in females. CK increased from T1 to T2 (Δ CK = 204.9 + 90.3 U/L, P<.05) before returning to baseline for females and increased from T1 to T3 (Δ CK = 141 + 57.1 U/L, P<.05) for males. GH decreased from T1 to T2 (Δ GH = -2.1 + 0.8 ng/mL, P<.05) and remained below baseline in females. IGF-1 decreased from T2 to T3 in females (Δ IGF-1 = -51 + 14.4 ng/ml, P<.05) while males increased from T2 to T3 (Δ IGF-1 = 50.8 + 12.5 ng/ml, P<.05). Females had greater total work load (T1-T3) than males (227.6 + 58.6 km vs. 183.2 + 49.2 km; 645.1 + 84.5 kcal/kg vs. 501.1 + 110.5 kcal/kg, P<.05, respectively). **CONCLUSIONS:** The increase in FC indicates an elevated stress response, which was particularly pronounced for females. Higher workloads for females in preseason were consistent with earlier elevations in CK compared to males. Additionally, only females had GH changes, suggesting a sex-dependent response. There were also differential changes in IGF-1 across sex. Significant changes in Fe were seen only in females, suggesting unique dietary needs during periods of increased work load. These results suggest differences in training demands and physiological responses for male and female college soccer players.

Biomarkers of Endocrine, Muscle, and Inflammatory Health Track Training Load of a Collegiate Soccer Season

Robert A. Huggins¹, Ryan M. Curtis¹, Andrea R. Fortunati¹, Maren S. Fragala², Matthew L. Hall³, Elaine C. Lee⁴, David P. Looney¹, Chris A. West⁴, Douglas J. Casa, FACSM¹. ¹Korey Stringer Institute, University of Connecticut, Storrs, CT. ²Quest Diagnostics Inc., Madison, NJ. ³UCONN Health, Storrs, CT. ⁴University of Connecticut, Storrs, CT.

Email: robert.huggins@uconn.edu

Reported Relationships: R.A. Huggins: Consulting Fee; Quest Diagnostics Inc.

Blood biomarkers signal health and performance concerns in athletes. However, serial comprehensive biomarker measurement to detect overtraining in elite soccer athletes remains unstudied. **PURPOSE:** To determine if comprehensive biomarker assessment of endocrine, muscle, and inflammatory health change with training progression in collegiate soccer players. **METHODS:** A comprehensive panel of 14 biomarkers was assessed in blood samples from 20 NCAA Division I male soccer players (mean±SD; height 181±6cm, body mass 77.9±6.2kg, BF% 11.9±2.4%, VO_{2max} 52.9±6.1 mL·kg⁻¹·min⁻¹) at 5 time points: prior to the start of preseason (PS), and in season at week 1 (W1), W4, W8, and W12. Blood samples from W1-W12 were obtained 32-34 hours post-match. PlayerLoad (PL) was recorded daily with GPS units. Significant changes in biomarkers over time were assessed via repeated measures ANOVA (α < 0.05) and the degree to which biomarkers explained PL were examined using stepwise regression. **RESULTS:** Total testosterone (T, mean±SD; ng·dL⁻¹) was lower at W1 (588±151) vs PS (665±198, p= 0.029) and W8 vs W4 (565±147, 645±170, p= 0.034). Free T (ng·dL⁻¹) was also lower at W1 (103±24) and W12 (99±33) vs PS (127±35, p< 0.025). Free T at W1 (103±24) and W12 (99±33) were decreased vs W4 (125±32, p< 0.022). No differences over time occurred for free cortisol (FC) and total cortisol (TC); however, FC (μg·dL⁻¹) was elevated at PS, W1, and W4 (1.02±0.41, 1.09±0.17, 0.94±0.35) compared to the reference range (ref.) (0.07-0.93 (μg·dL⁻¹) and TC was elevated W1 (22.1 ± 2.1) vs the ref. (4.6-20.6 μg·dL⁻¹). Growth hormone (GH), lactate

dehydrogenase, SHBG, IGF1, and TSH remained unchanged over time. Creatine kinase (CK) was elevated at W1 ($820 \pm 899 \text{ U}\cdot\text{L}^{-1}$; ref. $44\text{-}196 \text{ U}\cdot\text{L}^{-1}$) and exhibited a main effect for time ($p=0.001$) while myoglobin did not change. IL-6 ($\text{pg}\cdot\text{mL}^{-1}$) was increased W8 vs W1 ($1.61 \pm .87, 0.83 \pm 0.20, p=0.007$), however IL-1 β remained unchanged over time. Changes in PL were explained by T4, A1C, Free T, glucose, GH, and CK ($R=0.39, \beta=-0.490, p=0.001$). **CONCLUSION:** Comprehensive biomarker testing detected reduced FT, elevated TC, and increased CK after PS, consistent with a net catabolic state after PS, without apparent overtraining. Variation (39%) in PL was explained by routine monitoring indicating that these biomarkers track training progression.

2080 Board #93 June 1 3:30 PM - 5:00 PM
Monitoring Markers of Nutrition Status Throughout a Collegiate Soccer Season

Courtney L. Benjamin¹, Robert A. Huggins¹, Ryan M. Curtis¹, Andrea R. Fortunati¹, Maren S. Fragala², Mathew L. Hall³, Elaine C. Lee⁴, David P. Looney¹, Chris A. West⁴, Douglas J. Casa, FACSM¹. ¹Korey Stringer Institute, University of Connecticut, Storrs, CT. ²Quest Diagnostics, Madison, NJ. ³UConn Health, Storrs, CT. ⁴University of Connecticut, Storrs, CT.

 (No relationships reported)

Monitoring of nutritional markers is being used to optimize performance, improve overall health, and enhance recovery of athletes. **PURPOSE:** To analyze changes in nutritional biomarkers over the course of an athletic season. **METHODS:** A comprehensive panel of 23 biomarkers was assessed in blood samples from 20 NCAA Division I male soccer players (mean \pm SD; height: $181 \pm 6\text{cm}$, body mass: $77.9 \pm 6.2\text{kg}$, BF%: $11.9 \pm 2.4\%$, $\text{VO}_{2\text{max}}$: $52.9 \pm 6.1 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) at 5 time points: prior to the start of preseason (PS), and during season at week 1 (W1), W4, W8 and W12 of the season. Blood samples from W1-W12 were obtained 32-34 hours post-match. Significant changes in biomarkers over time were assessed via 1×5 (group \times time) repeated measures ANOVA ($\alpha < 0.05$) with Bonferroni correction. **RESULTS:** **CONCLUSION:** Comprehensive nutritional, vitamin, and mineral biomarker monitoring detected significant changes over the season in 60% of biomarkers obtained. Although all markers remained within normal reference ranges, future research examining the ability of non-clinical but statistically significant changes in these nutritional biomarkers to explain changes in training volume throughout a competitive soccer season is warranted. Optimization may result in improved health, performance, and recovery. Funding for this study in part by Quest Diagnostics Inc. Characters=1,036/2000

Inspiratory Performance is Significantly Related to Isokinetic Knee Power in Collegiate Women Soccer Players

Lawrence P. Cahalin, Nicholas H. Dibble, Tiffany J. Kasa, Robert O. Poliszuk, Rebecca M. Jones, Jagmit Dhah, Ian Scott, Leah Vertullo, Lesley-Anne King, Jeffrey T. Ruiz, Magno F. Formiga, Luis A. Feigenbaum, Michael G. Baraga. University of Miami, Miami, FL. (Sponsor: Dr. Thomas Best, FACSM)
 Email: l.cahalin@miami.edu
 (No relationships reported)

Sport specific tasks (SST) and exercise training are known to elicit specific changes in peripheral skeletal muscles (PSM), but adaptations to inspiratory muscles (IM) are poorly understood. **PURPOSE:** To examine the relationship of the PSM and IM in Division I collegiate women soccer players (DICWSP). **METHODS:** Thirteen DICWSP underwent maximal tests of PSM and IM via isokinetic dynamometry (ID)

and the Test of Incremental Respiratory Endurance (TIRE), respectively. Standard ID measurements were obtained during maximal extension (EXT) and flexion (FLEX) of the dominant knee at 60, 180, and 300 deg/sec as well as an endurance (ENDUR) test of repeated EXT and FLEX at 180 and 300 deg/sec. TIRE testing provided maximal inspiratory pressure (MIP), measured from residual volume (RV), and sustained maximal inspiratory pressure (SMIP), measured from RV to total lung capacity. **RESULTS:** The mean \pm SD age, height, and weight of the DICWSP was 19.5 ± 1.0 years, 172 ± 5 cm, and 63.5 ± 5 kg, respectively. The mean \pm SD peak torque of EXT and FLEX at 60, 180, and 300 deg/sec were 115 ± 17 and 75 ± 13 , 85 ± 9 and 55 ± 10 , and 65 ± 8 and 47 ± 10 ft-lbs, respectively. The mean \pm SD power of EXT and FLEX at 60, 180, and 300 deg/sec were 99 ± 13 and 65 ± 11 , 175 ± 18 and 114 ± 26 , and 170 ± 27 and 113 ± 34 watts, respectively. The mean \pm SD slope of ID ENDUR for EXT and FLEX at 180 and 300 deg/sec were -12 ± 7 and -8 ± 7 and -16 ± 5 and -11 ± 9 , respectively. The mean \pm SD MIP and SMIP were 88 ± 23 cm H₂O and 420 ± 132 PTU, respectively. Significant negative correlations were observed between MIP and slope of ID ENDUR for EXT at 180 and 300 deg/sec ($r = -.61$ and $-.58$, respectively; $p < 0.05$). Significant positive correlations were observed between SMIP and peak torque of EXT and FLEX at 60 deg/sec ($r = .51$ and $.55$, respectively; $p < 0.05$) and SMIP was significantly correlated in a positive direction to mean power of EXT and FLEX at 180 and 300 deg/sec ($r = .59$ and $.70$ and $r = .71$ and $.68$; $p < 0.05$, respectively). **CONCLUSIONS:** The significant positive relationships of SMIP to knee EXT and FLEX power at 180 and 300 deg/sec highlights the role that greater IMP appears to have in the development of greater power for both knee EXT and FLEX. SST appear to elicit similar adaptations in the PSM and IM highlighting the specificity of exercise especially as it relates to soccer.

Starters and Non-Starters Require Separate Load Monitoring and Analyses Throughout a Collegiate Soccer Season

Ryan M. Curtis, Robert A. Huggins, William M. Adams, Abigail C. Colburn, Garrett J. Fontaine, Andrea R. Fortunati, David P. Looney, Chris A. West, Douglas J. Casa, FACSM. University of Connecticut, Storrs, CT.
 Email: ryan.curtis@uconn.edu
 (No relationships reported)

Measures of internal and external load are used to quantify training volume and stress in athletes, however, differences in loads experienced between starters and non-starters is not well quantified in collegiate soccer. **PURPOSE:** To compare differences in measures of load between starters (S) and non-starters (NS) throughout a collegiate soccer season. **METHODS:** Twenty NCAA Division I male soccer players (mean \pm SD; age 20 ± 1 yrs, height 181 ± 6 cm, body mass 77.9 ± 6.2 kg, BF% $11.9 \pm 2.4\%$, $\text{VO}_{2\text{max}}$ $52.9 \pm 6.1 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) were monitored over specific intervals aligning with major time periods throughout the season; preseason to week 1 (PS-W1), W1-W4, W4-W8 and W8-W12. Mean session time (ST), PlayerLoad (PL), distance (DST), max velocity (Vel_{max}), velocity load (VL), heart rate (HR), time spent $>95\%$ HR ($\text{HR}>95\%$), and sprint efforts (SP_{E}) were recorded daily with GPS units. Players were placed into groups, S ($n=10$) and NS ($n=10$) based on total playing time in matches. A group \times time repeated measures ANOVA with Tukey-HSD post hoc test was used to assess differences between S and NS ($\alpha, p < 0.05$). **RESULTS:** Significant group by time interactions were found for ST ($F_{3,27}=5.398, p=0.005$), DST ($F_{3,27}=4.607, p=0.010$), PL ($F_{3,27}=3.183, p=0.050$), Vel_{max} ($F_{3,27}=8.918, p=0.001$), VL ($F_{3,27}=7.257, p=0.001$), $\text{HR}>95\%$ ($F_{3,27}=5.296, p=0.005$), and SP_{E} ($F_{3,27}=7.137, p=0.001$). Independent of group, ST was longer during PS-W1 (Mean \pm SE; 100 ± 9.7 min) than W1-4 (82.9 ± 1.4 min, $p=0.001$), W4-8 (81.8 ± 1.0 min, $p=0.001$), and W8-12 (76.5 ± 1.3 min, $p=0.001$). Furthermore, $\text{PL}\cdot\text{min}^{-1}$ was higher during W4-8 (7.19 ± 0.27 AU, $p=0.001$) and W8-12 (7.18 ± 0.18 AU, $p=0.001$) than PS-W1 (5.85 ± 0.26 AU). Vel_{max} was lower W1-4 ($6.56 \pm 0.10 \text{ m}\cdot\text{s}^{-1}$) and W8-12 ($5.90 \pm 0.20 \text{ m}\cdot\text{s}^{-1}$) than PS-W1 ($7.06 \pm 0.12 \text{ m}\cdot\text{s}^{-1}$, $p=0.025$, $p=0.006$). HR was elevated W4-8 (145 ± 2 bpm) than PS-W1 (135 ± 2 bpm, $p=0.004$) and W1-W4 (133 ± 2 bpm, $p=0.001$). **CONCLUSION:** Measures of load differed between various time intervals throughout the competitive soccer season, independent of match playing time, however significant differences between S and NS were present. These data suggest that load measures be analyzed separately for S and NS throughout the season due to influences of match play. This is particularly relevant when monitoring, periodizing, and prescribing training loads.

Comparison between Anthropometry and Bioelectrical Impedance in Estimating Fat and Muscle Masses in Soccer Players

Enrique O. Prada, Aldo F. Longo, Néstor A. Lentini, Marcelo L. Cardey, Gustavo D. Aquilino, Esteban R. Francia. *CeNARD, Buenos Aires, Argentina.*
 Email: cardiologia@deportes.gov.ar
 (No relationships reported)

Anthropometry-based models are broadly used to indirectly estimate body fat and muscle masses. Bioelectrical impedance analysis is an advanced method for indirect measurement of the main components of body composition. **PURPOSE:** This study intended to evaluate agreement in assessing body fat and muscle masses in soccer players between an anthropometry-based model and the bioelectrical impedance analysis.

METHODS: Data from 46 male competitive soccer players were analyzed (Age = 25.6 ± 3.5 yr, Body mass = 75.8 ± 6.7 kg, BMI = 24.9 ± 1.6 kg·m⁻²; mean \pm SD). The anthropometry-based estimations of fat and muscle masses were obtained by means of the four-compartment model of De Rose and Guimaraes (1980) (DRG). This model was modified using the regression equation of Withers *et al.* (1987, cited by Norton, 1996) to estimate body density, and Siri formula (1961) to compute the percentage of body fat. Fat and muscle masses were also assessed by means of bioelectrical impedance analysis (BIA). The paired *t*-test was used to evaluate the differences between the two measurement techniques. The Bland-Altman approach was applied to estimate 95% limits of agreement. The statistical significance level was set at $p < 0.05$.

RESULTS: Significant differences were observed in fat and muscle masses between DRG and BIA (respectively: 8.71 kg vs. 10.13 kg, $p < 0.001$; and 36.80 kg vs. 37.85 kg, $p < 0.001$). The 95% limits of agreement were from -5.13 kg to 2.29 kg for fat mass, and from -4.67 kg to 2.58 kg for muscle mass. On a percentage scale, the results were as follows: 11.36 % vs. 13.16 % ($p < 0.001$) for fat mass, and 48.63 % vs. 50.04 % ($p < 0.001$) for muscle mass; the 95% limits of agreement were, respectively, from -6.80 % to 3.20 %, and from -5.97 % to 3.16 %. The difference between methods revealed negligible to low sample correlations with the range of measurement for the two variables, both in absolute and percentage scales.

CONCLUSIONS: The anthropometry-based model on average underestimated the fat and muscle masses compared to BIA, in both cases in a quantity less than 1.5 kg (and less than 2 %). The bias between the methods had a harmful effect on the limits of agreement. Additional testing would be necessary to confirm these results.

2084 Board #97 June 1 3:30 PM - 5:00 PM
FIFA 11+ Warm-up: Effects On Movement Control And Performance In Young Female Soccer Athletes

Joanne L. Parsons¹, Haley Stenberg², Joanne Carswell².
¹University of Manitoba, Winnipeg, MB, Canada. ²Vista Place Physiotherapy and Sports Injury Centre, Winnipeg, MB, Canada.
 (No relationships reported)

In an effort to reduce soccer injury rates, the Fédération Internationale de Football Association (FIFA) developed the 11+ warm-up. Widespread uptake of this program remains a challenge despite its effectiveness, but may be increased if positive impacts on physical performance as well as injury risk factors such as neuromuscular control are shown. Effects of the program on physical performance measures and movement control have not been investigated in young female soccer athletes. **PURPOSE:** To determine the effect of the FIFA 11+ program, compared to a standard warm-up, on movement control, agility, vertical jump (VJ), and core stability in young female athletes after a 5 month indoor soccer season.

METHODS: Forty-seven girls from the U10 and U11 divisions of a developmental soccer club were randomized by team to the intervention group (IG) or the control group (CG). IG teams were taught the 11+ warm-up, consisting of 15 exercises broken into 3 sections: 1) slower running drills, 2) strength and plyometric exercises, and 3) faster sprints. The CG continued with their previously planned warm-up. Teams practiced and played 2-3x/week. Blinded assessors conducted pre- and post-season testing of movement control (Landing Error Scoring System), and physical performance (T-test, VJ, and static plank). Two-way Repeated Measures ANOVA analyses were used to compare movement control and physical performance of the groups over time. **RESULTS:** The IG demonstrated a significantly greater increase in static plank hold time compared to the CG (26.1 ± 38.5 vs. 2.1 ± 37.1 seconds, $p = .047$). All athletes, regardless of group, improved their LESS score (pre- 6.8 ± 1.6 ; post-season 6.2 ± 1.4 , $p = .005$) and agility T-test time (pre- 14.2 ± 1.2 ; post-season 13.8 ± 1.0 seconds, $p = .001$). No differences were found for the VJ.

CONCLUSIONS: The 11+ program, performed over a 5 month indoor soccer season by 9-11 year old soccer players, resulted in improved core stability compared to a regular warm-up, but this did not translate into a significantly greater change in LESS score in the IG. The 11+ program may not be more effective than other dynamic warm-ups at improving neuromuscular control and agility. However, time and space limitations inherent in the indoor soccer environment may have negatively impacted the program's ability to reach its full potential.

Implication Of Dynamic Balance In Change Of Direction Performance In Young Elite Soccer Players Is Angle Dependent?

Monoem Haddad¹, Mehdi Rouissi², Nicola Luigi Bragazzi³, Adam L. Owen⁴, Mokhtar Chtara², Karim Chamari⁵. ¹Qatar University, Doha, Qatar. ²High Institute of Sport and Physical Education, Ksar Said, Tunis, Tunisia., Tunis, Tunisia. ³School of Public Health, Department of Health Sciences (DISSAL), University of Genoa, Genoa 16132, Italy., Genoa, Italy. ⁴Servette Centre for Football Research (SCFR), Servette Football Club, Geneva, Switzerland., Geneva, Switzerland. ⁵Athlete Health and Performance Research Centre, ASPETAR, Qatar Orthopaedic and Sports Medicine Hospital, Doha, Qatar., Doha, Qatar.
 Email: mhaddad@qu.edu.qa
 (No relationships reported)

PURPOSE: Team sports require rapid whole body change of direction (COD) in order to regain, maintain possession of the ball or to avoid opponent. These actions are often performed through unilateral process, with the contralateral leg incurring no ground contact. As a result, maintaining unilateral dynamic balance remains important. The aim of this study was to examine the relationship between dynamic balance (DB) and COD performance in young elite soccer players.

METHODS: 20 right-footed young elite soccer players (age= 16.42 ± 0.55 year, height= 176 ± 2.5 cm; leg length= 95.70 ± 3.34 cm, body-mass= 67.03 ± 5.20 kg) participated in this study. All players performed star excursion balance test (SEBT) with dominant (DL) and nondominant leg (NDL). 10m sprint with COD of 45°, 90°, 135° or 180° after 5m were also assessed with COD on both right and left sides.

RESULTS: Correlations analysis showed significant negative relationships between COD tests (with DL and NDL) and SEBT. Stepwise multiple regression analysis showed that DB performance explained between 20% and 75% of the variance of COD tests. Likewise, dynamic balance contribution was dependent upon the angle of COD and the leg used to turn.

CONCLUSIONS: Dynamic stability performance was significantly correlated with COD's performance in young elite soccer players which, possibly due to similarities in movement demands and muscle recruitment. Furthermore, the contribution of dynamic balance on COD performance was angle dependent. Individualized specific dynamic stability exercises may be required to compensate players' deficit in each COD angle.

2086 Board #99 June 1 3:30 PM - 5:00 PM
Relationship Between Physiological Load, Body Composition, And Performance Across Season In Female Soccer Athletes

Angela S. Bruzina, Abigail Peairs, Robert Mangine, Kimberly Hasselfeld, John P. Detherage, III. University of Cincinnati, Cincinnati, OH. (Sponsor: Jon Divine, FACSM)
 (No relationships reported)

Body composition has been widely recognized as one of the many factors that could affect performance in the collegiate athlete, including body fat percentage and its changes across the competitive season. Zephyr Performance Systems have been used as a tool to measure physiological load in competitive athletes. Changes in body composition and fitness measures have been reported in female soccer athletes, but few have examined the relationship between them across the season, and their potential effect on post-season fitness measures. **PURPOSE:** The purpose of this study was to determine the relationship between physiological load and body composition across the season on the post-season performance of the Yo-Yo Intermittent Recovery Test 2 in Division I Female Soccer Athletes.

METHODS: Thirty female soccer athletes, age (19.4 ± 1 year) with pre-season body fat percentage ($22.7 \pm 5.3\%$), participated in the Yo-Yo Intermittent Recovery Test 2 (YYIR2) prior to their fall pre-season conditioning period. Body fat percentage was assessed pre and post-season using BodPod assessment. Zephyr Performance Systems were worn during home season games to quantify and record the athletes' physiological load, which was averaged over the season (AVEPL). Athletes completed a second YYIR2 at the conclusion of their post-season play and the change in the distance covered on this assessment from pre to post-season was recorded (ChangeDist).

RESULTS: No differences were observed in YYIR2 or body fat percentage between pre and post-season. However, AVEPL was negatively correlated with pre to post-season change in distance covered (ChangeDist), $r = -0.489$, $p = 0.040$. Linear regression analysis also revealed ChangeDist was inversely related to AVEPL ($\beta = -0.448$, $p = 0.048$). When adjusted for age and pre to post-season change in body fat percentage (ChangeBF), AVEPL remained inversely related to ChangeDist ($\beta = -0.446$, $p = 0.037$).

CONCLUSIONS: Athletes with higher average physiological load across the season exhibited a decrease in performance on the post-season Yo-Yo Intermittent Recovery Test 2 when compared to pre-season, regardless of change in body fat percentage.

Further research should be done to determine whether these results are due to a true decline in fitness levels or a decline in motivation to perform on the post-season assessment.

2087 Board #100 June 1 3:30 PM - 5:00 PM
The Effect of a Concurrent Strength and Conditioning Program in Female Soccer Players

Lauren Adlof, Ludmila Cosio-Lima. *University of West Florida, Pensacola, FL.*

(No relationships reported)

BACKGROUND: Due to the high metabolic and physical demands involved in soccer, an optimal strength and conditioning program for female high school soccer players essential. The benefits of resistance training and high intensity interval training in young athletes has been well documented; however, the effect of a concurrent strength and metabolic conditioning program on female athletes in specific sports has yet to be investigated. **PURPOSE:** To examine the effects of an 8-week concurrent strength and metabolic conditioning program on body composition, flexibility, speed, agility, anaerobic capacity, strength, and power in female soccer players. **METHODS:** Body composition and performance testing measures were recorded in female soccer players ($n = 14$, age = 16 ± 1.0 yrs) before and after an 8-week sports performance camp that combined concurrent high intensity interval training methods and periodized resistance training. Performance testing included 3-site skinfolds, sit and reach, pro agility test, 40yd sprint, 300yd shuttle run, and vertical jump. Strength testing included a 5-repetition maximum back squat, shoulder press, and bench press, and a 3-repetition maximum power clean. Comparisons were made using a paired samples t-test, and Pearson's correlations between variables were calculated. **RESULTS:** Significant improvements were made in vertical jump ($p < 0.05$), pro agility test ($p < 0.05$), 40yd sprint ($p < 0.05$), squat ($p < 0.05$), shoulder press ($p < 0.05$), bench press ($p < 0.05$), and power clean ($p < 0.05$). There were significant correlations between increases in power with agility and speed, as well as correlations between power and strength. **CONCLUSION:** An 8-week concurrent strength and conditioning program was effective for improving measures of fitness and performance in female soccer players. Overall, power and strength increased, as well as a significant decrease in time to complete the agility and speed testing.

Physiological Performance Measures in Female Collegiate Soccer Players

John C. Young, FACSM, James W. Navalta, FACSM, Tori M. Stone, Jeffrey Montes. *University of Nevada, Las Vegas, Las Vegas, NV.*

(No relationships reported)

Although participation in women's soccer has increased dramatically in the last two decades, the research into the physiological demands and physical characteristics of players is limited.

PURPOSE: To compare anaerobic and aerobic power in female intercollegiate soccer players with a reference group of elite international players.

METHODS: Subjects were 28 members of a division I university women's soccer team. Maximal aerobic power (VO_{2max}) was determined during an incremental treadmill run using a MOXUS metabolic measurement system. The Margaria-Kalamara power test was timed using switch mats to determine anaerobic power. Bone mineral density and percent body fat were determined by dual-energy X-ray absorptiometry (DEXA). Anaerobic power comparisons were made by converting literature values for vertical jump heights to watts by the Lewis formula.

RESULTS: VO_{2max} was similar between the collegiate players and the reference group of international players (52.7 ± 5.8 vs 51.5 ± 3.3 ml/kg/min for collegiate and reference players respectively). Similarly, anaerobic power was not different between the collegiate and the international players (841.2 ± 112.4 vs 808.8 ± 109.5 watts). Height (165 ± 6 vs 169 ± 2 cm) and mass (61 ± 7 vs 61 ± 2) were similar between the two groups; however the collegiate players had a higher percent body fat than the reference players (25.9 ± 5.2 vs 17.5 ± 2.6 %).

CONCLUSION: These results suggest that the female collegiate players have aerobic and anaerobic power comparable to that reported for international (primarily European) elite female soccer players. Although the collegiate players were of similar height and body mass as the international players, the collegians had considerably higher percent body fat.

Effect of Ages and Jump Types on Lower Limb Explosiveness in Elite Female Soccer Players

Frantisek Zahalka¹, Tomas Maly¹, Dai Sugimoto², Lucia Mala¹.
¹Charles University, FPES, Prague, Czech Republic. ²-Boston Children's Hospital, 3-The Micheli Center for Sports Injury Prevention, 2-Boston, 3-Waltham, MA.

Email: zahalka@ftvs.cuni.cz

(No relationships reported)

BACKGROUND: Explosiveness of lower limbs is an important skill as to be a quality soccer player. A few studies have been performed to investigate explosiveness using male soccer players; however, it is not well studied in females, especially during their growth process and different jump types.

PURPOSE: To compare explosiveness of lower limbs in three different age categories of national level female soccer players in three types of jumps.

METHODS: A total of 49 female national level soccer players of three age categories (U15 = players under 15 years $N = 17$, U17 = players under 17 years $N = 16$, U19 = players under 19 years $N = 16$) were tested using a two force platforms in three types of jumps: countermovement jump free arms (CMJFA), countermovement jump (CMJ), squat jump (SJ). The following parameters were evaluated: jump height (JH), maximum take-off force (F_{max}) and force difference between preferred and non-preferred leg (F_{diff}). All parameters were processed using MANOVA and Bonferroni post-hoc test, effect size (η^2).

RESULTS: Players achieved the following values: (U15: CMJFA = 32.58 ± 3.25 cm, CMJ = 28.19 ± 3.81 cm, SJ = 25.38 ± 3.33 cm, U17: CMJFA = 34.26 ± 4.22 cm, CMJ = 29.64 ± 3.34 cm, SJ = 28.05 ± 3.19 cm, U19: CMJFA = 37.20 ± 5.80 cm, CMJ = 31.89 ± 5.47 cm, SJ = 29.98 ± 5.17). Bonferroni's post hoc test revealed significant differences in explosiveness between U15 and U17 as well as U15 and U19 ($p < 0.05$). The MANOVA analysis revealed a significant age effect on JH ($F_{2,147} = 12.61$; $p < 0.01$, $\eta^2 = 0.16$) and F_{max} ($F_{2,147} = 4.19$; $p < 0.05$, $\eta^2 = 0.06$). Also, significant effect was detected by different type of jump on JH ($F_{2,147} = 33.28$; $p < 0.01$, $\eta^2 = 0.33$) and F_{max} ($F_{2,147} = 24.2$; $p < 0.01$, $\eta^2 = 0.26$). We also found significant effect of jump types on F_{diff} ($F_{2,147} = 6.49$; $p < 0.01$, $\eta^2 = 0.09$). Players achieved significantly higher F_{diff} in CMJ = 9.59 ± 6.79 % compare to SJ = 5.56 ± 3.89 cm ($p < 0.01$). Thirteen players (26.5 %) had a F_{diff} higher than 10% during take-off.

CONCLUSION: Explosiveness is different by ages in youth elite female soccer players. Jump types influence jump height and maximum take-off force as well as force difference between preferred and non-preferred leg. The study revealed significant differences F_{diff} with respect to the type of jump. More than 25% of female soccer players had F_{diff} greater than 10%.

The Lower Extremity Strength, Bilateral And Ipsilateral Strength Asymmetries In Elite Female Soccer Players

Tomas Maly¹, Frantisek Zahalka¹, Dai Sugimoto², Lucia Mala¹.
¹Charles University, FPES, Prague, Czech Republic. ²-Boston Children's Hospital, 3-The Micheli Center for Sports Injury Prevention, 2-Boston, 3-Waltham, MA.

Email: maly@ftvs.cuni.cz

(No relationships reported)

BACKGROUND

Soccer frequently involves one-sided activities such as kicking, tackling and passing, which may lead to strength asymmetries (SA), and effect of the age is not well studied.

PURPOSE

The aim was to investigate effect of limb-dominance and ages through relative strength measures of knee extensors (KE), knee flexors (KF), bilateral strength ratio (QQ, HH), and ipsilateral strength ratio (HQ) in youth elite female soccer players.

METHODS

National level female soccer players of three age categories (Under 16 years =17, Under 17 years =16, Under 18 years =16 players) performed isokinetic strength testing for KE, KF at three velocities (60, 180, 300 °.s⁻¹) for the dominant (DL) and non-dominant leg (NL). Mean peak torque of extensors (PTE) and flexors (PTF) values were calculated in Newton-meters relatively to body weight (N-m.kg⁻¹) and strength ratios were derived from peak torques. Three-way Mixed-design ANOVA with two between subject effect (age, limb dominance) and one within subject effect (angular velocity) were used. Bonferroni's *post-hoc* test was employed due to the multiple comparisons. Effect size was assessed using the η_p^2 coefficient.

RESULTS

Significant age effect was observed in PTE and PTF (PTE: $F_{2,91} = 4.60$, $p = 0.013$, $\eta_p^2 = 0.09$, PTF: $F_{2,91} = 11.31$, $p = 0.001$, $\eta_p^2 = 0.20$). Conversely, age did not indicate significantly effect on bilateral strength ratio (QQ, HH) ($F_{2,91} = 2.00$, $p = 0.141$, $\eta^2 = 0.04$) a HQ (HQ: $F_{2,90} = 1.03$, $p = 0.361$, $\eta^2 = 0.02$). Significant limb dominance effect was not identified in PTE, PTF and HQ (PTE: $F_{1,91} = 0.06$, $p = 0.810$, $\eta^2 = 0.01$, PTF: $F_{2,91} = 0.30$, $p = 0.587$, $\eta_p^2 = 0.00$, HQ: $F_{2,91} = 3.50$, $p = 0.065$, $\eta^2 = 0.04$). We found significantly higher strength asymmetries in KF compare to KF ($F_{1,91} = 15.89$, $p =$

0.000, $\eta^2=0.15$). Post-hoc analysis showed a significant difference in PTE between U15 vs. U19 and in PTF between U16 vs. older age category (U17, U19). The higher bilateral strength differences ($QQ > 10\%$) we found in following age categories (U16 = 53%, U17 = 50%, U19 = 56%). Moreover in knee flexors ($HQ > 10\%$) were even higher strength asymmetries (U16 = 71%, U17 = 75%, U19 = 79%).

CONCLUSIONS

The current results indicated effect of age on PTE, PTF but not in limb dominance. More attention should be paid to knee flexors where higher occurrence of strength asymmetries were found.

Multicomponent Training Distress Scale (MTDS) Questionnaire to Detect Training Distress in Collegiate Soccer Players
 Ifeoma C. Agwuenu, Haylee A. Bettencourt, Megan Darling, J Mark VanNess, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
 Email: i_agwuenu@u.pacific.edu
 (No relationships reported)

It may be helpful for coaches and trainers to understand risk factors that predict training distress in collegiate athletes. Recognizing who is at risk can assist in the detection of early symptoms so that training adjustments can be made and overtraining avoided. Subjective measurements of subjects' psychological state can be collected with simple questionnaires and are useful for determining training distress. **PURPOSE:** To utilize the Multicomponent Training Distress Scale (MTDS) questionnaire to examine athletes' mood and physical states for determination of training distress risk. Gender, season duration, and grade in school were considered variables of interest for predicting training distress. **METHODS:** 17 male and 26 female collegiate soccer players were enrolled in the study. The MTDS was administered at four time points throughout the season (at the beginning, twice during the season, and once during post-season play). Questionnaires were given to all athletes at the end of their training sessions. Multivariate analyses were performed with the dependent variables of the MTDS across time, grade in school and gender. Only the composite MTDS score is reported in this abstract. **RESULTS:** The overall multivariate was significant ($p < 0.05$); the main effects for gender, time, and year in school were also significant ($p < 0.05$). Overall, female scores were higher than males. Males exhibited less training distress throughout the season while females had increasing scores throughout the season, then declined at the end ($p = 0.042$). Post-hoc analysis for year in school showed that freshman and sophomores had higher training distress scores compared with juniors and seniors ($p = 0.001$). **CONCLUSIONS:** MTDS identified gender and year in school as possible variables that could serve as indicators for risk of training distress. College coaches and trainers should consider applying different training loads to men and women as well as underclassmen and upperclassmen.

2092 Board #105 June 1 3:30 PM - 5:00 PM
Stress and Mood Affect Sleep Quality and Quantity in Collegiate Female Soccer Players
 Tomas Barrett, Gavin Connolly, Shane Connolly, Paul L. O'Connor. *Central Michigan University, MT PLEASANT, MI.*
 Email: barre1t@cmich.edu
 (No relationships reported)

Despite a growing number of studies indicating that reduced sleep duration and quality have a negative influence on recovery and performance in many sports, data regarding the sleep habits of collegiate athletes is lacking. Highlighting factors that have a negative influence on sleep in collegiate athletes could lead to interventions that may increase sleep duration and quality, which could lead to increased performance and reduced injuries. College level athletes balance many physical and mental stressors, in order to be successful as student-athletes, and given the close relationship between mental states and sleep, these stressors may interfere with their sleep. **PURPOSE:** To explore associations between stress, mood, sleep quality, and sleep duration in a college female soccer team across an entire season. **METHODS:** Twenty-one Division I female soccer players (18.9±1.28 years; 167.5±4.91 cm; 63.8±6.9kg) participated in this study. Each participant was asked to record their levels of stress, mood, and sleep quality using a 7-point scale into a smartphone application, every day for an entire competitive season. Stress was rated from -3: Very anxious to 3: Very Calm; mood was rated from -3: Very Unpleasant to 3: Very Pleasant; and Sleep Quality was rated from -3: Very Restless to 3: Very Restful. Subjects were also asked to record the duration of their sleep. Pearson's correlations were conducted to test associations between stress, mood, sleep quality, and sleep quantity. **RESULTS:** There was a positive relationship between mood and sleep quality ($r = -0.230, p < 0.01$), and stress and sleep quality ($r = -0.305, p < 0.01$). There was also a correlation between mood and sleep duration ($r = -0.052, p < 0.05$), and stress and sleep duration ($r = 0.076, p < 0.01$).

CONCLUSIONS: Both sleep quality and sleep duration are negatively affected by increased stress and also by a perceived low mood. Interventions that could help players better manage their stress and elevate their mood could result in increased sleep quality and duration in college soccer players.

 Email: andrea.fortunati3@gmail.com
 (No relationships reported)

Consistent tracking of oxygen transport blood biomarkers may help inform coaching decisions to help reduce risk of overtraining. **PURPOSE:** To characterize changes in oxygen transport markers over the course of a collegiate soccer season. **METHODS:** A panel of 9 biomarkers was assessed in blood samples from 20 NCAA Division I male soccer players (mean ± SD; height 181 ± 6cm, body mass 77.9 ± 6.2kg, BF% 11.9 ± 2.4%, VO_{2max} 52.9 ± 6.1 mL·kg⁻¹·min⁻¹) at 5 time points: before preseason (PS) and during season at week 1 (W1), W4, W8, and W12. Blood specimens from W1-W12 were obtained 32-34 hours post-match. Significant changes in biomarkers over time were assessed via repeated measures ANOVA ($\alpha < 0.05$, Bonferroni post hoc). **RESULTS:** Post season VO_{2max} (53.9±5.3 mL·kg⁻¹·min⁻¹) was similar to PS ($p = 0.064$). Hematocrit (HCT) levels were lower at W1 vs PS (mean±SD, 45±1%, 47±1%, $p = 0.015$). Total iron binding capacity (TIBC) was higher W12 (314±26µg·dL⁻¹) vs PS (339±30µg·dL⁻¹, $p = 0.006$), W1 (315±6µg·dL⁻¹, $p = 0.004$) and W4 (320±7µg·dL⁻¹, $p = 0.005$). TIBC W8 (333±8µg·dL⁻¹) and W12 (339±7µg·dL⁻¹) were higher than W1 (315±6µg·dL⁻¹, $p < 0.048$). Total 25-hydroxy vitamin (VitD) decreased throughout the season. VitD at W12 (31±2ng·mL⁻¹) was lower than PS (39±2ng·mL⁻¹, $p = 0.004$), W1 (36±2ng·mL⁻¹, $p = 0.007$), W4 (35±2ng·mL⁻¹, $p = 0.028$), and W8 (35±2ng·mL⁻¹, $p = 0.007$). Percent saturation, total iron, red blood cells, ferritin, and vitamin D2 did not change significantly over time throughout the season. **CONCLUSION:** Select measures of oxygen carrying capacity (HCT, TIBC) were reduced after PS. However, assessment of the panel in a more inclusive approach determined that there was no consistent evidence of reductions in oxygen carrying capacity. Assessment of VitD as part of a panel assessing oxygen transport capacity is novel, given the putative role of VitD in VO_{2max} . Ongoing research aims to further characterize any relationship of oxygen carrying capacity biomarkers to performance during long training seasons. Funding for this study in part by Quest Diagnostics Inc.

Body Composition Changes In Female Collegiate Soccer Athletes From Preseason To Postseason
 Paul A. Burkett, Shawn D. Felton, Mitchell L. Cordova, FACSM. *Florida Gulf Coast University, Fort Myers, FL.*
 (Sponsor: Mitchell L. Cordova, FACSM)
 (No relationships reported)

Previous studies have suggested that percent body fat (%BF) and lean mass do not change from pre- to postseason in female collegiate soccer athletes even though changes may be seen in athletes competing in other sports. **PURPOSE:** To document changes from pre- to postseason in body mass, %BF, fat distribution, and lean mass in female collegiate soccer athletes using readily available skinfold measures. **METHODS:** Twenty-four healthy female collegiate soccer athletes with a mean age of 19.6 ± 1.2 years participated. Participants were screened pre- and postseason using standard anthropometric measurements that included: height, weight, and skinfold measure of the triceps, suprailiac, and thigh areas. The measurements were conducted by an exercise physiologist with 25 years of experience and the skinfold technique was selected for collection convenience. The measurements allowed for calculation of the BMI, lean body mass, lean body mass index (LBMI), and %BF, and for comparison from pre- to postseason. The individual skinfold sites were also compared from pre- to postseason. **RESULTS:** There were no differences between the measurements obtained on the two testing dates for body mass (62.18 & 62.26 kg; $t = -2.29$; $p \geq 0.05$), BMI (22.07 & 22.35; $t = -1.96$; $p \geq 0.05$), lean body mass (46.94 & 46.57 kg; $t = 1.65$; $p \geq 0.05$), LBMI (16.75 & 16.62; $t = 1.44$; $p \geq 0.05$), and %BF (24.38 & 25.25; $t = -1.79$; $p \geq 0.05$). There were differences in skinfold thickness at the triceps (19.5 & 20.5 mm; $t = -2.102$; $p < 0.05$) and suprailiac (15.98 & 17.70 mm; $t = -2.57$; $p < 0.05$) assessment sites. The covariate of field position was not a significant factor in the changes noted in triceps [$F(1,22) = 0.55$ $p = 0.47$] and suprailiac [$F(1,22) = 0.55$ $p = 0.47$] thickness.

CONCLUSION: These results suggest that female collegiate soccer athletes did not experience changes in %BF or lean mass from pre- to postseason. However, there may be small increases in fat accumulation at specific sites. Monitoring of individual athletes for these types of changes might also be important.

2095 Board #108 June 1 3:30 PM - 5:00 PM
Heart Rate and Energy Expenditure in Division I College Soccer Players during a Competitive Season
 Shane F. O'Riordan, Gavin Connolly, Tomas Barrett, Emmi Lawless, Marina Hartmann, Mikaela Gabler, Paul L. O'Connor. *Central Michigan University, Mount Pleasant, MI.*
 Email: orior1s@cmich.edu
 (No relationships reported)

PURPOSE: The use of monitoring systems (e.g. Global Positioning Systems (GPS), heart rate monitors) to determine metabolic and physiological requirements within different sports is increasing in popularity. However, little to no information exists on the metabolic and physiological needs during Division I women's soccer. The purpose of this project was to measure heart rate data and energy expenditure in Division I college soccer players during the regular competitive season. **METHODS:** 12 college female soccer players (19.3 ± 1.6 yrs, 167 ± 3.0 cm, 62.4 ± 4.9 kg) were included based on playing time criteria (>60%). Measures recorded for all players included average heart rate (AvHR), average heart rate percentage (AvHR%), peak exercise heart rate (HR_{peak}), percentage of time spent in predetermined zones (%TM1, %TM2, %TM3) and energy expenditure per kilogram (EE). Differences between positions, center backs (CB), full backs (FB), midfielders (MF) and forwards (FW), were assessed.

RESULTS: Significant differences (p≤0.05) were observed across positions for parameters measured. AvHR for CB and MF was significantly lower than FW (168.9 ± 5.8 vs. 179.6 ± 6.9 bpm, 172.7 ± 7.8 vs. 179.6 ± 6.9 bpm). CB AvHRs were also significantly lower than FB (168.9 ± 5.8 vs. 177.3 ± 5.9 bpm). MF HR_{peak} was significantly lower than all groups. CB HR_{peak} was also significantly lower than FW (195.5 ± 3.6 vs. 200.2 ± 5.0 bpm). AvHR% was significantly lower and %TM1 was significantly higher for CB compared to all groups. For %TM2, MF were significantly higher than CB (81.7 ± 12.7 vs. 68.7 ± 20.0%) and FW (81.7 ± 12.7 vs. 68.3 ± 16.0%). FW were significantly higher than MF for %TM3 (27.7 ± 17.4 vs. 11.1 ± 14.3%). EE was significantly higher for MF compared to all groups.

CONCLUSIONS: Results identified positional differences for metabolic and physiological needs during competitive DI college soccer. This information could contribute to the understanding of the game and implementing specific training regimens.

Workload-related Psychological And Physiological Changes In Female College Soccer Players During A Competitive Season
 Bridget A. McFadden, Alan J. Walker, David J. Sanders, Morgan Hofacker, Marissa Bello, Anthony Poysick, Nicholas Mackowski, Christopher Ordway, Brittany Bozzini, Shawn M. Arent, FACSM. *Rutgers University, New Brunswick, NJ.*
 (No relationships reported)

Adequate recovery from stressors is an essential aspect of an athletes training program. Insufficient recovery can present itself in the form of psychological and physiological changes that manifest as performance decrements. **Purpose:** To assess the influence of training demands on mood, sleep, biomarkers, and performance in D1 collegiate female athletes during a competitive season. **Methods:** Female D1 college soccer players (N=25; M_{age}=19.4 ± 1.4 yrs; M_{weight}=66.1 ± 1.3 kg) participated in blood draws prior to pre-season (T1), and at weeks 2 (T2), 6 (T3) and 10 (T4) of the regular season. Athletes arrived for blood draws fasted and euhydrated. T2, T3, and T4 draws occurred ~18 hours after a game. Creatine Kinase (CK), Free Cortisol (CF), Total Testosterone (TT), Estrogen (E), and Growth Hormone (GH) were analyzed. The Multi-Component Training Distress Scale (MTDS; Main & Grove, 2009), the Pittsburgh Sleep Questionnaire Index (PSQI; Buysse et al., 1989), and vertical jump (VJ) were also assessed at each time-point. Workload per session (km and kcal/kg) was monitored using the Polar Pro system. **Results:** Workload was at its highest from T1-T2, decreased from T2 to T3 (Akm=-36.9 ± 2.0 km, P<.05; Δ kcal=-7903.9±436.2 kcal, P<.05), and remained stable through T4. VJ remained consistent from T1-T3, before beginning to modestly decline (ΔVJ=-0.87 ± 0.59 cm) at T4. CK increased from T1-T2 (ΔCK=206.2 ± 94.1 U/L, P<.05), then returned to baseline. CF increased from T1-T2 (ΔCF=0.32±0.1 mg/dL, P<.05) and returned to baseline by T4. TT increased from T1 to T2 (Δ TT=39.5±17.3 ng/dL, P<.05) and returned to baseline by T4. No differences in E were seen (P>.05). GH decreased from T1-T2 (ΔGH=2.1±0.8 ng/mL, P<.05) and remained depressed. Total mood disturbance increased from T2-T3 (ΔMood=6.4 ± 1.9, P<.05) and remained elevated. Sleep quality (SQ) did not change from T1-T4 (P>.05), but sleep duration (SD) increased from T3-T4 (ΔSD=0.4±0.1, P<.05). **Conclusion:**

Biomarkers showed the greatest change following the period of highest workload. Mood disturbances occurred after observed biomarker changes despite increased SD. SQ may be more important for full recovery than SD, as increased SD did not mirror GH or VJ changes. Changes in biomarkers preceded decrements in mood, suggesting that they may be the earlier indicators of performance status.

2097 Board #110 June 1 3:30 PM - 5:00 PM
Range Of Motion In Lower Limbs: Comparison Between Dominant And Non-dominant Side In Young Soccer Players
 Sandra L. Prieto¹, Juan C. Mazza², Raúl R. Festa², Patricia Cosolito². ¹*Colombia State University, Bogotá, Colombia.* ²*Rosario Central Athletic Club, Rosario, Argentina.*
 Email: sanlipri@hotmail.com
 (No relationships reported)

BACKGROUND: The mechanics of sports abilities in professional soccer development requires extensive bilateral joint control of the lower limbs. The differences in the range of motion (ROM) from side to side in the lower limbs could imply a risk of musculoskeletal injury, especially for young athletes who are still during growing period. **PURPOSE:** The purpose of this study was to describe the range of motion and muscle length of the lower limbs, and to identify side to side differences, in young soccer players who belong to Rosario Central soccer club, Argentina. **METHODS:** Twenty young and healthy males soccer players participated in a cross-sectional cohort study (age: 14.18 ± 0.61 yr; weight: 58.74 ± 6.73 kg; height: 170.38 ± 6.20 cm). We included asymptomatic subjects, with no history of lumbar spine, hip, knee or ankle injuries. Three tests were performed for the active range of movement (hip flexion and extension, and knee flexion), and three tests for muscle length (iliopsoas, rectus femoris and hamstrings). Mean and standard deviation (SD) values were calculated by dominant and non-dominant leg, for all ROM measurements. We applied paired t-test differences to determine statistical differences (sd) between dominant and non-dominant leg at p<0.05 level. **RESULTS:** Analyzing ROM we have found sd (p≤ 0.01) for active hip flexion between dominant (111.73 ± 5.72) and non-dominant (108.55 ± 6.97) limb values. No sd were found in ROM for active knee flexion between dominant (138.00 ± 4.03) and non-dominant (138.18 ± 4.67) limb; active hip extension between dominant (17.98 ± 7.11) and non-dominant (16.23 ± 6.69) limb; muscle length for dominant (8.08 ± 4.50) and non-dominant (7.88 ± 4.82) iliopsoas, dominant (133.40 ± 4.84) and non-dominant (131.68 ± 5.87) rectus femoris and dominant (55.28 ± 7.47) and non-dominant (52.53 ± 8.11) hamstrings. **CONCLUSIONS:** Based on the results of the present study, we have found symmetrical ROM and muscle lengths of the lower limbs for young soccer players, with the exception of active hip flexion. In view of these results, it is recommended that professionals who work with this population assess symmetry of mobility, especially of the lower limbs, in order to guide active-passive stretching programs that maintain joint dynamic balance.

The Impact of Two Games in One Weekend on Soccer Performance in DI Female College Athletes
 Gavin Connolly, Shane F. O'Riordan, Thomas Barrett, Emmi Lawless, Paul L. O'Connor. *Central Michigan University, Mount Pleasant, MI.*
 Email: conno1g@cmich.edu
 (No relationships reported)

PURPOSE: Women's college soccer requires athletes to play two games in one weekend. Insufficient recovery due to the close proximity of the games may lead to an increased risk of injury, fatigue and decreased performance. To date, no study has investigated the effects of playing two games within a 48 hour period on measures of performance in women's college soccer. The purpose of this project was to investigate changes in performance parameters from Friday to Sunday games during a competitive playing season. **METHODS:** 12 NCAA Division I female soccer players (19.3 ± 1.6 yrs, 167 ± 3.0 cm, 62.4 ± 4.9 kg) were included based on playing time criteria (>60%). Global positioning system (GPS) data was collected for Friday (Game 1; (G1)) and Sunday (Game 2; (G2)) games over 5 weekends during the competitive season. Total distance (TD), high speed distance (HSD; 15.5km-19.9 km/h), sprint distance (SD; >20 km/h), meters per minute (m/min), high speed distance per minute (HSD/min), sprint distance per minute (SD/min), percentage HSD (%HSD), percentage SD (%SD), high-intensity efforts/min (HIE/min) and bodyload per minute were analyzed. **RESULTS:** : There was a significant decrease (p<0.05) in m/min from G1 to G2 for weeks 1, 2, 3 and 4. A significant decrease was observed for TD, HSD and HSD/min from G1 to G2 for weeks 1 and 2. There was also a significant decrease in SD and SD/min from G1 to G2 in week 2. SD/min and %SD were significantly greater during G2 compared to G1 in week 5. There were no significant differences between G1 performance parameters across the five weeks.

CONCLUSIONS: There was a significant decrease in a number of performance parameters during the second game when two games were played in one weekend. There were no changes in performances during G1, played one week apart over the five weeks.

Table1. Performance parameters.

	Week 1		Week 2		Week 3		Week 4		Week 5	
	Game		Game		Game		Game		Game

Acute Effects Of Custom Orthotics On Sprint Power And Steady State Cycling

Allan H. Goldfarb, FACSM¹, Alex Ehlert¹, Kerry Martin¹, Michael Rigby². ¹Univ. of North Carolina Greensboro, Greensboro, NC. ²Moses Cone Health, Greensboro, NC. Email: ahgoldfa@uncg.edu
 (No relationships reported)

Orthotic insoles are used to correct foot and knee position for better mechanics of movement and acute orthotic use in runners reported improved economy. However, acute usage of customized orthotics (O) have not been evaluated acutely in competitive cyclists. **PURPOSE:** The purpose of this study was to examine the acute effects of custom insoles on steady-state (SS) cycling physiological variables as well as sprint power output. **METHODS:** Eight competitive cyclists (6 males, 2 females) performed four bouts of cycling at 65-70% VO_{2max} for 10 min (two trials with standard insoles (S) and two with O) in randomized order. SS cycling VO₂, heart rate (HR) and respiratory exchange ratio (RER) were evaluated in minutes 2-7. In addition, peak power was determined to two 6 sec sprints 30 seconds apart at the end of SS bout on a Lode cycle ergometer. A repeated-measures ANOVA with an a priori alpha level of 0.05 was used to compare the differences in O vs S using SPSS. **RESULTS:** Steady state %VO₂ (S=66.70±1.33; O=67.13±1.41) HR bpm (S= 151.6±2.29; O=153.6 ±2.33; RER (S=.91±0.02; O=.90±0.01) with no difference with condition (p = > .6). Peak power was also not significantly different (S= 1109±54.9; O=1115± 47.6 W) in the sprints. **CONCLUSION:** Acute use of custom orthotics did not alter VO₂, HR or RER during steady state cycling nor peak power. It is suggested that follow-up to orthotic usage should be analyzed as it usually takes time (several weeks) to alter the mechanics with orthotic usage.

D-63 Free Communication/Poster - Energy Metabolism and Expenditure

A Study On The Status And Factors Of Energy Deficiency In Japanese Collegiate Rhythmic Gymnasts

ERINA MURAMATSU¹, MIZUKI YAMADA², TAMAKI FURUHATA², KANA HARADA², MIZUHO ADACHI¹, MIKAKO SAKAMAKI-SUNAGA¹, TAKAKO KOSHIMIZU³. ¹Nippon Sport Science University, Tokyo, Japan. ²Graduate School of Health and Sport Science, Nippon Sport Science University, Tokyo, Japan. ³Otsu Women's University, Tokyo, Japan.
 (No relationships reported)

PURPOSE:Energy deficiency affects many physiological aspects. The purpose of this study was to examine the status of energy deficiency in Japanese female collegiate rhythmic gymnasts and the factors that affect energy deficiency. **METHODS:**The subjects were Japanese female collegiate rhythmic gymnasts (RG group: n=7, age : 20.4±1.1yr, height : 159.0±5.9 cm, body weight : 48.6±3.4kg, BMI : 19.3±1.6 kg/m², fat free mass : 37.7±2.9kg, percent body fat : 22.4±2.9%). As a control group, Japanese female collegiate sprint runners (CON group: n=8, age

: 19.4±0.8yr, height : 162.8±5.8cm, body weight : 53.7±6.2kg, BMI : 20.2±1.1 kg/m², fat free mass : 44.8±4.7kg, percent body fat : 15.8±2.5%). The evaluation index of energy deficiency was energy balance (EB), which was calculated by subtracting the total energy expenditure (TEE) from energy intake (EI). TEE was determined by using the double-labeled water method, and the physical activity level (PAL) was TEE divided by resting energy expenditure (REE), which was measured by using a gas analyzer. Physical activity energy expenditure (PAEE) was calculated by subtracting REE plus dietary-induced thermogenesis from the TEE. EI was determined by using self-reported dietary records; and body composition, by using the dual-energy x-ray absorptiometry scan method.

RESULTS:The EB was -2065 ± 598 kcal/day in the RG group and -1230 ± 1003 kcal/day in the CON group. Therefore, both groups had a large negative balance, and the EB in the RG group was lower than that in the CON group. PAL was higher in the RG group (3.2 ± 0.4) than in the CON group (2.5 ± 0.8; p < 0.05). Although the EB in both groups did not correlate with REE, it negatively correlated with PAL and PAEE (p < 0.01). Therefore, high PAL and PAEE can be considered factors of energy deficiency. **CONCLUSION:**Our results indicate that the status of the energy deficiency of the Japanese female collegiate rhythmic gymnasts was severe because the EB in the group was lower than that in the CON group. Furthermore, high PAL and PAEE affected the energy deficiency status of the Japanese female collegiate rhythmic gymnasts.

2101 Board #114 June 1 2:00 PM - 3:30 PM
Cerebral Energy Metabolism And Executive Function After Repeated High-intensity Interval Exercise With Decreased Lactate Concentration

Hayato Tsukamoto¹, Niels D. Olesen², Lonnie G. Petersen², Henrik Sørensen², Henning B. Nielsen², Niels H. Secher², Shigehiko Ogoh, FACSM³, Takeshi Hashimoto, FACSM¹. ¹Ritsumeikan University, Kusatsu, Shiga, Japan. ²The Copenhagen Muscle Research Centre, Copenhagen, Denmark. ³Toyo University, Kawagoe, Saitama, Japan. (Sponsor: Takeshi Hashimoto, FACSM)
 Email: gr0168ir@ed.ritsumei.ac.jp
 (No relationships reported)

PURPOSE: We previously found that cognitive function was not impaired during prolonged exercise, despite a conflict between an increase in cerebral metabolism and a decrease in cerebral blood flow (CBF), and suggested that improved cognitive function during exercise may be due to the augmented cerebral neuronal activation and metabolism associated with exercise, rather than cerebral perfusion. On the other hand, previous studies have demonstrated that during heavy exercise, compensatory increases in the uptake (the difference between arterial and venous concentration) of lactate, glucose and oxygen support elevated brain neuronal activity and metabolism. The purpose of this study was to examine the relationship between cerebral metabolism (e.g., lactate, glucose, oxygen) and executive function (EF) to a repeated high-intensity interval exercise (HIIE), which decreases systemic lactate concentration and post-exercise EF in a later HIIE session. **METHODS:** 14 healthy male subjects performed two HIIE protocols (4 sets of high-intensity exercise for 4-min with 3-min active recovery) separated by a 60 min resting period. Blood samples were obtained from the bulb of the right internal jugular vein and a brachial artery to determine concentration differences (a-v diff) for lactate, glucose, and oxygen across the brain. Transcranial Doppler determined middle cerebral artery blood flow velocity (MCA V_{mean}) as an index of regional CBF. Cerebral metabolic rates of lactate (CMR_{lactate}), glucose (CMR_{glucose}), and oxygen (CMRO₂) were calculated as MCA V_{mean} × a-v diff, respectively. To evaluate EF, color-word Stroop tasks were performed. **RESULTS:** Post-exercise EF improvement, a-v diff_{lactate}, and CMR_{lactate} analyses showed a significant main effect for condition (P < 0.05, respectively), indicating that both EF improvement and brain lactate uptake were attenuated after 2nd HIIE compared to 1st HIIE. While a-v diff_{glucose}, CMR_{glucose}, and a-v diff_{oxygen} were no significant main effects for condition, chronological reduction in a-v diff_{lactate} and EF after HIIE were associated with decrease in CMRO₂ (P < 0.05, respectively). **CONCLUSION:** These results suggest that the reduction in brain lactate uptake concomitant with the decrease in CMRO₂ after repeated HIIE might be involved in the decline in EF improvement.

Accuracy of Indirect Calorimetry and Predictive Equations for the Measurement of Resting Metabolic Rate

Lucas K. Shrum, Karl G. Keczemethy, Jeremy T. Barnes, Thomas J. Pujol, FACSM, Jason D. Wagganer. *Southeast Missouri State University, Cape Girardeau, MO.* (Sponsor: Thomas Joe Pujol, FACSM)
 Email: lkshrum2s@semo.edu
 (No relationships reported)

Indirect calorimetry is used to measure oxygen consumption for the purpose of accurately estimating resting metabolic rate (RMR). Laboratory devices are available for the measurement of RMR, such as the BodyGem® indirect calorimeter and the Vacumed VO₂ Lab metabolic measuring system. Established prediction equations, such as the Mifflin-St. Jeor (MSJ), Harris-Benedict (HB), and Fleisch, can also be used to provide an estimate of RMR.

PURPOSE: The purpose of this study was to compare the RMR of college-aged participants measured using a BodyGem® indirect calorimeter, a Vacumed VO₂ Lab metabolic cart, and the aforementioned prediction equations.

METHODS: Each participant (male = 15; female = 15; age = 22.7 ± 3.3 yrs; wt = 77.5 ± 14.5 kg; ht = 173.5 ± 9.6 cm) completed a thirty-minute supine resting session in a quiet environment. Five minutes of resting data were then collected using the Vacumed while in the supine position. Immediately thereafter, five minutes of resting data was collected using the BodyGem® indirect calorimeter while in the seated position. The RMR values for the HB and Fleisch prediction equations were calculated using the proprietary software utilized by the Vacumed metabolic system, while the MSJ estimate of RMR was hand-calculated.

RESULTS: A repeated measures ANOVA showed a significant difference among the measurement methods (BodyGem® = 1995.0 + 540.5 kcal; Vacumed = 1520.9 + 452.5 kcal; MSJ = 1669.3 + 242.9 kcal; HB = 1749.0 + 275.1 kcal; Fleisch = 1690.3 + 220.7 kcal) ($p < .001$). A *post hoc* paired samples t-test showed that the BodyGem® measured RMR significantly higher than the Vacumed, HB, Fleisch, and MSJ ($p < .01$). The HB estimation of RMR was greater than that of the Vacumed measurement ($p < .025$). For the equations, the RMR estimate of the Fleisch was higher than the MSJ ($p < .025$), while the HB was greater than both the Fleisch and the MSJ ($p < .01$).

CONCLUSION: The Vacumed VO₂ Lab metabolic cart measured RMR closer to the prediction equation estimates compared to the BodyGem® indirect calorimeter. Further research needs to be conducted comparing laboratory instruments to established prediction equations, on various populations, before the estimative methods can be deemed accurate for measuring RMR.

The Comparison Of Energy Expenditure Between Continuous And Intermittent Exercise During And Post Exercise

Songtao Wang¹, Long Zhang², Fei Qin³. ¹South China Normal University, Guangzhou, China. ²Liupanshui Normal University, Liupanshui, China. ³Jinan University, Guangzhou, China.
 Email: songtaowang@126.com
 (No relationships reported)

PURPOSE: Intermittent training has been applied in athlete training for 100 years more. In the last 10 years, it attained additional application in the enhancement of physical fitness and the rehabilitation of multiple chronic diseases. Moreover, many evidence suggests that when compared with steady state exercise, intermittent training can result in comparable or greater improvement in heart failure, diabetes, obesity and other chronic diseases. However, due to the differences of exercise workload (exercise duration, intensity and pattern) in most of researches, it is hard to assert which one is better between continuous and intermittent exercise when faced to some certain of health issues. Therefore, this study aimed to compare the energy consumption and substrate utilization between continuous and intermittent exercise with equal workload during and post exercise, and analyze their relationship with the activity of autonomic nervous system.

METHODS: 12 male students (24.2 ± 1.2 years old), randomly performed 3 tests with 1 week interval: Control (C; rest), continuous exercise (CE; 65% VO_{2max}, 40 min), and intermittent exercise (IE; 85% VO_{2max}, 4min; 45% VO_{2max}, 4min; 5 sessions). Exercise is performed on treadmill with equal workload. In the period of pre- (30 min), during- (40min) and post-exercise (every 1 hour for 8 hours), respiratory metabolism, heart rate variability (HRV), blood pressure, and body temperature were monitored. Paired simple t-tests were used for statistical analysis. This study was funded by two fund from Guangdong (2013B031600003) and Guizhou (2014-7455) Science and Technology Department.

RESULTS: The energy expenditure (EE) and substrate utilization during exercise showed no significant difference between IE and CE. However, IE had higher total 8-hour's EE during post-exercise (1.1-fold, $p < 0.05$, ES=1.85) with much fat oxidation

(1.2-fold, $p < 0.05$, ES=2.63) and significant rising value of LF/HF of HRV analysis (1.7-fold, $p < 0.01$, ES=4.34). The total energy consumption (during exercise plus post-exercise) in IE is higher than CE (1.05-fold, $p < 0.05$, ES=2.17).
CONCLUSIONS: High intensity intermittent exercise can induce much fat oxidation during the period of post-exercise and raise total exercise consumption, which is probably relevant to enhanced sympathetic regulation.

Measurement Of Daily Energy Expenditure In Humans Using A Body-worn Calorimeter

Tracy L. Swibas¹, Seth A. Creasy¹, Victoria A. Catenacci¹, Neil Szuminsky², Edward L. Melanson, FACSM¹. ¹University of Colorado Denver Anschutz Medical Campus, Aurora, CO. ²Necessity Consulting, Pittsburgh, PA. (Sponsor: Edward Melanson, FACSM)
 (No relationships reported)

PURPOSE: Previous approaches using body-worn devices to measure free-living daily EE in humans using direct calorimetry have been limited by the inability to accurately measure evaporative heat loss. The Personal Calorie Meter (PCM) is a device that uses a heat flow gauge embedded in a permeable membrane, permitting the measurement of both dry and evaporative heat loss. Total heat flux and estimated body surface area are then used to estimate minute by minute EE. In this ongoing study, we are comparing daily EE measured using the PCM with simultaneous measurements using whole-room indirect calorimetry (WRC). **METHODS:** Subjects were studied on two separate days under low and high physical activity levels (PAL, ~1.4 and 1.7 x resting metabolic rate, respectively) in the WRC. During the low PAL condition, subjects performed 20 minutes of various housecleaning activities. During the high PAL condition, subjects performed 30 minutes of walking on a treadmill, 30 minutes of stationary cycling, and resistance exercises using dumbbells. Daytime EE was calculated as the total EE from the time the subject entered the WRC until bedtime. **RESULTS:** 14 subjects (10 F/4 M, 44±18 yrs., body mass index=26±6 kg m², mean±SD) have completed at least one study visit in the room calorimeter. During the low PAL condition (N=11), average daytime EE measured by the PCM (1369±220 kcal, mean±SD) did not differ from WRC (1304±757 kcal), but the range of intra-individual differences was large (-899 to +452 kcal). Five measurements were within ±150 kcal, and the minute-to-minute values corresponded closely in these cases. During the high PAL condition (N=9), average daytime EE measured by the PCM (1834±344 kcal) did not differ from WRC (1880±757 kcal), but there was a wider range of intra-individual differences than during the low PAL condition (-1188 to +1075 kcal). **CONCLUSION:** These preliminary data demonstrate the feasibility of measuring EE in humans using portable direct calorimetry. Further studies and refinements are needed to improve the accuracy of the PCM on an individual level.

Determination of Metabolic Pathway in Response to Cycling Versus Vinyasa Yoga

Colin E. Campbell¹, Lori K. Bogren², Carl J. Murphy¹, Kelly Drew¹, Robert H. Coker, FACSM¹. ¹University of Alaska Fairbanks, Fairbanks, AK. ²University of Colorado Denver, Denver, CO.
 Email: cecampbell2@alaska.edu
 (No relationships reported)

PURPOSE: The purpose of this experiment is to determine whether there is a difference in metabolic response to Cycling & Vinyasa Yoga.

METHODS: Six male and six female participants aged 19-35 participated in two exercise sessions spaced 1 week apart. The participants fasted 12 hours prior to a one hour Vinyasa yoga session, and again prior to a 1-hour session of stationary cycling the following week. Heart rate was collected at predetermined time points during the Vinyasa yoga session. In order to normalize the level of intensity in both exercise bouts, participants pedaled at a pace that matched their individual heart rate during the yoga session. Urine samples were collected from participants before and immediately after the yoga and cycling exercise bouts. Urine samples were frozen at -80 Fahrenheit, and later analyzed using a Bruker 600 ¹H-NMR running TopSpin 2.0 software. We were able to determine the identity of 13 metabolites with certainty. These metabolites are as follows: phylalalanine, creatinine, creatine, creatine/creatinine, glycine, choline, taurine, dimethylamine, citrate, pyruvate, alanine, lactate, and beta hydroxybutyrate. The data was analyzed using a combination of analytical techniques, including paired t-test, a bucketing strategy, and MetaboAnalyst 2.0.

RESULTS: We found no significant difference in the metabolites excreted in the urine between different exercise regimens.

CONCLUSION: Exercise intensity and/or lack of adequate sampling may have influenced the lack of significant differences with regard to urine metabolite levels in this study. Although our study did not find any significant change in metabolites, the application of this methodological approach has merit. For example, this methodology

could be used to study changes in metabolic pathways in many different environments that include logistical and/or cultural considerations, where urine samples could be collected and then transported for analysis via ¹H-NMR. Self-supported by Colin Campbell.

Pre-hydration Status, Fluid Intake, And Sweat Rate Of Males Participating In Hot Yoga

Cheri J. Bednarik, R C. Pritchett, Stephanie Campbell, K Pritchett. *Central Washington University, Ellensburg, WA.*
(No relationships reported)

Populations who participate in recreational exercise in hot and humid environments such as hot hatha yoga are at an increased risk for dehydration. Hot yoga continues to grow in popularity.

Purpose: This study investigates the pre-exercise hydration status, fluid balance, perception of sweat loss, of 13 male Hot Hatha Yoga participants. **Methods:** Male participants (n=13, 34 ± 12.7yr, 182.0 ± 9.8cm; 85.2 ± 10.0 kg) were examined during a one hour hot hatha yoga class (39.7 °C ± .53°C, 34.3 ± 2.4% rh). Pre-exercise urine specific gravity (USG), hydration status, body mass changes, and fluid intake were recorded and sweat rate was calculated. After the hot hatha yoga session, participants were asked to perceive their sweat loss. A paired sample t test was used to identify significance between measured sweat loss and perceived sweat loss and body mass loss. **Results:** Forty seven percent of the Participants began the session in a dehydrated state (USG <1.020). Sweat rate was 1.3 ± 0.6 L-h⁻¹, and although replacement fluid was available, consumption was low (0.4 ± 0.3 L-h⁻¹) and 32% did not consume any fluids. Mean percent body mass loss was 1.1 ± 0.7% from pre-exercise body mass, and about half the participants lost at least 1% of body mass. There was a considerable difference between perception of sweat loss and actual sweat loss (p=1.02). Mean perceived sweat loss was 0.8 ± 0.46 L-h⁻¹ and mean actual sweat loss was 1.05 ± 0.6 L-h⁻¹. **Conclusion:** These findings highlight the variability in hydration management among male hot yoga participants supports the notion that hydration guideline must be personalized and education would be beneficial.

Omega-3 Fatty Acids Supplementation did not Improve Cardiometabolic Benefits of 16 Weeks of Exercise Training

Juan F. Ortega, Felix Morales-Palomo, Miguel Ramirez-Jimenez, Ricardo Mora-Rodriguez. *University of Castilla-La Mancha, Toledo, Spain.*
Email: juanfernando.ortega@uclm.es
(No relationships reported)

PURPOSE: To determine if supplementation with omega-3 polyunsaturated fatty acids (omega-3 PUFA) either as enriched milk or capsules would improve the benefits of an aerobic exercise training program in the health of metabolic syndrome (MSyn) patients.

METHODS: Four groups of MSyn patients were enrolled, in a 16-week high intensity interval training program combined with n3-PUFA supplementation administered in a double-blind randomized design. Thirty six MSyn patients ingested during the training program 500 mL of milk daily, either enriched with 275 mg of omega-3PUFA or, semi-skim milk as placebo. Another 40 MSyn patients received capsules containing either 846 mg of omega-3PUFA or soybean oil as placebo. Before and after intervention, MSyn components (i.e., waist circumference, blood pressure, blood glucose, triglycerides and HDL concentrations), composite MSyn Z-score, cardiovascular risk factors (total cholesterol (TC) and LDL), glucose metabolism markers (HbA1c and HOMA), body weight and composition, and cardiorespiratory fitness (peak oxygen consumption; VO_{2PEAK}) and maximal rate of fat oxidation (FO_{MAX}) were assessed. Data was analyzed using split plot ANCOVA (Time x Treatment) controlling for body weight loss.

RESULTS: From the MSyn components, only blood pressure decreased significantly (P<0.001) after the exercise program without further benefit from omega-3 PUFA in any ingestion modality (P=0.340). MSyn Z-score, TC and LDL decreased significantly after training (P<0.001, P=0.016 and P=0.003, respectively) without differences among groups (P= 0.091, P=0.095 and P=0.156, respectively). HbA1c, HOMA and body weight did not change in any group (P=0.087, P=0.762, and P=0.203, respectively). However total fat mass decreased in all groups (P<0.001) without differences among treatments (P=0.942). VO_{2PEAK} and FO_{MAX} improved (P<0.001) in a similar fashion among experimental groups (P=0.651 and P=0.333, respectively).

CONCLUSIONS: Sixteen weeks of dietary omega-3 PUFA supplementation either administered as functional food (enriched skim milk) or at a higher dose provided in capsules, did not further enhance the benefits of high intensity interval training in a group of metabolic syndrome patients.

2108 Board #121 June 1 3:30 PM - 5:00 PM
Carbohydrate Mouth Rinse Does Not Affect 60-min Running Performance In Females

Giorgos Paradisis¹, Costas Chryssanthopoulos¹, Christos Ziaras¹, Tanja Oosthuysen², Ioannis Lambropoulos³, Eleni Tiktampanidi¹, Andreas Tsoukalis¹, Konstantinos Toumpoulidis¹, Anastassios Philippou¹, Elias Zacharogiannis¹, Maria Maridakis¹. ¹National and Kapodistrian University of Athens, Athens, Greece. ²University of the Witwatersrand, Johannesburg, South Africa. ³Biomedical Diagnostic and Research Laboratories, Athens, Greece.
Email: gparadi@phed.uoa.gr
(No relationships reported)

Mouth rinsing with carbohydrate may improve 60-min endurance cycling or running performance in males. However, no data exist regarding the effect of mouth rinsing on endurance performance in females. **PURPOSE:** To examine the effect of mouth rinsing with a carbohydrate solution on endurance running performance in females. **METHODS:** Fifteen female recreational endurance runners (30-57 years) ran 2 races of 1-hour duration on an indoor track after an 8 h post-prandial period with a 7 days interval between races. This time period corresponded to the 3rd-10th day of each runner's menstrual cycle, for the eumenorrhoeic premenopausal runners, or any time for the runners who were at menopause. Following a double-blind process and random order, participants rinsed their mouth, before the initiation of exercise and at 15, 30 and 45 min of exercise with 25 ml of either a 6.4% carbohydrate (RCHO) or a placebo solution (0% carbohydrate) (RP). Pre-race euhydration was insured by ingestion of 6 ml·kg⁻¹ water. No fluids were ingested during exercise. Races started at 18:00 hours. **RESULTS:** There was no difference between treatments in runners hormonal status prior to each race for serum 17β-Estradiol [median (inter-quartile range)], RCHO: 50.2(5; 74.1) pg·ml⁻¹ vs RP: 26.0(5; 61.1) pg·ml⁻¹, z= -0.533, (p= 0.59) and Progesterone (RCHO: 0.75(0.61; 1.64) ng·ml⁻¹ vs RP: 0.74(0.64; 0.9) ng·ml⁻¹, z= -0.938, (p= 0.35) . Percent body mass loss due to exercise was similar between treatments (mean ± SE, RCHO: 1.9% ± 0.1% and RP: 1.9% ± 0.1%). There was no difference in 1-hour running performance, neither by treatment (RCHO: 10621.88 ± 205.98 m vs. RP: 10454.00 ± 206.64 m; t= 1.784, p= 0.096), nor by race order (1st race: 10549.13 ± 213.67 m vs. 2nd race 10526.75 ± 201.16 m; t= 0.215, p= 0.833) (mean ± SE). Furthermore, the mean percentage effect (±99%CI) of RCHO relative to RP, 1.67% (-1.1% to 4.4%), and Cohen's effect size (d = 0.21) support a trivial outcome effect of RCHO for total distance covered. In addition, there was no difference between treatments in the rate of perceived exertion (p= 0.14) and heart rate (p= 0.06). **CONCLUSION:** Carbohydrate mouth rinsing did not improve 1-h running performance in female recreational runners competing in a low ovarian hormone condition, following an 8 h fast and when no fluid was ingested during exercise.

Influence Of Carbohydrate Intake On Pacing Changes During Prolonged Cycling

Michael J. Saunders, FACSM¹, Morgan A. Price¹, Nicholas D. Luden¹, Daniel A. Baur², Mark W. Pataky³, Christopher J. Womack, FACSM¹. ¹James Madison University, Harrisonburg, VA. ²Florida State University, Tallahassee, FL. ³University of Michigan, Ann Arbor, MI.
(No relationships reported)

PURPOSE: The effects of carbohydrate intake on temporal changes in power output during cycling were examined.

METHODS: Eight male cyclists (VO_{2max}: 62 ± 6 mL·kg⁻¹·min⁻¹) completed two trials consisting of 120 min of constant load cycling at 55% W_{max}, followed by a simulated 30 km time trial (TT). Subjects consumed 150 ml of a glucose-fructose solution (CHO) or a non-caloric placebo (PL) every 15 minutes during the constant-load portion of the trial, and at 7.5 km intervals during the TT. Average power output during the TT was compared between treatments, and changes in power output within trials were examined across four segments of the TT (S1 = 0-7.5 km, S2 = 7.5-15 km, S3 = 15-22.5 km, and S4 = 22.5-30 km). Power output was also averaged for three minutes immediately before and after each feeding, to determine if changes in pacing between treatments were influenced by the proximity to CHO feedings. Magnitude-based qualitative inferences were used to evaluate differences between treatments and/or time-points.

RESULTS: Average TT power output during the CHO trial (242 ± 30 W) was 'likely' greater than PL (217 ± 40 W). In the PL trial, cycling power 'almost certainly' decreased between S1 (235 ± 41 W) and S2 (223 ± 38 W), and 'likely' decreased further during S3 (201 ± 41 W). Subsequently, cycling power 'very likely' increased

between S3 and S4 (219 ± 43 W), but remained lower than S1 levels. By contrast, power output during the CHO trial showed no clear changes from S1 (246 ± 41 W) to S2 (242 ± 28 W). Thereafter, power output 'possibly' decreased during S3 (232 ± 27 W), followed by a 'likely' increase in power during S4 (249 ± 32 W), resulting in power levels during S4 that were similar to S1. Power output during the period immediately following each PL ingestion (210 ± 40 W) was not clearly different from the period prior to PL ingestion (213 ± 39 W); whereas power output immediately following CHO ingestion (244 ± 27 W) was 'possibly' increased versus pre-ingestion (236 ± 31 W).

CONCLUSIONS: CHO ingestion increased average power output during a cycling TT and attenuated declines in power output over the duration of the trial, compared to PL. In addition, improvements in power output with CHO were possibly greater in the periods immediately following each feeding, potentially due to effects of CHO on the central nervous system.

The Effects Of Pre-exercise Protein Vs. Carbohydrate Consumption On Energy Expenditure After High-volume Resistance Exercise
 Adam Osmond, Dean Directo, Michael Wong, Daniel Higuera, Edward Jo. *Cal Poly Pomona, Pomona, CA.*
 Email: adosmond1992@gmail.com
 (No relationships reported)

During the recovery period following a bout of resistance exercise, oxygen consumption remains elevated for a variable timeframe, reflecting an acute enhancement in resting energy expenditure. What remains uncertain is whether pre-exercise nutrient consumption further promotes these acute metabolic responses to a bout of resistance exercise and if the type of nutrient influences these effects. **Purpose:** Therefore, the objective of this study was to determine, in college-age, resistance trained male subjects, the extent by which pre-exercise supplementation of whey protein or carbohydrate modulates metabolic and substrate oxidation rates following a bout of high-volume, total body resistance exercise. **Methods:** In a randomized, placebo controlled, cross-over study, healthy, resistance trained male ($n=10$) subjects initially underwent baseline testing for resting energy expenditure and maximum strength. Subjects were familiarized with the resistance exercise protocol during the subsequent visit. Afterwards, across 3 separate subsequent visits, subjects consumed whey protein (PRO), carbohydrate (CHO), or no nutrients (CON) prior to a bout of high-volume resistance exercise. After exercise, subjects were tested for energy expenditure (EE), oxygen consumption (VO_2), respiratory exchange ratio (RER), and heart rate (HR). **Results:** PRO (+23.5%; $p=0.003$), CHO (+12.8%; $p=0.001$), and CON (+9.5%; $p=0.005$) increased EE from resting baseline with concomitant changes to VO_2 , RER, and HR. PRO ($p=0.019$) and CHO ($p=0.003$) demonstrated equivalently greater post-exercise EE than CON. Post-exercise VO_2 was significantly greater in PRO vs. CON ($p=0.034$) while CHO did not differ from PRO or CON. **Conclusion:** Overall, nutrient consumption prior to resistance exercise may augment the post-exercise elevation in EE. Consumption of whey protein pre-exercise may enhance excess post-resistance exercise oxygen consumption (i.e. EPOC) to a greater extent than carbohydrate intake.

The Effects of Carbohydrate Mouth Rinse Concentration on Cycling Time Trial Performance
 Jonathan D. Youell¹, Shawn R. Simonson¹, Matthew E. Darnell², Scott A. Conger¹. ¹Boise State University, Boise, ID. ²University of Pittsburgh, Pittsburgh, PA. (Sponsor: Dawn P. Coe, FACSM)
 Email: jonathanyouell@gmail.com
 (No relationships reported)

Mouth rinsing with a carbohydrate (CHO) solution during exercise has been shown to improve endurance exercise performance. Research suggests that the sensation of CHO in the oral cavity may stimulate neural pathways that attenuate the drop in motor output during exercise. However, it is unclear if performance is improved to a greater extent with different CHO concentration mouth rinses. **Purpose:** The purpose of this study was to determine if there is a dose-response effect of CHO mouth rinse concentration on endurance performance during a one-hour cycling time trial. **Methods:** Fifteen male participants, aged 18-45 years old, who cycled a minimum of 30 miles per week, were recruited for this study. Participants completed five, one-hour time trials on a cycle ergometer, each separated by at least five days. During the first visit, participants completed a familiarization trial during which they rinsed with 25ml of water every 15 minutes of the time trial, beginning at time zero. In a randomized, double-blind fashion, participants then completed trials during which a 0%, 3%, 6%, or 12% CHO solution was rinsed for five seconds in 15-minute intervals during each of the four experimental time trials. Average power (W), work completed (kcal), heart rate (HR), and rating of perceived exertion (RPE) were recorded during each trial and compared at each 15-minute time point using a repeated

measures ANOVA. **RESULTS:** A total of 14 participants completed all five time trials. Participants had 7.6 ± 5.9 years of cycling experience and rode 111 ± 66 miles per week in the six months prior to study participation. The results indicated that there were no significant differences ($p > 0.05$) between 0%, 3%, 6%, or 12% CHO solutions in total work performed (777 ± 182 , 766 ± 187 , 767 ± 159 , 752 ± 187 kcal, respectively), average power (236 ± 56 , 233 ± 56 , 233 ± 48 , 226 ± 53 W, respectively), average HR (155 ± 14 , 155 ± 13 , 152 ± 12 , 153 ± 14 BPM, respectively), or RPE (8.3 ± 1.1 , 8.4 ± 1.3 , 8.1 ± 1.5 , 8.4 ± 1.2 , respectively). **CONCLUSIONS:** The results of this study revealed that there is no ergogenic benefit of a CHO mouth rinse for a one-hour cycling time trial. Furthermore, there was no dose-response effect of CHO mouth rinse concentration on time trial performance.

Carbohydrate Mouth Rinse Improves Mean Power During Multiple Sprint Performance
 Garett Simpson¹, Robert Pritchett¹, Eric O'Neal², Garrett Hoskins¹, Kelly Pritchett¹. ¹Central Washington University, Ellensburg, WA. ²University of North Alabama, Florence, AL.
 Email: gsimpson@toppenish.wednet.edu
 (No relationships reported)

Multiple investigations have confirmed carbohydrate mouth rinse (CMR) enhances high intensity endurance performance lasting under 1 hour, but the effects of CMR on high intensity intermittent exercise have received little attention. **Purpose:** To determine the effect of a CMR on high intensity multiple sprint performance. **Methods:** Competitive, male, athletes ($n=8$) (31.1 ± 7.1 years, 185 ± 9 cm, 87.4 ± 15.3 kg, VO_2 peak 49.9 ± 7.8 ml/kg*min-132) completed two, 48 min high intensity intermittent cycling protocols that consisted of 6 bouts of 5 min cycling at 50% VO_2 peak followed by sets of three, 10-s Wingate sprints with 50 s of recovery between sprints. Prior to each set of Wingate sprints, either a 6.4% carbohydrate solution (CMR) or placebo (PLA) were rinsed for 10 s using a counterbalanced crossover design. **Results:** There was a significant main effect (CMR 912 ± 168 , PLA 896 ± 161 W; $p < 0.05$ ES=0.10) for mean power, but post hoc tests only revealed significant performance improvement with CMR during the 6th bout (CMR 912 ± 167 , PLA 885 ± 153 W; $p < 0.05$ ES=0.17). No treatment effect was exhibited for peak power, fatigue index, rate of perceived exertion, or blood glucose. Most team based sport provide multiple opportunities for access to carbohydrate beverages. **CONCLUSIONS:** Based on the 1.9% increase in performance with a CMR on mean power observed in the current study, a CMR may serve as a practical ergogenic option for high intensity intermittent sports. The Impact of Glucose Supplementation on Barbell Velocity and Fatigability in Weightlifters: A Pilot Study
 Andrew R. Hill, Jacob B. Davis, Soon-Mi Choi. *Midwestern State University, Wichita Falls, TX.*
 Email: endunamoox@gmail.com
 (No relationships reported)

Purpose: Fatigue has been shown to decrease velocity in training, decrease repetitions able to be performed while lifting weights, and increased fatigue level from weight training. This study investigated the changes in velocity and performance of weightlifters during training sessions with glucose supplementation. **Methods:** Three competitive Olympic weightlifters, aged 25.7 ± 4.0 yrs, participated in two trials; placebo (PL), and glucose supplement (GL). Every Minute On the Minute (EMOM) sets were used to simulate a training sessions. At the start of each minute, the subject performed a lift at 70% of their respective One repetition Maximum, and they continued these sets for 10 min. The snatch (ST) and Clean & Jerk (CJ) were performed for 10 sets at each. A pretest (PRE) consisted of both of the lifts 10 min EMOMs where peak velocity (PV), average velocity (AV), heart rate (HR) and rate of perceived exertion were recorded for each lift. A posttest (POST) mimicked the PRE and the recorded differences were compared between the PL and GL. Blood lactate (BL) and glucose (BG) were also recorded prior to trial testing (BASE), PRE, after 15 min recovery (REC), and POST. **Results:** BG increased 29% in GL (PRE: 98.0 ± 11.1 mg·dL⁻¹, REC: 125.3 ± 23.2 mg·dL⁻¹) and BL decreased 12% in GL (PRE: 4.2 ± 1.7 mmol·L⁻¹, REC: 3.2 ± 0.5 mmol·L⁻¹, $p=0.001$) and 20% in PL (PRE: 3.5 ± 1.2 mmol·L⁻¹, POST: 2.9 ± 1.8 mmol·L⁻¹). PV of ST increased 4% in GL (PRE: 1.51 ± 0.10 m·sec⁻¹, POST: 1.56 ± 0.11 m·sec⁻¹) and decreased 3% in PL (PRE: 1.72 ± 0.18 m·sec⁻¹, POST: 1.66 ± 0.08 m·sec⁻¹). PV of CJ increased 1% in GL (PRE: 1.56 ± 0.51 m·sec⁻¹, POST: 1.61 ± 0.69 m·sec⁻¹) and decreased 4% in PL (PRE: 1.65 ± 0.45 m·sec⁻¹, POST: 1.57 ± 0.47 m·sec⁻¹). HR of ST increased both PL (5%, PRE: 102.1 ± 29.8 beats·min⁻¹, POST: 107.8 ± 33.4 beats·min⁻¹) and GL (3%, PRE: 115.1 ± 30.4 beats·min⁻¹, POST: 118.2 ± 32.1 beats·min⁻¹). HR of CJ decreased both PL (1%, PRE: 124.5 ± 39.1 beats·min⁻¹, POST: 122.6 ± 37.7 beats·min⁻¹) and GL (4%, PRE: 135.4 ± 36.3 beats·min⁻¹, POST: 131.7 ± 40.7 beats·min⁻¹).

CONCLUSIONS: The results show that glucose supplementation intake in weightlifters is associated with exercise performance such as barbell velocity and may reduce their fatigue level. A larger sample size should be required to confirm the significance of these findings.

The Repercussion of Expectorations: When a Carbohydrate Rinse Becomes Detrimental to Performance

Hunter L. Paris, Kevin O. Murray, Timothy J. Fulton, Timothy D. Mickleborough, FACSM. *Indiana University, Bloomington, IN.*

(No relationships reported)

Amongst dietary strategies for performance enhancement a carbohydrate (CHO) mouth rinse is unique in that it may promote an increased rate of CHO oxidation without ingestion. Therefore, the possibility exists that a CHO mouth rinse may lead to a premature cessation of exercise due to a more rapid depletion of glycogen stores.

PURPOSE: To calculate the time course of when CHO mouth rinsing may begin to be detrimental to performance.

METHODS: Eight trained, competitive cyclists [age (mean \pm SEM) = 24 \pm 2 y; VO_{2max} = 64.5 \pm 2.8 ml/kg/min] completed three simulated 40-km time trials comprised of a familiarization trial, glucose mouth rinse trial (GLC), and placebo trial (PLA). A mouth rinse was administered prior to onset of exercise, and every 5-km throughout the time trial. CHO oxidation rates were calculated based on the equation: g/min = 4.210 VCO_2 - 2.962 VO_2 (Jeukendrup 2005) and then applied to previously established values of CHO stores in glycogen loaded individuals (Rapaport 2010) in order to estimate when stores would be exhausted.

RESULTS: Time to completion was statistically faster ($P < 0.05$) for GLC (67.1 \pm 1.1 sec) compared to PLA (67.9 \pm 1.0 sec). CHO oxidation rates were not statistically different ($P = 0.06$) between the GLC (3.43 \pm 0.80 g/min) and PLA (2.98 \pm 0.18 g/min) groups. Assuming a 70 kg man is fully glycogen loaded at a wet weight of 200 mmol/kg muscle and that 22% of his body mass is leg muscle, glycogen stores would roughly equal 570 g in leg muscle. There was no statistical difference ($P = 0.06$) between conditions in the time to deplete these stores. According to calculated oxidation rates, a 70-kg man would deplete leg stores in 175 \pm 17 min when using a CHO mouth rinse and 196 \pm 11 min when rinsing with a noncaloric sweetener.

CONCLUSIONS: Rinsing the mouth with a CHO solution prior to and during exercise does not result in a more rapid depletion of muscle glycogen stores despite improved performance. However, when using a CHO rinse glycogen stores will be depleted in approximately 3 h and recommending this ergogenic approach for longer duration exercise should therefore be approached with caution.

Six Grams of Fish Oil Supplementation Mitigates Perceived Muscle Soreness Following Acute Resistance Exercise

Alyssa J. Holmes¹, Trisha A. VanDusseldorp¹, Kurt A. Escobar², Kelly E. Johnson², Matthew Stratton², Terence Moriarty², Jeremy McCormick², Gerald Mangine¹, Tony P. Nuñez², Nick M. Beltz², Nathan Cole², Marvin Endito², Chad M. Kerksick, FACSM³, Christine M. Mermier². ¹Kennesaw State University, Kennesaw, GA. ²University of New Mexico, Albuquerque, NM. ³Lindenwood University, St. Charles, MO. (Sponsor: Chad Kerksick, FACSM)

(No relationships reported)

High-intensity eccentric exercise is known to cause skeletal muscle damage and microstructural changes to muscle tissue with an associated inflammatory response. Previous research demonstrates increased pro-inflammatory cytokine and prostaglandin concentrations are linked with perceived muscle soreness. The omega-3 fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), commonly found in fish oil supplements, exhibit anti-inflammatory properties that have been reported to attenuate the overall perception of muscle soreness. **Purpose:** To investigate the dose-response effect of fish oil (FO) supplementation on the magnitude and time-course of post-eccentric resistance exercise muscle soreness. **Methods:** Thirty-two, college-aged, resistance-trained males (n = 16; 23.8 \pm 2.7 years, 81.5 \pm 9.9 kg, 175.7 \pm 4.5 cm, 16.3 \pm 3.6 %) and females (n = 16; 23.4 \pm 3.1 years, 61.7 \pm 7.2 kg, 170.4 \pm 6.2 cm, 23.6 \pm 5.0 %) completed a double-blind placebo controlled 7-week supplementation period of either: 2.0, 4.0, or 6.0 g·d⁻¹ FO or placebo (PL). Subsequently, participants completed a muscle damaging resistance exercise protocol (10 sets of 8 four-second eccentric squats at 70% one-repetition maximum and 5 sets of 20 split-squat jumps). Perceived muscle soreness (PS; 0–10 cm scale) was measured pre-exercise (PRE), immediately post (IP), as well as 1, 2, 4, 24, 48, and 72 hours (h) post-exercise.

Results: Repeated measures analysis of variance revealed a group \times time interaction for PS ($p < 0.001$), where compared to PL, lower PS scores were observed at IP for 6 g·d⁻¹ (mean difference: 4.0 cm, $p = 0.024$), at 1h for 6 g·d⁻¹ (mean difference: 2.74 cm, $p = 0.046$), at 24h for 4 g·d⁻¹ (mean difference: 2.38 cm, $p = 0.023$), and 6 g·d⁻¹

(mean difference: 3.45 cm, $p < 0.001$), at 48h for 6 g·d⁻¹ (mean difference: 4.45 cm, $p < 0.001$), and at 72h for 6 g·d⁻¹ (mean difference: 3.0 cm, $p = 0.003$). Other group differences were variable by time point. **Conclusions:** These data indicate that supplementation with 6 g·d⁻¹ of FO is effective at attenuating PS following damaging eccentric resistance exercise for up to 72h. The Potential Of Omega 3 Supplementation To Reduce Muscle-inflammation After Muscle-damaging Exercise

Yvoni Kyriakidou¹, Rebeca Cielak Kantorovich¹, Jimmy Bell¹, Stefania Monterisi², Alberto Dolci¹. ¹University of Westminster, London, United Kingdom. ²University of Oxford, Oxford, United Kingdom.

Email: yvoni.kyriakidou@gmail.com

(No relationships reported)

Muscle inflammation which follows exercise-induced muscle damage (EIMD) relates to strength loss, muscle-soreness and impaired recovery (Lynn and Morgan, 1994). It remains unclear whether omega-3 fatty acids (O-3) supplementation blunts the exercise-induced inflammation associated with EIMD.

PURPOSE: Following supplementation with O-3, indirect markers of muscle damage were examined after EIMD to determine if supplementation had any beneficial effect in reducing muscle inflammation. **METHODS:** Eight healthy, recreationally active caucasian males (28.13 \pm 3.4 yrs) were randomly allocated to a supplementation group (SUP, n = 4) to receive 2.85g/day O-3 supplementation or a placebo group (CON, n = 4) for three weeks. After three-weeks, participants performed a bout of EIMD, which consisted of performing 10 sets of 15 repetitions of leg extension on a Rating of Perceived Exertion (RPE) of 7/10 (Borg, 1982). Creatine Kinase (CK) from venous blood samples, isometric right-leg strength, squat-jump test and perceived soreness were determined, as indirect markers of muscle-damage at Baseline, immediately after EIMD (POST) and 48 hours after EIMD to coincide with the delayed muscle inflammatory response. **RESULTS:** No differences were found between Baseline and POST. There was a trend for smaller increase of CK levels (pre vs 48-h post EIMD) on the SUP group (38.8% increase) compared with the CON group (105.6% increase; $P = 0.051$). There was no significant effect (baseline vs. 48-h post EIMD) on muscle strength between SUP and CON group ($P > 0.05$), however, CON showed a larger decrease in strength compared to SUP (>6.3% vs SUP). No differences in jump height were found between SUP and CON ($P > 0.05$). There was no significant difference in muscle soreness at 48-h post EIMD between SUP and CON group ($P = 0.171$).

CONCLUSION: Three weeks of O-3 supplementation decreased exercise-induced muscle inflammation after eccentric exercise. The encouraging results from this pilot study have led to designing further work related to this topic. The lack of statistical significance may be added to the limitations of the study design. Supplementation with O-3 can be beneficial in sedentary individuals re-starting physical activity and in athletes undergoing heavy exercise regimes, decreasing the exercise related muscle inflammation.

2117 Board #130 June 1 3:30 PM - 5:00 PM

Fish-oil Supplement and Eccentric Exercise on Lipid Profiles during Different Phases of Menstrual Cycle

Yonghyeon Jo¹, Sarah McKinley Barnard², Darryn Willoughby, FACSM¹, Yunsuk Koh¹. ¹Baylor University, Waco, TX. ²University of South Alabama, Waco, AL.

(No relationships reported)

Fish oil supplement has been widely recognized as a wholesome regimen, which may positively affect blood lipid and lipoprotein profiles and muscle damage caused by eccentric exercise. **PURPOSE:** To examine the effects of dietary fish oil supplement and acute eccentric exercise on blood lipids and lipoproteins including (TC, HDL-C, Lp(a), LDL-C, and VLDL-C) during two different phases of menstrual cycle (mid-follicular vs. mid-luteal phase). **METHODS:** As a randomized, double-blind design, 22 college-aged women (fish oil = 11, placebo = 11, age = 20.86 \pm 1.39 years) participated in the study. Participants in the fish oil group ingested 6 capsules of fish oil per day (total 6g; containing 2.4g eicosapentaenoic acid and 1.8g docosahexaenoic acid), while the placebo group took 6 capsules of safflower oil per day for 3 weeks. All participants performed an acute eccentric leg exercise (10 sets of 10 repetitions with 3-min rest between sets at an isokinetic speed of 30°/sec) during both mid-follicular (MF) and mid-luteal (ML) phases. The leg exercised for the MF phase was randomly selected and the opposing leg exercised during the ML phase. Blood samples were collected at baseline, 6-hr post-exercise, and 24-hr post-exercise for each phase. Data were analyzed by a 2 \times 2 \times 3 analysis of variance with repeated measures along with the Sidak's multiple comparisons for any significant interactions to compare means differences ($p < .05$).

RESULTS: There were no significant differences in blood lipids and lipoproteins between fish oil and placebo groups or baseline, mid-, and post-exercise. However, HDL-C was significantly higher ($p = 0.041$) during the ML (61.66 \pm 2.44 mg/dL)

phase than that of the MF (54.53 ± 2.44 mg/dL) phase. **CONCLUSION:** Although overall lipid and lipoprotein profiles tended to improve with a short-term fish oil supplement, it didn't reach a statistical significance. In addition, acute eccentric exercise did not negatively affect blood lipids and lipoproteins. However, HDL-C was significantly influenced by the different phases of menstrual cycle, where HDL-C increased during the mid-luteal phase possibly due to elevated estradiol levels. It is recommended that an extended period of fish oil supplement be implemented in different sample groups including both pre- and post-menopausal women for the future studies.

Five Grams Of Fish Oil Supplementation Improves Vertical Jump Performance Following Acute Eccentric Resistance Training

Kelly E. Johnson¹, Trisha A. VanDusseldorp², Kurt A. Escobar¹, Matt Stratton¹, Terence A. Moriarty¹, James J. McCormick¹, Gerald T. Mangine², Tony P. Nuñez¹, Nicholas M. Beltz¹, Nathan Cole¹, Marvin Endito¹, Chad M. Kerksick, FACSM³, Christine M. Mermier¹. ¹The University of New Mexico, Albuquerque, NM. ²Kennesaw State University, Kennesaw, GA. ³Lindenwood University, St. Charles, MO. (Sponsor: Chad Kerksick, FACSM) Email: kjohnson4@unm.edu
(No relationships reported)

A damaging bout of eccentric resistance exercise is known to hinder athletic performance. Fish oils are rich in omega-3-polyunsaturated fatty acids and have been purported to modulate the inflammatory response to exercise. It is possible that regular fish oil supplementation may assist in maintaining athletic performance following eccentric resistance exercise, but little is known regarding the optimal dose for stimulating benefits. **PURPOSE:** To examine the effect of fish oil (FO) supplementation dosing on athletic performance recovery following a muscle-damaging bout of eccentric exercise. **METHODS:** Thirty-two college-aged, resistance-trained males ($n = 16$; 23.8 ± 2.7 years, 81.5 ± 9.9 kg, 175.7 ± 4.5 cm) and females ($n = 16$; 23.4 ± 3.1 years, 61.7 ± 7.2 kg, 170.4 ± 6.2 cm) supplemented with 2.0, 4.0, 6.0 g·d⁻¹, FO or placebo (PL) for 7 weeks. Following 7 weeks of supplementation, participants completed pre-exercise (PRE) assessments of vertical jump (VJ) height, maximal voluntary contraction of the knee extensors, 40-yard sprint time, and T-test agility followed by a muscle damaging resistance exercise protocol (10 sets of 8 four-second eccentric squats at 70% one-repetition maximum, 5 sets of 20 split-squat jumps). All PRE-assessments were repeated immediately post (IP), 1, 2, 4, 24, 48, and 72 hours (h) post-exercise. **RESULTS:** Repeated measures analysis of variance indicated a treatment x time interaction ($p < 0.001$) for VJ. Although VJ was decreased from PRE (53.8 ± 8.7 cm) at IP (47.4 ± 9.3 cm) for all groups, VJ returned to PRE-values at 1h for the 6 g·d⁻¹ supplementation group (51.8 ± 6.5 cm, $p = 0.112$), while no other groups returned to baseline until 48h. No other differences were observed. **CONCLUSIONS:** These data indicate that supplementation with 6 g·d⁻¹ of FO is effective for enhancing recovery in jump performance following a damaging bout of exercise. Supported by the International Society of Sports Nutrition and MusclePharm Grant

Mobility Outcomes From Resistance Training Delivered via Flash Drive to Overweight/obese Patients In A Clinical Setting

Mary E. Sanders, FACSM¹, Karmella Thomas¹, Tayler Reynolds¹, Veronica J. Brady¹, Michael E. Rogers, FACSM². ¹University of Nevada, Reno, Reno, NV. ²Wichita State University, Wichita, KS. Email: Waterfit711@yahoo.com
(No relationships reported)

Elastic and isotonic resistance training can improve health and fitness. Little is known about the impact of a home-based, structured program delivered via flash drive videos to weight management patients in a clinical setting. **PURPOSE:** To measure functional fitness/mobility after 12 weeks of a home-based, video led resistance-training program (Mini BIRST) designed as short interval workouts using dumbbells or Theraband CLX elastic resistance bands. **METHOD:** Overweight/obese participants ($n=21$, 51.5 yrs, BMI 33.2 kg·m⁻²) enrolled in the Health Management

Resources (HMR) weight management program, self-selected to join the study and were assessed for baseline health and mobility. They were randomized into 2 groups: 3 weeks of isotonic resistance followed by 3 weeks of elastic resistance (10-20 min/day, 2-3 days/wk, 6 wks) using a cross-over design. Participants then performed full body CLX-only circuit exercises (20 min/day, 2-3 days/wk, 6 wks). Both home-based programs were delivered via written handouts and flash drive videos. Functional fitness/mobility was assessed using standardized tests. Repeated measures ANOVA were conducted and a p-value of <0.05 was used to indicate significant changes. An opinion survey was conducted to determine attitudes about the program and delivery. **RESULTS:** Participants exercised 3 days/wk for 12 weeks with 83% compliance. Mobility improved for chair stand (26%), arm curl (35%), aerobic endurance (25%), and flexibility in both legs (4% right, 2% left). Participants showed no changes for weight or BMI, but successfully maintained "weight neutral" during the 12-week. Participants trended toward an increase in physical activity (9%), over baseline. Participant opinions revealed they "Liked" the program overall" (75%), said they "Felt good" (70%), was "Convenient to do" (85%), "Liked the flash drive delivery" (85%) and would "Continue the program" (85%). **CONCLUSIONS:** Participants complied to and enjoyed the home-based, dumbbell and CLX resistance band short-burst workouts delivered via flash drive videos and illustrated handouts, resulting in improved mobility and aerobic endurance. Further study is needed to determine long-term impact on adherence, weight and health. **Support for this study provided by Performance Health, Akron, OH.**

A Two-minute, Energy-surge Exercise For Weight Loss: A Randomized, Controlled Trial

F. Buck Willis, MBBS, PhD, FACSM, FACSM¹, Raquel Pena, MD², Sarah Curran, PhD, BSc (Hons)³. ¹Galveston Clinical Research, Galveston, TX. ²Shriners Hospitals for Children, Galveston, TX. ³National University of Ireland, Galway, United Kingdom. Email: bwillisphd@yahoo.com
(No relationships reported)

The Center for Disease Control has reported that 70% of the US population are overweight and almost 40% are categorically obese, based on Body Mass Index (BMI). There are numerous programs, diets, and exercise regimens, but these are inadequate because of the continuous rise in obesity. A unique 2-minute Energy-surge exercise routine was developed for metabolism acceleration.

PURPOSE of this study was to determine if the Energy-surge protocol (performed four times/day) reduces subjects' weight and girth sizes. **METHODS:** Fifty-four subjects (mean age 39 ± 8) with BMI of >30 , and were recruited for this 60-day study. Subjects were randomly assigned to either the Experimental group which performed the 2-minute, Energy-surge exercises, four times a day or the Control group who were instructed to "exercise more." No dietary changes were required for either group.

The Experimental group were shown how to make many movements such as climbing stairs or curling dumbbells into an Energy-surge exercise in subjects' aerobic threshold for two minutes. Experimental subjects recorded their exercises and send daily to a research assistant via text or email. The dependent variables were weight (pounds) and Body Summation of 10 girth measurements. A 2x2 ANOVA was used to calculate differences.

RESULTS: There was a significant difference between groups ($P < 0.0001$). The change of the groups were as follows: Experimental ($N=24$) mean reductions = -15.2 lbs and -16.0 " vs. Control ($N=23$) mean changes = $+2.2$ lbs and $+2.5$ ".

CONCLUSION: The 2-minute Energy-surge exercise protocol performed four times a day was effective in reducing subjects' weight and body circumferences. Isolated tests of body composition showed that experimental subjects change were primarily in fat reductions. Future studies should measure this protocol for longer durations, including other variables such as diet changes (portion size and frequency) with body composition testing as the dependent variable.

Insulin Resistance Response to a Treadmill's High Intensity Interval Training in Postmenopausal Women

Mariana S. Nakagaki¹, Edilaine Michelin², Jose E. Corrente², Roberto C. Burini, FACSM². ¹Londrina State University, Londrina/PR, Brazil. ²UNESP Medical School, Botucatu/SP, Brazil. (Sponsor: Roberto Carlos Burini, FACSM)
 Email: msantorol16@hotmail.com
 (No relationships reported)

PURPOSE: Considering that high-intensity interval training (HIIT) might offer faster and/or more efficient results in improving insulin sensitivity and glycemic control than low-intensity exercise, we conducted a study to analyze the response of insulin resistance to a HIIT.

METHODS: 24 post-menopausal individuals were selected among those enrolled in our existing Lifestyle Modification Program (Move for Health). Physical activity level, socio-demographic characteristics, and health status were identified through the International Physical Activity Questionnaire (version 8 - long form). Fitness performance was determined by trunk flexibility, handgrip test, cardiorespiratory fitness on treadmill. After an overnight fast (8-12 hours), plasma or serum was used for glucose and insulin assays. For the intervention protocol the patients were subjected to 43 minutes of supervised exercise twice weekly for 10 weeks. The HIIT included 10 minutes of warm-up at 70% of HR max, followed by 4 series of 4 minutes each on 90% HRmax with 3-min intervals between series for active recovery at 70% of FCmax, ended with 5 minutes backing to calm. Results were expressed as mean, standard deviation, frequency and percentage. Chi-square test (χ^2), ANOVA repeated measure and the range model repeated measures were used with a 5% significance level.

RESULTS: The sample consisted of low-income post-menopausal women with intermediate education referring self-perception of good health, although overweight and with good weekly physical activity and grip strength fitness but poor trunk flexibility. After 10 weeks of HIIT, the values changed for cardiorespiratory fitness markers by increasing 23.8% (time on treadmill test). The 37.5% unfit flexibility (<P25) were reassigned either to P25-P75 (33.3%) or >P75 (11.1%). Regarding the insulin-resistance status, the HIIT resulted in normalization of 50% of the former hyperglycemics (25% at baseline) and also in 16.7% of the hyperinsulinemics with altered HOMA-IR. Nevertheless, there was no reclassification for body or abdominal obesity.

CONCLUSIONS: The protocol was shown to be effective in improving aerobic fitness and flexibility, additionally to discrete effects on insulin sensitivity although ineffective in reducing abdominal adiposity and overweight.

Effect Of Aerobic Exercise Intensity On Glycated Hemoglobin, Fitness, And Adiposity In Individuals With Type 2 Diabetes: Results From HART-D

Neil M. Johannsen¹, Damon L. Swift², Carl J. Lavie³, Conrad P. Earnest, FACSM⁴, Steven N. Blair, FACSM⁵, Timothy S. Church⁶. ¹Louisiana State University, Baton Rouge, LA. ²East Carolina University, Greenville, SC. ³Ochsner Medical Center, Ochsner Clinical School - University of Queensland School of Medicine, New Orleans, LA. ⁴Texas A&M, College Station, TX. ⁵University of South Carolina, Columbia, SC. ⁶Pennington Biomedical Research Center, Baton Rouge, LA. (Sponsor: Steven N. Blair, FACSM)
 Email: njohan1@lsu.edu
 (No relationships reported)

PURPOSE: To examine changes (Δ) in HbA1c, CRF, strength, and adiposity in individuals with T2DM while retrospectively categorizing AER by intensity.

METHODS: 196 men (n=74) and women (age=57.1±8.1y; BMI=34.4±5.8kg/m²; mean±SD) from the HART-D study (NCT00458133) were randomized to 9 months of AER, RES, or combined training (COMB) or to a non-exercise control (CON). Compliant participants (>70% of AER sessions) with complete baseline and follow-up data for HbA1c, CRF (maximal METS), isokinetic strength, and anthropometry (weight, waist circumference (WC), and fat mass) were included. AER intensity was determined using residuals (positive=HI; negative=LO) for average training intensity (%MET-R) adjusted for baseline CRF, age, and sex. **RESULTS:** Δ HbA1c was greater in COMB-HI, COMB-LO, and AER-HI (-0.53%, -0.82 to -0.18; -0.39%, -0.70 to -0.07; -0.48%, -0.82 to -0.14, resp; mean, 95%CI) compared to CON (0.18%, -0.12 to 0.49; all P<0.01) and COMB-HI compared to AER-LO (-0.00%, -0.36 to 0.35; p<0.04). A trend for greater Δ HbA1c was noted between AER-HI and AER-LO (P=0.05). Δ CRF was higher in COMB-HI and AER-HI (1.2 METs, 0.8 to 1.5; 1.3 METs, 0.9 to 1.6) compared to all other groups (range Δ CRF= -0.2 to 0.5 METs; all P<0.007). Δ strength was higher in COMB-HI and RES (14.0N, 5.8 to 22.2; 16.2N, 10.6 to 21.8) compared to AER-LO and AER-HI (-2.0N, -10.6 to 6.6; -4.2N, -12.3 to 3.8; all P<0.008). Significant change in weight was only observed in

COMB-HI (-1.6kg, -2.9 to -0.2) compared to CON (0.4kg, -0.8 to 1.6, P=0.03). WC was significantly reduced in all groups (range -1.7 to -3.1 cm; P≤0.03 for all) except AER-LO (P=0.07) compared to CON. COMB-HI, COMB-LO, and RES reduced fat mass (-2.1kg, -3.1 to -1.0, -1.5kg, -2.5 to -0.6; -1.3kg, -2.0 to -0.6, resp) compared to CON (0.0kg, -0.9 to 1.0; P≤0.02 for all). **CONCLUSION:** Our analysis suggests that individuals with T2D who conduct their AER at an intensity above age, sex, and CRF average responses may see greater improvements in glucose control, CRF, strength, and adiposity.

The Effect of Exercise and Diet Interventions on Type-2 Diabetic Patient

Mei Wang, Yan feng Zhang. China institute of sports science, Beijing, China.
 Email: wangmei@ciss.cn
 (No relationships reported)

Purpose: This study probes into intervention of exercise and diet for type-2 diabetic patient, in order to provide scientific basis for diabetic prevention. **Methods:** The research object is selected from the healthy people aged above 50. There are 160 type-2 diabetic patients in walking group; 186 in walking & strength exercise under diet control group; 56 in control group. Their disease course in 2-8 years and have a 3 months comprehensive intervention. Intervention plans: (1) Walking group: Add 20% of walking steps (at a speed of above 60 m/min) on basis of average daily exercise quantity, people in this group exercise for 3-5 times a week; (2) Comprehensive intervention group: On the basis of walking, resistance training is added, which includes 3 sets of press-up, sit-up and back extension, and people shall do more than 10 for each set of above exercise or a maximum number according to personal ability. At the same time, the diet intervention is carried out. First, determine a daily total heat, Then calculate the required daily food exchange list and make proper distribution by a proportion of one-fifth, two-fifths and two-fifths or equally one-third for breakfast, lunch and supper respectively. (3) Detection indexes: (1) Personal information, state of disease, daily physical exercise condition, medication condition and diet habits. (2) Blood glucose: FBG and HbA1C. (3) Blood fat: TC, TG, HDL-C and LDL-C. **Results:** (1) The FBG of intervention group is reduced from 8.67mmol/L to 7.32mmol/L, walking group reduced from 7.45mmol/L to 7.25mmol/L (p>0.05); however, the FBG of control group increases from 8.79mmol/L to 10.26mmol/L (p<0.05). (2) The HbA1C of comprehensive intervention group is reduced from 8.05% to 7.66% (p<0.05); walking group is reduced from 7.04% to 7.01% (p>0.05); control group increases from 8.63% to 9.07%. (3) The HDL-C of comprehensive intervention group is increased from 1.32mmol/L to 1.55mmol/L (p<0.01); walking group is increased from 1.41mmol/L to 1.54mmol/L (p<0.01); while, control group falls from 1.52mmol/L to 1.24mmol/L (p<0.01). **Conclusions:** Comprehensive intervention of exercise and diet is more effective.

Methods To Evaluate An Introductory Motivational Interviewing Workshop For Healthcare Professionals That Promote Weight Management

Robert Scales¹, Joseph H. Miller², Hamy Temkit¹, Michaele Menghini¹, Jacqueline Elder³, Amy Foxx-Orenstein¹. ¹Mayo Clinic, Scottsdale, AZ. ²University of New Mexico, Albuquerque, NM. ³Dominican University, River Forest, IL.
 Email: scales.robert@mayo.edu
 (No relationships reported)

PURPOSE: To evaluate the effect of a behavior change counseling training intervention on clinician proficiency.

METHODS: In this observational study, a self-selected group of 13 female clinicians (62% physicians/mid-levels) were evaluated before and after an introductory training in motivational interviewing (MI). Two experienced trainers conducted a standard 2-day workshop that focused on weight management. The clinicians were evaluated with the CARE Measure for 4-wks before and 6-wks after the workshop. This confidential 10-item questionnaire assessed relational empathy from the patient perspective on completion of clinical visits (n=531). The CARE Measure was scored on a 1-5 Likert scale. The clinicians provided an audio-taped recording of a clinical visit of their choice pre and post workshop (PW). The recording was anonymously analyzed by a coding expert. The MITI 4.2 Coding Instrument scored the visits on global ratings that used a 1-5 scale and an objective behavioral count to determine MI proficiency. A pre and PW clinician self-evaluation measured perceived proficiency and intent to use MI.

RESULTS: The overall mean score for the CARE Measure was 48.8 (SD=3.1) out of a maximum of 50 at baseline (BL) and 48.9 (SD=3.0) PW (p>0.05). The overall mean global rating for the MITI was 3.6 (SD=1.2) out of a maximum 5 at BL and 3.8 (SD=0.9) PW (p>0.05). For the behavioral count, the mean reflection-to-question ratio was 0.4 (SD=0.3) at BL and 0.5 (SD=0.3) PW (p>0.05). The mean MI adherent behavior count was 7.5 (SD=6.6) at BL and 8.3 (SD=3.8) PW (p>0.05). The mean MI

non-adherent behavior count was 1.4 (SD=0.6) at BL and 0.2 (SD=0.6) PW ($p < 0.05$). The mean persuasion behavioral count with and without permission was 6.8 (SD=3.5) at BL and 2.9 (SD=1.5) at PW ($p < 0.05$). The mean overall self-perceived proficiency and intent to use MI was 7.6 (SD=1.1) at BL and 8.8 (SD=0.7) PW ($p < 0.05$).

CONCLUSIONS: Preliminary findings of this pilot study did not identify significant change in MI proficiency. However, trainees used significantly less persuasion, patient evaluations remained high and clinician self-evaluation scores improved significantly. Short-term measures from these varied methods of evaluation may provide useful feedback to clinicians for ongoing MI skill development.

2125 Board #138 June 1 2:00 PM - 3:30 PM
Results Of An Eim Based Lifestyle Modification Program On Clinical Outcomes In Obese, Pre-diabetic Patients

David M. Nichols¹, Edward Seger², Peter Cummings³, Paul Washburn⁴, Peter Horvath⁵. ¹*Stony Brook University, Stony Brook, NY.* ²*SUNY Downstate Medical Center, Brooklyn, NY.* ³*Restore Medical Fitness, Buffalo, NY.* ⁴*Cheyenne Regional Medical Center, Cheyenne, WY.* ⁵*University at Buffalo, Buffalo, NY.*

Email: david.m.nichols@stonybrookmedicine.edu

(No relationships reported)

Purpose

To determine if an Exercise Is Medicine (EIM) modeled, lifestyle modification program, including nutrition education and support, exercise programming and health coaching would produce enhanced clinical outcomes and greater reduction in risk than current standard of care in an obese, pre-diabetic population.

Methods

Data was collected from a single center clinical practice with trained nutritionists and exercise physiologists. Inclusion criteria consisted of obese patients (BMI >30 m/kg²) which had additional comorbid health conditions. The 12-week program consisted of: initial assessment (baseline fitness and health markers and goal planning), a health intervention (lifestyle and nutrition counseling, personalized individual and group training, and health education), and outcome assessment (repeat fitness and health assessment). Participants in this program were compared to similarly matched control patients who were given standard of care treatment (physician recommendations on diet and exercise), and had received similar health marker screening at initial visit and again between 3 and 6 months post physician appointment.

Results:

A total of 362 participants met criteria to be included in this data set. 69 intervention group with a mean starting age of 60 years of age and a starting BMI of 38.0 kg/m². 293 control, with a mean starting age of 71 years and starting BMI of 34.8 kg/m². The intervention group saw reduction in HbA1C (5.9 vs 5.7%), Total cholesterol (170 vs 159 mg/dL), and Triglycerides (154 vs 136 mg/dL), and weight (238 vs 222 lbs). By comparison, the HbA1C and weight of the control group were not significantly changed from baseline (HbA1C 6.5 v 6.5%; Weight 219 v 217 lbs). Fitness levels were also significantly increased in the intervention group (22 v 26 ml/kg/min).

Conclusion:

In obese, pre diabetic patients, preliminary data reported shows a significant improvement in health markers and fitness levels following a comprehensive 12-week program utilizing trained exercise and nutritional professionals, individualized coaching and goals, and health education. This data suggests that this inclusive model of health intervention may be beneficial for at risk patients, and is promising for individuals choosing between various treatment modalities.

The Antihypertensive Benefits Of Yoga: A Meta-Analysis

Yin Wu¹, Hayley V. MacDonald², Blair T. Johnson¹, Rebecca Acabchuk¹, Jill Livingston¹, Crystal S. Park¹, Linda S. Pescatello, FACSM¹. ¹*University of Connecticut, Storrs, CT.* ²*University of Alabama, Tuscaloosa, AL.* (Sponsor: Linda Pescatello, FACSM)

Email: yin.2.wu@uconn.edu

(No relationships reported)

Yoga practice elicits changes in resting blood pressure (BP) ranging from -29 to +10 mmHg. Reasons for this large variability in the BP response are not clear. **PURPOSE:** To investigate the efficacy of Yoga as antihypertensive therapy and identify moderators of the BP response to Yoga. **METHODS:** Database searches identified 44 controlled Yoga trials that involved adults ≥ 19 yr, yielding 49 interventions. Analyses followed random-effects assumptions. **RESULTS:** Participants ($N=3,376$) were middle-aged (48.2 \pm 16.1yr), overweight (27.3 \pm 3.8kg/m²) adults with prehypertension (systolic BP [SBP]/diastolic BP [DBP], 129.3 \pm 14.0/ 80.9 \pm 9.1mmHg). Yoga was practiced 3.9 \pm 3.1 sessions/wk for 61.0 \pm 22.0 min/session for 14.8 \pm 13.5 wk. Overall, Yoga elicited

moderate reductions in SBP ($d = -0.48$, 95% CIs: -0.63, -0.33; -4.3mmHg) and DBP ($d = -0.50$, 95% CIs: -0.64, -0.35; -3.4mmHg) compared to control ($ps < 0.001$). Yoga produced greater SBP reductions among: samples with hypertension (-11.8mmHg, $k=13$) than prehypertension (-6.6mmHg, $k=20$) and normal BP (-2.9mmHg, $k=14$, $p < 0.001$); interventions located in India (-9.9mmHg, $k=21$) than non-India Asian (-7.0 mmHg, $k=9$) and non-Asian (-4.2mmHg, $k=17$, $p < 0.012$) countries; and interventions with the largest variance (i.e., standard error) in the BP response (-20.0mmHg, $k=15$) than moderate (-6.5mmHg, $k=16$) and small (-1.6mmHg, $k=16$, $p < 0.001$). Yoga produced greater DBP reductions among: samples with hypertension (-10.2mmHg, $k=5$) than prehypertension (-5.4mmHg, $k=14$) and normal BP (-2.1mmHg, $k=24$, $p < 0.001$); interventions located in India (-4.0mmHg, $k=20$) than non-India Asian (-2.3mmHg, $k=8$) and non-Asian (-0.8mmHg, $k=15$, $p < 0.019$) countries; and samples that practiced Yoga with a balanced combination of breathing, postures, and meditation/relaxation (-5.8mmHg, $k=25$) than Yoga largely focused on a single practice (e.g., left nostril breathing) (-2.3mmHg, $k=18$, $p = 0.006$). **CONCLUSION:** Overall, 60 min of Yoga practiced 4 sessions/wk lowered BP ~3-4 mmHg among adults with prehypertension. Yoga reduced SBP/DBP ~12/10 mmHg among adults with hypertension, reductions nearly double of those reported with aerobic exercise. Yet caution is warranted in the clinical translation of our findings until future controlled trials specifically designed to target BP confirm them.

Effectiveness Of A 10-wk Lifestyle Modification Program In Reducing Hypertension In Brazilian Free-Living Adults

Roberto C. Burini, FACSM, Loraine Gollino, Hugo T. Kano, Mariana S. Nakagaki, Franz H P Burini. *UNESP Medical School, Botucatu, SP, Brazil.*

Email: burini@fmb.unesp.br

(No relationships reported)

PURPOSE: High blood pressure (BP) is a strong, independent and etiologically relevant risk factor for cardiovascular diseases. Free distribution of more than 15 medications for HYPertension and DIAbetes (HIPERDIA program) clearly shows the important role of drugs in the Brazilian Government's effort to tackle these two diseases. Each medicated BP subject has an estimated cost of US\$ 39.50. However, drug therapy has been largely unsuccessful in halting and reversing the hypertension epidemic and more emphasis must be placed on primary prevention guidelines. BP is often associated with unhealthy lifestyles such as consumption of high fat and/or high-salt diets and physical inactivity.

METHODS: A lifestyle modification program (LSM) involving dietary counseling and regularly supervised physical activity ("Move for Health") has been used here, since 1991, for NCDs primary care. Cross-sectional analysis of clinical, anthropometric, dietary and physical activity data from 1317 subjects (2006-2016) was used to characterize the BP subjects at baseline. Next, a sub-sample ($n=453$) were submitted to a 10-wk LSM and repeated assessments. Statistical comparisons were defined by $p=0.05$.

RESULTS: The BP rate (higher than 140/90mmHg) was 51.2% for SBP and 42.7% for DBP. The top quartile of blood pressure (142.2/88.5mmHg) differed from the lower quartile (120.6/69.2mmHg) by being older and lower either, schooling, income, physical activity (IPAQ) and aerobic capacity (VO₂max.). The p75 showed a low quality diet (HEI score) with more processed foods (higher CHO/fiber, sodium/potassium and saturated fat). They showed also a higher body fatness and prevalence of metabolic syndrome (MetS) along with MetS comorbidities of inflammation, peroxidation and insulin resistance but, without differences in the Framingham score. After 10 weeks of LSM the BP normalization achieved 17.8% for SBP and 9.3% for DBP with a net effectiveness of 8.5% and 2.4%, respectively. The reduction of BP was followed by increased aerobic conditioning and reduced intake of processed foods along with decreased values of BMI, abdominal fatness and comorbidities.

CONCLUSIONS: Based on this effectiveness and, if applied nationwide, one would save medications for 3.1 million of Brazilian hypertensives at an estimated saving of US\$ 1.47 billion a year!

2128 Board #141 June 1 2:00 PM - 3:30 PM
The Effects of a Group Exercise Rehabilitation Session on Stroke Survivors

Steve Meadows, Roisin Sullivan. *University of Kent, Chatham Maritime, United Kingdom.*

Email: s.meadows@kent.ac.uk

(No relationships reported)

UK stroke mortality rates are falling, but > 50% of stroke survivors have functional disabilities. These impairments reduce capacity to perform activities of daily living (ADL) such as walking, basic self-care and independence, even several years post-stroke. Disability predisposes them to a chronic sedentary lifestyle, leading to further deconditioning and muscle atrophy, compounding disability. Cardiorespiratory fitness (CRF) is markedly reduced in a stroke population, with survivor VO₂ max \approx 50%

below a healthy age-matched population. Hypertension (HTN) is a modifiable risk factor for stroke, yet 75% of recurrent stroke sufferers have HTN. In the UK there is no routine exercise provision for chronic care of stroke survivors. **PURPOSE:** To investigate the impact of a weekly community-based group exercise session on key health parameters and functional capacity of stroke survivors.

METHODS: 10 (63.70±13.21 yrs; 4 females; 6 males) stroke survivors were referred by an acute stroke rehabilitation team to a community-based exercise session. This referral pathway was set-up as a collaboration between the local health care providers and the University of Kent. Participants attended once a week, completing a series of cardiovascular conditioning exercises (circuit format), strength and flexibility training. Health (weight, BMI, resting heart rate, resting systolic and diastolic blood pressure (SBP and DBP), waist circumference) and functional capacity (six-minute walk distance (6MWD), timed up and go, grip strength) assessments completed after 10 sessions (10 weeks).

RESULTS: Reductions in resting SBP (136.30±14.40 mmHg vs 150±14.19 mmHg $p=0.006$) and DBP 76.50±10.91 mmHg vs 83 mmHg $p=0.035$). 6MWD increased (392±112.29 m vs 321.90±106.88 m $p=0.001$). **CONCLUSIONS:** A once a week exercise session reduced SBP to < 140 mmHg and DBP in stroke survivors, who were already medicated with anti-hypertensives. Improved physical capacity evidenced by increased 6MWD. Walking speed increased from 53.65 m.min⁻¹ (3.2 kph) to 65.33 m.min⁻¹ (3.9 kph); improved walking speed ≈3.0 METs (≈2.5mph). This study emphasises the importance of continued exercise rehabilitation post-stroke for further HTN risk factor management (secondary prevention) and continued recovery of physical condition.

Mechanical Adaptations In Walking Performance Using Ankle Foot Orthoses For Patients With Peripheral Artery Disease

Ryan L. Mizner¹, Ashley A. Mays², Ryan J. Mays³. ¹University of Montana, Missoula, MT. ²North Memorial Medical Center, Robbinsdale, MN. ³University of Minnesota, Minneapolis, MN. Email: ryan.mizner@umontana.edu

(No relationships reported)

PURPOSE: Part of the limited success of community-based walking programs for people with peripheral artery disease (PAD) and intermittent claudication (IC) in the calf is a lack of strategies to manage pain during exercise. Carbon fiber ankle foot orthoses (AFO) could delay the onset of IC as they store elastic energy during stance that assists the calf muscles during gait propulsion. Clinical dogma may limit AFO implementation as many practitioners believe that AFO will reduce muscle recruitment during gait with a decline in function over time. Our purpose was to determine the gait adaptations in ankle mechanics, walking speed, and calf muscle recruitment when using AFOs to supplement a community walking program.

METHODS: Fifteen patients with PAD (Age=67±12 yrs) were fitted with bilateral AFO. An initial 3D gait analysis with plantar flexor electromyography data was completed 1 week after fitting. We used a within-session comparison of walking with/without the AFO. Patients were then given standard advice to walk at home using the devices ad libitum for 12 weeks. Twelve patients completed follow up testing after 12 weeks. Differences between conditions and test times were analyzed using paired t-tests.

RESULTS: The AFO reduced peak ankle plantar flexion power during the propulsion phase of walking at initial testing (mean±SE with AFO=1.5±0.2 W·kg⁻¹, without AFO=2.6±0.3, $p<0.001$). Reduced propulsion power was coupled with 4.5° less dorsiflexion during the terminal phase of stance (with AFO=8.6±0.7°, without AFO=13.6 ± 0.9°, $p<0.001$). Peak ankle plantar flexion moment and calf muscle recruitment did not change between conditions ($p>0.05$). The same pattern of results occurred at 12 weeks with no change in the variables over time ($p>0.05$). Gait speed was constant between conditions and over time ($p>0.05$; pooled initial=1.09 m·sec⁻¹, pooled 12 weeks=1.06 m·sec⁻¹). **CONCLUSIONS:** Maintenance of calf muscle recruitment when using the AFO was an unexpected, but favorable finding that contradicts conventional wisdom. Patients maintained normal values of ankle motion using AFO and sustained their gait velocity over time. The AFO reduces power demands on the calf muscle which has potential to reduce IC while still maintaining muscle integrity and walking function. Funding: Pilot and Mini-grants from NIH NIGMS 5U54GM104944.

The Acute Arterial Stiffness Response to Interval vs. Continuous Exercise in Postmenopausal Women

Emily M. Miele, Christa Winter, Richard J. Wood, Samuel A. E. Headley, FACSM. *Springfield College, Springfield, MA.* (Sponsor: Dr. Samuel A. E. Headley, FACSM)

(No relationships reported)

High Intensity Interval Exercise (HIIIE) has been associated with greater reductions in cardiovascular disease (CVD) risk factors when compared to continuous moderate

exercise. Arterial stiffness (AS) is an independent risk factor for CVD that increases exponentially in women following menopause. **PURPOSE:** The current research was designed to investigate the acute AS response to a single bout of HIIIE versus a single bout of moderate continuous endurance exercise (MCE) in postmenopausal women. **METHODS:** A total of 13 women (age = 60.85 ± 4.41 years) completed the study. Subjects completed both a HIIIE and a MCE treadmill protocol on separate occasions. Time of the MCE intervention was adjusted to match for the average number of heart beats obtained during the HIIIE intervention. Pulse wave velocity (PWV), augmentation index (AIx), central systolic blood pressure (CSBP), and central diastolic blood pressure (CDBP) were measured pre exercise, 15 min post exercise, and 30 min post exercise to assess arterial stiffness. **RESULTS:** No significant interaction ($p > .05$) between exercise intervention and time was determined for PWV, AIx, CSBP, or CDBP. No change in PWV was found from pre to post exercise ($p = .109$). A trend was found for a greater decrease in AIx following HIIIE compared to the decrease in AIx following MCE ($p = .086$). A significant decrease in AIx was found from pre exercise to 15 min post exercise ($p = .002$; $M_{pre} = 33.91$, $M_{15post} = 27.40$) and from pre exercise to 30-min post exercise ($p = .035$; $M_{pre} = 33.91$, $M_{30post} = 28.67$). **CONCLUSION:** The results of this study indicate that whether postmenopausal women perform MCT or HIIIE, the acute response of central arterial stiffness does not differ. No change in PWV from pre to post exercise was found for either exercise intervention.

Physical Activity After Hospitalization For Acute Coronary Syndrome: Correlates Of Exercise Days Using Objective Measures

Ashley M. Goodwin¹, Ian M. Kronish², Nathalie Moise², Andrea T. Duran¹, Carol Ewing Garber, FACSM¹, Joseph E. Schwartz², Keith M. Diaz². ¹Teachers College, Columbia University, New York, NY. ²Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY. (Sponsor: Carol Ewing Garber, FACSM)

(No relationships reported)

Exercise is essential in the secondary prevention of acute coronary syndrome (ACS). To date, there is a lack of data examining factors associated with objectively measured exercise in ACS patients post-discharge, a critical window for (re)forming health habits. **PURPOSE:** The purpose of this study was to examine factors associated with lack of exercise among ACS patients over the first 5 weeks post-discharge.

METHODS: ACS patients (myocardial infarction or unstable angina; N=269) from a hospital in Upper Manhattan were enrolled into an observational cohort study. Patients wore a wrist-based accelerometer for 35 days post-discharge. Days in which participants accumulated ≥30 min of moderate to vigorous physical activity in bouts ≥10 min were considered exercise days, expressed as % of days exercised over the 35 day wear period. Multivariable logistic regression models were used to examine correlates of non-exercise (0 days over the 35 day period), which included sociodemographic factors (age, sex, race, body mass index [BMI], partner status, social support), psychological factors (depression, post-traumatic stress disorder), health status/disease severity (GRACE risk score, Charlson comorbidity index [CCI], perceived mental and physical health [SF-12]), and hospital length of stay (LOS) and procedures (coronary artery bypass grafting [CABG], percutaneous coronary intervention [PCI]). All models were adjusted for age, sex, race, and ethnicity. Data are reported as odds ratios (OR) and 95% confidence intervals (CI). **RESULTS:** Among the 269 patients, 63.6% did not exercise at all. Factors associated with non-exercise were GRACE risk score (OR: 1.03; 95% CI: 1.01-1.04; $p=0.003$), LOS (OR: 1.15; 95% CI: 1.05-1.26; $p=0.002$), PCI (OR: 0.26; 95% CI: 0.12-0.58; $p=0.001$), CABG (OR: 5.46; 95% CI: 1.50-19.86; $p=0.010$), BMI (OR: 1.09; 95% CI: 1.03-1.15; $p=0.003$), and perceived physical health (OR: 0.96; 95% CI: 0.93-0.98; $p=0.002$). **CONCLUSION:** In ACS patients in whom exercise participation was objectively measured for 35 days post-hospitalization, factors related to poorer physical health and greater disease severity, but not psychological factors, were associated with low frequency of exercise. Future research may be warranted to elucidate how to address these factors to increase exercise post-ACS.

(No relationships reported)

PURPOSE: Breast cancer survivors (BCS) are at great risk for low physical activity (PA) levels and quality of life. Applying affordable wearable fitness bands to track PA while also serve to provide predictive utility regarding clinical biomarkers may

enhance health professionals' ability to prevent and manage disease recurrence for BCS. This cross-sectional study described objective PA data from the Xiaomi Mi wrist band among Chinese BCS while evaluating if PA data is predictive of clinical biomarkers.

METHODS: A total of 95 Chinese BCS ($\bar{X}_{age} = 44.8 \pm 7.9$ years; $\bar{X}_{BMI} = 22.2 \pm 3.5$) participated in baseline measurements of a larger parent intervention. Inclusion criteria were: 1) ≥ 21 years old; 2) diagnosed with stage 0-III breast cancer; and 3) completed primary cancer treatment 3 months to 10 years earlier with no new or recurrent cancer. BCS were given the fitness band for 4 weeks after which blood assays were taken to assess biomarker levels. The PA outcome was average steps/day while biomarkers included total cholesterol, triglycerides, high- and low-density lipoproteins (HDL and LDL, respectively), two-hour postprandial blood glucose (2HrBG) change, carcinoembryonic antigen (CEA), and cancer antigen 15-3 (CA 15-3). Descriptive statistics were conducted for all variables while regression analyses assessed if average steps/day predicted the aforementioned biomarkers.

RESULTS: Chinese BCS were observed to take an average 10,635 steps/day. Null to weak correlations between average steps/day and biomarkers (range $r = -.18$ to $.24$) were observed. Regression analyses indicated average steps/day to only be significantly predictive of HDL, $r^2 = .06$, $p = .04$, with marginal predictive utility of average steps/day seen for CEA, $r^2 = .04$, $p = .08$. Specifically, higher average steps/day was associated with slightly higher HDL and CEA levels. Yet, patients' PA failed to significantly predict other biomarkers.

CONCLUSIONS: Use of PA data from a wearable fitness band has some predictive utility for certain biomarkers. Notably, findings suggest health professionals may want to focus on increasing PA in BCS with lower HDL levels while tracking abnormally high CEA levels. Greater predictive utility of the Xiaomi Mi for clinical biomarkers might be seen with larger samples of BCS.

Cardiorespiratory Fitness And Muscle Strength In Pancreatic Cancer Patients

Joachim Wiskemann¹, Dorothea Clauss¹, Cornelia M. Ulrich², Thilo Hackert³, Lutz Schneider³, Christin Tjaden³, Karen Steindorf⁴. ¹National Center for Tumor Diseases, Heidelberg, Germany. ²Huntsman Cancer Institute, Heidelberg, UT. ³Heidelberg University Hospital, Heidelberg, Germany. ⁴German Cancer Research Center, Heidelberg, Germany.
Email: joachim.wiskemann@nct-heidelberg.de
(No relationships reported)

Pancreatic cancer is the fourth most common cause for cancer death. Despite progress in diagnosis and therapies in recent years, the 5-year survival rate of all stages is still only 6%. Exercise-related research in this patient group is widely missing. **PURPOSE:** It is well known, that cancer patients frequently experience reduced physical fitness due to the disease itself as well as treatment-related side effects. However, studies on physical fitness in pancreatic cancer patients are missing. Therefore, we assessed cardiorespiratory fitness and muscle strength in this patient group. **METHODS:** Sixty-five pancreatic cancer patients, mostly after surgical resection, were included in this study. Cardiorespiratory fitness was assessed using cardiopulmonary exercise testing (CPET) and 6-minute walk test (6MWT). Hand-held-dynamometry was used to evaluate isometric muscle strength. Physical fitness values were compared to reference values from a healthy population. Associations between sociodemographic and clinical variables with patients' physical fitness were analyzed with multiple regression models. **RESULTS:** Cardiorespiratory fitness (VO_{2peak} , 20.5 ± 6.9 ml/min/kg) was significantly lower (-24%) compared to healthy reference values. In the 6MWT pancreatic cancer patients nearly reached predicted values (555 vs. 562 meters). Maximal voluntary isometric contraction (MVIC) of the upper (-4.3%) and lower extremities (-13.8%) were significantly lower compared to reference values. Overall differences were larger in men than in women. Participating in regular exercise in the year before diagnosis was associated with greater VO_{2peak} ($p < .05$) and MVIC of the knee extensors ($p < .05$). **CONCLUSIONS:** Pancreatic cancer patients had significantly impaired physical fitness with regard to both, cardiorespiratory function and isometric muscle strength, already in the early treatment phase (median 95 days after surgical resection). Our findings underline the need to investigate exercise training also in pancreatic cancer patients to counteract the loss of physical fitness. Aerobic Exercise And Cancer-Related Fatigue In Adults: A Re-examination Using The Ivhet Model

George A. Kelley, FACSM, Kristi Sharpe Kelley. West Virginia University, Morgantown, WV.
Email: gkelley@hsc.wvu.edu
(No relationships reported)

BACKGROUND: Using the traditional random-effects model, a recent meta-analysis of randomized controlled trials reported a statistically significant standardized mean

difference (SMD) reduction in cancer-related fatigue (CRF) as a result of aerobic exercise (SMD, -0.22, 95% CI, -0.39 to -0.04, $p = 0.01$). However, a recently developed inverse heterogeneity (IVhet) model has been shown to be more valid than the traditional random-effects model. **PURPOSE:** The purpose of this study was to compare these previous meta-analytic results with those using the IVhet model. **METHODS:** Using data from a previous meta-analysis that included 36 SMD effect sizes (ES's) representing 2,830 adults (1,426 exercise, 1,404 control), results were pooled using the IVhet model. In addition, absolute and relative differences between the IVhet and random-effects results for CRF were calculated as well as influence analysis with each SMD ES deleted from the IVhet model once. Non-overlapping 95% confidence intervals were considered statistically significant. **RESULTS:** A statistically non-significant reduction in CRF fatigue was found as a result of aerobic exercise using the IVhet model (SMD, -0.08, 95% CI, -0.31 to 0.14, $p = 0.46$). The IVhet model yielded a SMD ES that was 0.14 (63.6%) smaller than the random-effects model. With each study deleted from the IVhet model once, results remained statistically non-significant with SMD ES's ranging from -0.11 (95% CI, -0.33 to 0.11) to -0.06 (95% CI, -0.28 to 0.16). **CONCLUSIONS:** The results of the current study suggest that there is currently insufficient evidence to support the use of aerobic exercise for reducing CRF in adults. Future studies should consider use of the IVhet versus traditional random-effects model when conducting aggregate data meta-analyses. Supported by NIH Grant U54GM104942

Examining The Relationships among Chinese Breast Cancer Survivors' Psychosocial Outcomes and Physical Fitness

Nan Zeng¹, Chunyuan Han², Ning Liao³, Zan Gao, FACSM¹. ¹University of Minnesota, Minneapolis, MN. ²South China University of Technology, Guangzhou, China. ³Guangdong People's General Hospital, Guangzhou, China. (Sponsor: Zan Gao, FACSM)
Email: zengx185@umn.edu
(No relationships reported)

Purpose: A decline in physical fitness has been evident among breast cancer survivors (BCS) following diagnosis. Yet, the relations among psychosocial beliefs and fitness in this population remains unexplored. This study investigated the correlates of psychosocial outcomes and fitness in Chinese BCS while determining the extent to which whether patients' fitness can be predicted by psychosocial factors.

Methods: A total of 135 BCS ($M_{age} = 44.3$, $SD = \pm 8.1$) were recruited from Southern region of China. Selected psychosocial outcomes were assessed by validated Patient-Centered Assessment and Counseling for Exercise Scale (2001), including physical activity confidence (PAC); physical activity family support (PAF); physical activity friend support (PAF); and physical activity environment factors (PAEF). Patients' fitness testing consisted of leg strength and endurance (LSE; 30-second chair stand test); upper body strength and endurance (UBSE; 30-second arm curl test); lower body flexibility (LBF; chair sit and reach test); shoulder range of motion (SRM; measured by back scratch test); aerobic endurance (AE; 2-minute step test); and mobility and balance (MB; up and go test).

Results: Correlation analyses revealed no significant relationships were observed among psychosocial outcomes and overall fitness ($p > .05$). However, PAC was positively correlated with LBF ($r = .18$, $p < .05$), despite correlation was low. Regression analysis indicated the overall model was statistically significant when PAC was used to predict LBF [$F(1, 133) = 4.1$, $p < .05$, $r^2 = .03$], suggesting PAC was a significant predictor of LBF ($t = 2.1$, $p < .05$).

Conclusion: Findings suggest that as BCS's PAC increases, their LBF is expected to increase modestly. Additionally, findings indicate that PAC significantly predict LBF—suggesting PAC may be a determinant of patients' low body fitness. Nevertheless, other psychosocial outcomes were not significantly associated with any fitness component. It appears that psychosocial factors may not serve as ideal determinants for BCS' fitness. Future research is warranted, therefore, to investigate other factors such as physiological and rehabilitative outcomes that may influence fitness in this population.

2136 Board #149 June 1 2:00 PM - 3:30 PM
Physical Activity Levels and Cardiometabolic Risk Factors in Adults with Asthma-COPD Overlap Syndrome (ACOS).

David Jagroop, Joshua Good, Shilpa Dogra. University of Ontario Institute of Technology, Oshawa, ON, Canada.
Email: david.jagroop@uoiit.net
(No relationships reported)

Asthma-COPD overlap syndrome (ACOS) is characterized by persistent airflow limitation and symptoms associated with both asthma and chronic obstructive pulmonary disease (COPD). However, those with ACOS have worse health outcomes than those with asthma or COPD alone. Regular physical activity may be important in the management of ACOS and the prevention of cardiometabolic comorbidities.

Purpose: To investigate the association between physical activity and the presence of ACOS, and second, to investigate the association between physical activity levels and cardiometabolic disease risk factors in adults with ACOS aged 45 years and older. **Methods:** The Canadian Community Health Survey (CCHS) is a cross sectional survey that collects information pertaining to the health determinants, health care utilization, and health status of Canadians. Data from respondents with ACOS (n= 1,569) and those without a respiratory condition (n= 64,175) from CCHS version 1.0, 2013 were analyzed. Self-reported physical activity was used to categorize respondents as active or inactive. Self-perceived health, body mass index and physician-diagnosed high blood pressure were used as outcomes. Descriptive statistics were used to calculate the frequencies of outcomes (physical activity level, self-perceived health, high blood pressure, and BMI) within the ACOS and no respiratory disease groups. Logistic regression analyses were conducted to determine the association between physical activity and ACOS, and between physical activity levels and cardiometabolic disease risk factors in ACOS. **Results:** Those with ACOS were 59% less likely to be physically active than those without a respiratory condition (OR = 0.59, CI = 0.50-0.71). Physically active adults with ACOS had higher odds of good self-perceived health (OR = 2.66, CI = 1.71-4.16), and were 60% less likely to report high blood pressure (OR = 0.60, CI = 0.43-0.86) than those who were inactive. BMI seemed to be an important correlate for self-perceived health, and high blood pressure, but was not significant when used as an outcome. **Conclusion:** Physical activity levels among adults with ACOS are low. This may increase their risk for poor health outcomes. Future research is needed to determine the effectiveness of exercise within this population.

Affective Response To Sprint Interval Exercise In Adults With And Without Exercise-induced Bronchoconstriction

Joshua Good, Shilpa Dogra. *University of Ontario Institute of Technology, Oshawa, ON, Canada.*
(No relationships reported)

Individuals with exercise-induced bronchoconstriction (EIBC) often experience symptoms such as wheezing, coughing and shortness of breath during or following exercise; this may lead to greater perceptions of in-task effort and less enjoyment. Adults with EIBC report higher affect after performing high intensity interval exercise compared to moderate intensity continuous exercise (MICE). **Purpose:** To examine in-task perceptions of effort, dyspnea, and affective feelings during a sprint interval exercise (SIE) and MICE session in adults with and without EIBC. **Methods:** Participants with EIBC (aged 22.0±2.6) and participants without EIBC (aged 21.7±0.6) completed SIE (4 x 30 second sprints at 0.075kg/kg bodyweight, separated by 4.5 minutes of unloaded cycling) and MICE (65% peak power output for 20 minutes) sessions. Ratings of perceived exertion (RPE), ratings of perceived dyspnea (RPD) and 1-item feeling scale (1-FS) were monitored each minute during exercise. The Physical Activity Enjoyment Scale was completed by participants following each exercise protocol. Participants were also asked if they preferred SIE or MICE after the second session. Sessions were completed in random order. **Results:** Among those with EIBC, average RPE was not different during MICE (13.4±1.9) compared to SIE (11.5±0.5, p=0.29), there were no differences in average RPD during MICE (4.5±1.4) compared to SIE (4.3±0.6, p=0.81), average affect was greater during MICE (2.8±1.6) compared to SIE (2.0±1.5, p<0.05), and differences in physical activity enjoyment scores for MICE (93.0±5.6) compared to SIE (77.0±4.6, p=0.09) were approaching significance. There were no differences in RPD or affect between those with and without EIBC for either SIE or MICE. Those without EIBC reported higher RPE during SIE and had a higher enjoyment scores for SIE compared to those with EIBC. Two thirds of participants with EIBC preferred MICE and all participants without EIBC preferred MICE. **Conclusion:** SIE was associated with similar exertion and dyspnea but lower affect and enjoyment compared to MICE. Therefore, SIE may not be recommended for adherence to regular exercise in adults with EIBC.

Physical Activity Interventions And Chronic Diseases: A Matched-Pair Analysis Comparing Cochrane And Non-Cochrane Systematic Reviews

Claudia Hacke¹, Kamal R Mahtani², Igho Onakpoya², Nia Roberts², David Nunan². ¹University of Oxford, Oxford, United Kingdom; ²University Medical Center Hamburg-Eppendorf, Hamburg, Germany. ²University of Oxford, Oxford, United Kingdom. (Sponsor: Reinhard G. Ketelhut, FACSM)
Email: c.hacke@uke.de
(No relationships reported)

PURPOSE: Systematic reviews and meta-analyses are important tools used to support evidence-based decisions in health care. A recent study concluded that non-Cochrane reviews report larger effect sizes with less precision when compared with Cochrane reviews. The analysis mainly considered pharmacological interventions. Therefore

we explored whether there were similar differences between the two types of reviews that examined the role of physical activity in chronic diseases. Such an analysis is particularly relevant to policy makers in ensuring that recommendations made to populations are based on the most accurate and precise evidence.

METHODS: This is a substudy of an overview of 56 Cochrane reviews with RCTs of physical activity interventions for chronic diseases (cancer; cardiovascular, respiratory, renal diseases; metabolic, mental, musculoskeletal disorders). A matched-pair analysis was chosen to contrast Cochrane and non-Cochrane reviews. A systematic literature search was undertaken to identify non-Cochrane reviews that matched based on intervention, condition, outcomes and publication year as in the corresponding Cochrane reviews. Methodological quality of the reviews was assessed using AMSTAR. The pairs will be contrasted in terms of frequency and degree of concordance in their results and whether differences affected the citation rate.

RESULTS: Of the 56 Cochrane reviews within our data set, we found 33 non-Cochrane reviews that met the eligibility criteria. The full analysis will be completed by the end of 2016 and final results will be presented fully for the first time at the ACSM meeting.

CONCLUSION: This is the first study comparing systematic reviews that were conducted within and outside the Cochrane Collaboration, in particular with respect to physical activity interventions for chronic diseases. Unlike a previous study using meta-analyses on medication therapy within the cardiovascular literature, we applied a more precise methodological approach that concurrently points out how differences can be explained. The findings of our study should make an important contribution to the field of evidence-based physical activity and emphasize that a critical appraisal of systematic reviews reporting physical activity interventions is highly recommended for health professionals.

P.p1 {margin: 0.0px 0.0px 0.0px 0.0px; Font: 24.0px Helvetica} Physical Activity For The Prevention And Treatment Of Major Chronic Disease: An Overview Of Systematic Reviews

David Nunan, Nikolas Bobrovitz, Ayo Ajanaku, Claudia Hacke, Igho Onakpoya, Nia Roberts, Sarah Thomas, Alice Tompson, Carl Heneghan, Kamal R. Mahtani. *University of Oxford, Oxford, United Kingdom.*
Email: david.nunan@phc.ox.ac.uk
(No relationships reported)

PURPOSE: Evidence of physical activity (PA) as beneficial for health stems mainly from observational studies. Findings from randomised controlled trials (RCTs) often differ and systematic reviews of RCTs demonstrate mixed results making translation into clinical practice difficult. An overview of existing review evidence is needed to identify PA interventions that are effective in preventing or treating major chronic disease.

METHODS: We searched the Cochrane Database of Systematic Reviews for reviews of RCTs restricted to 20 major chronic diseases. A minimum of two authors independently screened search outputs, selected studies, extracted data and assessed quality of included reviews using AMSTAR. Certainty of effect estimates was assessed using the GRADE method. Primary RCTs within included reviews found to demonstrate confounding were excluded, and affected pooled estimates were re-calculated. **RESULTS:** 56 Cochrane systematic reviews (49[88%] deemed high quality according to AMSTAR) across 20 chronic health conditions consisting a total of 829 RCTs and 65,032 participants were included. Data were extracted on 435 outcomes of which GRADE assessments were already available for 56 (13%) and newly derived for a further 189 (43%). We re-analysed 159 pooled-estimates across 27 reviews due to exclusion of 321 confounded trials. We found high quality evidence of a clinical and statistical benefit of PA for self-reported pain and self-reported pain and physical function in patients with osteoarthritis of the knee and hip; and dyspnoea and fatigue quality of life measures in patients with COPD. Conversely, high quality evidence for no effect of PA was found for bone mineral density of the neck, hip and trochanter in postmenopausal women; and disease activity and radiological damage in patients with rheumatoid arthritis. The remaining outcomes showed moderate (42[17%]), low (112[46%]) and very low (79[32%]) quality evidence, predominantly in favour of PA. **CONCLUSIONS:** A number of chronic health conditions for which clinical guidelines recommend physical activity may not be supported by high quality, clinically relevant evidence. Where there is a strong evidence-base, a formula of efficacious physical activity interventions is warranted but maybe hampered by heterogeneity within the available literature.

Evidence Of Benefits Of Exercise And Its Mechanisms In Inflammatory Arthritis

Dina C. Janse van Rensburg, FACSM, Audrey Jansen van Rensburg, Dimakatso A. Ramagole, Catharina C. Grant.
University of Pretoria, Pretoria, South Africa.
 Email: christa.jansevanrensburg@up.ac.za
 (No relationships reported)

INTRODUCTION: Rheumatoid arthritis (RA) and Ankylosing spondylitis (AS) are systemic, autoimmune diseases causing severe joint inflammation, leading to joint damage and functional disability. Both diseases may feature co-morbidities e.g. cardiovascular disease (CVD) and hypercholesterolemia. RA is most prevalent in individuals aged ≥ 18 years, with an estimated prevalence distribution of 0.4-1.3% worldwide. AS has an age onset of 15-35 years, typically affecting 7-9/100 000, with a 3:1 male-to-female ratio. **PURPOSE:** Evidence of benefits of exercise, and its hypothesised mechanisms in RA and AS patients were explored. **METHODS:** Research literature on stage of disease, amount and type of exercise and classification levels were assessed using Medline and Scopus databases.

RESULTS: Pre-evaluation includes staging of level of function (class I-IV) and assessment of disease activity and co-morbidities. Recommended amount and type of exercise vary depending on the site and amount of impaired joints, presence/absence of inflammation, joint stability and previous joint replacements. The FITT-Pro principle (frequency, intensity, time, type and progression) is followed in exercise prescription. Evidence of benefit of aerobic and resistance exercise programs shows an increase in aerobic capacity, muscle strength, self-reported functional ability, endothelial function, blood pressure, lipid profile, autonomic function and muscle mass, with a decrease in body fat percentage and trunk fat mass. Inflammatory disease is characterised by increased levels of circulating TNF α that induces cachexia and lead to deterioration of muscle strength. Pro-inflammatory cytokine production may also predispose patients to atherosclerosis, loss of muscle mass, and metabolic disorders (insulin resistance and dyslipidemia). Exercise not only improve functional outcome, but also induces an anti-inflammatory response, specifically suppressing TNF α production and stimulating the production of anti-inflammatory cytokines (IL-1ra and IL-10) via muscle derived IL-6. **CONCLUSIONS:** Scientific literature supports the benefit of exercise to both improve functional ability and reduce CVD mortality and other co-morbidities. Mechanisms of the effect of exercise are on functional and anti-inflammatory level.

Improving Strength and Mobility of Adults with Multiple Sclerosis Through a 16-week Exercise Program

Nadia R. Azar¹, Rosario Colomba², Kelly Carr¹, Krista J. Munroe-Chandler¹, Sean Horton¹, Chad A. Sutherland¹.
¹*University of Windsor, Windsor, ON, Canada.* ²*Xanadu Health Club, Lakeshore, ON, Canada.* (Sponsor: Dr. Russell Pate, FACSM)
 Email: azar5@uwindsor.ca
 (No relationships reported)

Canada has the highest prevalence rate of multiple sclerosis (MS) globally (291 per 100,000). People with MS often experience intense fatigue, muscle weakness, decreased aerobic endurance, loss of flexibility, and impaired balance and gait. To mitigate these symptoms, which negatively affect quality of life, physical activity is often recommended.

Purpose: To examine the effectiveness of a 16-week exercise program on improving common symptoms of MS.

Methods: Nine adults diagnosed with MS (M_{age} : 51.3 years; range: 42-65 years, 1 male) completed a progressive exercise program including cardiovascular, strength, flexibility, balance, and proprioception exercises (60 minutes, twice a week for 16 weeks). General measurements of health, physical fitness, functional movement, cognitive function, and quality of life were collected pre-, mid-, and post-program. A one-way ANOVA with repeated measures (Session: pre-, mid-, post-program) was performed on all dependent measures ($\alpha = 0.05$). Effect sizes were calculated using the partial omega-squared (ω^2_p) test.

Results: Collectively, participants showed significant ($p < 0.05$) improvements from pre- to post-program on the timed up-and-go (TUG) ($\omega^2_p = 0.21$) and wall push-up tests ($\omega^2_p = 0.45$). Strong trends ($p < 0.1$) toward improvement were shown for flexibility ($\omega^2_p = 0.19$), comfortable walking speed (CWS) ($\omega^2_p = 0.28$), gait cadence ($\omega^2_p = 0.20$), vitality ($\omega^2_p = 0.26$), fatigue ($\omega^2_p = 0.17$), and mental health ($\omega^2_p = 0.18$). Individually, five participants showed improvement in mental health, six showed improvement in cadence, and seven showed improvement in one or more of TUG, wall push-ups, flexibility, CWS, vitality, and fatigue (all pre- to post-program).

Conclusions: The progressive exercise program was successful in providing significant improvement in mobility (TUG) and upper body strength (wall push-ups). Although not statistically significant, strong trends were recognized in the areas of gait (CWS and cadence, which support the significant improvement in TUG) and quality of

life (vitality, fatigue, and mental health), which may be functionally meaningful. Future research could investigate the possibility of using exercise to slow the progression of the degenerative effects of the disease.

Supported by the University of Windsor Strategic Priority Fund.

Aquatic-Dietary Intervention On Fitness & Metabolism In SCI Individuals With Glucose > 100mg/dl

William H. Scott¹, Joanne Smith², Kylie James³, Peter H. Gorman¹, Paula R. Geigle¹. ¹*University of Maryland School of Medicine, Baltimore, MD.* ²*Fruitful Elements, Ontario, ON, Canada.* ³*Korunutrition, Ontario, ON, Canada.*
 Email: WilliamScott@umm.edu
 (No relationships reported)

PURPOSE: Assess dosed group aquatic exercise at 70-75% of heart rate reserve (HRR) and weekly nutritional guidance upon body mass, glucose, insulin, A1C, peak VO₂, and resting metabolic rate (RMR) for four individuals with CMISCI and a history of elevated fasting glucose concentrations greater 100 mg/dL.

METHODS: Four men (63 yo, AIS D, body mass index (BMI) 31.9; 34 yo non-ambulatory, AIS C, BMI of 31.6; 58 yo, AIS D, BMI 27.4; and 45 yo non-ambulatory, AIS C, BMI 28.56) enrolled in an individualized 10-week aquatic exercise (3 days per week for 40 minutes each session) and dietary guidance (by phone once per week) intervention. Nutritional guidance included reducing refined carbohydrates and processed food, limiting high glycemic fruits, and increasing vegetable, fluid and lean protein intake. Outcome measures (pre/post) included: three-day electronic food logs, weekly hard copy food logs, glucose, insulin and A1C (via standard fasting venipuncture), peak VO₂ and RMR.

RESULTS: Participant one decreased glucose, 20% (132 to 106 mg/dL); A1C, 11% (6.3-5.6); weight, 10%, (11.9 kg); RMR, 13%; and peak VO₂, 12%. Participant two showed no change in A1C or RMR; decreased weight, 3% (3.3kg); peak VO₂ (16.4%); and increased glucose 9%. Participant three decreased: glucose, 14%, (126 to 108 mg/dL); A1C, 5% (7.5 to 7.1); weight, 6% (88.9 to 83.8 kg); RMR, 12.5%; and increased peak VO₂ 8% (21.9 to 23.7). Participant four increased glucose, 9.3% (86 to 94 mg/dL); decreased A1C 5.5%; showed no change in weight; increased peak VO₂, 34.1%; and RMR, 24.6%.

CONCLUSIONS: Moderate exercise with weekly nutritional guidance decreased body mass, glucose, and A1C in individuals with CMISCI. Further examination of the impact of a low cost intervention of combined aquatic exercise with nutritional guidance exerts upon body mass, metabolic status, and cardiovascular fitness for individuals with CMISCI is indicated

D-66 Exercise is Medicine®/Poster - EIM - Older Adults

Long-term Exercise Program Enrolment in Older Adults: Effects on Cardiorespiratory and Musculoskeletal Fitness

Angelica M. McQuarrie, Maureen J. MacDonald. *McMaster University, Hamilton, ON, Canada.* (Sponsor: Dr. Stuart Phillips, FACSM)
 (No relationships reported)

Substantial research supports the benefits of exercise training for older adults, but much of the existing evidence comes from highly structured, laboratory-based interventions. A longitudinal investigation of the impact of enrolment in a community exercise program on cardiorespiratory fitness (CRF) and muscular strength among a heterogeneous population of older adults is warranted. **PURPOSE:** To examine changes in CRF and muscular strength among participants of the MacSeniors Exercise and Wellness program through a retrospective chart review. **METHODS:** Included subjects ($n = 124$) completed exercise tests prior to program entry and after a minimum of one-year participation in the program. One-sample t -tests were used to analyze rates of change in CRF and muscular strength (separately for each muscle group) in comparison to the population sample. The rate of 1.00% per year was selected for comparison because it is the minimum expected CRF decline. Rates of strength decline were compared to those established in the Health Aging and Body Composition Study (2006) by Goodpaster et al. (3.42% and 2.65% for men and women, respectively) due to its comparable design and participant characteristics. **RESULTS:** After a mean follow-up time of 5.2 ± 2.6 years, absolute- ($-0.29 \pm 0.58\%$, $p = 0.23$) and relative- ($0.06 \pm 0.62\%$, $p = 0.13$) changes in VO_{2peak} were not significantly different than the

minimum expected decline of 1.00% per year, among men. However, both measures of CRF significantly improved over time in women (absolute $\dot{V}O_{2peak}$ [2.25 ± 0.66%, $p < 0.001$]; relative $\dot{V}O_{2peak}$ [2.24 ± 0.68%, $p < 0.001$]). Changes in muscular strength were significantly less than the established rates of decline across all muscle groups in both men ([1-repetition maximum (1-RM) bench press: -0.38 ± 0.96%, 1-RM row: -0.01 ± 0.82%, 1-RM knee extension: 0.25 ± 0.83%], $p < 0.05$) and women ([1-RM bench press: 3.23 ± 1.11%, 1-RM row: 1.58 ± 0.91%, 1-RM knee extension: 0.73 ± 1.21%], $p < 0.05$). **CONCLUSION:** Enrolment in the MacSeniors Exercise and Wellness program attenuated the age-related decline in $\dot{V}O_{2peak}$ in women, but not in men in comparison to previously published rates of decline. Decline in upper and lower body large muscle force was attenuated in both men and women across all muscle groups compared to previously published normative rates of change.

Effects Of Mulan Quan On Physiological Functions In Middle-Aged And Elderly Women

Junzhi Sun, Qiang Jiang, Jie Feng. *Chengdu Sport Institute, Chengdu, China.* (Sponsor: Tongjian You, FACSM)
 Email: jzhsun@qq.com
 (No relationships reported)

Mulan Quan is a modern form of Tai Chi created specifically for women. **Purpose:** To explore the effects of Mulan Quan exercise on vascular function, pulmonary function and cardiovascular fitness in middle-aged and elderly women. **Methods:** Twenty middle-aged and elderly women were recruited from the Senile University of Chengdu, China. Women who were sedentary and had never practiced Mulan Quan were included in the control group ($n=10$, 57±5 years old), and those who had been practicing Mulan Quan for 4 years or longer were included in the exercise group ($n=10$, 60±5 years old). The exercise group practiced Mulan Quan 40-60 minutes each time, 3 times each week. Pulse wave velocity (PWV) and ankle-brachial blood pressure index (ABI) were determined by an Omron arteriosclerosis detector, forced vital capacity (FVC) was measured by spirometer, and cardiovascular fitness was evaluated by a step test. Independent t-tests were used for group comparisons. **Results:** For vascular function, PWV values from both sides were significantly lower in the exercise group than in the control group (left side: 1372.00±136.57 cm/s vs. 1687.00±1167.71 cm/s, $p<0.05$; right side: 1371.70±123.09 cm/s vs. 1661.30±180.25 cm/s, $p<0.05$), and ABI value from the right side was significantly lower in the exercise group than in the control group (1.07±0.07 vs. 1.14±0.06, $p<0.05$); there was no group difference in ABI values from the left side. For pulmonary function, the PVC was significantly higher in the exercise group than in the control group (2326.50±327.75 ml vs. 1938.00 ± 514.08 ml, $p<0.05$). For cardiovascular fitness, the step index was significantly higher in the exercise group than in the control group (66.50±8.57 vs. 59.20±6.27, $p<0.05$). **Conclusions:** Long-term Mulan Quan practice can significantly improve vascular function, pulmonary function and cardiovascular fitness in middle-aged and elderly women. Future studies are needed to elucidate the mechanisms through which Mulan Quan promotes health.

2145 Board #158 June 1 2:00 PM - 3:30 PM
Age, Physical Activity, And Body Composition Independently Influence Physical Function In Middle-aged And Older Women

Rachel E. Salyer¹, Rachele A. Reed¹, Chad R. Straight², Christie L. Ward-Ritacco³, Anne O. Brady⁴, Lauren Q. Higgins¹, Ellen M. Evans, FACSM¹. ¹University of Georgia, Athens, GA. ²University of Massachusetts, Amherst, MA. ³University of Rhode Island, Kingston, RI. ⁴University of North Carolina Greensboro, Greensboro, NC. (Sponsor: Ellen M Evans, FACSM)
 (No relationships reported)

PURPOSE: With aging, physical activity (PA) declines and adverse changes in body composition occur, including both increases in adiposity (%Fat) and reductions in lean mass (LM), negatively impacting lower-extremity physical function (LEPF) and risk for physical disability. However, the interactive effects of these factors on LEPF remains incompletely characterized in middle-aged and older women known to be at higher risk of physical disability compared to male counterparts. Thus, this study aimed to evaluate the associations of age, PA, %Fat, and leg LM relative to body weight (LEG-LM/BW) with LEPF in middle-aged and older females.

METHODS: Women ($n = 274$; 50-89 & 66.7±8.2 yo; 43.5 ± 6.8%Fat) were assessed for PA using accelerometry (NL-1000; 4 valid, 10-h days of wear), body composition via DXA and LEPF using a composite Z-score from 6-Minute Walk Test, Timed Up and Go, and 30-second Chair Stand scores.

RESULTS: Age, PA, %Fat, and LEG-LM/BW were all associated with LEPF ($r = -0.53, 0.58, -0.35, 0.27$ respectively; all $p < 0.01$). As expected mathematically, %Fat and LEG-LM/BW were strongly related ($r = -.95$; $p < 0.01$) thereby not included in the same regression model. Linear regression analyses revealed A) Age and %Fat independently explained 28% and 13% of the variance in LEPF, respectively (both $p < 0.05$); B) Age and LEG-LM/BW independently explained 28% and 12% of the

variance in LEPF, respectively (both $p < 0.05$). Within a subsample with objective PA ($n=166$; 50-77 & 62.8±6.7 yo; 6648 ± 2880 steps/day), linear regression analyses revealed A) Age, %Fat, and PA independently explained 21%, 26%, and 5% of the variance in LEPF, respectively (all $p < 0.05$); B) Age, LEG-LM/BW, and PA independently explained 21%, 21%, and 7% of the variance in LEPF, respectively (all $p < 0.05$). However, interactions among independent variables of interest (age, %Fat, LEG-LM/BW, and/or PA) were not predictors of LEPF (all $p>0.05$).

CONCLUSION: Our results confirm that age, %Fat, LEG-LM/BW, and PA are individually associated with LEPF but, the interactive influence of these inter-related factors on LEPF are less clear. Further study is warranted to determine the salient factors for intervention to ameliorate the age associated decline in LEPF increasingly observed in middle-aged women.

2146 Board #159 June 1 2:00 PM - 3:30 PM
Exercise-based Cardiac Rehabilitation Improves Physical Health And Quality Of Life In Elderly Women

Brendon H. Roxburgh, Stacey Reading. *The University of Auckland, Auckland, New Zealand.*
 Email: b.roxburgh@auckland.ac.nz
 (No relationships reported)

Post-event cardiac rehabilitation (CR) improves cardiorespiratory fitness (CRF) and quality of life (QoL) while reducing depression and anxiety. Unfortunately women are less likely than men to participate in CR, despite research showing women benefit from CR, more than men. Similarly, women who complete CR have a 64% reduction in mortality rate, compared to those who don't complete CR. Research on the efficacy of CR in elderly women is lacking and research is needed to assess exercise-based CR's role in physical health and quality of life post cardiac event.

PURPOSE: This study sought to examine the effectiveness of an exercise-based cardiac rehabilitation program on CRF, self-reported QoL, depression and anxiety in elderly women with CVD.

METHODS: Participants ($n=30$) with CVD (71.2 ± 5.2 yrs) were referred to an exercise-based CR program located in Auckland, NZ. All participants underwent baseline and follow-up assessment which included a ramped ECG monitored maximal exercise test with gas analysis, a QoL (Short Form-36), and Hospital Anxiety and Depression Scale (HADS) questionnaire. Participants completed 3 weekly sessions of aerobic (40-70% $\dot{V}O_{2R}$), resistance (1-2 sets; 12-15 reps at 40-80% 1RM) and balance and flexibility exercise, totalling approximately 60 minutes/session. Significantly different ($p<.05$) pre- vs. post-program values were identified by dependent t-tests. Data are the mean ± SD.

RESULTS: Post-program CRF significantly increased (18.5 ± 6.3 to 21.1 ± 7.5 $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) despite no significant increase in HRpeak (131.9 ± 28.7 to 132.1 ± 40.1 bpm) and respiratory exchange ratio (1.03 ± 0.1 to 1.03 ± 0.2) during maximal exercise testing. Resting heart rate decreased significantly (72.4 ± 11.8 to 68.6 ± 10.8 bpm), whilst no change in systolic (126.3 ± 24.2 to 129.8 ± 16.0 mmHg) or diastolic blood pressure (82.0 ± 16.0 to 79.2 ± 8.2) was observed. SF36 component scores for physical (49.4 ± 41.5 to 72.6 ± 37.3) and mental health (74.9 ± 15.9 to 82.8 ± 10.1) increased significantly while the HADs anxiety (5.6 ± 3.4 to 3.6 ± 2.3) and depression (2.9 ± 2.4 to 1.8 ± 1.8) scores were significantly lower post-program.

CONCLUSIONS: Twelve weeks of exercise-based exercise CR is safe and effective for increasing CRF, and QoL while reducing depression and anxiety in elderly women.

2147 Board #160 June 1 2:00 PM - 3:30 PM
Changes in Cardiometabolic Risk Factors after High-Velocity Circuit Resistance or Treadmill Training in Older Adults

Melanie Potiaumpai, Kirk Roberson, Kayla Widdowson, Sean Chowdhari, Annmarie Jaghab, Catherine Armitage, Katherine McGriff, Kevin A. Jacobs, FACSM, Joseph F. Signorile. *University of Miami, Coral Gables, FL.* (Sponsor: Dr. Arlette Perry, FACSM)
 Email: m.potiaumpai@umiami.edu
 (No relationships reported)

Cardiometabolic syndrome (CMS) is an aggregation of major risk factors that increases a person's risk for developing cardiovascular disease, diabetes mellitus and the risk of mortality from cardiovascular disease. Continuous treadmill training (TM) has been shown to effectively attenuate the magnitude of CMS risk factors in a multitude of clinical populations. However, there is a paucity of research on the effects of high-velocity circuit resistance training (CRT) on CMS risk factors in older adults.

PURPOSE: To compare the effects of CRT versus TM versus no exercise (CONT) on older adults with CMS risk factors. **METHODS:** Thirteen subjects (1M, 12F; 68.5 ± 7.3 years) with multiple risk factors for CMS participated in 12-weeks of CRT or TM. BMI, body fat % (BF), waist circumference (WC), systolic blood pressure (SBP), diastolic blood pressure (DBP), total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), triglycerides (TG), fasting glucose (GLUC), glycated hemoglobin (A1C), and C-Reactive Protein

(CRP) were measured before and after the training. Nutritional intake was monitored to eliminate influence on CMS biomarkers. **RESULTS:** A within-group analysis showed that CRT exhibited significant decreases in A1C (MD= -0.367, SE= .142, p=0.03), SBP (MD= -21.67, SE= 6.35, p<.01), and DBP (MD= 9.33, SE= 2.53, p=.01), while TM had a trend toward decreased LDL-C (MD= 15.25, SE= 8.16, p=.09), and CONT showed a trend toward increases in CRP (MD= -0.16, SE= .08, p=.08). CRT also exhibited greater decreases in BMI, BF, and CRP than TM and CONT after the intervention, although statistical significance was not reached. There were no significant changes in TC, LDL-C, TG, or GLUC in any group. A between-group analysis showed CRT had significantly greater decreases in DBP compared to TM (MD= -10.58, SE= 3.34, p=.03) and CONT (MD= -12.13, SE= 3.19, p=.01) and a trend toward decreased SBP compared to CONT (MD= -19.47, SE= 8.03, p=.08). **CONCLUSION:** These preliminary results indicate that CRT results in greater improvements in CMS risk factors than TM. Although statistical significance was not reached for certain risk factors, a larger subject pool may strengthen our results.

2148 Board #161 June 1 2:00 PM - 3:30 PM
Continued Improvement and Maintenance in Older Veterans After Two Years of Gerofit Exercise Program

Lydia Paden, Odessa Addison, Jamie Giffuni, Leslie I. Katzel.
Veterans Health Administration, Baltimore, MD.
 (No relationships reported)

PURPOSE: Gerofit is an outpatient facility-based clinical exercise program for Veterans ≥ 65 years that was developed at the Durham VA Medical Center. This model was implemented at the Baltimore VA Medical Center (BVAMC) Geriatric Research Education and Clinical Center (GRECC) in 2013. Participants in Gerofit receive individualized exercise programs based on their functional assessments to improve function and mobility. We assessed lower extremity function and mobility changes in Veterans who completed 2 years of Gerofit.

METHODS: Older Veterans (≥ 65 yr) with primary care at the BVAMC were referred to Gerofit. Veterans attended Gerofit sessions up to 3 d/wk. Assessments included measures of: lower extremity function (Short Physical Performance Battery (SPPB); 30 second chair stands), endurance (six-minute walk (6MW)), gait speed (10 meter walk), agility (8 foot up and go (TUG)) and balance (four-square step test (FSST)). A repeated measure ANOVA was used to compare function and mobility changes at baseline, 1 and 2 yrs of participation. When significant differences were found a Bonferroni Post-hoc was used.

RESULTS: Twenty-five Veterans (24 male, 69.7 ± 4.2 yr (mean \pm SD), 72% African American, BMI 32.9 ± 6.5 kg/m²) completed 2 yr of Gerofit. Data are presented as baseline, 1 yr, 2 yr. Lower extremity function improved 37% between baseline and 2 yr testing as measured by chair stands (12.1 ± 5 , 15.6 ± 7.1 , 16.6 ± 8.1 ; $p < 0.01$). Endurance increased 12% (502.8 ± 146.1 , 533.5 ± 179.6 , 563.9 ± 176 ; $p < 0.01$). TUG scores decreased 15% (7.6 ± 2.2 , 6.9 ± 2.6 , 6.7 ± 2.7 ; $p < 0.05$) and FSST decreased 8.7% (11.2 ± 3.8 , 9.8 ± 3.3 , 10.3 ± 5.6 ; $p < 0.05$). SPPB and 10 meter walk did not significantly improve ($p = 0.15$ and $p = 0.78$). No test resulted in significant changes between 1 yr and 2 yr ($p \geq 0.20$).

CONCLUSIONS: Veterans who participated in two years of Gerofit demonstrated significant improvements in dynamic balance, including lower body function, endurance, and agility. The SPPB did not significantly change and this may be due to a ceiling effect as baseline scores were 10 out of 12. These results demonstrate participation in Gerofit results in the significant changes in function after 1 year. These changes are maintained with exercise for a second year and suggest the importance of adhering to an exercise program to maintain physical function with aging.

The Challenges and Successes During a 12-week Exercise Program for Post-Menopausal Women: A Qualitative Study.

Ellen K. Payne¹, Joan Cebrick-Grossman². ¹Radford University, Radford, VA. ²University of Scranton, Scranton, PA.
 (No relationships reported)

Commitment and follow through to an exercise and weight-loss program can be challenging. One of the ways to improve retention is through self-monitoring techniques such as weekly journaling. During our study comparing high-intensity interval training (HIIT) and walking as forms of exercise among post-menopausal women we attempted use qualitative methods to explore what the participants experienced. **PURPOSE:** To investigate the thoughts and feelings, specifically related to the challenges and successes, participants experienced while completing a 12-week exercise program. **METHODS:** Participants (N=18) were post-menopausal (56 ± 5.94 years), sedentary female volunteers, randomly assigned into one of two exercise groups. Both groups exercised five out of seven days for 12 weeks. At the end of each week, participants submitted their answers to five open-ended reflective questions about their experience in the program, including the challenges and successes that week. This was done through an email exchange with a member of the research team. Additional specific follow-up questions were asked when needed.

A total of 187 weekly email exchanges were collected and coded using Dedoose software. Data were analyzed via a general inductive approach to identify significant themes. A constant comparison process was employed during analysis to identify commonalities and differences between the two groups and among individuals. Data saturation was reached. Trustworthiness was established via peer review. **RESULTS:** For both exercise groups, the major theme of support developed. This included support from family, peers, and the researcher. Between the groups different challenges were identified including time commitment and weather challenges for the walking group and the intensity of the workouts for the HIIT group. **CONCLUSION:** When working with clients attempting to lose weight and commit to an exercise program, support is a key component of success. When possible, family, co-workers, and others should be included in the process to encourage and help participants reach their goals. Weekly check-ins with a member of the research team is another way to facilitate program compliance and retention. Supported by Grant #CO-OP 2014-04 from University of Scranton and Marywood University, Scranton, PA.

Perceptions of Exercise Screening Among Older Adults

Andrea Petrella¹, Liza Stathokostas¹, Dawn Gill¹, Mary Duggan², Robert J. Petrella, FACS¹. ¹Western University, London, ON, Canada. ²Canadian Society for Exercise Physiology, Ottawa, ON, Canada. (Sponsor: Robert Petrella, FACS¹)
 Email: apetrel4@uwo.ca
 (No relationships reported)

PURPOSE: The older adult population is largely inactive and barriers and enablers to the initiation of exercise participation have been identified. To explore the perceptions of exercise screening among older adults in order to inform evolving screening guidelines, which seek to safely encourage as many people as possible to engage in regular healthful physical activity. **METHODS:** A convenience sample of 86 community-dwelling participants (mean age (SD): 75.7 ± 7.7 years; 44% female) underwent a physical exam and screening (stress test and the Get Active Questionnaire) at a research laboratory routinely conducting screening for community-based referrals. One week later, participants returned to the study site and were interviewed on perceptions of the screening process by a research assistant who documented all responses. Questions focused on physician evaluation, self-screening, how screening impacted willingness to exercise, and experiences in completing the questionnaire. Thematic analysis was conducted. **RESULTS:** Themes identified were that: (1) Older adults largely think it's a good idea to be screened for exercise (for precautionary reasons and to assess physical condition) and that screening independently of consulting their physician was positive; however, some older adults felt it was unnecessary as they were in good physical condition; (2) There is a lack of self-screening among most older adults, (3) Older adults may perceive that checking in with a health care provider is 'self-screening' and that a self-screening tool may be unnecessary and non-specific; (4) Most older adults do not feel that screening impacts their willingness to exercise and indicate that it is not inconvenient. For some older adults, screening increased their confidence and found the screening process reassuring and motivating. The questionnaire, while simple in design, had confusing format and wording for some; subjects suggested tools should address the need for simplicity of design, be convenient and instill motivation and confidence prior to starting or changing exercise behaviours. **CONCLUSION:** Our findings suggest older adults may find screening supportive of adopting exercise and that such tools should be simple, convenient and support motivation and confidence to exercise.

Fasting Plasma Glucose is Associated with the Heart Rate Response to Maximal Exercise

Nicole L. Koontz, Zoe G. Johnson, Mitchell H. Whaley, FACS¹, Leonard A. Kaminsky, FACS¹, Matthew P. Harber, FACS¹. Ball State University, Muncie, IN.
 (No relationships reported)

Introduction: Chronic hyperglycemia associated with diabetes impairs the exercise heart rate (HR) response. However, the relationship between fasting plasma glucose (FG) and chronotropic response to exercise has not been well characterized in individuals with normal and impaired FG values. **PURPOSE:** To evaluate the relationship between FG and multiple HR response indices during and after maximal cardiopulmonary exercise testing (CPX). **METHODS:** Data were obtained from

the Adult Physical Fitness Program cohort of CPX from 981 individuals (44±12 yr.; 51% male) without known cardiovascular or metabolic disease. Pearson and partial correlations examined the relationship between FG and resting HR, HR acceleration (HRacc), HR recovery (HRrec), HR reserve (HRres), % age-predicted max HR achieved (%APMHR), and chronotropic index (CI). Similar comparisons were made with HbA1c and HR responses in a subset of individuals (n=121). Additionally, individuals were grouped as (normal [NFG], impaired fasting glucose [IFG], diabetic [T2D]) based on ADA classification and compared for differences in HR responses. **RESULTS:** FG was positively correlated (P<0.01) with resting HR (r=0.085) and inversely with HRres (r=-0.125). HbA1c was positively correlated (P<0.01) with CI (r=0.200) and inversely with %APMHR (r=-0.214), HRrec (r=-0.233), and HRres (r=-0.338). After adjusting for age, sex, body mass index (BMI), and cardiorespiratory fitness (CRF), HbA1c remained inversely correlated with HRrec (r=-0.187, P<0.05). HRres displayed a graded relationship among groups being highest (P<0.05) in NFG and lowest (P<0.05) in T2D. Resting HR and CI were higher (P<0.05) while HRacc, HRrec, and %APMHR were lower (P<0.05) in T2D compared to NFG. HRacc and %APMHR were lower (P<0.05) in T2D compared to IFG. Differences among groups for CI, %APMHR, and HRres remained significant after adjusting for age, sex, BMI and CRF. **CONCLUSIONS:** These data suggest that impairment in exercise HR response observed in chronic hyperglycemia is also present in prediabetes which should be considered when interpreting CPX data and developing an exercise prescription.

Treadmill vs. Cycle Ergometry Graded Exercise Test Responses in Multiple Sclerosis Patients

Garett Griffith¹, Thessa Hilgenkamp², Alexander Rosenberg¹, Georgios Grigoriadis¹, Kanokwan Bunsawat¹, Sang Ouk Wee¹, Elizabeth Schroeder¹, Badeia Saed¹, Tracy Baynard, FACSM¹. ¹University of Illinois at Chicago, Chicago, IL. ²Erasmus MC University Medical Center, Rotterdam, Netherlands. (Sponsor: Tracy Baynard, FACSM)
 Email: gjgriff@uic.edu
 (No relationships reported)

INTRODUCTION: Cardiorespiratory fitness is measured by peak oxygen consumption (VO_{2max}) and is one of the strongest predictors of all-cause and cardiovascular disease mortality. In a healthy adult population, VO_{2max} values obtained on a treadmill are approximately 10-15% higher than those yielded by cycle ergometry. VO_{2max} testing in those with multiple sclerosis (MS) is typically performed on a cycle ergometer, as loss of walking mobility or balance issues may limit treadmill walking. Therefore, potential mode-specific differences in VO_{2max} may result in the inability to accurately assess MS patients' risk and lead to inaccurate exercise prescriptions in this cohort. **PURPOSE:** To compare hemodynamic, ventilatory, and cardiorespiratory responses between graded exercise tests performed on both a treadmill and cycle ergometer in individuals with relapsing-remitting MS. **METHODS:** Twenty persons with MS (42±11 years, 11±10 years since Dx, 26.9±6.5 kg·m⁻²) completed two VO_{2max} tests approximately 1 week apart, with random order of testing. Treadmill tests consisted of a constant, self-determined speed with an increase in grade of 2% every two minutes. Cycle ergometry tests increased wattage by 15 watts per minute. A repeated measures ANOVA was used to investigate differences in testing response to both treadmill and cycle ergometry. **RESULTS:** Treadmill testing resulted in VO_{2max} values that were 11% higher and respiratory exchange ratio (RER) values that were 8% lower than those obtained via cycle ergometry. See Table 1. **DISCUSSION:** Relapsing-remitting MS patients exhibit a mode-related difference in VO_{2max} similar to healthy adults. Therefore, exercise prescriptions or study designs cannot directly calculate submaximal workloads for one mode based on maximal data obtained from the other. Additionally, while HR_{peak} values are within normal limits, they're bordering chronotropic incompetence.

	Treadmill	Cycle Ergometer
VO _{2peak} (ml·kg ⁻¹ ·min ⁻¹)	27.0 ± 6.7*	23.9 ± 6.0
HR _{peak} (beats·min ⁻¹)	159 ± 19	153 ± 16
SBP _{peak} (mmHg)	166.8 ± 20.5	163.4 ± 27.5
DBP _{peak} (mmHg)	72.7 ± 13.3	75.1 ± 11.5
RPE	17.9 ± 1.9	18.0 ± 2.0
VE _{peak} (L·min ⁻¹)	75.5 ± 21.2	79.1 ± 23.6
RER	1.09 ± 0.08*	1.19 ± 0.07

The YMCA Submaximal Cycle Test and the 6-Minute Walk Test are Not Accurate Predictors of Cardiorespiratory Fitness During Mid-pregnancy

Rachel A. Tinius¹, Maples Jill¹, Maire Blankenship¹, Bailey Cooley¹, Alyssa Olenick¹, Hannah Fickey¹, Donald Hoover¹, W.Todd Cade². ¹Western Kentucky University, Bowling Green, KY. ²Washington University School of Medicine, St. Louis, MO.
 Email: rachel.tinius@wku.edu
 (No relationships reported)

PURPOSE: Assessing cardiorespiratory fitness is important for determining health status and prescribing exercise. Measurement of peak oxygen uptake (VO_{2max}) is the gold standard for the evaluation of cardiorespiratory fitness. However, VO_{2max} testing is not always feasible as it involves trained personnel, expensive equipment, and the ability of the test-subject to safely exercise until exhaustion. The ability to accurately predict VO_{2max} using submaximal protocols is important, particularly in special populations such as pregnant women. A validated test to predict fitness levels in pregnant women will allow health care providers to evaluate their patients' health status as well as tailor their patients' exercise prescriptions; thus, maximizing the established benefits of exercise during pregnancy. The 6-minute walk test (6MWT) and the YMCA submaximal cycle test (YMCAT) are currently validated tests to predict VO_{2max} in non-gravid populations; however, neither test has been validated during pregnancy. Therefore, the purpose of this study is to determine the validity of the 6MWT and the YMCAT as predictors of cardiorespiratory fitness in healthy weight women during mid-pregnancy. **METHODS:** Women (18-24 weeks gestation) with low-risk pregnancies participated. At Visit 1, participants completed the 6MWT and the YMCAT in randomized order. Both tests were used to predict VO_{2max} according to validated protocols/equations for non-gravid populations. At Visit 2, participants completed a graded exercise treadmill test (VO_{2max}) using the Bruce Protocol. The predicted VO_{2max} from each submaximal test and the measured VO_{2max} were compared using Pearson Product Moment Correlation Coefficients. **RESULTS:** 16 women participated in the study (pre-pregnancy BMI= 23.8±4.3 kg/m², Age=30.1±3.2 yr, Gestation age=22.0±1.3 wk). Mean predicted VO_{2max} values were 36.3±3.9 and 41.1±19.0 ml/kg/min for the 6MWT and the YMCAT, respectively. Mean VO_{2max} obtained from the graded exercise test was 34.9±10.0 ml/kg/min. Actual and predicted VO_{2max} values were not correlated for either submaximal test (6MWT: r=0.28, p=0.31; YMCAT: r=0.08, p=0.79). **CONCLUSIONS:** The 6MWT and YMCAT do not accurately predict VO_{2max} values during mid-pregnancy. These tests should not be used to estimate peak fitness levels among pregnant women.

A Novel Maximal Treadmill Exercise Testing Protocol in the Morbidly Obese: A Descriptive Report

Richard S. Severin, Shane Phillips. The University of Illinois at Chicago, Chicago, IL. (Sponsor: Tracy Baynard, FACSM)
 Email: rscseverin@gmail.com
 (No relationships reported)

INTRODUCTION: Although the results from treadmill exercise tests have been widely used as a marker of fitness and prognosis for various diseases, morbidly obese individuals often terminate testing at a level of discomfort far below their physiologic maximum. This early termination demonstrated in morbidly obese individuals may be due to bio-mechanical factors, low levels of fitness and the parameters of more traditional exercise testing protocols. Given the increasing obesity epidemic facing the United States and the world, it would be prudent to investigate exercise testing protocols for this population to assist with disease prognosis and stratification as well as the provision of appropriate exercise prescriptions. **PURPOSE:** To describe the utilization and psychometric properties of a novel treadmill test protocol used in morbidly obese individuals. **METHODS:** The data was pooled from baseline maximal exercise testing data of all subjects currently enrolled in a pre-bariatric surgery exercise training study who used this novel protocol. The protocol used a constant speed (2mph), graded exercise test which increased at a rate of 2% every 2 minutes. Metabolic data was collected, heart rate was measured with 12 lead ECG, blood pressures were measured manually, and rating of perceived exertion was assessed using the modified Borg Scale. **RESULTS:** In total, the results from 7 participants were included in this analysis, all female, non hypertensive and without diagnosed cardiopulmonary disease.

THURSDAY, JUNE 1, 2017

Baseline data								
	Age (yrs)	Height (cm)	Body Weight (kg)	BMI	Waist Circumference (cm)	Resting Heart Rate (bpm)	Rest SBP (mmHg)	Rest DBP (mmHg)
Avg	33.14	168.97	136.89	48.00	129.57	87.29	115.00	78.14
SD	6.64	4.73	27.60	10.01	24.67	19.19	5.80	8.69
Pooled testing data								
	Peak-VO ₂ (ml/kg/min)	Exercise Time (min)	Peak RER	Peak HR (bpm)	Peak % Age Predicted HR Max (APHRMax)	Peak SBP (mmHg)	Peak DBP (mmHg)	Peak RPE
Avg	19.52	12.00	1.00	166.00	0.89	170.00	74.00	6.36
SD	8.52	4.00	0.07	17.06	0.08	16.59	8.39	2.29

CONCLUSION: This novel treadmill exercise testing protocol yielded peak testing results that could be considered to be acceptable criteria for a maximal effort for this special population of morbidly obese individuals, based on pooled average values of Peak %APHRMax, peak RER, and test duration. More research is needed to investigate the psychometric properties of this test and to develop testing parameters specific to morbidly obese individuals.

Assessment Of Cardiorespiratory Fitness And Recovery Capacity Among Women With Fibromyalgia

Lucie Bouvrette LeBlanc, Nathaly Gaudreault, Daniel Tessier, Warner Mampuya, Pierre Arsenaux, Pierre Boulay. *Sherbrooke University, Sherbrooke, QC, Canada.*

Email: lucie.bouvrette.leblanc@usherbrooke.ca

(No relationships reported)

Cardiorespiratory fitness (CRF) level among women living with fibromyalgia (FM) has been documented with some contradictory results most probably due to differences in the methodological approaches used. Furthermore, some studies have suggested that aerobic capacity was affected in patients with Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) 24 hours after performing a maximal CRF test. To our knowledge, no research has looked at the capacity to recover after a maximal CRF test in FM patients, a disease often compared with ME/CFS.

PURPOSE: To describe and compare the CRF and recovery capacity of women, who are mildly or moderately affected with FM, 24 hours after a maximal exercise test.

METHODS: Twelve FM women were submitted twice to a maximal exercise test (BSU/Bruce ramp) interspersed by 24 hours (T1 & T2), until participants achieved volitional exhaustion. Gas exchange (Ergocard, Medisoft) and ECG (Quinton) were continuously monitored throughout the test. Blood lactate, blood pressure, pain intensity and rate of perceived exertion, were also assessed at different moments. The Revised Fibromyalgia Impact Questionnaire was completed by participants to determine their FM severity level. **RESULTS:** No significant differences in VO_{2peak} (25.5 ± 5.3 vs. 26.5 ± 5.3 ml $O_2 \cdot kg^{-1} \cdot min^{-1}$, $p > 0.05$) and VO_2 at ventilatory threshold (VO_{2VT} : 21.2 ± 4.8 vs. 21.7 ± 4.8 ml $O_2 \cdot kg^{-1} \cdot min^{-1}$, $p > 0.05$) were found between T1 & T2. When considering the severity of the disease, mildly affected FM patients had a significantly greater CRF only at T2 (VO_{2peak} : $T2 = 30.4 \pm 3.3$ ml $O_2 \cdot kg^{-1} \cdot min^{-1}$) and higher VO_2 at the ventilatory threshold at T1 and T2 (VO_{2VT} : $T1 = 24.0 \pm 4.0$; $T2 = 24.9 \pm 3.2$) when compared with moderately affected FM patients (VO_{2peak} : $T2 = 22.9 \pm 4.7$ ml $O_2 \cdot kg^{-1} \cdot min^{-1}$ and VO_{2VT} : $T1 = 18.5 \pm 4.4$; $T2 = 18.7 \pm 4.5$ ml $O_2 \cdot kg^{-1} \cdot min^{-1}$). Furthermore, CRF levels were lower than the general population. In fact, 75% of the VO_{2peak} results were below the «Fair» category, of which 25% were below the «Very Poor» category, when compared to the ACSM normative values for VO_{2peak} . **CONCLUSION:** In general, participants showed no significant difference in CRF and recovery after 24 hours. However, the severity of fibromyalgia negatively affected CRF in our study population and their CRF level was lower than the general population.

Indirect Assessment Of Vo2max

Jaroslav Novak¹, Milan Stork², Vaclav Zeman¹. ¹*Institute of Sports Medicine, Charles University, Plzen (Pilsen), Czech Republic.* ²*Western Bohemian University, Plzen (Pilsen), Czech Republic.*

Email: novakj@lfp.cuni.cz

(No relationships reported)

VO₂max is considered like the most valuable objective predictor of cardio-respiratory fitness and general health. Many evidence based studies prove that higher level of VO₂max is adversely related to prevalence of many diseases, such as cardio-metabolic syndrome, ischemic heart disease, hypertension, diabetes II and others. However, only very few general practitioners can afford complete equipment for direct estimation of this important fitness biomarker

PURPOSE: a) To find the highest correlation between the fitness markers, which don't need O₂-CO₂ analyzer for their assessment (W170, Wmax) on one side and VO₂max on the other side. b) To determine regression equations which could be used for calculation of VO₂max and VO₂max/kg

METHODS: The data of 2777 spiroergometric tests (2015 males and 762 females) from the data-base of our institute in the period 1995 till 2015 were included into the study. The subjects were healthy competitive and leisure athletes and also non-athletes aged 9 to 95 years. All performed bicycle ergometer test with step wise increased workload up to the exhaustion.

RESULTS: The highest correlations were found between maximal performance achieved in watts (Wmax) and VO₂max, and between Wmax/kg and VO₂max/kg in both men and women. Regression equations for indirect assessment of VO₂max are:

Men: $VO_{2max} = 0.0095 \cdot Wmax + 0.54$ (l/min) (R=0.89); $VO_{2max}/kg = 8.3 \cdot$

$Wmax/kg + 13$ (ml/min/kg) (R=0.83)

Women: $VO_{2max} = 0.0083 \cdot Wmax + 0.67$ (l/min) (R=0.85); $VO_{2max}/kg = 8.0 \cdot$

$Wmax/kg + 13$ (ml/min/kg) (R=0.83)

CONCLUSION: The regression equations can be used for assessment of VO₂max and/or VO₂max/kg body weight respectively even in those testing procedures, where bicycle ergometry enables to measure maximal performance during step wise increased workload, however, where no O₂-CO₂ analyzer is available. The data can serve as a feedback information about the effectiveness of physical activity in wider range of population than direct VO₂max measurement, limited by the capacity of specialized laboratories.

A Pregnancy-Specific Equation for Predicting Cardiorespiratory Fitness

McKenzie Driskill, Rachel A. Tinius, Donald L. Hoover. *Western Kentucky University, Bowling Green, KY.*

(No relationships reported)

PURPOSE: The ability to measure VO_{2max} is important for determining health status and prescribing exercise. However, directly measuring VO_{2max} is not always feasible, particularly in special populations such as pregnant women. Therefore, the purpose of this study was to create pregnancy-specific equations to predict cardiorespiratory fitness using baseline and exercise data.

METHODS: Nineteen pregnant women (Age: 29.8 ± 3.1 years, Pre-pregnancy BMI: 23.8 ± 3.9 kg/m², Gestation Age: 22.0 ± 1.4 weeks) participated in the study. Each participant completed baseline measurements/anthropometrics and the Bruce protocol maximal treadmill test. Exercise data was obtained from the maximal test using heart rate from stages 1, 2, 3, and 4, and used to create regression equations calculated to predict measured VO_{2max} levels. In addition, other variables such as body mass index, age, gestation age, and physical activity level were included in these regression models based on their predictive ability.

RESULTS: Stepwise multiple regression analysis (SPSS, version 24) was conducted to predict the VO_{2max} in pregnant women based upon baseline measures and exercise data. The results of this analysis indicated that VO_{2max} was significantly related to maximum heart rate (maxHR), $F(1,11) = 22.38$, $p < .001$, and demonstrated $R^2 = .670$ and adjusted $R^2 = .640$. The regression equation for this linear model is:

$VO_{2max} = -179.74 + (1.25 \times \text{maxHR})$

The other baseline and exercise variables did not predict significantly in this sample. Based upon these results, maxHR appears to be the best predictor of VO_{2max} in pregnant women.

CONCLUSIONS: Data from the current study was used to create an equation that can be used to predict cardiorespiratory fitness in pregnant women. A logical next step is to further validate such equations in a larger cohort of pregnant women. Validated equations created will allow healthcare providers to safely and effectively predict their pregnant patients' fitness level; thus, allowing them to best tailor their patients' exercise prescriptions in order to maximize the benefits of exercise in both the mother and her offspring.

 (No relationships reported)

PURPOSE: To evaluate a recent equation (FRIEND) for the estimation of peak exercise capacity (VO_{2peak}) in a heterogeneous clinical population of patients with cardiomyopathy against the current standard in estimation equations (Wasserman, 1986).
METHODS: 1100 consecutive ambulatory patients performed clinical cardiopulmonary exercise testing (CPX) at Stanford University. VO_{2peak} was measured directly during CPX (CosMed USA), and estimated VO_{2peak} were calculated using the FRIEND (Fitness Registry and the Importance of Exercise: National Database) registry equation and the equation from Wasserman et al. VO_{2peak} data were assessed for variation around the median and comparisons were made.
RESULTS: Patients were on average 48 (15) y and 62% male. VO_{2peak} as measured by CPX was on average 23.7 (9.8) ml/kg/min. The Wasserman equation average prediction for VO_{2peak} was 27.8 (9.4) which resulted in an percent predicted of 88%, whereas the FRIEND equation resulted in average predicted VO_{2peak} of 42.2 (10.3) ml/kg/min, resulting in 56% of predicted.
CONCLUSIONS: In a large sample of patients with known moderate to severe cardiomyopathy, the standard reference equation by Wasserman assessed them as slightly below average whereas the FRIEND equation assessed the same patients as having severely impaired performance. Caution should be used in the interpretation of CPX results when using current VO_{2peak} estimation equations and further development of these equations seems warranted.

Association Between Heart Rate Recovery, Cardiorespiratory Fitness, And Physical Activity In HIV+ Hispanic Adults
 Maria C. Pacheco-Parés, Farah A. Ramírez-Marrero, FACSM. University of Puerto Rico - Rio Piedras Campus, San Juan, Puerto Rico. (Sponsor: Farah A. Ramírez-Marrero, FACSM)
 Email: maria_pacheco13@hotmail.com
 (No relationships reported)

Heart rate recovery (HRR) after intense exercise is one aspect of chronotropic incompetence (CI), the inability to match HR response to metabolic demands. Impaired HRR after peak exercise has been observed in HIV+ adults. However, physical activity (PA) and cardiorespiratory fitness (CRF) are both associated with improved exercise recovery, but their influence on HRR in this population has not been established.
PURPOSE: To evaluate the association between PA, CRF, and HRR; and test the hypothesis that HIV+ Hispanic adults classified as active and with good CRF will have higher %HRR after peak exercise compared with those inactive and with low CRF.
METHODS: A group of 89 adults (59 HIV+ and 30 HIV-) completed an exercise test on a treadmill with ECG and gas exchange measures (i.e., HR and VO₂) using the modified Bruce protocol. Measurements continued for 6 minutes post-exercise. They also wore an ActiGraph GT3X+ accelerometer attached to an elastic waist band placed in the right hip area for 7-days. T-tests were used to detect differences by group and classification of PA and CRF. Correlation and regression analyses were used to evaluate associations between variables. **RESULTS:** No differences in the proportion of HIV+ and HIV- classified as active vs. inactive (42.4 vs. 52.5% & 53.6 vs. 46.4%; P=0.328), and with good vs. low CRF (44.1 vs. 55.9% & 60.0 vs. 40.0%; P=0.155) were observed. HRR was not different by group, but %HRR was lower in HIV+ compared with HIV- (38.4±7.4 vs. 44.0±5.6%; P<0.001). Considering PA classification, active HIV+ had lower HRR and higher %HRR than inactive HIV+ (91.0±11.8 vs. 98.4±10.6 bpm, P= 0.02; 41.6±4.3 vs. 36.0±8.4%, P=0.004; respectively); while HIV- showed no differences. Based on CRF classification, HRR was not different in both groups, but %HRR was higher in both HIV+ and HIV- with good CRF compared with those with low CRF (41.2±6.2 vs. 36.1±7.5%, P=0.007; 45.6±5.6 vs. 41.6±5.0%, P=0.05). Correlation and regression analyses confirmed associations between VO_{2peak}, PA, and %HRR. **CONCLUSION:** Impaired %HRR among HIV+ Hispanic adults compared with HIV- was apparent regardless of CRF and PA classification. However, both PA and CRF positively influenced %HRR in the HIV+ group, supporting our hypothesis. Supported by: NIH/CTSA KL2-RR024151, NIH/NIMHHD 8U54MD 007587-03.

 (No relationships reported)

Purpose: The posture an athlete holds during exercise may alter breathing pattern and increase reports of exercise induced respiratory symptoms. The purpose of this study was to investigate the effect of different postural positions during high-intensity cycling on breathing frequency (BF), tidal volume (VT), rating of perceived exertion (RPE) and dyspnoea.
Methods: Fifteen healthy male athletes (Mean +/- SD age: 26.1±7.0 yrs.) performed a 10-minute cycling test at 70% of their peak power in two conditions, in a randomised order: with normal shoulder position (C1) and with hunched shoulders (C2). BF and VT were continuously monitored during exercise. RPE and dyspnoea were gauged by using Borg RPE and Borg-10 scales, respectively.
Results: BF and VT showed no significant difference between conditions at any time point, however an alteration in BF was observed in C2 (Figure 1). Significant main effects of time emerged for BF, RPE and dyspnoea in both conditions (all p values <0.001).
Conclusions: Cycling with hunched shoulders at high intensities over a prolonged period leads to altered breathing mechanics and as a consequence, an increase in perceived exertion and dyspnoea. These findings suggest that posture may contribute to reports of respiratory symptoms during exercise in the absence of cardio-pulmonary disease.

C1 represents normal shoulder position and C2 represents hunched or lifted shoulder position. E1, E3, E5, E7, E10 represent minutes 1, 3, 5, 7 & 10 of the 10-minute cycling test.

Vertical Jump Height Measurements: Correlation Between Vertec And My Jump App.

Justin Usher, Rajab Intair, Dimitri Castro, Evranjeet Brar, Julio Gomez, Jenny O, Vanessa R. Yingling, FACSM. *California State University, East Bay, Hayward, CA.*
Email: jusher@horizon.csueastbay.edu
(No relationships reported)

Vertical jump testing is a commonly used method for measuring an individual's anaerobic (explosive) power (Markovic, et al., 2004). Reliable and repeatable assessment of the vertical jump has implications in many health, wellness, and physical activity domains. The Vertec™ and force plate (gold standard) are devices used for accurately measuring vertical jump height; research conducted on these devices have shown their validity in measuring jump height (Buckthorpe, et al. 2012). The force plate and the Vertec™, although accurate at measuring vertical jump height, are costly and not easily accessible to many coaches and the general public. An accurate and accessible field measure would allow assessment of vertical jump height and power in many settings. **PURPOSE:** The purpose of this experiment was to examine the reliability and validity of the My Jump app (utilized on Ipad mini) compared to the Vertec™.

METHODS: Sixty-five college-aged participants performed three maximal countermovement vertical jumps. A Vertec™ measurement device was used in conjunction with the My Jump app to measure jump height. Jump heights from the Vertec™ were then correlated to those from the My Jump app. Peak power values were calculated using the Sayers equation (Sayers et al. 1999). The Pearson product-moment correlation coefficient was determined between the jump heights measured by the Vertec™ and the My Jump app.

RESULTS: The average jump height measured by the Vertec™ 20.1 in. (5.4) was significantly higher than the height from My Jump app 16.1 in. (4.5). A strong and significant correlation was found between the two height measurements, $r=0.814$, $p<0.01$ and for peak power measures $r=0.933$ $p<0.01$.

CONCLUSIONS: The My Jump app may provide a reliable measure of vertical jump height in multiple settings without the need of costly equipment such as force plates or Vertec™. We chose to compare the My Jump app to the Vertec™ because the Vertec™ is more commonly used to measure jump height due to the expense compared to a force plate. The lower height values using My Jump app may stem from the fact that subjects reach for the rungs on the Vertec™ while My Jump app measures the flight time to determine the vertical height of the center of mass. However, the ease of use and portability makes the app an accessible tool for measuring jump height in multiple settings.

No Difference In Time To Stabilization Between Male & Female Dancers Following A Jump-landing Task

Hunter Loewen¹, Marijeanne Liederbach², Leigh Schanfein², Ian Kremenic³. ¹University of Manitoba, Winnipeg, MB, Canada. ²NYU Langone Medical Center Hospital for Joint Diseases, New York, NY. ³Lenox Hill Hospital Northwell Health, New York, NY. (Sponsor: Mal McHugh, FACSM)
(No relationships reported)

Dance is a jump intensive activity, and, similar to other sports, ankle sprains among dancers are the most common traumatic injury, typically occurring when landing from a single leg jump. Ankle sprain injuries happen among dancers most often by age thirteen and have a high recurrence rate often leading to long term disability. As dance medicine epidemiology studies continue to evolve, it is evident that a gender disparity exists among dancers with females having up to 55% higher relative frequency of ankle sprains compared to their male counterparts. **PURPOSE:** To determine the effect of gender on time to stability (TTS) after landing from a horizontal jump. **METHODS:** Forty-one professional ballet and modern dancers (14 men, 23.8±4.3 and 27 women, 26.1±4.7) without prior ankle injury consented to participate in this biomechanics laboratory study. Shod in personal, flat soled running shoes, subjects performed three submaximal (50% maximum) trials of the TTS test. Independent t-tests were employed with gender (male/female) as the independent variable and TTS (anterior-posterior [AP]/medial-lateral [ML]) as the dependent variables. **RESULTS:** No differences were found between men and women dancers for either AP or ML aspects of the horizontal TTS jump test (AP: men 2.707±0.11 seconds, women 2.709±0.11 seconds; $p=0.98$), (ML: men 2.718±0.294 seconds, women 2.853±0.177 seconds; $p=0.121$). **CONCLUSION:** Men and women dancers exhibited similar TTS after landing from

a horizontal jump task when wearing flat soled shoes on a flat surface. The gender disparity in landing mechanics found by other researchers may not have been found here due to jump type or to extrinsic factors such as the interaction of variable floor surfaces common in the dance workplace and different shoe wear often required of the women which place them in the loose pack position of the ankle joint.

Relationship Between the Ruffier Test and Maximal Treadmill Testing in Healthy Adults

Francois Modave, Trevor Leavitt, Ravi Kumar, Bian Jiang, Yi Guo, Heather K. Vincent, FACSM. *University of Florida, Gainesville, FL.* (Sponsor: Heather K. Vincent, PhD, FACSM)
Email: modavefp@ufl.edu
(No relationships reported)

PURPOSE: Estimating aerobic fitness in the busy outpatient clinical setting with gold standard maximal fitness testing is challenging due to time, staffing and equipment access limitations. Short tests that can be performed with minimal equipment and staff may overcome these limitations, and improve clinician ability to provide customized exercise recommendations and track fitness responses over time. This study piloted whether a peak fitness level could be estimated by a short, simple Ruffier exercise readiness test.

METHODS: Seventeen adults (32.6 ± 10.8 yrs; 26.0 ± 10.7 kg/m²; 9 F) participated. During one testing session, participants performed a Ruffier fitness readiness test (30 squats in 45 s) and a Balke maximal treadmill fitness test. In the Ruffier test, heart rate (HR) was measured pre-test, immediately post and 1-min post-test. Ruffier scores were calculated and classified from the 3 HR values. During the Balke test, endurance time and peak values for HR, rate of oxygen use (VO_{2peak}), ventilation (VE) and respiratory quotient (RQ) were captured.

RESULTS: Mean HR values during the Ruffier test were 68.7 ± 9.9 bpm (pre-test), 129.5 ± 9.7 bpm (immediately-post) and 88.4 ± 19.5 bpm (1-min post), which represented a significant change over time; $p<0.0001$. The Ruffier score averaged 8.8 ± 3.4 points (from 0-20 points). The Balke VO_{2peak} measure averaged 39.7 ± 11.6 ml/kg*min, with a peak HR of 179.3 ± 14.4 bpm and RQ of 1.2 ± 0.08. Average endurance time was 21.2 ± 4.5 min. Correlation between Ruffier scores and VO_{2peak} value revealed a Pearson correlation coefficient $r = 0.540$ (two-tailed p-value of $p=0.024$, at 0.05 level).

CONCLUSIONS: Moderate associations were found between the fitness scores of the two tests from this group. The 45 s Ruffier exercise test may be useful for quickly identifying patients with poor aerobic fitness levels in the clinical setting, but may not be long enough to produce physiological responses that could discern fine gradations of fitness.

2164 Board #177 June 1 3:30 PM - 5:00 PM

Hip Adductors are Stronger in Persons with Bilateral Compared to Unilateral Knee Injury: Pilot Study

Sara F. Voorhees¹, Phyllis Heyne-Lindholm¹, Scott Brown², Donald Bruenjes³. ¹University of Jamestown, Fargo, ND. ²Sanford POWER, Fargo, ND. ³Concordia College, Moorhead, MN.
Email: svoorhee@uj.edu
(No relationships reported)

Introduction: The role of hip adductor strength in persons with bilateral and unilateral knee injury is not well reported nor well understood. Studies that examined adductor strength often report no significant differences. Such studies include persons with unilateral and bilateral knee injuries, such as patellofemoral pain (PFPS). This pilot investigation separated those with unilateral or bilateral knee injury to assess differences in adductor strength and abductor-to-adductor strength ratio.

Purpose: Determine if differences in hip adductor strength is present in persons with unilateral compared to bilateral knee injuries.

Methods: Males and females, ages 18-24, with a history of unilateral (n=10; 6 F, 4 M; PFPS or anterior cruciate ligament reconstruction (ACLR)) or bilateral knee injuries (n=10; 6 F, 4 M; B PFPS or B ACLR) of at least 6 months ago, were recruited from local universities. The Knee Outcome Survey-Sport Activity Scale (KOS-SAS) questionnaire was completed by all participants. Hip adductor and abductor strength was measured with a calibrated dynamometer. The ratio of abductor-to-adductor strength, and peak hip muscle strengths were compared between groups and limbs ($p<0.05$).

Results: Between groups, there were no significant differences in age, height, weight, BMI, Tegner Activity Level, or KOS-SAS ($p>0.5$). Hip adductor strength was significantly weaker ($p=0.03$) in persons with unilateral (2.8 ± 1.7 %BW*HT) compared to bilateral (6.0 ± 1.9 %BW*HT) injury. The hip abductor-to-adductor ratio was significantly greater ($p=0.004$) in persons with unilateral (1.6 ± 0.5 %BW*HT) compared to bilateral (3.3 ± 1.9 %BW*HT) injury. There were no significant differences between limbs in abductor strength in either group ($p=0.2$).

Conclusion: Hip adductors were significantly stronger in both limbs in persons with bilateral knee injury compared to persons with unilateral knee injury. In order for the hip abductor-to-adductor ratio to be greater in persons with unilateral knee injury, the hip adductor strength [denominator] must be weaker. How persons compensate for an injury may depend on unilateral or bilateral involvement. This pilot study would be improved by including additional participants in PFPS or ACLR groups.

± 11.1 %) of $\dot{V}O_{2max}$ respectively, with no differences between the groups ($p=0.3$, $p=0.8$). **CONCLUSION:** The health and fitness of MU were not different from NU. We speculate that because all individuals in the study were physically active and had $\dot{V}O_{2max}$, LT and OBLA in higher fitness categories, it is possible that exercise provided protection against any marijuana related side effects in a healthy, male population. Funded by: FRBP-NPP at UNC

Impact Of CrossFit And Non-CrossFit Programs On Range Of Motion
 Amanda L. Moelk, Jennifer L. Welch, Rebekah G. Ellerbusch, Trevor W. Frosig, Gabrielle S. Turcotte, April A. Wheeler, Taylor K. Schmidt, Tara M. Roelofs, Justin R. Geijer. *Winona State University, Winona, MN.*
 (No relationships reported)

Range of motion (ROM) is vital for daily living and exercise. Flexibility is especially of interest since tightness limits ROM and often results in muscle imbalances leading to injury. Different types of training have different effects on ROM. CrossFit, a higher intensity program, is often stigmatized as a muscle building exercise regimen that decreases ROM. Previous studies have shown lower intensity programs may increase flexibility and decrease injury. To date, few studies have addressed ROM comparisons of CrossFit and non-CrossFit programs. **Purpose:** The purpose of this study was to compare shoulder and hip joint ROM in individuals participating in CrossFit and non-CrossFit fitness programs. **Methods:** An experimental design with random assignment was used to examine the ROM differences in a CrossFit and non-CrossFit fitness program observing 26 volunteers, consisting of nine males and 17 females aged 21.3 ± 4 years. Baseline ROM assessments for shoulder flexion, shoulder internal rotation, shoulder external rotation, hip flexion, hip extension, hip internal rotation were measured. Participants were randomly assigned to a CrossFit and non-CrossFit group. The participants completed eight-weeks of training, attending three, one hour sessions per week and refrained from any additional training. After training, the participants were tested using the same protocol as pretesting. Paired samples t-tests determined within group changes and one-way ANOVAs determined between group changes, and the alpha level was set at 0.05. **Results:** The CrossFit group revealed a statistically significant difference in left shoulder external rotation (pre: 80.85 ± 12.13 ; post: 62.28 ± 14.89 ; $p=0.033$). No other statistically significant differences were found in the non-CrossFit group or between groups when comparing joint ROM in bilateral shoulder flexion, shoulder internal rotation, shoulder external rotation, hip flexion, hip extension, and hip internal rotation. **Conclusion:** This study followed current research trends, as there were few significant differences in ROM between and within CrossFit and non-CrossFit programs. However, this study found the CrossFit group to have a decrease in shoulder joint external rotation.

2167 Board #180 June 1 3:30 PM - 5:00 PM
Effect Of Pacing Strategy During The Final Two Minutes of a Self-paced $\dot{V}O_{2max}$ Test (spv)
 Sangwoo Lee¹, Nicholas Hanson¹, Carter Reid¹, Timothy Michael, FACSM¹, Carol Weideman¹, Cory Scheadler². ¹Western Michigan University, Kalamazoo, MI. ²Northern Kentucky University, Highland Heights, KY.
 (No relationships reported)

Self-paced $\dot{V}O_{2max}$ tests (SPVs) have increasingly been used as an alternative to traditional closed-loop protocol with predetermined workload increases. SPVs have been shown to produce values that are as high, and sometimes higher, than traditional protocol. What is not known is if the pacing strategy during the final two minutes of the test affects the maximal values attained. **PURPOSE:** Compare two different pacing strategies, conservative and aggressive, during the final two minutes of a 10-minute SPV. **METHODS:** Fourteen healthy subjects (29.36 ± 5.6 years; mean \pm SD) volunteered to participate. After a familiarization session, subjects completed two SPVs. The SPV protocol was closed-looped and consisted of five two-minute stages with a total test time of 10 minutes exactly. Subjects were asked to maintain prescribed ratings of perceived exertion (RPE) levels of 11 (light), 13 (somewhat hard), 15 (hard), 17 (very hard) and 20 (maximal exertion). During the final stage, subject used either a conservative (CON) or aggressive (AGG) pacing strategy. In CON, subjects were asked to use the entire 2 min. stage and gradually build to RPE20. Conversely, in AGG they were asked to start the last stage immediately at RPE20, knowing full well they would have to decrease their speed toward the end of the test. The primary variables collected were relative $\dot{V}O_{2max}$ (ml/kg/min), respiratory exchange ratio (RER) and maximum heart rate (HRmax). After the study they were asked which strategy they preferred. Paired samples t-tests were used to compare the mean values found in each condition. **RESULTS:** There was no difference in $\dot{V}O_{2max}$ values between AGG (58.8 ± 8.8 ml/kg/min) and CON (58.3 ± 7.9). Similarly, no differences were seen in HRmax between AGG (186.7 ± 4.2 bpm) and CON (187.0 ± 4.9 bpm). The maximal RER recorded in AGG (1.25 ± 0.09) was significantly higher ($p < .05$) than CON (1.18 ± 0.07). Of the 12 subjects that responded to the question about preference, 7 (58%) preferred the AGG strategy. **CONCLUSION:** These results suggest that the pacing strategy used during the final two minutes of an SPV does not affect the maximal $\dot{V}O_{2max}$ or HR values that are elicited. The maximal RER was higher in AGG, which suggests a higher anaerobic component with this strategy. Perhaps more subjects chose that strategy because they felt that a greater amount of effort was involved.

Marijuana Use and The Health and Fitness of Physically Active Users and Non-Users
 Jonathon Lisano, Matthew Christensen, Alissa Mathias, Marcus Chavez, Kristina T. Phillips, Jeremy D. Smith, Laura K. Stewart. *University of Northern Colorado, Greeley, CO.*
 Email: lisa3700@bears.unco.edu
 (No relationships reported)

Although an increasing number of states are legalizing marijuana (MJ) for recreational use, research examining the chronic fitness and health related effects of MJ use in humans have been limited. **PURPOSE:** To examine the health and fitness of physically active MJ users and non-users. **METHODS:** Physically active, healthy males ($N=23$) were placed into groups based on MJ use: marijuana users (MU; $n=12$) or non-users (NU; $n=11$). Physical activity level and MJ use were confirmed using IPAQ-Short Format and the Marijuana Use Measure questionnaires. MU had used MJ products at least once per week for the past 6-months. NU had not used MJ within the past 12-months. Descriptive measures including age, body mass (BM), resting heart rate (RHR), body mass index (BMI), body fat (skinfold, BF) resting systolic (SBP) & resting diastolic (DBP) blood pressure were assessed. Pulmonary function was evaluated (forced expired volume in 1-second percent (FEV1%) and relative forced expired volume in 1-second (RFEV1_{max})) using spirometry. Cardiorespiratory fitness ($\dot{V}O_{2max}$), lactate threshold (LT) and onset of blood lactate accumulation (OBLA) (treadmill test with measurement of expired gasses) were assessed. Independent t-tests were used to identify differences between groups ($p < .05$). Data are presented as mean \pm SD. **RESULTS:** MU used MJ an average of 21 times out of the last 30-days. All MU were smoking MJ in some form. All participants (MU and NU) averaged 23 yrs. \pm 5 yrs. age, 80.4 ± 14.9 kg BM, 25.0 ± 3.6 kg/m² BMI, 12.0 ± 5.9 % fat, 65.8 ± 13.1 bpm RHR, 123.2 ± 8.4 mmHg SBP, and 70.3 ± 10.0 mmHg DBP. RFEV1_{max} (54.7 ± 10.2 ml/kg/s) and FEV1% (92.9 ± 12.8 %) were not different between groups ($p < 0.05$). $\dot{V}O_{2max}$ was not different between groups (MU= 51.1 ± 8.9 ; NU= 53.5 ± 5.5 ml/kg/min; $p=0.5$). Rate of perceived exertion at termination for MU and NU were (8.9 ± 0.9) and (9.5 ± 0.7), ($p=0.1$). LT and OBLA occurred at (69.3 ± 9.2 %) and (80.4

 (No relationships reported)

The 30-s Wingate Anaerobic Test (WAnT30) is frequently used to determine peak anaerobic power (PP). When PP, which is generally achieved within the first 5-s is the primary measure of interest, there may be no advantage in completing a 30-s test. It is not clear if a shorter test can be validated against the WAnT30. **Purpose:** To determine if a modified 6-s anaerobic test could be used to measure PP as an alternative to the traditional WAnT30 in recreationally active females. **Method:** Thirteen females (28.4 ± 6.3 yr., 163.2 ± 5.3 cm, 66.8 ± 10.9 kg⁻¹), previously familiarised with protocols, performed a WAnT30. In a subsequent separate session participants performed a modified 6-s Wingate Test (WAnT6) and a 6-s Wattbike Pro 'all out' sprint (Watt6) in a randomised manner. A 15 min standardised recovery was completed between sprints. Agreement was measured between WAnT6, Watt6 and WAnT30 using simple linear regression models and Bland Altman plots. **Results:** WAnT30 correlated with WAnT6 ($R^2 = 0.74$; $P < .001$) with a mean bias of -55 W. Between Watt6 and WAnT30 the agreement was $R^2 = 0.40$ ($P < .05$), with a mean bias of 41W. The bias between a WAnT30 and a WAnT6 could be corrected using the following equation: $WAnT30 = 0.691 * (WAnT6) + 156.1$ W ($r = 0.85$, $R^2 = 0.72$, $SEE = 60.3$ W; $P < 0.001$). **Conclusion:** A WAnT6 can be used instead of WAnT30 in recreationally active females when PP is the main measure of interest. This avoids unnecessary fatigue and

THURSDAY, JUNE 1, 2017

discomfort and would allow performance of other maximal tests in the same session. The regression equation provided in this study could be used to predict an individual's PP during WAnT30 from WAnT6.

2169 Board #182 June 1 3:30 PM - 5:00 PM

Evaluating Upper-body Strength And Power From A Single Test: The Ballistic Push-up

Ran Wang¹, Jay R. Hoffman, FACSM¹, Eliahu Sadres², Sandro Bartolomei¹, Tyler W.D. Muddle¹, David H. Fukuda¹, Jeffrey R. Stout, FACSM¹. ¹University of Central Florida, Orlando, FL. ²Wingate Institute for Physical Education and Sport, Netanya, Israel. (Sponsor: Jay Hoffman, FACSM)

(No relationships reported)

Muscular strength and power are major determinants for many explosive, short duration sporting events. Consequently, the assessment of muscular strength and power is imperative for training program design and talent identification purposes. The one repetition maximum (1RM) squat and bench press are the most frequently used field tests for assessing lower and upper body strength, respectively. However, time constraints and maximal testing for untrained individuals may limit the use of 1RM testing in large population groups. Additionally, there has been only a limited number of investigations that have focused on the evaluation of upper body muscular power. **PURPOSE:** The purpose of this study was to examine the reliability of the ballistic push-up (BPU) exercise, and to develop prediction equations for 1RM bench press and upper-body power. **METHODS:** Sixty recreationally-active men completed a 1RM bench press and two BPU in three separate testing sessions. Intraclass correlation coefficients (ICC) of peak and mean force, peak velocity, flight time, and peak and mean power were calculated and used to examine the reliability of the BPU. Mean force, flight time and peak velocity was used to develop equations to predict the 1RM bench press, and time-based and velocity-based upper-body power. **RESULTS:** ICC's ranged from 0.849 - 0.971 for the BPU measurements. Multiple regression analysis provided the following 1RM bench press prediction equations: $1RM = 0.31 \times \text{Mean Force} - 1.64 \times \text{Body mass} + 0.70$ ($R^2 = 0.837$, $SEE = 11$ kg); time-based power prediction equations: $\text{Peak Power} = 11.0 \times \text{Body Mass} + 2012.3 \times \text{Flight Time} - 338.0$ ($R^2 = 0.658$, $SEE = 150$ W), $\text{Mean Power} = 6.7 \times \text{Body Mass} + 1004.4 \times \text{Flight Time} - 224.6$ ($R^2 = 0.664$, $SEE = 82$ W); and velocity-based power prediction equation: $\text{Peak Power} = 8.1 \times \text{Body Mass} + 818.6 \times \text{Peak Velocity} - 762.0$ ($R^2 = 0.797$, $SEE = 115$ W); $\text{Mean Power} = 5.2 \times \text{Body Mass} + 435.9 \times \text{Peak Velocity} - 467.7$ ($R^2 = 0.838$, $SEE = 57$ W). **CONCLUSIONS:** Results indicate that the BPU is a reliable test for both upper-body strength and power. Furthermore, the mean force generated from the BPU can be used to predict 1RM bench press, while peak velocity and flight time measured during the BPU can be used to predict upper-body power. These findings support the potential use of the BPU as a valid method to evaluate upper-body strength and power.

Ntprobnp, Lactate And Bp Responses To The Want In Young Male Wrestlers And Untrained

Moran S. Saghiv, 58504, Kayla Cummings, Katie Kusser, Kellie Kvislen, Chris Knoll, John Dinkle, Levi Roemmich. University of Mary, Bismarck, ND.
Email: moransaghiv@gmail.com
(No relationships reported)

ABSTRACT

Purpose: To investigate the influence of the WAnT on blood pressure, lactate, and NTproBNP in trained Wrestlers and untrained young males. **Methods:** 20 males (n=20), ages 18-25 underwent the WAnT. The study included 2 groups. Group 1 included 10 untrained individuals, and group 2 included 10 wrestlers. NTproBNP (ng/mL), lactate (mmol/L), and blood pressure (mmHg) were measured at rest, immediate-post, two minutes post, and ten minutes post. The mechanical outputs (W) calculated for each subject. NTproBNP was analyzed utilizing ELIZA. **Results:** The wrestler's resting NTproBNP levels were higher (35.5 ± 7.59 vs 35.15 ± 4.82 accordingly), with non-significant differences between the groups. Immediate Post NTproBNP was higher for wrestlers (40.25 ± 14.08 vs 37.33 ± 9.94) with a positive and strong correlation between PP and IP NTproBNP ($r = 0.85$). While the untrained had a substantially higher post 10 NTproBNP (45.07 ± 11.75 vs 32 ± 5.57), both group's NTproBNP was elevated post 10 minutes with a significant difference from post 2 minutes values ($p=0.035$). PP was significantly higher for the wrestlers (1031.6 ± 188.65 vs 960.91 ± 189.01). No significant differences were found between groups for RPP and RMP. **Conclusions:** NTproBNP values were within the ranges reported in the literature. The WAnT did not put any of the subjects at risk due to cardiac stress. The recovery dynamics regarding NTproBNP were different between groups. Wrestlers recovered rapidly with a slight elevation 10 minutes post-test, while the untrained recovered slowly with a significant elevation of NTproBNP 10 minutes post-test.

(No relationships reported)

The repeated-sprint ability (RSA) test consists of 6 maximal sprints of 40m (20m + 180° turn + 20m) with 20s of passive recovery between each sprint. It has been used in most intermittent-like sport modalities (i.e. soccer, rugby) to match-relate athletes' performances, however, the RSA relationship with maximal exercise capacity as well as exercise tolerance needs to be investigated. **PURPOSE:** To verify the relationship between the RSA test with a maximal cardiopulmonary exercise test (CPX) and a constant speed test until time to exhaustion (TTE) of intermittent-sport female athletes. **METHODS:** Twenty-two professional female soccer athletes (23 ± 4 years, 55.4 ± 6.9 kg, 162 ± 6 cm, maximal oxygen uptake ($\dot{V}O_2$) 2341.8 ± 209.4 ml.min⁻¹) performed the RSA test in a grass field. RSA mean performance time and percentage of performance decrement were calculated afterwards (RSA_{mean} and RSA_{dec}, respectively). At least 48h later, all athletes underwent the CPX on a treadmill, where cardiac and respiratory variables were measured and calculated by a metabolic cart. Additionally, arterialized blood samples from earlobe puncture were collected in order to quantify blood lactate concentration ($[\text{lac}]_b$) during maximal exercise. Lastly, after 48h, all athletes performed a constant speed test (at 100% speed reached in CPX) until TTE to verify their exercise tolerance. **RESULTS:** Statistically significant correlations were found between: 1) maximal heart rate of CPX and RSA_{dec} ($P = .000$, $r = .692$); 2) $[\text{lac}]_b$ at the peak of CPX and RSA_{dec} ($P = .012$, $r = .539$); and 3) TTE and RSA_{dec} ($P = .000$, $r = -.632$). No correlations between RSA variables and $\dot{V}O_2$ were found. **CONCLUSION:** This study showed that maximal chronotropic and blood lactate responses to maximal exercise testing are related to RSA test performance. In addition, exercise tolerance obtained during a near maximal exercise performance is also associated to RSA test performance in female intermittent-like sport modality athletes. Supported by CNPq Grant #487385/2013-6 and FAPESP Grants #2014/10145-9 and #2015/04101-1.

Differences Between Open and Closed-Kinetic Chain Measurements for Assessing Bilateral Strength Deficits

Casey M. Watkins, Megan A. Wong, Saldiam R. Barillas, Ian J. Dobbs, Lee E. Brown, FACSM. California State University, Fullerton, Fullerton, CA.
(No relationships reported)

Rugby is an 80-minute closed-kinetic chain field sport with maximum bouts of speed, power, strength, and physicality. Assessing a player's strength capacity is important for determining position, eligibility, and return to play after injury. Bilateral strength deficits (difference between bilateral strength and the sum of both unilateral measures) could potentially put an athlete at greater risk for injury. The isometric mid-thigh pull (IMTP) is a closed-kinetic chain test examining multiple muscle groups force output involving the whole body, more similar to rugby, whereas the isometric knee extension is an open-kinetic chain test isolating the torque output of only the quadriceps muscle group. Some disagreement exists regarding whether open or closed-kinetic chain tests are more valid to assess an athlete's bilateral strength deficit. **PURPOSE:** To determine differences between an isolated open-kinetic chain and closed-kinetic chain tests to evaluate the bilateral deficit. **METHODS:** Seventeen club rugby athletes (men n=6, age=22.0±2.6 yrs, height= 172.66±6.12 cm, mass=80.28±11.13; women n=11, age= 24.72±3.66 yrs, height= 164.00±5.23 cm, mass =74.00±18.14 kg) completed a standardized warm-up then stood on an AMTI force plate and performed a bilateral IMTP, and two IMTP measured for each leg unilaterally in random order. They also performed a Biodex knee extension isometric test bilaterally, as well as each leg unilaterally in random order. **RESULTS:** ANOVA revealed that the Biodex bilateral deficit (20.99%±13.86%) was significantly greater than the IMTP (6.75%±9.78%). **CONCLUSIONS:** Injury rates have previously been associated with bilateral strength deficits, making strength assessments crucial for coaches. The IMTP closed-kinetic test may be more sport-specific, however, athletes may compensate for leg weaknesses with other muscle groups. The ability of the Biodex open-kinetic test to isolate specific muscle groups may be more beneficial for coaches testing bilateral strength deficits, and determining their athlete's return to play.

Physiological Attributes of an NCAA Intercollegiate Triathlon Team

Michelle Walters-Edwards¹, Michael Nordvall¹, Alexei Wong¹, David A. Edwards¹, Robert Axtell, FACSM². ¹Marymount University, Arlington, VA. ²Southern Connecticut State University, New Haven, CT.
Email: mwalters@marymount.edu
(No relationships reported)

The NCAA recently added women's triathlon to its "emerging sports" program. Prior literature has focused on the attributes of highly trained, junior elite, and recreational triathletes and comparative benchmark data of varsity intercollegiate triathletes are currently unavailable.

PURPOSE: To examine physiological attributes of NCAA varsity intercollegiate triathletes.

METHODS: Six male (age 19.0 ± 1.1 yrs) and 3 female (age 18.7 ± 0.6 yrs) varsity intercollegiate triathletes underwent physiological testing during maximal treadmill run and cycling protocols, and a 1km pool swim time trial performed on separate days. Physiological indices assessed for each protocol are presented in the table. Data were compared to determine sex differences between athletes in the present study and versus highly trained, junior elite and recreational triathletes as reported in the literature.

RESULTS:

Group differences were observed between males and females for the run and cycle tests and for the 1km swim.

	VARIABLE	MALE	FEMALE
RUN	VO _{2peak} (ml/kg/min)	66.2 ± 5.9	49.1 ± 4.6 *
	HRmax (bpm)	194.8 ± 8.3	201.0 ± 7.2 *
	Lactate Peak (mmol/l)	7.8 ± 2.5	11.0 ± 3.4 *
BIKE	VO _{2peak} (ml/kg/min)	60.9 ± 6.2	51.5 ± 2.1 *
	HRmax (bpm)	188.3 ± 3.6	184.7 ± 13.9
	Lactate Peak (mmol/l)	10.7 ± 2.5	8.4 ± 1.6 *
	Peak Watts	332.5 ± 14.4	283.3 ± 38.1 *
SWIM	Watts/kg	4.7 ± 0.2	4.7 ± 1.3
	HRmax (bpm)	182.2 ± 9.4	190.6 ± 9.2 *
	HRavg (bpm)	170.2 ± 8.8	180.6 ± 10.1
	Breaths per lap	8.7 ± 1.4	11.0 ± 0.8 *
	1 km time (min:sec)	12:45.6 ± 0:46	14:34.8 ± 1:03 *

* Sig. diff.; p ≤ 0.05; mean ± SD

Participants had lower VO_{2peak} values than highly trained (male 73.8 ± 1.6, female 59.7 ± 5.0 ml/kg/min; p ≤ 0.05) and junior elite triathletes for run (male 73.2 ± 7.4 ml/kg/min; p ≤ 0.05) and bike (male 68.2 ± 7.4 ml/kg/min; p ≤ 0.05) but had greater aerobic capacities than recreational triathletes for run (male 62.9 ± 7.2 ml/kg/min; p ≤ 0.05) and bike (male 59.6 ± 5.4 ml/kg/min; p ≤ 0.05). Mean (± SD) 1km swim times for male and female participants were significantly slower than national performance standards for 19 yr old triathletes (male 11:59.0 and female 12:48.0; p ≤ 0.05).

CONCLUSION: Our findings are the first to present physiological attributes of NCAA varsity intercollegiate triathletes and indicate favorable VO_{2peak} values compared to recreational triathletes, but not to highly trained or junior elite triathletes.

2174 Board #187 June 1 3:30 PM - 5:00 PM

Sex Differences In Bilateral And Unilateral Asymmetries In Recreationally Trained Individuals

Jasmine Wimbish, Christina N. Cooper, Elizabeth Montes, Lauren Bryant, Jason Ng, Guillermo Esacalante, Nicole C. Dabbs. California State University, San Bernardino, San Bernardino, CA. (Sponsor: Bryan Haddock, FACSM)
(No relationships reported)

PURPOSE: Limb musculature performance asymmetry can negatively impact various exercise and sport performance outcomes, but whether the percent difference of torque asymmetry between men and women is different remains less examined. Therefore, the purpose of the investigation was to determine sex differences in bilateral and unilateral asymmetries in recreationally trained individuals.

METHODS: Forty-five males (n = 24; age, 23.54 ± 2.24 yrs; mass, 83.07 ± 10.48 kg; height, 168.65 ± 2.14cm) and females (n = 21; age, 22.47 ± 2.42yrs; mass, 63.33 ± 6.80kg; height, 163.94 ± 5.71cm) participated in both a familiarization session and a testing session in one day. Participants signed an IRB approved informed consent, physical activity readiness questionnaire, and a health history questionnaire, followed by measuring age, weight, and height. Participants were instructed to perform 5 maximal repetitions of knee flexion and extensions on each leg at an angular velocity of 60°/s. Percent differences in torque were calculated for bilateral and unilateral asymmetries, bilateral quad percent difference (BQ%), bilateral hamstring percent

difference (BH%), unilateral right leg percent difference (UR%) and unilateral left leg percent difference (UL%). Independent t-tests were used to analyze sex differences between all variables. Additionally, independent t-tests were used to analyze sex differences between age, height, and weight.

RESULTS: There were no significant (p>0.05) differences between recreationally trained males and females for BQ% (M= 9.89 ± 5.95%; F= 7.26 ± 5.69%), BH% (M= 6.97 ± 5.97%; F= 10.02 ± 10.88%), UR% (M= 50.28 ± 6.86%; F= 46.65 ± 11.28%), and UL% (M= 50.19 ± 7.71; F= 50.13 ± 10.85%). There was no significant (p>0.05) difference between sex for age and height, however there was a significant (p<0.05) difference for weight.

CONCLUSIONS: Sex appears to have no significant effect on the percent difference of bilateral and unilateral torque asymmetries despite several different known physiological aspects. This could be due to the fact that our subject population was recreationally trained individuals, which can represent multitude of sports, workouts and training programs. Future research should investigate sex differences in sport-specific athletes.

2175 Board #188 June 1 3:30 PM - 5:00 PM

Correlation Between Bench Press and Pushup Repetitions to Failure Relative to Bodyweight

Taran E. Eckel, Casey M. Watkins, David C. Archer, Megan A. Wong, Lee E. Brown, FACSM. California State University, Fullerton, Fullerton, CA.
(No relationships reported)

The bench press and pushup are popular exercises used to develop strength and power. They are also often associated with equal benefits in developing upper body muscular endurance. However, it is unknown how they are related as pushups use a bodyweight load while the bench press uses greater weight. **PURPOSE:** To investigate the correlation between bench press and pushup repetitions to failure relative to a bodyweight load. **METHODS:** Fourteen recreationally trained males (age=24.71±2.64yrs, height=177.29±6.87, mass=83.74±9.41) performed a 1RM bench press test and an isometric pushup to determine bodyweight load supported in both the up and down positions. Grip width on the bench press was measured as the distance between middle fingers and this distance was used for hand placement during pushups. Subjects were positioned for a pushup with their hands on an AMTI force plate and their feet off the plate. Isometric force was measured for 3 seconds in the up and down positions, in random order. For the down position, triceps were parallel to the floor, while for the up position, triceps were perpendicular to the floor. Days 2 and 3 consisted of performing repetitions to failure for either the bench press or pushup exercise. For the pushup, subjects performed repetitions following an 80/s tempo. The test was terminated if they failed to complete a full repetition, could not maintain cadence or there were three faults in form. For the bench press, subjects performed repetitions to failure with a load that was equal to the average relative bodyweight force of the up and down pushup positions. **RESULTS:** There was a very low relationship (r=0.289) between bench press repetitions to failure (29.5±7.59) and push up repetitions to failure (33.0±6.53). Load for the bench press test, relative to their 1RM (0.51%±0.07) was significantly less than the pushup down position (0.75%±0.03), up position (0.71%±0.03), and the average of the up and down positions (0.73%±0.03) relative to their body mass. **CONCLUSIONS:** The bench press and pushup must be seen as two distinct and different exercises that use very different loads, which could result in dissimilar upper body muscular endurance adaptations.

2176 Board #189 June 1 3:30 PM - 5:00 PM

Hamstrings to Quadriceps Ratios Differ Between Legs and Isometric and Dynamic Tests in Amateur Rugby Players

Ian J. Dobbs, Casey M. Watkins, Megan A. Wong, Saldiam R. Barillas, Lee E. Brown, FACSM. California State University, Fullerton, Fullerton, CA.
(No relationships reported)

Non-contact knee injuries have been associated with large differences in strength between the quadriceps and hamstrings muscle groups. Similarly, favoring movements on the dominant vs. non-dominant leg may lead to imbalances that could result in injury. Screening players for hamstring to quadriceps ratios (HQR) by measuring isometric and dynamic strength prior to the season may demonstrate mode specific imbalances. **PURPOSE:** To measure the dynamic and isometric strength of the quadriceps and hamstrings in the dominant and non-dominant legs of rugby players prior to a collegiate season. **METHODS:** 19 amateur rugby players (11 females, age= 24.73±3.66 yrs, height=164.00±5.23 cm, mass=74.00±18.14 kg) and (8 males, age=22.38±2.45 yrs, height=175.38±7.44 cm, mass=83.24±10.99 kg) performed dynamic maximal effort 3-repetition isokinetic concentric knee flexion/extension at 60°/s, and maximal effort isometric tests on the dominant and non-dominant legs on a Biodex dynamometer at a 60° knee angle. Peak torque (PT) was measured for all tests. **RESULTS:** Dominant leg Q isometric PT was 231.61±58.11Nm and H was 140.90±39.76Nm. Dominant leg Q dynamic PT was 222.58±59.63Nm and H

was 152.60±47.04Nm. Non-dominant Q isometric PT was 240.02±80.49Nm and H was 132.42±38.65Nm. Non-dominant Q dynamic PT was 219.50±68.14Nm and H was 164.81±59.14Nm. A 1x4 repeated measures ANOVA revealed that dominant leg isometric HQR (.61±.10) was less than dominant leg dynamic HQR (.69±.12). Non-dominant leg isometric HQR (.57±.09) was less than non-dominant leg dynamic HQR (.76±.16). Dominant leg isometric HQR was greater than non-dominant HQR while non-dominant leg dynamic HQR was greater than dominant leg dynamic HQR. **CONCLUSIONS:** These results demonstrate that rugby players have greater HQR ratios in dynamic vs. isometric strength tests in both legs. Dynamic strength is displayed during rugby specific situations such as the scrum and therefore may be a more relevant measure. However, the importance of isometric HQR should also be of concern as isometric and dynamic muscle actions are performed by the hamstrings and quadriceps throughout a game. Therefore, test specificity should be considered when assessing muscle strength and ratios.

Effect Of Exercise Intervention On Health States Of Civil Servants In Chengdu City

Yushi Hu, Xihui Liu, Hua Shen, Quansheng Su, Junzhi Sun, Xiaorui Zhang. *ChengDu Sport Institute, ChengDu, China.*
 Email: 603457104@qq.com
 (No relationships reported)

PURPOSE: Understand the health states of civil servants in Chengdu city by physical measurement and blood test, and design different exercise prescription to the civil servants. Observe its effect, so as to provide practical information to the exercise intervention in health states.

METHODS: Through the random number table method randomly divide 110 Chengdu civil servants, aged 20-59 into 5 groups (control group, 6000 steps, 10000 steps, 6000 + joint gymnastic, 10000 + joint gymnastic, and each group of 22 people), took an exercise intervention 4 times per week for 12 weeks. The physical and blood parameters were measured before and after intervention, at the same time analyzed the intervention effect. Statistical analysis, T-test, and one-way ANOVA were conducted by SPSS19.0. $P < 0.05$ was considered statistically significant. **RESULTS:** Compared with pre-intervention: ① There were no significant difference in 6000 group. ② There were significant differences in body shape, SBP and muscle strength in 10000 group ($P < 0.05$), and TG was significantly decreased ($P < 0.05$). ③ There were significant differences in waist circumference and systolic blood pressure in 6000+group ($P < 0.05$). ④ The scores of physical fitness, body shape, BP, upper and lower limbs muscle strength and flexibility were significantly improved ($P < 0.05$) in 10000+group, TC, TG and LDL were significantly decreased ($P < 0.05$). ⑤ Compared between these interventions, walking+joint gymnastic is better than walking, 10000+joint gymnastic is the best.

CONCLUSIONS: ① The health status especially in blood indicators of Chengdu civil servant is not good compared with other people in China. We should strengthen the public health awareness. ② Exercise is medicine, exercise can effectively improve the health, physical quality and the state of blood of civil servant. The 10000+joint gymnastic it is worth promoting in change the health status of civil servants.

Validation Of An On-ice Continuous Multistage Test For Short Track Speed Skaters

Fanie St-Jean Miron, Andrée-Anne Parent, Vincent Gosselin Boucher, Alain Steve Comtois. *University of Quebec in Montreal, Montreal, QC, Canada.* (Sponsor: Jean P. Boucher, FACSM)
 Email: stj.fanie@gmail.com
 (No relationships reported)

PURPOSE: There are still no sport-specific tests to evaluate directly on ice the aerobic capacity for short track speed skating athletes. The aim of this project was to create an on-ice test to estimate skater's VO_{2max} .

METHODS: Two athletes of the men's Canadian national team participated in the pilot study. Participants were 22 years old, with mean body weight of 69.8 ± 1.0 kg and height of 176.5 ± 8.9 cm. The skaters performed a continuous multistage test on Olympic-sized ice rink (Maurice Richard arena, 111.12m course perimeter). An audio track was created (beep test audio track) so that the speed of skating would accelerate by 0.20 seconds every 2 lap stages. The first stage started at 13.0 seconds/lap, representing a speed of 8.55 m/s. The skaters had to follow the rhythm of increasing speed until exhaustion or until they could no longer maintain the pace (off on two consecutive beeps). Measurements during the test for oxygen consumption (VO_{2}), respiratory exchange ratio (RER) and heart rate (HR) were performed with a portable metabolic analyzer and an HR monitor.

RESULTS: Skater #01 stopped at stage 15 (10.89 m/s) with an HR of 185 bpm, a VO_{2max} of 61 ml/min/kg and a RER of 1.27, compared to skater #02 who stopped at stage 18 (11.58 m/s) with an HR of 194 bpm, a VO_{2max} of 66 ml/min/kg and a RER

of 1.28. These preliminary results suggest that the protocol brings athletes to their maximal capacity by reaching a plateau for the HR and VO_{2} , and a RER higher than 1.15.

CONCLUSIONS: A progressive speed skating test till exhaustion appears to measure maximum aerobic capacity of elite speed skaters. Nonetheless, many other data collections should be done with different levels of skaters, at different ages and gender, with the aim of creating a VO_{2max} estimating chart and also confirmed with a laboratory-based VO_{2max} measurement on cycle ergometer.

2179 Board #192 June 1 3:30 PM - 5:00 PM
Muscle Function Tests as Field Measures of Tibial Bone Strength

Rebekkah J. Reichert, Andrew Denys, Sherah McCurdy, Vanessa R. Yingling, FACSM. *California State University, East Bay, Hayward, CA.*
 (No relationships reported)

Osteoporosis is a leading cause of fracture and morbidity in older populations (Colon-Emeric & Saag, 2006). An effective strategy in minimizing the risk of osteoporosis is an active lifestyle in adolescence (Turner, 2004). Suboptimal bone strength in individuals who do not reach peak bone mass during childhood or adolescence may contribute to the development of fractures later in life (Bachrach, 2001). Bone strain and, thus, structural adaptations of bone are due to muscle forces acting on bone during activity (Robling, 2009). Therefore, field measures of muscle force could be used to assess skeletal health. **PURPOSE:** The purpose of this study is to investigate the relationship between common muscle function tests (1 rep max/body weight, relative grip strength, peak power) and bone strength variables in a healthy college-age population. **METHODS:** Twenty participants from CSU East Bay, 9 females and 11 males (age (yrs) 23.4 ± 2.5, height (m) 1.7 ± 0.1, body fat % 20.8 ± 9.6) performed a relative grip strength test using a hand dynamometer, a one repetition maximum (1 RM) on a leg press machine and a vertical jump test using the Vertec. Peak power was then calculated from vertical jump height. Moment of inertia (J), cortical area (Ct.Ar), cortical bone mineral density (cBMD), and strength-strain index (SSI) were measured using peripheral Quantitative Computed Tomography (pQCT) to determine bone strength at the 50% tibia site. Correlation analysis determined muscle bone relationships. **RESULTS:** 1 RM/BW and relative grip strength were not significantly correlated with bone strength parameters. Peak power resulted in significant, positive correlations with J ($R^2 = 0.6089$, $p = 0.008$), Ct.Ar ($R^2 = 0.6030$, $p = 0.008$), and SSI ($R^2 = 0.5948$, $p = 0.009$). Peak power resulted in a significant, but negative relationship with cBMD ($R^2 = 0.7080$, $p = 0.002$). **CONCLUSION:** Our findings suggest peak power is a significant surrogate measure of bone strength in a healthy college-age population. Although cBMD had a negative relationship with peak power, this finding is possibly due to low numbers of participants at this stage. This study is important because health professionals and physical educators can use peak power as a practical and non-invasive method of determining bone strength and health.

The Age-related Changes In Multi- And Single-joint Measures Of Power Output

Hayden Giuliani¹, Brennan Thompson², Eric Sobolewski³, Eric Ryan¹. ¹University of North Carolina-Chapel Hill, Chapel Hill, NC. ²Utah State University, Logan, UT. ³Furman University, Greenville, SC. (Sponsor: Abbie Smith-Ryan, FACSM)
 (No relationships reported)

Many previous studies have demonstrated age-related reductions in power output. However, few studies have identified if the age-related declines in power output during a functional lower body movement are similar to single-joint isokinetic testing.

PURPOSE: To compare the relationships between the age-related reduction in power output using a single-joint isokinetic muscle action versus a more functional multi-joint vertical jump (VJ) assessment.

METHODS: Forty middle- to older-aged men (mean ± SD; age = 59.2 ± 7.8 years; range = 50-74 years) visited the lab on two occasions, separated by 48-72 hours. During the second visit, and following a familiarization session on visit one, participants performed 2-3 maximal countermovement VJ attempts while attached to commercially available equipment designed to examine lower body power output. The equipment was placed on the floor behind the subject to allow the cord to be extended without impeding the VJ technique. Following the VJ assessment, the participants performed three maximal concentric isokinetic muscle actions of the right leg extensors at 240°·sec⁻¹ using a calibrated isokinetic dynamometer. The torque and position signals were sampled from the dynamometer at 2 kHz and were processed offline using custom written software. Isokinetic mean power (MP) was calculated as the product of the average torque (Nm) during the load range and isokinetic velocity (°·sec⁻¹). Pearson correlation coefficients (r) were used to evaluate the relationships between age and VJ, and age and isokinetic MP. The Steiger Z calculation and an effect size was used to determine the difference between the relationships. The alpha level was set at $P \leq 0.05$.

RESULTS: There were significant relationships between age and VJ power output ($r=-0.633$; $P<0.001$) and age and isokinetic MP ($r=-0.410$; $P=0.009$). The correlation coefficients were similar ($P=0.112$), however, there is a moderate difference (effect size=0.31) between the relationships.

CONCLUSIONS: Single-joint isokinetic power output may demonstrate a weaker, but similar relationship with age when compared with more functional VJ assessments.

Comparison Of Mechanical Efficiencies From Self-selected And Rapid Speed Rock Climbs

Rickelle Tallent¹, Andrea Woita¹, Charli Aguilar¹, John Young, FACSM¹, James Navalta, FACSM¹, Nathaniel Bodell¹, Elizabeth Tanner¹, Jeffery Montes¹, Grace MacDonald¹, Camille Thomas², Jacob Manning², Julie Taylor². ¹UNLV, Las Vegas, NV. ²Southern Utah University, Cedar City, UT. (Sponsor: Dr. James Navalta, FACSM)
 Email: rickelle.tallent@unlv.edu
 (No relationships reported)

Purpose: To determine if there is a difference in mechanical efficiency between a self-preferred and a rapid-speed rock climb.

Methods: Ten experienced climbers volunteered to participate in this study (ages 18-40 years, 7 males, 3 females, at least one year of recreational climbing experience). Participants climbed up and down a vertical route (30 feet) on a rock-climbing wall at a self-selected pace for ten minutes. They then climbed the same vertical route as fast as they could to cover the same distance achieved during the 10 minutes of the self-selected climb. VO₂ was measured at rest and then continuously during the climb using a portable COSMED device. Mechanical efficiency of each participant was calculated for both the self-selected pace and rapid-speed climbs, and then compared using a paired T-test on Microsoft Excel 2016 with statistical significance accepted at $p<0.05$.

Results: There was no significant difference in mechanical efficiency between the self-preferred and rapid speed climbs ($p=0.4211$).

Conclusion: The rock climbers did not experience a significant change in mechanical efficiency between the self-selected and rapid-speed climbs. Familiarity with the climbing route and forearm fatigue may have contributed to this finding. Future studies should consider using a counterbalance system for assigning climbing order.

The Relationship between Echo Intensity and Specific Strength as Measures of Muscle Quality

Jacob A. Mota, Gena R. Gerstner, Hayden K. Giuliani, Timothy J. Barnette, Eric D. Ryan. University of North Carolina at Chapel Hill, Chapel Hill, NC. (Sponsor: Abbie Smith-Ryan, FACSM)
 Email: jamota@unc.edu
 (No relationships reported)

The use of ultrasound (US) echo intensity (EI) as a measure of muscle quality has increased in popularity over recent years. However, in early studies muscle quality was quantified as a function of force per unit of muscle, or specific strength (MQ_{ST}). Limited data exist that have examined the relationship between these two measures of muscle quality. **PURPOSE:** The purpose of this study was to examine the relationship between US EI and MQ_{ST} as measures of muscle quality. **METHODS:** Thirty-one healthy volunteers (mean ± SD age, 35 ± 7 yrs; Body Mass Index [BMI], 28.66 ± 5.08) participated in this study. Following a familiarization session, participants visited the laboratory on a separate occasion for isometric strength testing and skeletal muscle US imaging. Peak torque (PT) was determined from highest mean value (500 ms) that occurred during three maximal voluntary contractions. Vastus lateralis (VL) cross-sectional area (CSA) and EI were assessed with a B-mode US device. The VL images were taken perpendicular to the longitudinal axis of the muscle at half of the distance between the greater trochanter and articular cleft of the knee. All US images were analyzed in ImageJ using the polygon function to determine the VL CSA that included as much muscle as possible without the surrounding fascia. The same region of interest was used for the EI (gray-scale) analyses and subsequently corrected for subcutaneous fat thickness. MQ_{ST} was defined as PT per unit of muscle size (VL CSA). Pearson correlation coefficients were used to examine the relationship between VL EI and MQ_{ST}, while separate partial correlation coefficients were used to examine the influence of BMI and sex. An alpha level of $P \leq 0.05$ was used to determine statistical significance. **RESULTS:** There was a significant relationship between VL EI and MQ_{ST} ($r = 0.409$, $P = 0.022$). In addition, similar relationships existed when controlling for BMI ($r = 0.376$, $P = 0.041$) and sex ($r = 0.411$, $P = 0.024$). **CONCLUSIONS:** A significant relationship exists between VL EI and MQ_{ST}, however a large amount of variance is left unexplained ($r^2 = 0.167$). Although both are considered to reflect muscle quality, each measure may be influenced by unique physiological variables (i.e. muscle activation, hydration status). **GRANT FUNDING:** National Institute of Occupational Safety and Health (T42OH008673)

Improved Fitness Trends In Firefighter Recruits Over A 12-year Span

Annamarie Chizewski¹, Tina A. Greenlee², Daniel R. Greene¹, Kathryn Rougeau¹, Denise L. Smith, FACSM³, Steven J. Petruzzello, FACSM¹. ¹University of Illinois at Urbana-Champaign, Urbana, IL. ²Center for the Intrepid, Fort Sam Houston, TX. ³Skidmore College, Saratoga Springs, NY. (Sponsor: Steven J. Petruzzello, FACSM)
 Email: chizews2@illinois.edu
 (No relationships reported)

Firefighting is a physically demanding occupation. As a population, firefighters (FFs) are at high risk for many health-related issues (e.g., sudden cardiac events, obesity, hypertension, fatigue, depression, post-traumatic stress disorder, anxiety). Physical fitness is an effective preventative strategies FFs can use to improve health and performance, as well as combat multiple health risks. **PURPOSE:** Examine physical fitness parameters and assessments in FFs from 2004 through 2016. **METHODS:** Participants were male FF recruits ($N=556$; 26.3 ± 4.2 yrs; ht: 179.98 ± 7.32 cm; wt: 87.20 ± 15.0 kg) from the Illinois Fire Service Institute. Baseline descriptive measurements included waist (89.99 ± 11.4 cm) and hip circumference (95.71 ± 9.8 cm), and BMI (26.97 ± 4.21). Baseline fitness testing included measurements of cardiovascular endurance (1.5-mi run (12.87 ± 1.77 min, $M \pm SD$); estimated VO_{2max} (41.54 ± 5.10 ml·kg⁻¹·min⁻¹), muscular endurance [60-s sit-ups (31.6 ± 8.5 reps), 60-s push-ups (40.3 ± 12.3 reps), bench press (28.99 ± 11.4 reps)], and flexibility [sit and reach (30.65 ± 7.8 cm)] during the first week of a 6-wk fire academy. **RESULTS:** Significant differences were shown across time ($P_s < 0.001$, all $ES_s = 0.86-0.99$) for weight and BMI, waist and hip circumference, 1.5-mi run time, 60-s push-ups, 60-s sit-ups, muscular endurance, and flexibility. Analyses examining trends over the 12-yr span revealed relationships between time and 1.5-mi run time ($r=0.67$), 60-s push-ups ($r=0.51$), muscular endurance ($r=0.56$), and flexibility ($r=0.74$). **CONCLUSIONS:** Over the span of 12 years, male FF recruits have shown increases in various fitness parameters (cardiovascular endurance, muscular strength/endurance, flexibility) while measures of weight, BMI, waist and hip circumferences have remained relatively stable and consistent. Measures of cardiovascular endurance (1.5 mi run time) improved by 11.9% over this time period, and measures of muscle strength/endurance (e.g., push-ups) increased by 21.8%. The data suggest that the fitness levels of male FFs are increasing as they begin their career in the fire service. These increases in fitness may reflect national efforts in the fire service to promote fitness and may lead to decreases in disease and work-related disability.

Physical Activity Intervention Fitness Of Male'S Middle Students In China: A Systematic Review And Meta-analysis

Jindong Chang¹, Ming Yang¹, Yan Peng¹, Yi Li¹, Hao Guo¹, Mingxi Guan². ¹Southwest University, Chongqing, China. ²Chongqing Business Vocational College, Chongqing, China. Email: changlai@163.com
 (No relationships reported)

Purpose: Approximately 50 % of Chinese weight are not reach the national standard. Approximately 70 % of Chinese adolescent are not physically active enough to achieve health benefits. The purpose of this study was to systematically review and meta-analyze the effect of fitness for Chinese middle students interventions on physical activity.

Methods: CNKI, Wanfang Data, Weipu Data and Web of Science Database were systematically searched to identify all relevant randomized controlled trials that evaluated the effect of fitness for Chinese middle students on physical activity from 2011 to 2015 years. According to the study design, the data of the boys were selected for analysis. The studies were described and effect size data were included in meta-analyses.

Results: Eighteen studies were included in the review and ten reported statistically significant improvements in physical activity. A meta-analysis of ten studies showed a statistically significant effect (SMD= 0.21, $p=0.004 < 0.01$) of Grip on physical activity immediately post-intervention. The intervention had a statistically significant effect (SMD=0.20, $P=0.006 < 0.01$) of the Sit and Reach. However, it is not statistically significant effect of Vital Capacity (SMD=0.19, $P=0.25$), Weight (SMD=-0.11, $P=0.12$) and Height (SMD=0.13, $P=0.06$) on physical activity immediately post-intervention.

Conclusion: Daily activity is to be effective at increasing weekly duration of exercise in middle students, but the effect size is small. Training Chinese adolescents to encourage increased physical activity may provide an effective method for reaching their fitness health. More studies with detailed quantification of total physical activity will help to find more precise relative estimates for different levels of activity of Chinese adolescents.

The Relationship between Vertical Power and Bone Mineral Content in College-Aged Women

Chelsea Wenrich¹, Brittany Masteller¹, Swapan Mookerjee¹, Curt B. Dixon, FACSM², Joseph L. Andreacci, FACSM¹.
¹Bloomsburg University, Bloomsburg, PA. ²Lock Haven University, Lock Haven, PA. (Sponsor: Joseph L Andreacci, FACSM)

(No relationships reported)

INTRODUCTION: Peak and mean power assessed, by a vertical jump, has been shown to be a strong predictor of bone mineral content (BMC) in children and adolescents. However, this relationship has not been demonstrated in young women. **PURPOSE:** To examine the relationship between vertical power and BMC in college-aged women. **METHODS:** Body composition and BMC was assessed by dual-energy X-ray absorptiometry in 77 women (age: 20.9 ± 2.2 years, height: 163.3 ± 12.7 cm, body mass: 60.9 ± 8.5 kg). Peak and mean vertical power was determined using a VertecTM scale and was calculated by the Sayers and Lewis equations, respectively. **RESULTS:** Peak and mean vertical power were 3109 ± 521 Watts and 841 ± 125 Watts, respectively. Relationships were observed between BMC and peak vertical power ($r = 0.52, p < 0.001$) as well as mean vertical power ($r = 0.58, p < 0.001$). Multiple linear regression ($r = 0.63, p < 0.001$) resulted in the following equation: $BMC = 0.436 - (0.00107 * \text{Peak Power}) + (0.00635 * \text{Mean Power})$. Additionally, a strong relationship was observed between body mass and BMC ($r = 0.75, p < 0.001$). **CONCLUSIONS:** The results of this study indicate that 40% of the variability of BMC in college-aged women can be predicted by peak and mean vertical power. These findings support the use of an assessment of vertical power as a predictor of bone strength in young women. We recommend that college-aged women with a goal to improve BMC perform plyometric types of activities that involve jumping and rebounding.

2186 Board #199 June 1 3:30 PM - 5:00 PM
Sex Differences in the Physiological Responses of Elite Collegiate Hockey Players during a Submaximal Test

Patrick Delisle-Houde, Nathan Chiarlitti, Jessica A. Insogna, Ryan ER Reid, Ross E. Andersen, FACSM. McGill University, Quebec, QC, Canada. (Sponsor: Ross E. Andersen, FACSM)
 Email: patrick.delisle-houde@mail.mcgill.ca

(No relationships reported)

To optimize the health and sport performance in athletes, sport scientists have recently turned to monitoring physiological variables and markers of performance. Currently, preferred types of monitoring have not been identified and past research has shown that males and females might react differently to physiological stress. **Purpose:** To compare the physiological response of male and female elite collegiate hockey players after a 4-minute submaximal cycling test performed at a predicted 75% of $\dot{V}O_2$ max. **Methods:** 52 elite Canadian collegiate hockey players, 28 males (age = 22.6 ± 1.3 , height = 182.59 ± 6.00 cm, weight = 87.12 ± 6.43 kg, body fat = $17.3 \pm 4.28\%$) and 24 females (age = 19.9 ± 1.3 , height = 166.97 ± 7.20 cm, weight = 67.75 ± 8.10 kg, body fat = $26.3 \pm 4.68\%$) participated in a 4-minute submaximal cycling test at a predicted 75% of $\dot{V}O_2$ max. Heart rate (HR) and rate of perceived exertion (RPE) were assessed during each stage and after the submaximal test, while blood lactate level was measured 2 minutes after the test. ANOVA was used to compare sex differences in HR, RPE and post exercise blood lactate. **summary of Results:** Females had higher heart rates at each stage of the exercise test: time 1 ($F(1,51) = 5.914, p \leq .05$), time 2 ($F(1,51) = 14.457, p \leq .05$), time 3 ($F(1,51) = 15.299, p \leq .05$) and time 4 ($F(1,51) = 14.628, p \leq .05$). There were no between sex differences in post exercise blood lactate and RPE at any stage of the exercise test. **Conclusion:** Under similar physiological stress, male and female athletes demonstrate similar post exercise blood lactate levels. However, submaximal heart rates at each stage of the submaximal test were higher among the female athletes. More work is needed to understand cardio-metabolic sex differences, which could help sport scientists better tailor training program for elite female athletes. This novel method of testing may be suitable for tracking physical fitness over the course of a playing season for male and female athletes.

Physical Activity Level Of College Students: Do We Really Know How Much?

Ashby M. Williamson, Danielle N. Ludlam, Sarah M. Henry, George W. Lyerly, FACSM. Coastal Carolina University, Conway, SC.

Email: amwilli9@g.coastal.edu

(No relationships reported)

Physical Activity Level of College Students: Do we really know how much? Ashby M. Williamson, Danielle N. Ludlam, Sarah M. Henry, G. William Lyerly. Coastal Carolina University, Conway, SC 29528
Background: Around the world, people in different populations are struggling with mental and physical disabilities that are caused by poor health. Poor health involves many factors including a low physical activity (PA) level. A person's PA can be measured in several ways, one that has become popular is an accelerometer. Most PA guidelines recommend that an adult must acquire 7,500-10,000 steps/day to be considered somewhat active. However, studies have found that different equipment can calculate different step counts. **Purpose:** To determine if college students are meeting recommendations for physical activity in regards to steps taken per day and if current measurement devices are accurately reporting these outcomes. **Methods:** Thirty one college students (20 y.o.; 69.93 kg) wore an Actigraph GT3X accelerometer (GT3X) around the waist during daily activities to determine steps taken in an average week. We compared our calculated outcomes versus GT3X's reported outcomes. All data used was collected via the GT3X. **Results:** The GT3X reported that the students averaged 5,746 steps/day, while we calculated an average of 4,493 steps/day, resulting in a difference of 1,253 steps/day. **Conclusion:** Our results indicated that college students either fall in a step count range of approximately less than 5,000 or a range of 5,000-7,499 steps/day. Our data suggests that college students may be categorized as low active or sedentary based on which count is accurate. The difference in steps may have resulted from how total time was calculated. Further research is warranted to gain a better understanding of how to monitor the accuracy of measurement devices when determining activity levels for a population. This gained knowledge could lead to healthier students with a lower risk of mental and physical disabilities across multiple college campuses.

2188 Board #201 June 1 3:30 PM - 5:00 PM
Agreement of Ventilatory Responses to Continuous and Interval Specific Taekwondo Cardiopulmonary Exercise Tests

Matheus Hausen¹, Pedro Paulo Soares¹, Marcus Paulo Araujo¹, Débora Esteves¹, Hilbert Julio¹, Roberto Tauil¹, Flávia Porto², Jonas Gurgel¹. ¹Fluminense Federal University, Niterói, Brazil. ²Rio de Janeiro State University, Niterói, Brazil.

(No relationships reported)

PURPOSE: To analyze the agreement of ventilatory responses of continuous and interval taekwondo cardiopulmonary exercise tests (CTKDet and iTKDet, respectively). **METHODS:** Twelve male taekwondo athletes (age: 20 ± 2 yrs; body mass: 67.5 ± 5.7 kg; height: 175 ± 8 cm) visited the laboratory three times. The University ethics committee approved this study (opinion #765.698). In the first visit, an anthropometric assessment was performed. In the next two visits, participants performed cTKDet and iTKDet, in a counterbalanced order. Taekwondo tests were constituted by progressive stages of kicking sequences, with 1 min duration, and kick intervals starting from 4,6s and reduced 0,4s every minute until fatigue. iTKDet also presented a passive recovery between every two stages. During all tests, respiratory variables were measured continuously with expired gas analyzer VO2000 (MedGraphics, Saint Louis, USA), with 20s sampling. Ventilatory thresholds were determined by the ventilatory equivalents method. Shapiro-Wilk test was performed to verify normality. Parametric data were described by average (standard deviation), 95% Confidence Interval of Mean, and compared using Paired T-test (effect size: Cohen's *d*). Non-parametric data were described by median (interquartile range), 95% Confidence Interval of Median, and compared using Wilcoxon test (effect size: z/\sqrt{n}). Ventilatory responses agreement was assessed with Intraclass Correlation Coefficient (ICC) and ICC 95% confidence interval calculation. $P < 0.05$ was adopted for all tests. **RESULTS:** The results are present in Table 1. **CONCLUSION:** Besides the absence of significant difference between the test, interval, and continuous methods may not be interchangeable to assess Taekwondo athletes' ventilatory responses. Additionally, interval seems to yield higher performance, with shorter kick intervals, for peak and ventilatory thresholds in the specific tests. Supported by CAPES, FAPERJ, and CNPq.

Table 1. Agreement of ventilatory responses to cTKDet and iTKDet.

		Mean (SD) or Median (IR)	95%CI	Comparison Test's ρ (ES)	ICC (ICC 95%CI)
VO ₂ PEAK (mL.kg ⁻¹ .min ⁻¹)	cTKDet	52.3 (5.3)	48.9 - 55.7	0.73 (0.10)	0.82* (0.34 - 0.95)
	iTKDet	52.7 (4.3)	50.0 - 55.4		
Peak Kicks Interval ^{NP} (s)	cTKDet	1.2 (0.2)	1.0 - 1.4	0.004* (-0.82)	0.19 (-0.24 - 0.63)
	iTKDet	0.9 (0.1)	0.8 - 1.0		
VT ₁ VO ₂ ^{NP} (mL.kg ⁻¹ .min ⁻¹)	cTKDet	38.8 (1.0)	37.8 - 39.9	0.14 (-0.43)	0.22 (-1.05 - 0.75)
	iTKDet	35.8 (3.8)	33.3 - 39.9		
VT ₁ VO ₂ (%)	cTKDet	73.6 (5.8)	68.0 - 79.0	0.11 (0.51)	-0.22 (-2.05 - 0.60)
	iTKDet	69.5 (4.9)	66.0 - 72.0		
VT ₁ Kicks Interval ^{NP} (s)	cTKDet	4.0 (0.2)	3.8 - 4.2	0.02* (-0.74)	0.17 (-0.61 - 0.69)
	iTKDet	3.8 (0.0)	3.4 - 3.8		
VT ₂ VO ₂ ^{NP} (mL.kg ⁻¹ .min ⁻¹)	cTKDet	46.9 (5.0)	41.6 - 50.8	0.64 (0.14)	0.74* (0.06 - 0.92)
	iTKDet	47.6 (5.5)	43.6 - 51.9		
VT ₂ VO ₂ (%)	cTKDet	89.7 (3.4)	88.0 - 92.0	0.80 (0.07)	0.34 (-1.66 - 0.82)
	iTKDet	90.2 (6.8)	84.0 - 97.0		
VT ₂ Kicks Interval ^{NP} (s)	cTKDet	1.8 (0.3)	1.4 - 2.2	0.02* (-0.68)	0.39 (-0.30 - 0.79)
	iTKDet	1.4 (0.0)	1.0 - 1.4		

cTKDet - continuous taekwondo cardiopulmonary exercise test; iTKDet - interval taekwondo cardiopulmonary exercise test. p - Significance level. 95% CI - 95% confidence interval. ES - Effect Size. ICC - Intraclass Correlation Coefficient. The absence of ^{NP} denotes parametric data, presented as mean (sd - standard deviation) and 95% confidence interval of mean (inferior limit - superior limit). ^{NP} Denotes non-parametric data, presented as median (IR - interquartile range) and 95% confidence interval of median (inferior limit - superior limit). Parametric data compared through Paired T-test (Cohen's d effect size). Non-parametric data compared through Wilcoxon signed rank test (z/\ln effect size). * Denotes $p < 0.05$. VO₂PEAK - Highest oxygen uptake value observed. VT - Ventilatory threshold. Percentage variables (%) were calculated with the peak value observed at each test.

2189 Board #202 June 1 3:30 PM - 5:00 PM

Training-Induced Change in Aerobic Fitness and Anaerobic Power among Female College Basketball Players

Ja'Da Brayboy, Tianna Knuckles, Chatori Major, Taylor Tramel, Bailey Parton, Aubrianna Rote. *UNC Asheville, Asheville, NC.*
(No relationships reported)

PURPOSE: To examine training-induced changes in aerobic fitness and anaerobic power in a sample of division I, female college basketball players.
METHODS: Aerobic fitness and anaerobic power were measured in a sample of female college basketball players before and after preseason training. Aerobic fitness was measured using a VO₂ max test, and anaerobic power was measured using a Wingate test. Preseason training lasted one month and consisted of 8 hours per week of a combination of weight training, high-intensity interval sprint training, and skill workouts. Paired-sample t-tests were used to examine change pre- and post-intervention. Pearson correlations were conducted to examine potential associations among variables.
RESULTS: A total of 13 female athletes completed this study. Maximal aerobic fitness significantly ($p = .013$) increased after preseason training, from 47.9 to 49.9 kg/ml/min. Relative peak power and relative mean power significantly increased after preseason training from 8.3 to 9.1 W/kg ($p = .025$) and from 6.7 to 7.6 W/kg ($p < .001$), respectively. Fatigue index did not significantly change as a result of preseason training. Despite these positive results, individual responses varied widely. Change in maximal aerobic fitness ranged from +0.2 to +6.1 ml/kg/min. Change in relative peak anaerobic power ranged from -1.0 to +3.0 W/kg, and change in relative mean anaerobic power ranged from +0.9 to +1.5 W/kg. Interestingly, change in maximal oxygen uptake and change in measures of anaerobic power were not significantly correlated with baseline levels of either of these variables. There were also no significant correlations between these changes in performance and age, year in school, or position played. There was, however, a significant, positive correlation ($r = .77, p = .002$) between change in relative peak anaerobic power and relative mean anaerobic power.
CONCLUSIONS: Preseason training can have a positive effect on aerobic endurance and anaerobic power. These changes varied widely between athletes. However, this variation was not related to baseline fitness levels, age, year in school, or position played. This information may be useful for strength and conditioning coaches to design individualized training programs to maximize effects.

2190 Board #203 June 1 3:30 PM - 5:00 PM

Gender Inequality and Sex Differences in 20 Meter Shuttle Run Test Performance across 45 Countries

Justin Lang¹, Joel D. Barnes¹, Taru Manyanga¹, Mark S. Tremblay, FACSM¹, Grant R. Tomkinson². ¹Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada. ²University of North Dakota, Grand Forks, ND. (Sponsor: Dr. Mark Tremblay, FACSM)
Email: jlang033@uottawa.ca
(No relationships reported)

PURPOSE: To determine if within-country sex differences in 20-meter shuttle run test (20mSRT) performance are related to global gender inequality indices. **METHODS:** A systematic review was carried out to identify studies that reported 20mSRT descriptive data on apparently healthy children and youth aged 9 to 17 years. Descriptive data were standardized to running speed (km/h) at the last completed stage. Within-country 20mSRT performance for girls and boys were calculated as population-weighted mean z-scores relative to children of the same age from all countries. Within-country population-weighted mean z-scores for girls and boys were subtracted to represent the mean z-score sex difference in 20mSRT performance for each country, described as Z_{diff} . Five gender inequality indices were identified as potentially relevant in describing sex differences in 20mSRT performance across countries (i.e., Gender Equity Index, Gender Empowerment Measure, Global Gender Gap Index, Gender Inequality Index, and Social Institutions and Gender Index). Pearson's correlations were calculated to describe the associations between Z_{diff} and indices of gender inequality. **RESULTS:** Sex-specific z-scores were calculated from 1,141,514 children and youth (48% female). Within-country 20mSRT performance of girls and boys were very strongly correlated ($r=0.92$; 95%CI: 0.87, 0.96). The sex differences in performance (Z_{diff}) were calculated for 45 countries representing five continents. The mean Z_{diff} was 0.04 ± 0.23 with values ranging from -0.48 (girls had a better 20mSRT mean z-score relative to boys) to 0.67 (boys had a better 20mSRT mean z-score relative to girls) standardized units across the 45 country sample. Z_{diff} across countries were moderately and negatively correlated with the Global Gender Gap index ($r=-0.42$; 95%CI: -0.65, -0.12). Correlations across all other indices were of low-to-moderate strength, ranging from $r=-0.23$ (95%CI: -0.46, 0.11) to $r=0.25$ (95%CI: -0.05, 0.52). **CONCLUSIONS:** Although various indices measure gender inequality, it appears that the underlying constructs of these indices vary substantially. Furthermore, gender inequality does not fully explain sex differences in 20mSRT performance, and other broad country-level aspects may better explain the differences between boys and girls.

Physical/Physiological Comparison between Cohorts of Marine Corps Forces Special Operations Command Experienced and Entry Level Operators

Scott D. Royer¹, Joshua D. Winters¹, John Abt, FACSM¹, Nick Heebner, FACSM¹, Kathleen Poploski¹, William Getsy², CAPT Necia Williams², Scott Lephart, FACSM¹. ¹University of Kentucky, Lexington, KY. ²Marine Corps Forces Special Operations Command, Camp Lejeune, NC. (Sponsor: John Abt, FACSM)
(No relationships reported)

Marine Corps Forces Special Operations Command Operators (MARSOC) must possess optimal musculoskeletal and physiological performance characteristics to sustain health and fitness, and maintain physical readiness. Upholding these characteristics can be difficult due to age, deployment cycles and the related demands of training. **PURPOSE:** To examine the effects of age and service time on physical and physiological characteristics of Experienced and Entry Level MARSOC Operators. **METHODS:** A total of 37 Experienced Operators (Age: 31.8 \pm 4.3 years, Height: 176.7 \pm 6. cm, Mass: 84.7 \pm 10.0 kg, 13.36 \pm 4.12 years of service) and 98 Entry Level Operators (Age: 25.1 \pm 2.2 years, Height: 178.6 \pm 6.7 cm, Mass: 85.0 \pm 8.4 kg, 6.52 \pm 1.07 years of service) participated. Testing included fat mass (FM), fat free mass (FFM), anaerobic power (PAnP), anaerobic capacity (MAnP), aerobic capacity (VO₂max) and knee and torso isokinetic strength testing (KF, KE, TF, TE). Differences between groups were evaluated using independent samples t-tests, or Mann-Whitney U tests if required ($p < 0.05$). **RESULTS:** Entry Level Operators demonstrated greater KF (144.4 \pm 27.1%BW, 127.4 \pm 23.6%BW; $p=0.011$), KE (268.6 \pm 41.7 %BW, 246.5 \pm 45.8%BW; $p=0.003$), and MAnP (9.2 \pm 0.7 W/kg, 8.8 \pm .9 W/kg; $p=0.028$). Entry Level operators demonstrated less TE (422.24 \pm 77.5 %BW, 387.25 \pm 77.1 %BW; $p=0.021$). No significant differences were found in FM ($p=0.726$), FFM ($p=0.915$), TF ($p=0.529$), PAnP ($p=0.598$), or VO₂max ($p=0.145$). **CONCLUSION:** Experienced Operators demonstrated less overall leg strength and anaerobic capacity than Entry Level Operators. Further consideration is necessary to determine what characteristics may be influenced by the combined effect of training demands, age, and overall service time and the impact on career longevity.

Relationship Between Heart Rate Variability Outcomes vs Firefighter Performance, Physical Activity, and Fitness Measures

Ashley Y. Lesniak¹, Mark G. Abel¹, Katie M. Sell², Chris Morris¹, ¹University of Kentucky, Lexington, KY. ²Hofstra University, Hempstead, NY.
 (No relationships reported)

PURPOSE: The purpose of this study was to determine the relationship between heart rate variability (HRV) versus firefighter (FF) occupational performance, fitness characteristics and physical activity measures. **METHODS:** Twelve male structural firefighters (age: 37.3±7.6 yr; height: 183.2±7.1 cm; body mass: 90.4±13.7 kg; body mass index: 26.9±2.4 kg·m⁻²) wore an accelerometer for 19.1±5.8 days to measure physical activity. Physical activity was also quantified by a self-reported log. HRV was determined with a portable ECG device upon waking for 20.8±4.6 days. HRV was assessed daily, upon waking, and included SDNN, RMSSD, High frequency (HF) and low frequency (LF) components. FFs completed a simulated fire ground test (SFGT) and a battery of fitness tests including estimated 1-repetition maximum shoulder press, deadlift, bench press, bent over row and kettlebell swing, and a submaximal prediction of aerobic capacity. HRV was assessed the day of the SFGT (acute) and averaged over all days during the observation period (chronic). Descriptive statistics were calculated as mean ± standard deviation and Pearson product moment correlation coefficients were calculated. The level of significance was set at $p < .05$. **RESULTS:** SDNN values recorded the same day as the SFGT were correlated with decreased SFGT time on 3 individual SFGT tasks ($r = -.7$ to $-.745$, $p < .05$) and overall SFGT time ($r = -.735$, $p = .016$). Chronic HF was correlated with frequency of moderate-to-vigorous physical activity ($r = .728$, $p = .011$). RMSSD and SDNN were also correlated with shoulder press strength ($r = .885$, $p < .01$; and $r = .875$, $p < .01$ respectively) and bench press strength ($r = .775$, $p = .008$; and $r = .758$, $p = .011$ respectively). **CONCLUSIONS:** Increased acute HRV was associated with more efficient SFGT performance, whereas chronic HRV was associated with physical activity and strength measures. These outcomes indicate that HRV parameters may reflect the physiological status of FFs and the complex interaction between HRV, physical activity and fitness outcomes. Supported by the NSCA's Senior Investigator Research Grant

Relationship Between Anthropometric Profiles and Sports Specific Physical Performance Tests in College Football Players

Brian D. Smith, Brian Miller, Matt Gildersleeve, Ronald Otterstetter, FACSM. The University of Akron, Akron, OH.
 Email: bds63@zips.uakron.edu
 (No relationships reported)

INTRODUCTION: Football specific testing is done at all levels of football to assess player's strength, speed, and agility. Differences exist in anthropometric profile between skill position players and non-skill position players. These differences in physical performance measurements are due to the nature of physical requirements based on position. **PURPOSE:** To look at the relationship between body fat percentage (BF%), and speed, agility, jumping, and strength performance measurements. **METHODS:** Eighty-five (n=85) football players participated and were categorized into two groups: skill players (n=55) and non-skill players (n=30). BF% was assessed via air plethysmography for all players. Physical performance measurements included: clean and jerk, bench press, squat, 40-yard dash, pro agility, broad jump, and vertical jump. Pearson's product moment correlation coefficient was applied to BF% across the physical assessments. Bivariate correlation comparisons were conducted to identify significant differences in between skilled and non-skilled athletes using the Fisher's r-to-z transformation, followed by an independent sample z-tests to assess statistical differences in correlation coefficients of skilled to non-skilled athletes. Statistical significance set at $p \leq 0.05$. **RESULTS:** For non-skilled players, the relationship between BF% and all performance measurements showed significance except for the broad jump. In the skill positions, significance was observed in the relationship between speed, explosion and agility assessments compared to BF%. No significance was found in the strength measurements. When comparing skilled and non-skilled positions, both bench and pro agility showed significant differences. For bench press, non-skilled players had a higher correlation coefficient compared to skill players. For pro-agility, skilled players had a higher correlation coefficient than non-skill players. **CONCLUSION:** These findings suggest that BF% is related to measurable performance advantages across different types of tests, depending on player position and position-specific demands. Results from both of these types of testing parameters can possibly be utilized to predict future player performance and to better evaluate player development and progress.

Physical Activity Classes Improve Health-Related Physical Fitness Levels

Ethan E. Hull, Wenhao Liu, FACSM, Istvan Kovacs. Slippery Rock University, Pgh, PA. (Sponsor: Wenhao Liu, FACSM)
 Email: ethan.hull@sru.edu
 (No relationships reported)

PURPOSE: College is sometimes associated with weight gain and a decline in physical fitness levels, yet very few universities require physical activity classes even though the health and academic benefits are well known. This study investigated the effect of a college-level physical activity (PA) class on fitness level and BMI. **METHODS:** Participants were 124 college students (mean age: 20.8 ± 1.0 years, 59% male) who enrolled in a 16-week PA class at a university in the USA. The PA classes met two or three times a week for a total of 150 minutes/weekly, focusing on different activities addressing health-related physical fitness. Body mass index (BMI), Progressive Aerobic Cardiovascular Endurance Run (PACER), curl-ups, push-ups, trunk lift, and sit and reach tests were administered to the participants at the beginning (pretest) and end (posttest) of the semester. Performances of each measure at the two test points were compared separately by gender with paired-samples t-tests and with an alpha level set at 0.05. **RESULTS:** For males, significant improvements ($p < 0.001$) occurred between pre and post-test results in PACER laps (59.4 ± 21.8 vs. 65.6 ± 22.4), curl-ups (55.4 ± 20.7 vs. 62.1 ± 19.0), push-ups (23.6 ± 6.6 vs. 27.2 ± 7.8), and trunk lift inches (10.2 ± 2.2 vs. 12.5 ± 2.1). Sit and reach (inches) showed a non-significant improvement (17.3 ± 3 vs. 17.5 ± 3, $p < 0.10$), and no improvement was shown in BMI (25.8 ± 4.7 vs. 25.8 ± 4.5, $p = 0.38$). As for females, significant improvement ($p < 0.01$) was observed in PACER laps (35.3 ± 11.7 vs. 40.7 ± 12.7), curl-ups (43.6 ± 21.8 vs. 50.4 ± 20.4), push-ups (18.8 ± 6.6 vs. 21.1 ± 8.1), trunk lift inches (11.8 ± 2.5 vs. 13.0 ± 1.7), and sit and reach inches (18.6 ± 3.6 vs. 19.3 ± 3.9). The only measure remaining unchanged in females was BMI (23.6 ± 3.1 vs. 23.6 ± 3.0, $p = 0.73$). **CONCLUSIONS:** While there may be a tendency of weight gain and fitness decline among university students, PA classes focused on health-related physical fitness may be effective in maintaining body mass index and improving health-related physical fitness in college students. Future research needs to examine the longevity of these changes in fitness, find ways to help students continue along a similar trajectory of improved health, and explore whether improved fitness levels lead to improved academic performance.

Inonotus Obliquus Polysaccharide Extract (IOP) Does Not Enhance Exercise Duration or Alter Interstitial Oxygen Kinetics in Rat Skeletal Muscle

Scott A. Cammack, Sarah E. Dobard, William L. Sexton, FACSM. A.T. Still University, Kirksville, MO.
 Email: scammack@atsu.edu
 (No relationships reported)

Skeletal muscle produces reactive oxygen species during contractions, that lead to fatigue by depressing force in contracting muscle. The polysaccharide extract of the mushroom *Inonotus obliquus* (IOP) has been proposed to have antioxidant properties and to delay the onset of fatigue. Contractile function in skeletal muscle is dependent on the balance between oxygen delivery (QO₂) and oxygen consumption (VO₂) as reflected by the interstitial partial pressure of oxygen (PO_{2i}) within the muscle. **PURPOSE:** To determine whether IOP supplementation in rats 1) reduced muscle fatigue (treadmill run time to exhaustion) and 2) altered PO_{2i} kinetics in the isolated soleus and extensor digitorum (EDL) muscles. **METHODS:** Rats (n=10) were acclimated to treadmill running (at 20% incline) then randomly divided into two groups; control (C, n=5) and IOP supplementation (IOP, n=5). IOP was dissolved in the drinking water at 300 mg/kg/day. On day 14 of IOP, all rats performed a time to exhaustion treadmill test (Test 1) in which speed was increased 5 ft/min each minute until the rats could no longer continue. On day 16, a second treadmill test (Test 2) was performed in which speed was held constant at 70 ft/min and the rats ran until they could no longer maintain this speed. Starting on day 18 of IOP, the rats were anesthetized with pentobarbital sodium (50 mg/kg ip) and the soleus and extensor digitorum longus (EDL) muscles of the rats were surgically isolated. The muscles were electrically stimulated to study PO_{2i} kinetics using phosphorescence quenching at a low intensity (1 Hz, 2 ms) and at a higher intensity (2 Hz, 20 ms). **RESULTS:** Time to exhaustion during both treadmill tests was not different between groups (Test 1: 15:28

$\pm 1:11$ vs. $15:26 \pm 1:10$ min; Test 2: $7:44 \pm 0:06$ vs. $7:45 \pm 0:04$ min). During isolated muscle contractions, the initial PO_{2i} and PO_{2e} kinetics at the onset of contractions were not different between C and IOP groups in either the soleus or EDL muscles, at either low or high intensity. **CONCLUSION:** These data indicate that IOP supplementation did not reduce fatigue or enhance exercise duration, and did not result in changes in QO_2 to VO_2 matching during muscle contractions. Supported by a grant from the Graduate Program, KCOM-ATSU.

Upper Limits Of Exercise Tolerance

Andrew M. Alexander, 66502, Shane M. Hammer, Kaylin D. Didier, Dryden R. Baumfalk, Joshua R. Smith, Thomas J. Barstow, FACSM. *Kansas State University, Manhattan, KS.* (Sponsor: Thomas J. Barstow, FACSM)
 (No relationships reported)

The power-duration relationship accurately predicts exercise tolerance for constant power exercise performed in the severe intensity domain. At intensities above critical power (CP, highest sustainable power without impending failure), the power-duration relationship establishes a hyperbolic curve. This curve can be linearized as a 1/time model. However, the prediction of exercise tolerance is currently unclear for work rates (WR) within the extreme intensity domain (durations <2 min). **PURPOSE:** To test the hypothesis that the power-duration relationship deviates from a linear 1/time relationship for WRs within the extreme intensity domain. **METHODS:** To date, two men (age 21 yrs) completed the experimental protocol. Two-legged knee extension was performed to determine peak aerobic power (Ppeak). A one-repetition maximum (IRM) was determined by progressively increasing weight until a pre-determined range of motion could not be achieved. Subjects performed exercise tests to exhaustion at 6 different %Ppeak intensities (40, 60, 90, 130, 170, and 180 %Ppeak; 20, 30, 40, 60, 75, and 85 % IRM, respectively), each on different days. Test durations between 2 - 15 min (40 - 90 %Ppeak) were used to determine CP (1/time model) with a 95% confidence interval (95% CI). WRs with durations < 2 min (130 - 180 %Ppeak, 60 - 85 % IRM) were plotted on the previously determined 1/time model. **RESULTS:** The r2 for 1/time models were 0.99 (p < 0.05). CP, Ppeak, and IRM were 20, 35, and 75 kg, respectively. IRM and CP were 200 and 57 %Ppeak, respectively. The 130 %Ppeak (60 % IRM, test duration of 114.86 s) and 170 %Ppeak (75 % IRM, test duration of 71.02 s) WRs fell within the 95% CI, however, the 180 %Ppeak (85 % IRM, test duration of 46.39 s) did not. **CONCLUSIONS:** Our hypothesis was partly explained by the data. These data show that exercise bouts lasting less than 60 s deviate from the linear model of the power-duration relationship. However, time to exhaustion greater than 60 s can be predicted using the power-duration relationship. This suggests that mechanisms that may not have had a significant role at lower intensities become the limiting factor to exercise tolerance at intensities greater than ~170 %Ppeak (75 %IRM).

2197 Board #210 June 1 2:00 PM - 3:30 PM
Body Composition, Nutritional Profile And Muscular Fitness Affect Bone Health In A Sample Of Schoolchildren From Colombia: The Fuprecol Study

Monica Adriana Forero Bogotá¹, Mónica Liliana Ojeda-Pardo¹, Antonio Garcia-Hermoso², Robinson Ramirez-Vélez¹. ¹Centro de Estudios para la Medición de la Actividad Física «CEMA». Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá D.C, Co, Bogota, Colombia. ²Laboratorio de Ciencias de la Actividad Física, el Deporte y la Salud, Universidad de Santiago de Chile, Santiago, Chile.
 Email: robin640@hotmail.com
 (No relationships reported)

PURPOSE: The objective of the present study is to investigate the relationships between body composition, nutritional profile, muscular fitness (MF) and bone health in a sample of children and adolescents from Colombia. **METHODS:** Participants included 1,118 children and adolescents (54.6% girls). Broadband ultrasound attenuation (BUA) was obtained by using quantitative ultrasound technique at the calcaneus as a marker of bone health. Body composition (fat mass and lean mass) was assessed using bioelectrical impedance analysis. Furthermore, height, weight, waist circumference and Tanner stage measured and body mass index (BMI) was measured. Standing long-jump and isometric handgrip dynamometry were used as indicators of lower and upper body muscular fitness, respectively. Also, a muscular index score was computed by summing up the standardised values of both standing long-jump and handgrip strength. Dietary intake and degree of adherence to the Mediterranean diet were assessed by a 7-day recall questionnaire for food frequency and the Kidnet questionnaire, respectively. Poor bone health was considered using a Z-score cut off of ≤ -1.5 . **RESULTS:** Once the adjustment was performed (by age and Tanner stage), the predisposing factors of having a c-BUA z-score ≤ -1.5 SD included: being underweight [OR 2.30 (95% CI 1.53 to 1.69)], or being obese [OR 0.17 (95% CI 0.04

to 0.69)], having an unhealthy lean mass [OR 2.51 (95% CI 1.74 to 3.60)], unhealthy levels of fat mass [OR 0.46 (95% CI 0.29 to 0.74)], unhealthy SLJ performance [OR 1.55 (95% CI 1.09 to 2.19)], unhealthy handgrip performance [OR 3.77 (95% CI 2.29 to 6.20)], and unhealthy muscular index score [OR 2.22 (95% CI 1.42 to 3.47)]. **CONCLUSIONS:** In conclusion, body composition and MF influence bone health on a sample of children and adolescents from Colombia. Thus, promoting strength adaptation and preservation in Colombian youth will help to maximize bone health, an important protective factor against osteoporosis later in life.

Relation between Hand Grip Strength and Body Composition Associated with Cardiovascular Risk in University Students

Marlucio De Souza Martins¹, Sandra Posada-Bernal¹, Aura Catalina Zea Robles². ¹Pontificia Universidad Javeriana, Bogota - Colombia, Colombia. ²Universidad Santo Tomás, Bogota - Colombia, Colombia.
 Email: mdesouzamartins@javeriana.edu.co
 (No relationships reported)

The measurement of Hand Grip Strength (HGS) is one of the methods for evaluating the maximum isometric strength of the hand and forearm muscles, that is related to predictive factors of health conditions of people. In addition, this is an indicator that relates the physical condition of young people with their Body Composition (BC), identifying Cardiovascular Risk (CR) factors in the university population. **Purpose:** The purpose of this study is to relate the HGS and the BC associated with the CR in the Students of Elective Course of Physical Activity and Sports (SECPAS) of the Pontificia Javeriana University (PJU) Bogota, D.C. Colombia. **Methods:** Descriptive correlational study, which 91 students aged an average of 22.5 ± 4.5 years old, were assessed n=40 (44%) males and n=51 (56%) females. To evaluate the HGS was used an hydraulic hand dynamometer owner's manual JAMAR[®], it was registered two measurements of Right Hand (RH) and Left Hand (LH) in seated position, using the best result for analysis. A bioelectrical impedance scale OMRON[®] HBF-510LA, was used to evaluate the BC, which shows the percentage of Body Fat (BF) and Skeletal Muscle (SM). **Results:** Values of HGS for RH and LH were compared, demonstrating that in the RH were higher than the LH for both genders, the difference of HGS was 8.4% (4.5 kg). For 78% of students (n=71), are in an average classification of low HGS for the population. BC shows that the BF was classified as high, 24.2% (n=22) and very high, 35.2% (n=32) for both genders. It was evidenced that the BF of females 23.1% (n=21) was classified as very high in comparison to males, 12.1% (n=11). The SM, had a behavior classified as normal 65.9% (n=60), with a trend to the lower limit of SM with low level in males 62.5% (n=25), according to OMRON[®] parameters. **Conclusion:** For males, was found a relation between HGS and BC, lower SM, greater BF and less HGS, become predisposing factors to develop CR. On the other hand, females showed a normal SM, higher BF and less HGS, it looks apparently normal, but hides a healthy appearance that prevents the CR control. Those indicators are useful to reorient the objectives of integral formation towards create healthy habits to SECPAS.

The Effects Of A Muscle Biopsy On Motor Unit Firing Properties

Ryan J. Colquhoun¹, Cody T. Haun², Petey W. Mumford², Paul A. Roberson², David D. Pascoe², Mary P. Feeney², Kaelin C. Young², Jeffrey S. Martin², Michael D. Roberts², Tyler W.D. Muddle¹, Joshua J. Riffe¹, Michael J. Luera¹, Mitchell A. Magrini¹, Cameron S. Mackey¹, Matt S. Stock³, Nathaniel D.M. Jenkins¹, Jason M. DeFreitas¹. ¹Oklahoma State University, Stillwater, OK. ²Auburn University, Auburn, AL. ³University of Central Florida, Orlando, FL.
 Email: ryan.colquhoun@okstate.edu
 (No relationships reported)

INTRODUCTION: Muscle biopsies have played a large role in the understanding of skeletal muscle physiology. While discomfort from the biopsy process is often reported, it is unknown if the activation of pain pathways and/or the administration of lidocaine during the procedure affects the motor control of the same muscle. **PURPOSE:** To examine the effects of a skeletal muscle biopsy on the motor unit firing properties of the vastus lateralis (VL) in young men. **METHODS:** Fifteen young men (Age: 22 ± 2 years) underwent skeletal muscle biopsies of the VL of the right leg. Prior to and following the biopsy, subjects completed a maximal effort contraction. Four surface electromyographic signals were detected from the VL during the maximal contraction and decomposed into their constituent motor unit action potential trains. The relationship between maximal motor unit firing rate (FR_{max}) and recruitment threshold (RT) were calculated for each subject pre- and post-biopsy. Separate Paired-Samples T-Tests were run to examine for changes in slope coefficients and y-intercepts. **RESULTS:** Our findings showed no significant change in slope (Pre: -0.40 ± 0.32 ; Post: -0.40 ± 0.21 ; p = 0.96) or y-intercept (Pre: 29.0 ± 7.3 ; Post: 30.8 ± 7.6 ; p =

0.26) following the biopsy process. Figure 1 below depicts the relationship between group mean FR_{max} (x-axis) and group mean RT (y-axis) both pre- and post-biopsy. **CONCLUSION:** Despite reports of discomfort, the results of the present investigation suggest that the motor unit firing properties of the VL of young males are minimally affected by the process of a skeletal muscle biopsy. Specifically, our data shows no significant change in the relationship between FR_{max} and RT. Researchers and scientists that utilize muscle biopsies can take comfort in knowing that the process does not affect the motor control of the muscle during subsequent contractions.

Hormonal Responses After Eccentric Exercise In Humans

Anastassios Philippou¹, Maria Maridakis², Loukas Kollias¹, Argyro Papadopetraki¹, Ioannis Pennas¹, Michael Koutsilieris¹. ¹Medical School, National and Kapodistrian University of Athens, Goudi-Athens, Greece. ²Faculty of Physical Education and Sport Science, National and Kapodistrian University of Athens, Dafni-Athens, Greece. Email: tfilipou@med.uoa.gr (No relationships reported)

Following muscle damage, multiple responses associated with an inflammatory and degenerative phase are activated before the completion of muscle repair or regeneration. The final outcome of those responses is influenced by a crucial balance between anabolic and catabolic, among others, factors. Nevertheless, less is known about the responses of the competitive (anabolic vs catabolic) hormones growth hormone (GH) and cortisol (CORT) following muscle damaging exercise. **PURPOSE:** The purpose of this study was to investigate serum levels of CORT and GH during muscle degeneration/regeneration after eccentric exercise-induced muscle damage in humans. **METHODS:** Ten healthy men volunteers (age: 25±5 yrs, height: 180±5 cm, mass: 77±8 kg) performed 50 maximal eccentric muscle actions using the knee extensor muscles of both legs on an isokinetic dynamometer. Blood samples were withdrawn before and at 6, 48 and 120 hrs post-exercise, while muscle soreness was evaluated at 24, 48 and 120 hrs post-exercise. Serum levels of CORT and GH were measured by ELISA using commercially available kits. One-way ANOVA was used for statistics. **RESULTS:** The participants reported significant muscle strength decrement and muscle soreness post exercise (p<0.01-0.001). Serum CORT levels showed a 40% increase 6 hours post exercise and remained elevated throughout the experimental period, however without reaching significance (393.0±66.6 ng/ml, 362.8±48.5 ng/ml and 370.7±34.9 ng/ml, at 6, 48 and 120 hours after exercise, respectively, compared to 306.5±29.8 ng/ml at baseline; mean±SE, p>0.05). Serum GH levels exhibited a more than 2.5-fold increase 6 hours post exercise and then gradually decreased (506.7±144.5pg/ml, 701.1±161.4 pg/ml, 647.0±205.5pg/ml and 509.5±144.1pg/ml at baseline, 6, 48 and 120 hours post-exercise, respectively). However, those GH changes also failed to reach significance (p>0.05) due to a large variability shown between the subjects' responses. **CONCLUSION:** Our findings suggest that muscle damaging eccentric exercise triggers mild adaptive responses of CORT and GH, which may reflect a specific drive towards a balance between anabolic and catabolic processes during muscle regeneration. More studies are needed to further characterize the hormonal responses to eccentric exercise in humans.

2201 Board #214 June 1 2:00 PM - 3:30 PM

Evidence Of A "Male Athlete Triad" In Competitive Triathletes

Micol S. Rothman, Wendy M. Kohrt, FACSM, Deborah Saint-Phard. University of Colorado, Aurora, CO. Email: micol.rothman@ucdenver.edu (No relationships reported)

PURPOSE: To look for low energy availability, hormonal dysfunction and low bone mineral density in male triathletes, a group not previously well described with this disorder.

METHODS: Blood, urine and DXA testing were assessed on a series of 4 male triathletes who presented to our Sports Medicine/Metabolic Bone Clinics at University of Colorado for repeated or poorly healing lower extremity stress fractures.

RESULTS:

Age	BMI	Stress fracture type	DXA (g/cm2) and Z-score spine	DXA (g/cm2) and Z-score hip	Total T (ng/dL)	Vitamin D (ng/mL)	Serum Ca (mg/dL)	PTH (pg/mL)	24 hour urine Ca (mg/day)
40	22.0	Femoral neck	.882 -2.2	-858 -0.9	372	59	9.8	21	259
47	27.7	Tibial metatarsal	0.982 -0.7	0.691 -1.1	216	48	9.4	33	440
44	23.5	Tibial	1.092 -1.1	1.116 0.4	230	23	9.8	32	188
22	23.1	Metatarsal	1.024 -1.1	1.002 -0.4	242	36	10.0	24	476

Levels of testosterone (T) were low normal in 3 of the 4 men. 24 hour urine calcium was elevated in 2 of the 4 men. DXA Z-score at the spine was frankly abnormal in 1 man with a femoral neck stress fracture.

The remaining 3 of 4 men had Z-scores within normal limits, however lower than expected for an endurance athlete (less than -1.0.)

CONCLUSIONS:

Alterations in testosterone as well as pituitary gonadotrophins (FSH and LH)[1] have mainly been reported in long distance runners [2], but we suspect such alterations exist in endurance athletes of all types. With the increase in US participation in triathlons, this finding may become more prevalent.

Studies at our institution have suggested concerns for low BMD in competitive cyclists with increases in markers of bone resorption. [3, 4] However, abnormal T levels have not been found in this cohort. There may be alterations in urinary calcium and transient changes in PTH playing a role.

The combination of endurance activities coupled with limited energy availability may lead to low T and stress fractures, features of a "male athlete triad." Patients may not complain of hormonal symptoms such as muscle loss or low libido at these levels.

Thus, we urge our colleagues to ask endurance male athletes about energy balance and nutrition.

 (No relationships reported)

Mechanical loading, i.e. physical activity and/or exercise, promotes bone formation during growth. Sclerostin, a glycoprotein, mediates osteocytes' response to mechanical loading by inhibiting the Wnt/ β -catenin pathway thereby inhibiting bone formation. **PURPOSE:** to examine the response of circulating sclerostin following an acute session of three different sport activities. **METHODS:** Fifty-five pre-adolescent boys (age 10.1 \pm 1.2yrs) participated in a single practice of either soccer (N=20), running (N=17) or swimming (N=18). Anthropometry, habitual PA, nutritional intake, biological maturity, bone mineral density and content, and fitness status were measured at baseline. Blood samples were collected before and within 30 min post-exercise. Participants did not differ in any baseline measures. **RESULTS:** Sclerostin showed a modest decline (P<0.5) in response to soccer (pre: 213 \pm 45 pg/ml vs. post: 189 \pm 41 pg/ml) and running (pre: 221 \pm 56 pg/ml vs. post: 193 \pm 49 pg/ml) but not in response to swimming (pre: 209 \pm 45 pg/ml vs. post: 203 \pm 58 pg/ml). Sclerostin changes (independent of group) were correlated with mean speed (r=-0.41; P<0.05), total number of accelerations and decelerations (r=0.51; P<0.05) and number of jumps (r=0.6; P<0.05). **CONCLUSION:** Results of this study suggest that acute weight bearing exercise inhibits sclerostin levels slightly. Further work is needed to determine if this slight reduction alters bone mineral content.

Foot Posture and Mobility in Normal and Pronated Feet during Gait using High-Speed Stereo Radiography

Elizabeth C. Bachman¹, Amira Othman¹, Stuart J. Currie², Kevin B. Shelburne¹, Thomas G. McPoil³, Bradley S. Davidson¹, Erin M. Mannen¹. ¹University of Denver, Denver, CO. ²Mojo Feet, Denver, CO. ³Regis University, Denver, CO.
 (No relationships reported)

Background and Purpose: Individuals with extremely flat or high arch foot postures have been shown to be at risk for the development of orthopaedic foot disorders. The longitudinal arch angle (LAA) as quantified by video camera and 3D motion capture has been used to measure change in the medial longitudinal arch associated with midfoot motion (Fig 1). The purpose of this study was to use high-speed stereo radiography to assess midfoot posture and mobility in normal and pronated feet throughout the stance phase of gait. **Methods:** A total of 13 feet from 7 subjects (mean age = 24 years; range 22 to 29 years) were examined in this study. Clinical LAA measures assessed with a goniometer were used to select 7 pronated feet (129.6°) and 6 normal feet (140.5°). Radiopaque beads (2 mm dia) were taped to the navicular tuberosity, the medial aspect of head of the first metatarsal, and the medial malleolus prior to static loaded and walking trials. 3D coordinates of the beads were captured during gait using a high-speed stereo radiography system. The LAA in the sagittal plane was measured throughout the stance period (Fig 3).

Results: Static loaded LAA compared to clinical LAA values were identical for pronated feet and similar for normal feet (2.5° diff). The LAA decreased throughout stance period indicating a decrease in medial arch height. The static loaded LAAs were different than the dynamic measures (p<0.05) between 42% to 80% in the normal feet, and between 57% to 79% in the pronated feet. Both groups experienced similar LAA excursion (10.7° and 10.3° for the normal and pronated feet respectively), while the normal group had a higher average LAA than pronated (136.2° and 128.0° respectively) (Fig 2).

Conclusions: The results indicate that LAA measured with stereo radiography is a responsive metric to assess midfoot posture during walking and is sensitive to foot type differences. This methodology can be effectively used to assess the effect of foot orthoses on midfoot posture when using shoes.

The Effects Of A Six-week HIIT Program On CVD Risk Factors In Sedentary Individuals

Melissa A. Whidden, Nicholas M. Hoster, Melissa A. Reed. West Chester University, West Chester, PA.
 (No relationships reported)

Regular physical activity is linked to improved cardiovascular (CV) health. High intensity interval training (HIIT) is a type of CV exercise that involves interchanging intervals of high intensity exercise (usually 80-100% of maximum heart rate) with lower intensity recovery periods. **PURPOSE:** The purpose of this study was to assess the effect of a six-week HIIT program on modifiable cardiovascular disease (CVD) risk factors. **METHODS:** Total cholesterol (TC), high-density lipoprotein (HDL) cholesterol, low-density lipoprotein (LDL) cholesterol, fasting plasma glucose (FPG), blood pressure (BP), resting heart rate (RHR), and body fat percentage (BF %) were assessed before, halfway through, and after the six-week program in nine sedentary young adults. Subjects performed three sessions per week for six weeks at a work-to-rest (W:R) ratio of 1:4, where they were required to sprint and walk. **RESULTS:** There was a significant increase in FPG from the pre-program to the post-program assessment (P=0.03). There was also a significant decrease in diastolic BP (DBP) (P=0.03) and RHR (P=0.04) from the pre-program to post-program assessment. **CONCLUSIONS:** These data suggest that HIIT is effective in significantly reducing DBP and RHR. However, a six-week, 18 session HIIT program at a 1:4 W:R ratio may not be effective for reducing the risk for CVD through idealizing blood lipids, SBP, body composition, or anthropometry measurements in this population. This study contributes to the necessity to find an optimal HIIT program length, training session duration, and W:R ratio to help establish the most advantageous training program to reduce the risk of CVD.

2205 Board #218 June 1 2:00 PM - 3:30 PM
High-Intensity Interval Training Elicits Higher Enjoyment Than Moderate Intensity Continuous Exercise

Jacob S. Thum, 92592. California State University - San Marcos, San Marcos, CA.
 Email: thum001@cougars.csusm.edu
 (No relationships reported)

Lack of adherence to exercise programs is widespread in the United States, with approximately 50% of individuals withdrawing within 6 mo of initiation. Insufficient time is cited as the greatest barrier to adherence, yet in order to improve overall health, 150 min/wk of moderate-intensity continuous exercise (MICT) is recommended for all adults. Recently, scientists have identified superior health-related adaptations in response to high-intensity interval training (HIIT) compared to MICT. In addition, some data show higher enjoyment with HIIT compared to MICT; however, these findings are not universal. **PURPOSE:** To examine potential differences in enjoyment of low-volume high-intensity interval training (HIIT) compared to MICT in an attempt to elucidate the feasibility of HIIT as a component of regular exercise programming. **METHODS:** Differences in enjoyment, affect, and perceived exertion between MICT and HIIT were monitored in 12 recreationally active men and women (age=29.5 \pm 10.7 yr, VO₂max=41.4 \pm 4.1 mL/kg/min, BMI=23.1 \pm 2.1 kg/m²). Initially, maximal oxygen uptake was determined to establish workloads for two subsequent exercise bouts, whose order was randomized: HIIT (eight 1 min bouts of cycling at 85% maximal workload (Wmax) with 1 min of active recovery between bouts) and MICT (20 min of cycling at 45% Wmax). Rating of perceived exertion (Borg 1-10), affect, heart rate (HR), and blood lactate concentration (BLA) were measured during exercise. Additionally, the Physical Activity Enjoyment Scale was completed 10 min after

exercise. **RESULTS:** Higher enjoyment ($p=0.013$, Cohen's $d=1.54$) in HIIT (103.83 ± 9.44) versus MICT (84.17 ± 19.11) was observed, with 11/12 participants (92%) preferring HIIT to MICT. Affect was lower ($p<0.05$, $d=0.78$) and HR, RPE, and BLA were higher ($p<0.05$) in HIIT versus MICT. **CONCLUSIONS:** Despite greater physiological strain, HIIT was cited as more enjoyable than MICT due to its ever-changing stimulus, greater sense of accomplishment, and relative time-efficiency. Future studies in various populations are merited to examine the potential for greater adherence to HIIT compared to MICT, and whether this leads to superior adaptations and concurrent health-related benefits.

2206 Board #219 June 1 2:00 PM - 3:30 PM
Aerobic and Anaerobic Effects of Manipulating Sprint Interval Training Work and Rest Period Durations
 Greg L. McKie¹, Hashim Islam², Logan K. Townsend³, Jennifer Robertson-Wilson¹, Mark Eys¹, Tom J. Hazell¹. ¹Wilfrid Laurier University, Waterloo, ON, Canada. ²Queen's University, Kingston, ON, Canada. ³University of Guelph, Guelph, ON, Canada.
 (No relationships reported)

Performance benefits resulting from short (10-15 s) sprint interval training (SIT) bouts suggest that peak speed generation may be an important adaptive stimulus, though the optimal work and rest period duration has not been established. **PURPOSE:** To determine the effects of manipulating SIT work and rest period durations while maintaining total exercise duration on aerobic and anaerobic performance. **METHODS:** Thirty-four recreationally active males ($n=20$) and females ($n=14$) trained for four weeks (3 times/week) using one of the following SIT protocols: 1) 30:240 (4-6 x 30 s work, 4 min rest); 2) 15:120 (8-12 x 15 s work, 2 min rest); 3) 5:40 (24-36 x 5 s work, 40 s rest). Protocols were matched for total work (2-3 min) and recovery (16-24 min) duration, as well as the work-to-recovery ratio (1:8 s). Pre- and post-training measures included a graded $\dot{V}O_{2max}$ test, 5-km running time trial, and 30 s running sprint test. Post-training psychological measures of task self-efficacy, enjoyment, and intentions were assessed immediately following the last training session. **RESULTS:** Training improved $\dot{V}O_{2max}$ (5.5%; $P<0.001$), 5-km time trial performance (5.2%; $P<0.001$), peak speed (2.6%; $P<0.05$), and time to peak speed (32.4%; $P<0.001$) with no differences between groups. There were no anaerobic effects. There were no main effects for group on measures of perceived self-efficacy ($P=0.926$), enjoyment ($P=0.249$), or intentions to perform SIT three ($P=0.533$) or five ($P=0.951$) times/week over the coming month. **CONCLUSION:** Manipulating the SIT work and rest period duration while maintaining total exercise duration does not compromise aerobic and anaerobic benefits typically observed with traditional, longer SIT work bouts. This suggests that the generation of peak speed sufficiently stimulates adaptive mechanisms that lead to increases in aerobic and anaerobic capacity. However, psychological perceptions of self-efficacy, enjoyment, and intentions to participate were not different between groups post-training. Future research should investigate these perceptions throughout the training program duration.

Effects Of 5 Days Of HIIT On Exertional Rhabdomyolysis In Trained And Untrained Individuals
 Katie Ertel. Marywood University, Scranton, PA.
 (No relationships reported)

Exertional Rhabdomyolysis is potentially life threatening, and has been diagnosed in individuals who overexert themselves during exercise. Individuals who participate in exercise beyond their level of physical fitness may be at higher risk for excessive muscle breakdown due to overexertion. **PURPOSE:** To measure the severity of skeletal muscle breakdown via myoglobin and creatine kinase after five days of high and low intensity interval training in previously trained and untrained individuals. **METHODS:** 18 males and females (9 trained (TR) and 9 untrained (UT); Age: 22 ± 1) completed five consecutive days of high intensity interval training and five consecutive days of low intensity interval training with a two week washout period between. Blood was drawn at the initial visit and immediately after completion each exercise intensity period. Individuals rated their perceived muscle soreness before each exercise session. **RESULTS:** Levels of myoglobin in UT were significantly higher after high intensity exercise (65.2 ng/ml; $p=0.05$); however, there was no significant difference between myoglobin in TR after high intensity exercise vs. baseline (41.0 ng/ml). While CK was elevated post exercise training for both groups ($p<0.01$), this was higher for trained individuals (UT: 143.4 vs. TR: 203.6 ng/ml; $p<0.01$). There was no significant difference in perceived muscle soreness between TR and UT individuals; however, UT individuals experienced soreness significantly sooner ($p<0.01$). Specifically, UT individuals had significantly higher perceived soreness after one day of high intensity exercise, while TR individuals experienced significant soreness after 3 and 4 days of exercise ($p=0.04$, $p=0.02$). There were no significant differences in perceived muscle soreness in either TR or UT individuals after low intensity exercise.

CONCLUSIONS: The current study suggests that high intensity exercise results in greater muscle damage in both previously trained and untrained individuals vs. low intensity exercise; however this is greater in untrained individuals. Therefore, previously untrained individuals should take caution when beginning exercise programs that require consecutive sessions of high intensity exercise.

Effects of High Intensity Interval Training Frequency on 1.5 Mile Run Times in Air Force Cadets
 Jared Dahle¹, Dale Wagner². ¹United States Air Force Academy, USAF Academy, CO. ²Utah State University, Logan, UT.
 Email: jhdahle75@gmail.com
 (No relationships reported)

SCIENTIFIC ABSTRACT

High intensity interval training has gained popularity in military settings in recent years, but no research has investigated how varying HIIT frequency impacts performance in the cardiovascular fitness component of an official military physical fitness test. **PURPOSE:** Effects of varying high intensity interval training (HIIT) frequency on 1.5 mile (2.4 km) run performance in U.S. Air Force Reserve Officer Training Corps (ROTC) cadets was studied. **METHODS:** Twenty-seven cadets (21.6 ± 2.8 years) were stratified then randomly assigned to 3 groups: a high frequency group (HF) that performed HIIT 3x week, a low frequency group (LF) that performed HIIT 2x week, and a continuous training group (CG) that performed moderate intensity training 3x week. HIIT protocols consisted of 4 x 3 min intervals at 90-100% of velocity at maximal oxygen consumption ($\dot{V}O_{2max}$) with 4 min of recovery and 4 x 30s all out sprints with 4 min recovery. Baseline 1.5 mile run performance was measured, then retested at 6 and 10 weeks. **RESULTS:** All groups significantly improved in mean run time (LF, $7.3\% + 4.2$, $p<0.001$; HF, $9.7\% + 3.5$, $p<0.001$; CG, $8.7\% + 4.8$, $p<0.001$). No significant differences between groups were found ($p>0.05$). Additional workouts beyond the 6-week point yielded no significant gains in run performance for any group. **CONCLUSION:** Two days per week of HIIT training was as effective at improving 1.5 mile run performance as either 3 days/week of HIIT or continuous training.

Effects of Different Tempos of a Side-step Interval Exercise on Heart Rate and Muscle Activation
 Robert S. Thiebaud¹, Takashi Abe², Jonathan C. Bravo¹, Nicolas Giovannitti¹, Avery P. Sullivan¹. ¹Texas Wesleyan University, Fort Worth, TX. ²National Institute of Fitness and Sports, Kanoya, Kagoshima, Japan.
 Email: rthiebaud@txwes.edu
 (No relationships reported)

One barrier to meeting fitness recommendations may include time constraints. Finding exercises that can promote improvements in both aerobic and muscular fitness while minimizing the duration of the exercise and the required equipment are needed. One such exercise may be the side-step interval exercise. Currently, it is unknown how different tempos influence this exercise and how heart rates and muscle activation differ between tempos. **PURPOSE:** To investigate how different tempos of a side-step interval exercise influence heart rate and muscle activation responses. **METHODS:** Recreationally active men ($n=8$) and women ($n=2$) participated in this study. The average maximum oxygen uptake ($\dot{V}O_{2max}$) of participants was 50.1 ± 10 yrs and age was 21 ± 3 yrs. The side-step interval exercise consisted of moving from side to side repetitively over a two-meter distance for 1 minute with 1-minute rest periods in between sets. Four sets of these exercise intervals were performed. The fast (112 bpm) or slow (84 bpm) tempo was randomly assigned during the first exercise session with the other tempo being used in the next visit. Surface electromyography (EMG) measured muscle activation of the vastus lateralis and a heart rate monitor (Polar) measured heart rate (HR). Two-way repeated measures ANOVA analyzed differences between tempos and sets. Pearson product moment correlations analyzed associations between $\dot{V}O_{2max}$, HR response and muscle activation. Statistical significance was set at $p<0.05$. **RESULTS:** Slow tempos produced significantly lower amounts of muscle activation compared to the fast tempos [46% vs. 59% of the maximum isometric voluntary contraction muscle activation (EMG_{max}), $p=0.002$]. HR significantly increased at the end of sets 3 (150 ± 8 bpm, $p=0.012$) and set 4 (152 ± 8 bpm, $p=0.001$) when compared to set 2 (146 ± 8 bpm). The fast tempo produced significantly greater HR than the slow tempo (82% HRmax vs. 70% HRmax, $p<0.001$). A significant inverse relationship was also found between $\dot{V}O_{2max}$ and vastus lateralis muscle activation ($r=-0.855$, $p=0.003$), fast tempo HR ($p=-0.896$, $p<0.001$) and slow tempo HR ($p=-0.924$, $p<0.001$). **CONCLUSIONS:** Side-step interval exercise acutely produces sufficient levels of HR and muscle activation to promote improvements in aerobic and muscular fitness but future chronic studies are needed.

2210 Board #223 June 1 2:00 PM - 3:30 PM
Sprint Interval Training and Power Output In College Age Females

Jenna Thompson, Sophie Olson, Leigha Embertson, Mark Blegen, FACSM. *St. Catherine University, St. Paul, MN.*
 (Sponsor: Mark Blegen, FACSM)
 (No relationships reported)

High intensity interval training (HIIT) is a rapidly growing area of research due to the beneficial physiological outcomes achieved in a time efficient manner. Sprint interval training (SIT) decreases exercise duration even more by utilizing supramaximal intensity intervals of even shorter duration while still maintaining significant improvements. However, research on effects of SIT in women is lacking. **PURPOSE:** The present investigation focuses on SIT and power development in college-aged (21.1 ± .62 years), recreationally active women. **METHODS:** Participants (n=11) were randomized into one of three groups: two intervals (2INT), three intervals (3INT), or endurance group (END). All groups completed their assigned protocols three times a week for eight weeks for a total of 24 sessions. 2INT sprinted two 20-second all-out bouts with active recovery between sprints for a total of 5 minutes. 3INT sprinted three 20-second all-out bouts with active recovery between sprints for a total of 10 minutes. END cycled continuously for 20 minutes at 60% of their $\dot{V}O_{2max}$. Wingate testing (anaerobic power) was completed at baseline, mid-, and post-intervention. **RESULTS:** Average power in both 2INT ($6.9 \pm 0.17 \text{ v } 7.1 \pm 0.41 \text{ watts}\cdot\text{kg}^{-1}$) and 3INT groups ($7.03 \pm 0.53 \text{ v } 7.02 \pm 0.265 \text{ watts}\cdot\text{kg}^{-1}$) remained unchanged while the END group average power ($6.6 \pm 0.44 \text{ v } 5.89 \pm 0.914 \text{ watts}\cdot\text{kg}^{-1}$) decreased by 10.7%. **CONCLUSIONS:** Although not significant, it is important to point out that 2INT and 3INT were able to maintain their average power; even though exercising for a limited duration. The findings of this study demonstrate that SIT may be utilized to maintain anaerobic fitness in women.

Sprint Interval Training and Development of Peak Power in Females

Sophie Olson, Jenna Thompson, Leigha Embertson, Mark Blegen, FACSM. *St. Catherine University, St. Paul, MN.*
 (Sponsor: Mark Blegen, FACSM)
 (No relationships reported)

Interest in interval training has been expanding rapidly while it has been shown to induce numerous beneficial physiological outcomes. High intensity interval training (HIIT) is comprised of submaximal high-intensity interval training lasting >30 seconds. A subset of HIIT is sprint interval training (SIT) and consists of supramaximal sprints of very short durations (10-20 seconds). This study aimed to investigate the responses of SIT on peak power output in females. Recreationally active females (n=11) (21.1 ± 0.62 years) performed a Wingate Cycle Test at baseline, mid-intervention (4 weeks), and post-intervention (8 weeks) to measure peak power. Subjects were randomized into one of three groups: two intervals (2INT), three intervals (3INT), or endurance group (END). All groups cycled three times a week for eight weeks, for a total of 24 sessions. 2INT sprinted two 20-second bouts and cycled five minutes total and 3INT sprinted three 20-second bouts and cycled ten minutes total. The END group cycled 20 minutes at 60% of their $\dot{V}O_{2max}$. Upon completion of the study, subjects completing 2INT had a modest, but significant improvement of 2.3% in peak power ($9.10 \pm .62 \text{ v } 9.22 \pm 0.73 \text{ watts}\cdot\text{kg}^{-1}$), compared to both the 3INT ($8.45 \pm .57 \text{ v } 8.30 \pm 0.71 \text{ watts}\cdot\text{kg}^{-1}$) and the END group ($8.54 \pm .43 \text{ v } 7.99 \pm 0.93 \text{ watts}\cdot\text{kg}^{-1}$). The present data demonstrate the importance of SIT on power development in females. In addition, more research is needed into SIT and its impact on performance measures specific to women.

Changes in $\dot{V}O_{2max}$ and Muscular Strength Over A 24-Week Cycle Ergometer Interval Program Among Active Middle-Age Adults

Montana L. Pruettt¹, Ashley N. Triplett¹, Christopher R. Hill¹, Samantha J. Deere², Lori Ploutz-Snyder, FACSM³, James M. Pivarnik, FACSM¹, Deborah L. Feltz¹. ¹Michigan State University, East Lansing, MI. ²Saginaw Valley State University, University Center, MI. ³University of Michigan, Ann Arbor, MI.
 Email: pruetttmo@msu.edu
 (No relationships reported)

Cycling training induces adaptive cardiovascular benefits both centrally and peripherally in previously sedentary individuals. Less is known about what exercise prescription is necessary to improve fitness in already active, healthy middle aged adults. Cycling is not a well-accepted exercise to enhance strength, especially in healthy active adults. **PURPOSE:** To determine if participation in a novel cycling

program affects aerobic fitness ($\dot{V}O_{2max}$) and leg strength. **METHODS:** Participants (N=41, M±SD age=45.5±8.1) were healthy adults recruited to complete a 6-day/wk exercise program on a cycle ergometer for 6-months. All participants self-reported at least 30 min of vigorous exercise, 3 times/wk prior to joining the study and met NASA developed fitness standards. Participants exercised 6 day/wk, using high intensity routines (SPRINT) developed and designed to protect fitness of middle aged active healthy astronauts. SPRINT includes (a) 30 min continuous aerobic cycling at or above 75% of max heart rate (HRmax), (b) long, 4x4 min intervals at or above 90% HRmax with 3 min active rest, (c) medium 6x2 min intervals at 70, 80, 90, 100, 90, and 80% of HRmax, respectively with 2 min active rest, and (d) short, 30 sec max sprint intervals with 20 sec active rest. Participants reported that they did not change other exercise behavior during the study. $\dot{V}O_{2max}$ was measured (via indirect calorimetry) pre, mid (3 month), and 6 month post intervention. Isometric leg strength, including peak torque extension (PTE) and flexion (PTF) was measured (pre and 6 month post intervention) on the right leg using the Biodex3 dynamometer. Results were assessed via repeated measures ANOVA. **RESULTS:** Average $\dot{V}O_{2max}$ increased from pre to mid-test ($33.8 \pm 6.2 \text{ ml/kg/min}$ vs. $38.5 \pm 6.8 \text{ ml/kg/min}$), and was maintained from mid to post-test ($38.5 \pm 6.8 \text{ ml/kg/min}$ vs. $38.3 \pm 7.3 \text{ ml/kg/min}$), $F(2,62) = 57.65$, $p < 0.001$. PTE increased significantly from pre to post test ($119.6 \pm 42.6 \text{ ft/lbs}$ vs. $131.7 \pm 48.8 \text{ ft/lbs}$), $F(1,35) = 8.00$, $p < 0.008$. PTF did not change from pre to post-test ($71.2 \pm 21.4 \text{ ft/lbs}$ vs. $70.2 \pm 21.7 \text{ ft/lbs}$), $F(1,35) = 0.13$, $p = 0.73$. **CONCLUSION:** SPRINT interval cycle ergometer training is effective for increasing aerobic fitness and muscular strength over a 6-month training period among physically active middle-age adults. Grant: NASA/NSBRI MA03401

Metabolic Efficiency Between Two Types of High-Intensity Interval Training

Christopher Buschmann, Johnathon Childress, Michael Harris, Adrian Aron. *Radford University, Roanoke, VA.* (Sponsor: Trent A. Hargens, FACSM)
 (No relationships reported)

High intensity interval training (HIIT) is an effective and well-documented training method that utilizes periods of maximum effort followed by periods of moderate to low effort to achieve aerobic adaptations. CrossFit® (CF) is a novel training program defined as a strength and conditioning system built on constantly varied functional movements executed at high intensity aimed to improve both anaerobic and aerobic systems.

PURPOSE: To compare the total caloric expenditure between a traditional HIIT protocol and a best-matched CrossFit® protocol.

METHODS: Measurements were obtained from 22 CrossFit® male athletes (age = 34.8 ± 8.0 years, BMI = $28.3 \pm 3.7 \text{ kg/m}^2$). Graded exercise tests (GXT) were performed in order to determine speeds at which the HIIT protocol was performed. The protocol consisted of 20 total intervals, 10 at 90% of the max speed during GXT and 10 at 50% of the max speed of GXT. Participants also completed a Crossfit® protocol consisted of as many rounds as possible of a 15 calorie row, 10 pushups, and 5 deadlifts at 135 lbs. Caloric expenditure was measured using the Oxycon mobile metabolic system by multiplying the average oxygen consumed over the 20 minute trial by 5.0 kcal. Intensities were matched amongst all participants based on pre-exercise data, ensuring that all participants were performing the HIIT at the same relative intensities.

RESULTS: The high speed of the HIIT routine was $13.6 \pm 1.6 \text{ km/h}$, while the low speed was $7.5 \pm 0.9 \text{ km/h}$. The two routines did not differ in terms of caloric expenditure; 358.2 ± 47.2 calories during HIIT compared to 340.8 ± 41.0 calories during CF, $P = 0.2$. After controlling for history of CrossFit® exposure, no significant difference was observed between the two routines ($P = 0.3$). Respiratory exchange ratio was higher during the CF routine ($1.0 \pm 0.6 \text{ VCO}_2/\text{VO}_2$) compared to HIIT routine ($0.9 \pm 0.4 \text{ VCO}_2/\text{VO}_2$), $P = 0.04$.

CONCLUSIONS: These data suggest that CrossFit® routines have similar metabolic demands compared to HIIT. The CF routine appears to reflect a greater exercise intensity that may lead to higher blood lactate concentration from the high glycolytic pathways involvement. The constant variation seen during CF may challenge the energy systems differently than HIIT while creating similar total metabolic demands during exercise.

Cardiovascular and Workload Responses to High Intensity Interval Training in Adolescents

Shannon Moree, Rebecca Mitchell, Kody Brandt, Amanda Schultz, Cara Wilck, Annelle Weir, Stephen P. Bailey, FACSM. *Elon University, Elon, NC.*
 (No relationships reported)

Despite the promising evidence supporting positive health benefits of high-intensity interval training (HIIT) in adults, there is limited research focusing on adolescents. **PURPOSE:** The purpose of this study was to describe the impact of HIIT training on

cardiovascular responses to exercise in male and female adolescents. **METHODS:** Ten (4 male, 6 female; Age=11.7±1.4 years; VO_{2peak} =27.33±6.89; BMI=28.6±6.6) adolescents, referred from local pediatricians, completed 16 HIIT sessions over an 8 week period. Each HIIT session consisted of a 5 min warm up, a 20 minute stimulus, and a 5 min cool down. During the stimulus period, subjects completed twenty 30 sec "on", 30 sec "off" intervals. During the initial session the "on" workload was set to be equivalent to 90% of maximal workload recorded during the VO_{2peak} test, while the "off" workload was set to be equivalent to 50%. Subsequent to this initial session, workload was adjusted so that RPE during the last 5 intervals was equivalent to at least 9 out of 10 on the Borg RPE scale. Workload, heart rate, and RPE were recorded at the end of each interval. **RESULTS:** Maximal workload during HIIT increased in all subjects from the first (152±8 watts) to the last (240±18 watts) session ($p<0.001$). In comparison, no differences were seen between the genders at any time point (Male: First Session=155±14 watts, Last Session=255±15 watts; Female: First Session=150±11 watts, Last Session=230±13 watts). Similarly, heart rate (Male: First Session=186±9 bpm, Last Session=185±6 bpm; Female: First Session=184±8 bpm, Last Session=177±7 bpm) and RPE (Male: First Session=9+1, Last Session=10+1; Female: First Session=9+1, Last Session=10+1) were maintained across the HIIT sessions. **CONCLUSION:** The results of this investigation indicate that HIIT is well tolerated and facilitates significant cardiovascular adaptation in both male and female adolescents.

Mechanical Efficiency During Repeated Attempts of Indoor Rock Climbing

Andrea C. Woita¹, Jack Young, FACSM¹, James W. Navalta, FACSM¹, Nathaniel G. Bodell¹, Jeffrey Montes¹, Elizabeth A. Tanner¹, Grace A. MacDonald¹, Jacob W. Manning², Camille Thomas², Julie Taylor². ¹University of Nevada, Las Vegas, Las Vegas, NV. ²Southern Utah University, Cedar City, UT. (Sponsor: John Young, FACSM)
 (No relationships reported)

Rock climbing is characterized by repeated short bouts of high-intensity climbs requiring upper body strength and muscular endurance. There is an inverse relationship between work rate and mechanical efficiency and it is hypothesized that mechanical efficiency would decrease from the first to the last climb during a series of repeated climbs. **Purpose:** To determine mechanical efficiency of repeated rock climbing attempts at a self-selected speed. **Methods:** Twenty-four experienced climbers volunteered to participate in this study (ages 18-40 years, 20 males, 4 females, at least one year of recreational climbing experience). Participants climbed up and down a vertical route (30 feet) on an indoor climbing wall at a self-selected pace for ten minutes. VO_2 was continuously measured during the upward portion of the climb using a portable COSMED device. Work was calculated from height climbed and body mass. **Results:** Four climbers' data were discarded due to incomplete data. From the remaining twenty subjects, there was no significant difference in mechanical efficiency from the first climb ($M=18.4\%$, $SD=11.3\%$) to the last climb (17.8% , $SD=11.0\%$); $t(20)=0.89$, $p=0.19$. **Conclusions:** The recreational climbers did not experience a significant decrease in mechanical efficiency. It was thought that fatigue would result in decreased mechanical efficiency due to an increased work rate from continuous climbing action. One possible explanation is the repeated attempts resulted in a learned effect causing the subjects to become more familiar with the route. The familiarity of the route likely led to improved technique and possibly offset the impact of fatigue on mechanical efficiency. Future studies should consider investigating the difference in mechanical efficiency on repeated climbs of varying routes.

Comparing Daily Class Schedule and its Influence on Undergraduate Students' Physical Activity Patterns

Matthew D. Moran, Dina D. Kendle, Matthew B. Rhudy, Kristen Gift, Marissa Ruggiero, Carolyn Gray, Praveen Veerabhadrapa. The Pennsylvania State University, Reading, PA.
 (No relationships reported)

Full-time undergraduate students' daily physical activity patterns may be affected due to Penn State University's different class schedules -Monday/Wednesday/Friday (M/W/F) and Tuesday/Thursday (T/Th). A no class period (common hour: 1:00pm-2:30pm) on M/W/F is offered as scheduled breaks in the academic course schedule for student activities at different Penn State University Commonwealth campuses. **Purpose:** To objectively determine the differences in daily step count and energy

expenditure of Kinesiology students on different days of the week. **Methods:** Sixty eight (35M/33F, 21.6±2.9 years, average BMI 25.9±5.2 kg/m²) apparently healthy juniors and seniors were recruited from the Penn State Berks. A wrist-worn activity-tracker was deployed for one week to assess students' free-living physical activity levels. **Results:** M/W/F vs. T/Th (Mean±SD) step count (10387 ± 3560 vs. 9268 ± 2899 steps/day; $p=0.015$) and activity calories (1056.4±535.2 vs. 963.5±608.3 kcal/day; $p=0.097$) were measured. Students were most active on Mondays (10691±4531 steps/day) compared to the rest of the week. **Conclusion:** Students achieved the recommended 10,000 steps daily goal on M/W/F and did not meet the step goal on T/Th. This difference in steps could be attributed to the mandatory no class 'common hour' which may allow students to be more physically active than the T/Th schedule. In addition, the shorter class structure on M/W/F (50 min/class) might also provide opportunities for students to be more active than T/Th (75 min/class). These preliminary results may be useful for planning early physical activity interventions on specific days of the week among college students.

Comparison of Effectiveness in Online vs. Hybrid Courses in College Wellness Courses

Ruth N. Henry, Frank M. Romeo. Lipscomb University, Nashville, TN. (Sponsor: Kent Johnson, FACSM)
 Email: ruth.henry@lipscomb.edu
 (No relationships reported)

Online courses have gained popularity in recent years; research has supported its effectiveness while also pointing out the limitations of online delivery. Hybrid courses have been developed in response to some of the challenges, with course content delivered both online and in a face to face setting. **Purpose:** The goal of this research was to determine whether 100% online or hybrid online courses are more effective in delivering a college-level wellness course. **Methods:** 47 students were enrolled in Fitness/Wellness courses; 23 students enrolled in the 100% online section which met in class only for fitness tests and written exams. The other 24 enrolled in the hybrid section, which met once per week for exercise in addition to class meetings for fitness testing and exams. Assignments were identical in both sections. All students were assessed for knowledge via weekly open-book online quizzes (QUIZ) and closed-book exams (EXAM) in the classroom. Fitness tests were performed before and after an 8-week self-prescribed, instructor-graded exercise program, and fitness improvement was analyzed. Students also responded to open-ended questions about course delivery preference. **Results:** There were very few differences between groups in written work or fitness outcomes. Written work between groups was statistically equal; (EXAM online mean = 79.9% ± 9.57; hybrid mean = 81.58% ± 7.55; $p=0.49$); (QUIZ avg. online mean = 83.7% ± 10.1; hybrid mean = 84.5% ± 10.7; $p=0.81$). Improvements in fitness parameters were calculated as post-score minus pre-score. Only the 1.5-mile run test yielded a significant difference, with the hybrid group (mean improvement = 2.3 ± 2.2 minutes) improving significantly more than the online group (mean improvement = 0.60 ± 0.96 minutes; $p=.003$). Improvement in pushups (Online = 4.45 ± 6.11, Hybrid = 2.67 ± 4.75; $p=0.28$), sit-ups (Online = 3.4 ± 3.59, Hybrid = 2.77 ± 5.82; $p=0.68$) and sit-and-reach (Online = 2.47 ± 3.42, Hybrid 2.05 ± 2.32; $p=0.64$) were statistically equal between groups. In the open-ended questions, students in both sections cited the value of weekly class meetings and face-to-face time with teacher and classmates, although online students expressed enthusiasm for the online format for convenience. **Conclusion:** Student outcomes in wellness courses with online and hybrid delivery are similar.

2218 Board #231 June 1 2:00 PM - 3:30 PM
Self-reported Measures Of Strength And Sport-specific Skills Distinguish Ranking Among Females In An International Online Fitness Competition

Paul Serafini, Yuri Feito, FACSM, Gerald Mangine. Kennesaw State University, Kennesaw, GA. (Sponsor: Dr. Yuri Feito, FACSM)
 Email: paul.serafini21@gmail.com
 (No relationships reported)

PURPOSE: To determine if self-reported performance measures could distinguish ranking amongst female competitors in an international online fitness competition (OFC). **METHODS:** The top one-thousand five hundred female competitors (28.72 ± 4.87 y; 63.65 ± 5.80 kg; 163.71 ± 6.60 cm) of the OFC were split into quintile groups (Q1 - Q5) based upon their final OFC ranking. Then, self-reported performance scores for one-repetition maximum (1RM) squat (SQ), deadlift (DL), clean and jerk (CJ), snatch (SN), 400-m sprint, 5,000-m run, and benchmark workouts (Fran, Helen, Grace, Filthy-50, and Fight-gone-bad) were compared between quintiles using separate one-way analysis of variance. **RESULTS:** Q1 reported greater ($p < 0.05$) 1RM loads for DL (148.3 ± 14.5 kg), SQ (126.1 ± 13.0 kg), CJ (95.69 ± 8.42 kg), and SN (76.5 ± 7.6 kg) compared to all other quintiles (Q2 - Q5). In the 400-m sprint, though Q1 (71.0 ± 9.2 sec) was not different from any other quintile, Q2 (67.5 ± 8.8 sec) reported faster ($p < 0.05$) times than Q3 - Q5 (73.5 - 74.8 sec). For the 5,000-m run, differences were

only observed between Q1 (21.3 ± 1.8 min) and Q4 (22.6 ± 2.2 min, p = 0.008) and between Q1 and Q5 (22.6 ± 1.9 min, p = 0.016). In benchmark workouts, Q1 reported the fastest (p < 0.001) times in Fran (159.4 ± 28.3 sec) compared to all other groups and better (p < 0.005) performances compared to Q3 - Q5 in Grace (1.9 ± 0.5 min) and Fight-gone-bad (388 ± 45 repetitions). Differences between groups for Helen and Filthy 50 varied amongst quintiles. **CONCLUSIONS:** In female athletes, the most elite OFC competitors (i.e., Q1) possessed the greatest strength and power, and generally performed the best on benchmark workouts that emphasized muscle strength and endurance (i.e., Fran, Grace, and Filthy-50). Though aerobic and anaerobic fitness also appeared to be greater in higher-ranking competitors, distinctions between quintiles were more broad.

Analysis Of Anthropometric Profiles And Long-term Career Progression In 24 Years Of German Junior Rowing

Kay Winkert, Gunnar Treff, Werner Lormes, Katja Machus, Jürgen M. Steinacker, FACSM. *University Ulm, Sports and Rehabilitation Medicine, Ulm, Germany.*
 Email: kay.winkert@uniklinik-ulm.de
 (No relationships reported)

Talent identification in rowing typically includes standing height (SH) and body mass (BM), because successful rowers are on average taller and heavier than their opponents. Moreover, successful elite senior rowers are significantly taller and heavier than Juniors, but it remains unclear if those athletes who became elite rowers later, were already taller and heavier as adolescents.

PURPOSE: We aimed to retrospectively analyze anthropometrical differences of national team junior rowers considering their long-term career progression level and to define minimal anthropometric requirements allowing for later success.

METHODS: 706 male German junior rowers (age 17.5±0.7 y) of the years 1991 - 2015 were grouped according to their highest progressive career level, more precisely U19-, U23-, Senior World Championships (WCh), or Olympic Games (OG). To analyze differences in SH and BM a one-way ANOVA with Post-Hoc test was calculated.

RESULTS: Distribution for highest progressive career level were 46.7% U19- (191.0±4.6 cm, 85.5±6.1 kg) 35.6% U23- (192.3±4.7 cm, 86.5±6.7kg), 6.9% Senior WCh (192.8±4.9 cm 87.4±6.5 kg) and 10.8% OG (193.7±4.4 cm, 88.2±6.4 kg). Significant small effects in SH (F(3,702) = 9.30, p = .000, η² = 0.038) and BM (F(3,702) = 4.31, p = .005, η² = 0.018) among progression levels were found. Rowers competing not higher than U19-WCh were smaller (-0.69 - -1.42%; p < .005) and exhibited less BM (-1.08 - -3.05%; p < .007) compared to higher progression levels. This effect increased by 0.45 % (R² = .97) for SH and 1.01% for BM (R² = .99) with rising progression level. No significant differences were found between U23, Senior WCh, and OG. Minimal anthropometric requirements within the higher progression levels can therefore be calculated as 188 cm SH and 80.3 kg BM.

CONCLUSIONS: This finding suggest that higher SH and BM within a homogenous group of adolescent elite junior rowers are already associated with long-term career progression in international elite rowing. Minimal anthropometric requirements could be established and can be interpreted as thresholds associated with later success. However, anthropometric variables must not be solely or exclusively used for talent identification, because maturation to elite status is inherently multi-dimensional.

2220 Board #233 June 1 2:00 PM - 3:30 PM
Bioelectrical Impedance Analysis and Skinfold Prediction of Percent Fat in Male College Athletes

Zane Starks¹, Amanda Starks², Richard M. Schumacher², Jerry L. Mayhew², William F. Brechue, FACSM¹, J. Bryan Mann³.
¹A.T. Still University, Kirksville, MO. ²Truman State University, Kirksville, MO. ³University of Missouri, Columbia, MO.
 Email: zstarks@atsu.edu
 (No relationships reported)

Determination of body fat (%fat) in athletes is now a common component of the preparation for competition. Various techniques have been developed to estimate %fat in athletes. However, some question may remain concerning the accuracy of these methods to accurately determine %fat in male college athletes. **PURPOSE:** To compare various methods of obesity classification in male college athletes. **METHODS:** NCAA Division II athletes (n = 183) from 6 sports were assessed during the off-season for skinfolds (SKF), BIA, and DEXA. Skinfold sites included biceps, triceps, subscapula, midaxilla, chest, suprailium, abdomen, thigh, and calf. Skinfolds were measured in triplicate and averaged for analysis. Eight SKF equations utilized to estimate %fat in athletes were evaluated. Single-frequency (50 Hz) hand-to-hand BIA (H-BIA) and foot-to-foot BIA (F-BIA) devices using an athletic setting were also assessed. **RESULTS:** All prediction methods significantly underestimated DEXA %fat (18.2 ± 5.8%, range = 9.5 to 36.3%) despite high correlations with the criterion (ICC = 0.78 to 0.93). Of the SKF equations, the Durnin-Wormsley equation produced

the closest estimate (16.2 ± 4.0%, ICC = 0.91). H-BIA (13.6 ± 4.9%) and F-BIA (13.4 ± 5.8%) were comparable in their underestimation of %fat (-4.8 ± 4.4%) with similar correlations with the criterion (ICC = 0.83). Significant negative correlations for the difference between SKF predicted and DEXA %fat (r = -0.71 to -0.97) indicated greater discrepancy between the two methods at higher %fat values. There were smaller but significant negative correlations for the difference between SKF predicted and actual %fat values and body mass (r = -0.22 to -0.56), suggesting greater underestimation of DEXA %fat by SKF at higher body masses. **CONCLUSIONS:** All prediction techniques produced significantly lower estimates of %fat in male college athletes than when measured by DEXA. Prediction error typically increased at greater actual %fat and body mass values. If DEXA is to be accepted as the new standard for assessing body composition, new prediction equations may need to be developed. Higher %fat values than previous accepted may need to become the new normal standard for college athletes when using DEXA as the criterion.

2221 Board #234 June 1 2:00 PM - 3:30 PM
Influence of Lower Extremity Strength on Physical Activity in Young Adults

Neal Glaviano¹, Andrea Baellow², Susan Saliba². ¹University of Toledo, Toledo, OH. ²University of Virginia, Charlottesville, VA.
 (Sponsor: Jay Hertel, FACSM)
 Email: neal.glaviano@utoledo.edu
 (No relationships reported)

Decreased physical activity has been identified as a risk factor for many health related conditions. Lower extremity muscular strength is an important aspect for the completion of physical activity. Differences have been found to exist between males and females with their lower extremity strength. However, limited evidence exists evaluating the influence of strength of the hip and knee muscles on physical activity between sexes. **PURPOSE:** To explore if a relationship between lower extremity isometric strength and physical activity exists between male and female young adults.

METHODS: Isometric strength was recorded on the dominant limb in 47 college aged participants with a handheld dynamometer (30 females and 17 males). Strength was assessed for participant's hip flexors, extensors, external rotators, internal rotators, abductors, adductors and knee flexors and extensor muscle groups. Strength was normalized as a percentage of body weight. Physical activity was recorded with a commercial activity monitor over 2-weeks, with steps per day being the main outcome. Relationships between lower extremity muscle strength and activity level were explored with pearson product moment correlations, controlling for age and body mass. A linear regression was utilized to explore if lower extremity strength could predict physical activity.

RESULTS: Significant correlations were found between activity level and strength in females for their hip flexors (r = .484, p = .007), hip abductors (r = .629, p < .001), hip external rotators (r = .453, p = .012), knee flexors (r = .393, p = .032) and knee extensors (r = .421, p = .020). Isometric hip abductor strength was found to a significant predictor of physical activity when assessed by steps per day (p < .001), accounting for 39% of the variance in the model. No significant correlations were found in males between activity level and strength.

CONCLUSIONS: Lower extremity strength appears to play a role in physical activity levels in female college aged individuals, with hip abductor strength significantly predicting activity level. Intervention programs should evaluate strength training for females as one potential approach to improve physical activity.

Predicting Maximal Oxygen Uptake in Adults Using a Walking Test

Taylor Rowley, Chris Cho, Ann Swartz, FACSM, Nora Miller, Scott Strath, FACSM. *University of Wisconsin- Milwaukee, Milwaukee, WI.* (Sponsor: Dr. Scott Strath, FACSM)
 Email: tkwenos@gmail.com
 (No relationships reported)

Purpose: Maximal oxygen consumption (VO_{2max}) testing is not always feasible, practical, or safe. The purpose of this study was to find a good fitting VO_{2max} prediction equation using a 9-minute walking test. **Methods:** Healthy adults aged 18-79 years participated in this study. Resting heart rate (RHR) and a VO_{2max} test to volitional fatigue were assessed. Participants were asked to complete a 9-minute, ramped-intensity, over-ground walking test, where they were instructed to walk for 3-minutes each at a self-selected slower than normal, normal, and faster than normal walking speed. VO₂ and heart rate (HR) responses were collected using a portable metabolic device and averaged the last two minutes of each stage. These represent the main predictors of interest in this study. Other covariates were age, gender, body mass (kg) and change in HR from RHR (delta HR). A stepwise selection method with a p-value criterion of .05 for inclusion and exclusion was used to determine the predictive model. **Results:** The final sample (N=123) was 57.7% female, average age 46.4±17.2 years, BMI 25.8±4.6 kg/m², VO_{2max} 34.7±10.5 ml/kg/min, and RHR 60.5±9.2 bpm. A null model with only age (p<0.001), gender (p<0.0001), and body mass (p<0.0001)

was able to account for 73.5% of the variance in VO_{2max} ($R^2=.736$). The estimated prediction model using measurements from the normal walking speed stage including VO_2 ($p<0.0001$), HR ($p<0.0001$) and delta HR ($p=0.0051$) along with covariates age ($p<0.0001$), gender ($p<0.0001$) and body mass ($p<0.0001$) was able to achieve an R^2 of 83.3%. The addition of these variables increased the strength of the prediction model by ~10%. **Conclusion:** The results from this study indicate that a 3-minute over-ground walking test at a self-selected normal pace, where only VO_2 and HR are recorded in conjunction with demographic variables, is able to provide a good fitting model to predict VO_{2max} . Compared to other reported over-ground submaximal prediction equations, the model obtained in this study was able to achieve a similar fit in predicting VO_{2max} .

Core Strength/Endurance and Inspiratory Muscle Performance - Are They Related?

Marlon L. Wong, Magno F. Formiga, Luis A. Feigenbaum, Michele A. Raya, Robyn P. Rice, Taylor M. Galmarini, Lacey Scrima, Lawrence P Cahalin, 33129. *University of Miami, Miami, FL.* (Sponsor: Dr. Thomas Best, FACSM)
 Email: MWong2@med.miami.edu
 (No relationships reported)

Core strength/endurance (CSE) is believed to be an important component of physical performance in sport and functional tasks. A standard measure of CSE is the side plank (SP) during which the duration it can be held is measured. **PURPOSE:** To examine the effects of a test of inspiratory muscle performance (IMP) done in the SP position on SP duration and several measures of IMP. **METHODS:** 28 healthy subjects (15 men, 13 women with a mean±SD age, height, and weight of 36±14 and 34±11 years, 176.0±8.6 and 165.6±6.1 cm, and 80.8±8.3 and 64.5±7.2 kg, respectively) underwent in random order two tests of SP duration (with and without IMP tests) and IMP (at the onset of SP and in sitting) with at least 5 minutes of rest between each of the tests. IMP was measured via the Test of Incremental Respiratory Endurance (TIRE) yielding maximal inspiratory pressure (MIP), sustained maximal inspiratory pressure (SMIP), and inspiratory duration (ID). MIP was measured from residual volume while SMIP and ID were measured from residual volume to total lung capacity. **RESULTS:** Men were found to have significantly ($p<0.05$) greater height and weight compared to women. The SP duration decreased significantly ($p<0.05$) for the entire cohort when IMP was tested during SP (104.2±41.5 sec to 81.1±33.0 sec), but no significant difference in SP duration between men and women under both test conditions was observed. MIP and SMIP also decreased significantly ($p<0.05$) for the entire cohort when IMP was tested during SP (117.9±21.8 to 92.6±18.3 cm H₂O and 683.9±191.0 to 535.6±173.9 PTU) and a significantly ($p<0.05$) lower MIP and SMIP was observed in the SP position of both men and women with men having significantly ($p<0.05$) greater values compared to women during both test conditions. Men were observed to have a significantly ($p<0.05$) different ID compared to women (16% increase versus 9% decrease, respectively) when IMP was tested in the SP position. **CONCLUSIONS:** SP duration and IMP decreased significantly when IMP was tested in the SP position with men having significantly greater MIP, SMIP, and ID compared to women. The increase in ID in men suggests that men use a different strategy to optimize CSE which may be due to their significantly greater height, weight, and IMP. CSE and IMP appear related, but further investigation of this relationship is warranted.

Physiological Predictors of Fatigability in Healthy Adults

Zoe Williams¹, Lisa Chin¹, Leorey Saligan², Leighton Chan², Randall Keyser, FACSM¹. ¹George Mason University, Fairfax, VA. ²National Institutes of Health, Bethesda, MD.
 (No relationships reported)

Fatigability is represented by a decline in performance in relation to the frequency, intensity and duration of physical activity. The use of anaerobic threshold (AT) as an index of endurance is well accepted in the literature. In patients with cardiopulmonary disease, ventilatory efficiency is related to exercise capacity, and therefore may have clinical significance as a fatigability measure. However, this has yet to be determined in healthy individuals. **PURPOSE:** To characterize physiological determinants of the time to fatigue (TTF) during a vigorous bout of treadmill exercise. **METHODS:** Subjects were 19 healthy participants (13 females, 6 males; age 26.6±9.1 years; BMI 24.2±2.7 kg/m²) enrolled in the National Institutes of Nursing Research, Fatigue in Healthy Individuals Protocol. Subjects completed a ramp treadmill cardiopulmonary exercise test (CPET) to volitional exhaustion during the initial visit. The anaerobic threshold and two measures of ventilatory efficiency (lowest VE/VCO₂ ratio and VE/VCO₂ slope at AT) were determined from the CPET. A subsequent visit consisted of a constant work rate test at vigorous-intensity performed to exhaustion in which the TTF represented a measure of performance fatigability. Data are presented as mean ± SD. **RESULTS:** The TTF was 436.12 ± 175.9 seconds at 240.05 ± 66.48 watts. Subjects achieved an AT of 18.1 ± 4.56 ml/min/kg, lowest VE/VCO₂ ratio of 24.72 ± 2.18

and VE/VCO₂ slope of 22.49 ± 2.16. Pearson product-moment correlation analysis suggests that both measures of ventilatory efficiency were not significantly correlated to the TTF. The anaerobic threshold was found to be the best predictor of the TTF, with a strong effect size ($d=0.865$) suggesting that AT is a reliable predictor of TTF explaining 15% of the variance. **CONCLUSIONS:** Results from this study suggest that AT remains a better predictor of fatigability compared to measures of ventilatory inefficiency. Further research is needed to determine other objective measures of fatigability.

Funding: Intramural Funds from the National Institutes of Nursing Research

Step Test as a Predictor of Law Enforcement Pursuit Requirement

Paul O. Davis, FACSM. *First Responder Institute, Silver Spring, MD.*
 Email: PODIII@aol.com
 (No relationships reported)

PURPOSE: Develop a simple, field expedient, pre-hire aerobic fitness tool to predict success in effecting a standardized foot pursuit and job-simulation arrest scenario as well as the job-related graduation criteria of 10 METs.

METHODS: A Job Task Analysis (JTA) was conducted via survey, on-site observations, and interviews of incumbent federal officers (n=1025) with the objective of establishing an aerobic fitness standard for the essential function of foot pursuit and effecting arrest. Respondents were asked to provide best estimates of distances, heights, and weights associated with critical and arduous tasks. Graduation criteria were based upon previously published research of a 2.6 l·min⁻¹ requirement for a foot pursuit and arrest scenario, nominally determined to be 10 METs.

SUBJECTS: Applicants (N=756, including 99 females (13%)) who presented for employment from October of 2005 through May of 2007 served as subjects for this study. Because they had received no prior physical screening these subjects represent a sample of applicants that was not range restricted on physical ability. A pass-fail, 5-minute step test (ST) (40cm, 24 repetitions·min⁻¹) was administered prior to starting a 13.5-week training program. Subjects embarked on their customary program of instruction (POI) and were tested on 1.5-mile run pre/post training. **RESULTS:** Students improved their run time by an average of 12%. Individuals who passed the ST had a 98% probability (sensitivity) of completing a 1.5-mile run in less than 16:30 min ($p<0.001$). Of the 57 applicants (9% of total sample) who could not complete the ST, performance on the 1.5-mile run was generally poor, with 89% (55/62) failing (specificity) to complete the run in less than 16:30 min (≈8METs). **CONCLUSIONS:** The ST is an easy to administer, job-related, valid field expedient test of aerobic fitness for predicting a 1.5 mi run graduation standard in a law enforcement setting. This study funded by the Department of Homeland Security

Predicting 2015 NBA Rookie Class On-Court Contribution Using Draft Combine and Performance Measurable's

Sarah Henry, 31419¹, Greg A. Ryan¹, Robert L. Herron², Jasmine Holmes¹, Kaitlyn J. Weiss³. ¹Georgia Southern University, Statesboro, GA. ²The University of Alabama, Tuscaloosa, AL. ³Auckland University of Technology, Auckland, New Zealand.
 Email: sh07478@georgiasouthern.edu
 (No relationships reported)

PURPOSE: The National Basketball Association (NBA) conducts an annual combine to assess anthropometric and athletic ability of collegiate and international prospects in preparation for the draft. Additionally, in-game performance variables are tracked

and used by scouting and personnel departments to determine players to draft. The purpose of this study was to determine how well the variables measured of the athletes invited to the 2015 NBA Combine predicted on-court contribution during their rookie season, as measured by Player Impact Estimate (PIE) (player's overall statistical contribution against the total statistics in played games). **METHODS:** Data from 12 tests (six anthropometric, six performance) recorded during the NBA Combine and data from 7 in-game performance variables recorded during the 2014 collegiate/international season were used for analysis. 64 athletes' rookie season player contribution was measured in PIE. A multiple linear stepwise regression was calculated to predict on-court contribution based on the 19 variables recorded during the NBA Combine and 2014 season. **RESULTS:** A significant regression equation was found among three variables (three quarter court sprint, 2014 assist:turnover ratio, 2014 field goal percentage) ($F(3,21) = 6.080, p = 0.005; R^2 = 0.503$). The three predictor model was able to account for 50.3% of the variance in PIE. $PIE = -37.208 + 9.245(\text{three quarter court sprint}) + 9.245(2014 \text{ assist:turnover ratio}) + 0.254(2014 \text{ field goal percentage})$, 95% CIs [-68.196, -6.220], [-0.455, 18.944], [0.593, 3.143] and [0.210, 22.843], respectively. **CONCLUSIONS:** The findings of this study suggest that the performance testing conducted at the 2015 NBA Combine and in-game performance variables could partially predict on-court contribution during the 2015 NBA regular season, though R^2 prediction was varied. However, of the 19 variables assessed, only three provided significant predictive value. These findings may help teams and scouts to assess performance and determine potential on-court contribution of draftees and undrafted free agents.

Comparison Of Physiological Demands Of Basketball Practice Sessions To A Pre-season Game
 Anthony D. Speckhard, Jeremy L. Knous, Adam M. Coughlin.
Saginaw Valley State University, University Center, MI.
 (No relationships reported)

An athlete's practice is ideally constructed to prepare them for game-type conditions. Training volume however, can be influenced by several factors including frequency, intensity, time, type, and volume of practice. Differences between basketball practices, scrimmages, and games are already illustrated (Montgomery et al., 2010 & Klusemann et al., 2013). The ability to improve practices to mimic game-type conditions could better prepare the athletes to perform in games. **PURPOSE:** To compare the physiological demands of practice to a pre-season game. **METHODS:** Ten Division II men's basketball players participated in this study (20.7 ± 0.9 yrs, 94.0 ± 13.2 kg, 1.90 ± 0.09 m). All players wore Hexoskin activity monitors (Hexoskin, Montreal, CAN) which measure heart rate (HR) via ECG, g-force (above that of the earth's gravity) via triaxial accelerometry, and time of day (including time spent wearing the monitor). Monitors were worn at practices for the week leading up to and the week following a pre-season game. A dependent, two-tailed t-test compared the average of twelve days of practice (P) to the pre-season game (G). Coefficient of determination was utilized to compare change in time while wearing the monitor to change in training volume (total g-force). **RESULTS:** Time spent in practice was significantly greater than the game ($P = 144 \pm 2; G = 126 \pm 2$ min; $p \leq 0.05$). While average HR did not differ ($P = 121 \pm 5; G = 121 \pm 17$ bpm), maximal HR was higher in the game ($P = 180 \pm 6; G = 189 \pm 7$ bpm; $p \leq 0.05$). Average g-force was higher in practice ($P = 0.38 \pm 0.05; G = 0.30 \pm 0.11$ m/s²; $p \leq 0.05$), however maximal g-force did not differ between the two ($P = 3.64 \pm 0.42; G = 3.97 \pm 0.71$ m/s²; $p = 0.10$). Total g-force (average g-force of the session multiplied by the minutes of the session) differed between the two conditions ($P = 55.2 \pm 7.7; G = 37.4 \pm 13.6$ min-m/s²; $p \leq 0.05$). A coefficient of determination elucidated an $r^2 = 0.175$, indicating that only 17.5% of the change in total g-force was explained by the difference in time between P and G. **CONCLUSION:** Practices were longer, less intense based on maximal HR and a trending maximal g-force, with a higher average g-force and total g-force compared to the pre-season game. Volume of training for practices could be better tailored to more closely mimic game-type conditions, although the goals of practice should be considered.

Comparisons Between Jump Power, Swing Velocity, and Hitting Measures in Collegiate Baseball and Softball Athletes
 Ryan M. Miller¹, H. S. Strohmeyer², Michael G. Bembem, FACSM¹. ¹University of Oklahoma, Norman, OK. ²University of Central Missouri, Warrensburg, MO. (Sponsor: Dr. Michael G. Bembem, FACSM)
 (No relationships reported)

Successful performance in baseball and softball requires the ability to perform multiple skills efficiently. The skills most critical to the game include fielding, throwing, and hitting and each have components of strength, agility, and muscular power. **PURPOSE:** To evaluate the relationships and differences between maximal leg power and swing velocity in collegiate baseball and softball players. **METHODS:**

Thirty-four subjects (20.4 ± 1.3 yrs, 176.8 ± 9.8 cm, and 77.7 ± 13.9 kg) were assessed for vertical jump power and swing velocity using a force plate and visual 3D technology, respectively. Mean differences were calculated by independent t-tests and relationships between parameters of interest were calculated using Pearson Correlation coefficients. Statistical significance was set at 0.05 **RESULTS:** Baseball ($n=17$) and softball ($n=17$) player mean age, height (cm), and weight (kg) were 20.7 ± 1.2 yrs, 184.8 ± 4.1 cm, 88.3 ± 9.8 kg and 20.1 ± 1.4 yrs, 168.9 ± 6.7 cm, 67.0 ± 8.0 kg, respectively. Vertical jump power and swing velocity means were 1528.3 ± 169.7 W, 38.6 ± 1.4 m/s and 1045.4 ± 121 W, 29.8 ± 1.8 m/s, respectively. Baseball players were significantly taller ($p \leq 0.01$) and heavier ($p \leq 0.01$) than softball players. They also generated significantly more jump power ($p \leq 0.01$) and achieved higher swing velocities ($p \leq 0.01$) but no differences were revealed for hitting measures. Vertical jump power tests revealed moderate to strong relationships for baseball players ($r = .58-.96, p < 0.05$) between height, weight, swing velocity, batting average, and slugging percentage for baseball but only height and weight for softball players. Swing velocity revealed poor to moderate relationships for both groups ($r = -.28-.51$) for batting average, slugging percentage, and home runs. **CONCLUSION:** Statistical evaluation revealed moderate to strong relationships between vertical jump power and anthropometric measures for both groups. Furthermore, baseball players display moderate to strong relationships between vertical jump power, swing velocity, batting average, and slugging percentage. In conclusion, evaluating and predicting performance from physiological variables remains a challenge, however, maximal leg power could serve as a moderate indicator of performance in baseball athletes.

Limb Mass And Passive Muscle Tension Contributions To Knee Flexion Torque At Long Muscle Lengths
 Malachy P. McHugh, FACSM¹, Susan Y. Kwiecien¹, Jesse M. Galina¹, Brandon M. Schmitt², Timothy F. Tyler¹. ¹Nicholas Institute of Sports Medicine and Athletic Trauma, Lenox Hill Hospital, New York, NY. ²Pro Sports Physical Therapy of Westchester, Scarsdale, NY.
 Email: mchugh@nismat.org
 (No relationships reported)

Purpose: During isokinetic and isometric strength testing it is important to correct torque for the contribution of limb mass and passive muscle tension. This is particularly important in testing hamstring strength since weakness at long muscle lengths is a factor in recurrent hamstring strains. The purpose of this study was to quantify the relative contributions of passive muscle tension and limb mass during strength testing with the hamstrings in a stretched position. **Methods:** Isometric strength tests were performed on 50 athletes (30 men, 20 women) prior to return to sport after a hamstring strain. Strength was assessed at 80°, 60°, 40°, and 20° knee flexion in sitting with the test thigh flexed 40° above horizontal and the seat back at 90° to the horizontal. In this set up the leg was horizontal at 50° knee flexion. Passive torque (limb mass + passive hamstring tension) was recorded at each angle. Passive torque at 80° was defined as limb mass with no muscle tension; limb mass at 80° and 20° were equal (30° below/above horizontal); limb mass at 60° and 40° were calculated [(passive torque at 80°/cos 30°) * cos 10°]. Torque due to passive muscle tension = measured passive torque - limb mass. **Results:** Passive muscle tension contributed 21%, of total torque at 20° with limb mass contributing 16% and contractile torque accounting for only 63% of total torque. Angle of peak torque occurred at a significantly shorter muscle length ($P < 0.01$) when calculated from contractile torque (62°) versus total torque (49°).

Table 1	Total Torque (Nm)		Contractile Torque (Nm) (% of Total Torque)		Passive Muscle Tension (Nm) (% of Total Torque)		Limb Mass Torque (Nm) (% of Total Torque)		
	INV	NON	INV	NON	INV	NON	INV	NON	
Knee Flexion	20°	73±32	74±27	48±27	48±22	15±6	14±7	11±3	11±4
		100%	100%	63%	63%	21%	21%	16%	16%
40°		79±31	81±28	60±28	62±25	6±4	6±5	12±4	12±4
		100%	100%	74%	76%	8%	8%	17%	16%
60°		78±31	82±28	64±28	67±25	2±2	2±3	12±4	12±4
		100%	100%	80%	81%	3%	3%	17%	16%
80°		72±31	73±25	61±28	62±23	0±0	0±0	11±3	11±4
		100%	100%	84%	85%	0%	0%	16%	15%

INV=involved, NON=noninvolved
Conclusions: Currently "gravity correction" functions for isokinetic testing measure passive torque at only one joint angle and therefore cannot account for changing passive muscle tension from short to long muscle lengths. This invalidates isokinetic assessment of hamstring angle of peak torque or weakness at long muscle lengths where passive muscle tension is considerable.

2230 Board #243 June 1 2:00 PM - 3:30 PM
Predicting Success in Division I College Football Players Based on Initial Physical Performance Tests
 Anthony Caterisano, FACSM¹, Michael Gentry². ¹Furman University, Greenville, SC. ²Virginia Tech, Blacksburg, VA.
 Email: tony.caterisano@furman.edu
 (No relationships reported)

A recent study looked at the relationship between performance variables and success in the NFL among players who participated in NFL combine events, which features college seniors aspiring to make an NFL roster. To date no studies have looked at a similar relationship among high school seniors entering college, who aspire to make an NCAA Division I football roster. **Purpose:** The purpose of the study was to identify initial performance variables that predict success among aspiring Division I college football players. **Methods:** Archival data were analyzed from 310 college football players, which focused on their initial testing as they entered the program, who played during the decade from 1999-2009 at an NCAA top 5 nationally ranked university. Players were categorized by training group with skill players (G1; n=124) including running backs, defensive backs and wide receivers; fullbacks, tight ends and linebackers (G2; n=76); and offensive and defensive linemen (G3; n=110). Tests were conducted within a week of each player joining the program included height (HT), body mass (BM), 1 repetition maximum (1RM) in the squat (SQ), bench press (BP), power clean (PC), push jerk (PJ), vertical jump (VJ), sit and reach test (SR), 40-yard dash (40YD), 10-yard dash (10YD), and 20-yard shuttle (20YS). All data were collected by the same strength coach over the ten-year period. Success was determined by three criteria: level 1 included players who never made the starting line-up in their college careers, level 2 were players that made the starting line-up but never made it to the NFL, and level 3 were player that played at least one full year in the NFL. Data were analyzed using ordinal regression analysis. **Results:** The best predictors by training group were as follows: Skill players (G1) by 10YD ($p = 0.001$); Linebackers and related positions (G2) by BP1RM ($p=0.026$) and 20YS ($p=0.044$); Linemen (G3) by BM ($p=0.32$), PC ($p=0.043$), and 40YD ($p=0.043$). **Conclusions:** These results suggest that it may be possible to predict the success of high school recruits entering a NCAA Division I football program by position grouping, by looking at selected performance parameters. Our data suggests that for G1 acceleration is important, G2 upper-body strength and lateral speed are paramount, and G3 size combined with speed and explosive hip extension predicts success.

Relationship Between Dynamic Postural Control And Core Strength In Collegiate Women's Basketball Players
 Brenda Hardman. California State University, Long Beach, Long Beach, CA.
 Email: brenhardman@hotmail.com
 (No relationships reported)

RELATIONSHIP BETWEEN DYNAMIC POSTURAL CONTROL AND CORE STRENGTH IN COLLEGIATE WOMEN'S BASKETBALL PLAYERS

Hardman, Brenda, Burns, Karlee, Vargas, Tiffany, Wu, Wilbur, Nakajima, Mimi. Center for Sport Training and Research, California State University, Long Beach. **Context:** Core strength and balance have been emphasized as important pieces to injury prevention, however, there is limited research regarding the relationship between the two. The Star Excursion Balance Test (SEBT) has been used to predict injury rate in athletic populations. **Purpose:** The purpose of this study was to evaluate the relationship between dynamic postural control using the modified SEBT and core strength in NCAA Division I women's basketball players. **Methods:** Fourteen Division I collegiate women's basketball players (age 19.71 ± 1.20 years; height 175.26 ± 7.32 cm; mass 71.36 ± 12.76 kg) completed a modified SEBT and core strength tests in a single testing session. Reach distance during the modified SEBT was collected in the anterior, posteromedial, and posterolateral directions and normalized by leg length. Composite score was calculated by adding individual directions. Core strength was measured using endurance tests for back extension, trunk flexion, and single leg wall sits, all for time. **Results:** There was a significantly moderate correlation $r(12) = 0.599$, $p = 0.024$ between combined composite SEBT score and trunk flexion holds. There was a significantly moderate correlation $r(12) = 0.568$, $p = 0.04$ between right leg anterior reach and back extension holds. A regression analysis was performed and determined that back extension holds was a good predictor of right anterior reach $R^2 = 0.460$, $p = 0.009$. **Conclusion:** This study corresponds with previous studies that shows the positive relationship between core strength and dynamic balance. Despite sample-size limitations, this study showed that increase in some core strength parameters may influence dynamic postural control.

2232 Board #245 June 1 2:00 PM - 3:30 PM
Comparison of Lung Volumes and Estimated VO₂MAX in College-aged Wind Musicians Versus Aerobic Athletes
 Brian Larouere, Morgan Petro, Jenna Bracken, Ted DiSanti. Seton Hill University, Greensburg, PA.
 (No relationships reported)

It is well known that aerobic athletes and musicians have higher dynamic lung functions than the general population. There is a gap in the current literature comparing the lung volumes of college-aged aerobic athletes to the lung volumes of college-aged wind musicians. **PURPOSE:** To compare the lung volumes (SVC, FVC, FEV₁, MVV) and VO₂MAX between college-aged Division II athletes and physically inactive wind musicians. **METHODS:** Subjects (n=21) were recruited based upon age and medical criteria. Athletes (n=11) were defined as individuals who accumulated at least or more than 150 minutes of moderate intensity aerobic activity per week and participated on an aerobic based athletic team. Wind musicians (n=10) were defined as individuals who played a wind instrument at the collegiate level who did not meet aerobic exercise guidelines. Three respiratory tests (SVC, FEV₁, MVV) were performed to assess lung volume using a spirometer. VO₂MAX was also estimated using an 8-minute treadmill walk test that elicited a heart rate between 50% and 85% of their maximal heart rate. Collected results were analyzed using a two-tailed independent t-test and Pearson correlations. **RESULTS:** There was a significant difference in VO₂MAX ($p=0.013$) between groups with the athletes (42.1 ± 7.2) having higher values than musicians (30.44 ± 11.9). There were no significant differences in the other lung volumes between groups. However, there were strong positive correlations between FVC and SVC ($r=0.927$), as well as, MVV and SVC ($r=0.911$) with musicians. There were also strong correlations between FEV₁ and FVC ($r=0.980$), FEV₁ and SVC ($r=0.946$), and FVC and SVC ($r=0.937$). **CONCLUSION:** The VO₂MAX results were greater in athletes when compared to wind instrument musicians. Interestingly, physically inactive musicians had similar lung functions as athletes. This difference could be attributed to athletes training their cardiorespiratory system and not solely their respiratory system.

2233 Board #246 June 1 2:00 PM - 3:30 PM
Predictability Of Vo2max Using A Gps Watch
 Andrew G. Pearson, Delaney C. Schoff, Marissa A. Hall, Andrea D. Workman, Christopher W. Herman, Jeff Schulz, Rebecca W. Moore. Eastern Michigan University, Ypsilanti, MI. (Sponsor: Lanay Mudd, FACSM)
 Email: appears12@emich.edu
 (No relationships reported)

Using accurate submaximal methodologies to estimate VO₂max is a convenient alternative to maximal exercise testing. Submaximal testing is practical because it provides a cheaper, more time-efficient alternative to maximal testing and allows a wider range of individuals to be tested. **PURPOSE:** To examine the predictability of VO₂max based on a submaximal 15-minute outdoor run using a GPS sports watch compared to measured VO₂max. **METHODS:** Twenty-three participants (16 M, 7 F; 20-55 years old) volunteered for this study. Participants came to the laboratory on two separate occasions. On day 1, participants arrived in a fasted state (no intake in the past 3 hours) and completed a treadmill graded exercise test (GXT) to determine VO₂max. Participants completed the test using a self-selected pace (mph). The self-selected pace remained constant throughout the test while the grade increased 2% every 2 minutes until volitional exhaustion. During the test, heart rate (HR) and VO₂ (ml/kg/min) were recorded every minute. On day 2, participants completed a 15-minute submaximal outdoor run. Participants were fitted with a GPS sports watch, which was used to estimate VO₂max based on subject characteristics (gender, age, height (in), weight (lbs.), maximal HR (recorded on day 1 of testing)) as well as total distance of the run, pace, time (15 minutes), and HR. A paired samples t-test was used to determine if there was a significant difference between directly measured VO₂max and estimated VO₂max using the GPS watch. Statistical significance was determined by $p < 0.05$. **RESULTS:** Five participants (3 males, 2 females) were excluded from the analysis due to the GPS watch malfunctioning, not reaching a true max, or dropping out of the study. The remaining 18 participants were 27.61 ± 7.94 years old, had a height of 172.28 ± 5.23 cm, and weighed 75.44 ± 12.67 kg. A significant difference was found between measured VO₂max (52.41 ± 8.61 ml/kg/min) and estimated VO₂max (49.33 ± 4.88 ml/kg/min) from the GPS sports watch. **CONCLUSIONS:** The GPS sports watch was not a valid estimate of VO₂max. Variability of HR could have potentially influenced the results from the GPS watch.

Effect of Plyometrics and Whole Body Vibration on Vertical Jump Height: A Meta-analysis
 Lucía Marín-Guillén, Alejandro Salicetti-Fonseca. *University of Costa Rica, San José, Costa Rica.*
 Email: lucia.maringuillen@yahoo.com
 (No relationships reported)

PURPOSE: the purpose of the study was to analyze the effect of plyometric and whole body vibration training methods on vertical jump height in athletes. **METHODS:** A meta-analysis was performed where the inclusion criteria for the studies were: (a) only athletic population, (b) active control group, (c) only one experimental intervention, (d) statistical data necessary to calculate effect sizes (ES). Hedge's standardized mean difference ES was calculated for each result; then, ESs pooled using random-effects models. On-overlapping 95% confidence intervals (CI_{95%}) were considered statistically significant. Heterogeneity was assessed using Q and I², while funnel plots and Egger's regression test were used to assess small-study effects (potential bias). **RESULTS:** One hundred and fifteen effect sizes were calculated from 36 studies. Global effect sizes (ES) were statistically different from zero in both training methods. Plyometric training had an ES = 1.046 (CI_{95%} = 0.82 to 1.27, p < 0.001) and the control group an ES = 0.032 (CI_{95%} = -0.12 to 0.18, p = 0.73). The ES for the experimental group in the whole body vibration training method was 0.652 (CI_{95%} = 0.3 to 1.0, p = 0.001) and the control group an ES = 0.038 (CI_{95%} = 0.3 to 1.0, p = 0.75). ESs were correlated to age (r = 0.454, p = 0.002), number of weeks of training (r = 0.309, p = 0.039), final number of sessions per week (r = 0.348, p = 0.019), final duration of sessions (r = 0.619, p = 0.014), initial series of exercises (r = 0.572, p = < 0.00), final series of exercises (r = 0.601, p = < 0.00) and initial number of jumps per session (r = 0.633, p = 0.027) in the plyometric experimental method. No significant associations between ESs and moderator variables were observed in the whole body vibration method. **CONCLUSIONS:** The overall results showed a statistically significant improvement on the vertical jump height of athletes when plyometrics or whole body vibration were used as training methods.

2235 Board #248 June 1 2:00 PM - 3:30 PM
Relationships Between Assessments Of Athletic Ability In NAIA Athletes
 Andy P. Bennett, Kaitlyn L. Kelpe, Christopher A. Fahs, Lindy M. Rossow. *Lindenwood University - Belleville, Belleville, IL.*
 Email: apb708@lionmail.lindenwood.edu
 (No relationships reported)

PURPOSE: To examine the relationships between flexibility, body composition, and several field methods indicative of athletic ability in a population of National Association of Intercollegiate Athletics (NAIA) athletes. **METHODS:** Shoulder flexion (SF), hip flexion (HF), and ankle plantar flexion (APF) were assessed by goniometry. %BF and FFM were assessed using BodPod. Athletic ability was assessed by the Illinois Agility Test (IAT), Queens College Step Test (QCST), vertical jump (VJ), isometric handgrip (IH), and a push-up muscular endurance test (PU). Subjects (n = 18) included both sexes across a variety of sports. Relationships between range of motion at each site, %BF, FFM, and all indicators of athletic ability were examined using Spearman's correlation coefficients. For relationships involving IAT and QCST, only 10 subjects are reported as the others did not complete this assessment. **RESULTS:** Relationships between variables are presented in Table 1. Means and standard deviations for each variable were as follows: SF (191 ± 22°), HF (77 ± 11°), APF (37 ± 13°), FFM (73 + 8 kg), %BF (16.8 ± 6.6 %), VJ (66 ± 10 cm), IH (45 + 6 kg), PU (41 ± 19 PU/min), QCST (55 + 14 steps), IAT (17.4 ± 1.2 s).

	SF	HF	APF	FFM	%BF	VJ	IH	PU	QCST	IAT
SF	1	.34	.15	.65 p=.003	.41	-.06	-.23	.05	.20	.41

Low Correlation Between Bench Press One-Repetition Maximum and Angle Specific Isometric Bench Press
 Cameron N. Munger, David C. Archer, RoQue A. Harmon, Kylie K. Harmon, Derek N. Pamukoff, Jared W. Coburn, FACSM, Lee E. Brown, FACSM. *California State University, Fullerton, Fullerton, CA.*
 (No relationships reported)

Administration of bench press 1-repetition maximum (1RM) tests can be time consuming, require trained personnel, and are risky for beginners. Therefore, alternative testing procedures for upper body push strength should be considered. **PURPOSE:** To quantify strength and determine the relationship between dynamic bench press 1RM and angle specific isometric bench press. **METHODS:** Twelve recreationally trained males (age=24.83±2.89yrs, height=172.33±6.6cm, mass=83.18±8.53kg), capable of bench pressing a minimum of 1.25x their bodyweight, volunteered to participate. On day 1, subjects performed a bench press warm-up and had 5 attempts to reach their 1RM using a self-selected grip that remained the same for the entire study. On day 2, subjects performed an isometric bench press warm-up, then completed 2 max effort repetitions at 4 different angles of elbow flexion (60, 90, 120, and 150 degrees) and at 50% of their arm length in randomized order. **RESULTS:** Pearson correlations were very low and not-significant (P>0.05) between dynamic bench press 1RM (115.43±12.68kg) and isometric bench press at all angles (60°=56.60±9.72kg, r = -.04; 90°=65.25±9.77kg, r = -.26; 120°=110.39±20.79kg, r = -.11; 150°=121.46±29.83kg, r = -.24; 50% arm length=57.72±8.09kg, r = -.25). **CONCLUSIONS:** Traditionally, dynamic movements are the focus of strength testing. The 1RM bench press is dynamic while the isometric bench press produces no movement. Thus, muscular length-tension or force-velocity differences between modes may explain the low relationships. Therefore, isometric bench press may not be a proper substitute for a 1RM bench press test.

Prediction Of Lactate Threshold By Physiological Variables Utilizing Human Motion During Exercise
 Govindasamy Balasekaran, FACSM¹, Yoon Yong Jin¹, Tan Wei Tyng¹, Men Hong Yip¹, Visvasuresh Victor Govindaswamy².
¹Nanyang Technological University, Singapore, Singapore.
²Concordia University Chicago, Chicago, IL.
 Email: govindasamy.b@nie.edu.sg
 (No relationships reported)

Running at Lactate threshold (LT) for training is a frequent training method used by healthy and elite athletes. However, LT determination is usually done in the laboratory with an invasive method. **PURPOSE:** To predict LT by physiological variables utilizing human motion during exercise. **METHODS:** 12 male athletes (Age: 23.6±1.8years, Percentage (%) body fat: 12.4±3.3%, height: 173.4±4.7cm, weight: 68.2±5.8kg, bone mineral content: 2738.6±252g and lean mass: 56233.7±4751.4g) completed an incremental discontinuous submaximal to exhaustion protocol on the treadmill. VO₂ ml*kg⁻¹*min⁻¹ was determined at every stage and VO₂max ml*kg⁻¹*min⁻¹ was determined at volitional exhaustion. Human motion, blood lactate, heart rate (HR), VO₂ and Rate of Perceived Exertion (RPE) were constantly measured. **RESULTS:** Among the 32 human motions, 8 human motions (4 on left leg and 4 on right leg) demonstrated strong relationship (correlation r > 0.700) to human bioenergetics during running. The range of human motion on left leg (10% - 70%) significantly varies than right leg (5% - 15%) due the right leg being dominant. Two human motions had the highest correlation with human bioenergetics 1) the angle between left (thigh & leg) phase 1 and 2) (r = 0.908) and angle between right (thigh & leg) phase 3 (r = 0.858). The equations derived with human motions (A) VO₂ = (VO₂ - 7.56)±10.83ml*kg⁻¹*min⁻¹ and (B) VO₂ = (VO₂-15.81)±15.76ml*kg⁻¹*min⁻¹ can be used to predict the VO₂ at LT if VO₂max is known. **CONCLUSIONS:** Results indicated that human motions have significant relationship with HR, VO₂, and blood lactate during running at submaximal intensities. The human motion derived equation can predict VO₂ at LT if VO₂ at exhaustion is known without using an invasive method.

Comparison of Prediction Models for Cardiorespiratory Fitness from Maximal Anaerobic Capacity in Young Adults
 Elizabeth A. Tanner, James W. Navalta, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.*
 (No relationships reported)

The superior method of cardiorespiratory fitness assessment is often considered an incremental treadmill VO₂max protocol. During these protocols energy production pathways switch from primarily aerobic to anaerobic by the point of VO₂max

attainment. Similarly, the Wingate cycle test is a commonly accepted method of anaerobic capacity assessment which stresses anaerobic energy pathways. Based on the energy systems utilized at the point of $\dot{V}O_{2\max}$ attainment and during a Wingate protocol it has been shown that peak power obtained from a Wingate cycle test is a good predictor of $\dot{V}O_{2\max}$. However, it is unclear whether a non-consecutive testing day protocol produces a more accurate predictive model compared to a same day testing protocol. **PURPOSE:** to develop and compare the predictive accuracy of the regression model for a non-consecutive day testing protocol and a same day testing protocol. **METHODS:** Participants (N=23) completed an incremental treadmill $\dot{V}O_{2\max}$ protocol and 30 second Wingate cycle test. Participants (n=12) completed testing on non-consecutive days (NON) and participants (n=11) completed testing on the same day (SAME). $\dot{V}O_{2\max}$ (L/min) and peak power (PP) were collected. All data were analyzed using simple linear regression. **RESULTS:** Linear regression analysis of NON revealed $R^2=0.808$ and prediction equation $\hat{Y}=1.499+0.004X$ and SAME showed $R^2=0.861$ and prediction equation $\hat{Y}=1.407+0.003X$. NON and SAME standard error of estimate percent (SEE %) were 15.23% and 10.98% respectively. **CONCLUSION:** These results indicate PP obtained the same day of $\dot{V}O_{2\max}$ testing is a better predictor of cardiorespiratory fitness. SEE % also shows the predictive accuracy of the SAME prediction equation is superior to the NON prediction equation. This may be due to the diminished effect of potential training adaptations that could occur 2-7 days between testing sessions during the NON testing protocol in healthy, active young adults.

2239 Board #252 June 1 2:00 PM - 3:30 PM
The Development Of A Metabolic Equation To Estimate Caloric Consumption On A Non-motorized Sport-performance Treadmill

Silvano Zanuso¹, Giuseppe Fedele², Simonetta Senni², Francesco Cuzzolin³, Ethan Esser Horsham², Paolo Benvenuti⁴. ¹University of Greenwich, Gillingham, United Kingdom. ²Technogym, Cesena, Italy. ³University of Padova, Padova, Italy. ⁴University of Verona, Verona, Italy.
 Email: szanuso@gmail.com

Reported Relationships: S. Zanuso: Honoraria; Receive honoraria from Technogym.

PURPOSE: To create a Metabolic Equation (ME) predicting caloric consumption in walking and running speeds on a new non-motorized treadmill, named as the 'Skillmill' (SK). On the SK the running surface is moved mechanically by the user, specifically designed to develop sports performance qualities.

METHODS. A group of 27 healthy individuals (18 male and 9 female; age 35.8 ± 9.3; BW 76.2 ± 19.1) were enrolled in the study. All subjects executed two familiarization sessions with the SK, one dedicated to walking and another to running. Each subject performed two trials, trial one required the subjects to walk at 4 and 6 km/h and trial two required the subjects to run at 8, 10 and 12 km/h. Each speed consisted of an 8 minute duration in order to obtain a steady state condition. The rest between speeds and trials consisted of 5 minutes. Oxygen consumption was continuously monitored with a metabolic cart (Cosmed Quark b², Rome, Italy). $\dot{V}O_2$ consumption was then measured when the subject achieved a steady state of metabolic intensity. Overall, 135 steady state points were collected.

RESULTS. The steady state $\dot{V}O_2$ ranged from 13.32 to 31.09 ml.kg⁻¹.min⁻¹ when walking and from 31.27 to 47.67 ml.kg⁻¹.min⁻¹ when running. To estimate the $\dot{V}O_2$ consumption expressed in ml.kg⁻¹.min⁻¹ related to a given speed, both Speed (S) in km/h and Body Weight (BW) in kg were considered. The equation that better predicts actual $\dot{V}O_2$ consumption is $p_{00}+p_{10} *BW+p_{01} *S+p_{20} *(BW^2)+p_{11} *BW*S$.

The different coefficients of this polynomial equation of the 2nd degree relative to BW are: $p_{00}= 16.42$; $p_{10}= -0.3036$; $p_{01}= 4.547$; $p_{20}= 0.001826$; $p_{11}= -0.01816$ with a Root Mean Squared Error of 1.751 when (S) is lower than 8 km/h.

$p_{00}= 0.808$; $p_{10}= 0.248$; $p_{01}= 4.21$; $p_{20}= -0.002509$; $p_{11}= -0.004976$ with a Root Mean Squared Error of 2.081 when (S) is equal to or higher than 8 km/h. The correlations between the values predicted by this equation and the $\dot{V}O_2$ measured with the metabolic cart are $r^2=0.83$ when (S) is lower than 8 km/h and $r^2=0.84$ when (S) is equal to or higher than 8 km/h.

CONCLUSIONS. The present Metabolic Equation that predicts oxygen consumption and caloric expenditure from the subject's speed and body weight, provides a good estimate of the actual values.

Allometric Scaling for Endurance Variables in Croatian Army

Cvita Gregov. Faculty of Kinesiology, University of Zagreb, Zagreb, Croatia.

Email: cvita.gregov@kif.hr

(No relationships reported)

Body mass bias is widely spread among physical performance testing and may confound the results often leading to misinterpretation. Endurance testing is a part of

physical performance testing in the army and is generally assessed by running distance time. Two such tests, 2-mile run (2MR) and 300 yards run (300YR), are used to assess soldiers' endurance. Also, incremental $\dot{V}O_{2\max}$ treadmill test is used as a measure of aerobic capacity. If expressed as a relative value (ratio of $\dot{V}O_{2\max}$ and body mass) or $R\dot{V}O_{2\max}$ it is a good predictor of endurance or long distance running time. Considering that longer distances running time and $R\dot{V}O_{2\max}$ are measures dependent of body mass, it is important to determine how to allow comparisons between subjects independent of their body mass. One practical solution is to determine body mass allometric exponent for distance running time. **PURPOSE:** To determine experimental body mass allometric exponent (eAE) for endurance variables and if it corresponds to proposed theoretical body mass allometric exponent (tAE) which equals 0.33. **METHODS:** 572 healthy male army recruits (mean age 29.4y) underwent endurance assessment comprised of a standard endurance testing battery in Croatian Army: 2-mile run (2MR), 300-yards run (300YR) and incremental $\dot{V}O_{2\max}$ treadmill test. Their body mass (BM) was also measured. Relative maximal oxygen uptake ($R\dot{V}O_{2\max}$) was taken as a measure of endurance since it is a better predictor of long distance running time. A regression technique was applied on the log-transformed data in order to determine the values of the allometric exponent for each particular test. One sample t-test was used to determine statistical differences between average eAE and tAE. **RESULTS:** Regression analysis yielded BM allometric exponents for 2MR, eAE=0.33 (95%CI=0.23 - 0.43); $R\dot{V}O_{2\max}$, eAE=-0.47 (95%CI= -0.55 - (-0.38)); 300YR, eAE=0.22 (95%CI=0.15 - 0.28). Mean eAE=0.34 and compared with tAE=0.33 was not significantly different ($p>0.05$) when tested by one sample t-test. **CONCLUSION:** The results indicate that experimentally derived mean AE for endurance variables correspond to theoretical one and as such should be used for scaling endurance variables and comparing results of endurance tests recorded as running times. Supported by Grant of Ministry of Defence of the Republic of Croatia

Self reported Performance Measures Of Males Are Predictive Of Overall Performance In The Crossfit Open

Oladeji S. Olowojesiku, Paul Serafini, Gerald Mangine, Yuri Feito, FACSM. Kennesaw State University, Kennesaw, GA.

(Sponsor: Yuri Feito, FACSM)

(No relationships reported)

PURPOSE: To determine if measures of strength and skill, obtained from online athlete profiles, could distinguish overall performance in an international online fitness competition (OFC). **METHODS:** The highest ranking male competitors (n = 1500; 27.18 ± 8.4 y; 85.2 ± 7.88 kg; 177.01 ± 6.47 cm) were split into quintile groups (Q1 - Q5). Subsequently, quintile comparisons were made using self-reported performances for a one-repetition maximum (1RM), squat (SQ), deadlift (DL), clean and jerk (CJ), snatch (SN), 400-m sprint, 5,000-m run, and benchmark workouts (Fran, Helen, Grace, Filthy 50, and Flight-gone-bad) via separate one-way analysis of variance. **RESULTS:** Greater ($p < 0.011$) performance scores were reported by Q1 for DL (232.4 ± 20.5 kg), SQ (201.6 ± 19.1 kg), CJ (148.9 ± 12.1 kg), SN (119.4 ± 10.9 kg) and Fran (2.3 ± 0.2 min) compared to all other quintiles. For Grace, Q1 (1.7 ± 0.4 min) reported faster ($p < 0.001$) completion times than Q3 - Q5, while their performances in the 400-m sprint (59.3 ± 5.9 sec), Helen (7.6 ± 0.6 min) and Flight-gone-bad (430 ± 70 repetitions) were only better than Q3 (62.6 ± 7.3 sec, $p = 0.022$), Q4 (7.9 ± 0.7 min, $p = 0.007$) and Q5 (398 ± 73 repetitions, $p = 0.010$) respectively. No specific quintile differences were observed in 5,000-m or Filthy-50 performance. **CONCLUSION:** The data indicates that the most successful male athletes in this OFC possessed the greatest strength and power. Further, these athletes performed the best in a short-duration (< 3 min) sports-specific workout (i.e., Fran) that emphasized these characteristics. Lower ranking athletes should focus on emphasizing strength and power development once sufficient anaerobic, aerobic, and sports-specific proficiency has been attained.

2242 Board #255 June 1 2:00 PM - 3:30 PM
Increases in Maximum Oxygen Consumption and Lactate Threshold Predict Improvements in Race Performance during a Cross Country Season

Kaitlyn Arnold, Payton Hirschenburger, Brooke VandePolder, Jeff Schlicker, John E. Davis. Alma College, Alma, MI.

Email: arnold1ke@alma.edu

(No relationships reported)

To our knowledge, the relationship between many physiological adaptations due to in-season training and their impact on racing performance remains unclear.

PURPOSE: To investigate multiple physiological variables that contribute to the greatest improvements in 6,000m cross country race performance. **METHODS:** Nine female collegiate cross country athletes (1.8±0.1m, 59.6±3.9kg) were evaluated twice during their competitive cross country season: pre-season (T1) and mid-season (T2). Subjects completed a graded exercise test to volitional fatigue on a motor driven treadmill. Oxygen consumption was measured by a Parvo TruOne 2400 Metabolic cart. Near-infrared spectroscopy (Portamon, Artinis Inc.) of the vastus lateralis was used to measure tissue saturation index (TSI) for each stage of the graded exercise

test. In this study, the slope of the decline in TSI was determined and used to quantify the muscle oxygenation response. Blood lactate was analyzed at each workload by a handheld lactate analyzer (Nova Biomedical) to determine the inflection point of lactate accumulation. Efficiency was determined from work output and energy input during running. Changes in these variables along with standardized race performance times were analyzed. **RESULTS:** $\text{VO}_{2\text{max}}$ significantly increased ($p < 0.05$) from T1 to T2 (51.6 ± 3.2 ml/kg/min to 56.6 ± 4.3 ml/kg/min) indicating an average gain of 4.9 ± 3.9 ml/kg/min or 9.7%. The slope of the TSI became more positive from T1 ($-14.8 \times 10^{-3} + 6 \times 10^{-3}$) to T2 ($-7.9 \times 10^{-3} + 7 \times 10^{-3}$), indicating less of a decline in muscle deoxygenation. The LT increased by one workload in four of the nine subjects. The subjects who experienced an increase in LT also experienced an increase in racing performance. Lastly, running efficiency did not significantly change between T1 and T2. **CONCLUSIONS:** On average, $\text{VO}_{2\text{max}}$, LT, and muscle oxygenation improved from pre- to mid-season. The greatest gains in $\text{VO}_{2\text{max}}$ and in LT from pre-season to mid-season correlated to the greatest improvements in racing performance. About 40% of the variance in race performance can be explained by the changes in $\text{VO}_{2\text{max}}$ whereas improvements in LT explained 32% of the variance in racing performance. These data suggest that improvements in $\text{VO}_{2\text{max}}$ are most important in predicting race performance in collegiate cross country runners.

2243 Board #256 June 1 2:00 PM - 3:30 PM
Comparison of Training Impulse and Training Load Estimation Among Soccer Players Using the Edwards Equation and Polar Team2 System

Jason Melnyk, Kimberly Kostelis. *Central Connecticut State University, New Britain, CT.* (Sponsor: Sean Walsh, FACSM)
 Email: jmelnyk@ccsu.edu
 (No relationships reported)

Heart rate (HR) based methods are commonly used to monitor training stress and are referred to as training load (TL) or training impulse (TRIMP). Edwards TRIMP equation is based on time spent in HR training zones above 50% HR_{max} , whereas Polar's TL is measured via their Team2 system using a proprietary equation that incorporates anthropometrics and maximal oxygen consumption ($\text{VO}_{2\text{max}}$) combined with time spent in HR training zones. **PURPOSE:** To examine if TL estimates from proprietary Team2 software correlate with Edwards TRIMP in order to assess the training readiness of athletes. Secondly, the Beep test assessed fitness levels both pre and post-season to determine if training adjustments based on TL influenced post-season fitness. **METHODS:** Twenty-eight male Division III soccer athletes (19.8 ± 1.8 yrs) had their heart rates continuously monitored during the fall 2014 season, as well as pre and post-season testing using the Beep test to estimate $\text{VO}_{2\text{max}}$. In instances where TL was >300 per match, athletes had reduced intensity during practice sessions to aid in improved recovery. Data recorded included time spent in each of five heart rate zones, ranging from 50% to 100% HR_{max} , in 10% increments. **RESULTS:** When comparing Edwards TRIMP and TL, significant correlation coefficients were found for the first half, second half, and both halves combined ($r=0.992$, $r=0.972$, and $r=0.936$, $p < 0.01$). Although TRIMP and TL had high variability due to individual players playing for different time periods, mean TRIMP (190.9 ± 102.1) and TL (219.5 ± 92.4) for the season were similar. Estimated $\text{VO}_{2\text{max}}$ scores were not significantly different pre to post-season (52.0 ± 4.84 vs. 53.7 ± 3.14 ml·kg⁻¹·min⁻¹, $t=-1.794$, $p > 0.05$). **CONCLUSIONS:** Estimating TRIMP using the Edwards equation is a valid option for coaches to gauge training readiness. TRIMP may be used if TL is unavailable to determine athlete readiness. Subsequent training sessions may be modified based on the amount of TL/TRIMP undergone in order to maintain fitness levels of athletes throughout the season.

Predictor Variables for Success in Collegiate Wrestling

Paul D. House, Shea Ware. *University of Central Oklahoma, Edmond, OK.*
 (No relationships reported)

Upper body strength has been found to be greater in more successful wrestlers compared to their less successful counterparts. Additionally, elite high school wrestlers have shown a lower percent body fat (skinfold), and greater upper and lower body anaerobic power (Wingate tests) compared to non-elite wrestlers. **Purpose:** To determine if there are certain additional attributes that can predict success in wrestling. **Methods:** The study consisted of 6 NCAA division II collegiate level male wrestlers. Their ages ranged from 18-25 years. The following served as independent variables: Wingate arm cranking test, wrestling shot velocity, percent change in body weight, vertical jump height, and grip strength of the non-dominant hand. The dependent variable was percent wins during the wrestling season. A multiple regression with a stepwise progression was the statistical technique used to analyze the data. Significance was set at $p=0.05$. **Results:** The model summary only included one independent variable, percent change in body weight. Thus the model summary was: $r=0.838$, $r^2=0.702$, adjusted $r^2=0.627$, Beta=1.507, with $F=9.402$, and $p=0.037$. Therefore, based on this study, 70.2% of the percent wins in wrestling was accounted

for by increases in body weight throughout the season. The regression equation for predictive success is: $\hat{y}=62.148 + 1.507 \times \text{kg}$. Although not significant, the next most influential independent variable was shot velocity with $r=0.649$ and $p=0.148$. **Conclusion:** The results of our study indicate that for every 1 kg increase in body weight, there is an accompanied 1.507 increase in percent wins. The authors assume this profitable increase in body weight would be in the form of lean muscle mass, hydration levels, and possibly glycogen stores. Perhaps there would have been more significant predictors had there been more than 6 participants. Furthermore, only two of the wrestlers qualified for the NCAA national championships. Additionally, none of the wrestlers placed at the NCAA national championships. Therefore, the lack of success in our sample of wrestlers could have influenced the outcome.

2245 Board #258 June 1 2:00 PM - 3:30 PM
Validity of Commercial Electrical Impedance Myography as a Predictor of Grip Strength

Brian W. Ivy. *Bay Path University, East Longmeadow, MA.*
 (No relationships reported)

PURPOSE: Electrical impedance myography has gained recognition throughout the literature as an effective assessment of neuromuscular disorders. However, evidence regarding the efficacy of commercial electrical impedance myography (cEIM) devices is limited. Therefore, there were two aims of this independent research. First, the author aimed to assess the validity of a cEIM device as a predictor of grip strength. The second aim was to determine whether the number presented by the cEIM device was a direct representation of grip strength force produced. **METHODS:** Muscle quality and grip strength were measured in 17 female subjects ($M_{\text{age}} = 20$ years, $SD = 1.5$) via cEIM and a Jamar hand dynamometer, respectively. The cEIM device was placed on the volar surface of the dominant forearm midway between the medial epicondyle of the humerus and ulnar styloid on each participant. Grip strength measurements were then taken in accordance with recommendations from the American Society of Hand Therapists. True scores were documented as the results for each assessment before grouped into normative categories. The true scores for each assessment were compared using the Wilcoxon signed ranks test. The results were then categorized into either *normal* or *abnormal* according to their respective normative data. Spearman's ranked correlation (r_s) was utilized to assess the relationship between the true scores and the two categorical groupings of normal and abnormal. Statistical significance was accepted at $p < 0.05$.

RESULTS: The average grip strength score of all participants was 30.82 kilograms ($SEM = 1.20$, 95% CI [28, 33]). Muscle quality scores averaged 41.29 ($SEM = 3.70$, 95% CI [33, 49]). A strong correlation was observed between the categorical groupings of each assessment ($r_s = 0.618$, $p = 0.008$). No significant relationship was observed between the true scores of the cEIM device and grip strength ($r_s = 0.23$, $p = 0.38$). The true scores were observed as significantly different from each other (Wilcoxon test, $p = 0.015$).

CONCLUSIONS: Although the commercial electrical impedance myography device did not provide a direct representation of grip strength force produced, the device was effective at predicting normal versus abnormal grip strength.

2246 Board #259 June 1 2:00 PM - 3:30 PM
Relationship Between Physiological/Anthropometric Profiles and Future NHL Status Among Division I Collegiate Ice Hockey Players

Ashley N. Triplett, David P. Carrier, James M. Pivarnik, FACSM. *Michigan State University, East Lansing, MI.*
 Email: triple18@msu.edu
 (No relationships reported)

Measurement of physiologic and anthropometric variables can be conducted to assess training progress and to estimate an athlete's potential to perform at an elite level. However, the use of such measures for predicting ice hockey performance at the professional level has resulted in equivocal findings and to our knowledge, has not been assessed in collegiate ice hockey players. **PURPOSE:** The purpose of this study was to determine if the results of a discontinuous graded exercise test and selected anthropometric measures could predict a collegiate ice hockey player's likelihood of playing professionally in the NHL.

METHODS: Physiologic and anthropometric player profiles were obtained through yearly preseason fitness testing of a NCAA Division I men's ice hockey team from 1980 through 2015. Players participated in a discontinuous treadmill graded exercise test to volitional exhaustion, consisting of 3 min run stages and 90 sec rest stages. Aerobic capacity was measured (indirect calorimetry) and total test time (including treadmill stage completed) was recorded. Height, weight, and % fat were also measured for each athlete. Athletes who later played at least one game in the NHL ($n=55$) were compared to non-NHL athletes ($n=190$) to determine if any outcome variables of interest predicted their NHL status. Binary logistic regression was performed, and Odds Ratios (OR) and 95% Confidence Intervals (CI) were calculated for each variable. **RESULTS:** Average values for variables of interest were similar in future NHL vs non-NHL players across 36 years: height (182.0 ± 4.9 vs 181.5 ± 6.1 cm), weight

(83.8±5.3 vs 83.6±7.2 kg), body fat (11.2±2.9 vs 12.5±3.1 %), BMI (25.3±1.5 vs 25.3±1.6 kg/m²), VO₂max (59.0±4.1 vs 58.0±4.0 ml/kg/min), completing treadmill stage 5 (45% vs 40%), and year of last college season (1994 vs 1998). Entering all variables into the logistic model showed that the only significant predictors of achieving NHL status were %fat and playing year (OR=1.19; CI=1.06, 1.33). **CONCLUSIONS:** According to our findings, players with the lowest %fat values and earlier careers were 19% more likely to play in the NHL. These NCAA Division I players' physiologic profiles and overall size are very similar; therefore, NHL success may be more influenced by other factors such as player skill, other fitness variables, and mental focus.

The Relationship between Hamstring/Quadriceps Strength and Field Test Measures in Collegiate Track Athletes

Mary L. Williams, Matthew C. Wagner, Patrick R. Davis, Devin Anderson, Kendall Mehlhorn. *Sam Houston State University, Huntsville, TX.*

Email: mlw049@shsu.edu

(No relationships reported)

Hamstring strain injuries are one of the most common sports injuries, especially in sprinting sports (Liu, Garrett, Moorman, & Yu, 2012). Hamstring strength imbalance quantified via hamstring strength asymmetry or by a hamstring to quadriceps ratio is a commonly proposed risk factor for hamstring strains (Liu, et. al., 2012; Freckleton & Pizzari, 2012). Knowledge concerning the relationship among hamstring to quadriceps isokinetic ratios, speed, and power in sprinting athletes can assist in the development of training protocols and injury prevention strategies. **PURPOSE:** The purpose of this study was to identify the relationship between hamstring/quadriceps (H:Q) isokinetic strength ratios and its correlation with lower extremity power and speed field test measures. **METHODS:** Participants for this study included 10 NCAA Division I Track Athletes who compete in sprinting events. Peak torque (PT) was determined using an isokinetic dynamometer at speeds of 60 and 180 degrees per second in both hamstrings and quadriceps. Power was measured using the standing broad jump test and vertical jump test. Speed was assessed using light gates to measure sprint speed at 5, 10, 20, and 40 meter increments. A correlational approach was used to identify relationship between isokinetic measures with measures of lower extremity power and speed. **RESULTS:** Significant correlations ($p<0.05$) were found between peak torque (PT) values and most field tests (vertical jump, standing broad jump, and 40 meter sprint speed). However, there was no significant correlation ($p<0.05$) between H:Q ratios and field test measures (vertical jump, standing broad jump, and 40 meter sprint speed). **CONCLUSIONS:** The results of this study confirm that PT values correlate highly with field test measures used to assess power and speed. Unexpected findings include the lack of significant correlation between H:Q ratios and field test measures. Therefore, future research should focus on examining adjusted H:Q ratio values using body weight and lean mass of participants. Answering these questions could assist sport performance professionals in program development, and sports medicine personnel with injury prevention interventions.

VO₂ Off-Kinetics Following Exhaustive Upper Body Exercise Test in Spinal Cord Injury

Donal Murray¹, Rachel E. Cowan², Suzanne L. Groah³, Inger H. Liungberg³, Amanda K. Rounds³, Andrew A. Guccione¹, Randall E. Keyser, FACSM¹. ¹George Mason University, Fairfax, VA. ²University of Miami, Miami, FL. ³Medstar National Rehabilitation Hospital, Washington, DC.

(No relationships reported)

Introduction: People with spinal cord injury (SCI) present with impaired autonomic control when the lesion is above T6. This could lead to impaired recovery following vigorous physical activity. **Purpose:** To compare VO₂ off-kinetics following a maximal cardiopulmonary exercise test (CPET) in SCI and un-injured healthy individuals. **Methods:** Subjects were 13 patients with SCI who reported inability to voluntarily lift legs against gravity (age: 39.1 ± 10.9 years, paraplegic: 11, tetraplegia: 2, incomplete injury: 4) and 10 healthy controls (CON group; age: 30.5 ± 5.3 years). All subjects performed an arm ergometer cardiopulmonary exercise test (CPET) to volitional exhaustion followed by a 10-minute passive recovery. VO₂ off-kinetics

was determined using a mono-exponential model in which a time constant (τ_{off}) was calculated and amplitude of change in VO₂ (AMP) was measured over the recovery period. Student's t-tests were used to compare SCI vs CON group means and Pearson product moment correlation coefficients were used to assess the relationships amongst VO_{2peak} and the VO₂ off-kinetic variables. **Results:** CON had a significantly higher VO_{2peak} compared to SCI (22.41 ± 5 vs. 14.64 ± 6.36 ml/kg/min, $p=0.005$). Compared to CON, SCI had significantly longer τ_{off} (83.4 ± 34.7 vs. 54.7 ± 10.2 seconds, $p=0.021$). A significant difference in AMP was not seen between the subjects with SCI and CON (0.85 ± 0.57 vs. 1.31 ± 0.48 L/min, $p=0.054$) however the ratio of AMP/ τ_{off} was significantly smaller in the group with SCI than in CON (0.0126 ± 0.0108 vs. 0.0243 ± 0.008 L/min/sec, $p=0.011$). VO_{2peak} and τ_{off} were inversely related ($r=-0.524$, $p=0.01$). **Conclusions:** Potentially explained by the time taken to replenish muscle ATP stores and lactate clearance, VO₂ off-kinetics is one measure of cardiorespiratory fitness. Despite an observable decline in AMP, the prolonged VO₂ off-kinetics suggested that cardiorespiratory fitness was impaired in these subjects with SCI. Funding: DoD Award #W81XWH-14-1-0613

The Effect Of Low Intensity Eccentric Exercise On Torque angle Relationship, Muscle Strength And Flexibility

Satoru Nishida¹, Tsubasa Tomoto², Kiyoshi Maehara¹, Syumpei Miyakawa¹. ¹University of Tsukuba, Tsukuba, Japan. ²National Institute of Advance Industrial Science, Tsukuba, Japan.
Email: baros5521@yahoo.co.jp

(No relationships reported)

PURPOSE: The angle of peak torque (APT) with shorter muscle length tends to have high probability of muscle strain injury. It is conceivable that APT with longer muscle length might be desirable condition of injury prevention. Although high intensity eccentric exercise (Ecc-Ex) which transiently shift the APT to longer muscle length associated with weaken muscle strength and decrease flexibility is well known, the acute effect of low intensity Ecc-Ex is unclear. The purpose of this study was to investigate the effect of low intensity Ecc-Ex on APT, muscle strength and flexibility. **METHODS:** Thirteen healthy male college students (24.5±2.4 yrs., 68.5±5.9 kg) performed Romanian deadlift (RDL) without weight as a low intensity hamstring Ecc-Ex. Before and after RDL, muscle strength and APT during maximum eccentric knee flexion (60deg/s) and flexibility were measured on both legs. After the experiment, each leg were divided into two groups based on the change in APT after RDL: the group with increase in APT (16 legs) and decrease in APT (10 legs) after RDL. Variables of interest were compared before and after RDL. **RESULTS:** After RDL, muscle flexibility defined by range of motion in straight leg raise test increased significantly in both groups. The group with increase in APT, peak torque and power significantly decreased (141.3±37.8 vs. 127.9±26.4 %BW, 106.3±22.8 vs. 89.3±14.4 %BW/deg, $p<0.05$, respectively) and muscle stiffness increased significantly (0.85±0.22 vs. 0.89±0.22 Nm/deg, $p<0.05$). In contrast, the group with decrease in APT, there was no significant change in peak torque, power and muscle stiffness. **CONCLUSIONS:** These results suggest that the low intensity Ecc-Ex induced APT decrease has no harmful impact on the muscle strength and flexibility. Thus, low intensity Ecc-Ex might be a useful method of muscle strain injury prevention.

(No relationships reported)

Low-load resistance exercise rehabilitation combined with blood flow restriction (BFR) has been suggested as an effective and safe alternative way to improve muscle strength and size compared to traditional high-load resistance exercise in clinical populations. However, there are few studies conducted to investigate the effect of low-load resistance exercise rehabilitation with BFR following total knee replacement. **PURPOSE:** To compare the result of rehabilitation with or without BFR on muscle function in the patients who were treated with total knee replacement surgery. **METHODS:** Twenty-one participants were randomized into two different interventions: low-load resistance exercise rehabilitation with BFR (BFR group, n=11) and without BFR (control group, n=10). Exercise sessions were performed 6 times per week, 30 minutes per session, for 2 weeks in all participants. Over the twelve exercise sessions in BFR group, an elastic cuff was worn on the subject's proximal thigh in its intensity being progressively increased from 160 mmHg at the first session

up to 240 mmHg at the end by adjusting the external compression. For the analysis, muscle strength, rate of torque development (RTD), range of motion (ROM), muscle mass, thigh circumference, the Timed Up and Go test, 10-m walking test and single-limb stance were measured. All outcome measures were assessed before and after the intervention.

RESULTS: In knee extensor strength, the degree of change in the BFR group was significantly larger than that in the control group (0.33 ± 0.21 vs. 0.11 ± 0.11 Nm/kg, $p < 0.05$). In knee extensor RTD, although there was no statistical difference between the two groups, it was nearly significant ($p = .051$). However, we found no significant results between groups in other outcome variables.

CONCLUSIONS: Low-load resistance exercise rehabilitation with BFR led to significant increases in knee extensor strength. Rehabilitation combined with BFR may be useful for the patients who are in need of fast recovery in muscle function following a total knee replacement surgery.

 (No relationships reported)

Electronic stimulation can be used to stimulate contraction of paralyzed muscle, and when coordinated via computer processing, lower body muscles can power a cycle ergometer in a manner which increases whole-body energy expenditure. **Purpose:** When matched for charge input determine if calorie (kcal) expenditure and fuel partitioning measured during and immediately following a bout of functional electrical stimulation (FES) cycling differed when performed on two FES devices. **Method:** Six males with spinal cord injury (SCI; age: 49 ± 17 yr; weight: 76 ± 6 kg; level of injury: C4-T11) completed 30 min of steady-state FES exercise on four separate occasions at a charge-matched moderate stimulation intensity. Two sessions were completed on a commercially available unit (RT300, Restorative Therapies, MD) and two on a device that is in pre-production testing (MyoCycle, MYOLYN, FL) that employs a different electrical control paradigm. Before, during, and after cycling, energy expenditure and fuel homeostasis were calculated via pulmonary gas exchange (Oxycon, Jeager, CA), and central hemodynamics (for the MyoCycle device only) via impedance cardiography (PhysioFlow, Manatec Biomedical, FR). **Results:** Rate of oxygen consumption ($\dot{V}O_2$) and cardiac output (CO) during FES were $34 \pm 20\%$ and $49 \pm 23\%$ of their respective $\dot{V}O_{2peak}$ and CO_{peak} achieved during maximal effort arm cycling. Both FES devices elicited similar rates of exercise energy expenditure (1.06 ± 0.20 kcal/min) and fuel homeostasis (74:26 %CHO:%FAT). However, only the MyoCycle showed a statistically significant increase in energy expenditure at 20-30 min post-exercise time point (11.2% increase vs pre-exercise, $p = .02$), with this increase in energy expenditure accompanied by a 54% increase in CHO oxidation during the first 30 min of exercise recovery. **Conclusion:** Moderate intensity FES cycling qualifies as "low intensity" aerobic exercise according to authoritative guidelines, although increases in carbohydrate oxidation during and after cycling might have a meaningful impact on daily glucose regulation. Furthermore, the energetics of the recovery period seem to be influenced by the electrical control system.

 (No relationships reported)

Insulin is a vasoactive hormone and second messenger of nitric oxide that facilitates endothelial-mediated dilatation of the microvasculature with assistance by the sympathetic nervous system (SNS). The sensitivity or resistance of endothelial-mediated mechanisms that regulate skin blood flow may play an integral role in optimizing skin perfusion in vascular beds where SNS vasomotor impairment is present. Spinal cord injury (SCI) is characterized by interruption of supraspinal SNS control of sublesional vasomotor tone. **Purpose:** To determine the effects of insulin resistance (IR) on sublesional cutaneous perfusion responses to insulin provocation in persons with SCI. **Methods:** A prospective, open-label, non-randomized, placebo-controlled investigation was performed in persons with SCI and an able-bodied (AB) cohort. These groups were subdivided based on fasting plasma insulin (FPI) concentration cut-

offs for IR (≥ 13.13 mIU/ml) or insulin sensitive (IS: < 13.13 mIU/ml) designations into four subgroups: ABIS (n=21); SCIS (n=21); ABIR (n=9); SCIR (n=11). Laser Doppler flowmetry characterized the peak blood perfusion unit (BPU) responses (percent change from baseline) to insulin or placebo iontophoresis in the lower extremities, and the corresponding BPU responses were \log_{10} transformed to facilitate comparisons. The NetIns BPU response was calculated (Insulin-Placebo BPU responses) to provide the effect of insulin to that of the acetylcholine-mediated BPU response.

Results: The groups were matched for demographics. By study design, FPI was different between the IS and IR subgroups. In ABIS, the BPU responses to insulin were significantly greater than placebo ($p < 0.05$ and $p < 0.0001$, respectively). In ABIR and SCIR, insulin did not produce a BPU response that differed from placebo. In SCIS, the insulin BPU response was greater than placebo ($p < 0.0001$). The NetIns response was significantly greater in both IS groups compared to their corresponding IR group.

Conclusions: Persons with SCI have sublesional microvascular endothelial dysfunction. The presence of IR has a further confounding effect on endothelial-mediated changes to cutaneous perfusion and appears to be an important modifiable risk factor for the optimization of cutaneous perfusion in the lower extremities of persons with SCI.

Within-Session Responses to High Intensity Interval Training in Spinal Cord Injury

Jackie M. Godinez, Elyse A. Palumbo, Jacob S. Thum, Todd A. Astorino. California State University San Marcos, San Marcos, CA.
 (No relationships reported)

High intensity interval training (HIIT) has shown to be a robust alternative to traditional aerobic training (Gillen et al. 2014, 2016; Astorino et al. 2011). In most individuals, incorporation of HIIT elicits increases in maximum oxygen uptake and overall health status, yet its feasibility in persons with spinal cord injury (SCI) is unknown. **PURPOSE:** The aim of this study was to compare acute changes in cardiorespiratory and metabolic variables during different HIIT regimens versus moderate intensity continuous exercise training (MICT). **METHODS:** Nine habitually active men and women (injury duration = 6.8 ± 6.2 yr) with SCI initially underwent determination of peak oxygen uptake (VO_{2peak}) on an arm ergometer. During subsequent sessions, they completed MICT, HIIT, or sprint interval training (SIT). MICT consisted of 25 min of arm cycling at 45 %Wpeak. HIIT consisted of eight 60 s bouts at 70 %Wpeak separated by 90 s of active recovery at 10 %Wpeak, while SIT required eight 30 s bouts at 105 %Wpeak separated by 120 s of active recovery at 10 %Wpeak. Gas exchange data, heart rate (HR), and blood lactate concentration were measured. Each session was broken up into 16 phases (eight exercise and eight recovery data points for HIIT/SIT) for which mean oxygen uptake and HR were determined. **RESULTS:** Peak VO_2 was higher ($p = 0.03$) in response to HIIT (1.13 ± 0.44 L/min at bout 8) and SIT (1.02 ± 0.37 L/min at bout 8) compared to MICT (0.90 ± 0.29 L/min), but mean VO_2 was similar ($p > 0.05$) between MICT (0.86 ± 0.17 L/min), HIIT (0.89 ± 0.20 L/min), and SIT (0.82 ± 0.19 L/min). Peak HR was higher ($p < 0.05$) with HIIT (90 % VO_{2peak} and 99 % HRpeak) and SIT (80 % VO_{2peak} and 96 % HRpeak) versus MICT. There was no difference in mean HR across bouts ($p = 0.16$) which was equal to 130.7 ± 19.3 , 129.3 ± 18.6 , and 126.9 ± 14.9 b/min for HIIT, SIT, and MICT, equivalent to 79 - 82 %HRpeak. **CONCLUSION:** Despite a higher intensity, all participants preferred HIIT or SIT versus MICT. Compared to MICT, submaximal or supramaximal interval training elicits higher peak oxygen uptake and heart rate. The long-term efficacy and feasibility of HIIT in this population should be explored, considering that exercise intensity seems to be the most important variable manipulated in exercise programming to optimize maximal oxygen uptake. This study was partially funded by a University GPSM grant.

Knee Extensor Asymmetry in Multiple Sclerosis Patients Before and After Single-Leg Cycling

David J. Lantis, Greg S. Cantrell, John P. Hintz, Daniel J. Larson, John W. Farrell, III, Brian A. Pribble, 73019, Rebecca D. Larson. University of Oklahoma, Norman, OK.
 Email: dlantis@ou.edu
 (No relationships reported)

Multiple Sclerosis (MS) is an immune-mediated disorder of the central nervous system that is both chronic and progressive. MS is one of the most common neurological diseases that affect young adults; causing fatigue, debilitating ambulatory effects, as well as impacting quality of life. There have been clinical observations of bilateral differences (asymmetry) in lower extremity strength and function in people with MS. **Purpose:** Therefore the purpose of this study was to quantify lower extremity strength asymmetry before and after a bout of single-leg cycling exercise to failure. **Methods:** Eight individuals (6 women and 2 men) with mild MS (Age 51.6 ± 9.2 yrs, BMI 25.0 ± 3.9 kg/m², Extended Disability Status Scale 2.6 ± 1.6) and seven (5 women and 2

men) non-MS controls (CON) (Age 49.4 ± 14.3 yrs, BMI 26.0 ± 8.3 kg/m²) completed bilateral assessments of muscle knee extensor strength (KES) before and immediately after a single leg incremental cycling (SLC) test to induce localized musculature fatigue. KES asymmetry scores (weak/strong) were calculated for both groups (scores equal to 1.0 indicates symmetry between limbs). Body composition (lean and fat mass) was assessed using Dual X-Ray absorptiometry (DXA). Independent and dependent t-tests were used to detect between and within group differences respectively. Cohens d effect size (ES) was calculated, and level of significance was set to $p < 0.05$. **Results:** No significant differences in baseline demographic measures were observed. No significant differences were observed in lower limb lean mass and fat mass within or between groups. There was a significant between group difference for leg asymmetry before the SLC test (CON: 0.933 ± 0.131 , MS: 0.818 ± 0.0942 , $p < 0.034$, ES: 1.0); however, following the SLC test no between group differences were observed ($p > 0.05$). **Conclusion:** The group of individuals with MS exhibited asymmetry in KES that was significantly different than CON group. The SLC test did not appear to cause fatigue of the knee extensors in either group, and appeared to improve strength in the MS group. The increase in strength could possibly be related to potentiation from the SLC test. However, further studies should utilize different fatigue protocols to determine the effects of exercise on asymmetries in people with MS.

 (No relationships reported)

Multiple sclerosis (MS) is a neurological disorder that afflicts ~400,000 people in the US. Common symptoms include sensory impairment, fatigue, and reduced mobility. Neuromuscular electrical stimulation (NMES) can be used to restore muscle function and improve mobility, but little is known about the relative influence of pulse width on treatment efficacy. Wider pulse durations (1 ms) activate a greater proportion of sensory axons, whereas narrower durations (0.26 ms) selectively activate motor axons. **PURPOSE:** To compare the effects of narrow- and wide-pulse NMES on the walking endurance of persons with MS. Wide-pulse NMES (WP) was expected to engage the nervous system more effectively and produce greater gains in walking performance than narrow-pulse NMES (NP). **METHODS:** Twenty-seven persons with MS (52.6 ± 7.4 yrs) participated in the study. Participants were randomly assigned to two groups: NP group (0.26 ms; 50 Hz; $n=13$; 54 ± 6.3 yrs), and WP group (1 ms; 100 Hz; $n=14$; 51.2 ± 8.3). NMES was applied at a tolerable level for 3 sessions/wk for 6 wks. Current was progressively increased to new tolerance and tapered to limit fatigue at testing. NMES was applied to the dorsiflexors and plantar flexors muscles (10 min each muscle, 4 s on and 12 s off) for both legs. Walking endurance (6 MWT) and walking speed (25-FWT) were assessed before (0 wk), after (6 wks), and after a 4 wk retention period (10 wks). **RESULTS:** Both groups (NP & WP) improved walking endurance and walking speed after the intervention (P values < 0.05). The 6MWT (m) results: NP - before (mean \pm SD) = 345 ± 138 , after = 387 ± 154 , retention = 396 ± 178 ; WP - before = 409 ± 131 , after = 442 ± 155 , retention = 450 ± 149 . Mixed ANOVA indicated no significant difference between NP and WP groups (P 0.302) in 6MWT. The 25-FWT (s) results (non-parametric test: Friedman test): NP - before (mean \pm SE) = 11.9 ± 5.5 , after = 9.9 ± 4.4 , and retention = 10.5 ± 5.1 ; WP - no significant differences. Wilcoxon signed rank tests for the changes in walking speed for both groups indicated no statistical difference between the two groups (P values 0.075, 0.173). **CONCLUSION:** 6 wks of either wide- or narrow-pulse NMES improved walking performance for persons with MS. Wide-pulse NMES didn't produce greater gain in walking performance than narrow-pulse NMES.

 (No relationships reported)

PURPOSE: Individuals with Multiple Sclerosis (MS) often exhibit slowed walking speed, foot tap speed, and longer Timed-Up-and-Go (TUG), and Six Spot Step Test (SSST) times. The goal of this study was to evaluate within- and across-day reliability of these measures in individuals with MS. **METHODS:** On 3 visits, each separated

by 7 days, women with MS ($n=11$; mean \pm SE, age: 53 ± 3 yrs; self-reported EDSS: median=4.5, range=0-6.5) completed two 25-foot walk and 2 TUG trials, and the fastest trial for each visit was used for analysis. Next, participants completed the SSST and the average time for 4 trials was recorded for each visit. Participants were instructed to complete all measures of mobility "as fast and safely as possible." They then performed 10 trials of the foot tap test (FTT, 10s rapid tapping) on each foot, with the distal half of their foot positioned on a force plate and the number of taps in each trial determined from the force data. Foot tap count from all 10 trials was used to assess within-day reliability of each foot using the coefficient of variation (CoV) and rmANOVA, with Bonferroni post-hoc analyses. The fastest trial for each mobility test was used to assess across-day reliability with intraclass correlations (ICC), CoV, and rmANOVA. **RESULTS:** Within-day CoV for the FTT showed good reliability for both feet (right: $7.4 \pm 1.1\%$, left: $6.5 \pm 1.0\%$). There was a significant within-day effect of trial number for the FTT ($p=0.02$) and post-hoc analyses revealed differences at visit 3 such that the right foot was faster in trial 1 than trial 8 (37.5 ± 2.4 vs. 33.8 ± 2.4 , $p=0.02$), and the left foot was faster in trial 1 than trial 10 (36.5 ± 3.0 vs. 33.6 ± 3.2 , $p=0.03$). No other within-day differences were observed. The ICC's for the 4 mobility tests varied across visits (25-foot walk: ≥ 0.95 ; TUG: ≥ 0.92 ; SSST: ≥ 0.94 ; FTT: ≥ 0.75). The CoV for the 25-foot walk (4.7%), TUG (6.7%), SSST (7.3%), and FTT (right: 6.5%, left: 7.3%) demonstrated good reliability. There were no differences across visits for the 25-foot walk, TUG, and FTT ($p > 0.05$). However, there was a difference across visits for the SSST ($p=0.02$), such that participants were quicker at visit 3 compared with visit 1 (8.0 ± 1.0 vs. 8.7 ± 1.0 s, $p < 0.05$). **CONCLUSIONS:** The 25-foot walk, TUG, and FTT appear more reliable than the SSST for quantifying mobility in the MS population.

Effect of Exercise Training on Cellular Inflammation and Fitness in Individuals with Multiple Sclerosis

Kelly N. Z. Fuller¹, Garett Griffith¹, Rachel E. Klaren², Jacob M. Haus¹, Tracy Baynard, FACSM¹, Robert W. Motl³, Bo Fernhall, FACSM¹. ¹University of Illinois at Chicago, Chicago, IL. ²University of Illinois at Urbana-Champaign, Urbana, IL. ³University of Alabama-Birmingham, Birmingham, AL.
 (Sponsor: Bo Fernhall, FACSM)
 (No relationships reported)

Multiple Sclerosis (MS), an immune-mediated disease of the central nervous system (CNS), is characterized by chronic neuroinflammation and demyelination. Interleukin-6 (IL-6), a major cytokine released by monocytes and macrophages, promotes a robust downstream inflammatory cascade, including the release of C-Reactive Protein (CRP), a common clinical marker of inflammation. Physical activity is known to be protective against inflammation and recent evidence suggests that increasing soluble form of the receptor for advanced glycation endproducts (sRAGE) may be an additional mechanism by which this occurs. **PURPOSE:** To characterize the relationship between fitness and inflammatory markers (CRP, IL-6) in persons with MS, and to elucidate the effects of a 12-week home-based exercise program on inflammation, estimates of insulin resistance (HOMA-IR), circulating sRAGE, and fitness in persons with MS. **METHODS:** Forty-eight participants with MS (45 ± 2 yrs, 28.8 ± 0.9 kg/m², 35 females) were randomly assigned to either a home-based aerobic exercise program or an attention-control stretching group. The exercise intervention consisted of cycling 3-4 d/wk at 40-60% $\dot{V}O_{2\text{peak}}$ 30 min/d. $\dot{V}O_{2\text{peak}}$ was assessed using open-circuit spirometry on a cycle ergometer. Blood was drawn at baseline and following the 12-week intervention and plasma metabolites were assessed using commercially available ELISA kits. **RESULTS:** Baseline $\dot{V}O_{2\text{peak}}$ was negatively correlated with baseline plasma levels of CRP ($r=-0.43$, $p < 0.01$) and IL-6 ($r=-0.51$, $p < 0.01$). $\dot{V}O_{2\text{peak}}$ increased 8% in individuals with MS ($p < 0.001$), with no change in the attention-control group. No between or within group differences were observed for sRAGE, IL-6, CRP or HOMA-IR. **CONCLUSION:** Despite no effect of the exercise intervention, the relationship between $\dot{V}O_{2\text{peak}}$ and CRP, IL-6 at baseline suggest that higher fitness levels are advantageous to individuals with MS and may be related to the well-known anti-inflammatory effects of exercise. This relationship is promising for the use of exercise on modulating cellular inflammation in individuals with MS, however longer duration, higher intensity or supervised exercise may be necessary in order to elicit changes in circulating IL-6, CRP, sRAGE and HOMA-IR. Supported by the National Multiple Sclerosis Society RG 4702A1/2.

Relationship Between Peak Power Asymmetry and Self-Reported Measures of Fatigue in People with Multiple Sclerosis

Gregory Cantrell, David Lantis, John Farrell, III, Brian Pribble, Daniel Larson, Rebecca Larson. *University of Oklahoma, Norman, OK.*
Email: gcantrell1984@gmail.com
(No relationships reported)

Multiple Sclerosis (MS) is a disease of the central nervous system that has been associated with increased levels of fatigue. Recently, research has shown asymmetry in muscle function and performance in people with MS (PwMS) where one side of the body performs better than the other. Interestingly, and of clinical concern, would be how asymmetry might be associated with generalized fatigue. **Purpose:** The intent of this study was to correlate isometric knee extensor strength and peak power (PP) asymmetry scores to measures of fatigue in PwMS. **Methods:** Fourteen volunteers, eight with relapsing-remitting MS and six healthy controls without MS participated in the study. Participants completed a single leg incremental cycling test to determine peak power (PP) of each limb, as well as maximal voluntary isometric contractions of the knee extensors to determine strength (KES). The Modified Fatigue Impact Scale (MFIS), the Fatigue Severity Scale (FSS), and the Short Form Health Survey (SF-36) questionnaires were used to assess feelings of fatigue. A higher score on the MFIS and FSS indicates greater levels of fatigue, whereas a higher score on the SF-36 indicates better feelings of health. KES and PP asymmetry scores were calculated as weaker leg (more affected) / stronger leg; a lower score indicates a greater magnitude of imbalance. Pearson correlations were used to determine relationships between KES and PP asymmetry and all self-reported measures of fatigue. **Results:** The mean Expanded Disability Status Scale score was 2.6 ± 1.6 in the MS participants, indicating mild to moderate impairment. No significant correlations were observed between KES asymmetry scores and measures of self-reported fatigue. Significant correlations were observed between PP asymmetry scores and the MFIS physical sub-scale ($r = -0.554$; $p = 0.04$), the FSS ($r = -0.524$; $p = 0.05$), and the SF-36 (physical health subscale; $r = 0.606$; $p = 0.02$). **Conclusions:** Asymmetries in function (as measured by PP) and not strength appear to be significant contributors to self-reported measures of fatigue. This might suggest that assessments using a more dynamic measure such as peak power may be more appropriate compared to static strength. More importantly, preliminary findings suggest PP asymmetry appears to influence generalized fatigue in PwMS.

(No relationships reported)

Multiple sclerosis (MS) is an immune-mediated disease of the central nervous system that results in physiological deconditioning and walking disability. High-intensity interval exercise (HIIE) has induced significant improvements in physiological conditioning in healthy and clinical populations. However, the effects of engaging in HIIE on cardiorespiratory functioning, gait, and walking performance in persons with MS who have mobility disability are relatively unknown. **PURPOSE:** To examine the effects of single sessions of recumbent stepping (HIIE) and continuous (CON) exercise on physiological and functional outcomes in persons with MS. **METHODS:** 5 participants with mild-to-moderate MS underwent HIIE and CON exercise bouts. The HIIE bout included 10 cycles of 1-min intervals at the wattage associated with 90% VO_{2peak} followed by 1-min recovery intervals at 15W, totaling 20 min in length. The CON bout consisted of 20 min at the wattage associated with 50-60% VO_{2peak} . Physiological measures were collected within session, and functional measures were collected pre-, immediately-post, and 10-minutes post-exercise. **RESULTS:** We observed significant differences between the CON and HIIE protocols for VO_2 ($t = -4.36$, $P = 0.01$), power output ($t = -4.20$, $P = 0.01$), and RER ($t = -7.24$, $P < 0.01$), with the HIIE condition inducing higher values than the CON condition. Heart rate approached a statistically significant difference between conditions ($t = -2.61$, $P = 0.06$). There were no significant interaction effects or effects of time or condition on walking speed and gait kinematics ($P > 0.05$). **CONCLUSIONS:** We determined that HIIE exercise taxes the cardiorespiratory system significantly more than CON exercise, yet without deleterious effects on walking and gait in persons with MS. This has important implications for informing an evidence-based exercise prescription in persons with MS who have walking impairments that is appropriate for improving physiological conditioning.

Acute Physiologic Responses During Alternative Modes of Treadmill Exercise in Adults with Parkinson's Disease

Nicholas Levine, Brandon R. Rigby, Ronald Davis, David Nichols, FACSM, Marco Avalos, Leah Goudy, Patricia Moo, Cecil Frederick, Desiree Patterson, Mitchell Robuck, Gena Guerin, Karrie Beck, Georgette Reyes, Doris Patino, Brenda De La Cruz. *Texas Woman's University, Denton, TX.*
Email: nlevine@twu.edu
(No relationships reported)

Parkinson's disease (PD) is a neurodegenerative condition characterized by muscle tremors, rigidity and dyskinesia leading to balance and gait abnormalities that could alter physiologic responses during exercise. Locomotion on an aquatic treadmill (ATM) or anti-gravity treadmill (AGTM) may be a safe alternative to exercise on a traditional land treadmill (LTM) in those with PD. **Purpose:** To determine the acute cardiovascular and metabolic responses to three different modes of treadmill exercise in older adults diagnosed with Parkinson's disease. **Methods:** Eight adults diagnosed with PD (68 ± 3 years of age) completed one exercise session on an LTM, one session on an ATM, and one session on an AGTM at 50% body weight. Participants walked from 1 to 3 mph in 0.5 mph increments at 0% grade during each exercise session. Heart rate (HR), energy expenditure (EE), systolic blood pressure (SBP), and diastolic blood pressure (DBP) were measured at rest and during steady-state exercise at each speed on each treadmill. Rate of perceived exertion was also measured during steady-state exercise. Rate pressure product (RPP) was calculated. **Results:** All variables, with the exception of DBP, increased as speed increased across all treadmill modes ($p < 0.001$). Between treadmill modes across all speeds, EE was statistically different ($p = 0.025$). There was a significant interaction effect for mode and speed for HR ($p < 0.001$) and RPP ($p = 0.003$). At all speeds except 1.5 mph, HR was higher on the LTM versus the AGTM ($p < 0.05$). **Conclusion:** Exercising on an ATM or an AGTM elicits similar physiologic responses to exercise on an LTM in adults with PD.

Table 1: Heart rate response and rate pressure product at rest and at all speeds on each treadmill

Variable	Treadmill Mode	Rest	Treadmill Speed (mph)				
			1.0	1.5	2.0	2.5	3.0
HR (bpm)	LTM	73±11 ^a	84±17 ^{ab}	86±18 ^{bc}	92±16 ^d	99±16 ^e	107±18 ^f
	ATM	72±11 ^a	77±14 ^a	80±17 ^{ab}	83±17 ^{ab}	90±13 ^b	97±10 ^b
	AGTM	73±11 ^a	80±15 ^{ab}	83±16 ^{bc}	85±14 ^{cd}	88±13 ^{bcde}	93±15 ^{cde}
RPP	LTM	91±26 ^{ab}	106±32 ^a	112±38 ^{ab}	123±37 ^b	135±36 ^c	149±42 ^d
	ATM	89±14 ^{ab}	97±21 ^a	107±36 ^{bc}	106±27 ^a	118±28 ^{bc}	130±29 ^c
	AGTM	91±19 ^a	102±22 ^{ab}	108±25 ^{bc}	111±24 ^c	116±25 ^{bc}	126±28 ^d

Values are mean ± s.d. Means with the same superscript are statistically similar ($p > 0.05$). ATM = aquatic treadmill; AGTM = anti-gravity treadmill; LTM = land treadmill; HR = heart rate; RPP = rate pressure product.

Changes in Balance, Gait and Motor Control Following Treadmill Exercise in Adults with Parkinson's Disease

Marco Avalos, Brandon R. Rigby, Ronald Davis, Kevin Becker, David Nichols, FACSM, Nicholas Levine, Leah Goudy, Patricia Moo, Cecil Frederick, Desiree Patterson, Mitchell Robuck, Gena Guerin, Kristen Codish, Karrie Beck, Georgette Reyes, Doris Patino, Brenda De La Cruz. *Texas Woman's University, Denton, TX.*
Email: mavalos1@twu.edu
(No relationships reported)

Locomotion on an aquatic treadmill or anti-gravity treadmill may be a safe and effective alternative to exercise on a traditional land treadmill in those with Parkinson's disease as the removal of body weight in these environments may allow the participant to exercise with less concern of falling at higher speeds before reaching volitional fatigue. **Purpose:** To determine the training effects of three different treadmill modalities on dynamic balance, gait, and fine motor control in older adults diagnosed with Parkinson's disease. **Methods:** Ten adults diagnosed with Parkinson's disease (70 ± 5 years of age) completed 8 exercise sessions (4 weeks, 2x/week) each separately on a land treadmill, aquatic treadmill, and anti-gravity treadmill at 50% body weight. Two weeks separated each intervention and the order was randomized. A 4-week control period occurred at the start of the study in which no treadmill exercise was performed. Each exercise session included a 2-minute warm-up and 30 minutes at a moderate intensity. Before and after each intervention, balance, gait and fine motor control were measured. Dynamic balance and gait were assessed using a Timed-Up-and-Go test

and Performance Oriented Mobility Assessment (POMA). Fine motor control was assessed with the Purdue Pegboard Test. **Results:** The gait assessment of the POMA was significant across all time points ($p = 0.028$). All other variables were statistically similar ($p > 0.05$) across all time points. **Conclusion:** Exercising on a traditional land treadmill, aquatic treadmill, or anti-gravity treadmill for 60 min/week for 4 weeks at a moderate intensity did not alter balance, gait or fine motor control in adults with Parkinson's disease.

Variable	Pre-Control	Post-Control	Post-LTM	Post-ATM	Post-AGTM
TUG (s)	8.4±1.4	9.3±3.3	8.5±2.6	7.9±2.1	8.8±3.6
POMA Balance	13.5±3.0	14.3±1.2	13.5±2.3	14.3±2.0	14.0±1.6
POMA Gait*	10.3±1.6	9.2±3.1	11.7±1.5	10.8±2.3	10.8±0.9
FMC (left hand)	8.7±3.2	9.1±2.8	9.0±3.4	8.8±2.8	9.0±3.2
FMC (right hand)	8.4±3.3	8.6±3.0	9.2±2.7	10.1±2.8	9.8±2.6
FMC (both hands)	6.1±2.4	6.6±2.7	7.3±2.9	6.8±2.2	6.2±1.9

Values are mean ± s.d. * = main effect for time point ($p = 0.028$); ATM = aquatic treadmill; AGTM = anti-gravity treadmill; LTM = land treadmill; TUG = timed-up-and-go; POMA = performance oriented mobility assessment; FMC = fine motor control.

D-73 Free Communication/Poster - Oxygen Uptake Kinetics

Thursday, June 1, 2017, 1:00 PM - 6:00 PM
Room: Hall F

2262 Board #275 June 1 3:30 PM - 5:00 PM Oxygen Uptake during Three Varying Duration High-Intensity Functional Training Sessions

Jesse A. Stein, Joshua R. Smith, Carl J. Ade, Ryan M. Broxterman, Brian Sanborn, Thomas J. Barstow, FACSM, Katie M. Heinrich. *Kansas State University, Manhattan, KS.*
(No relationships reported)

PURPOSE: To determine oxygen uptake during three varying duration high-intensity functional training (HIFT) sessions. **METHODS:** Six healthy men with >1 year of HIFT experience were recruited (age:29±5 yrs). Participants completed an incremental exercise test on a treadmill to determine maximal oxygen consumption ($\dot{V}O_{2max}$), gas exchange threshold (GET), and respiratory compensation point (RCP). Participants completed three HIFT sessions. Session 1 (S1) consisted of 3 rounds of power cleans and ring dips. Session 2 (S2) consisted of 3 rounds of a 400-meter run, 21 kettlebell swings and 12 pull-ups. Session 3 (S3) consisted of as many rounds as possible of 5 pull-ups, 10 push-ups and 15 squats in 20 minutes. Participants were encouraged to complete S1 and S2 as fast as possible, while performing as many repetitions as possible in S3. Pulmonary gas exchange ($\dot{V}O_2$, $\dot{V}CO_2$, VE) were measured during each session. **RESULTS:** The mean $\dot{V}O_{2max}$ was 55.9±5.6 mL/kg/min with GET and RCP representing 61% and 79% of $\dot{V}O_{2max}$ respectively. The average time to complete S1 was 513±59s and elicited a mean % $\dot{V}O_{2max}$ of 70±7% that was not different from GET or RCP ($p > 0.05$). S2 required on average 783±79s to complete, with a mean % $\dot{V}O_{2max}$ of 82±7% of $\dot{V}O_{2max}$ that was significantly higher than GET ($p < 0.05$), but not different compared to RCP ($p > 0.05$). Mean % $\dot{V}O_{2max}$ across S3 was 66±6%, however the average % $\dot{V}O_{2max}$ was significantly higher than GET ($p < 0.05$) at minutes 2-8, but not different at any other interval and was not different compared to RCP ($p > 0.05$). Furthermore, $\dot{V}O_2$ demonstrated significant oscillations during all sessions ($p < 0.05$). **CONCLUSIONS:** Participants with HIFT experience who completed sessions as quickly as possible or performed as many rounds as possible elicited an oxygen consumption from 66-82% of $\dot{V}O_{2max}$. Moreover, the oscillating $\dot{V}O_2$ during HIFT suggests that metabolic demands, which ranged from 46-92% of $\dot{V}O_{2max}$ within-subjects, do not achieve a steady-state. Previous work suggests that the oscillating $\dot{V}O_2$ response could be a potent stimulus for improving health and fitness characteristics.

2263 Board #276 June 1 3:30 PM - 5:00 PM Characterization of Ventilatory Off-Kinetics Following Arm and Leg Cycling in Incomplete Spinal Cord Injured Men

Gino S. Panza, Khalid Alwadeai, Jeffrey E. Herrick. *George Mason University, Fairfax, VA.* (Sponsor: Randall Keyser, FACSM)
Email: gpanza@masonlive.gmu.edu
(No relationships reported)

Introduction: The minute ventilation (\dot{V}_E) off-kinetics phase has been associated with greater muscle oxygen deficiency and slower muscle oxygen adjustments to exercise. Neural mechanisms are implicated in \dot{V}_E off-kinetics as recovery from exercise may be mediated by breathing frequency. Motor incomplete spinal cord injury (miSCI) is associated with significant cardiopulmonary impairment that may alter the off-kinetic response during arm and leg exercise. **Purpose:** The purpose of this study was to characterize the \dot{V}_E off-kinetics following both arm and leg exercises in adults with cervical miSCI compared to a group of age matched peers (CON). **Participants:** miSCI: Age: 31 (18.1) years, Height 185.7 (6.0) cm, Weight 75.9 (14.4) kg. CON: Age: 32 (4.6) years, Height: 178(3.6)cm, Weight 92.9(16.3) kg **Methods:** Both groups completed arm and leg cycle tests on separate days at an intensity that elicited a \dot{V}_E equal to 30% of measured maximum voluntary ventilation ($MVV \times L \cdot min^{-1}$). \dot{V}_E off-kinetics was analyzed over the 5 minutes following the 30% MVV bout using a mono-exponential model. Amplitude (Amp), in liters (L), was defined as the change from exercise to steady state of asymptote approaching baseline and tau(τ)(seconds) as the time taken to reach 63% of the of the end-recovery amplitude. **Results:** miSCI group: τ (s) and Amp(L) for arm and leg cycling were as follows: 67.9(9.8) and -20.5 (11.53), and 101.6 (19.5) and -23.4(14.5). The average arm τ was 33.7(29.27) faster than leg cycling with a 2.8(9.41) liter decrease in amplitude. CON group: τ (s) and Amp(L) for arm and leg cycling were as follows: 56.7(5.9) and -43.4(4.4) and 90.13 (17.83) and -49.2(4.9), respectively. On average, arm τ was 33.39(16.5) seconds faster than leg cycling while the Amp was 5.8(3.29) liters lower. On average, τ was 11.19 and 11.50 s slower for arm and leg cycling, respectively when compared to CON. Amplitude was also lower with 22.8 and 25.8 liter difference in arm and leg cycling, respectively. **Conclusion:** The miSCI group reported a longer τ following both arm and leg exercise than the CON group suggesting a prolonged recovery phase. A prolonged \dot{V}_E off-kinetic phase may, in part, contribute to reduced functional performance in adults with chronic miSCI. Character count w/o spaces: 1907/2000

2264 Board #277 June 1 3:30 PM - 5:00 PM Prior Supramaximal Cycling Transiently Increases Submaximal Cycling Energetics in Cyclists and Non-cyclists

Eric Homestead, William C. Byrnes, FACSM. *University of Colorado Boulder, Boulder, CO.* (Sponsor: William C. Byrnes, FACSM)
(No relationships reported)

PURPOSE: We sought to examine the effects of supramaximal cycling on the energetics of submaximal cycling at and below the lactate threshold (LT) in cyclists and non-cyclists. **METHODS:** On 3 separate days, endurance-trained cyclists (CYCL, n=10) and recreationally active non-cyclists (N-CYCL, n=9) performed 3 sub-LT cycling bouts at 60%, 80%, and 100% LT before (PRE) and after (POST 1, POST 2, and POST 3) supramaximal cycling bouts (3x2 min) at 110% of power at $\dot{V}O_{2peak}$ (SUPRA). POST 1, POST 2 and POST 3 occurred 2, 22, and 52 min after SUPRA. Metabolic variables, core temperature (T_c), and blood lactate concentration ([Lactate]) were measured. $\dot{V}O_2$ -power and EE-power linear relationships were developed for each subject from the 3 intensities and compared between conditions (PRE, POST 1, POST 2 and POST 3). **RESULTS:** $\dot{V}O_{2peak}$ and power at LT were significantly higher by 51% and 131% in CYCL compared to N-CYCL ($p < 0.01$). CYCL and N-CYCL responded the same across conditions so the estimated marginal means are reported which combines groups. $\dot{V}O_2$ was significantly greater during POST 1 compared to PRE, POST 2, and POST 3 regardless of intensity (2.0±0.5 vs. 1.8±0.5, 1.8±0.5, and 1.8±0.5 L·min⁻¹, $p < 0.05$). $\dot{V}O_2$ -power slopes were different between conditions ($p < 0.05$), but not when EE-power slopes were analyzed. The $\dot{V}O_2$ -power intercept during POST 1 was significantly greater compared to PRE, POST 2, and POST 3 (0.68±0.25 vs. 0.58±0.20, 0.55±0.19 and 0.53±0.20 L·min⁻¹, $p < 0.05$). The same results were found for EE-power intercepts. \dot{V}_E , HR, and T_c were significantly higher during POST 1 compared to PRE ($p < 0.05$). Only HR and T_c were higher during POST 2 and POST 3 compared to PRE ($p < 0.05$). [Lactate] increased from PRE to POST 1 and then progressively decreased over time ($p < 0.05$). **CONCLUSION:** Prior supramaximal cycling increases the energetic cost of submaximal cycling (at and below LT) in endurance-trained cyclists and recreationally active non-cyclists. For both groups, energy cost returns to baseline values within 20 minutes. No change in the EE-power slope and a greater EE-power intercept during sub-LT cycling immediately following supramaximal cycling suggests that muscle efficiency was unaltered and that the greater energetic cost is associated with metabolic demands that do not increase with increasing workrate.

2265 Board #278 June 1 3:30 PM - 5:00 PM
Do Training Masks Enhance Oxygen Utilization Capacity?
 Devin Olsen, Dalton Brady, Colton Cardon, Mitchell Dahl, Daniel Hansen, Jace Wirick, Ellis Jensen. *Utah Valley University, Orem, UT.*
(No relationships reported)

PURPOSE: High-altitude or oxygen-limited training has received a lot of attention as a way to increase oxygen utilization capacity. Due to the impracticality involved in traveling to high altitudes, endurance athletes and coaches have employed methods of simulating high-altitude (low-oxygen) conditions as an effective alternative. Some low-oxygen devices may not be available to all due to prohibitive cost or inconvenience. A recent simple alternative is altitude-simulating masks. However, the effectiveness of these masks is in question. This research looks at the effect of masked training on VO₂max and hematocrit levels.

METHODS: 14 subjects participated in a 6-week interval-training experiment. Subjects VO₂max, hematocrit, and lactate levels were measured. Half of the subjects were given a training mask and asked to complete 3 workouts per week in the range of 60%-80% of VO₂max. The control group was given the same task of working out 3 times a week without a mask. Hematocrit and VO₂max were measured after the 6 weeks of training and analyzed for significant differences.

RESULTS: There was no difference between the pre and post-training VO₂max values in the masked and no-mask groups. There was no difference in the percent change in VO₂max between the two groups. The no-mask group experienced a +8.974% change in hematocrit while the masked group had a decrease in hematocrit of 1.194% after training. There was a significant difference in how the two groups hematocrit levels responded to training. **CONCLUSIONS:** We found no support for the use of training masks helping athletes use oxygen better than using no mask at all. Perhaps training masks may help athletes use oxygen more effectively if they used them for longer than 6 weeks. A training protocol of longer duration would likely yield more conclusive results.

2266 Board #279 June 1 3:30 PM - 5:00 PM
High Intensity Interval Training (HIT) Increases Muscle Deoxygenation During Ramp Incremental Exercise.
 Dai Okushima¹, Harry B. Rossiter, FACSM², Thomas J. Barstow, FACSM³, David C. Poole, FACSM³, Masato Nishiwaki⁴, Narihiko Kondo⁵, Shunsaku Koga¹. ¹*Kobe Design University, Kobe, Japan.* ²*Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA.* ³*Kansas State University, Manhattan, KS.* ⁴*Osaka Institute of Technology, Osaka, Japan.* ⁵*Kobe University, Kobe, Japan.*
 Email: oumanooyako1119@hotmail.co.jp
(No relationships reported)

Endurance exercise training increases whole-body maximum O₂ uptake (V_{o₂peak}) by increasing both convective and diffusive O₂ conductances within the active muscles. High intensity interval training (HIT) very effectively increases V_{o₂peak} but it is unknown whether HIT enhances muscle O₂ diffusive properties.

PURPOSE: We investigated the effect of HIT on deoxygenated hemoglobin and myoglobin (Hb+Mb) concentration (HHb, reflecting fractional O₂ extraction) and total Hb+Mb concentration (tHb, reflecting diffusive O₂ potential) in quadriceps during ramp-incremental cycling (RI) using quantitative time-resolved near-infrared spectroscopy (TRS-NIRS).

METHODS: Fifteen men volunteered for exercise training (TR, n = 8) or non-training control (CN, n = 7). TR performed HIT (4 repeats of 30 s all-out sprint cycling and 4 min recovery) 3 times/week, for 5 weeks. All subjects performed RI to exhaustion pre- and post-intervention. V_{o₂} was measured breath-by-breath. Absolute HHb and tHb were measured in the *vastus lateralis* (VL) and *rectus femoris* (RF) by TRS-NIRS. HHb and tHb profiles were modeled by a double linear response ($y_1 = m_1 * x + b_1$, $y_2 = m_2 * x + b_2$, $y = if [x < IP, y_1, y_2]$), where m_x is the slope of heme chromophore accumulation above and below an inflection point, (IP).

RESULTS: V_{o₂peak} increased in TR (48.9±4.6 vs. 52.7±5.3 ml·kg⁻¹·min⁻¹, p < 0.05) but not in CN (46.1±8.9 vs. 45.2±10.1 ml·kg⁻¹·min⁻¹). The amplitude of HHb from rest to intolerance increased only in TR, in both the VL and RF muscles (29.5±13.5 vs. 34.8±13.7 μM, mean of both sites, p < 0.05). In contrast, post-training tHb amplitude was unchanged in both groups and both muscles. Moreover the slopes (m₁, m₂) of HHb and tHb were unchanged between pre- and post-intervention in either group or muscle.

CONCLUSIONS: Five weeks of HIT increased V_{o₂peak} and regional (VL and RF) muscle deoxygenation without altering HHb slope or peak tHb - reflecting a gain of O₂ flux to active muscle with an unchanged O₂ delivery to utilization matching during submaximal exercise and an unchanged diffusive O₂ potential. This supports the notion that greater muscle O₂ consumption following HIT in young adults occurs by the improvement of O₂ extraction capacity without an obligatory [Hb]-induced enhancement of diffusive O₂ conductance. Supported by JSPS-15K16476, 24247046, 26560362.

Relationship Between SMO₂ Measured By NIRS And VO₂ During Severe Intensity Intervals Of Running
 Lee Shearer, Kaitlin Bruneau, Sun Lee, Kristine Knowles, Randolph E. Hutchison. *Furman University, Greenville, SC.*
 (Sponsor: Anthony Caterisano, FACSM)
 Email: Randolph.Hutchison@furman.edu
(No relationships reported)

Near infrared spectroscopy (NIRS) has been shown to be a non-invasive wearable alternative to measured blood oxygenation levels. **PURPOSE:** The purpose was to determine whether a significant relationship exists between SMO₂% and VO₂ during the last two stages of treadmill interval testing past LT₁. **METHODS:** Five volunteer members of a collegiate cross country team, (2 male, 3 female, 18.6±1.5 years, 169.4±10.9 cm, 61.3±7.8 kg) completed a maximal effort stepwise test to volitional exhaustion. Each subject was fitted with a calf sleeve containing the BSX NIRS Insight device, a ventilatory mask connected to the COSMED system, and a heart rate monitor. After a 5 minute recovery pace warm up, the subject ran four minute intervals, each increasing 0.4 mph in pace, with a one minute standing recovery period between each four minute stage. After blood lactate levels increased 1.5 millimoles from baseline levels, the final stage consisted of one-minute periods with the incline increased by 1 percent each minute, until volitional exhaustion ending the test. **RESULTS:** A Pearson correlation coefficient was calculated for the relationship between each participant's SMO₂% and VO₂ during the final ramp stage, the 4 minute stage preceding the ramp stage, and for those two stages combined. A strong negative correlation was found for each participant's total rest data, ranging from r = -0.660 to -0.925, and an average +/- standard deviation of -0.852±0.110. All correlations were significant at p<.01, indicating a significant linear relationship between the two variables. **CONCLUSIONS:** The study suggests that the BSX Insight device is a valid option for non-invasively measuring SMO₂% during ventilatory maximal interval training. Given that the study concentrated on elite runners, further testing would need to be done to generalize the results to a larger population.

The Effect Of Stride Frequency On Running Economy In Collegiate And Recreational Runners

Guillermo A. Cuevas, Michael Reeder, Brent Alumbaugh,
 Colorado Mesa University, Grand Junction, CO.
 Email: gacuevas@mavs.coloradomesa.edu
 (No relationships reported)

Running economy (RE) is often a good predictor of running performance among athletes with a similar VO₂ max. Additionally, economy differences have been seen when comparing elite distance runners to recreational runners. **PURPOSE:** To explore the effect that varied stride frequencies (SF) have on RE in both collegiate and recreationally trained runners. **METHODS:** Four collegiately trained male distance runners and four college-aged recreational runners ran on a treadmill at speeds of 3.9 m/s and 2.7 m/s, respectively, which corresponded with 60 to 65% of their VO₂ max. Subjects completed 5 bouts of running for 5 minutes at their preferred stride frequency (PSF), ±5%, and ±10% of their PSF, in a random order. The first three minutes of each trial were used to match the prescribed stride frequency and to reach a steady state, the last 2 minutes were used for data analysis. Subjects were given three minutes between trials to recover from the prior prescribed SF session. PSF was determined prior to data collection and prescribed stride frequencies were defined with a metronome. Subjects were given a familiarization phase prior to data collection to aid in matching the prescribed SF and video was used to verify that prescribed SF was achieved. **RESULTS:** Mean VO₂ differences in collegiately trained runners were significant (p < 0.05) in all but one of the trials (-5% of SF) where p = 0.07. There was a U-shaped relationship that was observed between SF and running economy in collegiate runners, where any variation above or below PSF resulted in a decrease in RE. In all cases, however, the collegiately trained runners' PSF corresponded to what was most economical. Recreational runners saw mean VO₂ differences that were only significant (p < 0.03) when running at a SF that was below their PSF, where some subjects experienced a small but not statistically significant (p = 0.06) improvement in RE as SF increased. **CONCLUSION:** Experienced runners tend to have a PSF that corresponds with what is most economical, whereas lesser trained, recreational runners could potentially see improvements in RE from an increase in SF.

 (No relationships reported)

Since the 1995 physical activity guidelines, a number of studies investigated as to whether a single bout of continuous exercise and several intermittent (i.e. accumulated) bouts of exercise produced the same physiological responses and health benefits. Various studies focused on walking and compared the physiological responses between a single bout of continuous walking and during multiple 10-min bouts of intermittent walking. However, no study investigated the energy expenditure (EE) accumulated during very short bouts of intermittent walking (e.g., 30 s), which would better match with the daily life walking pattern. **PURPOSE:** to compare EE accumulated during a continuous walking exercise (CW) and during an intermittent walking exercise (IW) including very short bouts of walking. **METHODS:** Ten healthy young adults (F/M: 5/5; 22±1 years; 67.9±8.2 kg; 176±8 cm) performed, in a counter-balanced randomized order, two treadmill walking trials of 20 min each: i) Trial A: one 10-min bout of CW followed by a 10-min recovery bout in standing position; ii) Trial B: twenty 30-s walking bouts (20 x 30 s = 10 min) interspersed with twenty 30-s recovery bouts in standing position. For both walking trials, subjects walked at the same absolute intensity on a motorized treadmill: speed of 5.5 km/h and 0% grade. EE (kcal) was calculated from gas exchange measured using a portable metabolic system (K4b²). **RESULTS:** the EE accumulated during the 10-min single bout of CW (54.72±8.87

kcal) was significantly higher than the EE accumulated during the twenty 30-s recovery bouts of the IW (43.37±10 kcal; P<0.05). The EE accumulated during the 10-min recovery bout following CW (21.13±6.58 kcal) was significantly lower than the EE accumulated during the 20 recovery bouts of IW (38.50±9.42 kcal; P<0.05). No difference was found between the whole continuous and intermittent walking trials regarding total EE (78.97±14.58 kcal vs. 82.15±19.08 kcal respectively, P=0.185). **CONCLUSION:** A low absolute intensity intermittent exercise of walking, including bouts of very short-duration, enables young adults to reach a similar total EE as during a continuous walking exercise. While additional studies are needed, this study opens interesting applications not only in healthy subjects but also in very deconditioned or functionally-impaired subjects.

 (No relationships reported)

Cardiopulmonary exercise testing (CPET) is the gold standard method for assessing maximum heart rate (HR_{max}) and maximal oxygen uptake (VO_{2max}). However, performing a CPET is not always practical or feasible. Alternative methods that utilize submaximal protocols and non-exercise regression models have been developed to estimate HR_{max} and VO_{2max}. However, these methods fail to account for inter-individual variability and are associated with a large degree of uncertainty and error. **PURPOSE:** The aim of this study was to develop a novel method for estimating HR_{max} and VO_{2max} that applies a dynamical system model to data collected from a submaximal exercise protocol. The dynamical system model accounts for the nonlinear dynamics and inter-individual aspects of the heart rate and oxygen uptake responses. **METHODS:** Twelve regularly exercising healthy adult males performed a CPET on a cycle ergometer to determine their true HR_{max} and VO_{2max}. Participants then performed a submaximal bout of exercise, and the dynamical system model was applied to the time series data in conjunction with a heuristic parameter estimation algorithm to estimate the participants' HR_{max} and VO_{2max}. **RESULTS:** The submaximal dynamical system model predictions were compared to the true maximal values for HR_{max} (R² = 0.96, SEE = 2.4 bpm) and VO_{2max} (R² = 0.93, SEE = 2.1 mL/kg/min). **CONCLUSIONS:** A dynamical system model that accounts for nonlinear dynamics and inter-individual physiological aspects can provide accurate submaximal predictions for HR_{max} and VO_{2max}. Supported by the ARO through an NDSEG Fellowship.

 (No relationships reported)

The VO₂ kinetics response describes the rate of adjustment of the oxidative phosphorylation, providing an overall estimate of the efficiency of the cardiovascular system. Recent lines of evidence have demonstrated that, at least in young individuals, VO₂ kinetics can become faster even after only a single session of endurance training, likely due to improvement in the provision of oxygen (O₂) to the active tissues. Additionally, sprint interval training (SIT) has been shown to induce positive adaptations in oxidative metabolism. However, the effects of an acute bout of exercise, and more specifically SIT, in the VO₂ kinetics response of older individuals are unknown. **PURPOSE:** to investigate whether a very short session (3 bouts) of Sprint Interval Training (SIT) induces speeding of the VO₂ kinetics in older participants. **METHODS:** Before, as well as 24, 48, and 72 hours post SIT exercise intervention, the time-constant of the VO₂ kinetics response (τVO₂) was measured in eight older adults (67.3 ± 3.7 years; 21.5 ± 2.4 BMI) through three step transitions in work rate (WR) from 20 W to a moderate-intensity WR that elicited a VO₂ corresponding to 90% of the gas exchange threshold. The SIT session consisted of 3 consecutive "all-out" sprints (Wingate protocol) against a resistance corresponding to 5% of the body weight, interspersed by 4.5 min recovery. **RESULTS:** The average mean power throughout the three Wingate sprints was 366 ± 74 W, while the average peak power was 602 ± 106 W, and the average total work was 22.0 ± 4.4 kJ·min⁻¹. τVO₂ at the baseline was 41.8 ± 5.9 s. Significantly (p < 0.05) smaller values in τVO₂ kinetics were found 24 h (35.0±4.9 s; -16.2%), 48 h (35.5±3.4 s; -15.1%), and 72 h (37.2±7.2

s; -10.9%) post SIT intervention. **CONCLUSIONS:** This study demonstrated that a “low-volume” SIT session has the potency to speed the rate of adjustment of the oxidative phosphorylation in older adults. Despite the low dose of exercise, the speeding of the VO₂ kinetics occurred within 24 h and was sustained for 72 h, reinforcing the idea that SIT offers beneficial effects to the oxidative system, and that older individuals are capable of favorably adapting to this type of interventions.

was observed among duration of EPOC (steady-state = 11±2.75 min, maximal effort = 12.6±2.76 min, p=0.129). The time of completion for the maximal climb was 22% faster than the steady-state climb (7:47.3min±0.002).

CONCLUSIONS: A 23% increase in oxygen post-exercise was observed in the rapid trial despite being completed 22% faster (7:47min±0.002). Our results extend the noted increase in EPOC with rising intensity to climbing activities.

VO₂, RER, And Heart Rate During Recovery Following A Whole-body High-Intensity And Moderate-Intensity Workout
 Kara A. Witzke, FACSM, Naomi Bedingfield, Robin Burt, Mimi Charter, Arielle Frasher-Slavin, Charles Galles, Lewis Gehring, Pablo Gonzalez, Trevor Lizee. *Oregon State University - Cascades, Bend, OR.*
 Email: kara.witzke@osucascades.edu
 (No relationships reported)

Whole-body high-intensity interval training (WB HIIT), including CrossFit®, has gained wide popularity, partly because HIIT benefits can be achieved in less time than moderate-intensity exercise. Most HIIT research, however, has used bicycle ergometer or treadmill-based exercises that emphasize only the lower body. **PURPOSE:** To compare heart rate (HR), respiratory exchange ratio (RER), and VO₂ following a 10-minute functional, WB HIIT CrossFit® workout and a 20-minute steady-state, moderate-intensity workout. **METHODS:** Fourteen CrossFit® athletes (11 F/3 M) aged 36.6±9.2y performed a 20-minute rowing ergometer exercise at 70% +5 bpm of age-predicted max and a 10-minute WB HIIT workout consisting of as many continuous reps as possible of 10 barbell thrusters (men 75lbs/women 55 lbs) and 10 burpees over the barbell, on separate days. VO₂ and RER were measured using indirect calorimetry immediately following each exercise and throughout recovery until VO₂ and RER returned to pre-workout levels. Heart rate was continuously monitored. Differences in time to return to baseline for VO₂ and RER between the two modalities were determined using dependent t-tests (p<0.05). **RESULTS:** Participants achieved 96.4±4.4% of age-predicted max HR during the WB HIIT workout, classifying it as a max-effort exercise. Time to return to resting RER values between the two workouts was significantly different (19.1±3.8 ml/kg/min after rowing vs. 32.5±5.4 min after WB HIIT, p<0.001). Peak VO₂ levels immediately after exercise also differed (19.5±4.8 ml/kg/min after rowing vs. 32.9±6.0 ml/kg/min after WB HIIT, p<0.001), as did the time for VO₂ recovery (8.2±1.6 min after rowing vs. 22.3±7.7 min after WB HIIT, p<0.001). **CONCLUSION:** RER and VO₂ remained elevated over 11 and 14 min longer, respectively, following WB HIIT, despite half the workout time. This is likely due to a longer time to restore ATP-PC stores, recycle lactate, and reduce body temperature. Heart rate remained elevated following the observed recovery period after WB HIIT suggesting a higher EPOC and caloric expenditure compared to moderate-intensity exercise. Our equipment prevented the measurement of VO₂ during the workout, so future research should use equipment that would allow for testing VO₂ during WB HIIT exercise so that EPOC can be accurately calculated.

 (No relationships reported)

While recent research debates the potential benefits and risks of barefoot and simulated barefoot running, the long-term effects on biomechanical and physiological parameters remain unclear. **PURPOSE:** To investigate the effects of transitioning from traditional cushioned (CF) to minimalist footwear (MF) on running economy (RE) in recreational runners. **METHODS:** We used a prospective randomized controlled design. Thirty-two habitual shod recreational male runners (mean ± SD age 38.3 ± 8.5 years, length 178 ± 5.1 cm, weight 78.2 ± 11.2 kg, BMI 24.34 ± 2.9 kg/m² and weekly mileage of 53.1 ± 29.8 km) were allocated randomly in either an eight weeks training intervention in minimalist (=intervention) or cushioned running shoes (=control). The intervention consisted of a gradually increase of the new footwear (CF or MF) by 5% of weekly mileage per week. Before and after the intervention a VO₂max test and seven days apart a submaximal RE test at 70%, 80% and 90% of vVO₂max in both shoe conditions were conducted. Steady state oxygen consumption during the last of five minutes was captured and used to calculate the relative oxygen consumption per distance and bodyweight. A paired sample t test was used to determine differences between pre and post interventional RE values. **RESULTS:** The oxygen consumption of the intervention group showed a reduction in all tested conditions. The intervention group showed a statistically significant reduction from 222.4 to 217.5 mL·kg⁻¹·km⁻¹ (p=0.0479) for running in MF at 90% of vVO₂max. Interestingly, the VO₂ values were also reduced for the intervention group (training in MF) when running with CF at 80% (from 228.4 to 221.8 mL·kg⁻¹·km⁻¹, p=0.0186) and 90% (from 222.9 to 217.9 mL·kg⁻¹·km⁻¹, p=0.02) of vVO₂max. For all other stages and the control group (training in CF) no significant differences were observed. Five participants in the control and two participants in the intervention group did not finish the study (respectively one injury per group). **CONCLUSION:** In this study, transitioning to MF improved the RE for running in MF and in CF. Within the debate of pros and cons of (simulated) barefoot running, this adds evidence for improvements when transitioning gradually in small steps over 8 weeks to MF. Future research should investigate dose-response relationships and effects on running performance.

 (No relationships reported)

PURPOSE: It has been observed that sustained, steady-state, rock climbing elicits a mean oxygen consumption (VO₂) of 20-25ml·kg⁻¹·min⁻¹ and VO₂ remains elevated into the post-climb recovery period for as much as 10-min (1). To our knowledge, the extent of metabolic recovery time has not been examined following vigorous climbing activity. The purpose of this investigation was to compare excess post-exercise oxygen consumption (EPOC) following bouts of rock climbing at moderate intensity and vigorous intensity. **METHODS:** Ten experienced climbers (male=7, female=3, age: 24.5±5, height: 177.4±8.4cm, mass: 70±11.25kg) performed 15min of seated rest to obtain baseline VO₂ measures, followed by an indoor rock-wall climb at a self-regulated moderate pace for 10min while connected to the Cosmed k4b2 portable metabolic analyzer. Recovery VO₂ was recorded for 15min immediately following the climb. A climb of maximal effort was then conducted across the same distance covered in the steady-state climb and VO₂ was recorded for 15min immediately following the maximal climb. All testing was performed in the morning between 0600-1000h. EPOC duration and the magnitude were calculated for both climbs. A within-subjects dependent paired-samples t-test was used for data analysis (p≤0.05). **RESULTS:** Significance was observed for EPOC magnitude (steady-state = 65.93±25.32 mL O₂, maximal effort = 85.88±23.24 mL O₂, p=0.23). No significance

 (No relationships reported)

Both serum lipoprotein subclass pattern and cardiorespiratory fitness (CRF) are strong predictors of cardiovascular (CV) health in adults. By means of chemical measurements techniques and multicomponent data analysis more detailed descriptions of lipoprotein distributions can now be acquired. These sophisticated methods allow for a better understanding of how CRF impacts CV health through its association to lipoprotein pattern. **Purpose:** Determine the association between lipoprotein subclass pattern and CRF in prepubertal children by using a combination of sophisticated chemical measurements techniques and multicomponent data analysis. **Methods:** Serum concentrations of lipoprotein subclasses were quantified in 94 (64% boys) ethnic rural Norwegian 10-year-old children. Twenty-four lipoprotein features were used as input to multivariate regression analysis to investigate the underlying pattern describing CRF. CRF was measured in two ways: 1) directly by a peak oxygen consumption (VO_{2peak}) test using a continuous running to exhaustion treadmill protocol, 2) indirectly by the 10-minute Andersen intermittent field test. Predictive cross-validated multivariate regression models, including BMI and sex, were obtained for both CRF measures. **Results:** CRF correlated positively to average particle size for high-density lipoprotein (HDL) and its subclasses of large HDL particles and

negatively to triglycerides (TGs) and average size and concentration of very low-density lipoprotein (VLDL) particles and their subclasses of large particles. BMI was negatively correlated to both measures of CRF, but exhibited a stronger association with VO_{2peak} than to the Andersen test. **Conclusions:** Our data showed a strong association between CRF (both the VO_{2peak} -test and the Andersen-test) and lipoprotein pattern in prepubertal healthy children, and this adds to the understanding of CRFs as a good measure of children's CV health. Furthermore, the Andersen test showed even stronger association to children's lipoprotein pattern compared to the VO_{2peak} -test. This is encouraging as the Andersen-test is a practicable field test that involves only minimal equipment and has a low cost.

2277 Board #290 June 1 3:30 PM - 5:00 PM
The Effect of Continuous versus Intermittent Exercise on VO_2 Slow Component and Muscle Activation

Jakob D. Lauver¹, Timothy R. Rotarius², Barry W. Schuermann². ¹Adrian College, Adrian, MI. ²The University of Toledo, Toledo, OH.
 Email: jlauver@adrian.edu
 (No relationships reported)

During heavy exercise intensity exercise (above lactate threshold (LT)), a higher O_2 cost than predicted by VO_2 -work rate relationship for exercise below LT occurs which has been termed, the oxygen uptake (VO_2) slow component (VO_{2SC}). Interestingly, a decrease in the overall VO_2 response during heavy intensity intermittent versus continuous heavy intensity exercise has been previously reported. However, intermittent exercise results in less total work being performed and perhaps muscle activation, which may affect the amplitude of the VO_{2SC} . **Purpose:** To examine the magnitude of the VO_{2SC} and muscle activation in response to heavy intensity continuous (CON) and intermittent (INT) exercise when the same total work was performed. **Methods:** Four healthy males (27 ± 3 yrs, (±SD)) performed 2 bouts of CON and INT on separate days, each bout lasting 6 min at an intensity of 50% of the difference between peak VO_2 and LT ($\Delta 50\%$). In the INT condition, 3 s recovery periods (20 W) were inserted every 10 s for the last 3 min of exercise. The work rate (WR) for the INT protocol corresponded to an intensity (greater than $\Delta 50\%$) which resulted in the same total work (i.e. area under the work curve) performed in CON. Pulmonary VO_2 was recorded breath-by-breath, while muscle activation (vastus medialis (VM), vastus lateralis (VL)) was assessed by surface electromyography (EMG). **Results:** The phase II τVO_2 (CON: 24.6 ± 10.8 s; INT: 25.0 ± 4.5 s) and VO_{2SC} , as measured by $\Delta VO_{2(6-3)}$ (CON: 534 ± 159 mL/min; INT: 402 ± 117 mL/min) were similar ($p > 0.05$) between CON and INT. The change in EMG, as measured by $\Delta EMG_{(6-3)}$ for VM (CON: 1.95 ± 3.51 mV; INT: -4.16 ± 13.95 mV) and VL (CON: 4.45 ± 3.31 mV; INT: -2.05 ± 13.78 mV) was similar ($p > 0.05$) between CON and INT. However, since end exercise VO_2 was similar (CON: 3258 ± 648 mL/min; INT: 3239 ± 682 mL/min, $p > 0.05$) and absolute exercise WR was lower ($p < 0.05$) for CON (203 ± 56 W) than INT (262 ± 80 W), the VO_2 /WR relationship was higher ($p < 0.05$) for CON (16.0 ± 2.0 mL/min/W) compared to INT (12.8 ± 1.3 mL/min/W). **Conclusion:** While considerably different absolute WRs were necessary to achieve the same total work performed, the similar VO_{2SC} and muscle activation, but lower VO_2 /WR relationship for INT versus CON suggests that brief periods of recovery significantly alter the O_2 cost of heavy intensity exercise.

 (No relationships reported)

The mechanisms regulating O_2 delivery and utilization during endurance exercise differ with maturation and are incompletely understood. This is important to understand the development of cardiovascular and neuromuscular diseases that originate early in life. Time-resolved near-infrared spectroscopy (TRS-NIRS) provides a quantitative non-invasive measurement of deoxy-hemoglobin + myoglobin concentration ([HHb]) at the muscle, an indicator of muscle deoxygenation during exercise. **PURPOSE:** To compare [HHb] dynamics during incremental ramp exercise in healthy early pubertal children and young adults. **METHODS:** 23 early pubertal children (16 F; 7-11 years) and 15 young adults (7 F; 21-35 years) underwent an incremental ramp exercise test on a cycle ergometer. Pulmonary gas exchange was measured breath-by-breath (V_{max} , Carefusion). *Vastus lateralis* [HHb] was quantified by TRS-NIRS (TRS-21, Hamamatsu Photonics). **RESULTS:** Peak VO_2 was not different between children and adults normalized to body mass (46.7 ± 8.1 vs. 48.9 ± 7.7 mL/min/kg). Absolute [HHb] was not different

between children and adults during unloaded pedaling (23.5 ± 5.5 vs 26.8 ± 10.0 uM, $p = 0.20$) but adults had a higher peak exercise [HHb] (32.0 ± 8.2 vs 44.4 ± 22.6 uM, $p = 0.01$). Two way RM-ANOVA of relative HHb dynamics revealed an effect of age ($F(1,36) = 6.895$, $p = 0.013$) and interaction with % peak power ($p = 0.001$, Figure). Post-hoc, relative HHb was lower at 60% peak power in children vs adults (57 ± 10% vs 68 ± 13%, $p = 0.0006$), while VO_2 did not differ (33.5 ± 4.9% vs 30.6 ± 6.2%, $p = 0.12$). **CONCLUSION:** Muscle deoxygenation is both attenuated and delayed during incremental exercise in children compared to adults, despite similar relative VO_2 . This is consistent with a closer matching of muscle microvascular O_2 delivery to utilization over a greater range of aerobic power in children. The mechanisms contributing to this improved regulation of muscle blood flow during exercise in children warrant further study.

Effects of Bodyweight Exercise on Excess Post-exercise Oxygen Consumption and Metabolic Expenditure

Casey C. Curl, Melanie Lolmaugh, Marialice Kern, FACSM, Taylor R. Valentino, Kent A. Lorenz, James R. Bagley. San Francisco State University, San Francisco, CA. (Sponsor: Marialice Kern, FACSM)
 Email: ccurl@mail.sfsu.edu
 (No relationships reported)

Introduction: Body weight exercises (BWE; push-ups, squats, lunges) are popular modes of exercise, yet little is known regarding their effects on caloric expenditure. Classic hypertrophy training results in up to four-hour excess post-exercise oxygen consumption (EPOC) and elevated 24-hour resting metabolic rate (RMR). The purpose of this study was to determine if BWE 1) alters the length and amount of EPOC and 2) increases 24-hour RMR. **Methods:** Four healthy adult volunteers (3 males, 1 female; age: 22 ± 2y, height: 168 ± 11 cm, mass: 74.7 ± 18.6 kg, body fat: 27.8 ± 4.7%) consumed standard diets and underwent two RMR measures [pre- (morning) and post- (following morning) BWE]. Three hours following pre-RMR, participants completed a BWE bout [4 sets of push-ups (~9 reps), squats (~14 reps), and lunges (~14 reps)], followed by a 4 hour EPOC test. To standardize the work done participants performed 1-repetition maximum tests for bench-press and leg-press (to determine number of repetitions for BWE). **Results:** It was found that a bout of BWE elevated relative VO_2 (rVO_2 ; mL/kg/min) and energy expenditure post-exercise. When comparing pre-RMR to EPOC there was a significant difference at minute 15 in both rVO_2 ($p < 0.02$) and caloric expenditure ($p < 0.05$). Yet, there was no significant difference in both rVO_2 and caloric expenditure when pre-RMR and post-RMR were compared. **Conclusions:** As expected, we found that EPOC occurs after BWE, but is only elevated up to 30 minutes after exercise. This shows that BWE is an efficient and practical way to elevate metabolic rate, leading to increased caloric expenditure while potentially saving time and money. More participants are needed to fully understand the physiological implications of BWE related to caloric expenditure in healthy adults.

Effects Of Prolonged, Fatiguing Exercise On Critical Power: Reliability And Physiological Characterisation

Ida E. Clark¹, Andrew M. Jones, FACSM¹, Stephen J. Bailey¹, Brett S. Kirby², Brad W. Wilkins², Lee J. Wylie¹, Anni Vanhatalo, FACSM¹. ¹Exeter University, Exeter, United Kingdom. ²Nike Inc, Beaverton, OR. (Sponsor: Associate Professor Anni Vanhatalo, FACSM)
 Email: ic266@exeter.ac.uk
 (No relationships reported)

The critical power (CP) is an important parameter of aerobic fitness and a strong predictor of endurance performance. Establishing how prolonged, fatiguing exercise may influence the CP is important for accurate performance prediction. **PURPOSE:** To assess the reliability of the CP in a fatigued state established using a 3-min all-out

cycling test (3MT), and to assess the effects of fatigue on CP. **METHODS:** Subjects in Study 1 (n=6, 31 ± 6 yr, 76.8 ± 6.7 kg) and Study 2 (n=9, 29 ± 11 yr, 75.9 ± 7.1 kg) completed a ramp incremental test, a control 3MT test (C-3MT) and a 3MT immediately following 2 h of heavy-intensity constant work-rate (CWR) cycling (F-3MT). In Study 1 subjects performed the F-3MT condition twice. In Study 2 subjects completed 2 h of heavy exercise immediately followed by CWR exercise to exhaustion at 15 W above and below CP measured in F-3MT. Oxygen uptake (VO₂) and blood [lactate] were measured during all tests. **RESULTS:** In Study 1, CP estimates from repeated F-3MTs were not different (test 1: 273 ± 52 W vs test 2: 276 ± 58 W; *P* > 0.05), with an intraclass correlation coefficient of *r*=0.99 (*P*<0.05) and typical error of 5 W (2%). In Study 2, CP was lower in the F-3MT (282 ± 52 W) compared to C-3MT (306 ± 56 W; *P*<0.05). Four of nine subjects completed 30 min of exercise below F-3MT CP with sub-maximal steady state VO₂ and blood [lactate] profiles, whereas five subjects exhibited steady state VO₂ but non-steady state blood [lactate] and reached exhaustion in ~9-18 min. Subjects reached exhaustion in ~4-22 min when exercising above F-3MT CP. The VO₂peak and end-exercise blood [lactate] were not different between exercise bouts performed above (4.05 ± 0.41 L·min⁻¹) and below F-3MT CP (3.93 ± 0.50 L·min⁻¹) but the VO₂peak values were lower than the VO₂max in the ramp incremental test (4.33 ± 0.52 L·min⁻¹) (both *P*<0.05). **CONCLUSION:** The CP estimated in a 3-min all-out test evidenced high reliability in a fatigued state. We found that exercise in close proximity below the CP in the fatigued state was not sustainable beyond ~18 min and did not exhibit steady state blood [lactate] profiles. The VO₂ responses during exercise above and below CP were characterised by inability to attain the same VO₂max as in the rested state. These findings suggest that the well-characterised physiological definition of the CP is altered under conditions of extreme fatigue.

Priming Exercise Speeds VO₂ Kinetics and Increases Critical Power During Supine but not Upright Cycling
 Richie P. Gouilding, Denise M. Roche, Simon Marwood.
Liverpool Hope University, Liverpool, United Kingdom.
 Email: gouldir@hope.ac.uk
 (No relationships reported)

Critical power (CP) is a fundamental parameter in defining high-intensity exercise tolerance, however its physiological determinants are unclear. CP has been shown to correlate with the phase II time constant (τ) of oxygen uptake (VO₂) kinetics, however causative evidence confirming this effect is lacking. A prior bout of high-intensity "priming" exercise speeds τ in the supine, but not upright, position; therefore, if τ is causally related to CP priming exercise would be expected to increase CP in the supine but not upright position. **PURPOSE:** To determine the impact of priming exercise on τ and CP in the supine and upright body positions. **METHODS:** 16 healthy men were assigned to either upright or supine groups, and completed an incremental ramp test to determine VO₂ max and the gas exchange threshold. This was followed by 8 visits whereby CP, pulmonary VO₂ and muscle deoxyhaemoglobin ([HHb]); via near infrared spectroscopy) kinetics were determined via constant load exercise tests to exhaustion in two conditions: 1) without priming exercise (CON) and 2) following a bout of priming exercise at ~30%Δ. **RESULTS:** During supine exercise, priming exercise shortened τ (CON: 53 ± 17 vs. PRI: 31 ± 9 s; *P* < 0.001) and increased CP (CON: 177 ± 31 vs. PRI: 185 ± 30 W; *P* = 0.006) compared to control. However, priming exercise had no effect on τ (CON 35 ± 8 vs. PRI 37 ± 11 s; *P* = 0.82) or CP (CON: 235 ± 42 vs. PRI 232 ± 34 W; *P* = 0.57) during upright exercise. Priming exercise also resulted in a slowing of [HHb] kinetics during supine (CON: 8 ± 4 vs. PRI: 11 ± 4 s; *P* = 0.003) but not upright (CON: 10 ± 5 s vs. PRI: 14 ± 10; *P* = 0.10) position. **CONCLUSIONS:** The present study provides the first experimental evidence that VO₂ kinetics are an important determinant of CP. Specifically, priming exercise resulted in a concomitant speeding of VO₂ kinetics and increased CP in the supine position that was absent in the upright position. This was associated with a slowing of [HHb] kinetics in the supine position, suggesting that this effect might be mediated by increased O₂ availability.

Fatigability And Vo₂ On-kinetics In Adults With Incomplete Spinal Cord Injury
 Jared M. Gollie¹, Jeffrey E. Herrick¹, Randall E. Keyser, FACSM¹, John P. Collins¹, Richard K. Shields², Lisa MK Chin¹, Andrew A. Guccione¹. ¹George Mason University, Fairfax, VA. ²University of Iowa, Iowa City, IA.
 (No relationships reported)

It has been reported that, in people with spinal cord injury (SCI), prolonged VO₂ on-kinetics may contribute to fatigability and exercise intolerance. **Purpose:** Examine the relationship between fatigability and VO₂ on-kinetics in incomplete SCI (iSCI) during self-selected treadmill walking. **Methods:** Eight participants (age: 38.4 ± 17.8 years; gender: 7 male, 1 female; BMI: 25 ± 4.5 kg/m²) classified with iSCI C & D according to the American Spinal Injury Association Impairment Scale (AIS) and eight able-bodied participants (age: 34.6 ± 11.3 years; sex: 7 male, 1 female; BMI: 26 ± 4.2 kg/

m²) were enrolled in the study. Fatigability was calculated as the ratio of perceived fatigability and performance fatigability. Perceived fatigability was measured using a perceived fatigability scale while performance fatigability was determined during constant work-rate treadmill test to exhaustion or 30-minutes, whichever came first, at preferred walking speed. VO₂ on-kinetics was determined using a mono-exponential model in which a time constant (τ) and amplitude (AMP) was calculated during phase 2 of the biphasic kinetic response. Differences in fatigability and VO₂ on-kinetics between the groups were analyzed using Student's *t*-test. Pearson product correlation was used to determine the relationship between fatigability and VO₂ on-kinetics. Statistical significance was set at *p*<0.05 for two-tailed hypotheses. Values are expressed as means ± SD. **Results:** The iSCI group demonstrated greater fatigability compared to the able-bodied group (6.62 ± 4.86 vs 1.87 ± 0.98; *p*=0.017). Performance fatigability was also higher in the iSCI group compared to the able-bodied group (1153 ± 529 vs 1800 seconds; *p*=0.011). iSCI group had a significantly greater τ (41.2 ± 7.7 vs 23.3 ± 6.5; *p*<0.0001) with no difference in AMP between groups (613 ± 128 vs 745 ± 174 ml/min; *p*=0.106). Fatigability was significantly correlated with τ (*r*=0.56; *p*=.024). **Conclusion:** Individuals with iSCI in this study demonstrated higher levels of fatigability as determined by both perceived and performance fatigability, and prolonged VO₂ on-kinetics compared to able-bodied individuals. Furthermore, the observed relationship between fatigability and VO₂ on-kinetics suggest τ may be a biomarker of fatigability during treadmill walking in adults with iSCI.

Attenuation of the Oxygen Uptake Slow Component During Intermittent Compared to Continuous Heavy Intensity Exercise

Timothy R. Rotarius¹, Jakob D. Lauver², Barry W. Scheuermann¹. ¹University of Toledo, Toledo, OH. ²Adrian College, Adrian, MI.
 (No relationships reported)

During constant load exercise at intensities above the lactate threshold, an additional increase in oxygen uptake (VO₂) of delayed onset, termed the VO₂ slow component (VO₂SC), becomes readily apparent. Results of a previous study have shown a considerable decrease in the overall VO₂ response to high intensity exercise when the exercise bout is interrupted by intermittent periods of recovery. However, the extent that the addition of the brief recovery periods, which began at the onset of exercise, affected the magnitude of the VO₂SC remains unclear. **Purpose:** The purpose of this study was to examine the magnitude of the VO₂SC in response to heavy intensity continuous (CON) and intermittent (10 s work: 3 s recovery (INT)) exercise when the on-transition (i.e. phase II response) was altered by intermittent recovery periods. **Methods:** Five healthy males (27.0 ± 2.8 yrs, (±SD)) performed heavy intensity exercise, each bout lasting 6 minutes with 6 minutes of recovery, at an intensity of 50% of the difference between peak VO₂ and lactate threshold (Δ50%). To control for phase II kinetics, exercise was performed for 6 min for CON and the first 3 minutes for INT. In the INT condition, 3 s recovery intervals (20 W) were inserted every 10 s for the last 3 min of exercise. Pulmonary VO₂ and minute ventilation (V_E) were recorded breath-by-breath using a metabolic measurement system, while heart rate (HR) was recorded using a 3 lead electrocardiogram (ECG). Phase II VO₂ responses (time constant, τ VO₂) were analyzed using either a 2 or 3 component exponential model after interpolating to 1 s and ensemble averaging each trial. **Results:** The τ VO₂ was similar (CON: 30.3 ± 11.1 s; INT: 37.4 ± 14.9 s, *p*>0.05) as expected. The amplitude of VO₂SC, as measured by Δ VO₂₍₆₋₃₎ was decreased in the INT compared to the CON condition (-153 ± 216 mL/min vs. 522 ± 140 mL/min, *p*<0.05). Δ V_{E(6-3)} and Δ HR₍₆₋₃₎ were decreased in INT (-4.8 ± 11.8 L/min; -3 ± 7 bpm) compared to CON (18.4 ± 8.3 L/min; 15 ± 6 bpm), respectively (*p*<0.05). **Conclusion:** While phase II kinetics were similar between protocols, INT heavy intensity exercise led to a significant attenuation of the VO₂SC compared to CON exercise performed at the same WR. This may be due, at least in part, to a reduction in myocardial and respiratory work, as evidenced by the reduction in end exercise HR and V_E in the INT condition.

Prediction of Oxygen Uptake from Pedometer Output across Different Activities**

Poram Choi, Anthony T. Allred, Roland O. Webster, Ben R. Abadie, Agiovlasis Stamatis, FACSM. *Mississippi State University, Mississippi State, MS.* (Sponsor: Stamatis Agiovlasis, FACSM)
Email: pc839@msstate.edu
(No relationships reported)

Pedometers may be used to estimate participation in physical activity (PA) of moderate-to-vigorous intensity. Step rate thresholds for moderate-to-vigorous PA varying by height have been developed in research employing primarily locomotion activities. Whether pedometer output can accurately predict the energy cost across different locomotion, occupational, and household activities, and during sedentary behavior has not been thoroughly studied. **PURPOSE:** We examined if step rate and height predict the rate of oxygen uptake (VO_2) across different types of activities and sedentary behavior. Following development of a prediction model, we also evaluated its accuracy. **METHODS:** Participants were 36 healthy young adults (21 ± 4 yrs; 16 women). They completed 8 activities each lasting 6 min: (a) sitting; (b) level walk at 2.5 mph; (c) walk at 3.5 mph and 5% grade; (d) jog at 5 mph; (e) moving a box between 2 carts 7m apart; (f) washing dishes; (g) ascending and descending a 20-step staircase; and (h) vacuuming. We measured VO_2 with a portable open-circuit spirometer and step rate with a pedometer (NL-1000, New Lifestyles) worn on the non-dominant hip. We used multi-level regression to predict VO_2 , accounting for nesting of observations within participants. Possible predictors included step rate, step rate square, and height. Using VO_2 predicted from the model, we determined the absolute percent error across all activities combined and at each activity separately. Within-subject ANOVA was used to test differences in percent error across activities. **RESULTS:** Significant predictors of VO_2 were step rate and its square ($p \leq 0.001$; $R^2 = 0.72$), but not height. The prediction equation was $VO_2 = 7.6300 + 0.0872 \times \text{step rate} + 0.0004 \times \text{step rate}^2$. Absolute error across all activities combined was $29.4 \pm 27.3\%$. Absolute error differed between activities ($p < 0.001$): (a) sitting, $66 \pm 30\%$; (b) walk at 2.5 mph, $62 \pm 25\%$; (c) walk at 3.5 mph, $11 \pm 13\%$; (d) jog, $16 \pm 17\%$; (e) moving box, $15 \pm 14\%$; (f) washing dishes, $15 \pm 15\%$; (g) stairs, $22 \pm 8\%$; and (h) vacuuming, $29 \pm 13\%$. **CONCLUSION:** Pedometer-determined step rate and its square are significant predictors of VO_2 across different activities and sedentary behaviors in healthy young adults. Height does not contribute to VO_2 prediction. Accuracy of prediction across activities is low to moderate.

Zero Cadence as a Proxy Indicator of Sitting Behaviors in Objective Monitoring**

Ho Han, Elroy J. Aguiar, Scott Ducharme, Jongil Lim, Christopher Moore, Michael A. Busa, John R. Sirard, Stuart R. Chipkin, John Staudenmayer, Catrine Tudor-Locke, FACSM. *University of Massachusetts Amherst, Amherst, MA.*
Email: hohan@umass.edu
(No relationships reported)

Consistent evidence has been presented regarding the potentially deleterious health consequences of prolonged sitting time independent of physical activity level. Zero cadence (0 steps/min) determined using accelerometers may be a suitable proxy measure of sitting behaviors since theoretically no steps should be registered in this position. **PURPOSE:** The purpose of the current study was to determine the capability of accelerometer-determined zero cadence to predict seated activities of daily living. **METHODS:** A total of 80 young adults (mean age 29.8 ± 6.7 years), 10 men and 10 women representing each 5-year age-group category between 21-40 years (21-25, 26-30, 31-35, 36-40) performed lab-based simulated daily living activities (i.e., seated rest, watching a movie, computer work, folding laundry while standing, vacuuming, stair stepping and a self-paced over-ground walk) while concurrently wearing multiple ($n=7$) research-grade (e.g., ActiGraph, ActivPAL, ActiCal and StepWatch) and consumer-grade (e.g., Fitbit One and Vivofit2) accelerometers on manufacturer-indicated locations (i.e., hip, wrist, thigh or ankle). Receiver Operating Characteristic (ROC) analyses were conducted to examine the accuracy of zero cadence for classifying sitting behaviors (e.g., seated rest, watching a movie and computer work) among the performed activities. Sensitivity, specificity, accuracy and area under the ROC curve (AUC) values were compared for each device. **RESULTS:** All devices demonstrated the capability of using zero cadence to determine sitting activities with high combined sensitivity and specificity (e.g., ranges between 75-98%). AUC values

of all devices were above 0.8 ($p < .001$) indicating good or excellent discrimination ability of zero cadence. Vivofit2 and wrist-worn ActiGraph provided the highest (93%) and lowest (75%) accuracy, respectively. **CONCLUSION:** In agreement with zero cadence, both research- and consumer-grade activity monitors provided valid capacity for discriminating seated activities from common daily living activities. Based on this preliminary analysis it appears that accumulated time spent at zero cadence obtained by activity monitors can be used as a proxy indicator of time spent sitting. Effect of Wear Location on ActiGraph Activity Counts**

Samuel R. LaMunion, David R. Bassett, Jr., FACSM, Lindsay P. Toth, Scott E. Crouter, FACSM. *The University of Tennessee, Knoxville, TN.*
Email: slamunio@vols.utk.edu
(No relationships reported)

PURPOSE: Y-axis and vector magnitude (VM) counts of the ActiGraph accelerometer plateau at running speeds >10 km/hr, when worn on the hip. However, it is not known if counts plateau at other wear locations. This study examined if activity counts plateau with increasing running speed at alternative wear locations (wrist and ankle). **METHODS:** Participants ($N=20$) completed ten treadmill walking and running speeds (3-20 km/hr) for 30-s each with 30-s rest between speeds. Speeds 3-7 km/hr were walking and speeds 8-20 km/hr were running. An ActiGraph GT3X+ was worn on the right hip, both wrists, and both ankles. Acceleration data for y-axis and VM were converted to 5-s epochs. Mean counts (5 to 25-s) were used for analysis of each speed condition. Repeated measures ANOVAs were used to examine effect of speed on y-axis and VM activity counts for each wear location. Pair-wise comparisons with Bonferroni adjustments were performed to determine where differences occurred. A plateau was defined as no significant increase in counts with an increase in speed when running. Correlation analysis was used to assess the association between counts and speed. **RESULTS:** Hip y-axis and VM counts increased significantly up to 10 km/hr and significantly decreased at speeds above 16 km/hr. For the wrists and ankles, significant increases in counts were seen for y-axis across all running speeds and VM across all speeds. The table shows counts/5-s for y-axis and VM at each location and speed. Asterisks indicate no significant increase in counts from the previous speed ($P > 0.05$).

	Speed (km/hr)										R ²	
	3	5	7	8	10	12	14	16	18	20		
Hip												
Y-axis	94	268	417	662	728	735*	707*	664*	604*	544*	0.43	
VM	185	328	484	698	769	783*	761*	731*	690*	658*	0.53	
Wrist												
Left y-axis	196	315	414*	1166	1388	1631	1888	2110	2439	2740	0.97	
Right y-axis	199	293	395*	1253	1535	1791	2045	2260	2618	2906	0.96	
Left VM	279	445	692	1604	1813	2068	2317	2524	2867	3197	0.95	
Right VM	288	433	720	1702	1982	2262	2505	2711	3087	3383	0.95	
Ankle												
Left y-axis	393	559	603	392*	618	861	1062	1259	1432	1673	0.92	
Right y-axis	469	637	699	472*	687	943	1162	1132	1411	1640	0.92	
Left VM	550	1037	1627	1959	2444	2911	3308	3673	4007	4242	0.98	
Right VM	672	1143	1714	2050	2555	3069	3510	3906	4071	4419	0.98	

CONCLUSION: When the ActiGraph is worn on the wrist or ankle the y-axis and VM counts do not plateau as is seen with the hip location. The wrist and ankle wear locations result in a stronger linear relationship between speed and counts than the hip does.

Email: johnmarq@uwec.edu
(No relationships reported)

The StepWatch 3 ankle-mounted pedometer has been used to capture free-living ambulatory activity in published research, however, this device does not accurately count running steps. It is unclear from published literature if device setting impacts the accuracy of counting running steps. **PURPOSE:** To examine the step count accuracy of the StepWatch 3 at various running speeds by altering device settings. **METHODS:** Thirty participants aged 21.32 ± 3.72 participated in the study. Participants completed

THURSDAY, JUNE 1, 2017

4-minute trials of treadmill ambulation at 6 different speeds ranging from 2.24 to 3.35 m·s⁻¹ while wearing one device on the lateral aspect of each ankle, directly above each malleolus for a total of 2 devices overall. Each device was programmed using either the “default” setting or “Quick Step” setting. A counterbalanced design was used to minimize order effect. Direct observation was used as the criterion of step count (total steps/trial). One-way repeated measures ANOVAs were used to determine differences between step count estimates from devices/settings at the ankle compared to criterion. ANCOVAs were used to determine the impact of stride length and cadence on device determined step counts. Mean absolute percent error (MAPE) was also determined for all running speeds. **RESULTS:** StepWatch determined steps were significantly different from criterion for all speeds regardless of device setting ($p < .05$), with the exception of device “Quick Step” setting at 2.24 m·s⁻¹ ($p = .18$) and MAPE was $< 3\%$ (1.9). MAPE values for the default setting were $\geq 24.4\%$ for all treadmill speeds. The remaining MAPE values for the “Quick Step” setting were $\geq 4.9\%$ for treadmill speeds beginning at 2.46 m·s⁻¹. When stride length was considered, StepWatch determined steps were not statistically different from criterion for all speeds regardless of device setting. **CONCLUSION:** StepWatch default and “Quick Step” settings do not accurately report steps at ambulatory speeds ≥ 2.24 m·s⁻¹, with the exception of device “Quick Step” setting at 2.24 m·s⁻¹. After accounting for stride length, device output accurately reported steps regardless of device setting and treadmill ambulation speed. Further research is needed to explore the advanced setting features of the StepWatch with a goal of improving accuracy.

 (No relationships reported)

The time-stamped sampling nature of accelerometry-based wearable technologies allows minute-by-minute study of step accumulation, and specifically cadence (steps/min). **PURPOSE:** Considering cadence has been strongly correlated with absolute intensity defined using metabolic equivalents or METs (e.g., 3 METs=moderate intensity and 6 METs=vigorous intensity), the purpose of this study was to identify objectively observed, manually counted cadence criterion cut points that can inform heuristic (i.e., reasonably acceptable or guiding) values associated with 3 and 6 METs. **METHODS:** Ten men and 10 women representing each 5-year age-group category between 21-40 years (21-25, 26-30, 31-35, 36-40) for a total of 80 adults (mean age 29.75±6.7 years; BMI 24.76±3.4 kg/m²) participated in a lab-based study of videotaped cadence and oxygen consumption (indirect calorimetry). Data were collected during a series of 5-min treadmill bouts (starting at 0.5 and increasing up to 6 mph in 0.5 mph increments) as tolerated, until running occurred, or until reaching 75% of maximum heart rate or a rating of perceived exertion (RPE) > 13 . MET level was calculated by dividing steady state VO₂ by resting (seated) energy expenditure (both expressed in ml/kg/min). **RESULTS:** Two distinct areas of linearity emerged from the cadence versus METs data and a bilinear or ‘hockey stick’ model was subsequently applied to ascertain 3 and 6 MET cut points. Cadence accounted for 78% of the variance (least-squares bilinear regression model) in intensity with the bilinear break point apparent at 103 steps/min. The cadence cut point (95% Prediction Intervals; broader than more conventional Confidence Intervals) for 3 METs was 104.2 (34.8-113.7) steps/min and for 6 METs was 131.4 (120.5-140.9) steps/min. **CONCLUSIONS:** Heuristic values are practical, guiding, rounded quantities which may be imprecise but serve effectively to convey generalized and reasonably accurate information. We confirmed previous speculation that, despite individual variability, 100 steps/min can serve as a reasonable heuristic value indicative of moderate intensity in this age group. Further, 130 steps/min appears to be a similarly useful indicator of vigorous intensity ambulatory movement. NIH/NIA Grant 5R01AG049024-03 - CADENCE-Adults study.

 (No relationships reported)

Accelerometer-based physical activity monitors (AMs) and their associated prediction models are often validated in structured settings, but it is unclear if including AM data from less structured settings improves AM accuracy for free-living energy expenditure (EE) prediction.

PURPOSE: This study compared the accuracy of machine learning models developed to predict EE from AM data collected in structured and semi-structured settings. **METHODS:** Twenty-four adults (age 45.8±19.4 y, 50% female) completed two sessions, performing 11-21 activities over 80-90 min protocols while wearing four AMs (right hip, ankle, and both wrists) and a portable metabolic system (EE criterion). Session 1 (V1, structured setting) involved performing 3 sedentary, 4 household, and 4 ambulatory activities for 5 min each, with activities selected by the research staff. Session 2 (V2, semi-structured setting) involved performing ≥ 4 sedentary, ≥ 4 household, and ≥ 4 ambulatory activities, with activity type, order, and duration chosen by participants. Artificial neural network EE prediction models were developed for each AM via a leave-one-out approach using three training methods, incorporating data from either one training setting (V1 or V2) or both settings (V1/V2). Model accuracy (r² and root mean square error [RMSE]) for EE prediction was evaluated in the semi-structured setting. Repeated measures ANOVA was used to assess differences in prediction accuracy among training methods.

RESULTS: The V1, V2, and V1/V2 training methods had r² ranging from 0.58-0.68, 0.55-0.70, and 0.60-0.72, respectively. The r² value for the V1 training method was significantly higher than the V2 method for the left wrist AM, and the r² values for the V1/V2 method were significantly higher than the other training methods for the hip and left wrist AMs ($p < 0.05$). No differences were found among training methods for RMSE (1.17-1.28, 1.10-1.34, and 1.04-1.23 METs for V1, V2, and V1/V2 methods, respectively).

CONCLUSIONS: Developing prediction models using data from both structured and semi-structured data settings in a small improvement in EE prediction accuracy for particular monitor placements compared to using data from a single setting and should be considered when developing EE prediction models for AMs.

Physical Activity Assessment in African Americans: Modified International Physical Activity Questionnaire vs. Objective Measurement

Amanda A. Price¹, Melicia C. Whitt-Glover, FACSM², Tyrone Ceaser³. ¹Winston-Salem State University, Winston-Salem, NC. ²Gramercy Research Group, Winston-Salem, NC. ³Winthrop University, Rock Hill, SC.
 Email: priceaa@wssu.edu
 (No relationships reported)

Physical activity (PA) assessment is critical for understanding PA levels. Self-report tools are useful but can be inaccurate. **PURPOSE:** To determine: 1) reliability/validity of the 7-item Modified International Physical Activity Questionnaire (MIPAQ) compared to objective measurement in African Americans and, 2) the effect of a 10-minute bout of moderate-intensity PA prior to survey administration on response accuracy.

METHODS: Participants (N=91; 55 male, 33 female; aged 46.5 ± 12.6 years) were randomized to: 1) complete the MIPAQ only or 2) complete the MIPAQ after a 10-minute PA bout. Following the survey, participants wore a pedometer and accelerometer for seven days. Upon return, a random sample of participants completed the MIPAQ a second time for test-retest reliability, computed by Chronbach's alphas. Spearman's rank-order correlations compared objective and self-report PA measures. **RESULTS:** Walking PA ($r = .3$, $p < .01$) and Total PA ($r = .28$, $p < .01$) were correlated with the accelerometer PA. Among those who performed a pre-MIPAQ PA bout, Walking PA and Total PA were significantly correlated with the accelerometer ($r = .43$ and $.31$, respectively) and pedometer ($r = .33$ and $.37$, respectively). Associations remained significant in overweight participants. Chronbach's alphas ranged from $.88$ -. $.94$, indicating high survey reliability. **CONCLUSIONS:** The MIPAQ is a valid and reliable measure of PA in African Americans. Adding a brief period of activity prior to survey completion may increase reporting accuracy. Research supported by Award Number R01HL094580.

 (No relationships reported)

Physical activity decreases the risk of chronic disease, while sedentary behavior increases this risk. Questionnaires are an easy, inexpensive way to quantify sedentary behavior. However, there tends to be error with self-report. **PURPOSE:** To compare time in sedentary behaviors assessed via activity monitor (objective) with sedentary time assessed by self-report (subjective). **METHODS:** Office staff and administrators with a sedentary job description at a University were recruited. The activPAL3 activity monitor was placed on the participants' ($n=44$) thigh and worn continuously for seven days. Participants completed the Occupational Sitting Questionnaire (OSPAQ) and Paffenbarger Physical Activity Questionnaire (PPAQ) for the timeframe that the activPAL3 was worn. Data were expressed in total time (hrs/day) spent sedentary over a typical work week. A Pearson Product Correlation was utilized to examine the relationship between the subjective sedentary time at work (OSPAQ) and over a 24hr period (PPAQ) and objective (activPAL3) sedentary time. The agreement between the objective and subjective assessments was evaluated using a Bland-Altman analysis. Differences between objective and subjective scores for each individual were calculated and the mean error was determined. **RESULTS:** Participants were predominantly Caucasian (95%), middle-aged ($48 \text{ y} + 10$), and had an average BMI ($30.5 + 8.2$). A positive, weak correlation between sedentary time assessed subjectively from the OSPAQ ($r = .100$; $p = .518$) and PPAQ ($r = .317$; $p = .036$), and objectively by the activPAL3 activity monitor was found. The mean error of the sedentary time estimated during the workday was approximately one hour ($1.07 + 1.02$) and approximately four hours ($3.52 + 2.31$) for the entire day, with most participants underestimating sedentary time. The Bland Altman analysis found no systematic bias in the OSPAQ ($p = .743$), while a trend of proportional underestimation bias in the PPAQ ($p = .001$) was found relative to the activPAL3 measures. **CONCLUSION:** Self-reported sedentary time subjectively assessed by the PPAQ and OSPAQ was weakly correlated to sedentary time objectively assessed by the activPAL3 activity monitor over a 24 hour period and while at work. The lack of a relation demonstrated substantial error in self-reported assessment.

 (No relationships reported)

Advancements in physical activity measurement now afford researchers the capacity to measure proximity between accelerometers using Bluetooth low energy hardware. However, further research is needed to interpret the available proximity data to estimate distances from devices, which provide radio propagation measurements between accelerometers. **Purpose:** To estimate metered distances in indoor and outdoor environments from accelerometer-derived proximity data, and 2) compare the predictive accuracy of machine learning models in estimating distance. **Methods:** The study was two-phased: 1) calibration and 2) simulation. During calibration, received signal strength indicator (RSSI) data were collected from stationary accelerometers within indoor and outdoor environments at metered intervals (1m to 10m) in a major urban center. Observations of distances between devices (i.e., "ground truth") were recorded by the researchers, and approximately $N = 2,000$ observations were recorded in each respective environment. Calibration results were used to simulate free-living proximity data as a Markov chain for indoor (1m to 20m) and outdoor (1m to 50m) ranges. Using $N = 10,000$ simulated indoor and outdoor proximity data cases, respectively, distance was estimated under measurement conditions wherein 1) calibration data are available and 2) calibration data are unavailable and are therefore estimated from RSSI. Three competing machine learning models were used to predict distances for both conditions, and cross-validated Root Mean Squared Error was calculated and reported in meters (ranges). **Results:** The regression tree model (RT) had the lowest error for indoor 1.65m and outdoor 1.35m calibration data. Using measured calibration data, RT had the lowest error for simulated indoor (2.9m to 3.8m) and outdoor data (7.5m to 11.8m). With estimated calibration data, RT showed errors of 4.0m and 11.1m for simulated indoor and outdoor data, respectively. **Conclusions:** A regression tree model estimated distances from simulated indoor and outdoor accelerometer-derived proximity data with the lowest error; however, error in the outdoor range was large. Researchers collecting proximity data via accelerometry can estimate metered distances from radio signals propagated between accelerometers.

Within-person Reliability Of Step-rate Cut-offs For Physical Activity Intensity
 Anthony T. Allred, Poram Choi, Roland O. Webster, Ben
 R. Abadie, Stamatis Agiovlasis, FACSM. *Mississippi
 State University, Mississippi State, MS.* (Sponsor: Stamatis
 Agiovlasis, FACSM)
 Email: ata54@msstate.edu
 (No relationships reported)

The intensity of physical activity (PA) can be monitored with pedometers. Step-rate cut-offs for PA intensity are developed from the relationship between oxygen uptake (VO_2) and step-rate. This is based on the assumption that the relationship between VO_2 and step-rate across different activities is stable within people, but this has not been evaluated. **PURPOSE:** To examine if the relationship between VO_2 and step-rate, and the cut-offs for moderate- and vigorous-intensity PA based on step-rate are reliable within people. **METHODS:** Thirty six healthy persons (21 ± 4 yrs; 16 women and 20 men) completed two sessions with identical procedures within 7 days. VO_2 was measured with open-circuit spirometry and step rate with a pedometer (NL-1000, New Lifestyles) placed on the non-dominant hip during sitting and seven activities: walking at 2 intensities, jogging, ascending and descending a staircase, washing dishes, vacuuming, and moving a box. Using individual linear regressions of VO_2 against step rate for each participant, we determined 5 variables: the slope, intercept, and R^2 of the relationship between VO_2 and step-rate, and the cut-offs for moderate- and vigorous-intensity activity defined as step-rate at 3 and 6 Metabolic Equivalent units, respectively. We evaluated differences in these variables between sessions with paired t-tests, Intra-class Correlation Coefficients (ICCs; 2-way random model with absolute agreement), and Bland-Altman plots. **RESULTS:** There were no significant mean differences between sessions in any of the dependent variables ($p > 0.05$). All ICCs were significant ($p \leq 0.023$). ICC was strong for the slope (0.80), but moderate-to-low for the intercept, R^2 , and the moderate- and vigorous-intensity cut-offs (0.76, 0.58, 0.57, and 0.50, respectively). Bland-Altman plots showed nearly-zero mean error. The plots also showed that the variation in the difference between sessions was relatively small for the moderate-intensity cut-off (95% CI: -24 to 24 steps \cdot min $^{-1}$), but wider for the vigorous-intensity cut-off (95% CI: -48 to 49 steps \cdot min $^{-1}$). **CONCLUSION:** The relationship between VO_2 and step-rate, and the cut-offs for moderate- and vigorous-intensity PA are moderately reliable within people. Calibration procedures should advance for better prediction of PA intensity from pedometer data.

Correlations between Objective and Subjective Instruments on the Measurement of Energy Expenditure in Older Adults
 Wanyi Wang, Mindy P. Maziarz, Alexis Ortiz, FACSM. *Texas
 Woman's University, Houston, TX.* (Sponsor: Alexis Ortiz,
 FACSM)
 Email: wwang@twu.edu
 (No relationships reported)

PURPOSE: Many objective and subjective instruments have been developed to estimate energy expenditure (EE). However, the validity and correlations on these measurements are lacking especially in the older adult population. American Association of Retired Persons (AARP) questionnaire and Community Healthy Activities Model Program for Seniors (CHAMPS) questionnaire are common self-reported questionnaires. The purpose of the study was to examine which self-reported physical activity instruments correlated with objective data from ActiGraph accelerometers and fitness tests. We also compared outcomes from the above instruments with total EE (TEE) measured by the gold standard of doubly labeled water (DLW).

METHODS: Data sets were obtained from the Interactive Diet and Activity Tracking in AARP (IDATA) study through the National Cancer Institute. A total of 681 participants aged between 50-74 years were included in the analysis. The outcomes of our interest from each instrument were as follows: total number of steps and EE from ActiGraph, VO_2 max from fitness test, activity EE (AEE) from CHAMPS and AARP, and TEE from DLW. Pearson's correlations were conducted to examine the relationships between objective and subjective measures.

RESULTS: The results showed that AEE from AARP was moderately significantly associated with VO_2 max ($r = .348$) and EE from ActiGraph ($r = .365$). A weak but significantly positive relationship was also observed between AEE from AARP and steps from ActiGraph ($r = .136$). However, AEE from CHAMPS was only related to steps from ActiGraph ($r = .172$). No significant correlations were found between AEE from CHAMPS and the other objective measures. Each instrument was also compared to DLW. The strongest positive relationships with TEE from DLW were seen in EE from ActiGraph ($r = .484$) and VO_2 max ($r = .474$). However, there was no significant association between AEE from CHAMPS and TEE from DLW, $p > .05$.

CONCLUSIONS: AEE from AARP appears to be the subjective instrument most positively associated with the objective instruments in older adults. Of all subjective

Denver, Colorado

and objective instruments, objective measures may estimate TEE more accurately than the subjective instruments. AEE from CHAMPS performed the worst estimate on TEE and was least likely to be related to the objective instruments.

Improved Count Based Metrics For Estimation Of Energy Expenditure With Waist Worn Actigraph

Andrew S. Kaplan, Samuel R. LaMunion, David R. Bassett, Jr., FACSM, Scott E. Crouter, FACSM. *University of Tennessee-Knoxville, Knoxville, TN.*

(No relationships reported)

Traditional methods for analyzing accelerometer activity counts rely on the assumption that there is a linear relationship between counts and increasing energy expenditure. However, this relationship varies depending on the type of activity being performed and intermittent activities can have a 2-3 fold higher energy cost than walking and running at the same count level. **PURPOSE:** This study explored the effects of using the 75th percentile of counts to characterize the relationship between counts and energy expenditure (EE) in an effort to make walking/running counts more comparable to counts from intermittent activities. **METHODS:** Twenty-nine participants completed ten lifestyle activities ranging from sedentary behaviors to vigorous intensities for seven minutes each. Participants wore an ActiGraph GT9X on the right hip. A Cosmed K4b² was used as the criterion measure of EE. Acceleration data was converted to 5-s epochs. Oxygen consumption data from the Cosmed was averaged over 30-s and converted to metabolic equivalents (METs) for each activity (1 MET = 3.5 ml/kg/min). Mean counts and 75th percentile of the 5-s counts for y-axis and vector magnitude (VM) were calculated using the middle 4-min from each activity bout. The relationship between activity counts and METs was summarized using R² values. **RESULTS:** Across all activities, the y-axis mean counts and METs had a R² of 0.789, which was improved to a R² = 0.835 when using the 75th percentile of the y-axis counts. For the VM mean and 75th percentile count metrics, the R² was 0.871 and 0.875, respectively. **CONCLUSIONS:** The relationship between EE and y-axis counts can be improved using the 75th percentile of the counts. However, both VM count metrics had a stronger relationship to EE than their y-axis counterparts. This new count metric may provide an alternative for those utilizing data collected with older single axis accelerometers.

The Relationship Between Walking Cadence and Percentage of Maximum Heart Rate

Elroy J. Aguiar, Scott W. Ducharme, Ho Han, Jongil Lim, Christopher Moore, Michael A. Busa, John R. Sirard, Stuart R. Chipkin, John Staudenmayer, Catrine Tudor-Locke, FACSM. *University of Massachusetts Amherst, Amherst, MA.*

Email: eaguiar@umass.edu

(No relationships reported)

Previous studies report that walking cadence (steps/min) is strongly correlated with intensity measured using indirect calorimetry. **PURPOSE:** The aims of this study were: 1) to investigate the relationship between cadence and percentage of maximum heart rate (%HRmax), an often used proxy-measure of intensity; and 2) to specifically identify cadence cut points associated with ACSM defined %HRmax thresholds for moderate and vigorous intensity. **METHODS:** Ten men and 10 women representing each 5-year age-group category between 21-40 years (total n=80; mean [±SD] age 29.8±6.7 years; BMI 24.8±3.4 kg/m²) were recruited. Participants completed a treadmill walking test comprised of 5-min bouts at incrementally faster speeds from 0.5 to 6 mph, with a 2-min rest between bouts. The test was terminated at the completion of the 5-min bout during which the participant began to run, achieved >75% HRmax, or reported a Borg rating of perceived exertion >13. Cadence was visually observed (steps per bout / 5 min) and heart rate (HR) was measured using a chest-worn monitor during all bouts (average of final 2-min). HRmax was estimated using the standard equation: 220 - age. Based on the data, a bilinear regression model with random effects to account for repeated measures was applied. Cadence cut points associated with moderate (64% of estimated HRmax) and vigorous (77% of estimated HRmax) intensity were calculated using the regression model. **RESULTS:** Over half of the variance in %HRmax was explained by cadence (i.e., R²=0.54, least-squares bilinear regression model) with the bilinear break point at 103 steps/min. Cadence cut points (95% prediction intervals) for 64% and 77% of estimated HRmax were 128.6 (106.9-149.04) and 146.3 (124.6-164) steps/min, respectively. **CONCLUSION:** Cadence explained over half of the variance in %HRmax, with ~130 steps/min and ~145 steps/min representing reasonable heuristic (i.e., guiding) values for moderate and vigorous intensity, respectively. Further analysis is warranted investigating the cadences associated with moderate and vigorous intensity defined by percentage of HR reserve. This may account for some of the inter-individual variability in resting HR and HR response, thereby strengthening the relationship observed. Supported by NIH/NIA Grant 5R01AG049024-03 - CADENCE-Adults study

Identifying Physical Activity Type using Wrist Models Constructed for High-frequency Accelerometer Data

Matin Kheirkhahan, Amal Asiri Wanigatunga, Duane Benjamin Corbett, Vincenzo Valiani, Sanjay Ranka, Todd Matthew Manini, FACSM. *University of Florida, Gainesville, FL.* (Sponsor: Todd Matthew Manini, FACSM)

Email: matinkheirkhahan@ufl.edu

(No relationships reported)

Accelerometer-based measurements have played an important role in assessing physical activity (PA). Hip-worn accelerometer data is the most validated based on current literature, but wrist-worn accelerometer has greater user acceptability. There is an emerging focus to understand the data from wrist-worn accelerometers to assess PA but data is still lacking.

PURPOSE: To investigate the capability of the wrist-worn accelerometer to identify sedentary behavior, levels of activity intensities, and locomotion.

METHODS: This study evaluated 25 adults (n = 14 females, mean age = 33.8 years, mean BMI = 26.4 kg/m²) who performed 34 simulated tasks of sedentary (e.g., computer work) and locomotion (e.g., self-paced walk). Data were collected using a 100 Hz tri-axial wrist-worn accelerometer. Energy expenditure was measured in parallel using a portable calorimetry system. Constructed features included time and frequency domain variables, such as vector magnitude (VM) and its angle with the vertical axis, dominant frequency (DF), fractions of power by DF and human movement frequencies (i.e., 0.6 - 2.5Hz). Regression and classification methods were used to estimate metabolic equivalent score (METs) and detect sedentary behaviors, locomotion tasks, and intensities of activity.

RESULTS: The time and frequency features were capable of estimating METs (rMSE = 1.2 METs), activity intensity (accuracy > 80%), sedentary behavior (accuracy > 94%), and locomotion (accuracy > 92%). All features were found significantly different (p < 0.05) between groups of tasks. However, sedentary and locomotion tasks could be distinguished using as few as two features. With little variation in VM (< 0.06 m/s²) and the angle between VM and the vertical axis (< 7 degrees), sedentary tasks were distinguished versus other tasks (accuracy = 92%). Locomotion tasks could also be detected (accuracy = 90%) by examining DF (< 1.6 Hz) and its fraction of power (< 0.05).

CONCLUSION: Time and frequency domain features defined for wrist accelerometer data can detect sedentary activity with 94% accuracy. Further, locomotion within activity can be identified with 92% accuracy. Future work will require evaluations during free-living conditions to confirm the accuracy.

Development and Validation of Universal Step Detection Threshold for Raw Accelerometer Data

Jongil Lim, Ho Han, Elroy J. Aguiar, Michael A. Busa, Scott Ducharme, Christopher Moore, Stuart R. Chipkin, John Staudenmayer, Catrine Tudor-Locke, FACSM. *University of Massachusetts Amherst, Amherst, MA.*

(No relationships reported)

PURPOSE: To develop a universal and computationally inexpensive algorithm for accurately detecting steps from GENEActiv raw acceleration data relative to the criterion measure of directly observed steps and improve on the accuracy of ActiGraph's proprietary step-counting algorithm. **METHODS:** A total of 80 young adults (mean age = 29.8±6.7 years, BMI = 24.76±3.4 kg/m²) performed 5-min bouts of 7-lab based simulated activities of daily living and treadmill walking (beginning at 0.5 and increasing up to 6 mph in 0.5 mph increments). GENEActiv and ActiGraph GT9X accelerometers were worn concurrently on the right anterior-axillary line. For ActiGraph, step counts detected in 1-s epochs using the manufacturer's default and proprietary algorithm were summed over the duration of each 5-min bout of activity. Raw accelerometer data from the GENEActiv's Y-axis (which captures vertical motion) was filtered using a band-pass filter (cut-off frequency of 0.25 and 2.5 Hz) and de-trended to the mean. All peaks greater than zero gravity were detected for each activity in a subsample (n=40, gender and age balanced) and used to 'train' the threshold. The threshold was developed by identifying the median of the peaks detected in the training dataset; which was then tested on the remaining sample (n=40). Mann-Whitney U nonparametric tests were used to compare mean step counts obtained from the ActiGraph, GENEActiv, and observed criterion in each activity. **RESULTS:** The threshold obtained from the training dataset (i.e., 0.0318 g) corresponded with 0.5 mph treadmill walking in 80% of the testing dataset. ActiGraph and GENEActiv step counts at treadmill speeds ≥ 2.5 mph did not differ, nor were they different than the criterion measure. The application of the thresholding technique to GENEActiv testing dataset resulted in significant improvements in step detection in both simulated activities of daily living and walking at slow speeds (0.5 ~ 2 mph)

(all $p < .05$) compared to the ActiGraph's proprietary algorithm. **CONCLUSIONS:** An approximate threshold based on the median amplitude of the acceleration peaks detected across a range of activities could serve as a universal data treatment technique to detect steps from raw accelerometer data with improved accuracy relative to the ActiGraph's proprietary algorithm.

Self-Reported Fitness and Objectively Measured Physical Activity among Older Adults

Katja Waller¹, Henri Vähä-Ypyä², Noora Lindgren³, Jaakko Kaprio⁴, Harri Sievänen², Urho M. Kujala¹. ¹University of Jyväskylä, Jyväskylä, Finland. ²UKK Institute, Tampere, Finland. ³PET Centre, Turku, Finland. ⁴Institute for Molecular Medicine Finland, Helsinki, Finland.
 Email: katja.waller@jyu.fi
 (No relationships reported)

PURPOSE: To study the relationship between self-reported fitness and objectively measured physical activity and sedentary behavior among elderly. **METHODS:** The study is based on the older Finnish Twin Cohort. All same-sex twin pairs born 1940-1944 with both co-twins alive were invited to participate in the study. They first participated in a telephone interview followed by an objective activity monitoring (a hip-worn triaxial accelerometer, Hookie AM20) and activity related questionnaire. By end of 2015, altogether 406 individuals (mean age 74 years, 209 male and 197 female) had used accelerometer for at least four days and had answered a following question on perceived fitness: "Is your current physical fitness in your opinion; 1) Very good 2) Fairly good 3) Satisfactory 4) Fairly poor 5) Very poor. Groups four and five were combined for the analyses. In this study twins were studied as individuals. Analysis was done using linear regression and Sidak post-hoc test was used to analyses differences between fitness groups.

RESULTS: According to preliminary data, self-reported fitness explained moderately different objectively measured activities as R-squared for daily steps was 29% ($p < 0.001$), for overall daily MET 29% ($p < 0.001$) and sitting down 32% ($p < 0.001$). Better self-reported fitness was associated with more steps taken an average each day (8 545 steps (most fit) vs. 3 168 steps (poor fitness), $p < 0.05$), more light (1.5-3 MET: 3.3 h/day vs. 2.1 hours/day, $p < 0.05$), moderate (3-6 MET, 0.93 h/day vs 0.28 h/day, $p < 0.05$) and vigorous (> 6 MET, 3.6 min/day vs. 0.005 min/day, $p < 0.05$) activity compared to subjects who reported poor fitness when the model was adjusted with accelerometer wear time, age, BMI and movement restricting injury. Better self-reported fitness was also associated with less sitting (7.3 h/day (most fit) vs. 8.1 h/day (poor fitness) $p < 0.05$). **CONCLUSION:** These preliminary results show that self-reported fitness is associated with objectively measured daily activity profile among elderly. Most differences were seen in variables describing activity, but also some differences were seen even in sitting down. Among elderly subjects who perceive themselves as having poor fitness, it would be important to find factors associated with low mobility and try to find ways to improve them.

Validation of a Biometric Smart Shirt for Assessment of Physical Activity

Joe R. Mitrzyk, Monroe J. Molesky, Alexander H.K. Montoye.
 Alma College, Alma, MI.
 (No relationships reported)

Smart shirts are embedded with sensors to collect physiologic data (e.g., heart rate and breathing rate/volume) and an accelerometer to assess kilocalories (kcal) and steps. However, little is known about measurement accuracy of smart shirts. **PURPOSE:** The purpose of this study was to validate a smart shirt for assessment of physiologic and physical activity variables.

METHODS: Participants ($n=32$) aged 18-51 years wore a smart shirt and performed 15 total activities, 12 in the laboratory and 3 on a 200-m indoor track. Lab activities were performed for 5 min each and included lying, sitting, standing, walking at various speeds (2.0, 3.0, 3.5-4.0 miles*hr⁻¹) and inclines (0%, 5%, 10%), jogging, and cycling. Track activities included self-paced walking (200 m, 2 speeds) and jogging (400 m). Steps, kcal, heart rate, and breathing rate and volume from the smart shirt were compared to criterion measures (metabolic analyzer for kcal and breathing rate/volume, pedometer for steps, and pulse oximeter for heart rate). Percent (%) errors were calculated between smart shirt estimates and criterion-measured variables. A threshold of 10% was used for low ($\leq 10\%$) vs. high ($> 10\%$) predictive error. Paired samples T-tests were conducted to determine significant differences between smart shirt estimates and criterion measurements with $p < 0.05$ used to denote statistical significance.

RESULTS: Estimates made by the smart shirt had high % error (shown as mean [standard error]) for kcal (29.8% [3.1]), breathing rate (19.4% [4.3]), and breathing volume (33.6% [3.8]). The smart shirt had low % error for steps (9.4% [0.7]) and heart rate (2.7% [0.3]). For all activities, kcal and breathing rate and volume performed poorly ($> 10\%$ error), whereas heart rate had $< 10\%$ error for all activities. Step

predictions were significantly underestimated for slow walking speeds (16.7-36.1%, $p < 0.05$), and kcal were significantly overestimated during all activities (5.6-94.7%, $p < 0.05$).

CONCLUSIONS: The smart shirt performed well estimating and heart rate, but performed poorly estimating kcal, breathing rate and breathing volume. Future research should further examine accuracy of this smart shirt during sport-specific activities as well as in free-living protocols.

This study was supported by the Alma College CORE Research Grant.

The Reasoned Action Approach Better Predicts Self-report Measures of Active Play than Accelerometer Measures

Elizabeth A. Mooradian, Andrea K. Chomistek, Jeanne D. Johnston, Susan E. Middlestadt, Georgia C. Frey, FACSM.
 Indiana University, Bloomington, IN. (Sponsor: Georgia Frey, FACSM)
 (No relationships reported)

The Reasoned Action Approach (RAA) has been successfully used to identify factors that predict a child's intention to be physically active, however, the predictive ability of intention to physical activity (PA) behavior has been weak. **PURPOSE:** To determine if subjective (i.e. self-report) vs objective (accelerometry) measures impact the predictive ability of intention to engage in physical activity behavior in children ages 9-12 years. **METHODS:** 210 5th and 6th grade students completed a 17-item RAA survey assessing after-school active play. Extensive pilot work was conducted to ensure the instrument was developmentally appropriate for the target population. The survey was administered on Monday inquiring about after-school active play that same week. On Friday, self-reported (SR) behavior was assessed by two questions during a face-to-face, semi-structured interview. Accelerometry (AC) was used as an objective measure of after-school active. Students wore an AC on the hip during waking hours, for the school week. Minutes spent in moderate-vigorous PA during the hours of 3:00-8:00 PM were determined using ActiLife software and the Evenson (2008) cutpoints. The strength of relationship between Intention and SR, and between Intention and AC, was measured via Pearson correlations. Multivariate linear regression was used to determine the predictive ability of Intention for the number of days the behavior was performed as determined by SR and AC. **RESULTS:** 100 participants met the AC wear inclusion criteria (female=60%; fifth grade = 48%, age = 11.25 +0.58y, height = 149.5 +8.14 cm, weight = 45.3 + 13.44 kg). Intention was significantly correlated to both SR ($r=0.679$; $p < 0.01$) and AC ($r=0.268$; $p < 0.01$). SR was better predicted by intention than AC ($F=83.84$; $p < 0.01$ vs. $F=7.57$, $p < 0.01$), explaining 46.1% and 7.2% of the variance, respectively. **CONCLUSION:** SR should be used to measure PA when using the RAA, due to the higher predictive ability, compared to AC. The stronger relationship between intention and SR is likely due to the higher correspondence between the measures. The developmental appropriateness of the measures may have also contributed to the higher predictive ability seen in this study, compared to other studies.

Performance Of Actigraph's Wear-time Sensors For Wear/non-wear Time Classification

Diego J. Arguello¹, Kristie Andersen¹, Alvin Morton², Dinesh John¹. ¹Northeastern University, Boston, MA. ²University of Tennessee Knoxville, Knoxville, TN.
 (No relationships reported)

PURPOSE: To evaluate the performance of the wear-time sensor in ActiGraph's wGT3X+BT and GT9X monitors under controlled laboratory and uncontrolled free-living settings.

METHODS: The lab protocol tested the accuracy of a wrist worn GT9X in capturing wear-on and off 'instances' (round minute) against direct observation as criterion. Participants ($N = 26$; mean \pm SD: age= 23.2 \pm 3.8 years, BMI= 23.2 \pm 3.7 kg/m²) wore and removed an Actigraph GT9X on 4-5 occasions during a 3-hour physical activity protocol. In the free-living setting we tested the accuracy of the wrist-worn wGT3X+BT and GT9X in classifying wear (i.e. sensitivity) and non-wear time (i.e. specificity) over a 2-day period. The criterion for the free-living condition was determined using an independent temperature sensor and self-report. Sensor-based free-living measures of wear-time were also compared to the commonly used Troiano 2007 and Choi 2011 wear/non-wear algorithms, which are based solely on motion signals.

RESULTS: In the lab protocol the GT9X wear sensor detected 83.95% of wear-on and wear-off 'instances,' and had significant delays (4.7 \pm 11.6 min) in detecting the minute when the monitor was taken off. Sensitivity and specificity of the GT9X in the laboratory protocol was 93% and 49%, respectively. In the free-living protocol, the sensitivity and specificity of the wGT3X+BT and GT9X was 82% and 95%, and 72 and 90%, respectively. The wear sensors from both devices had inferior sensitivity but superior specificity to Troiano 2007 and Choi 2011 wear/non-wear algorithms.

CONCLUSIONS: Actigraph wear-time sensors yielded inferior wear detection performance and superior non-wear detection performance over Troiano 2007 and Choi 2011 algorithms. Motion-based algorithms may have inferior non-wear detection capabilities because of a reliance on pre-determined durations of inactivity (i.e. 20-60 min) to classify non-wear. This strategy may not distinguish between the lack of motion that occurs during both monitor wear and non-wear. Conversely, Actigraph wear sensors are capable of making this distinction. The inferior wear detection performance of the ActiGraph wear-sensor may stem from the sensor's exclusive reliance in detecting skin conductance. For example, a loose strap may inaccurately yield a higher rate of non-wear.

2303 Board #316 June 1 2:00 PM - 3:30 PM
A Decision-tree Model For Classifying Physical Activity Types Using A Three-axis Accelerometer In Japanese Adults

Hideaki Hoshino¹, Ryuji Takigawa¹, Mothohiko Miyachi², Haruka Murakami², Shigeho Tanaka², Ryoko Kawakami³, Satoshi Nakae², Kiyoji Tanaka, FACSM⁴, Kazunori Ohkawara¹.
¹University of Electro-Communication, Tokyo, Japan. ²National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan. ³Waseda University, Saitama, Japan. ⁴University of Tsukuba, Ibaraki, Japan.
 (No relationships reported)

Accelerometry is a valid method for assessing physical activity in free-living conditions. Although there are numerous studies on estimating physical activity-induced energy expenditure (PAEE), classification of physical activity types using an accelerometer is not well established.

PURPOSE: To develop a physical activity classification model using a three-axis accelerometer in Japanese subjects

METHODS: Eleven healthy adults (age, 33.3±10.4 years) stayed in a human calorimeter for 23 hours and performed activities (sitting, standing, walking, lying down) while wearing a three-axis accelerometer (Actigraph-wGT3X-BT). Raw three-axis acceleration values were obtained at 30 Hz. Raw acceleration values were processed into five feature quantities: filtered acceleration values (FAC), raw acceleration values (RAC), absolute value of filtered accelerations (ABS), standard deviation of FAC (SD), and peak-to-peak of FAC (PP). A classification model was proposed using a decision tree and an 11-fold cross-validation method with time resolutions of 1, 5, or 10 seconds.

RESULTS: The classification model achieved the following accuracy levels for each time segment for all activities: 75.1% with 1-second segments, 76.1% with 5-second segments, and 77.7% with 10-second segments. Selected feature quantities in these models were RAC, ABS, and PP in 1-second segments; FAC, RAC, ABS, SD, and PP in 5-second segments, and FAC, RAC, and PP in 10-second segments. The classification model with a 10-second time resolution had better accuracy than with 5- or 1-second time resolution. The model's accuracy for each type of physical activity with 10-second segments was 80.6% for sitting, 59.6% for standing, 99.7% for walking, and 84.1% for lying down.

CONCLUSIONS: These results suggest that the decision tree is a valid method for physical activity classification in Japanese subjects. The addition of other features and classification methods, e.g., random forest, needs to be discussed in future studies.

Twenty-four hour accelerometer assessments create the opportunity for concurrent measurement of daily behaviors previously examined in isolation, including physical activity (PA), sleep, and sedentary behavior (SB), as well increasing device wear compliance and simplifying data capture. Evidence demonstrates that understanding how these behaviors make up the 24 hour day will help understand their compositional impact and interrelationships on health. This shift in research focus calls for the integration of methods to assess PA, SB and sleep to allow for the evaluation of overall 24-hour daily activity using a single device. Devices currently being used to assess daytime PA have not been substantially validated to evaluate sleep. **Purpose:** The objective of this study was to: 1) validate commonly used PA accelerometers using a gold standard polysomnography (PSG) test in a sample of older adults and; 2) to examine common sleep actigraphy data processing methods. **Methods:**

Twenty-two subjects (50 to 75 years) were recruited for participation. Of them, 17 participants completed an in-home overnight PSG while concurrently wearing three PA accelerometers. Total Sleep Time (TST) and Sleep Efficiency (SE) were compared for each device against PSG. **Results:** Across devices mean TST ranged from 361.6 - 403.2 minutes. Mean SE estimates ranged from 86.9% (PSG) to 96.9% (hip-worn accelerometer). We found significant differences between TST measured with hip-worn accelerometers compared to PSG (p=0.03, paired t test). We did not find significant differences between TST estimated by PSG and wrist-worn accelerometers (ranged from 0.49- 0.94). For SE, we did not find significant differences between PSG and wrist-worn accelerometers, but found a significant difference between PSG and hip-worn sleep estimated SE (p<0.001). **Conclusions:** When compared to gold standard PSG, PA wrist-worn devices worn on either wrist may be used to evaluate TST and SE. Further studies to investigate new algorithms to predict in bed and out of bed time and improve the assessment of sleep by PA devices seem warranted to advance the evaluation of sleep in addition to other 24-hour daily activity behaviors in both the clinical and population settings.

 (No relationships reported)

Machine learning has been used to accurately recognise physical activity patterns; however, classifiers for recognising targeted bone loading exercises have not been developed. **PURPOSE:** The purpose of this study was to determine the accuracy of machine learning models for classifying the intensity of exercises necessary for bone adaption in older adults. **METHODS:** Triaxial accelerometer data was collected from forty-four older participants (60-70 yrs) wearing a GCDC X16-1C accelerometer on their hip during three aerobic classes consisting of impact aerobic exercises performed at high and low intensities. Multi-class support vector machine (M-SVM) classifiers were trained in parallel for activity type detections where one classifier trained with low intensity activity samples and the other with high intensity samples. In a multi-view scoring manner, the classification confidence of these two learners was utilised for predicting the activity intensity. The leave-one-out cross-validation technique was used for assessment purpose. **RESULTS:** Overall recognition accuracy of the M-SVM classifier for detecting exercise intensity was 73%. For each aerobic class, the M-SVM classifier accurately recognised exercise intensity by 82%, 73% and 65%. **CONCLUSIONS:** Machine learning techniques such as M-SVM accurately recognised the intensity of bone promoting exercises from triaxial accelerometer data in community-dwelling older adults. First results of the developed classifier demonstrate significant potential of machine learning models for the evaluation of exercise adherence and performance in older adults.

 (No relationships reported)

While the SenseWear Armband has been validated for a variety of physical activities, it has not been validated with circuit-style exercise for individuals who overweight or obese. **PURPOSE:** The purpose of this study was to validate the SenseWear Armband for measuring energy expenditure in overweight or obese females during circuit-style training. **METHODS:** Overweight and obese females, N = 40, 20-59 years of age, completed a pre-recorded circuit-style exercise session consisting of eight exercises. An SenseWear Armband and portable metabolic analyzer were worn by each participant throughout the exercise session to measure energy expenditure. **RESULTS:** While the total overall energy expenditure between devices was not significantly different (p = .882), both energy expenditure excluding rest periods (p < .001) and rest periods between exercises (p = .007) were significantly different when the SenseWear Armband was compared to the portable metabolic analyzer. The SenseWear Armband overestimated exercise energy expenditure, but underestimated rest period energy expenditure compared to the portable metabolic analyzer. **CONCLUSION:** The results suggest females who are overweight or obese could use a SenseWear Armband to aid in tracking caloric expenditure with circuit-style training. However, care must be used if looking at individual exercise components.

 (No relationships reported)

PURPOSE: To examine the congruency of wearable cameras (WC) and direct observation (DO) to identify posture, activity category, and type during semi-structured (Semi) and free-living (Free) conditions in older adults.

METHODS: 824 observations were analyzed (n=8; 5 female; 69±5.1 y; 169.1±5.2 cm; 69.5±12.5 kg) over a 20-minute Semi bout of activity (sit, stand, walk) while video recorded. Videos were analyzed by DO. An independent sample of 1499 observations were analyzed (n=5; 3 female, 71±5.1 y; 162.1±5.1 cm; 64.5±10.6 kg) during a three-hour bout of community-dwelling Free activity while a researcher performed DO. Both groups wore a WC placed at the sternum. WC images and DO were annotated independently for posture (sedentary, standing, movement), activity category (sedentary, walking, household, exercise/sport), and type (laundry, dishes, cooking, general cleaning). Cross tabs and Kappa statistics were run to assess accuracy between the WC images and the DO results across both conditions for observations. Time spent in each attribute was tested with the Wilcoxon signed-rank test.

RESULTS: Posture had a 96.4% (Kappa=0.93; SE=0.10; p<0.0001) and 93.1% (Kappa=0.89; SE=0.07; p<0.0001) agreement between the WC and DO during the Semi and Free conditions, respectively. For activity category, there was 76.7% (Kappa=0.45; SE=0.10; p<0.0001) and 94.6% (Kappa=0.92; SE=0.08; p<0.0001) agreement between the WC and DO during the Semi and Free conditions, respectively. For activity type, obtained from Free only, there was 100% (Kappa=1.0; SE=0.20; p<0.0001) agreement across measures. WC total time spent in seconds was not significantly different to that obtained from the DO for posture during Semi (186±47 vs. 199±50, z=0.9342) or Free conditions (1341±414 vs. 1400±418, z=0.3170). For activity category, time spent across each measurement type did not significantly differ for Semi (WC = 162±38 vs. DO = 171±44, z=0.7348) or Free conditions (WC = 1082±322 vs. DO = 1256±342, z=0.4806). For activity type, time estimates for Free only were not statistically different 827±333 for WC and 145±70 for DO, z=0.7459.

CONCLUSIONS: Results from this study suggest that there is high congruency between wearable cameras and direct observation for behavioral observations and time spent in posture, activity category and type.

Metabolic Cost Of Resistance Exercise

Eric W. Slattery, Randal Claytor. *Miami University, Oxford, OH.*
 (Sponsor: Helaine Alessio, FACSM)
 Email: slatteew@miamiOH.edu
 (No relationships reported)

PURPOSE: Determine if the Total O₂ cost (TO₂) of RE differs during & following RE as a function of RE type & relative intensity (RI) & Determine if TO₂ during & following RE, differs across 3 RI, when the volume of Work is held constant.

METHODS: 8 Ss, 6 female, volunteered. Ss underwent testing for VO₂Max, body composition, and 1-RM for Chest Press (CP) & Leg Press (LP). RI were 33, 50, & 75% 1-RM, with 22, 15, & 10 reps performed, respectively to control for volume of work during RE. RE consisted of: 5min Rest, followed by RE, & 10min Post RE Rest; RE & Post RE Rest were repeated for RE type (LP & CP) & RI. RE & RI were counterbalanced. Metabolic measures & HR were recorded using a Cosmed K4b². Body composition was measured with BodPod.

RESULTS: Age=21.5±0.5, Height=166.5±6.2, Mass=65.4±11.7, BMI=23.5±3.7, BodyFat%=20.7±7.5, FatMass=13.8±7.5, LeanMass=51.5±7.7, VO₂max=46.4±8.4, RERmax=1.13±0.03, & HRmax=200±6.2. TO₂ cost was measured as the O₂ used during exercise & through 10min Post RE Rest using Integral estimation of breath-by-breath intervals. TO₂ cost during RE & 10 min Post RE Rest was significantly greater for LP when compared to CP at each corresponding RI: LP75-CP75 p=0.005, CI95% (6.72, 13.58); LP50-CP50 p=0.003, CI95% (4.12, 13.98); LP33-CP33 p=0.005, CI95% (1.81, 7.33). TO₂ cost was significantly (p<0.02) greater for LP75 & LP50 when compared to LP33. TO₂ cost for CP was not significantly different at any RI. LP & CP RE times differed significantly for RI: LP75-50 p=0.000, LP75-33 p=0.001, LP50-33 p=0.016, CP75-50 p=0.007, CP75-33 p=0.000, CP50-33 p=0.002. TO₂ cost for LP75 & CP75 returned to Pre RE Rest at min 3.

CONCLUSIONS: Results suggest TO₂ cost is related to RE type, muscle mass activated, O₂ deficit incurred during RE, & O₂ debt repaid during recovery. Further, the O₂ cost during recovery from LP75 & LP50 is greater when compared to LP33 even though Work was held constant. This suggests factors other than the O₂ deficit contribute to the O₂ debt.

2309 Board #322 June 1 2:00 PM - 3:30 PM
A Comparison Between Actual Energy Expenditure Measurements And A System Dynamics Model Output

David L. Wenos, Michael L. Deaton. *James Madison University, Harrisonburg, VA.*
 Email: wenosdl@jmu.edu
 (No relationships reported)

Portable metabolic units afford a practical utility for field measurements of energy expenditure (EE). This methodology has proven useful to assess EE related to terrain, intensity, and duration during a single event. Similarly, system dynamics (SD) modeling has been used to describe the relationship between exercise and obesity as it relates to EE. However, there is paucity of literature that report SD to predict EE in real time.

PURPOSE: To compare actual EE from a portable metabolic unit to predicted EE from a System Dynamics model.

METHODS: Seven subjects (4 males, 3 females; 24.4 +/- 1.71) walked selected routes of varied terrain paced by a metronome at 2.7 mph. EE was measured using a Cosmed K4b2 portable metabolic unit with each subject completing four trials per route. An integrated GPS receiver recorded latitude and longitude coordinates of each route. The modeling software STELLA was used to design the SD model which incorporates subjects' weight, walking pace, route elevation profile and distance. Pandolf's et al (1977) prediction equation for EE was run in the model to compare with the real-time K4b2 data.

RESULTS: In simulation modeling parameters (stocks and flows) are adjusted to increase accuracy. Model parameters were adjusted to provide agreement for EE to within +/- 1% of the actual total EE as measured by the Cosmed K4b2 unit. A paired t-test comparing the actual versus the SD model predictions of total EE were not significantly different (p = .034).

CONCLUSION: It appears that SD modeling can be an effective tool to predict EE of individuals walking on varied terrain. Once user parameters have been entered, simulation modeling can provide feedback on EE with suitable accuracy of a selected route. Compared to a single event measurement, SD allow users to compare EE of multiple defined routes simultaneously. Feedback has been identified as a critical component of adherence and motivation for physical activity. In this case of SD modeling, accurate feedback and route selection may encourage users to engage in regular physical activity.

Accuracy Of Wrist-worn Activity Monitors During Walking And Swimming

Eun Hye Kwon, John D. Smith. *Texas A&M University San Antonio, San Antonio, TX.*
 Email: eunhye.kwon@tamusa.edu
 (No relationships reported)

Wrist-worn activity monitor market has been growing at a rapid pace with many manufacturers. **PURPOSE:** To assess the accuracy of wrist-worn activity monitors during walking and swimming. **METHODS:** Twenty-seven participants (age=48.4±12.5 yrs, ht=171.1±9.0 cm, wt=71.6±15.0 kg) were fitted with five wrist activity monitors (XT and VS on the left wrist, PL, MF, and LT on the right wrist). After walking for 200m at a self-selected pace and swimming freestyle for 200m at a self-selected pace, monitor counts and actual step counts from a hand tally (AC) were recorded. Repeated measures ANOVA was used to determine significant differences between the counts. Pedometer error was calculated as [(monitor counts-actual counts)/actual counts]*100. **RESULTS:** All monitors registered counts significantly lower (p<.05) than AC during the walk (26.8±40.5, 29.1±47.8, 20.8±33.8, 37.0±65.0, and 28.5±34.6 counts for XT, VS, MF, LT, and PL, respectively). Percent error was lowest in MF while walking, followed by XT, PL, VS, and LT (7.2±12.6, 8.9±12.8, 9.0±12.1, 9.7±15.5, 11.9±20.8 percent, respectively). LT and PL counts were significantly higher (p<.05) than AC during the swim (378±93.4 and 198.2±143.5 counts, respectively) while XT, VS, and MF were not significantly different than AC (21.8±139.4, 15.4±112.3, and 44.7±120.1 counts, respectively), p>.05. During the swim, VS exhibited the lowest percent error, followed by XT, MF, PL, and LT (10.4±108.0, 24.6±130.4, 45.4±111.2, 177.9±119.7, 365.8±86.2 percent, respectively).

CONCLUSIONS: While four out of five activity monitors registered less than 10% error during the walk, the differences in counts compared to AC was significant. It is noted in some participants the step counts were extreme compared to the AC, thus the unusually high standard deviations. This was especially evident in the swim. The ability of a monitor to register a count is determined by the manufacturer and while different monitors have different construction, those who wear them do not always move in the same way, particularly in walking and swimming gait. These variables should be considered when using wrist-worn monitors to track different modalities of activity.

Effect Of Pace On Stabilization After Rising From A Chair In Young And Older Adults
Kimberly M. Burke, Brian L. Tracy, FACSM, Raoul F. Reiser, II, FACSM. *Colorado State University, Fort Collins, CO.* (Sponsor: Raoul F. Reiser II, FACSM)
Email: kimberly.burke@colostate.edu
(No relationships reported)

Falls are a significant concern for an aging population, with 14% of falls thought to occur during the transition from sitting to standing. **PURPOSE:** To determine the effect of chair rising speed on stabilization time in young and older adults. **METHODS:** Twenty healthy older (71.8±4.2 yrs; mean±SD) and 20 young adults (22.5±2.7 yrs) were first assessed for functionality using the Short Physical Performance Battery (SPPB). Then, each performed 4 single repetitions each of comfortable pace (CSTS) and maximal fast pace sit-to-stand (FSTS) in a randomized block design while on a force platform. The stabilization phase was defined as the period from when the vertical ground reaction force returned to bodyweight after knee extension until center of pressure (COP) variability was within 2 standard deviations of their quiet stance. The anterior-posterior (A-P) and medial-lateral (M-L) directions were assessed independently. **RESULTS:** The older adults had higher scores on the SPPB (11.3±0.8 vs 12.0±0.2; p=0.002). The stabilization phase was significantly longer in the A-P direction during FSTS (3.13±1.01 vs 2.70±0.88 s; p=0.039), with no differences between groups or within the M-L direction. However, the older adults did have significantly greater movement of the COP during the first 2s of stabilization, regardless of pace (A-P Path Length: 5.17±1.47 vs 3.96±1.17, p=0.002; M-L Path Length: 3.35±0.94 vs 2.57±0.64 % standing height, p=0.001). Furthermore, this A-P Path Length was significantly correlated between the CSTS and FSTS amongst the older adults, but not for the young (r=0.598, p<0.01 vs r=0.438, p>0.05). **CONCLUSION:** Although a healthy and high functioning group of older adults were examined, differences between groups existed during the STS, most notably at the beginning of the stabilization phase. It also appears that performance during CSTS and FSTS are more closely coupled in the older adults than the younger adults. This coupling suggests that older adults might dynamically control slow and fast STS similarly with a singular strategy while younger adults may have multiple strategies. This reduced flexibility of response may be adding to the increased risk of falls in older adults during the STS task.

2312 Board #325 June 1 3:30 PM - 5:00 PM
The Effect of Prolonged Standing on Ground Reaction Force Control
Kylie M. Soliday¹, Wayne J. Board¹, Erika Nelson-Wong², Raoul F. Reiser, II, FACSM¹. ¹*Colorado State University, Fort Collins, CO.* ²*Regis University, Denver, CO.* (Sponsor: Raoul F. Reiser II, FACSM)
(No relationships reported)

Prolonged standing (PS) substantially increases the risk of experiencing low back pain. However, the specific factors involved, and sex related differences are not fully understood. One factor may be bilateral asymmetries in posture. **PURPOSE:** The goal of this study was to examine the effect of prolonged standing on weight-bearing and ground reaction force control within healthy young adults during quiet stance. **METHODS:** Twenty-four subjects (12 male, 12 female) voluntarily participated in the study (age = 22.3 ± 2.4 years, height = 1.70 ± 0.09 m, mass = 69.89 ± 11.31 kg, BMI = 24.1 ± 2.5 kg/m² [mean ± SD]). Subjects performed two 60 sec quiet standing trials separated by one 30 min free standing trial while ground reaction forces under each foot were measured. Forces were normalized to percent body weight (%BW). Sway, maximum velocity (maxV), and path length (PL) were calculated from the center of pressure (CoP) for both the dominant (D) and non-dominant (ND) foot, as well as net combined values. All CoPs were calculated in both the anterior-posterior (AP) and medial-lateral (ML) directions, and were normalized to standing height (%height). Weight-bearing (WBAs) and CoP asymmetries (CoPAs) were calculated by subtracting the ND limb from their D limb. **RESULTS:** There were no differences in WBA or CoPA between the pre- and post-PS trials, nor between the men and the women (p>0.05). In both of the quiet stance trials, there were no significant differences between the D and ND limbs for WBAs, but the ND limb generally had a greater contribution to CoP movements than the D limb. There was an increase in four of the net CoP variables after PS exposure (p≤0.003). Significant negative correlations were found between WBAs and some CoPAs during the pre-PS trial (p≤0.018, r≤-0.660) and the level of these significant correlations changed during the post-PS trial (p≤0.024,

r≤-0.628). Men and women exhibited different significant correlations for both trials. **CONCLUSION:** While these results suggest that 30 min of PS does not have an effect on WBA or CoPA during quiet stance, there appears to be an effect on net CoP movements, as well as sex related differences in the correlations between WBAs and CoPAs. These findings suggest that fatigue is potentially occurring.

Optoelectronic Plethysmography Characterises Thoracic Excursion In The Evaluation Of Dysfunctional Breathing (DB)
Irisz K. Levai¹, Carlo Massaroni², James Hull³, Greg Whyte, FACSM⁴, Sergio Silvestri², John W. Dickinson¹. ¹*University of Kent, Chatham, United Kingdom.* ²*Campus Bio-Medico University of Rome, Rome, Italy.* ³*Royal Brompton Hospital, London, United Kingdom.* ⁴*Liverpool John Moores University, Liverpool, United Kingdom.* (Sponsor: Prof Greg Whyte, FACSM)
Email: irisz.levai.dr@gmail.com
(No relationships reported)

PURPOSE: Ventilatory pattern and thoracic excursion, can vary during exercise and impact on ventilatory performance. A deviation away from an optimal trunk lumbopelvic recruitment pattern may affect lung volumes, work of breathing and may be relevant in the development of exertional dyspnoea. The aim of the study was to investigate the effect of different postural positions on the ventilatory excursion using optoelectronic plethysmography (OEP) and a spirometer. **METHODS:** Fifteen healthy male athletes (Mean ± SD age: 30.3±6.5 yrs.) completed the study. Ninety reflective markers were placed on the chest, abdomen and back (Figure 1). Participants underwent simultaneous OEP and spirometry data collection in two conditions, in a randomised order: (C1) with normal shoulder position or (C2) with hunched shoulders. Forced vital capacity (FVC) was assessed by the spirometer and data was gathered on the chest wall volume (CW) and the compartmental volumes of the rib cage (RC) and the abdomen (AB) by OEP. **RESULTS:** The correlation between the two instruments in measuring FVC was good in both normal (R²=0.89) and hunched (R²=0.84) positions. FVC was significantly lower in hunched position during both spirometry (5.22±0.69 L vs. 5.35±0.69 L; p=0.03) and OEP measurements (5.22±0.62 L vs. 5.42±0.69 L; p=0.01). When volume contributions in the two conditions were compared the RC/AB ratio was significantly lower in hunched position (1.84±0.74 vs. 2.12±0.79; p=0.01). **CONCLUSIONS:** These findings suggest that respiratory excursion and lung volume compartmentalisation are affected by the position of the shoulders. Specifically, a hunched shoulder position leads to increased abdominal motion to vital capacity and decreased lung volumes. OEP may be a useful tool to detect altered parameters associated with development of exertional dyspnoea.

Effect of Respiratory Activity on Traditional Center of Pressure Related Measures during Standing in Parkinson's Patients
 Jamal Roper¹, Matthew Gloss¹, Paul Wright¹, Christina Odeh¹, David Benner¹, Shuqi Zhang¹, Li Li, FACSM². ¹Northern Illinois University, Dekalb, IL. ²Georgia Southern University, Dekalb, IL.
 Email: jroper2@niu.edu
 (No relationships reported)

Parkinson patients are at a high risk of falling due to the neurological disorder. Standing balance is an important indicator of postural control capacity among people with falling risks. During standing, respiratory activity, as the internal perturbation, may alter the motion of center of gravity. Therefore, in Parkinson patients, different respiratory activities could influence balance outcomes related to Center of Pressure (COP). **PURPOSE:** this study was to examine the effects of different breathing patterns on balance performance in patients with Parkinson. **METHODS:** ten Parkinson patient (PG) and ten age-matched health individuals (CG) were recruited. Each participant randomly performed 3 trials of balance test under three respiratory conditions (neutral, thoracic, and abdominal breathing patterns) with eyes closed. 95% sway area ($A_{95\%}$ in cm^2), average velocity (V_{Average} in cm/s) and standard deviation at ML (SD_{ML}) and AP (SD_{AP}) directions were recorded for each trial. Two-way MANOVA was performed to examine the effects of group and respiratory activity on the association among COP-related measures listed above. Post Hoc Tukey's test was applied when necessary. **RESULTS:** Significant differences were observed between groups on all measures ($P < .05$). Compared to control group, Parkinson group exhibited greater $A_{95\%}$ (PG: $10.36 \pm 9.89 \text{ cm}^2$, CG: $7.52 \pm 7.07 \text{ cm}^2$), higher V_{Average} (PG: $3.18 \pm 1.24 \text{ cm/s}$, CG: $2.56 \pm .92 \text{ cm/s}$), more SD_{ML} (PG: $.58 \pm .30$, CG: $.54 \pm .28$) and SD_{AP} (PG: $.84 \pm .31$, CG: $.68 \pm .24$). No other significant difference was observed. **CONCLUSIONS:** Parkinson's group showed a worse balance performance as expected. However, the effect of respiration on traditional COP related measures was not observed. This may be because that traditional measures could not detect the alteration of COP induced by the internal perturbation of respiratory activity. Instead of using traditional measures, future studies should adopt the nonlinear dynamic analysis to assess the complexity of COP motion potentially altered by respiratory activity.

2315 Board #328 June 1 3:30 PM - 5:00 PM
Wii-Based and Supervised Exercise Training Decrease Falls Risk in Older Adults with Type 2 Diabetes
 Rachel Simmons, Sheri R. Colberg, FACSM, Steven Morrison. Old Dominion University, Norfolk, VA. (Sponsor: Sheri Colberg-Ochs, FACSM)
 Email: rsimm009@odu.edu
 (No relationships reported)

Loss of balance resulting in falls is a serious health issue for older persons with type 2 diabetes (T2D). One intervention shown to produce benefits for these individuals is various types of exercise training. However, motivation is commonly cited as a barrier to consistent physical activity participation in unsupervised conditions. Interactive video games, such as the Nintendo Wii system, have been viewed as an innovative tool for engaging individuals in activity at home. **PURPOSE:** To assess the differences between supervised and unsupervised (using the Nintendo Wii) exercise training aimed at improving balance, reaction time, lower limb strength, and falls risk in older adults with T2D. **METHODS:** 47 older adults with T2D participated in 12 weeks of training: 32 (mean age 67.7 ± 5 yr) completed supervised training (ST) while 15 (mean age 66.3 ± 5 yr) completed unsupervised Wii training. ST sessions (40 min each, 3 times a week) consisted of lower limb stretches followed by leg, abdominal, and lower back exercises. The Wii training group completed three 40-min sessions on the Wii balance board per week. The Wii-based exercises were self-selected to emphasize balance and postural control. Prior to and following training, assessments of lower limb strength (i.e., isometric knee extension and flexion), falls risk (using the Physiological Profile Assessment), balance, postural coordination, vision, proprioception and reaction time were performed. **RESULTS:** Following training, participants in both the ST and Wii groups showed a significant decline in overall falls risk (ST, 0.59 ± 0.12 to 0.22 ± 0.14 ; Wii, 0.33 ± 0.13 to 0.17 ± 0.11 ; $p < 0.05$). Falls risk reductions were driven by significant improvements in knee extension (ST, 31.5 kg to 36.4 kg; Wii, 31.1 to 34.3 kg), knee flexion (ST, 16.9 to 19.3 kg; Wii, 17.0 to 18.3 kg), faster reaction times (ST, 278 to 247 ms; Wii, 244 to 225 ms) and improved postural coordination (ST, 13.4 to 9.1 errors; Wii, 9.7 to 6.5 errors). **CONCLUSION:** Both ST and unsupervised Wii exercise training interventions led to a reduction in falls risk in older adults with T2D, accompanied by increases in leg strength, faster reaction times, and improved balance coordination. Thus, both supervised and unsupervised exercise may lead to improvements in falls risk in older adults with T2D.

Effects of Backpack Load and Load Height on Lower and Upper Body Reaching Ability
 Patrick O'Malley, Jordyn Fera, Robbie Dolph II, Matthew D. Beekley, FACSM. University of DePauw, Greencastle, IN.
 Email: patrickomalley_2018@depauw.edu
 (No relationships reported)

PURPOSE: Reaching performance with lower and upper body has not been examined during load carriage with a backpack, particularly with the load in the backpack distributed high or low in the backpack.

METHODS: Lower extremity reaching during backpack carriage was tested using the Y-Balance Test (measuring leg reach in posterolateral, posteromedial and anterior directions), and upper extremity reaching was tested using the Functional Reach Test (FRT). Subjects were healthy males ($n=4$) and females ($n=3$), ages 18-49, who wore a backpack (REI) and performed in bare feet using the dominant leg and arm. Subjects were tested with no backpack, and then (in random order on different days) with the backpack empty (0), or load (weight) equivalent to 10, 30, and 50% of bodyweight in the bottom of the backpack. Trials were repeated with the load high in the backpack using a specially designed box. Three trials were completed for each reach. Results were analyzed with paired t-tests and Bonferroni corrections.

RESULTS: In Table 1, data presented as normalized for limb length reach, mean \pm SD; BW = bodyweight; ld high = load (weight) in backpack at ~ level C5 vertebrae instead of bottom; * = sig diff from ld high via t-test with Bonferroni; † = sig diff from No backpack via t-test with Bonferroni. Backpack load at 30% and 50% bodyweight resulted in reductions in lower body reach in all three directions for both load high or low in the backpack compared to no backpack. When compared to no backpack, load high in the backpack resulted in significant reductions in upper body reach (FRT) at 10, 30, 50% bodyweight and load low in the backpack resulted in no significant reductions in upper body reach.

CONCLUSIONS: Backpack load height effects upper body, but not lower body, reach.

Sprint Interval Training: Dissociating Stamina and Stability in Older Adults
 Alissa A. Ackerman, Timothy W. Brodsky, Nathan C. Grimm, Jeremy Theisen, Simon P. Fredericks, Erika Rigel, Raoul F. Reiser, II, FACSM, Christopher Bell. Colorado State University, Fort Collins, CO. (Sponsor: Raoul F. Reiser II, FACSM)
 Email: alissa.ackerman@colostate.edu
 (No relationships reported)

The risks and consequences of falling are appreciable in sedentary older adults. Regular exercise has been proposed as an intervention, however the perceived time commitment may prove problematic for exercise initiation and/or compliance. Sprint interval training (SIT) evokes rapid and appreciable physiological adaptation in a time efficient manner, but the utility of SIT for improving stability in older adults is unknown. **PURPOSE:** To determine the effect of SIT on fatigue resistance and stability in young and older adults. **METHODS:** Sedentary young (Y: $n=7$, age: 21 ± 1 years (mean \pm SE)) and older (O: $n=6$, age: 69 ± 2 years) men and women completed three weeks of SIT (9 sessions of 4-8 30s maximal efforts on a cycle ergometer). Maximal oxygen uptake ($VO_{2\text{max}}$) and time to exhaustion while cycling at 75% $VO_{2\text{max}}$ were determined prior to and following SIT. Stability (amount of sway of center of pressure with eyes closed) was determined prior to and following a single bout of sprinting, prior to and following SIT. **RESULTS:** $VO_{2\text{max}}$ (Y: 39.5 ± 2.7 vs. 41.3 ± 3.1 ; O: 22.8 ± 1.5 vs. $24.6 \pm 0.8 \text{ ml/kg/min}$), and time to exhaustion (Y: 25.8 ± 4.0 vs. 37.0 ± 3.1 ; O: 31.5 ± 3.9 vs. $54.0 \pm 8.8 \text{ min}$) were increased (all $P < 0.05$) in young and older adults. Stability (normalized to height) prior to a single bout of sprinting was unaffected by short term SIT in either young (214 ± 13 vs. $268 \pm 38 \text{ mm/m}$) or older (230 ± 10 vs. 186 ± 10) adults; similarly, SIT did not attenuate the decline in stability following a single bout of

sprinting (Y: 302±21 vs. 334±72; O: 235±14 vs. 246±22). CONCLUSION: Short term SIT dissociated stamina (VO_{2max} and fatigue resistance) from stability in young and older adults.

The Relationship Between Hip Musculature Range of Motion and BESTest Scores
 Matt Paxton, Adam Alfaro, Kady Dieringer. *Baker University, Baldwin City, KS.* (Sponsor: Matthew Ganio, FACSM)
 Email: matthewdpaxton@stu.bakeru.edu
 (No relationships reported)

Limited range of motion (ROM) is often considered detrimental to both athletic performance and everyday function similar to balance. **PURPOSE:** The purpose of this study was to determine a relationship between hip range of motion and BESTest scores. **METHODS:** 20 college age women (19.55 ± 3.45 years) with no prior lower extremity injuries or previous concussions volunteered for this study. Using standard goniometer measuring techniques, participants passive range of motion for flexion (FL), extension (EX), internal rotation (IR) and external rotation (ER) was established and compared to scores from the BESTest (Balance Evaluation Systems) to determine a correlation. Overall BESTest scores were compared to each aspect of hip musculature ROM. **RESULTS:** Although there was no significant correlation between any specific aspect of ROM and overall BESTest scores (P>0.05), both right and left internal rotation showed a statistically significant moderate correlation (R=0.52 (P<0.05) and, R=0.51 (P<0.05) respectively) to stability in gait. **DISCUSSION:** Despite no correlation between overall BESTest score and range of motion, internal rotation was shown to have a statistically significant moderate correlation to a single aspect of the BESTest, stability in gait. We determined that range of motion does not pose as a limiting factor to balance as measured by the BESTest.

Examining Postural Control Without Feedback in Individuals with history of Ankle Sprain
 Devan Groulx¹, Michelle Fadool¹, Stephanie Manning¹, Erik Wikstrom, FACSM², Jane Freund¹, Srikant Vallabhajosula¹.
¹Elon University, Elon, NC. ²UNC Chapel Hill, Chapel Hill, NC.
 Email: dgroulx@elon.edu
 (No relationships reported)

Lateral ankle sprains are common orthopedic injuries and often result in chronic ankle instability (CAI). Studies have shown that the CAI population typically has decreased ankle proprioception and possibly a greater reliance on visual feedback when compared to healthy controls. However, little is known about how the postural control characteristics change in those with and without CAI when external visual feedback is manipulated. **Purpose:** To compare postural control characteristics of persons with CAI, Copers and healthy adults when performing a single leg balance test with and without external feedback. **Method:** The definition for CAI used for this study includes persons who have experienced recurrent ankle sprains, in addition to self-reported “feelings of instability” and “giving way,” and a score on the Identification of Functional Ankle Instability (IdFAI) of 11 or greater. 18 participants with CAI, 15 Copers, and 18 healthy controls (mean age of all groups: 22 years) performed the Athlete Single Leg Test on the Biodex Balance System (BBS) at Level 4, which involved a high degree of platform instability. All participants completed 2 trials without and with feedback in that order. Center of pressure position was recorded and the two trial mean was used for further analysis. Overall stability index (OSI) defined as the mean distance of the center of pressure from the center of the platform was obtained from the system. Sway area was calculated using custom Matlab script. Separate 3 (Group) x 2 (Feedback) mixed ANOVAs were run using overall stability index (OSI), and sway area as dependent variables. **Results:** Significant feedback main effect showed participants had significantly lower (better) OSI value with feedback (1.4±0.1) compared to without feedback (2.6±0.2; P < 0.001) but sway area with feedback (8.61±2.33cm²) was similar to without feedback (10.94±2.43 cm²). There was no significant group main effect or interaction observed for either of the variables. **Conclusion:** Results suggest that external visual feedback may not play a significant role in helping persons with CAI improve their postural control.

 (No relationships reported)

PURPOSE: Previous research suggests that an improvement in body composition could potentially lead to a substantial improvement in balance performance in previously obese and overweight individuals (Handrigan et al., 2010; Maffiuletti et al., 2005). However, few studies have evaluated the balance of a person before and after weight loss following an exercise intervention that did not include any directed balance exercises. The purpose of this study was to evaluate if an exercise intervention alone can lead to a substantial decrease in body weight and therefore improvement in standing balance. **METHODS:** Fifteen overweight, but otherwise healthy adults (9 females, 6 males) (age: 23.5 years; height: 1.70 m, starting body mass: 92.8 kg) participated in this study. Balance performance was assessed with a sensory organization test (SOT) and motor control test (MCT) prior to and after a 10-week exercise intervention. SOT equilibrium scores were analyzed using a repeated-measures ANOVA. **RESULTS:** Results from the SOT equilibrium (EQ) scores revealed significant differences in the eyes open, sway referenced visual surrounding and platform (EOSRVP) condition (p = 0.033). Post hoc pairwise comparisons for this variable revealed significantly higher SOT equilibrium scores in post-intervention evaluation versus pre-intervention. No other SOT EQ scores were found to be significant (p > 0.05). Also, no significant differences were seen in MCT postural latency scores (p > 0.05). **CONCLUSIONS:** The results of the current study suggest that an exercise intervention alone without a significant loss in weight and also without any form of specific balance training can lead to an improved balance performance, but that it may be limited to the conditions where the somatosensory system plays a larger role in balance maintenance.

Effects of Long Term Marijuana Use On Postural Steadiness During Quiet Standing
 Grace Rhodehouse, Brian C. Garcia, Jonathon Lisano, Laura K. Stewart, Jeremy D. Smith. *University of Northern Colorado, Greeley, CO.*
 (No relationships reported)

The legalization of marijuana in a number of states has resulted in increased accessibility to the drug. However, little is known about the influence of marijuana on everyday tasks, such as quiet standing. **PURPOSE:** To determine whether marijuana influences postural steadiness during quiet standing. **METHODS:** All participants were physically active, defined by at least 150 minutes of moderate-intensity exercise per week, and were either marijuana users (MU, n = 10, mass = 81.4 ± 20.0 kg; ht = 1.75 ± 0.08 m; age = 25 yrs ± 6 yrs) or non-marijuana users (NU, n = 15, mass = 73.5 ± 13.5 kg; ht = 1.80 ± 0.08 m; age = 25 yrs ± 6 yrs). MU were consuming marijuana products at least once a week for the past 6 months and NU had not used any form of marijuana in the past 12 months. Participants were asked to stand quietly with each foot on a separate force plate for 30 seconds under four conditions: rigid surface eyes open, rigid surface eyes closed, compliant surface eyes open, and compliant surface eyes closed. Center of pressure (COP) under each foot (100 Hz) was evaluated to determine 95% confidence, mean velocity and mean frequency of the mediolateral (ML) and anteroposterior (AP) components of the COP trajectories. 2-factor (group, condition) MANOVA was used to identify main effects (p < 0.05). **RESULTS:** There was no interaction between group and standing condition. However, a group effect was observed, (left leg: Λ* = .843, F=2.706, DF=6,87, p=.019; right leg: Λ* = .822, F=3.129, DF=6,87, p=.008). Mean velocity in the AP direction for the right leg was greater among NU (p = .044, 19% difference), respectively) and approached significance for the left leg (p = .054, 18% difference). Mean frequency in the AP (p = .006, 24% difference) and ML direction (p < .001, 27% difference) for the left leg was greater among NU. Similarly, mean frequency in the AP and ML direction for the right leg was also higher among NU (p = 0.068, 16% difference, p = 0.024, 20% difference, respectively). **CONCLUSION:** These data suggest a suppressed central nervous system drive to modulate posture in marijuana users. This is consistent with anecdotal evidence that marijuana has calming effects on the body.

Effect of Abdominal Wall Muscle Fatiguing Exercise on Balance in Healthy College-Age Individuals

Greg Ehlers, Allison Tresner, Cole VanAirdale, Jessica Rice, Taylor Kirkpatrick, Jason Meyer, Hunter Maki, Taylor Devenport, Martin Rodriguez, Sarah Gamoke, Joseph Krier.
Concordia University Wisconsin, Mequon, WI.
 (No relationships reported)

Abdominal wall muscle function is thought to be an important factor affecting balance. **PURPOSE:** The purpose of this study was to determine if an acute fatiguing stimulus to the abdominal muscle groups affects balance in healthy college-age individuals. **METHODS:** A randomized pre-test post-test counterbalanced crossover design was utilized. Twenty healthy college-age students (age = 20.5±1.1 years; body mass = 71.3±14.5 kg; height = 168.8±10.4 cm; n = 10 males; n = 10 females) completed the trial and underwent two sets of seven different core muscle exercises to volitional fatigue after an aerobic full-body warm-up. The seven exercises were: Front plank, right side plank, left side plank, double leg raise, Russian twist, partial curl ups, and spine extension. Fatigue was determined as the point in which the participant could no longer maintain proper biomechanical form. Static single leg balance was assessed on each foot using a computerized balance assessment system (CBAS) and dynamic balance was assessed using the Star Excursion Balance Test (SEBT). Averages between the left and right side were calculated for both balance assessments and used during the statistical analysis. **RESULTS:** 2 X 2 repeated measures analysis of variance tests were calculated to assess for balance differences between the control group and the exercise group. Cohen's d effect sizes were calculated on pre and post measurements within each group. A statistically significant time-group interaction was noted on the CBAS mean scores (control pre vs post: 2.99±1.48 vs 2.53±0.81 degrees; exercise pre vs post: 2.91±1.13 vs 3.21±1.22 degrees; $p = 0.021$). However, the effect size of the exercise group pre vs post measure was small (Cohen's $d = 0.34$). No statistically significant differences occurred on the SEBT (control pre vs post: 670.5±85.6 vs 673.3±95.4 cm; exercise pre vs post: 664.9±78.6 vs 664.9±74.6 cm; $p = 0.687$). **CONCLUSIONS:** The abdominal wall muscle exercise protocol induced a statistically significant decrease in static balance but the size of the effect was small. Dynamic balance was not affected by the exercise protocol. Considering the small effect size and the statistical disagreement between the two assessments, it is possible that acute abdominal wall muscle fatigue may not functionally affect balance, but more research is needed.

2323 Board #336 June 1 3:30 PM - 5:00 PM
The Correlation of Forward Head Posture Measured via The Craniovertebral Angle to Neck and Low Back Pain

Mike F. Dahlinghaus, 52803. *St. Ambrose University, Davenport, IA.*
 Email: dahlinghausmichaelf@sau.edu
 (No relationships reported)

Abstract

Physical health practitioners often recommend special attention and care for postural misalignment. The postural adaptation of forward head posture (FHP) has been assumed to compromise the structural integrity of the body causing or leading to pain. There has been limited studies examining the direct correlation between the degree of forward head posture and neck and low back pain. **PURPOSE:** To determine if there is a correlation between FHP angle and neck and low back pain. **METHODS:** Thirty nine male and thirty seven female subjects completed this study. Forward head posture was measured with via the craniovertebral angle (CVA) utilizing the Head Posture Spinal Curvature Instrument (HPSCI). The Northwick Neck Pain Questionnaire (NPQ) and the Oswestry Low Back Pain Questionnaire (ODQ) were used to assess pain in the neck and back, respectively. **RESULTS:** There was no correlation ($r = -0.09$) found between CVA measurement and total score of NPQ and no correlation ($r = -0.03$) was found between CVA and ODQ; however, a moderate correlation ($r = 0.54$) was found between the subjects' NPQ total score and the ODQ score. **CONCLUSION:** No correlation was found from increased forward head posture and neck and low back pain.

Proprioception, Postural Sway and Mobility in Parkinson's Disease Patients And Healthy Individuals

Yejun Wang¹, Jia Han¹, Judith Anson², Gordon Waddington², Roger Adams². ¹*Shanghai University of Sport, Shanghai, China.* ²*University of Canberra, Canberra, Australia.*
 (No relationships reported)

Previous studies have shown that ankle proprioceptive ability is significantly correlated with sports performance. It is unknown if ankle proprioceptive ability is related

to postural sway and mobility in healthy individuals (HI) and Parkinson's Disease patients (PD) and, if there is a relationship, how the groups may differ. **PURPOSE:** To examine ankle proprioception, postural sway and mobility performance in PD and HI. **METHODS:** PD (n=27) and HI (n=27) volunteers were matched for age (mean 62 years old), weight (mean 62 kg), and height (mean 161cm). Ankle proprioception was measured while standing, using the active movement extent discrimination apparatus (AMEDA). Bipedal postural sway was assessed via the Biodex Balance System, with eyes open and close in anterior-posterior and medio-lateral directions (EOAP, EOML, ECAP, and ECML, respectively). Mobility measures included the 30 seconds sit-to-stand (STS) and timed-up-and-go (TUG) tests. **RESULTS:** Compared to HI, PD showed significantly worse ankle proprioception, STS and TUG ($p = 0.03$, 95% CI = -1.03~-0.01, $p < 0.01$, 95% CI = -7.89~-3.52; $p < 0.01$, 95% CI = 1.90~4.19, respectively) but no differences were evident in any postural sway measures. Ankle proprioceptive discrimination scores were not significantly correlated with STS, TUG, or any postural sway measures in either PD or HI. However, both STS and TUG scores were significantly correlated with ECML in PD ($r = -0.548$, $p < 0.01$, and $r = 0.494$, $p < 0.01$, respectively), but not in HI. **CONCLUSIONS:** Our findings support the sensory-reweighting theory, suggesting that PD and elderly HI may use other sensory input, not ankle proprioception, to achieve optimal postural control. Given that PD's mobility is significantly correlated with ECML, specific exercise should be designed to address medio-lateral control in PD to promote mobility.

Impact Of An Exercise Intervention On Human Balance Center Of Pressure Sway Parameters In Previously Sedentary, Overweight Adults

Alyssa K. Dispennette, FACSM¹, Cody E. Morris¹, Harish Chander², John C. Garner³, Hunter DeBusk², Scott G. Owens⁴, Melinda W. Valliant⁴, Mark Loftin, FACSM⁴. ¹*Western Kentucky University, Bowling Green, KY.* ²*Mississippi State University, Mississippi State, MS.* ³*Troy University, Troy, AL.* ⁴*University of Mississippi, University, MS.*
 Email: alyssa.dispennette311@topper.wku.edu
 (No relationships reported)

PURPOSE: Previous research suggests that a loss in excess body weight could potentially lead to a substantial improvement in overall balance in previously obese and overweight individuals (Maffiuletti et al., 2005). However, very few studies have evaluated balance performance before and after weight loss due strictly to exercise. The purpose of this study was to evaluate if an exercise intervention aimed at weight loss could lead improvement in standing balance. **METHODS:** Fifteen overweight, but otherwise healthy adults (9 females, 6 males) (age: 23.5 years; height: 1.70 m, starting body mass: 92.8 kg) participated in this study. Balance performance was assessed with a sensory organization test (SOT) prior to and after a 10-week exercise intervention. Center of pressure (COP) sway velocities and root-mean-square (RMS) sway were analyzed using a repeated-measures ANOVA and potential relationships with changes in body mass was evaluated employing a Pearson correlation. **RESULTS:** Results from the SOT COP sway parameters revealed significant differences in the eyes closed (EC) for anterior-posterior sway velocity (AP VEL) ($p = 0.006$), and in the eyes open sway referenced (EOSRV) conditions for AP VEL ($p = 0.048$). Post hoc pairwise comparisons for both variables revealed significantly lower postural sway in post-intervention evaluation versus pre-intervention. In addition, there was shown to be a significant correlation between degree of weight change and the following variables: EOSRV medial-lateral (ML) VEL ($p = 0.002$), EOSRV ML RMS sway ($p = 0.011$), eyes open sway-referenced platform (EOSRP) ML RMS sway ($p = 0.029$), EOSRP AP RMS sway ($p = 0.049$), eyes closed sway-referenced platform (ECSR) ML VEL ($p = 0.003$), ECSR ML RMS sway ($p = 0.036$). **CONCLUSIONS:** The results of the current study suggest that improved balance performance can result from an exercise intervention without any directed balance exercises. This could especially be true in situations where the somatosensory system plays a greater role in maintaining balance.

2326 Board #339 June 1 3:30 PM - 5:00 PM
Recovery Of Center Of Pressure Variability Following Total Ankle Arthroplasty

Douglas W. Powell¹, Lindsey E. Allison¹, Robin M. Queen, FACSM². ¹*University of Memphis, Memphis, TN.* ²*Virginia Tech University, Blacksburg, VA.* (Sponsor: Robin Queen, FACSM)
 (No relationships reported)

Postural stability is achieved through the integration of multiple systems including proprioceptive, vestibular and visual systems. Following a total ankle arthroplasty (TAA), balance is compromised due to the loss of joint sensory input. Variability is an inherent aspect of performance and a measure of neuromuscular adaptability. No previous research has investigated the recovery of variability following TAA.

PURPOSE: To quantify the recovery of center of pressure variability following TAA. **METHODS:** Forty-six individuals (63.3±9.6 years; 1.70±0.10 m; 83.7±17.1 kg) with severe ankle arthritis were recruited for this study. Each patient completed three trials of quiet standing for a period of 10 seconds with their feet placed together at three time points: before surgery (PRE-OP), and then one-year (POST-1yr) and two-years (POST-2yr) following TAA. Center of pressure (CoP) was recorded bilaterally using two embedded force platforms (1200 Hz, AMTI, Watertown, MA). Standard deviation (SD) of the CoP time-series was calculated for each limb (surgical and non-surgical) at each of the three time points. SPSS was used to conduct two 2 x 3 (side by time) repeated measures ANOVAs were used to determine the effect of surgical limb and time on CoP variability in the mediolateral and anteroposterior directions. Significance was set at $p < 0.05$. **RESULTS:** No significant time by limb interaction existed for either the anteroposterior or mediolateral CoP. No main effects for time ($p=0.35$) or limb ($p=0.44$) were observed in the anteroposterior CoP SD. No significant effect of limb was observed ($p=0.25$) for the mediolateral CoP, however, a main effect of time was present ($p=0.02$). Post-hoc tests revealed smaller SDs in PRE-OP compared to POST-1yr ($p=0.04$; PRE: 5.4±2.4; POST1yr: 6.4±5.8) while no differences were observed between PRE-OP and POST2yr ($p=0.11$; POST2yr: 6.8±7.0) or POST1yr and POST2yr ($p=0.43$). **CONCLUSIONS:** CoP variability magnitude was increased and maintained at two years post-TAA surgery. These data may suggest the presence of altered somatosensory input to the central nervous system increasing adaptability of postural control. Alternatively, increased variability may represent changes in postural control associated with reduced pain and inhibition associated with osteoarthritis.

A 6-week Rehabilitation Training Improves Single-leg Static Postural Control In Patients With Chronic Ankle Instability
 Alyssa Evans¹, S. Jun Son¹, Hyunsoo Kim², Sunku Kwon¹, Dustin Breuning¹, Matthew K. Seeley¹, J. Ty Hopkins, FACSM¹.
¹Brigham Young University, Provo, UT. ²West Chester University, West Chester, PA.
 Email: alyssa7evans@gmail.com
 (No relationships reported)

Ankle sprains occur at a high rate and often develop into chronic ankle instability (CAI). Impaired postural control may be a contributing factor to CAI. Effective rehabilitation programs and preventative measures for CAI are needed.

PURPOSE: To examine the effect of a 6-week ankle and hip rehabilitation program on center of pressure (COP) total distance and 95% ellipse area during single-leg static balance among groups of strength, strength with balance, and control.

METHODS: 14 CAI subjects in a strength group (22±1 yrs, 173±9 cm, 73±12 kg, 82±8% FAAM ADL, 58±13% FAAM Sports, 3.0±0.8 MAII, 3.7±1.5 ankle sprains) completed a series of 5 ankle and hip strength exercises (isometric, concentric, and eccentric contraction with theraband). 15 CAI subjects in a strength and balance group (23±2 yrs, 178±8 cm, 76±9 kg, 83±7% FAAM ADL, 56±10% FAAM Sports, 3.6±1.1 MAII, 4.7±2.0 ankle sprains) completed a series of 10 ankle and hip strength and balance exercises (theraband, wobble board, ankle disk, etc.). 14 CAI subjects participated in a control group (22±2 yrs, 177±9 cm, 75±12 kg, 81±9% FAAM ADL, 56±12% FAAM Sports, 3.4±1.2 MAII, 5.9±3.3 sprains). The rehabilitation intervention was administered 3 times/week for 6 weeks under supervision. Subjects performed 2 trials of single-leg stance on a force plate (1000 Hz) for 30 sec. 3 x 2 (group x time) mixed model ANCOVA analyses (covariate: pre-intervention value) with repeated measures were used to detect group x time differences in the COP total distance and 95% ellipse area.

RESULTS: Results are shown in Table 1.

Table 1.

	Strength (n=14)		Strength and balance (n=15)		Control (n=14)		F Value
	Pre	Post	Pre	Post	Pre	Post	
COP total distance (m)	18.9(4.2)	18.7(3.1)	18.8(3.7)	15.7(5.9)*	17.9(3.1)	17.5(3.8)	2.39 = 5.89 P < 0.05
COP 95% ellipse area (cm ²)	8.5(3.5)	8.0(3.0)	8.6(3.6)	5.9(1.9)§	8.0(3.6)	7.9(2.4)	2.39 = 5.88 P < 0.05

Values are mean (SD)
 *Changes in COP total distance (m) are significantly different than the strength and control groups (P < 0.05).
 §Changes in COP 95% ellipse area (cm²) are significantly different than the strength and control groups (P < 0.05).

CONCLUSION:

CAI patients in the strength and balance group improved postural control. Strength training alone did not have a significant impact on postural control. This may be due to the lack of proprioceptor activation during training. More data are needed to understand if this intervention may be used as a rehabilitation tool to reduce the risk of CAI.

Maintenance of Postural Steadiness throughout Chemotherapy Treatment
 Shane P. Murphy, Jessica Brown, Reid Hayward, Jeremy D. Smith. University of Northern Colorado, Greeley, CO.
 Email: shane.murphy@unco.edu
 (No relationships reported)

Chemotherapy negatively affects postural steadiness of cancer patients, contributing to an increased risk of falling. Physical activity improves postural steadiness, and has been shown to reduce toxic effects of chemotherapy such as peripheral neuropathy and vestibular dysfunction; two known causes of decreased postural steadiness.

PURPOSE: To determine whether postural steadiness improves in cancer patients undergoing chemotherapy following 12-weeks of exercise.

METHODS: Cancer survivors (n = 25; mass = 79.0 ± 22.6 kg; ht = 1.66 ± 0.08 m; age = 61.3 ± 10.0 yrs) receiving chemotherapy participated in this study. Postural stability was assessed prior to and following a 12-week individualized exercise intervention that included cardiovascular, muscular strength, flexibility, and balance training. In both pre- and post- measures, center of pressure (COP) data were collected (1000 Hz) for 10 seconds in four conditions: rigid surface eyes open (RSEO), rigid surface eyes closed (RSEC), compliant surface eyes open (CSEO), and compliant surface eyes closed (CSEC) using the Bertec BalanceScreener™ (Bertec Corporation, Columbus Ohio). Root-mean square (RMS), mean velocity (VEL), 95% confidence ellipse area (95CE), and mean frequency (FREQ) were investigated (Prieto et al., 1996). A MANOVA with repeated measures ($p < 0.05$) was used to identify main effects between pre- and post-training assessments.

RESULTS: From pre- to post- assessments mediolateral RMS decreased significantly for all conditions ($p < 0.04$ across all comparisons; RSEO by 35%, RSEC by 45%, CSEO by 43%, CSEC by 43%). A significant decrease was also observed in FREQ between pre- and post- assessments ($p < 0.044$ across all comparisons; RESEO by 29%, RSEC by 29%, CSEO by 31%, CSEC by 23%). No other variables changed significantly between pre and post assessments ($p > 0.05$).

CONCLUSIONS: Postural stability in the mediolateral direction was improved in cancer patients after 12-weeks of individualized exercise training. In addition, there was evidence of increased postural control based on an increased mean frequency of the COP trajectory after training. These results suggest that exercise training is beneficial to postural stability in cancer patients undergoing chemotherapy treatment.

2329 Board #342 June 1 3:30 PM - 5:00 PM
Preliminary Analysis: No Differences in Leg Strength Between Fallers and Non-Fallers
 Stuart McCrory¹, Shane Caswell¹, Amanda Estep¹, Jatin Ambegaonkar¹, Oladipo Eddo¹, Steven Morrison², Nelson Cortes¹. ¹George Mason University, Manassas, VA. ²Old Dominion University, Norfolk, VA.
 (No relationships reported)

Previous research suggests that increased leg strength in aging adults can decrease the risk of falling. Individuals with a history of falling are at increased risk for a recurrent fall. However, there is limited research in evaluating leg strength between Fallers and Non-Fallers.

PURPOSE: To evaluate isometric knee extension strength in aging adults that are classified as Fallers and Non-Fallers.

METHODS: Eighty-two aging adults (Fallers, n=39 age: 76±9.82 years, height: 1.61±0.09 m, mass: 79.63±7.74 kg, and Non-Fallers, n=43, age: 75±8.54 years, height: 1.61±0.07 m, mass: 78.99±20.38 kg) participated in this study. "Fallers" were defined as participants who had fallen within the year prior to the study, whereas "Non-Fallers" were participants that had not fallen within that time frame. A leg strength dynamometer (American Weight Scales, Inc.) was used to measure knee extension maximal voluntary isometric contractions (MVIC) for all participants. Participants were required to complete three valid trials of a unilateral knee extension MVIC for five seconds while sitting in a chair with the knee flexed at 90 degrees. Participants were given 20 seconds of rest between trials; the highest score was recorded. This protocol was performed for the right and left leg. Independent samples T-test were performed to compare leg strength values between Fallers and Non-Fallers ($p < 0.05$).

RESULTS: No significant differences ($p > 0.05$) were found between the two groups for right leg (Fallers=15.22±7.63 kg, Non-Fallers=13.72±5.87 kg) or left leg (Fallers=15.33±6.92 kg, Non-Fallers=14.93±6.91 kg) strength values.

CONCLUSION: No difference in isometric knee extension strength between Fallers and Non-Fallers was found. However, leg strength remains an important modifiable factor suggested in the falls prevention literature. Furthermore, research should evaluate if intervention programs have similar effects on leg strength on both Fallers and Non-Fallers. The effects of intervention programs should particularly target aging adults with a history of falls. These examinations may provide information to develop targeted intervention programs focusing on leg strength for Fallers. Research supported by grant from the Potomac Health Foundation.

 Email: bm06389@georgiasouthern.edu
 (No relationships reported)

Baseline assessments are vital in the evaluation of concussion and are recommended for any person competing in organized athletics. Following a head injury, the same assessments are administered and results are directly compared to baseline scores. Previous literature has suggested re-baseline assessments be administered to all athletes who have sustained a concussion, as the longitudinal effects of a single concussion are not well understood. However, the clinical utility of re-baseline concussion assessments has not been well investigated. Limited literature exists examining clinical change when evaluating postural control and cognition from baseline to re-baseline assessment following a concussion. **PURPOSE:** The purpose of this study was to examine the differences in clinical postural control and cognition with the Balance Error Scoring System (BESS) and the Standard Assessment for Concussion (SAC) in athletes who had previously sustained a concussion. **METHODS:** 34 NCAA athletes and cheerleaders (males = 13, females = 21) participated in this study. All athletes had previously been diagnosed with a concussion during the 2014-15¹ and 2015-16² athletic seasons. Pre-season concussion baselines (PRE) were administered before the first athletic season for each athlete and all athletes completed BESS and SAC evaluations. The same assessments were administered following full recovery from concussion (POST). A medical doctor confirmed the diagnosis and recovery of concussion. The SAC is a verbal assessment evaluating orientation, memory recall, and concentration. The BESS is a subjective evaluation used to identify balance impairments. One-way ANOVAs evaluated the scores on SAC and BESS between each time point. **RESULTS:** From PRE to POST no significant differences were observed with the BESS (PRE = 15.5 ± 7.34 errors, POST = 16.62 ± 8.04 errors; $p = .468$; $\Delta -2.12 \pm 8.69$) and SAC (PRE = 26.79 ± 1.59 units, POST = 27.24 ± 2.24 units; $p = .234$, $\Delta 0.44 \pm 2.12$). **CONCLUSIONS:** From PRE to POST assessment, scores on the SAC and BESS did not change significantly. This could suggest that re-baseline of the SAC and BESS has limited clinical utility. Future studies should include more sensitive assessments to adequately detect postural changes from baseline to re-baseline.

Effect Of Different Protein Ratio Beverages On Blood Glucose Regulation

Chi Yang¹, Chang Hong Guo², Chi Hong Lu¹, Chun Tai Chen¹. ¹University of Taipei, Taipei, Taiwan. ²Shih Hsin university, Taipei, Taiwan.
 (No relationships reported)

When protein and essential amino acids are the most popular supplementation in sports nutrition. It has been recommended that protein plus carbohydrate in a certain ratio 1:3 or 1:4 improve the muscle glycogen synthesis and promote recovery. These benefits from protein and carbohydrate complex are compelling compared to supplement protein or carbohydrate alone. However different protein ratio on blood glucose regulation remains unclear.

PURPOSE: In this study we investigated a single supplement different protein beverage in different ratio on blood glucose regulation.
METHODS: We used cross-over study design. Twelve healthy college baseball players (21 ± 0 y). Thereafter the subjects were divided into four groups: protein0% (PRO0), protein12% (PRO12), protein36% (PRO36) and protein75% (PRO75). Fasting blood were collected. After drinking protein supplement, blood glucose and insulin were measured every 30 min for 2 h. The data were analyzed by one-way ANOVA with repeated measures.
RESULTS: PRO0 on glucose area under the curve (GAUC) was significantly higher than other groups (4241 ± 446 vs. 2538 ± 275, 1784 ± 234, 196 ± 287, $P < 0.05$) and PRO75 GAUC was significantly lower than other groups (196 ± 287 vs. 4241 ± 446, 2538 ± 275, 1783 ± 234, $P < 0.05$). After supplement 30 min PRO75 blood glucose was significantly lower than other groups (107 ± 2 vs. 166 ± 8, 139 ± 6, 146 ± 6 mg/dL, $P < 0.05$). After supplement 60 and 120 min PRO12 was significantly higher compared with PRO36 (123 ± 3 vs. 107 ± 4 mg/dL, $P < 0.05$ and 118 ± 3 vs. 108 ± 1 mg/dL, $P < 0.05$). PRO36 on insulin area under the curve (LAUC) was significantly higher compared with

PRO75 (2972 ± 336 vs. 1178 ± 158, $P < 0.05$). After supplement 30 min PRO36 produced higher insulin concentration compared with other groups (56 ± 7 vs. 31 ± 5, 35 ± 7, 14 ± 2 mU/L, $P < 0.05$).

CONCLUSION: High protein ratio did not have better glucose and insulin response. However PRO36 may increase insulin level faster than other groups, but did not secrete more insulin.

Relationship Between Autophagy and Heat Shock Response in Peripheral Blood Mononuclear Cells Following Resistance Exercise

Trisha A. VanDusseldorp¹, Kurt A. Escobar², Kelly E. Johnson², Roger A. Vaughan³, James J. McCormick², Terence Moriarity², Matthew Stratton², Nathan Cole², Karol Dokladny², Chad M. Kerkick, FACSM⁴, Len Kravitz², Christine M. Mermier². ¹Kennesaw State University, Kennesaw, GA. ²University of New Mexico, Albuquerque, NM. ³High Point University, High Point, NC. ⁴Lindenwood University, St. Charles, MO. (Sponsor: Chad Kerkick, FACSM)
 Email: tvanduss@kennesaw.edu
 (No relationships reported)

Autophagy and protein degradation occur during the proximal hours (hr) post-exercise (PE) and are then followed by a gradual transition to protein synthesis. Previous works suggest that this biphasic relationship is mediated in-part by the heat shock response which may influence autophagy activity and may be influenced by the presence of amino acids. **Purpose:** To determine the effect of acute resistance exercise and branched-chain amino acid (BCAA) supplementation on autophagy and the heat shock response. **Methods:** Twenty males (22.3 ± 1.5 yr, 86.4 ± 15.6 kg; 175.4 ± 6.7 cm) were randomly assigned to complete 8 days of 0.22 g/kg/d BCAA or placebo (PL) supplementation. On day 5 participants performed a bout of eccentric resistance exercise. Peripheral blood mononuclear cells (PBMC) were isolated pre-exercise, immediately post-exercise (IPE), and 2, 4, 24, 48, and 72 hr. PBMC protein expression of autophagy markers (LC3I & II, & p62) and HSP70 were measured using Western blot. All autophagy and heat shock markers were assessed in relation to a standard baseline (1.0RQ). Red cell lysate was collected pre-exercise, IPE, and 1, 2, 4, and 24 hr to assess glutathione/total glutathione ratio (GSSG/tGSH). **Results:** No group differences ($p > 0.05$) were detected for protein expression of autophagy markers, HSP70, or GSSG/tGSH ratio at any time-point. When combining groups, LC3II decreased significantly ($p < 0.01$) at 2 (0.51 ± 0.38RQ) and 4 (0.41 ± 0.36RQ) hr PE. p62 decreased significantly ($p < 0.001$) at IP (0.56 ± 0.33RQ), 2 (0.24 ± 0.23RQ), and 4 (0.33 ± 0.31RQ) hr PE and significantly increased ($p < 0.01$) at 24 (1.43 ± 0.44RQ) hr PE. HSP70 increased significantly ($p < 0.001$) increased at 48 (1.59 ± 0.96RQ) and 72 (4.71 ± 3.84RQ) hr PE. GSSG/tGSH ratio significantly ($p < 0.05$) increased from baseline (0.11 ± 0.04RQ) at 1 (0.39 ± 0.05RQ), 2 (0.69 ± 0.22RQ), and 4 (0.39 ± 0.17RQ) hr post-exercise. **Conclusion:** These data support previous work that the heat shock response may exert regulatory control of autophagy in-part through HSP70. HSP70 may assist in transitioning the cell from an initial degradation phase immediately following exercise towards protein synthesis in the latter phases of the post-exercise period. The initial autophagy upregulation may be influenced by oxidative stress.

Matrix Metalloproteinases and Tissue Inhibitors of Metalloproteinases Following High Fat Diet and Acute Exercise

Yunsuk Koh¹, Yonghyeon Jo¹, Eric K. O'Neal², Angela Hollingsworth², Lauren G. Killen², Ashton F. Waddell², Alexander J. Heatherly². ¹Baylor University, Waco, TX. ²University of North Alabama, Florence, AL.
 (No relationships reported)

Matrix metalloproteinases (MMPs) play a major role in apoptosis, angiogenesis, and inflammation by degrading extracellular matrix proteins. Specific endogenous proteases, tissue inhibitors of MMPs (TIMPs), are known to inhibit MMPs.

PURPOSE: The current study examined the effects of a high fat diet and an acute bout of exercise on MMPs and TIMPs in runners. **METHODS:** Eight middle-aged, aerobically trained male runners ($\text{VO}_{2\text{max}} = 48.5 \pm 4.5$ mL/kg/min, age = 39.5 ± 9.9 years) participated in the study. As a crossover design, participants maintained their habitual high carbohydrate diet (HC, 60-70% of carbohydrate) in the beginning of the study and shifted to a high fat (HFLC, ~70% of total calories from fat) diet with < 50 g of carbohydrate per day for 3 weeks during the second phase. At the end of each phase, participants performed a 50-min acute bout of treadmill exercise at varying race paces in an environmental chamber (29 °C with 60% relative humidity) followed by an outdoor 5-km time trial (average = 23 min). Overnight fasting serum samples were collected at pre- and 24-hr post-exercise during both HC and HFLC phases to analyze MMPs (MMP-1, -2, -9, and -10) and TIMPs (TIMP-1, -2, -3, and -4). Data were

analyzed using a 2 X 2 (phases: HC and HFLC X time: pre- and 24-h post-exercise) analysis of variance with the Sidak's multiple comparisons when necessary ($p < 0.05$). **RESULTS:** There was no significant difference in MMPs or TIMPs between HC and HFLC phases. Furthermore, an acute bout of exercise in the heat did not alter MMPs or TIMPs. There were, however, significant positive correlations between TIMP-2 and MMP-2 ($r(14) = 0.51, p = 0.01$) and TIMP-2 and MMP-9 ($r(14) = 0.49, p = 0.01$). Additionally, a significant negative correlation was found between TIMP-4 and MMP-4 ($r(14) = -0.57, p = 0.02$). **CONCLUSION:** A 3-week high fat diet and an acute intense exercise in the heat did not negatively affect serum MMPs and TIMPs in healthy, trained male runners. It seems that MMP-4 activity may be inhibited by TIMP-4, whereas both MMP-2 and -9, interestingly, may be upregulated by TIMP-2. Future studies examining the effects of a long-term high fat diet on metabolic pathways of circulating or tissue MMPs and TIMPs in active individuals along with a variety of populations are highly recommended.

2334 Board #347 June 1 3:30 PM - 5:00 PM

Whey Hydrolysate Supplementation Following Resistance Exercise Elicits Similar Anabolic Responses in Both Young and Older Adults

Bradley Lambert¹, Teru Kato², Paul Reidy³, Ted Graber⁴, Michael Borack⁴, Rachel Deer⁴, Blake Rasmussen⁴, Elena Volpi⁴.
¹Texas A&M University, College Station, TX. ²Megmilk Snow Brand, Tokyo, Japan. ³University of Utah, Salt Lake City, UT. ⁴University of Texas Medical Branch, Galveston, TX.
(No relationships reported)

Skeletal muscle sensitivity to dietary protein and exercise typically declines during aging. However, previous data presented by our group indicates that whey protein hydrolysate (WH, di- and tri-peptide mixture) may be able to stimulate muscle anabolism at lower dosages than observed with intact whey protein in older adults. **PURPOSE:** To compare the effect of a minimal dose (10 g) of WH provided after resistance exercise (REX) on skeletal muscle anabolism in young and older adults. **METHODS:** Twenty healthy recreationally active adults (YOUNG: M=8, F=2; 25±4yr, 25±4 kg·m² | OLD: M=7, F=3; 65±4yr, 25±4 kg·m²) were studied pre- and post-ingestion (PI) of 10 g of WH 1 h after high-intensity REX (8x10@~70% 1RM, leg ext). We measured mixed-muscle protein fractional synthetic rate (FSR) and plasma BCAA concentrations by stable isotopic methods. Western-blotting was used to assess anabolic signaling and the presence of peptide transporters in muscle. Muscle biopsies from the vastus lateralis were collected at rest and during the early (0–2 h) and late (2–4 h) PI periods. Mixed muscle FSR and anabolic signaling was analyzed using a 2(group) x 3(time) mixed model ANOVA repeated across time. BCAA concentrations were modeled separately per time point using a 2 (group) x 2 (time) mixed-model ANOVA. Type I error for all analyses was set at $\alpha=0.05$.

Effects on Post Resistance Exercise Mixed-Muscle FSR (%/h)						
Groups	Basal	(0-2h) Post Ingestion	(2-4h) Post Ingestion	Entire Post Ingestion Period (0-4h)		
YOUNG (n=10)	0.058% ± 0.003	0.075% ± 0.003 †	0.100% ± 0.009 †	0.087% ± 0.005 †		
OLD (n=10)	0.067% ± 0.005	0.106% ± 0.012 †*	0.091% ± 0.014 †	0.086% ± 0.005 †		
Plasma BCAA Concentrations (Δ From Basal, umol·L)						
Time Post Ingestion	20min	40min	60min	80min	100min	180min
Leucine						
YOUNG	259 ± 29†	206 ± 24†	112 ± 20†	68 ± 9†	50 ± 7†	42 ± 7†
OLD	247 ± 28†	255 ± 22†*	149 ± 20†	146 ± 22†*	114 ± 25†*	57 ± 16†
Isoleucine						
YOUNG	103 ± 12†	87 ± 13†	39 ± 8†	20 ± 4†	13 ± 3†	10 ± 3
OLD	90 ± 9†	98 ± 6†	54 ± 6†	45 ± 5†*	31 ± 4†*	13 ± 4
Valine						
YOUNG	126 ± 17†	123 ± 13†	62 ± 11†	31 ± 8†	16 ± 7	6 ± 6
OLD	99 ± 10†	128 ± 8†	74 ± 7†	70 ± 13†*	44 ± 6†*	10 ± 8
Data are means ± SE. † different from basal value; * different from the YOUNG group ($p < 0.05$)						

RESULTS:

Compared with rest, increases in p-mTOR (Young: +2.0 fold, Old: +2.5 fold) and p-4E-BP1 (Young: +1.5 fold, Old: +1.4 fold) were observed in both groups at 4h PI ($p < 0.05$). Increases in p-S6K1 were observed in both groups at 2h PI but to a greater extent in the OLD group ($p < 0.05$). Peptide transporter-1 (PEPT1) expression was found in muscle samples from both groups. **CONCLUSION:** WH provided after REX enhances muscle anabolism in older adults at a dose previously shown to be ineffective with intact whey isolate. Future studies will be required to determine if WH may aid in the long-term preservation of muscle in this population.

Recovery is Not Facilitated with Protein Supplementation Following Muscle-Damaging Concurrent Exercise

Lee Eddens¹, Sarah Browne¹, Emma Stevenson², Brad Sanderson¹, Ken van Someren¹, Glyn Howatson, FACSM³.
¹GSK Human Performance Lab, Brentford, United Kingdom. ²Newcastle University, Newcastle upon Tyne, United Kingdom. ³Northumbria University, Newcastle upon Tyne, United Kingdom.
Email: lee.j.eddens@gsk.com
(No relationships reported)

Concurrent exercise is an important training modality for many sports and the dynamic nature of concurrent training imposes significant physiological stress that can lead to exercise-induced muscle damage (EIMD). Additional protein is frequently consumed with the intention to improve exercise recovery following EIMD; however the evidence for this practice is equivocal at best because of limitations in the research, which are attributable, at least in part to poor dietary control. **PURPOSE:** To investigate the efficacy of protein as a recovery aid following damaging exercise in a concurrent training paradigm, when rigorous dietary control and supplementation are provided. **METHODS:** Twenty-four well-trained male cyclists were randomised to three groups receiving supplement servings of 20 g protein, or an iso-caloric carbohydrate or low-calorific placebo. Supplements were provided twice daily from the onset of the muscle-damaging exercise and for a total of four days. During this time a controlled diet was consumed by all participants (6 g·kg⁻¹·d⁻¹ carbohydrate, 1.2 g·kg⁻¹·d⁻¹ protein, remainder fat). The concurrent exercise consisted of a simulated high-intensity road cycling trial followed by 100 drop-jumps; dependent measures were taken before and at 0, 24, 48 and 72 h following the concurrent exercise bout. **RESULTS:** Significant time effects for decrements in maximal voluntary contraction (MVC) and countermovement jump (CMJ) performance, along with increased muscle soreness, serum creatine kinase (CK) and C-reactive protein (CRP) concentrations provided evidence that EIMD had been induced ($p < 0.001$). No group or interaction effects ($p > 0.05$) were observed for any of the dependent measures, with both MVC and CMJ performance reaching a nadir immediately post-exercise (MVC: 83 ± 8, 85 ± 11 and 89 ± 11% of baseline for PRO, PLA and CHO; CMJ: 93 ± 8, 91 ± 8 and 93 ± 6% of baseline for PRO, PLA and CHO) and both CK and CRP values peaked at 24 h post-exercise (CK: 282 ± 166, 341 ± 167 and 291 ± 177% of baseline for PRO, PLA and CHO; CRP: 206 ± 110, 260 ± 207 and 241 ± 178% of baseline for PRO, PLA and CHO). **CONCLUSION:** Protein supplementation did not attenuate any of the indices of EIMD imposed by concurrent exercise, when employing high degrees of rigour around the habitual diet and the provision of appropriate supplemental controls.

2336 Board #349 June 1 3:30 PM - 5:00 PM

The Effects of Whey vs. Soy Protein at Breakfast on Satiety Response, Energy Intake and Metabolism

Caroline Melson, Svetlana Nepocatych, Takudzwa Madzima.
Elon University, Elon, NC.
(No relationships reported)

PURPOSE: To determine the effects of animal-based (whey) compared to plant-based (soy) protein on perceived satiety, hunger, fullness, desire to eat, prospective food consumption, thirst, energy metabolism and subsequent energy intake. **METHODS:** Seventeen healthy men and women (age: 27 ± 7, BF%: 21.5 ± 6.9) consumed three isocaloric breakfast smoothies with 40% of energy from either whey, soy, or control (no protein) in a double blind, randomized crossover design. Participants completed a visual analog scale (VAS) of appetite profile and thirst (before, 0, 60, 120, 180 minutes). Indirect calorimetry was used to determine the effect of a meal (TEM) (at 45-60, 105-120, 165-180 minutes). In addition, energy intake at lunch was recorded. **RESULTS:** There was a significant difference in hunger ($p = 0.03$), satiety ($p = 0.001$), fullness ($p = 0.001$), desire to eat ($p = 0.03$), and prospective food consumption ($p = 0.04$) between the three breakfast conditions. Measures of satiety and fullness were higher whereas hunger, desire to eat, and prospective food consumption were lower after consumption of whey protein compared to control. A significantly higher ($p < 0.05$) respiratory quotient (RQ) and lower oxygen consumption (VO₂) was observed for whey and soy compared to control condition. In addition, a significantly higher (p

THURSDAY, JUNE 1, 2017

<0.05) energy intake at lunch was observed after control (770 ± 289 kcals) compared to whey condition (654 ± 252 kcals). However, there was no significant difference ($p > 0.05$) in energy intake between soy (696 ± 296 kcals) and whey or control conditions. **CONCLUSIONS:** Consuming whey or soy protein at breakfast led to similar perceptions of appetite profile as well as lower energy intake at lunch, which may aid in weight management efforts among individuals following a vegan or vegetarian diet.

Room: Hall F

2337 Board #350 June 1 3:30 PM - 5:00 PM Hydration and Renal Responses During Pre-Season High School American Football

Cory L. Butts¹, Aaron R. Caldwell¹, Richard A. Perry, Jr.¹, Kathleen M. Heath¹, J.D. Adams¹, Matthew S. Ganio, FACSM¹, Lisa T. Jansen¹, Hyun-Gyu Suh¹, Lesley W. Vandermark¹, M. Kyle Smoot², Brendon P. McDermott¹. ¹University of Arkansas, Fayetteville, AR. ²University of Kentucky, Lexington, KY.
Email: clbutts@uark.edu

Reported Relationships: C.L. Butts: Consulting Fee; Gatorade Sports Science Institute.

American football athletes often report to practices and games in a hypohydrated state, potentially increasing the risk for performance and thermoregulatory impairments. However, the renal responses to progressive dehydration with environmental and workload stressors, have not been elucidated in this population. **PURPOSE:** To observe the hydration status and renal function of high school American football players during preseason practices. **METHODS:** High school American football players ($n = 31$ males, age 16 ± 1 y, ht 1.79 ± 0.07 m, mass 88.4 ± 19.9 kg, body fat $19.9 \pm 9.4\%$) participated in this observational study. Body mass (BM), blood, and urine samples were obtained 2-3 days prior to the start of pre-season practices (Base) and at Days 4 (D4), 7 (D7), and 10 (D10). D4 and D7 samples were collected prior to practice while D10 samples were obtained post-practice. Serum osmolality (S_{osm}), urine specific gravity (U_{sg}), and urine color (U_{color}) were measured at each time point. Renal stress was assessed by measuring plasma neutrophil gelatinase-associated lipocalin (pNGAL) via enzyme linked immunosorbent assay. Wet bulb globe temperatures (WBGT) were also recorded for each practice. **RESULTS:** BM did not change significantly from Base (91.6 ± 22.9 kg) through D10 (90.2 ± 23.2 kg; $p = 0.26$). S_{osm} at Base (292 ± 4 mOsm/kg) was significantly lower than D10 (295 ± 4 mOsm/kg, $p = 0.05$). Further, $S_{osm} > 290$ mOsm/kg was present in 67-73% of players reporting to practices on D4 and D7, and 80% finishing practice on D10. U_{sg} at Base (1.023 ± 0.007) and D10 (1.027 ± 0.005) were greater than D4 (1.018 ± 0.009) and D7 (1.019 ± 0.009 , all $p < 0.05$). U_{color} on D4 (3 ± 1) was lower than Base (4 ± 1) and D10 (4 ± 1 , all $p < 0.05$). pNGAL was not different throughout preseason (Base, 50.7 ± 12.5 ng/mL, D10, 52.8 ± 14.7 ng/mL, $p = 0.19$). Further, there was no relationship between S_{osm} and pNGAL ($r = -0.03$, $p = 0.77$) or U_{sg} and pNGAL ($r = 0.05$, $p = 0.63$). Average WBGT ranged from 20.0°C to 31.1°C . **CONCLUSIONS:** At least two-thirds of players reported for or completed practice sub-optimally hydrated. However, renal stress assessed via pNGAL was not elevated throughout preseason. Thus, despite suboptimal hydration and environmental stress, these American football players experienced minimal renal injury as measured via pNGAL.

Supported by AMSSM-ACSM Grant

2338 Board #351 June 1 3:30 PM - 5:00 PM Low Estimated Glomerular Filtration Rate (eGFR) is Associated with Skeletal Muscle Function Deficit in Elderly Persons

Jae Seung Chang, Tae Ho Kim, In Deok Kong. *Yonsei Institute of Sports Science & Exercise Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic of.*

(No relationships reported)

Physical performance is closely associated with chronic diseases and dysfunction of numerous organ systems. Old persons with chronic renal failure have shown the apparent decline in physical performance, especially in the end-stage. However, it is unclear whether the subclinical kidney dysfunction is associated with skeletal muscle function deficit in the elderly population.

PURPOSE: To determine the association between renal function and skeletal muscle function deficit in old persons without nephropathy. **METHODS:** Eight hundred fifty-four Korean elderly (female, 75.3%) aged 65 to 89 years were included in this cross-sectional study. All participants were interviewed face-to-face and received

measure of anthropometry, body composition and serum biomarkers of metabolic diseases. eGFR was calculated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation based on serum creatinine concentration. The following physical performance tests were performed: handgrip strength (absolute and relative values), timed up-and-go (TUG), chair stand, 2 min stationary walking, figure-eight walk and sit-and-reach. Skeletal muscle function deficit was defined as a combination of weakness and slowness based on the relative handgrip strength (men < 1.32 , women < 0.792) and converted TUG to walking speed (< 0.8 m/s), respectively. **RESULTS:** Of the subjects, the prevalence of $30 \leq \text{eGFR} < 45$ mL/min/1.73m² was 16.2%. The subjects with $30 \leq \text{eGFR} < 45$ mL/min/1.73m² showed significantly lower physical performance for muscular strength and functional mobility than those with $45 \leq \text{eGFR} < 60$ and $\text{eGFR} \geq 60$ mL/min/1.73m², respectively (all for $p < 0.05$). Multinomial (polychotomous) logistic regression analysis, with three categories of eGFR as the dependent variable, showed the significant association between eGFR and skeletal muscle function status even after adjustment for potential confounders (odds ratios [95% CI] were 4.8 [1.3-17.2] for a GFR of 45 to 59, 12.9 [3.1-52.9] for above 60 mL/min/1.73m², p for trend < 0.01). **CONCLUSION:** Taken together, skeletal muscle function status is associated with even moderately reduced eGFR in an older population. This finding suggests that maintenance of physical and functional fitness may be a contributory factor for preserving renal function in elderly persons.

2339 Board #352 June 1 3:30 PM - 5:00 PM Impact of Moderate Intensity Endurance Exercise on Kidney Injury

Coen C.W.G. Bongers¹, Mohammad Alsady², Yvonne A.W. Hartman¹, Thijs M.H. Eijvogels¹, Peter M.T. Deen², Maria T.E. Hopman, FACSM¹. ¹Radboudumc, Radboud Institute for Health Sciences, Nijmegen, Netherlands. ²Radboudumc, Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands.
Email: coen.bongers@radboudumc.nl

(No relationships reported)

Purpose. Exercise-induced redistribution of blood results in a decreased renal perfusion and changes in glomerular permeability and filtration ratio. These alterations may lead to a deterioration of renal function or even acute, but transient, renal failure. Kidney Injury Molecule-1 (KIM1) and Neutrophil gelatinase-associated lipocalin (NGAL) are new urinary biomarkers to detect kidney injury in an early stage. Therefore, the purpose of this study was to examine the effects of an acute bout of endurance exercise on urinary KIM1 and NGAL levels.

Methods. A total of 60 subjects (56 ± 10 years) participated in an annual walking event and walked 30-50 km at a self-selected pace. Heart rate was recorded every 5 km. Baseline and post-exercise blood and urine samples were taken to assess fluid balance and kidney injury and body mass was measured to determine the relative body mass loss. Urinary KIM1 and NGAL levels were corrected for variations in urine volume and for urinary concentration changes using urinary cystatin C.

Results. Subjects completed the exercise bout at $71 \pm 9\%$ of their predicted maximal heart rate. At baseline, kidney function, measured as estimated glomerular filtration rate (eGFR) was 89.3 ± 11.6 mL/min, whereas 49% of the subjects had a slightly decreased kidney function ($\text{eGFR} < 90$ mL/min). Post-exercise body mass loss was $0.9 \pm 1.2\%$ and 20% of the subjects were dehydrated after exercise (relative body mass loss $> 2\%$). We observed a significant increase in post-exercise cystatin C-corrected urinary NGAL levels (3.0 ± 1.5 ng/10 μg cystatin C) compared to baseline (2.3 ± 1.3 ng/10 μg cystatin C, $p = 0.025$). Moreover, 65% of subjects demonstrated elevated NGAL levels after exercise. In contrary, corrected urinary KIM1 levels did not change after exercise (0.70 ± 0.45 versus 0.74 ± 0.49 ng/10 μg cystatin C, $p = 0.63$). At baseline, 2 subjects were detected with proteinuria, whereas 8 subjects had post-exercise proteinuria ($p = 0.048$).

Conclusion. The increased levels of cystatin C corrected NGAL and proteinuria after an acute bout of endurance exercise suggest that an acute bout of endurance exercise may cause transient kidney injury.

2340 Board #353 June 1 3:30 PM - 5:00 PM Changes in Glomerular Filtration Rate after Maximal and Submaximal Exercise in Olders

Marina M. Trejo¹, Francisco J. Diaz², Carlos Kornhauser², Maciste Macias², Antonio Rivera², Magdalena Nájera², Citlalli Arce¹, Arturo Figueroa-Galvez, FACSM¹. ¹Universidad Autonoma de Baja California, Baja California, Mexico. ²Universidad de Guanajuato, Guanajuato, Mexico. ³Florida State University, Florida, FL. (Sponsor: Figueroa Galvez Arturo, FACSM)

(No relationships reported)

PURPOSE: Strenuous exercise may decrease Glomerular Filtration Rate (GFR) in older adults. However, kidney function in older adults has not been investigated utilizing the new creatinine-cystatin C equation for GFR during exercise. The

purpose of this study was to analyze the effect of maximal and submaximal bicycle exercise utilizing the equation for GFR of creatinine-cystatin C in older adults (≥ 65 years). **METHODS:** Twenty healthy subjects (13 men and 7 women; 70 ± 4 years) participated in the study. Subjects performed 3 bicycle exercise tests one week apart: one maximal (MAXCAP-B), and two 20-minute submaximal at 80% (SUBMAX-B80) and 60% (SUBMAX-B60) of heart rate reserve (HRR), respectively. Blood samples were obtained before and after the test in the seated position to measure the plasma concentration of creatinine and cystatin C. GFR was estimated according to the equation of Creatinine-Cystatin C Equation (CKD-EPI 2012). **RESULTS:** MAXCAP-B produced a significant reduction in GFR (87.3 ± 18.3 ml/min to 80.9 ± 18.8 ml/min, $P < 0.05$). SUBMAX-B80 (80.6 ± 14.03 ml/min to 82.7 ± 16.9 ml/min) and SUBMAX-B60 (84.7 ± 15.0 ml/min to 80.3 ± 12.7 ml/min) produced no significant reduction in GFR. **CONCLUSIONS:** Although maximal exercise produced a decrease in GFR, the changes were minimal. Intense and moderate exercise did not alter significantly GFR when the equation of creatinine-cystatin C was used. Kidney function after intense and moderate exercise in older adults was preserved, indicating safe incorporation of exercise at these intensities.

D-78 Clinical Poster Reception

Back Injury - Cheerleading

Michael Stilller, Michelle A. Miller. *The Ohio State University, Columbus, OH.*

(No relationships reported)

HISTORY: A 15-year-old high school cheerleader sustained a back injury while cheering on her school's football team. She was performing a "toe touch" jump and upon landing, she felt a "pop" and a sharp pain posteriorly between her shoulder blades. An hour later, she developed a "pins and needles" sensation from her belly button to her toes bilaterally. The next morning, the numbness had spread to just under the ribcage and she fell when trying to stand upright from bed. She presented to the emergency room later that morning.

PHYSICAL EXAMINATION: Examination revealed that she was afebrile with normal vital signs. There was no tenderness on palpation over the spinous processes or the paraspinal musculature. Her neurologic exam was significant for decreased sensation to light touch at the T8 dermatome and caudally with a proprioception deficit in the great toe bilaterally. Strength was 4/5 throughout the left lower limb. The patellar reflexes were 3/4 and the Achilles were 2/4 bilaterally. She demonstrated a wide-based gait with significant loss of balance.

DIFFERENTIAL DIAGNOSIS:

1. Spondylolysis/spondylolisthesis
2. Vertebral fracture
3. Intervertebral disc herniation
4. Transverse myelitis
5. Psychogenic

TESTS AND RESULTS:

ESR and CRP normal

T-spine MRI:

1. Mild age related change/disc degeneration at T7-8 and T8-9 with a small acute appearing central disc protrusion at T8-9 that abuts the adjacent spinal cord.
2. No findings to indicate transverse myelitis.

FINAL/WORKING DIAGNOSIS: T8-9 intervertebral disc herniation resulting in myelopathy.

TREATMENT AND OUTCOMES:

1. Neurosurgery consult with no surgical intervention taken. Patient admitted for continued monitoring, PT, and OT.
2. Notable lower limb strength improvement seen over the first three days, however, acute inpatient rehabilitation was needed to assure ability for safe ambulation with impaired lower limb sensation.
3. After 12 days of inpatient rehab, lower body sensation was still impaired, but patient demonstrated improved lower limb strength and was ambulating with proper technique multiple times around the unit without assistance.
4. Patient discharged with outpatient therapy and a follow-up with neurosurgery in one month with repeat spine MRI.
5. Patient instructed to not return to cheerleading until follow-up.

2342 Board #2 June 1 5:45 PM - 6:45 PM

Wrist Injury - Go karting

Jonathan T. Napolitano, Anastasia Fischer, FACSM. *Nationwide Children's Hospital, Columbus, OH.*

(No relationships reported)

HISTORY: A 15 year old right handed female basketball player presented to the sports medicine clinic of a pediatric hospital four months after a go-karting accident. The go-kart rolled and landed on her right wrist. With no significant pain or disability after the injury she did not seek immediate medical attention. Four months later she presented with increased pain and swelling in the wrist. She was immobilized with a cock-up splint and instructed to follow up after further imaging and occupational therapy. Her pain improved with bracing and she was lost to follow-up, attending only one occupational therapy visit. She presented again eight months later with improved pain and swelling but severe loss of range of motion. **PHYSICAL EXAMINATION:** Inspection of the right upper extremity revealed atrophy of right forearm, wrist, and hand, and a volar angular deformity of the wrist. No tenderness to palpation. Active and passive range of motion was severely limited in all directions. No soft tissue swelling or effusion. No temperature or skin texture changes. **DIFFERENTIAL DIAGNOSIS:** Post-traumatic arthritis, complex regional pain syndrome, juvenile idiopathic arthritis. **TEST AND RESULTS:** X-ray attached. MRI: Diffuse infiltrative process suggestive of ongoing inflammatory process. 3 Phase Bone Scan: Increased uptake along the right wrist and carpal joints. Sedimentation Rate: 45mm/h. Anti-CCP: 160 U. Rheumatoid Factor: 250 IU/mL. X-Rays of bilateral elbows reveal possible joint effusions. Ankle x-ray with irregular dorsal contour of the navicular. **FINAL WORKING DIAGNOSIS:** Rheumatoid factor positive, polyarticular, juvenile idiopathic arthritis. **TREATMENT AND OUTCOMES:** The patient was referred to rheumatology for further workup and close follow-up, started on methotrexate, etanercept, and prednisone, and subsequently referred to orthopedic surgery for evaluation for wrist fusion, and to physical and occupational therapy for joint range of motion and preservation.

2343 Board #3 June 1 5:45 PM - 6:45 PM

Hepatotoxicity Associated With Frozen Shoulder In A 47 Year Old Tennis Player; What's The Link?

Michael J. Murphy, Brian Keisler. *Palmetto Health Richland - University of South Carolina, Columbia, SC.*

(No relationships reported)

HISTORY: A 47 year-old female recreational tennis player with no past medical history presented with 4 months of increasing shoulder pain and stiffness. She was diagnosed with adhesive capsulitis and started on diclofenac sodium 75mg BID. Over the next month she started having abdominal pain and stopped taking diclofenac. Her pain continued to worsen and she developed intractable vomiting and jaundice and went to the hospital at that time.

PHYSICAL EXAMINATION: Alert and oriented. Scleral icterus and jaundice present. No spider telangiectasias or angiomas. No JVD. Lungs were clear. Heart regular rate and rhythm, no murmur, rub, or gallop. Abdomen soft with minimal RUQ tenderness and no ascites. Right shoulder with full ROM and normal strength. Left shoulder had severely restricted ROM in all directions with significant pain. Her neurologic exam was normal including no asterixis.

DIFFERENTIAL DIAGNOSIS: Primary Biliary Sclerosis, Viral Hepatitis, Wilson's Disease, Hemochromatosis, Medication Hepatotoxicity, Malignancy, Autoimmune Hepatitis, $\alpha 1$ -Antitrypsin Deficiency, Porphyria, Granulomatous Liver Disease, Idiopathic Portal Fibrosis

TEST AND RESULTS: Bilirubin 24.4 (Direct 20.3), AST 650, ALT 859. Lipase, iron studies, ceruloplasmin, IgG, IgA, IgM, ANA, viral hepatitis panel, PT, INR, CBC, chem-7, alkaline phosphatase, and total protein all within normal limits. PPD negative. RUQ US: cholelithiasis without evidence of cholecystitis. CT Abdomen/pelvis with contrast: hepatosplenomegaly without any masses or ascites.

FINAL WORKING DIAGNOSIS: Diclofenac induced hepatotoxicity

TREATMENT AND OUTCOMES: 1.Cessation of diclofenac. 2.In addition to inpatient GI consult and outpatient follow up, she also saw hepatology who agreed with diagnosis and treatment. 3.Initially followed LFT's daily, which was spaced to bi-weekly at discharge and continued to be spaced as she improved. Her transaminases decreased and normalized within a week. Her bilirubin increased to 30.6, and then gradually decreased until normalizing 8 months later. 4.Her adhesive capsulitis gradually improved, although she continued to have decreased ROM at last follow up which continued to restrict her ability to play tennis. 5.NSAIDs are now completely contraindicated for her. 6.She has annual follow up with GI for labs.

2344 Board #4 June 1 5:45 PM - 6:45 PM

**Proximal Muscle Weakness in 10-year-old Female
Gymnast**

Peter Waller, David Lessman, Philip Skiba. *Advocate Lutheran General Hospital, Park Ridge, IL.*

(No relationships reported)

History:

A 10-year-old gymnast initially presented with three weeks of right hamstring pain, and was started on a home exercise program. After 4 weeks without improvement, the patient was started on a program of formal physical therapy. After ten weeks of therapy, the patient began to develop core muscle weakness and right anterior hip pain, and reported an inability to walk more than a mile without limping. She went on to develop similar pain with stair climbing, as well as activities of daily living. Shortly thereafter, the patient began to complain of quadriceps weakness and thoracic back pain.

Physical Examination:

Afebrile. Muscle strength 4/5 with bilateral shoulder elevation and abduction. Strength 5/5 with elbow flexion and extension. Bilateral hip flexor strength 3/5. Sensation intact in upper and lower extremities bilaterally. Deep tendon reflexes 2+ bilaterally. Scaly erythematous rash on each side of nose. Erythema present across knuckles bilaterally.

Differential Diagnosis:

1. Juvenile Dermatomyositis
2. Polymyositis
3. Viral myositis
4. Lupus Erythematosus

Tests and Results:

Labs: CPK: 524 H, AST: 75 H, ALT: 32 H, ESR: 18 wnl, Aldolase 11 H, CRP <0.3 wnl, LDH Total 317 H

X-Ray: 3V of bilateral hips-No acute fractures, subluxation, or dislocations.

MRI Pelvis: Diffuse intramuscular edema, predominantly involving gluteal muscles.

Consistent with myositis.

Final Working Diagnosis: Juvenile Dermatomyositis

Treatment and Outcomes:

1. Patient admitted to outside hospital, and patient started on daily prednisone, weekly methotrexate, and hydroxychloroquine.
2. Patient started on IV methylprednisolone weekly, and monthly IVIG infusion by rheumatology
3. Evaluation at NIH Myositis Clinic. Recommended increasing IVIG dosing and pulse doses of IV steroid with every IVIG infusion.

2345 Board #5 June 1 5:45 PM - 6:45 PM

Cardiovascular Injury-Marathon Running

Stephen Schaaf, Beth Stepanczuk. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

(No relationships reported)

HISTORY: A 48-year-old female competitive marathon runner with no significant past medical history developed right sided neck pain while running a race. The patient completed the race at her typical pace, finishing top five in her age group. After the race, her right sided neck pain persisted. Around thirty minutes post-race she began to have sudden onset dizziness, causing her to fall to the ground. While on the ground, she soon developed severe vertigo, nausea, and emesis. EMS was immediately called and she was transported to the hospital. During transport the patient had loss of consciousness.

PHYSICAL EXAMINATION: Examination in the emergency room found the patient to be hemodynamically stable. She was noted to be lethargic but arousable, unable to stand due to vertigo, and had continued nausea and emesis. The rest of her physical exam was benign.

DIFFERENTIAL DIAGNOSIS:

Cardiac arrest
Carotid artery dissection
Exercise associated hyponatremia
Exercise associated hypotension
Hemorrhagic stroke
Hypoglycemia
Ischemic stroke
Vertebral artery dissection

TEST AND RESULTS: BMP, CBC, Troponin, UDS, EKG, and CT Head without contrast were all normal. CT angiography of the neck: Acute focal right vertebral artery dissection at C2-C3. MRI of the brain and MR angiography of the neck: Right cerebellar vermis infarct and confirmed right vertebral artery dissection at C2-C3 with associated thrombus. Cerebral angiography: Dissection of the right vertebral artery with associated non-occlusive thrombus and distal occlusion of the right PICA.

FINAL WORKING DIAGNOSIS: Right vertebral artery dissection and right cerebellar vermis infarct

TREATMENT AND OUTCOMES:

The patient was started on a heparin drip with transition to warfarin for anticoagulation and secondary stroke prevention. The patient will continue on warfarin for at least 3 months.

The patient was admitted to inpatient stroke rehabilitation and discharged to home after 5 days at an independent level.

The patient continued to suffer from vertigo for which she was started on Clonazepam 0.5mg three times daily as needed which controlled her symptoms.

She is enrolled in vestibular outpatient physical therapy.

The patient is determined and plans to run the 2017 Boston marathon which she has already qualified for.

2346 Board #6 June 1 5:45 PM - 6:45 PM

Sternoclavicular Injury - Rugby Union (15-players-a-side)

Victor Lopez Jr, (Sponsor: Robert C. Cantu, MD, FACS¹), Richard Ma², Douglas E. James³, Michael S. Wilinski⁴, Answorth A. Allen⁵. ¹Rugby Research and Injury Prevention Group, Inc, Hospital for Special Surgery, New York, NY. ²Missouri Orthopaedic Institute & Thompson Laboratory for Regenerative Orthopaedics, Columbia, MO. ³State University of New York Medical Center (Downstate), Brooklyn, NY. ⁴Lake Erie College of Osteopathic Medicine, Bradenton, FL. ⁵Hospital for Special Surgery, New York, NY.

Reported Relationships: V. Lopez Jr: Contracted Research - Including Principle Investigator; USAR New England and Empire GU RFU's and National Operating Committee on Standards for Athletic Equipment.

HISTORY: A 19-year-old men's college Rugby-15s winger collapsed during match play. The player had no impact with another player, dizziness and no loss of consciousness. A medical history revealed the player had sustained a right clavicular injury in a previous match 25 days prior to this incident. Where he complained of right shoulder pain, after impacting the ground with a multi-player tackle. The player had presented to an Urgent Care facility after that injury and provisionally diagnosed with shoulder sprain -vs- pectoralis strain, placed in arm-sling and sent home on oral analgesics. Right shoulder radiographs at Urgent Care visit were read as normal. **PHYSICAL EXAM:** Exam in ED revealed slurred speech, and complaints of localized pain and tenderness on right medial clavicle. Right sternoclavicular joint pain on palpation. Limited upper extremity range of motion secondary to pain, no facial droop, decreased left sided upper and lower extremity sensation, reflexes and strength. Symmetrical radial pulses with brisk capillary refills. **DIFFERENTIAL DIAGNOSIS** 1. Cervical Neck Injury 2. Stroke 3. Fracture Clavicle 4. Rib Fracture 5. Scapular Fracture 6. Sternal Fracture **TEST AND RESULTS:** Chest anterior-posterior radiographs: -abnormal right SCJ MRI Brain no contrast: -Large area/acute infarction. Mass effect of right lateral ventricle. No hydrocephalus. Midline shift 1-2mm. CT brain no contrast: -Right MCA infarction with right frontal/parietal lobes, insular cortex, thalamus, caudate nucleus, internal/external capsule, and lentiform nucleus. -Mass-effect on the right lateral and third ventricles. Increased midline shift 8mm. No hydrocephalus. Carotid Duplex: -Arteries bilaterally, normal velocities/waveforms. CT chest: -Right clavicular head dislocated posterior to the sternum, in the superior mediastinum. Subperiosteal hematoma around proximal right clavicle. **FINAL/WORKING DIAGNOSIS:** Missed posterior sternoclavicular joint dislocation with brachiocephalic artery compromise leading to hemiparesis **TREATMENT AND OUTCOMES:** 1. Surgical Emergency. Often missed on radiograph. 2. Open repair of brachiocephalic artery, right clavicular reduction/SCJ capsulorrhaphy with hamstring tendon allograft. 3. Patient recovered with left sided hemiparesis. No return to sport. Sponsor: NOCSAE.org

2347 Board #7 June 1 5:45 PM - 6:45 PM
Exercise Vital Sign and Health Care Utilization
 Alex Mroszczyk-McDonald, Sponsor: Robert Sallis, FACSM.
Kaiser Permanente Southern California, Fontana, CA.
(No relationships reported)

Background: It is well established that >150 minutes of weekly physical activity significantly improves health and Kaiser Permanente Southern California (KPSC) has pioneered the use of an Exercise Vital Sign (EVS) to record Physical Activity (PA). However, there is less data on exercise and impact on healthcare utilization.
Purpose: To evaluate the correlation of EVS and healthcare utilization, in our SCKP patient population. Specifically, do those patients who report consistent exercise for >150 minutes per week have reduce utilization of the health care system.
Methods: KPSC Electronic Health Record data was abstracted to determine 3 cohorts of adults (18-65yrs) (N=2,534,895) who were Consistently Sedentary (CS) (EVS=0min/wk consistently), Insufficiently Active (IA) (EVS=1-149min/wk), or Consistently Active (CA) (EVS>150min/wk consistently), meeting the World Health Organization recommendations. Each cohort had at least 3 encounters and self reported EVS that were consistent. Each cohort was then compared to their health care utilization over a 1, 3 and 5 year period. Because KPSC is a closed system we were able to accurately capture utilization of pharmacy, hospital, radiology, laboratory and outpatient departments. Data was adjusted for age, gender and ethnicity.
Results: Compared to CS patients, CA patients have consistently lower use of the KPSC health care system. This relationships held true across the 1, 3 and 5 year analysis. Of note patients who were CA were 75% less likely to be hospitalized (OR 0.23-0.26), 43% less likely to use the ER (OR 0.55-0.58) and 45% less Urgent Care services (OR 0.54-0.56), 25% less laboratory blood draws (OR 0.73-0.74), and 27% less pharmaceuticals fills (OR 0.71-0.74). Other factors that were associated with lower health system utilization were female gender, caucasian ethnicity and
Conclusion: Based on EVS data, and analysis of health utilization we conclude that CA individuals have significantly lower utilization of the health care system than those who are CS.

2348 Board #8 June 1 5:45 PM - 6:45 PM
Association of Interrelated Neuromechanical Factors with Injury Occurrence among College Football Players
 Gary B. Wilkerson, (Sponsor: Daniel C. Herman, FACSM).
University of Tennessee at Chattanooga, Chattanooga, TN.
Reported Relationships: G.B. Wilkerson: Honoraria; Arkansas Athletic Trainers' Association, American College of Sports Medicine, National Athletic Trainers' Association.

PURPOSE: The purpose of this prospective cohort study was to assess the predictive value of injury risk screening methods that collectively assess aspects of environmental awareness, cognitive processing of neural input, and motor control, as well as any persisting effects of previous injuries.
METHODS: Prior to participation, 43 NCAA Division I-FCS college football players (20.2 ±1.2 years; 185.7 ±5.8 cm; 105.4 ±20.6 kg) completed the 10-item Sport Fitness Index (SFI) survey and performed both a 60-second Reactive Peripheral Response (RPR) test and a 10-second Unilateral Forefoot Squat (UFS) test of postural stability. The 0-100 SFI score quantified perceptions of persisting effects of previous injuries. The RPR represented the number of outermost target hits (rings 4 and 5 of 64 target buttons arranged in a pattern of 5 concentric rings on a 1.2 m x 1.2 m board) while simultaneously reciting text that scrolled across a centrally located screen. The UFS test utilized a smartphone accelerometer to quantify the root mean square (RMS) of instantaneous change in body mass acceleration (Jerk) on the dominant extremity. All sprains, strains, and head injuries sustained from the beginning of practice sessions to the end of the 13-game season were documented, along with the number of player appearances in games.
RESULTS: Injuries were sustained by 14 of 43 players (33%). Univariable associations of binary risk classification with injury occurrence were: SFI ≤ 86 (OR=1.77), UFS Jerk RMS ≥ 0.06 (OR=4.19), RPR ≤ 11 Hits (OR=2.95), and Games Played ≥ 8 (OR=3.16). A large SFI X UFS X RPR interaction effect was identified (OR=11.20). Logistic regression results for the combination of the 3-way interaction (Adjusted OR=21.32) with Games Played ≥ 8 (Adjusted OR=6.19) yielded a strong prediction model ($\chi^2 = 9.04, p = .011; R^2 = .265$). Cox regression results for a binary SFI X UFS X RPR risk classification, adjusted for the potentially confounding effect of differential game exposure among players (0-13 games), demonstrated a strong association with time to injury occurrence (HR=4.65; 90% CI: 1.74, 12.44).
CONCLUSIONS: The findings support the potential for reduction of football injury risk through targeted interventions that address modifiable deficiencies in peripheral visual awareness, reaction time, and postural stability.

2349 Board #9 June 1 5:45 PM - 6:45 PM
Sex Differences in Competition Volume, Club Sport Participation, Specialization, and Injury Among High School Athletes
 Eric G. Post, David R. Bell, Stephanie M. Trigsted, Dan A. Schaefer, Madeline M. Miller, Adam Y. Pfaller, Scott B. Hetzel, M. Alison Brooks, Timothy A. McGuine. *University of Wisconsin-Madison, Madison, WI.*
(No relationships reported)

Female adolescent athletes are at greater risk for certain injuries, such as ACL injuries or overuse knee injuries. One theory for this increased risk is the increasing trend towards intense, year-round sport participation and specialization. However, it is unknown whether characteristics of sport participation, including competition volume, club sport participation, specialization, or history of lower extremity injury (LEI) differ between female and male athletes.
PURPOSE: To compare level of competition volume, club sport participation, sport specialization, and previous lower LEI between males and females in high school athletes.
METHODS: 1525 high school athletes (780 female, age=16.1±1.1 years old, grades 9-12) from 29 high schools were recruited to complete a pre-season questionnaire regarding their sport participation patterns and previous injury history. Sport competition volume in the previous 12 months was classified as high (>60 competitions), moderate (30-60 competitions), or low (<30 competitions). Sport specialization status was classified as low, moderate, or high using a widely utilized 3-point specialization scale. Chi-square tests were used to investigate associations of competition volume, club sport participation, specialization, and LEI by sex (a-priori p<.05). **RESULTS:** Females were more likely than males to participate in high competition volume (23.2% vs 11.0%, $\chi^2=84.7, p<0.001$), participate on a club team (61.2% vs 37.2%, $\chi^2=88.3, p<0.001$), and be highly specialized (16.4% vs 10.4%, $\chi^2=19.7, p<0.001$). A total of 487 subjects (31.5%) reported sustaining a total of 599 previous time-loss LEI. Female athletes were more likely to report a previous LEI than males when considering all sports (36.5% vs. 27.0%, $\chi^2=15.9, p<0.001$) and when the sample was restricted to sex-equivalent sports (37.3% vs. 28.2%, $\chi^2=9.0, p=0.003$). **CONCLUSIONS:** Female athletes were more likely to participate in sports at high volumes, on club teams in addition to their high school teams, be highly specialized, and report previous LEI. Female high school athletes may be at greater risk of injury due to these differences in sport participation patterns.
 Supported by grants from the American Medical Society for Sports Medicine and the National Federation of State High School Associations.

An Analysis of Female Athlete Triad Components in Elite Para-Athletes
 Cheri A. Blauwet¹, Emily M. Brook¹, Adam S. Tenforde¹, Elizabeth Broad², Elizabeth G. Matzkin¹. ¹Brigham and Women's Hospital/Harvard Medical School, Boston, MA. ²United States Olympic Committee, Chula Vista, CA.
(No relationships reported)

The Female Athlete Triad (Triad) is a syndrome defined as the interaction of three interrelated conditions: low energy availability with or without disordered eating, menstrual dysfunction, and low bone mineral density (BMD). The Triad may also impact males, and may have long term health consequences if unaddressed. Although participation in elite para-sport is rapidly growing, no studies have assessed the prevalence of Triad risk factors in this population.
PURPOSE: To evaluate the prevalence of Triad risk factors in an elite para-athlete population and association to sex and para-sport type.
METHODS: Subjects were United States para-sport athletes who were training to qualify for the 2016 Summer or the 2018 Winter Paralympic Games. Participants completed an online questionnaire characterizing nutrition, menstrual status (if female), bone health, and awareness of the triad. Responses were analyzed to determine overall prevalence of Triad components, and significant differences based on sex and sport type (leanness vs. non-leanness).
RESULTS: A total of 248 (144 male, 104 female) athletes completed the survey. Of these, 137 athletes competed in leanness sports and 109 athletes in non-leanness sports. Of the cohort, 40% (53 male, 45 female) of athletes indicated that they were currently trying to lose weight, and 61% (n = 151; 90 male, 61 female) indicated they were attempting to change their body composition to improve sport performance. Only 3% (1 male, 6 female) of athletes indicated that they had been previously diagnosed with an eating disorder. For pre-menopausal women, 32% (n = 29) reported less than 9 menstrual cycles in the past year. A total of 21% (27 male, 25 female) of athletes reported a history of a bone stress injury, yet 9% (8 male, 13 female) reported a diagnosis of low BMD based on DXA scan. There were no differences in risk factor prevalence between sexes or those competing in leanness versus non-leanness sports. Only 9% of athletes were aware of the Triad.

THURSDAY, JUNE 1, 2017

CONCLUSIONS: Elite para-sport athletes have high prevalence of Triad components, regardless of sex or sport type. Awareness of the Triad in athletes is low. While consequences of the Triad in a para-athlete population are poorly understood, screening tools and education to increase awareness are required to optimize overall health of this population.

2351 Board #11 June 1 5:45 PM - 6:45 PM

Pre-Race Medical Screening and Educational Intervention Reduces Medical Complications: A SAFER Study in 153208 Runners

Martin Peter Schwellnus, FACSM¹, Karen Schwabe², Sonja Swanevelder³, Esme Jordaan³, Wayne Derman⁴. ¹University of Pretoria, Pretoria, South Africa. ²University of Cape Town, Cape Town, South Africa. ³South African Medical Research Council, Cape Town, South Africa. ⁴Stellenbosch University, Cape Town, South Africa.

(No relationships reported)

We previously reported a high rate of medical complications (1/121 race starters) in a cohort of 65 865 runners participating in 21.1km and 56km races over a 4-year period (2008-2011) (SAFER study 1). PURPOSE: To determine if an online pre-race medical screening and educational intervention program reduces medical complications in distance running events. METHODS: An online pre-race medical screening (based on the European guidelines for pre-screening of leisure athletes participating in moderate- to high-intensity sports) and an educational intervention program was designed and introduced as part of the race registration process, in the period 2012 to 2015 at the Two Oceans Marathon races (21.1km and 56km). The incidence of medical complications (per 1000 race starters; all and serious life-threatening) during the 4-year post-intervention period (2012-2015: 87 343 race starters) was compared with the pre-intervention period (2008-2011: 65 865 race starters). RESULTS: Compared to the pre-intervention (baseline) period, there was a significant reduction in the incidence (per 1000 starters, 95% CI; adjusted for age group, gender and race distance) of all medical complications in all runners by 29% [pre=8.6 (7.9-9.4); post=6.1 (5.6-6.7), $p<0.0001$], 21.1km runners by 19% [pre=5.1 (4.4-5.9); post=4.1 (3.6-4.8), $p=0.0356$], and 56km runners by 39% [pre=14.6 (13.1-16.3); post=9.0 (7.9-10.1), $p<0.0001$]. Serious life-threatening complications were significantly reduced in all runners by 64% [pre=0.6 (0.5-0.9); post=0.2 (0.1-0.4), $p=0.0003$; adjusted for age group and gender]. CONCLUSION: A pre-race medical screening and educational intervention program significantly reduced medical complications and serious life-threatening complications among all runners in community-based mass participation distance running events. The reduction in all medical complications was significant in both the 21.1km and 56km races. Pre-race screening and educational intervention programs could be introduced to reduce medical complications during endurance running events.

E-10 Thematic Poster - Cardiovascular Responses to Heat Exposure

Friday, June 2, 2017, 9:30 AM - 11:30 AM

Impact Of Progressive, Chronic Dehydration On Cardiovascular Responses To Exercise In A Heated Environment

Kate S. Early¹, Bailey Theall², Nathan Lemoine², Brian Harrell³, Conrad P. Earnest, FACSM⁴, Neil M. Johannsen². ¹Columbus State University, Columbus, GA. ²Louisiana State University, Baton Rouge, LA. ³Baton Rouge General, Baton Rouge, LA. ⁴Texas A&M, College Station, TX. (Sponsor: Conrad Earnest, FACSM)

Email: early_kate@columbusstate.edu

(No relationships reported)

PURPOSE: 1) To examine the effects of chronic hypohydration on cardiovascular (CV) responses during exercise in a heated environment; 2) determine if resting CV health influences CV responses during exercise. **METHODS:** Participants (n=18, 21±1y; mean±SD) followed 3 days of self-determined dehydration (DEH) or hydration (HYD) in a counterbalanced, cross-over design. Exercise trials included 30-min of cycle ergometry in a heated environment (30.2±0.8°C, 26.5±7.4%RH). Heart rate (HR) and blood pressure (BP) were taken every 10-min. Weighted skin temperature (T_{sk}) (4 site: chest, arm, thigh, leg) and skin blood flow (SkBF) were collected continuously during exercise, followed by calculations of total body (T_b) temperature from T_{sk} and rectal temperature (T_{re}), and heat storage [HS = (0.97*weight*ΔT_b)/(body surface area*time)]. Resting CV health was assessed by brachial-artery flow-mediated dilation (FMD), pulse wave velocity (PWV), and heart rate variability (HRV). **RESULTS:** Weight (P<0.005), urine color, and specific gravity (P<0.001) were different between DEH and HYD pre-exercise. HR was greater in DEH vs. HYD at 10, 20 and 30-min (P=0.05). Body temperature responses (n=12) after 30-min of exercise were not different between HYD and DEH (T_{sk} P=0.47, T_b P=0.72). SkBF tended to be greater in the HYD vs. DEH (SkBF slope: HYD vs. DEH, 3.5±2.6 vs. 2.4±1.1, P=0.05; ΔSKBF: HYD vs. DEH, 370.0±156.3% vs. 169.0±130.4%, P=0.05). Though no association was found with PWV and T_{sk} (P=0.80) and T_b (P=0.69), greater changes in T_{sk} and T_b were associated with increased FMD (P=0.006) and increased rate of HS associated with decreased HRV (P=0.04) across all trials (n=24). **CONCLUSIONS:** Progressive, chronic dehydration alters CV and SkBF response during exercise. Resting CV profile was related to increased rate of HS and greater change in T_b, suggesting CV health plays a role in the mechanism of heat dissipation, especially when hypohydrated.

The Independent Effect of Heart Rate on Stroke Volume When Skin Temperature is Hot and Cool During Exercise

Ting-Heng Chou, John D. Akins, Charles K. Crawford, Jakob R. Allen, Edward F. Coyle, FACSM. *The University of Texas at Austin, Austin, TX.*

Email: tinghengchou@gmail.com

(No relationships reported)

There are two hypotheses of how stroke volume (SV) is affected during hyperthermic exercise. The traditional hypothesis is that an increase in cutaneous blood flow (CBF) is thought to lead to a decline in SV. An alternate hypothesis is that a decline in SV is due to an increase in heart rate (HR). However, these two hypotheses have not been tested under the same thermal stress. **PURPOSE:** 1) To determine the independent effect of HR on SV by using low dose β₁-blockade (BB) when skin temperature (T_{sk}) is high (>38°C) during exercise. 2) To see how the rapid lowering of T_{sk} reverses the changes in cardiovascular variables. **METHODS:** Tsk was manipulated by wearing a water perfused suit that covered the whole body, except head, hands, and feet and maintained a perfused water temperature of 30 or 50°C. Subjects (n=8, active men 24 ± 4 y) cycled at 60% VO_{2peak} for 20 min in three conditions: 30°C water with placebo (30-PL), 50°C water with PL (50-PL), and 50-BB. Tsk was rapidly cooled at 20 min of exercise in all trials by perfusing cold water through the suit (0°C) plus fans. Subjects continued to cycle for another 20 min with cool Tsk. Esophageal temperature (T_{es}), Tsk, VO₂, cardiac output (CO), HR, mean arterial pressure (MAP), cutaneous blood flow (CBF), and forearm venous volume (FVV) were measured during exercise. **RESULTS:** Mean Tsk during the first 20 min of exercise were 33.4 ± 0.2, 38.1 ± 0.2, and 38.2 ± 0.2 °C, for 30-PL, 50-PL, and 50-BB, respectively. Mean Tsk during

the last 20 min of exercise were 29.5 ± 0.2, 29.8 ± 0.3, and 30.0 ± 0.3 °C, for 30-PL, 50-PL, and 50-BB, respectively. When HR was lowered to the same level as 30-PL (147.9 ± 3.8 bpm) by BB in 50-BB (151.7 ± 4.0 bpm), SV was also restored to the same level as 30-PL (132.0 ± 7.3 ml) in 50-BB (135.6 ± 7.5 ml). SV was restored even with a significantly higher CBF (77.1 ± 3.4% vs 55.9 ± 3.6% for 50-BB vs 30-PL; p<0.05) and lower MAP (98.5 ± 2.6 mmHg vs 105.4 ± 3.3 mmHg for 50-BB vs 30-PL; p<0.05). When Tsk was rapidly cooled, HR and CBF were significantly decreased while SV was maintained in 50-PL. There was no apparent effect of Tsk on FVV responses. **CONCLUSION:** The increase in HR was responsible for the decrease in SV when Tsk was above 38°C. Rapidly cooling Tsk while T_{es} remains elevated decreased CBF and HR.

Heart Rate Variability as Potential Indication to the Mechanism of Heat Intolerance

yuval heled, FACSM. *Heller Institute of Medical Research, Ramat Gan, Israel.*

Email: yuval.heled@sheba.health.gov.il

(No relationships reported)

¹Yuval Heled, ¹Yoram Epstein, ^{1,2}Ran Yanovich, ^{1,2}Itay Ketko, ¹Amit Druyan ¹Heller Institute of Medical Research, Sheba Medical Center, Tel Hashomer, Israel ²The IDF Institute of Military Physiology

BACKGROUND: Heat intolerance is a phenomenon associated with relative inability to properly maintain body temperature during exposure to heat stress. Since normal thermoregulatory function is influenced by mechanisms mediated by the autonomic nervous system (ANS) (e.g. sweat rate, vasodilatation), heart rate variability (HRV) which is an established, non-invasive tool for assessing ANS activity, can serve as an assistive tool for evaluating candidate mechanisms of heat intolerance. **PURPOSE:** To determine whether non-linear HRV measures during heat tolerance test (HTT) may be used as an indication to the mechanism of heat intolerance. **METHODS:** HTTs from the IDF Institute of Military Physiology database performed between the years 2012-2015 were analyzed. Analyses of the non-linear HRV indices D2, SD1/SD2 and ApEn have been made for the full HTTs (120 minutes) by a researcher blinded to the HTT results and to the patients' clinical records. HRV indices were then compared between heat intolerant (HI) and heat tolerant (HT) individuals. **RESULTS:** Our data included 283 HTTs (215 HT; 76%, and 68 HI; 24%) HI. We found significant differences between HT and HI tests in D2 (HI - 0.0355±0.0261, HT - 0.0896±0.104, p<0.001) and ApEn (HI - 1.429±0.079, HT - 1.395±0.11, p=0.0207) but not in SD1/SD2 (HI - 0.331±0.067, HT - 0.335±0.007, p=0.721). We found a weak correlation between the HRV indices and the initial and final core temperatures and heart rates. **CONCLUSIONS:** We found that HT and HI individuals differ in some non-linear HRV measures during an HTT. Although the differences are statistically significant, the values overlap between HT and HI individuals, thus HRV during an HTT (using the non-linear methods examined in this study) does not seem to be valuable tool for heat intolerance diagnosis, but it may serve as potential indirect indicator to the relative contribution of the ANS to HT vs. HI states, and thus to the mechanism associated with HI phenomenon.

(No relationships reported)

Whole-body heat stress improves cardiac systolic function, which is vital towards the maintenance of stroke volume despite reductions in central blood volume and cardiac filling pressure. However, the mechanisms by which cardiac systolic function is enhanced during heat stress are unclear. **PURPOSE:** To test the hypothesis that whole-body passive heat stress sensitizes β₁-adrenergic receptor mediated increases in cardiac systolic function. **METHODS:** In ten healthy participants (five females: age 23 ± 2 and five males: age 26 ± 3), echocardiographic indices of cardiac systolic function (average peak systolic tissue velocity at the septal and lateral mitral sites - S'_{avg}) were obtained prior to and during intravenous infusion of a low (5 μg/kg/min) and a moderate (15 μg/kg/min) dose of dobutamine (a β₁-adrenergic receptor agonist) under normothermic (NT) and hyperthermic (HT; increase internal temperature of 1.2 ± 0.1°C) conditions. **RESULTS:** HT increased S'_{avg} at baseline (NT, 9.5 ± 0.5 cm/s vs HT, 14.0 ± 1.0 cm/s, P<0.01). However, the low dose of dobutamine during HT further increased S'_{avg} (Δ 6.5 ± 1.2 cm/s) compared to S'_{avg} in NT (Δ 4.0 ± 0.7 cm/s, P=0.03).

Furthermore, the infusion of the high dose of dobutamine during HT also resulted in greater increases in S'_{avg} ($\Delta 13.3 \pm 1.3$ cm/s) compared to NT S'_{avg} ($\Delta 9.4 \pm 1.2$ cm/s, $P < 0.01$). **CONCLUSION:** These data suggest that cardiac β_1 -adrenergic receptors are sensitized during hyperthermia, which likely contributes to increases in cardiac systolic function and accompanying preservation of stroke volume during whole-body heat stress.

Effect of Exercise Mode on Cardiovascular Drift and Maximal Oxygen Uptake During Heat Stress

Tori M. Stone¹, Jonathan E. Wingo, FACSM¹, Jason Ng². ¹The University of Alabama, Tuscaloosa, AL. ²California State University, San Bernardino, San Bernardino, CA. (Sponsor: Jonathan E Wingo, FACSM)
 Email: tmstone3@crimson.ua.edu
 (No relationships reported)

Cycling has been reported to result in greater cardiovascular drift (CV drift) compared to running in a temperate environment. It remains unknown whether this holds true in a hot environment. It also remains unknown whether a greater magnitude of CV drift during cycling is associated with a greater decrement in maximal oxygen uptake ($\dot{V}O_{2max}$) compared to running. **PURPOSE:** To test the hypothesis that cycling elicits a greater magnitude of CV drift and accompanying greater decrement in $\dot{V}O_{2max}$ compared to running in the heat. **METHODS:** Seven men (mean \pm SD; age = 25 ± 6 y, body fat = $12.0 \pm 2.2\%$, bike $\dot{V}O_{2max} = 54.7 \pm 5.5$ mL/kg/min, treadmill $\dot{V}O_{2max} = 58.9 \pm 4.3$ mL/kg/min) completed a graded exercise test on a cycle ergometer and a treadmill (separate days) in ~ 22 °C to determine $\dot{V}O_{2max}$. Then on separate visits (counterbalanced) they cycled or ran for either 15 or 45 min at 60% mode-specific $\dot{V}O_{2max}$ in 35 °C. CV drift was measured between 15 and 45 min during the 45-min trials. The purpose of the separate 15- and 45-min trials was to measure $\dot{V}O_{2max}$ over the same time interval that CV drift occurred. **RESULTS:** The increase in heart rate (HR; $\sim 13\%$ for bike and treadmill, $p < 0.001$) and decrease in stroke volume (SV; $\sim 12\%$ and $\sim 15.5\%$ for bike and treadmill, respectively, $p < 0.001$) between 15 and 45 min were not different between exercise modes ($p = 0.91$ and 0.53 for mode \times time interaction for HR and SV, respectively). $\dot{V}O_{2max}$ decreased 15% from 15 to 45 min ($p = 0.002$), but the reduction was not different between exercise modes ($p = 0.54$ for mode \times time interaction). **CONCLUSIONS:** Contrary to our hypothesis and to previous findings in a temperate environment, the magnitude of CV drift during prolonged exercise in the heat was not different between cycling and treadmill running. The rise in HR and concomitant decrease in SV associated with CV drift in the heat—regardless of the exercise mode—corresponded to a proportional decrease in $\dot{V}O_{2max}$.

Blood Pressure and Cardiovascular Responses to Emergency Calls in Volunteer Firefighters and Emergency Medical Technicians

Meaghan E. Corbin¹, Cassandra C. Derella¹, Kelly C. McLaughlin¹, Allyson K. Getty¹, Lauren N. Chavis¹, Tia R. Wisdo¹, Christian K. Roberts, FACSM², Deborah L. Fearheller¹. ¹Ursinus College, Collegeville, PA. ²Occidental College, Los Angeles, CA. (Sponsor: Christian K Roberts, FACSM)
 Email: mecorbin@ursinus.edu
 (No relationships reported)

Hypertension and obesity are both primary risk factors for cardiovascular (CV) disease. Among the firefighter (FF) population cardiac events remain the leading cause of line-of-duty deaths. Work related stress can cause a surge in heart rate and blood pressure (BP) and studies have noted that FF and Emergency Medical Technicians (EMTs) have increased heart rate and BP throughout the day. Thus, understanding the risk factors associated with work related stress in FF and EMTs, including BP surges and CV disease risk are important factors in continual need of study. **PURPOSE:** To examine the relationship between BP responses to emergency calls and CV health. **METHODS:** Eight FF and EMTs (7M/1F; 2EMTs/6FFs; 32.8 ± 9.3 yrs) wore ambulatory brachial BP cuffs during a 12-hour work shift to observe BP responses to emergency calls. Additionally, plasma glucose levels, total cholesterol levels and triglyceride (TG) levels, and central BP through radial artery tonometry was obtained and measured after a 10-hour fast. In addition, a preliminary sub-analysis was completed between 4 lean and 4 obese (BMI > 30 kg/m²). **RESULTS:** Average 12-hr BP was $118.2 \pm 8.0 / 74.0 \pm 8.7$ mmHg. With emergency calls, the brachial BP surge was $20.7 \pm 14.9 / 10.0 \pm 6.7$ mmHg compared to the measured brachial BP immediately before alarm. When compared to the mean 12-hr BP, the BP surge was larger ($22.9 \pm 11.7 / 13.6 \pm 6.2$ mmHg). We found no relationship between central BP surge and CV health measures in the group and no relationship between core BP and BP surge. In the sub-analysis, the average brachial BP for lean group (BMI 22.9 ± 4.7 kg/m²) was $118.4 \pm 2.3 / 71.7 \pm 4.1$ mmHg, and the average brachial BP for the obese group (BMI 37.2 ± 6.3 kg/m²) was $136.3 \pm 5.1 / 84.9 \pm 4.4$ mmHg. Central BP in the lean population was $103.6 \pm 6.6 / 72.9 \pm 5.8$ mmHg, while in the obese population it was $118.5 \pm 9.0 /$

85.0 ± 11.8 mmHg. We found a relationship between diastolic BP surge and glucose levels in both groups, as well as a correlation between diastolic BP surge and TG in the lean group ($p < 0.05$). **CONCLUSION:** This pilot data suggests that both systolic and diastolic BP surge during emergency calls. The data also preliminarily indicates that obese emergency workers exhibit higher brachial and central BP. Further research is needed to determine whether obese firefighters are at risk of CV events during emergency calls.

 (No relationships reported)

Firefighters' work routines vary worldwide, but generally include fire suppression, rescues and medical emergencies. These job activities may expose firefighters (FF) to an elevated cardiac strain. **PURPOSE:** We evaluated the heart rate (HR) and blood pressure (BP) profile during a routine 12-hour work period among career FF. **METHODS:** 30 male military FF, aged 40 ± 3.2 yrs, BMI = 26.3 ± 3.1 kg/m², were recruited from a Brazilian Fire Department. BP and HR were measured in a basal condition on an off-duty day (Eva1) and before (Eva2) and after (Eva3) a 12-hour period of work, in resting supine (SUP) and orthostatic (ORT) postures. HR was also continuously measured during work period by the Polar_V800 and on-duty cardiac strain was categorized by the absolute and relative time spent on 4 intensity zones: light ($< 63\%$ Max_age_predicted_HR), moderate (63-76%), hard (77-93%) and very hard ($\geq 94\%$). HR and BP were compared between the 3 evaluations (Friedman test), at 5% level of significance. **RESULTS:** $97.3 \pm 4.2\%$ of on-duty time was spent on light and $1.8 \pm 2.8\%$ on moderate intensities. An important absolute time was performed on hard (4.7 ± 10.0 min) and very hard (0.7 ± 2.8 min) intensities. 46.7% of FF engaged on hard and 16.7% on very hard intense activities. Mean on-duty peak HR was equivalent to $76.8 \pm 17.1\%$ of Max_HR and achieved $107.1 \pm 10.7\%$ among those who performed very hard activities. HR and BP comparisons in the 3 evaluations are shown on Table. **CONCLUSION:** Our data show a significant increase in resting HR after 12-hour on-duty, suggesting a change on resting cardiovascular regulation toward a more stressful condition. The majority of FF was exposed to high cardiac strain during a routine 12-hour shift work. Although the time spent on vigorous activities was short, its intensity might represent an acute elevated risk for fatal and non-fatal cardiovascular event in susceptible firefighters.

HR and BP in SUP and ORT position, at control condition (Eva1), before (Eva2) and after work (Eva3)

Firefighting is a hazardous profession with high on-duty cardiovascular mortality, which might be associated with cardiac autonomic dysfunction (CAD) and/or low cardiorespiratory fitness (CRF).

PURPOSE: We aimed to evaluate the vagal modulation of the heart in resting supine (SUP) and orthostatic (ORT) postures during a routine 12-hour work period among career firefighters (FF), in association with the CRF.

METHODS: We evaluated 30 male military FF, aged 40±3.2 yrs, BMI = 26.3±3.1 kg/m², CRF = 11.4±1.4 METs, recruited from a Brazilian Fire Department. Vagal modulation was evaluated by means of the short-term time-domain heart rate variability index PNN50%, which is the percentage of successive R-R intervals greater than 50 ms and reflects the beat-to-beat parasympathetic modulation. CRF was estimated by a validated self-reported physical activity questionnaire (Jackson & Blair, MSSE, 1990). PNN50% was measured in a basal condition on an off-duty day (Eva1) and immediately before (Eva2) and after (Eva3) a 12-hour period of work, in resting supine (SUP) and orthostatic (ORT) postures. PNN50% values were compared between the 3 evaluations (Friedman test), two postures (Wilcoxon-test) and by CRF categories (<12 METs vs ≥ 12 METs) after 12 hours of work in ORT (Kruskal Wallis test), at 5% level of significance.

RESULTS: Median (min-max) values of PNN50% in SUP and ORT in Eva1-3 are shown on Table. Those with better CRF (n=10) showed higher values of PNN50% in ORT after 12-hours of routine work: 3 (0-60%), as compared to FF with lower CRF: 0 (0 - 8%) (p = 0.047)

CONCLUSION: Our data show a physiological decrease on PNN50% to active standing up. We also observed a significant reduction on the vagal modulation in ORT-Eva3 as compared to Eva1. The association between the reduced resting vagal modulation after a 12-hour period of work and low CRF reinforce previous recommendation for implementing physical training among FF as a cardioprotective strategy.(CNPq 480092/2013-3)

Moderate Intensity Exercise Ameliorates Negative Impacts of Simulated Altitude on Executive Function.
 Laura Q. Jimenez, Brian Arwari, Arlette C. Perry, FACSM, Joseph F. Signorile, FACSM, Soyeon Ahn, Sarah Kamakawiwo'ole, Kevin A. Jacobs, FACSM. *University of Miami, Coral Gables, FL.* (Sponsor: Dr. Kevin Allen Jacobs, FACSM)
 Email: lquirola@umiami.edu
 (No relationships reported)

PURPOSE: The present study was conducted to examine the behavioral cognitive and neurophysiological effects of acute exposure to simulated moderate and high altitudes at rest and during exercise in an effort to delineate whether there is a level of simulated altitude beyond which executive cognitive functions are impaired and whether exercise improves or worsens cognitive function during exposure to simulated altitude. **METHODS:** Fourteen recreationally active college students (M=9, F=5) aged 18-35 participated in this study, which consisted of six experimental days, with three simulated altitude conditions: sea level (SL), simulated moderate altitude (MA; 15.4% F_IO₂, ~2400 m) or simulated high altitude (HA; 12.8% F_IO₂, ~3900 m); and two exercise conditions: rest or moderate intensity cycling exercise at 60% altitude-specific peak power output, in a randomized-order, crossover design. Dependent variables included accuracy and reaction time on two executive cognitive function tasks (a modified Flanker task and a Stroop task), and the amplitude and latency of their associated event-related potentials.

RESULTS: For the Flanker task, both MA and HA slowed down reaction time (p=0.04), while exercise improved reaction time (p=0.01). Similarly, for the Stroop task, HA (though not MA) slowed reaction time (p=0.02), while exercise improved reaction time (p=0.04). Accuracy was preserved under all conditions. These effects were partially explained by alterations in associated event-related potential amplitudes and latencies, such as slower N200 latencies with altitude (p=0.04) but faster latencies with exercise (p<0.01), as well as reduced P300 amplitude and slower latency with altitude (p<0.01), and reduced amplitude but faster latency with exercise (p=0.03).

CONCLUSIONS: Acute exposure to simulated altitudes slows behavioral cognitive reaction time on executive function tasks while preserving task accuracy. An acute bout of moderate intensity cycling exercise improves reaction times so that they are comparable to those achieved without exercise or simulated altitude exposure, at least in instances where exercise does not exacerbate the peripheral oxygen saturation drops seen with simulated altitude.

Relation Between Affective Valence During Exercise and Exercise Behavior
 Zachary Zenko¹, Panteleimon Ekkekakis, FACSM². ¹Duke University, Durham, NC. ²Iowa State University, Ames, IA.
 (No relationships reported)

Theories currently used to understand exercise behavior focus on cognitive constructs but overlook the potential role of affect. However, recent studies have yielded evidence of an association between exercise-induced affect and exercise behavior, focusing on single assessments of affect during and post-exercise or pre-post changes. We extend this line of research by (a) tracking the affective response with multiple assessments during exercise and calculating individual slopes of change and (b) setting exercise intensity at the ventilatory threshold (VT), where interindividual variability in affective responses is expected to be maximized, according to the dual-mode theory. **Purpose:** To assess the relations between slope of affective valence (AV; i.e., pleasure-versus-displeasure) and the mean AV during exercise at the VT with exercise behavior. **Methods:** Volunteers (N=93; 62.4% female; VO_{2peak}: 31.77±8.73 ml·kg⁻¹·min⁻¹; BMI: 25.05±4.86 kg·m⁻²; age: 25.27±9.11 years) completed a maximal exercise test to determine the VT. One week later, participants completed a 5 min warm up followed by 10 min of exercise at the watts corresponding to the VT. During exercise, AV was assessed every 2 min using the Feeling Scale (FS; Hardy & Rejeski, 1989). Leisure-time moderate- and vigorous-intensity exercise behavior were assessed one week earlier using the International Physical Activity Questionnaire (Craig et al., 2003). **Results:** As anticipated, considerable heterogeneity in the slope of AV during exercise was evident; 62% of participants reported declines whereas 23.9%

reported improvements. The slope of AV was related to moderate ($r=.22, p=.03$) but not vigorous exercise behavior ($r=.04, p=.72$). Mean AV during exercise was also related to moderate ($r=.28, p=.006$) but not vigorous exercise behavior ($r=.08, p=.46$). **Conclusions:** AV during exercise is associated with moderate, but not vigorous, exercise behavior. Future investigators should determine if changes in AV during exercise correspond to changes in exercise behavior in longitudinal studies.

Does A Mentally Demanding Cognitive Task Influence Motor Reaction Time?

Bart Roelands¹, Jeroen Van Cutsem¹, Samuele Marcora², Romain Meeusen, FACSM¹. ¹Vrije Universiteit Brussel, Brussels, Belgium. ²University of Kent, Kent, United Kingdom. (Sponsor: Romain Meeusen, FACSM)
Email: bart.roelands@vub.ac.be
(No relationships reported)

PURPOSE: Recent research has reported mental fatigue not only impairs endurance, but also sport-specific technical performance. Therefore we sought to examine the effect of a mentally fatiguing task on a motor-reaction time (M-RT) task.

METHODS: A M-RT task was developed with Fitlight-hardware and -software in order to evaluate the effect of mental fatigue on stimuli-type (simple vs. response inhibition) and visual-field position (central vs. peripheral). Eleven untrained healthy subjects (age: 25 ± 4 y; 6 female, 5 male) performed two experimental trials in a randomized crossover order. Participants first completed a baseline M-RT task (~6min30sec), followed by a Flanker task. Next they performed either a 90min mentally fatiguing task (Stroop task; MF) or watched a 90min documentary (CON). Immediately thereafter again the Flanker task and the M-RT task were completed. Accuracy (ACC) and reaction time (RT) were followed up in all tasks but the documentary. In addition multiple physiological and psychological measures were assessed during the protocol.

RESULTS: ACC on both the Stroop task ($p=0.021$) and the Flanker task (~3%; $p=0.048$) dropped over time in MF. Participants got faster over time on the Stroop task in MF ($p \leq 0.004$). RT on the Flanker task did not change over time in both MF and CON. Subjectively, higher ($p=0.001$) mental fatigue was perceived in MF compared to CON. Concerning the M-RT-performance, no effects were observed for the simple stimuli. For the response inhibition-stimuli, only in MF participants became significantly slower in time (~7.5%; $p=0.007$).

CONCLUSION: Mental fatigue negatively affects sport-specific response inhibition-RT. Therefore, besides endurance capacity, also sport-specific cognition appears to be impaired by mental fatigue. The impairment in RT was independent from the visual-field position of the stimulus and was not perceived by the participants.

2404 Board #4 June 2 9:30 AM - 11:30 AM
Regulating Pleasure During Exercise: Impact on Exercise Adherence

Nicole B. Doolen, Walter R. Bixby, FACSM. *Elon University, Elon, NC.*
(No relationships reported)

PURPOSE: To compare the impacts of an affect-based exercise prescription (Feeling Scale) versus an intensity-based exercise prescription (Rating of Perceived Exertion) on changes in exercise adherence. **METHODS:** Participants were assigned to an FS prescription ($n = 26$) or an RPE prescription ($n = 24$) for a 6-week intervention consisting of at least 30 minutes of cardiovascular exercise on at least 3 days per week. The FS prescription required participants to maintain a perceived FS value of at least +3 (good), and the RPE prescription required participants to maintain a perceived RPE value of 12-13 (somewhat hard) throughout each exercise bout. Exercise logs were used to assess exercise participation and minutes of exercise per week at 1, 3, and 6 months post-intervention. **RESULTS:** For the 26 participants in the FS group who began the intervention, 77% completed the 6 weeks, 62% reported exercise at 1 month, 46% reported exercise at 3 months, and 31% reported exercise at 6 months. For the 24 people in the RPE group who began the intervention, 67% completed the 6 weeks, 38% reported exercise at 1 month, 21% reported exercise at 3 months, and 25% reported exercise at 6 months. For minutes of exercise per week, a 2 (group) x 3 (time) ANOVA with repeated measures on the time factor revealed a significant main effect for time, $F(2, 48) = 3.20, p = 0.049$. Minutes of exercise for the FS and RPE groups varied at 1, 3 and 6 months: FS = 96.2, 61.4, & 57.3; RPE = 89.1, 37.7, & 94.5. **CONCLUSION:** Drop-out rate was lower for the FS group across all time points. Three months post-intervention, more participants in the FS group reported exercise and they did more minutes of exercise per week. At 6 months, this trend in adherence for the FS group had disappeared. A more robust intervention may have improved 6 month adherence.

2405 Board #5 June 2 9:30 AM - 11:30 AM

Effect Of High-intensity Intermittent Games-based Activity On Cognitive Function In Adolescents

Simon B. Cooper¹, Karah J. Dring¹, Maria L. Nute¹, John G. Morris¹, Caroline Sunderland¹, Stephan Bandelow², Mary E. Nevill¹. ¹Nottingham Trent University, Nottingham, United Kingdom. ²Loughborough University, Loughborough, United Kingdom.
Email: simon.cooper@ntu.ac.uk
(No relationships reported)

Whilst moderate intensity exercise has been shown to enhance cognition in adolescents, the activity patterns of young people are typically high-intensity and intermittent in nature, with team games providing an enjoyable and attractive exercise model. Yet, the effect of games-based exercise on cognition remains unknown.

PURPOSE: To examine the effects of a bout of games-based exercise on adolescents' cognitive function. **METHODS:** Following ethical approval and familiarisation, 28 adolescents (12.2 ± 0.7 y) completed an exercise (E) and resting (R) trial in a counter-balanced, randomised crossover design. Following a standardised breakfast of 1.5 g carbohydrate per kg body mass, participants completed 1 h of games-based activity (basketball), during which average heart rate was 154 ± 8 beats min^{-1} and maximal heart rate was 196 ± 8 beats min^{-1} . A battery of cognitive function tests (Stroop test, Sternberg paradigm and Trail Making test) were completed 30 min pre-exercise, immediately post-exercise and 45 min post-exercise. Data were analysed using mixed effect models in R. **RESULTS:** Response times on the simple level of the Stroop test were unaffected, but on the complex level there was an improvement in response times immediately (E: -78 ms, R: +1 ms, $p = 0.004$) and 45 min (E: -96 ms, R: +21 ms, $p < 0.001$) post-exercise. Accuracy on the simple level of the Stroop test was better maintained 45 min post-exercise (E: +0.8%, R: -3.1%, $p = 0.015$), but unaffected immediately post-exercise and on the complex level. Response times on the one item level of the Sternberg paradigm were enhanced immediately post-exercise (E: -37 ms, R: -2 ms, $p = 0.014$) and on the 5 item level were enhanced immediately (E: -79ms, R: -1 ms, $p = 0.002$) and 45 min (E: -70 ms, R: -8 ms, $p = 0.047$) post-exercise. Accuracy on the Sternberg paradigm was unaffected, as was the time taken to complete both levels of the Trail Making test (all $p > 0.05$). **CONCLUSION:** Cognitive function was enhanced following intermittent high-intensity team games-based activity in adolescents, as observed by improved response times and accuracy on the Stroop test and improved response times on the Sternberg paradigm. These data support the inclusion of opportunities for team games-based exercise during the school day to enhance cognitive function; a key consideration for school policy makers.

2406 Board #6 June 2 9:30 AM - 11:30 AM

Comparison Of The Effects Of Self-selected And Prescribed Intensity Exercise On Exertion And Feeling

Walter R. Bixby, FACSM, Kristen A. Fontela. *Elon University, Elon, NC.*
Email: wbixby@elon.edu
(No relationships reported)

PURPOSE: To determine if participants rate an exercise intensity as more enjoyable when permitted to self-select rather than when the intensity is prescribed to them. **METHODS:** Twenty-three healthy (13 females) participants (age = $20.9 \pm .55$) completed a graded exercise test (VO2 max male: 39.4 ± 6.8 & female 33.9 ± 3.8), a session of self-selected exercise, and a session of prescribed intensity exercise, all on a Lode recumbent bicycle. Each session was separated by 48 hours. During exercise, perceptions of the exercise were recorded using the Ratings of Perceived Exertion (RPE), Feeling Scale (FS), and Felt Arousal Scale (FAS). Following completion of each test, participants rated their enjoyment of the session using the Physical Activity Enjoyment Scale (PACES). The intensity of the prescribed intensity session was identical to the self-selected condition, although participants were not aware of this. **RESULTS:** A 2 (day) x 5 (time) repeated measures ANOVA was conducted. For RPE, there was a significant time main effect $F(4, 59.5) = 165.25, p < 0.001$. For FS, there was a significant condition main effect, $F(1, 22) = 6.76, p = 0.016$, and a significant time main effect, $F(4, 69.1) = 11.12, p < 0.001$. For PACES, a one factor repeated measures ANOVA revealed a significant effect of condition, $F(1, 22) = 5.02, p = 0.035$. **CONCLUSIONS:** In line with self-determination theory, when participants were able to self-select their intensity, they felt better throughout and reported greater enjoyment after the exercise session when compared to a prescribed intensity that was identical. Based on hedonic theory, this would suggest that self-selecting intensity may lead to increased adherence in the future.

Postseason Emotion Dysregulation in High School Athletes
 Melissa A. Fraser. *Texas State University, San Marcos, TX.*
 Email: missyfraser@txstate.edu
 (No relationships reported)

Sex, contact level, and concussion history have been associated with preseason aggression, impulsivity, anxiety, and depression in high school athletes. However, postseason scores have not been investigated. **PURPOSE:** Determine the association of postseason depression, anxiety, aggression, and impulsivity with sex, contact level and concussion history in high school athletes. **METHODS:** Postseason concussion history and emotion dysregulation measures were collected at one high school during 2013-2014 and 2014-2015 and at three high schools during 2015-2016. Sports were categorized into no-contact (cross country, swimming, tennis, track), low-contact (baseball, basketball, diving, softball, volleyball), and high-contact sports (field hockey, football, lacrosse, soccer, wrestling). Concussion history and incident concussion were analyzed as dichotomous variables (any vs. none). One-way analysis of variance was used for all analyses. Preseason emotion dysregulation scores and sport were used as covariates for all analyses. **RESULTS:** Postseason data were collected from 717 athletes (n=392 males, 325 females; age=15.7 ±1.2 years) who averaged 5.7 ± 3.5 years of sport participation. Females reported significantly lower aggression scores compared to the males (B= -10.489, p=0.008, 95% CI: -18.219,-2.759). Low contact sports reported significantly lower postseason aggression compared to high contact sports (B= -10.4887, p=0.0079, 95% CI: -18.2188,-2.7586). No other significant postseason behavior dysregulation differences were found between sex (p≥0.020), contact levels (p≥0.0202), concussion history (p≥0.1110), or incident concussion (p≥0.2060). **CONCLUSIONS:** In univariate analyses, sex and contact level were associated with emotion dysregulation in high school athletes. Concussion history and incident concussion were not associated with postseason emotion dysregulation in high school athletes. Longitudinal studies over several years may be needed to determine these relationships.

2408 Board #8 June 2 9:30 AM - 11:30 AM
A Randomized Control Intervention Investigating the Effects of Acute Exercise on Emotional Regulation
 Meghan K. Edwards, Paul D. Loprinzi. *The University of Mississippi, Oxford, MS.*
 Email: medward3@go.olemiss.edu
 (No relationships reported)

PURPOSE: To examine the effects of an acute bout of aerobic exercise on emotional regulation among young adults. **METHODS:** Participants (N= 27, mean age = 24.2 years) were randomly assigned to stretch (control group, n= 10), walk (n= 9), or jog (n= 8) for 15-minutes (exercise 1), after which they were exposed to a film clip (3 min) intended to elicit a negative emotional response (e.g., sadness, anger, anxiousness). Participants then completed the same stretching, walking, or jogging protocol (exercise 2) for a second time. Notably, walking and jogging occurred at a self-selected intensity on a treadmill. Participants' emotions were monitored before and during both exercise bouts, as well as after the film clip using the Exercise Induced Feelings Inventory (EFI) and an affective circumplex scale. **RESULTS:** A group x time split-plot (baseline vs. post-film clip) ANOVA interaction effect was significant for anger (P=.046) and anxiousness (P=.038). Follow-up analyses (paired t-tests) showed that only the stretching group (P=.048) had a significantly increased anger score from baseline to post-film clip, suggesting a protective emotional effect from walking and jogging. For anxiousness, the P-values for the stretching, walking, and jogging groups were .21, .21, and .06, respectively, suggesting that anxiousness was more significantly different between baseline and post-film clip in the jogging group (vs. walking or stretching). **CONCLUSIONS:** Fifteen minutes of aerobic exercise (via walking or jogging) was more effective in regulating anger and anxiousness after a stressful event (i.e., there was an attenuated negative emotional response) when compared to a stretching control group. These findings provide evidence supporting the potential utility of exercise in regulating emotions, after exposure to an environmental stressor.

E-12 Thematic Poster - Moving Beyond Cancer

Friday, June 2, 2017, 9:30 AM - 11:30 AM

Progressive Resistance Training In Breast Cancer Patients Undergoing Adjuvant Therapy: Adherence To Training Principles

Joachim Wiskemann¹, Martina E. Schmidt², Cornelia M. Ulrich³, Andreas Schneeweiss¹, Karen Steindorf². ¹*National Center for Tumor Diseases, Heidelberg, Germany.* ²*German Cancer Research Center, Heidelberg, Germany.* ³*Huntsman Cancer Institute, Salt Lake City, UT.* (Sponsor: Kathryn Schmitz, FACS M)
 Email: joachim.wiskemann@nct-heidelberg.de
 (No relationships reported)

Progressive resistance training (PRT) is recommended for breast cancer patients (BC) to prevent or mitigate treatment-related side effects. However, little attention has been paid to the following of principles of exercise training in various cancer treatment settings.

PURPOSE: To investigate principles of exercise training in BC undergoing a 12-week twice-weekly supervised PRT concomitant to adjuvant radiotherapy (RT) vs. chemotherapy (CT).

METHODS: PRT documentation sheets were analyzed from 128 BC participated either in a randomized controlled trial investigating the effect of 12-week PRT vs. a relaxation control group during adjuvant CT (BEATE-Study; NCT01106820) or RT (BEST-Study; NCT01468766). Extracted variables were: Exercise frequency, progression and depression steps made, as well as %-change in weight load during the intervention period for three lower and four upper extremity machine-based exercises. Furthermore, %-change of maximal isokinetic peak torque (MIPT) in knee extensors and flexors measured by stationary dynamometry were available.

RESULTS: Training frequency in CT patients were significantly lower than in RT patients (1.38 vs. 1.77 sessions/week; p<.001). Progression steps were made in 76% of patients under CT vs. 78% in RT treated patients. Comparable results were found for depression steps made (37% vs. 33%). The number of progression steps was significantly higher in shoulder external rotators for RT patients (p=.045) and borderline significant results were found in leg press and seated row (p=.07 and .15). In general, number of progression steps made for each exercise was low (median: 2, range: 0-11). Change in training weight load was significantly different in favor for the RT treated patients in four out of seven exercises (p<.05) and borderline significant in the other three (p=.07 to .15). The correlation between change in training weight load and change in MIPT for knee flexors and extensors was weak (r=.10 and .22). **CONCLUSIONS:** BC undergoing CT faced greater challenges to adhere to principles of PRT than patients undergoing RT treatment. As a consequence increases in training weight load during the intervention period was lower. Correlation analyses further indicate that changes in training weight load do not necessarily result in higher strength values.

Cancer Survivor Preferences, Barriers, And Facilitators To Exercise After Participation In A Cancer-specific Community Exercise Program

Kirsten Suderman¹, Kathryn Nishimura¹, Nicole Culos-Reed², Janice Yurick³, Margaret McNeely⁴. ¹*University of Alberta, Edmonton, AB, Canada.* ²*University of Calgary, Calgary, AB, Canada.* ³*Cross Cancer Institute, Edmonton, AB, Canada.* ⁴*University of Alberta, Cross Cancer Institute, Edmonton, AB, Canada.*
 Email: miazga@ualberta.ca
 (No relationships reported)

Including cancer survivors and their families in the planning of cancer-specific community exercise programming supports person-centred care, and allows for the identification of exercise barriers, facilitators and preferences to optimize program uptake and sustainability. The Alberta Cancer Exercise (ACE) pilot multi-centre randomized controlled trial examined the feasibility of implementing a cancer specific community-based exercise program. The current project was a sub-study (Edmonton site) utilizing an integrated knowledge translation (iKT) approach to inform future ACE program implementation. iKT can be described as involving knowledge users in the research process, in this case cancer survivors, to yield research that is more

applicable and helpful to the knowledge users. **PURPOSE:** To identify barriers, facilitators and preferences towards exercise of cancer survivors after participation in the ACE pilot study. **METHODS:** A longitudinal descriptive design using mixed methods research methodology was used to better understand the participant exercise experience. Following study completion, a post-study satisfaction questionnaire was administered and a focus group session was held. Quantitative data were analyzed descriptively and qualitative data used to interpret, clarify and further describe quantitative results. **RESULTS:** 82% of participants indicated a preference for a combination of unsupervised and supervised exercise, 77% preferring to exercise with other cancer survivors, and 67% for exercise programming to occur in a community facility. 76% perceived little to no difficulty in continuing to exercise independently. A major theme emerging was the lack of counselling from healthcare providers on exercise during the cancer treatment period. Oncologist referral to the ACE pilot was minimal, with 93% of survivors indicating they self-referred to the program. Specifically, participants identified a lack of (1) communication on the value of exercise for recovery and (2) provision of information on the availability of cancer-specific exercise programming. **CONCLUSIONS:** An iKT approach, involving survivors and their families, can help inform exercise programming issues and the need for program modification to optimize survivor satisfaction and adherence.

Cardioprotection in Breast Cancer Survivors: Sports Activity Vs Exercise As Prescription Model

Laura Stefani¹, Gianni Pedrizzetti², Stefano Pedri³, Benedetta Tosi¹, Giorgio Galanti¹. ¹*Sports and Exercise Medicine Center, Florence, Italy.* ²*University of Trieste, Trieste, Italy.* ³*ESAOTE-Italy-Florence(Italy) -Medical Affairs Manager, Florence, Italy.*
Email: laura-stefani@tiscali.it
(No relationships reported)

PURPOSE: Cardiotoxicity is the second leading cause of long-term morbidity and mortality among cancer survivors. Regular exercise program and sport are normally proposed to maintain myocardial performance. No data is available about actual myocardial benefits when different levels of physical exercise are allowed. The study aims to report clinical and cardiac outcomes, by the 2D Speckle tracking (ST) analysis, in order to detect the eventual differences between the sports activity and exercise model to protect patients survived to breast cancer. **METHODS:** From a cohort of 55 previous cancer patients, a group of 23 subjects trained in competitive sports activity Dragon Boat Athletes (DBA) for at least 5 yrs, were selected. They were evaluated by echo exam including LV Longitudinal Strain (SI) assessment (XStrain - Esaote) and matched with a group of 23 previous cancer patients following the Exercise as prescription therapy program. They were compared with two groups of healthy subjects: 20 athletes (HA) from different kinds of non competitive sports, and 20 volunteers submitted to the exercise as prescription program. **RESULTS:** All data were compared by T-Student test. Despite not significant differences of the EF values, the SI resulted to be different among the groups. Significantly higher in healthy subjects (p<0.01) both athletes and volunteers. No difference between the cancer subjects, athletes if compared to the exercise prescription model.

Groups	LV Global SI % (GLS)	LV SI-Medium %	LV SI Bas Lat %	LV SI Bas Sept%	LV SI Lat Apex %	LV SI Sept Apex %	EF %
Dragon Boat Athletes	-21.87±5.3	-20.02±5	-19.14±7.9	-19.29±5.3	-18.0±5.8	-24.0±5.9	57.2±5.5
Healthy Athletes	-25.4±2.1*°	-24.1±2.1*°	-25.0±4.1*°	-23.5±5.5*°	-23.8±5.5*°	-25.9±3.8*°	64.8±5.1
Patients submitted to Exercise as Prescription	-19.93±4	-19.21±4.4	-20.81±5.9	-17.89±5.7	-17.64±5.3	-20.52±7.2	59.95±7.3
Healthy subjects submitted to Exercise as prescription	-22.19±4.4	-21.87±3.8	-22.0±6.7	-19.22±4.9	-21.59±5.8	-24.35±6.8	61.39±5.4

Legend: * HA > ALL; ° HA > DBA; **CONCLUSIONS:** appropriate cardiac management by ST method can improve the supervision of the intensity of exercise. More than EF, 2D STE analysis can complete the exercise as prescription therapy. Regular 2D ST pattern revision can optimize and improve cancer therapy supporting and creating efficiencies within the health system. In addition 2D Lo Strain (S_i) confirms exercise as prescription therapy contributes in maintaining normal heart function at the same level of Dragon Boat Athletes.

Effect of an Argentine Tango Intervention on Gait Variability in Cancer Survivors

Ajit M.W. Chaudhari, FACSM, Scott M. Monfort, Marie T. Lamantia, Maryam B. Lustberg, Lise C. Worthen-Chaudhari. *The Ohio State University, Columbus, OH.*
(No relationships reported)

BACKGROUND: Advances in cancer diagnoses and treatment have contributed to improved outcomes for many cancers. The increasing number of cancer survivors and increased risk of falling in cancer survivors support the need for interventions to mitigate functional impairments in this population. Argentine tango has demonstrated efficacy as a dance-based intervention in improving function in the elderly as well as patients with Parkinson's disease; however, the efficacy of this intervention in cancer survivors has yet to be elucidated.

PURPOSE: To investigate the efficacy of an Argentine tango intervention on a measure of fall risk (i.e., stride-to-stride gait variability) in a group of cancer survivors. **METHODS:** Seven cancer survivors (2m/5f; 63.9 ± 10.2yr; 1.74 ± 0.11m; 79.7 ± 12.1kg) participated in a 10-week Argentine tango intervention, which consisted of one hour of instructed class held twice a week. Gait assessments were conducted before starting the intervention – baseline, at a five week midpoint, and at the conclusion of the 10-week intervention. Gait analysis consisted of survivors walking on a treadmill while bilateral lower extremity kinematics were recorded (MTP Series 2 system, Metria Innovation). During all testing timepoints, survivors walked at the same self-selected speeds that were identified at the baseline timepoint. Mean, standard deviation (SD), and coefficient of variation (CV) of stride-to-stride fluctuations in speed, stride length, stride time, and step width were calculated. Linear mixed models for repeated measures with survivors as a random effect, and testing timepoint as the fixed effect, were used to estimate changes for each gait parameter.

RESULTS: The CV of stride-to-stride fluctuations in speed decreased post-intervention (pre: CV = 3.0%, post: 2.2%, p = 0.003). Additionally, the SD of stride-to-stride speed decreased post-intervention (pre: σ = 0.026 m/sec, post: 0.019 m/sec, p = 0.004). No other gait parameters differed significantly between study timepoints (p>0.05).

CONCLUSION: Argentine tango was found to improve stride-to-stride variability in gait speed. This study supports the efficacy of dance-based exercise interventions to improve gait variability and potentially decrease falls risk in cancer survivors.

Exercise Maintenance After a Randomized Resistance Training Intervention in Breast Cancer Survivors Undergoing Adjuvant Therapy

Martina E. Schmidt¹, Joachim Wiskemann², Cornelia M. Ulrich³, Andreas Schneeweiss², Karen Steindorf¹. ¹*German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT), Heidelberg, Germany.* ²*University Hospital Heidelberg and National Center for Tumor Diseases (NCT), Heidelberg, Germany.* ³*Huntsman Cancer Institute and University of Utah, Salt Lake City, UT.* (Sponsor: Juergen Scharhag, FACSM)
Email: m.schmidt@dkfz.de
(No relationships reported)

Exercise is highly recommended for breast cancer patients and survivors and may be increased by supervised interventions. Yet, still little is known about factors influencing the longterm physical activity behavior after the end of an Intervention.

PURPOSE: To investigate the course and determinants of physical activity of breast cancer patients during and up to 12 months after a supervised resistance exercise intervention concomitant to adjuvant cancer treatment. **METHODS:** Physical activity was assessed in 227 breast cancer survivors before, during, and 3, 6 and 12 months after they participated in two randomized controlled trials investigating 12-week supervised resistance exercise vs. a relaxation control group concomitant to adjuvant chemotherapy (BEATE-Study, NCT01106820) or radiotherapy (BEST-Study, NCT01468766). To identify determinants of physical activity multiple ordinal logistic regression analyses were performed. **RESULTS:** During adjuvant therapy the intervention group exercised a median 1.8 h per week (interquartile range: 1.4-2.5), while 68% of controls did not engage in any exercise. Yet, irrespective of the intervention 32% of patients did not engage in any exercise at 12-month follow-up. Of the patients who cycled for transportation pre-diagnosis about half stopped cycling in the long run in both groups. In contrast, walking was maintained over time. Low levels of exercise at 12 months were determined by low pre-diagnosis levels of exercise (p<.001), lower education (p=0.0032), being postmenopausal (p=0.028), and having breast problems (p=0.0099) or depressive symptoms (p=0.059). At 12-month follow-up strength exercise was more common in the exercise group compared to the control Group. **CONCLUSIONS:** Breast cancer patients markedly decreased the exercise level and cycling for transportation after diagnosis and treatment. Yet, our resistance training intervention effectively counteracted this decline and boosted strength

exercise in the months following the intervention. However, in the longer term many survivors were insufficiently active. Our results that identified subgroups especially vulnerable to physical inactivity may help to develop better individually tailored strategies to improve the physical activity behavior in breast cancer survivors in the long run.

2415 Board #6 June 2 9:30 AM - 11:30 AM
Effects Of Exercise On Sleep Problems In Breast Cancer Patients Receiving Radiotherapy: A Randomized Trial

Karen Steindorf¹, Joachim Wiskemann², Cornelia M. Ulrich³, Martina E. Schmidt¹. ¹German Cancer Research Center, Heidelberg, Germany. ²University Hospital, Heidelberg, Germany. ³Huntsman Cancer Institute, Salt Lake City, UT. (Sponsor: Juergen Scharhag, FACSM)
 Email: k.steindorf@dkfz.de
 (No relationships reported)

Sleep problems frequently affect breast cancer patients during and after treatment and reduce their quality of life. However, coping and treatment strategies are mostly unknown or understudied. Only few studies have investigated the effect of exercise on sleep quality, particularly during the course of radiotherapy. **PURPOSE:** To assess within a large randomized controlled trial whether a 12-week exercise program starting with the radiotherapy influences sleep trajectories. **METHODS:** Sleep problems were assessed via self-report in 160 breast cancer patients before, during, and 3, 6 and 12 months after they participated in a trial investigating 12-week resistance exercise versus a relaxation control group concomitant to adjuvant radiotherapy (BEST-Study, NCT01568766). In addition, 25 age-matched women without cancer were exercising and followed the same study protocol for comparison purposes. **RESULTS:** Ordinal logistic regression analyses revealed significant exercise intervention effects regarding the changes in sleep problems (scale: 0-100) from baseline to the end of radiotherapy (mean between-group difference (MD): -10.2, p=0.03) and to the end of intervention (MD= -10.9, p=0.01), with sleep problems decreasing in the exercise group and increasing in the control group. At 12 months, differences were still observed but were statistically non-significant (MD=-5.9, p=0.3). Further adjustment for potential confounders did not change the results. The course of sleep problems in exercising women during the exercising phase was similar in breast cancer patients and in healthy exercisers, yet, patients experienced significantly higher levels of sleep problems at all times. **CONCLUSIONS:** Our large randomized exercise intervention trial confirmed results from earlier but mostly small studies that radiotherapy aggravates sleep problems in breast cancer patients and that exercise represents an effective treatment option. Given the strong link between quality of life and sleep problems, our finding that a 12-week resistance training for breast cancer patients undergoing radiotherapy reduces sleep problems is of high importance for many cancer patients.

2416 Board #7 June 2 9:30 AM - 11:30 AM
Cancer Related Fatigue and Muscle Quality in Hodgkin's Lymphoma Survivors

Filipe Dinato de Lima¹, Claudio L. Battaglini, FACSM², Ricardo Jacó de Oliveira¹, Ritielli de Oliveira Valeriano¹, Lorena Cruz¹, Carlos Alexandre Vieira³, Martim Bottaro¹. ¹University of Brasília, Brasília, Brazil. ²University of North Carolina at Chapel Hill, Chapel Hill, NC. ³Federal University of Goiás, Goiânia, Brazil. (Sponsor: Claudio L Battaglini, FACSM)
 Email: fdinatolima@gmail.com
 (No relationships reported)

Cancer-related fatigue is the most commonly reported side effect in cancer patients. This debilitating fatigue is often accompanied by reductions in overall physical activity and physical function. Whereas fatigue in cancer survivors seems partially dependent on neuromuscular factors, these relationships have not been established in Hodgkin's lymphoma survivors (HLS).

PURPOSE: To assess self-perceived fatigue and muscle quality in Hodgkin's Lymphoma survivors.

METHODS: A total of 12 HLS, age 32.16 ± 8.06, and 36 control healthy subjects (CON) matched by age, gender and level of physical activity were enrolled in the study. Fatigue was measured using MFI-20. Muscle thickness of knee extensors (MT) was measured using B-mode ultrasound. Muscle quality was assessed by echo intensity (EI) of rectus femoris and specific torque (ST) of the knee extensors. The ST was calculated as follows: isokinetic peak torque (PT)/ MT. Isokinetic PT was measured by two sets of four maximal isokinetic knee extension at 60°/s⁻¹. Independent samples T-tests were used to compare physical characteristics, muscle function and fatigue between HLS and CON.

RESULTS: No significant differences (p > 0.05) in any physical characteristics between HLS and CON were observed. There was no difference in PT (HLS: 184.58 ± 55.91 vs. CON: 199.14 ± 60.57 N.m; p = 0.552), MT (HLS: 27.35 ± 8.70 vs. CON: 28.55 ± 7.58 mm; p = 0.439), EI (HLS: 63.18 ± 11.12 vs. CON: 65.36 ± 11.76; p

= 0.575), and ST (HLS: 6.89 ± 1.59 vs. CON: 7.05 ± 1.46 N.m.mm⁻¹; p = 0.737). However, there was a significant difference between HLS and CON for self-perceived fatigue (HLS: 14.00 ± 3.91 vs. CON: 10.80 ± 3.36; p = 0.009; ES = 0.8778). **CONCLUSION:** A higher level of self-perceived fatigue was observed in HLS when compared to CON. However, no differences in muscle quality were observed when HLS are matched by age, gender and physical activity level with CON. It appears that as HLS are further out from the completion of their major treatments, their muscle characteristics and function are preserved if they maintain certain level of physical activity. This study provides insight on the potential similarities between HLS and CON, with same physical activities level, regarding muscle characteristics, function, and performance, which should be considered when prescribing exercise training to this population.

2417 Board #8 June 2 9:30 AM - 11:30 AM
Exercise Effects On Mental Fatigue, Cognitive Impairment And Inflammation In 479 Cancer Patients

Karen M. Mustian, Ian Kleckner, Po Ju Lin, Calvin Cole, Charles Heckler. University of Rochester School of Medicine, Rochester, NY.
 (No relationships reported)

PURPOSE: Mental fatigue and cognitive impairment (CI) are side effects experienced by cancer patients that arise due to chronic inflammation and diminish functional capacity and quality of life (QOL). We conducted a nationwide, multi-site, phase III RCT examining the efficacy of exercise for improving mental fatigue, CI and inflammation through the URCC NCORP Research Base nationwide network.

METHODS: Non-metastatic cancer patients receiving chemotherapy were randomized into 2 arms: 1) chemotherapy and 2) chemotherapy plus a 6-week (wk) exercise intervention. The intervention used the Exercise for Cancer Patients (EXCAP) program: a home-based, personalized prescription of aerobic walking and anaerobic resistance band training. Mental fatigue, CI and inflammation were assessed via the Multidimensional Fatigue Symptom Inventory, FACT-Cog and standard serum Luminex assays, respectively, at pre- and post-intervention.

RESULTS: 479 patients beginning chemotherapy were accrued (94% female, 84% breast cancer, mean age = 54). ANCOVAs controlling for baseline mental fatigue, CI and chemotherapy cycle (1 wk, 2 wk, 3 wk) revealed significant differences in mental fatigue, CI total score, perceived CI, impact of CI on QOL, and perceived CI by others (all p < 0.05) with a trend for differences in perceived cognitive ability (p < 0.10) between groups at post-intervention. Exercisers demonstrated less mental fatigue and cognitive impairment (all domains) than participants in the chemotherapy-only arm. T-tests revealed an exercise-induced anti-inflammatory response with down-regulation of pro-inflammatory cytokines (IFNγ, IL-8, IL-1b) and up-regulation of anti-inflammatory cytokines (IL-6, IL-10, sTNFα) in exercisers (all p<0.05). Conversely, t-tests revealed down-regulation of IL-10 and less up-regulation of sTNFα in controls (all p < 0.05).

CONCLUSIONS: EXCAP exercise improves mental fatigue, CI and inflammation in cancer patients receiving chemotherapy. Clinicians should consider prescribing EXCAP to reduce mental fatigue, CI and inflammation. Funding: NCI UGCA189961 and K07CA120025.

E-13 Thematic Poster - Nutritional Status of Athletes I

75g/day Supplemental Protein Improves Lean Mass Index and Dance Performance Aesthetics in Female Collegiate Dancers

Ann F. Brown¹, Tom Welsh², Lynn Panton, FACSM², Robert Moffatt², Michael J. Ormsbee, FACSM². ¹University of Idaho, Moscow, ID. ²Florida State University, Tallahassee, FL. (Sponsor: Dr. Michael J. Ormsbee, FACSM)
 (No relationships reported)

Body composition and fitness are just as important as technique development for dancers. Supplemental protein may be a simple way to optimize body composition, performance, and aesthetics without dramatically changing classical training. To date, no studies have investigated the impact of supplemental protein on body composition and performance in dancers. **PURPOSE:** To determine the extent to which 12

weeks of supplemental whey protein (PRO) would optimize body composition and performance in female dancers compared to an isocaloric placebo (PLA; maltodextrin). **METHODS:** Female collegiate dancers (N=21; 19.6 ± 1.4 years) completed a randomized, double-blind study. Participants were randomly assigned PLA or PRO and consumed one dose (25g) three times daily for 12 weeks. Testing was completed at baseline, 6, and 12 weeks which included 24-hour urine collection, body composition assessment (DXA), performance tests, and a functional dance performance assessment. Data were reported as mean ± SD. Dependent variables were analyzed by one-way ANOVA. Significance was accepted at $p < 0.05$. **RESULTS:** There were no significant differences between groups at baseline. PLA consumed significantly lower protein (0.9 g/kg/day) than PRO every week of the study (2.4 g/kg/day; $p < 0.001$). Body weight, fat and lean mass did not change between groups or over time. Lean mass index (LMI; absolute value of fat change plus muscle change) was significantly higher in PRO (+0.6 ± 1.9) compared to PLA (-1.8 ± 3.1; $p = 0.048$) at week 12. PLA significantly increased peak power during the Wingate anaerobic power test from baseline to week 12 absolute (746.4 ± 92.9 W, 856.3 ± 51.6 W; $p = 0.005$). Although not significant, PLA completed the study in negative nitrogen balance whereas PRO was in positive nitrogen balance. Differences detected in aesthetic presentation from baseline to week 12 were significantly lower in PLA (1.9 ± 0.5; 1.0-5.0 scale) compared to PRO (2.6 ± 0.8; $p = 0.048$). **CONCLUSIONS:** Protein supplementation for 12 weeks significantly improved LMI as well as aesthetic presentation during dance performance. Additionally, protein supplementation provides a simple way to improve the diet and LMI in a group of dance athletes that require nutritional attention. This study was supported by a Dymatize Nutrition Sports Performance Institute grant.

2420 Board #2 June 2 9:30 AM - 11:30 AM
Inadequate, Habitual Dietary Protein Intake Amid Inadequate Caloric Intake In Collegiate Female Gymnasts
 William R. Lunn. *Southern Connecticut State University, New Haven, CT.*
 Email: lunnw1@southernct.edu
 (No relationships reported)

Collegiate, women's gymnastics is a sport that requires explosive muscular contraction, muscular endurance, and demands twice-daily workout schedules. What is lesser known is if day-to-day variations in eating exist, and if so, would they tend to result in balanced energy requirements, or a deficit. **PURPOSE:** To determine if daily variations in energy intake and nutrient insufficiency occurs during a competition week for female gymnasts. **METHODS:** Female, NCAA gymnasts (n=14; 20.1±1.2 y; BMI=23.4±2.5 kg·m⁻²) provided 7-day food and physical activity recalls during a competition week. Athletes also completed a resting metabolic rate (RMR) test using indirect calorimetry with a calibrated metabolic system (Parvo Medics). The Mifflin-St. Jeor formula was also used to compare total daily energy expenditure (TDEE) estimation to the laboratory determination. Exercise-induced thermogenesis was determined using the activity recall and MET values from the compendium of physical activity. Dietary-induced thermogenesis was calculated as 10% of mean caloric intake. A nutritional database software package (Nutritionist Pro v. 5.0) was used to analyze the 7-day food recalls. **RESULTS:** By ANOVA, RMR estimated using Mifflin-St. Jeor was significantly less than that measured via indirect calorimetry (1320 ± 75 vs. 1618 ± 204 kcal; $p < 0.01$), which resulted in a significantly lower TDEE from the formula than lab measurement (1746 ± 131 vs. 2074 ± 261 kcal; $p < 0.01$). Daily kcal intake was significantly lower than lab TDEE (1832 ± 399 vs. 2074 ± 261 kcal; $p = 0.01$), but similar to the formula estimation (1746 ± 131 kcal). Dietary protein intake (1.20 ± 0.27 g/kg/d) was at the low end of the ACSM-recommended range for active athletes (1.2-1.7 g/kg/d), and remarkably lower than the recommended range for athletes in negative energy balance (2.0 g/kg/d). Daily leucine intake (2.7 ± 1.0 g/d) was also notably lower than the recommended intake (8 g/d). **CONCLUSION:** Female, collegiate gymnasts do not consume enough calories, dietary protein, or leucine to meet recommended guidelines for athletes. The Mifflin-St. Jeor formula for TDEE estimation underestimated the kcal expenditure for the athletes, but was similar to the athletes' dietary self-report. Gymnasts should consume almost twice their habitual protein intake during a competition week.

2421 Board #3 June 2 9:30 AM - 11:30 AM
Comparison Of Dietary Energy And Macronutrient Intakes Of Division Iii Athletes To Sports Nutrition Guidelines
 Trisha Sterringer, Elizabeth Goecke, Haley Murrell, Erin Simon, Kristen Ruckstuhl, Madeline Deabler, Lynn Cialdella-Kam. *Case Western Reserve University, Cleveland, OH.*
 (No relationships reported)

Sports nutrition guidelines have been proposed that aim to enhance sports performance and support overall health. However, collegiate athletes often struggle to meet these guidelines for several reasons (e.g., cafeteria meal plans, travel schedules, and lack of nutrition knowledge). **PURPOSE:** To determine if Division III athletes are

meeting recommended intakes for energy and macronutrients based on the guidelines set forth by American College of Sports Medicine Position Stand on Nutrition and Athletic Performance. **METHODS:** This retrospective chart review assessed energy and macronutrient intakes of 56 Division III athletes from 3-day food analyzed in Food Processor (Salem, OR). Data was summarized as means (standard deviations). Wilcoxon Sign Rank t-test was used to evaluate macronutrient intakes against recommendations. **RESULTS:** Energy and macronutrient intakes by sports are presented in Table 1. Overall, carbohydrate intake was 4.6(0.4) g/kg/d for all athletes and below targeted levels appropriate for their sports ($p < 0.0001$). Protein intake of 1.4(0.4) g/kg/d was adequate across sports and greater than lower end of recommended range for protein of 1.2 g/kg/d ($p = 0.0013$). However, ~one-third of athletes had intakes <1.2 g/kg/d. Dietary fat intake was on the upper end of recommendations (intake=32.6 (6.4)% of total kcal/d) with 19 athletes having intakes >35% of total kcal/d. **CONCLUSIONS:** Overall, collegiate athletes could benefit from strategies to include carbohydrate-rich foods in their diet and a possible reduction in saturated dietary fat intake.

Table 1: Energy and Macronutrient Intakes by Sports Expressed as Means (SD)

Description (SD)	Women's Basketball (n=5)	Women's Swimming (n=15)	Women's Tennis (n=8)	Men's Tennis (n=8)	Women's Track and Field (n=12)	Men's Wrestling (n=5)
Energy (kcal/d)	2,188 (307)	2,347 (389)	1,960 (372)	2,979 (594)	2,267 (510)	2,253 (540)
Carbohydrates (g/kg/d)	3.7 (0.6)	4.6 (1.1)	4.5 (1.0)	5.5 (1.4)	5.1 (1.3)	2.8 (1.0)
Protein (g/kg/d)	1.2 (0.1)	1.3 (0.3)	1.1 (0.2)	1.7 (0.6)	1.5 (0.2)	1.3 (0.5)
Fat (% of Total Kcal/d)	33 (7)	33 (6)	30(9)	31 (6)	33 (3)	37 (12)
Fiber (g/d)	31 (15)	24 (9)	25 (9)	24 (8)	27 (9)	23 (12)

Effect of Vitamin D Supplementation on 25(OH)D Status in Elite Athletes with Spinal Cord Injury
 Kelly L. Pritchett¹, Robert C. Pritchett¹, Lauren Stark¹, Elizabeth Broad², Melissa LaCroix³. ¹Central Washington University, ELLENSBURG, WA. ²US Olympic Committee, Chula Vista, CA. ³Canadian Sport Institute Pacific, Richmond, BC, Canada.
 (Sponsor: Enette Larson-Meyer, FACSM)
 Email: kelly.pritchett@cwu.edu
 (No relationships reported)

Recent studies suggests that a substantial proportion of elite athletes with SCI (spinal cord injury) have insufficient 25(OH)D status which may be associated with decreased muscle strength. **Purpose:** This study: 1) examined the effects of a 16-wk Vitamin D supplementation protocol on 25(OH)D concentration and 2) determined whether subsequent 25(OH)D status impacts muscle function/performance in elite athletes with SCI. **Methods:** Thirty-four members of the US Olympic Committee Paralympic program, and the Canadian Wheelchair Sports Association from outdoor and indoor sports participated. Serum 25(OH)D concentrations, lifestyle and dietary factors were assessed during the Winter and Spring. Participants were assigned to a 16-week sliding scale vitamin D3 (cholecalciferol) (KleanAthlete Brand) supplementation protocol based on initial 25(OH)D levels. Participants with deficient 25(OH)D (<20ng/mL⁻¹) status received 50,000 IU/wk for 8 wks, and participants with insufficient status (20-30 ng/mL⁻¹) received 35,000 IU/week for 4 weeks followed by a maintenance dosage of 15,000 IU/wk. Participants with sufficient status (>30ng/mL⁻¹) received the maintenance dosage of 15,000 IU/wk. Performance measurements were assessed using a 20 meter wheelchair sprint, and handgrip strength. A paired t-test was used to assess differences in 25(OH)D status and performance before and after supplementation, respectively. **Results:** 25 (OH) D concentrations increased significantly after supplementation ($P < .001$; 26.5 ± 9.7 ng/mL⁻¹; 44.5 ± ng/mL⁻¹; mean ± SD) for Winter and Spring, respectively, 26% of athletes had sufficient 25(OH)D concentrations prior to supplementation, and 94% had sufficient concentrations post supplementation. 60% of participants improved handgrip strength post supplementation. However, no change in wheelchair sprint performance time was observed. **Conclusion:** The 16-week sliding supplementation protocol used in the current study is effective for achieving sufficient vitamin D concentrations during the winter months in elite athletes with SCI. Furthermore, handgrip strength improved in 60% of participants post supplementation.

 (No relationships reported)

Optimal nutrition enhances athletic performance. Eating adequate amounts of energy and meeting recommendations for macronutrients are essential and a priority for athletes. **PURPOSE:** To evaluate the dietary intakes of macronutrients of Masters Athletes. **METHODS:** This cross-sectional study included 25 Masters Athletes (14 females, 11 males), 39.4±10.1 years of age. Body composition was determined by dual-energy X-ray absorptiometry (DXA). Participants completed a self-administered Block Food Frequency Questionnaire (FFQ) used to assess dietary patterns over the previous year. The FFQs were analyzed by a third party source; however, statistical analyses were conducted by the researchers. For the purposes of this study, athletes were classified as either lean or non-lean based on percent body fat. Female athletes with < 24.4% and male athletes with < 17.4% body fat were considered lean. **RESULTS:** Average carbohydrate intake was 44.7±6.6% and 47.7±7.6% of total energy intake for lean and non-lean athletes, respectively. Average protein intake was 15.3±2.8% and 15.02±2.0% of total energy intake for lean non-lean athletes, respectively. Average fat intake was 38.1±7.4% and 36.5±4.9% of total energy intake for lean and non-lean athletes, respectively. There were no significant differences between groups in percent of carbohydrate, fat and protein consumed to total energy intake diet. **CONCLUSION:** Macronutrient recommended intakes for carbohydrates and proteins are being met for Masters Athletes, which helps to ensure optimal performance; yet proportional fat intake is above recommendations. Nonetheless, aside from the Dietary Reference Intakes, specific recommendations for Masters Athletes have not been established. These represent data from an unfunded research project

 (No relationships reported)

BACKGROUND: Healthy Eating Index 2010 (HEI-2010) is a tool that was developed to assess diet quality and adherence to the 2010 Dietary Guidelines for Americans. Lower total HEI scores have been associated with higher rates of obesity, heart disease, cancer and chronic systemic inflammation. **PURPOSE:** To Evaluate the diet quality in Seal Qualification Training (SQT) students. **METHODS:** 264 SQT students (age: 24.3±2.6 (mean±SD), height: 179.5±6.6 cm, weight: 85.0±8.2 kg; body fat: 14.3±4.1) completed a 24-hour diet recall using the Automated Self-administered 24-hour recall (ASA24) diet assessment tool (National Cancer Institute). The HEI is made up of 12 food group components, broken down into 2 categories: adequacy (foods to eat enough nutrients for overall health) and moderation (foods to limit). **RESULTS:** The total HEI-2010 score was 56.2±15.0. The adequacy HEI-2010 component scores (mean±SD/max score, higher score = higher consumption) were: total Veg 3.0±1.5/5, Green/Bean Veg 2.3±2.3/5, Total Fruit 2.4±2.0/5, Whole Fruit 2.4±2.1/5, Whole Grain 3.8±3.6/10, Total Dairy 6.2±3.1/10, Total Protein 4.7±0.8/5, Seafood/Plant Protein 2.8±2.2/5, Fatty Acid Ratio 4.7±3.5/10. The moderation components of HEI-2010 (mean±SD/max score, higher score = lower consumption) were: Sodium 2.8±3.1/10, Refined Grains 7.5±2.9/10, 13.7±5.5/20. **CONCLUSION:** The HEI score for SQT was 56.2 (out of a total 100), slightly lower than the US population score of 59. Students scored particularly low in the Vegetable, Fruit, Whole Grain, Seafood/Plant Protein and Fatty Acid categories and had, higher consumption of empty calorie foods/beverages (with added sugar, fat and alcohol). A dietary pattern low in fruits, vegetables, whole grains and fish, high in refined foods with added sugar, fat and alcohol promotes a pro-inflammatory state, higher body fat and earlier onset of chronic disease. Improving diet quality by increasing fruit, vegetable, whole grains and healthy fats, may have implications in reducing systemic inflammation, which can aid with recovery from training, improved immune response, prevention of chronic diseases and improved overall health.

Behavioural Predictors Of Muscle Dysmorphia Symptomatology In Natural Bodybuilders
 Lachlan Mitchell¹, Stuart B. Murray², Matthew Hoon³, Daniel
 Hackett¹, Tania Prvan⁴, Helen O'Connor¹. ¹University of Sydney,
 Sydney, Australia. ²University of California San Francisco,
 San Francisco, CA. ³Australian Catholic University, Canberra,
 Australia. ⁴Macquarie University, Sydney, Australia. (Sponsor:
 Melinda Manore, FACSM)
 Email: lachlan.mitchell@sydney.edu.au
 (No relationships reported)

Muscle dysmorphia (MD) is a psychological disorder characterized by a pervasive belief that one is insufficiently muscular, despite often being large and strong. Nosological similarities are recognized between MD and eating disorders (EDs).

PURPOSE: To identify predictors of MD symptomatology in natural competitive bodybuilders (BB).

METHODS: An online survey was developed to investigate the relationship between MD, ED and competition practices used in competitive bodybuilding. To be included, participants needed to have competed in a drug tested bodybuilding contest in the past 18 months. The survey assessed demographic characteristics, diet, supplementation and training practices, MD symptoms via the muscle dysmorphic disorder inventory (MDDI) and ED symptoms via the eating attitudes test (EAT-26). Stepwise linear regression was performed to assess the relationship between MD and ED symptoms, diet, supplementation and training practices.

RESULTS: Sixty participants (age 30±7 yrs) met inclusion criteria and completed the survey. Mean scores on the EAT-26 (8.5 ± 6.3) were low, and on the MDDI (35.2 ± 8.0), mid-range. No nutrition, supplementation or training factors were found to predict MD symptomatology. The EAT-26 score (β=0.268, p=0.032) and rate of pre-competition weight loss (β=0.307, p=0.012) were significant predictors of MD. Competition experience was negatively associated with MD (β=-0.243, p=0.051). The model explained 21.1% of the variance in MD. Despite its known association with ED, weight suppression was not associated with MD (p=0.746).

CONCLUSIONS: The predictive validity of eating disorder psychopathology underscores the salience of disordered eating pathology in presentations of MD. These results suggest that it is the presence of disordered eating attitudes and beliefs that separate BB with MD from BB without MD. In support of this, greater rate of pre-competition weight loss, which may reflect disordered eating practices, is also predictive of MD symptomatology. Lastly, an inverse relationship between competition experience and MD symptoms may suggest that although those susceptible to MD may be attracted to bodybuilding, their cognitive and behavioural symptoms may potentially impede longer-term engagement in the sport. Longitudinal studies are needed to confirm this.

 (No relationships reported)

Athletes in weight category sports practice various methods of acute weight loss, with recent research and long standing "grey literature" demonstrating the popularity of 'water loading' (the consumption of large volumes of fluid for several days, prior to withholding intake) as a means to increase body water losses following fluid restriction. No research has examined this technique or its risk of causing hyponatremia. **PURPOSE:** To determine the effectiveness and safety of water loading and assess potential mechanisms. **METHODS:** Male combat sport athletes (n=21, 77.5±8.1kg 177.5±6.1cm, 26.6±4.0years) were separated into a control (CON, n=10) and water loading (WL, n=11) group. Subjects were fed a standardised isoengetic diet based on fat free mass (assessed via DXA scan) controlling for macronutrient, sodium and fibre content for 6 days. Day 1-3 fluid intake was 40mL/kg CON and 100mL/kg WL. Day 4 fluid intake was 15mL/kg CON and WL. Day 5 no fluid was consumed until midday with both groups following the same rehydration protocol until day 6. Urine sodium, specific gravity (USG) and volume were recorded alongside training sweat losses and sleep quality/ duration (measured via actigraphy) throughout. Renal hormones (vasopressin, renin, and aldosterone), blood urea and electrolytes (U+Es) and body mass (BM) were measured each morning (fasted) and evening following 30 min supine rest. Physical performance was assessed pre and post intervention. Two way repeated measures ANOVAs were used to assess differences between groups. **RESULTS:** Following fluid restriction, significant differences with large effect sizes were found in fluid input/output ratio (39.11%, p < 0.01, ES=1.2) and BM loss (0.6%BM, p=0.02, ES=0.82). No differences in sleep or performance

measures existed. Time had a significant effect on USG, all U+Es and renal hormones ($p < 0.05$). An interaction effect existed between time and intervention on blood sodium, potassium, chloride, urea, creatinine, USG and vasopressin ($p < 0.05$) but not on other hormones or electrolytes. No mean U+Es differed from reference range or approached critical values. **CONCLUSION:** Water loading appears to be a safe and effective method of acute BM loss under the conditions utilised in this study. Changes in vasopressin may in part underlie the mechanism facilitating this technique.

E-14 Thematic Poster - Rehab and Recovery in Skeletal Muscle and Connective Tissue

Knee Morphology After Secondary Ipsilateral ACL Injury Compared to Those that Have Not Reinjured

Lindsey K. Lepley¹, Jessica E. Digiacoio¹, John A. Redman², Riann M. Palmieri-Smith². ¹University of Connecticut, Storrs, CT. ²University of Michigan, Ann Arbor, MI.
Email: lindsey.lepley@uconn.edu

(No relationships reported)

Modifiable and non-modifiable risk factors have been identified for primary anterior cruciate ligament (ACL) injury, however less research is available examining risk factors for a second ACL rupture. Identifying whether bony morphological factors are different (or more exaggerated) among those that experience a secondary ACL injury is critical to understanding if non-modifiable risk factors are associated with re-injury. **PURPOSE:** To identify if bony morphology is different among those that experience a secondary ACL re-injury as compared to ACL individuals that do not. **METHODS:** ACL participants were tracked after return-to-play following primary reconstruction, and if individuals experienced a second ipsilateral injury (ACLx2, n=14, 8f/6m, 17.9±4.0yrs), the primary clinical magnetic resonance imaging was analyzed for bony morphological risk factors. ACLx2 participants were matched to individuals (sex, age, height, gender and activity level) that had undergone reconstruction but did not experience re-injury (ACLx1, n=14, 8f/6m, 18.7±4.0yrs). 10 healthy controls were also enrolled (5m/5f, 20.8±3.9yrs) for the purposes of comparing our ACL data against healthy knees. Lateral and medial posterior tibial slopes (LPTS, MPTS), notch shape index (NSI), and medial tibial plateau depth of concavity (MDC) were compared between all ACL participants (combined ACLx1 and ACLx2 groups) and controls using independent t-tests and across groups (ACLx1, ACLx2, controls) using one-way ANOVAs. **RESULTS:** All ACL reconstructed patients had a steeper LPTS than controls (6.5±2.7deg vs. 3.9±3.7deg, $d=0.87$, 95% CI 0.11-1.60, $P=0.023$), however no difference in LPTS was found between ACLx1 and ACLx2 (6.8±3.2deg vs. 6.3±2.4deg, $P>0.05$). No differences in MPTS, NSI and MDC were found between all ACL participants (combined ACLx2 and ACLx1) and controls, or between ACLx1 and ACLx2 ($P>0.05$). **CONCLUSION:** Compared to healthy individuals, a steeper LPTS is a common bony abnormality among all ACL injured participants. Individuals that go onto experience a second ipsilateral ACL injury, do not have more exaggerated bony morphology than those that do not, suggesting that differences in modifiable risk factors at return-to-play may contribute to re-injury.

Focused Shockwave Therapy & Low Level Laser Therapy In Patella Tendinopathy Among German Soccer Players

Karsten Knobloch. *SportPraxis Prof. Dr. Karsten Knobloch, Hannover, Germany.*

Email: kknobi@yahoo.com

(No relationships reported)

PURPOSE: To assess the feasibility and efficacy of combined focused extracorporeal shockwave therapy (ESWT) & low level laser therapy (LLLT) in addition to conventional eccentric training in patella tendinopathy among elite professional soccer players with patella tendinopathy.

METHODS: 34 German Bundesliga soccer players suffering from patella tendinopathy > 4 weeks underwent both, conventional and Power Doppler ultrasound determining the size of tendon diameter as well as the amount and location of neovascularisation by PowerDoppler ultrasound in my practice. The multimodal tendon treatment consisted of three sessions of: • Focused extracorporeal shockwave therapy (Storz Ultra device, 0.15-0.3mJ/mm2, 1000-2000 impulses per session) • Low

Level Laser Therapy (LLLT, Irradia 904nm 12-fold laser device) • Eccentric training on a 25° decline board (daily 6x15 repetitions per leg according to Alfredson's scheme) **RESULTS:** Pain at exercise (on a visual analogue scale 0-10) was reduced from 6±2 to 2±2 at six weeks and 1±1 after 12 weeks of treatment. Morning stiffness was reduced at six weeks by 56% and 87% after 12 weeks. The degree of neovascularisation in PowerDoppler ultrasound was reduced from Öhberg degree 3+ to 0-1+ after 12 weeks as was the tendon diameter by 38% in grey scale ultrasound. VISA-P scores improved by 32% at six weeks and 51% at 12 weeks. Players were able to return to sport at mean 18±12 days after initiation of the weekly therapy. **CONCLUSIONS:** Combined focused shockwave & low level laser tendon therapy accompanied by daily eccentric training are able to improve patella tendon function with a sustained effect in soccer athletes with an early return to game play.

Progenitor Cells From Cartilage: Grade Specific Differences In Stem Cells Markers Expression

Marija Mazar¹, Annabelle Cesaro¹, Mazen Ali², Thomas M. Best, FACSM³, Eric Lespessailles¹, Hechmi Toumi¹. ¹Service de Rhumatologie, Centre Hospitalier Régional d'Orléans, La Source, France, Orleans, France. ²Service chirurgie orthopédique et traumatologique Centre Hospitalier Régional d'Orléans, La Source, France, Orleans, France. ³Department of Orthopedics, Division of Sports Medicine, Miami, FL. (Sponsor: Thomas best, FACSM)

Email: hechmi.toumi@univ-orleans.fr

(No relationships reported)

BACKGROUND: Recent research confirmed the presence of Mesenchymal stem cell (MSC) - like progenitors (MPC) in both normal and osteoarthritic cartilage. However, there is only limited information concerning how MPC markers develop with osteoarthritis progression. The purpose of this study is to determine the prevalence of MPC markers in different OA grades. **MATERIALS AND METHODS:** Human osteoarthritic tibial plateau were obtained from ten patients undergoing total knee replacement. Each sample had been classified into a mild or severe group according to OARSI scoring. Tissue was taken from each specimen and mRNA expression levels of CD105, CD166, Notch 1, Sox9, Acan and Col II A1 were measured at day 0 and day 14 (2 weeks *in vitro*). Furthermore, MSC markers: Nucleostemin, CD90, CD73, CD166, CD105 and Notch 1 were studied by immunofluorescence. **RESULTS:** mRNA levels of MSC markers did not differ between mild and severe OA at day 0. At day 14, protein analysis showed that proliferated cells from both sources express all 6 MSC markers. Only cells from mild OA resulted in a significant increase of mRNA CD105 and CD166 after *in vitro* expansion. Moreover, cells from the mild OA showed significantly higher levels of CD105, Sox9 and Acan than those from severe OA. **CONCLUSION:** Results confirmed the presence of MSC markers in mild and severe OA tissue on both mRNA and protein levels. We found potential differences between cells obtained from mild compared to severe which suggests that mild OA derived cells may have a greater MSC potential.

Relaxin Influences Knee Laxity Changes Across the Menstrual Cycle

Travis Anderson, Zachary Kincaid, Laurie Wideman, FACSM, Sandra J. Shultz, FACSM. *University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Dr. Sandra J. Shultz, FACSM)

Email: t_ander2@uncg.edu

(No relationships reported)

Greater knee laxity is associated with an increased risk for anterior-cruciate ligament (ACL) injury, particularly in women. Research suggests that the hormone relaxin may influence the structural integrity of the ACL, rendering a weaker and more lax ligament. **PURPOSE:** To assess the impact of relaxin on knee laxity once progesterone and testosterone (potential endocrine antagonists) are accounted for. **METHODS:** College-aged females (166.0±5.7cm, 65.9±8.5kg, 20.8±2.9yr) provided blood samples for the first 6 days of menses and first 10 days of luteal phase of one menstrual cycle. Knee laxity was recorded as anterior knee laxity (AKL; mm), genu recurvatum (GR; °), and general joint laxity (GJL; score, 0-9), and dependent variables were calculated as mean (X), cyclic Δ (max - min), coefficient of variation (CV), and standard deviation (SD). Progesterone (P; ng/ml), testosterone (T; ng/dl), and relaxin (R; pg/ml) were analyzed via ELISA assays. The sum of the 6 greatest hormone concentrations during menses (M) and luteal phase (L) and the change in exposure from M to L (MLΔ) were calculated. Only subjects with captured R and P peak were included in analysis (n=18). M and MLΔ for each hormone were entered into backward stepwise (in: $p=.05$, out: $p=.20$) multiple linear regression models to predict each laxity measure. **RESULTS:** R and P were significantly different between M and L ($p<.001$, $R_M=22.2±29.4$ vs. $R_L=147.0±96.3$; $p<.001$, $P_M=5.8±1.8$ vs. $P_L=89.7±36.6$), whereas T was less variable ($p=.07$, $T_M=203.8±63.0$ vs. $T_L=222.7±82.6$). All laxity

showed variation across the menstrual cycle (range [min-max]: AKL=5.9-7.6; GR=2.6-5.6; GJL=8-2.1). Significant models were observed for GR_X (p=.014; R²=.418; GR_X=3.501+1.024R_{MLA}-757R_M-395P_{MLA}), GJL_{MLA} (p=.044; R²=.253; GJL_{MLA}=-.469R_{MLA}-440T_M), and GJL_X (p=.035; R²=.379; GJL_X=-.317R_M-353P_M-440P_{MLA}-507T_M). Models for AKL_{MLA}, AKL_{CV}, GR_X, and GJL_{SB} approached significance (all p<.075). **CONCLUSION:** Once controlling for P and T, R was a significant predictor of knee laxity mean and cyclic changes. These findings would suggest that R, combined with other sex hormones, may affect the structural integrity of the ligament and impact injury risk. Further study is needed to explore potential mechanisms for this association.

The Human Piriformis Muscle: Sensory, Postural, Or Just A Pain

Matthew C. Kostek, FACSM, Rachel Sweetnich, Tim Dusch. *Duquesne University, Pittsburgh, PA.*
 Email: kostekm@duq.edu
 (No relationships reported)

Piriformis syndrome is a form of low back pain that is debilitating and difficult to treat. Physical therapy is often effective but in some cases the Piriformis muscle is disconnected or removed entirely through surgery. The short term consequences of this procedure are negligible but the long term consequences have not been studied. Furthermore, because of its size and anatomical location, it is not thought to be a primary mover of the body. The purpose and necessity of the muscle is an area of speculation. We hypothesized that it is a sensory and postural muscle, which could explain why short term consequences of its removal are minimal. **PURPOSE:** To determine the density of muscle spindles and fiber type composition of the human Piriformis muscle. **METHODS:** Six human cadavers (male = 3, female = 3) had their right and left Piriformis muscles removed for histological analysis. Whole muscles were paraffin embedded, sectioned, H&E stained or stained with myosin heavy chain antibodies. Microscopy analysis examined spindle density and fiber type composition. **RESULTS:** The average spindle density per muscle was 3.4+1 and was not significantly different between male and female (p=0.46). Fiber type composition was 84+8% slow twitch and was not different between male and female (p=0.23). **CONCLUSIONS:** The human Piriformis muscle does not appear to be a sensory muscle due to the low concentration of muscle spindles but is very likely a postural muscle. The results of this characterization may better inform treatments including the surgical removal and long term rehabilitation.

The Effects Of Cryo-compression Therapy On Recovery From An Acute Bout Of Resistance Exercise.

William H. DuPont, Vincent H. Hardesty, Emily C. Barnhart, Brek J. Meuris, William J. Kraemer, FACSM. *The Ohio State University, Columbus, OH.* (Sponsor: William J. Kraemer, FACSM)
 Email: dupont.35@osu.edu
 (No relationships reported)

Compression and cold therapy used separately have consistently shown to reduce these deterrents. However, the effects of combining compression and cold therapy (cryo-compression) as a single recovery modality has yet to fully be examined. **PURPOSE:** To examine the effects of Aquilo Cryo-compression Pants (Aquilo Sports, Louisville, KY) on recovery from a lower body resistance exercise bout typically used by recreationally active individuals. **METHODS:** Sixteen healthy adult men were matched and then randomly assigned to either Control (CON) or the Aquilo Cryo-Compression Pants (ACC) groups. Participants performed a typical lower body workout consisting of barbell back squats, stiff legged deadlifts, and Nordic hamstring curls. and then received 20 minutes of either cryo-compression using the Aquilo Cryo-Compression Pants (ACC) or nothing (CON) post exercise. Pain, soreness, mood, sleep quality, power, and reaction time, and muscle fatigue/damage biomarkers were measured at specific time points. **RESULTS:** The mean value comparisons show that after exercise ACC had significantly (P ≤ 0.05): lower levels of soreness 24hrs (ACC: 44.3, CON: 52.5) and 48hrs (ACC: 36.6, CON: 41.3); pain 60min (ACC: 3.0, CON: 4.1), 24hrs (ACC: 3.4, CON: 4.0) and 48hrs (ACC: 2.6, CON: 3.4); reduced muscle fatigue (reduced CK levels) 24hrs (ACC: 577 U/I, CON: 966 U/I) and 48hrs (ACC: 399 U/I, CON: 613 U/I); better sleep quality 24hrs (ACC: 58.0, CON: 52.5) and 48hrs (ACC: 56.75, CON: 47.6); better power output (reduced decrement) 24hrs (ACC: 5031.0 CON: 4087.2) and 48hrs (ACC: 5065.4, CON: 4879.8); and experienced a better overall mood 24hrs (ACC: 0.55, CON: 0.9) and 48hrs (ACC: 0.28, CON: 0.68). **CONCLUSION:** Aquilo Sports has developed a practical, portable recovery device that synergistically combines compression and cold therapy which effectively helps reduce muscle fatigue, soreness, pain, and poor sleep quality that may result from an acute bout of exercise. Funding, in part, was provided by Aquilo Sports, Inc.

Performance-related And Molecular Effects Of External Pneumatic Compression Treatment As An Adjuvant To Heavy, Voluminous Resistance Exercise

Cody Haun. *Auburn University, Auburn, AL.*
 Email: cth0023@auburn.edu
 (No relationships reported)

Cody T. Haun¹, Matthew A. Romero¹, Shelby C. Osburn¹, Gillis L. Langston^{1C}, Brooks Mobley¹, Richard G. Anderson¹, Michael D. Goodlett^{2,3}, David D. Pascoe¹, Michael D. Roberts^{1,2}, Jeffrey S. Martin^{1,2}
¹School of Kinesiology, Auburn University, Auburn, AL, ²Department of Cell Biology and Physiology, Edward Via College of Osteopathic Medicine - Auburn Campus, Auburn, AL; ³Athletics Department, Auburn University, Auburn, AL
Purpose: We sought to determine the effects of external pneumatic compression (EPC) when used concurrently with resistance training on functional and molecular measures related to recovery. **Methods:** Twenty (N=20) resistance-trained male participants (aged 21.6±2.4 years) were randomized to sham or EPC intervention groups. The protocol consisted of 3 consecutive days of voluminous back squat exercise followed by EPC/sham treatment (Days2-4) and 3 consecutive days of recovery (Days5-7) with EPC/sham only on Days5-6. On Day1 (PRE), and Days3-7, venipuncture, flexibility and pressure-to-pain threshold (PPT) measures were performed. *Vastus lateralis* muscle was biopsied at PRE, 1-h post-EPC/sham treatment on Day2 (POST1) and 24-h post-EPC/sham treatment on Day7 (POST2). Isokinetic peak torque was assessed at PRE and POST2. **Results:** The PPT was significantly lower on Days3-6 with sham, indicating greater muscle soreness, though this was largely abolished in the EPC group. A significant decrease in flexibility with sham was observed on Day3 (+16.2±4.6% knee joint angle; P<0.01) whereas there was no change with EPC (+2.8±3.8%; P>0.01). *Vastus lateralis* poly-ubiquitinated proteins significantly increased at the POST2 time point relative to PRE with sham (+66.6±24.6%; P<0.025) and were significantly greater (P<0.025) than those observed with EPC at the same time point (-18.6±8.5%). 4-hydroxyphenol values were significantly lower at POST2 relative to PRE with EPC (-16.2±5.6%; P<0.025) and were significantly lower (P<0.025) than those observed with sham at the same time point (+11.8±5.9%). **Conclusion:** EPC mitigated a reduction in flexibility and the PPT that occurred with sham. Moreover, EPC appeared to reduce select skeletal muscle oxidative stress and proteolysis measures during recovery from heavy resistance exercise.

Fascicle Lengthening During Eccentric Exercise Determines The Magnitude Of Muscle Damage

Dr Kirsty Hicks¹, Gladys Onambele-Pearson², Keith Winwood², Christopher Morse². ¹Northumbria University, Newcastle, United Kingdom. ²Manchester Metropolitan University, Crewe, United Kingdom. (Sponsor: Glyn Howatson, FACSM)
 Email: kirsty.hicks@northumbria.ac.uk
 (No relationships reported)

The characteristics of the muscle-tendon interaction during eccentric contractions suggests that tendon properties and the magnitude of fascicle lengthening contribute to the extent and the variability of exercise-induced muscle damage (EIMD). The mechanical processes which predispose the severity of EIMD remains unclear. **PURPOSE:** To determine whether: 1) patella tendon stiffness, at rest and during eccentric contractions, 2) the magnitude of *vastus lateralis* (VL) fascicle lengthening during eccentric contractions, and/or 3) eccentric torque, are determinants of EIMD. **METHODS:** Combining dynamometry, electromyography and ultrasonography, patella tendon properties and VL architectural properties were measured pre and during the first of 6 sets of 12 maximal voluntary eccentric knee extensions (range of motion 20 - 90°, 0° = full extension). The eccentric phase of the contraction was performed at an isokinetic angular velocity of 30°s⁻¹ and the concentric phase was performed passively at an angular velocity of 60°s⁻¹. Maximal isometric torque loss and creatine kinase (CK) activity were measured pre-damage (-48 h), 48, 96 and 168 h post-damage as markers of EIMD. **RESULTS:** Compared to pre-damage, a significant reduction in maximal isometric torque (264 ± 35 Nm, 221.0 ± 48.4 Nm, p = 0.004) and a significant increase in CK (136 ± 114, 796 ± 723 UL, p = 0.014) was reported 48 and 96 hrs post EIMD respectively. Relative changes in CK correlated with the relative change in fascicle length during eccentric contractions (r = 0.53, p = 0.02) and eccentric torque (r = 0.50, p = 0.02). Additionally, the relative change in CK tended to correlate with estimated patella tendon lengthening during eccentric contractions (r = -0.41, p < 0.10). However, relative change in CK did not correlate with resting measures of patella tendon properties or VL properties. Similarly, torque loss did not correlate with any patella tendon or VL properties at rest or during eccentric contractions. **CONCLUSION:** The extent of fascicle lengthening during eccentric contractions is related to the magnitude of the CK response. Furthermore, at rest, patella tendon properties are not determinants of indices of EIMD. During eccentric contractions of the VL, the patella tendon might play a modulatory role during exercise, to the susceptibility of EIMD.

Lower Limb Muscle Fatigue Perturbs Gait Balance during Dual-Task Walking

Szu-Hua (Teresa) Chen, Jocelyn Taylor, Li-Shan Chou.
University of Oregon, Eugene, OR.
Email: szuhua@uoregon.edu

(No relationships reported)

Walking and simultaneously performing an attention demanding task may occur concurrently with increasing muscle fatigue toward the end of some daily activities or job performance. Although previous research have demonstrated independent effect of these factors, their interaction are rarely taken into consideration.

PURPOSE: To examine changes in gait balance and working memory performance in healthy college-age adults after lower extremity muscle fatigue.

METHODS: Ten healthy adults (5 females, 20.6±1.0 yrs) performed the following three tasks before and after a muscle fatigue protocol: 1) Walking with a self-selected pace, 2) Sitting and performing a 3-back test, in which participants listened a series of digits over a loudspeaker and were instructed to verbally respond "yes" whenever a digit is heard that is the same as presented three positions back in the series, and 3) Walking and performing a 3-back test simultaneously. Sit-to-stand task at a pace of 0.5 Hz was performed to induce muscle fatigue. Maximal voluntary isometric strength of knee extensors was assessed using Biodex before and after the fatigue protocol and at the end of study. Whole body motion data were collected from a set of 29 retro-reflective markers placed on bony landmarks with a 10-camera motion system. Gait balance control was examined using the total medial-lateral CoM displacement (M-LCoM). Two-way ANOVA with repeated measures were used to detect differences between single and dual-task conditions.

RESULTS: An average of 21% knee extensor strength reduction was observed immediately after the completion of fatigue protocol, and it was recovered to approximately 10% by the end of study. In both gait conditions, M-LCoM was found to increase significantly after fatigue (3.1±0.2 vs. 3.7±0.3 cm, $p = .01$). Accuracy of the 3-back test was not significantly affected by the fatigue or gait condition.

CONCLUSIONS: Our preliminary findings indicated that gait balance control, as measured by the CoM sway, during a dual-task gait task might be more sensitively affected by the acute muscle fatigue induced in the current study.

2438 June 2 9:45 AM - 10:00 AM

The Validity of the Zebris FDM System for Measuring Static Balance

Robert W. Gregory, Marc I. Robertson. *Southern Connecticut State University, New Haven, CT.*
Email: gregoryr3@southernct.edu

(No relationships reported)

There are various instrumented methods of assessing static balance. One of the most common devices used to assess balance is the Biodex Balance System SD (BBS) (Biodex Medical Systems, Inc.), a specialized force platform that utilizes strain gauges to measure center of pressure (COP) sway patterns in the anterior-posterior (A-P) and medio-lateral (M-L) directions. An alternative device used to assess balance is the Zebris FDM System (FDM) (Zebris Medical GmbH), which is a platform that uses pressure sensors to measure COP sway patterns in the A-P and M-L directions.

PURPOSE: To establish the validity of the FDM for assessing static balance by determining the relationship between measures of static balance using the FDM and the previously validated BBS. **METHODS:** Thirty-seven healthy individuals (14 M, 23 F; age range: 20-71 yr) participated in this study. Participants performed static balance tests using both the BBS and the FDM in accordance with the BBS Postural Stability Test protocol during quiet stance. **RESULTS:** The following measures of static balance were obtained using the BBS: 1) A-P Stability Index (0.19 ± 0.18), 2) M-L Stability Index (0.10 ± 0.06), 3) Overall Stability Index (0.24 ± 0.11), 4) standard deviation of A-P COP sway (0.21 ± 0.06), and 5) standard deviation of M-L COP sway (0.13 ± 0.05). The following measures of static balance were obtained using the FDM: 1) 95% confidence ellipse area (175.2 ± 107.2 mm²), 2) COP path length (274.4 ± 103.2 mm), and 3) COP average velocity (4.5 ± 1.7 mm/s). The coefficients of correlation between the measures of static balance obtained using the BBS and the FDM ranged between $r=0.42-0.66$. All of the measures of static balance obtained using the FDM were significantly correlated with all of the measures of static balance

obtained using the BBS ($p<0.01$). For all measures of static balance obtained using the BBS, the strongest and weakest correlations were with COP path length and the 95% confidence ellipse area, respectively, obtained using the FDM. **CONCLUSION:** The FDM pressure platform is a valid instrument for measuring static balance in clinical and research settings since all of its measures were significantly correlated with measures of static balance obtained using the BBS force platform (a widely used and previously validated instrument for assessing balance).

The Influence Of Proximal Versus Distal Strength On Balance Control In Athletes Versus Non-athletes

Iktesh K. Chahal, Morgan F. Meyer, Erica M. Casto, Jean L. McCrory, FACSM. *West Virginia University, Morgantown, WV.*
(Sponsor: Jean McCrory, FACSM)
Email: ichahal@mix.wvu.edu

(No relationships reported)

Minor correlations between measurements for lower-extremity muscle strength and balance in individuals, regardless of the age, have been revealed. Similarly, maximal strength and balance have been individually investigated between an athletic population and a non-athletic population. However, comparisons between lower extremity strength (specifically ankle strength and hip strength) and balance between an athletic versus a non-athletic population have not been established. **PURPOSE:** The purpose of this pilot study was to find correlations in hip strength and balance versus ankle strength and balance in an athletic (NCAA athletes) and non-athletic population. **METHODS:** Twelve NCAA Division-1 athletes (age: 20.42 ± 1.51 years, height: 179.27 ± 11.2 cm, mass: 79.07 ± 14.89 kg, gender: 6M, 6F) and twelve healthy college students (age: 22.58 ± 2.47 years, height: 171.65 ± 8.00 cm, mass: 72.72 ± 14.21 kg, gender: 6M, 6F) participated. Following informed consent, balance on the dominant leg was measured using a BOSU ball in timed trials with eyes open and eyes closed. Using a Biodex System 4 Isokinetic Dynamometer, the isokinetic muscular strength and directional torque of eight muscle groups in the sagittal and frontal planes were measured. Lastly, multivariate regression models were performed ($\alpha=0.05$). Eyes open and eyes closed analyses were performed separately. **RESULTS:** Athletes had a higher ability to balance (athletes: 61.61 ± 42.67s vs non-athletes: 26.48 ± 27.19s) ($p=0.030$) in the eyes open trial and presented a correlation for ankle dorsiflexion ($R=0.674$) ($p=0.008$) when regressed with eyes open and ankle eversion ($R=0.833$) ($p=0.002$) with eyes closed. Meanwhile, non-athletes demonstrated a correlation for hip extension when regressed with eyes closed ($R=0.705$) ($p=0.005$). **CONCLUSIONS:** This study revealed a stronger correlation for ankle strength and balance in an athletic population while a stronger correlation between hip strength and balance was observed for a non-athletic population. Hence coaches, clinicians, or physical therapists can use these findings to tailor exercise protocols specific to individual cases and potentially increase balance to prevent injuries and falls.

2440 June 2 10:15 AM - 10:30 AM

Limb Strength and Balance in Community-Dwelling Older Women

Yuanyuan Tian¹, Jia Han¹, Junpeng Zhu¹, Liping Lu¹, Roger Adams², Judith Anson², Gordon Waddington². ¹Shanghai University of Sport, Shanghai, China. ²University of Canberra, Canberra, Australia.

(No relationships reported)

Strength and balance deficits are important factors contributing to falls risk in the community-dwelling older women. **PURPOSE:** To investigate upper and lower limb strength and static and dynamic balance in community-dwelling older women. **METHODS:** Forty-three active female volunteers, aged 60 to 89, were divided into three groups: G1 (under 65 years, n=16); G2 (65 to 74 years, n=14); and G3 (75 years and above, n=13). Their upper limb strength - hand grip (HG), lower limb strength - 30 seconds chair stand (STS), dynamic balance - timed up-and-go test (TUGT) and static balance - bipedal anterior-posterior sway with eyes open and closed (APO and APC, respectively), and bipedal medial-lateral sway with eyes open and closed (MLO and MLC, respectively) were assessed. **RESULTS:** Polynomial Trend analysis showed that most variables decreased significantly and linearly across the 3 age categories (HG: $F=4.92$, $p=0.032$; STS: $F=5.82$, $p=0.021$; TUGT: $F=7.92$, $p=0.008$; APC: $F=6.27$, $p=0.016$; MLO: $F=5.63$, $p=0.023$; MLC: $F=4.59$, $p=0.038$), but HG and MLC also had a quadratic component ($F=11.31$, $p=0.002$ and $F=4.30$, $p=0.045$, respectively). Specifically, HG held up well into the mid-seventies, then dropped markedly; while MLC declined immediately after women turned 65. GH and STS were significantly inter-correlated ($r=0.39$ $p=0.01$), and both were significantly correlated with dynamic balance function - TUGT ($r=-0.40$ $p=0.008$ and $r=-0.65$ $p<0.001$, respectively); however neither of them was significantly correlated with any static balance measures. In addition, significant correlations were only observed between open and closed eyes balance conditions in the same postural sway direction (APO and APC: $r=0.55$ $p<0.001$; MLO and MLC: $r=0.55$ $p<0.001$), not between different postural sway directions.

CONCLUSIONS: These findings have important implications for therapeutic exercise interventions designed to maintain and improve strength and balance in community-dwelling older women.

Effects Of A Short, Intensive, Multi-component Physical Exercise Program In Elderly At Risk Of Falls

Antonio Sgadari, Alessandra Martina, Aluena Battaglioli, Roberto Bernabei. *Catholic University Sacred Heart, Rome, Italy.*

Email: antonio.sgadari@unicatt.it

(No relationships reported)

Among older adults, falls are the leading cause of injuries and are responsible for significant disability, hospitalization, loss of independence, and reduced quality of life. Previous research showed that physical exercise (PE) is effective in preventing falls and has the potential to reduce serious fall-related injuries, emergency department visits, hospitalizations, nursing home placements, and functional decline. In most clinical trials the effect of PE was assessed by means of tests which assess a single "balance system", while balance control is very complex and involves many different underlying systems. The BESTest Scale consists of 36 items, grouped into 6 systems: biomechanical constraints, stability limits/verticality, anticipatory postural adjustments, postural responses, sensory orientation, and gait stability.

PURPOSE: To investigate the effects of a short (4 weeks), intensive (75 min sessions 3 times per week) PE program which included strength, coordination, gait, multisensory training, and single- and dual-task balance exercises on the balance of elderly subjects at risk of falls.

METHODS: Thirty sedentary subjects aged 70+ years at risk of falls (Berg's Balance Scale < 52) were recruited and randomly allocated to a Multi-Component Exercise group (MCE) or a Control group (CON). Main outcome was change in BESTest Scale (BT) total score.

RESULTS: At baseline, the two groups were similar with respect to age, gender distribution, anthropometric measures and risk of falls (BESTest Scale Score 53.7±14.8 in CON and 55.0±10.8 in MCE, n.s.). At the end of the study, BT total score was 55.5±16.7 in CON group (n.s. vs. baseline) and 72.7±8.8 in MCE group ($p < 0.001$ vs. baseline). The change of BT total score was 1.8 (95% CI -1.9-5.5) in the CON group and 17.7 (13.4-22.1) in the MCE group ($p < 0.001$ between groups). Also, the MCE group significantly increased the scores of all the six balance subsystems of the BT. Eventually, the change of Berg's Scale score was 0.9 (-0.2-2.1) in CON and 6.0 (4.4-7.6) in MCE ($p < 0.001$). At the end of the study MCE subjects could not be considered at risk for falling any more.

CONCLUSIONS: A 4 weeks, intensive, multi-component training program significantly improved balance in elderly subjects at risk of falls. The improvement affected the many systems involved in balance control.

Relationship of Fall Risk Questionnaires to Computerized Dynamic Posturography in Older Adults: A Pilot Study

Cody Sipe, 72143, Brianne Hillier, Tyler Wolfe. *Harding University, Searcy, AR.*

Email: csipe@harding.edu

(No relationships reported)

PURPOSE: Falling poses a significant potential health risk for older adults. Fall risk questionnaires have been identified as a quick and easy way to screen for the potential for falling compared to objective balance testing. However, the relationship between these questionnaires and formal balance assessments is not fully understood. Therefore, the purpose of this study was to elucidate the relationship between validated fall risk questionnaires and selected measures of balance using computerized dynamic posturography (CDP) in older adults of varying functional abilities. **METHODS:** Ten male (n=4) and female (n=6) elderly (72.7 ± 6.1 yrs) subjects completed testing and were included in the final analyses. All subjects passed the Mini-Mental Status Exam (MMSE) with a score > 24 prior to participating. Each subject completed two fall risk questionnaires (in random order): the Falls Efficacy Scale (FES) and the Activities-Specific Balance Confidence Scale (ABCS), as well as CDP testing for Limits of Stability (LOS) and the Sensory Organization Test (SOT) in a single session. The associations between the FES, ABCS, SOT composite score and selected LOS measures [end-point excursion (EPE), maximal excursion (MXE) and directional control (DCL) for forward (F) and backward (B) directions] were calculated using the Pearson correlation coefficient using pairwise deletion for missing variables. Alpha levels were set at 0.05. **RESULTS:** Scores on the FES and ABCS were significantly correlated ($r = -0.826$, $p = 0.003$) with one another. FES was significantly correlated with SOT ($r = -0.828$, $p = 0.011$), FEPE ($r = -0.574$, $p = 0.046$) and FMXE ($r = -0.684$, $p = 0.042$) but not with any backward measures. The ABCS was not significantly correlated with any CDP measures. No injuries occurred during the study. **CONCLUSION:** Although the ABCS and FES are similar tools and are highly correlated with one another this

data suggests that they are possibly capturing unique dimensions of balance confidence and capability in older adults. It is surprising that the ABCS, which includes a more robust mix of physical activities, was not significantly correlated with either SOT or LOS while the FES was. More investigation into the relationship of these questionnaires with objective balance measurements is warranted.

Treadmill-based Perturbation Training For Preventing Falls Among Young Adults

Patrick A. Cereceres, Christina Carrera, Fabricio Saucedo, Feng Yang. *University of Texas at El Paso, El Paso, TX.*

Email: pacereceres@miners.utep.edu

(No relationships reported)

Falls present a serious challenge not only among older adults, but for young adults, especially those whose working condition exposes them to a high fall hazard. Treadmill-based perturbation training, as a task-specific training, has emerged as a new paradigm used to prevent falls. However, the training program contained up to 30 perturbation trials in previous studies. It is unclear if a reduced number of perturbation trials could still induce positive effect in preventing falls. **PURPOSE:** To investigate the effect of a treadmill-based perturbation training paradigm consisting of 8 slip perturbations on reducing slip-related falls in young adults. **METHODS:** Thirteen healthy young adults (24 ± 4.34 years) were randomly assigned into either training ($n = 6$) or control ($n = 7$) groups. The training group underwent 8 unexpected slip trials on a special treadmill during gait while the control group received a "mock" training in which they walked on the same treadmill. After the training, both groups were subjected to an unexpected slip induced by releasing a movable platform when walking overground (OG). Subjects wore a safety harness equipped with a load cell. Body kinematics were captured and used to calculate dynamic gait stability on the OG slip. The load cell force was used to determine the OG slip outcome (fall vs. no-fall). A Chi-square test and independent *t*-test were used to respectively compare the fall incidents and dynamic stability between groups. **RESULTS:** Responding to the OG slip, 4 out of 7 (57.1%) subjects in the control group while 1 out of 6 (16.7%, $p = 0.18$) in the training group fell. The training group displayed a lower instability than the control at recovery foot touchdown (-0.56 ± 0.12 vs. -0.69 ± 0.07, $p < 0.05$). **CONCLUSIONS:** This study suggests that treadmill-based perturbation training with less perturbation trials could lower the risk of falls among young adults when exposed to a real-life like OG slip. Given that treadmill-based slip training is easy to use, portable, controllable, and reproducible, this training could provide a relatively novel modality to reduce falls among both young and older adults. Further studies based on a large sample size are needed to symmetrically evaluate the effectiveness of this type of training. Supported by the PiMSA Graduate Student Grant.

A Cost-Effective Method for Repeated Slip Training Increases Recovery Rate Following Laboratory-Induced Slips

Leigh J. Allin¹, Maury A. Nussbaum², Michael L. Madigan¹. ¹Texas A&M University, College Station, TX. ²Virginia Tech, Blacksburg, VA. (Sponsor: Kevin Davy, FACSM)

Email: lallin@tamu.edu

(No relationships reported)

Walking is commonly promoted as a way to increase physical activity; however, walking involves an inherent risk of slips and falls. Prior research has shown that repeated exposure to slips or slip-like perturbations improves balance recovery following actual slips. Researchers have explored repeated slip training (RST) as a fall prevention intervention by repeatedly exposing subjects to slips or slip-like perturbations in a safe, controlled manner. However, current methods for RST require non-trivial financial resources. **PURPOSE:** To evaluate the efficacy of a cost-effective method for RST compared to no-training (NT). **METHODS:** Twenty-four adults (18-28 years, 12 male) were randomized to RST or NT ($n = 12$ in each), and completed one training session and one session the following day to assess recovery rate after an actual slip. For RST, subjects repeatedly walked along a 10m walkway. During 20 randomly selected walks, a 0.9 x 0.9 m thin plastic sheet was placed at random locations along the walkway to induce a slip. The material of this sheet (e.g. polyethylene) was selected to provide low-friction with the floor and was camouflaged to match the floor surface. The NT group walked along the walkway 20 times. On the following day, vegetable oil was applied to the walkway to expose subjects in both groups to an actual unexpected slip. Balance was successfully recovered if less than 4.5% body weight, averaged over 1s periods, was applied to a safety harness worn during both sessions. Slip severity and slipping foot kinematics were measured using reflective markers on the calcanei, first metatarsal heads, and sacrum. **RESULTS:** Seven of 12 RST subjects recovered balance while only two of 12 NT subjects recovered ($p = .045$). RST subjects experienced less severe slips, with 94 cm/s slower peak slip speeds ($p < .001$) and 17 cm shorter slip distances ($p < .001$), and maintained slipping heel positions more proximal to the sacrum at heel contact ($p = .019$) and

non-slipping foot lift-off ($p=.002$) and touch-down ($p=.005$). **CONCLUSION:** RST increased recovery rate by reducing slip severity and maintaining slipping heel positions more proximal to the sacrum. This cost-effective method for RST may improve its potential for adoption as a slip-and-fall prevention intervention.

Medial Foot Pain in a Youth Soccer Player

Christine Bender¹, Heather Gillespie, FACSM¹, Abby Markham².
¹Maine Medical Center, South Portland, ME. ²Maine Medical Center, Falmouth, ME. (Sponsor: Heather Gillespie, FACSM)

(No relationships reported)

HISTORY: 13 yo male presents with right foot pain. Started 3 yrs ago with a forced eversion injury during soccer game when he collided with another player. He recalls swelling and bruising at that time. He went to the ER and had xrays done which were "inconclusive" as his mother recalls. Pain never completely went away and worsened several weeks ago. He has been doing a lot of hiking recently, very uneven surfaces and he reports pain with these activities. He has used an ankle brace and tried arch supports with no significant improvement.

PHYSICAL EXAMINATION: Inspection of feet and ankles reveal pes planus R>L on standing exam, with a neutral arch at rest while seated. Forefoot abduction R>L. Hindfoot valgus bilaterally. Tenderness to palpation of right foot over medial navicular eminence, slight tenderness over deltoid ligament and retrocalcaneal bursa. No tenderness at base of 5th metatarsal, medial malleolus, or lateral malleolus. Full active ROM but pain with inversion of right foot. No pain with eversion, dorsiflexion or plantarflexion. Pain with resisted inversion felt along distal posterior tibial tendon. No pain with heel or toe raise. No laxity with forced eversion. Negative talar tilt, anterior drawer, Thompson tests.

DIFFERENTIAL DIAGNOSIS: Posterior tibial tendonopathy
Navicular stress fracture
Deltoid sprain

Accessory navicular syndrome

Tarsal coalition Kohler disease **TEST AND RESULTS:** X-ray Right Foot: No evidence of acute or prior fracture or abnormal periosteal reaction. There is an accessory navicular noted.

FINAL WORKING DIAGNOSIS: Pes planovalgus with Accessory navicular syndrome

TREATMENT AND OUTCOMES:

Referred by PCP to orthopedics for evaluation of medial foot pain in setting of accessory navicular bone. Discussed option of surgical management (double calcaneal osteotomy and tendon transfer) given degree of planovalgus deformity but ultimately recommended conservative management. Discussed use of orthotics. Provided with a medial heel wedge and scaphoid pad to alter load on right foot. Also provided with exercises for hamstring and achilles. Offered short leg cast for 6wks but ultimately declined at this time due to upcoming activities.

Email: alkhamisi.ashkan@mayo.edu

(No relationships reported)

Foot Injury in a Recreational Runner

Ashkan Alkhamisi, MD, Glenn G. Shi, MD, and George G.A. Pujalte, MD, FACSM

HISTORY: A 37-year-old, healthy, young female presented with 5 weeks of left foot pain. She denied any major trauma or precipitating event, but did recall doing holiday

shopping for 10 hours straight a few days prior to experiencing symptoms. Patient stated that she used to wear heels all the time at work as a school-teacher. She reported numbness and tenderness over the plantar aspect of the first metatarsophalangeal joint. She wore a metatarsal pad and took ibuprofen with no relief of symptoms. The pain was exacerbated with weightbearing.

PHYSICAL EXAMINATION:

Left foot: No tenderness to palpation of the hindfoot or midfoot. Pain was elicited with passive dorsiflexion and plantarflexion of first metatarsophalangeal (MTP) joint. Tenderness to palpation along the lateral aspect of the first MTP joint, with no erythema or swelling. Sensation was intact.

DIFFERENTIAL DIAGNOSES:

1. Sesamoid osteoarthritis
2. Sesamoid stress fracture
3. Sesamoid dislocation
4. Sesamoiditis

TEST AND RESULTS:

Left foot, standing, 3 views: Fragmentation of the left lateral hallux sesamoid, with small surrounding foci of mineralization. Remainder of osseous structures were intact. No focal soft tissue swelling.

FINAL DIAGNOSIS:

Left lateral (fibular-sided) non-union sesamoid fracture

TREATMENTS AND OUTCOMES:

1. Immobilization within a boot, with non-weightbearing status for 6 weeks
2. At 2 months post-injury, she continued to have pain and wanted to wear the walking boot for another 1-2 months
3. Repeat radiographs at 3 and 4 months post-injury showed continued non-union of the lateral sesamoid bone.
4. Orthopedic referral was made at 4 months post-injury and she decided to proceed with a left lateral sesamoidectomy with immobilization within a boot for 4 weeks.
5. At 4 months post-operatively, she was able to run with no pain and good range of motion of her left first MTP joint.

2450 June 2 10:10 AM - 10:30 AM

A Rare Cause of Foot Pain in an Adolescent Male Multisport Athlete

John Franco, Edward Laskowski, FACSM, Cara Prideaux. *Mayo Clinic, Rochester, MN.* (Sponsor: Edward Laskowski, FACSM)

Email: franco.john@mayo.edu

(No relationships reported)

HISTORY: A 13 year old male football, basketball, and baseball athlete presented to sports medicine clinic with a 3 month history of non-traumatic exertional right lateral foot pain. He reported 8/10 pain with strenuous activities, such as running and jumping. He had no pain with walking. He reported aching discomfort in the morning upon waking. He denied numbness, tingling, or abnormal sensation.

PHYSICAL EXAMINATION: There was no significant deformity. He was able to walk with a non-antalgic gait. There was tenderness to palpation over the lateral base of the 5th metatarsal. Range of motion of the foot and ankle was normal. There was normal strength upon manual muscle testing, but resisted ankle eversion reproduced pain. He was neurovascularly intact.

DIFFERENTIAL DIAGNOSIS: 1. Metaphyseal-Diaphyseal (Jones) Fracture 2. Fifth Metatarsal Stress Fracture 3. Traction Apophysitis (Iselin's Disease) 4. Insertional Peroneal Tendinopathy 5. Avulsion Fracture

TESTS AND RESULTS:

- Right foot radiograph:

Well-corticated bone fragment proximal and perpendicularly-oriented to the base of the 5th metatarsal, representing an accessory ossicle (os vesalianum) versus ununited fracture. No evidence of acute fracture and normal-appearing apophysis.

- Right foot MRI: Osseous body at base of the 5th metatarsal with irregular margins, hyperintense T2 fibrous union, and internal edema of the ossicle and adjacent proximal metatarsal, favored to represent a symptomatic os vesalianum. No increased apophyseal distraction.

FINAL WORKING DIAGNOSIS:

Symptomatic Accessory Os Vesalianum

TREATMENT AND OUTCOMES:

1. Immobilize in a walker boot for 6-8 weeks.
2. Physical therapy after immobilization, with emphasis on peroneal muscle strengthening and range of motion.
3. If complete resolution of symptoms, may gradually return to sport as tolerated. If symptoms persist, consider surgical excision.

2451 June 2 10:30 AM - 10:50 AM

Not Your Average Ankle Injury

Hassen Berri, Phillip Troy Henning. *University of Michigan, Ann Arbor, MI.* (Sponsor: Robert Kiningham, FACSM)

(No relationships reported)

Ankle Injury- Soccer

History: 43 year old male soccer player presented with persistent medial and lateral ankle pain since sustaining an injury 9 days prior during soccer. He came down strongly on his left heel. He heard a “pop” and felt immediate pain on both sides of his ankle. He also reported that his foot felt “numb”, but this resolved in about five minutes. He had severe pain with weight bearing but was able to limp off the field. He did not seek formal medical attention and used crutches for a few days. He continued to experience a snapping sensation along his lateral ankle that was mostly resolved by the day of appointment.

Physical Examination:

Ecchymosis and swelling diffusely at the ankle. Tenderness to palpation in deltoid and lateral ligaments, mild at peroneal tendon, no bony tenderness. Active and passive range of motion is uncomfortable but within functional limits except restricted dorsiflexion to just past neutral. There is a + anterior drawer test and a + talar tilt test for laxity. Negative squeeze test. No pain along the syndesmosis with passive dorsiflexion/eversion. Patient/examiner unable to sublux lateral tendon to reproduce snapping. Patient is otherwise neurovascularly intact

Differential Diagnosis: medial ankle sprain, lateral ankle sprain, peroneal tendon strain, posterior tibial tendon strain, peroneal retinaculum injury, ankle fracture

Test and Results: X-ray 9/6/2016- no evidence of acute fracture.

Final Working Diagnosis: Left ankle, multiple injuries: Peroneal Retinaculum Injury, Grade 3 lateral ankle sprain (complete rupture of anterior talofibular ligament and some injury to calcaneonavicular ligament), Deltoid ligament sprain without avulsion

Treatment and Outcomes:

Ankle support orthosis (ASO) brace, elevation, compression, PT, X-rays, No return to play until follow up in 4 weeks, NSAIDs vs. Tylenol for pain.

Follow up: Increased lateral tendon snapping recurring. Noncompliant with ASO.

MSK Ultrasound: partial avulsion of peroneal retinaculum off of distal fibula with effusion in the peroneal tendon sheaths. Dynamic evaluation shows anterior subluxation of the peroneal tendons into defect. **Management:** Stop PT. Discussed with ankle surgeon. Continue conservative care with ASO when ambulating. No return to sport. Follow up in 4 weeks. Consider surgery if not improving.

2452 June 2 10:50 AM - 11:10 AM

Not Your Ordinary Ankle Sprain

Juraj Zahatnansky, Robert Baker, FACSM, Mark Sytsma. *Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI.* (Sponsor: Robert Baker, FACSM)
Email: juraj.zahatnansky@med.wmich.edu

(No relationships reported)

HISTORY: This is a case of an otherwise healthy 19-year-old running back who sustained a left ankle eversion type injury during a football game when an opponent landed on his lower leg forcing it into external rotation. He did not finish playing due to the inability to bear weight.

PHYSICAL EXAMINATION: During initial evaluation, limited due to a significant amount of pain, he had tenderness over the deltoid, anterior talofibular, and calcaneofibular ligaments. During reevaluation two days later he was also complaining of some tenderness around the lateral aspect of his left knee. His exam showed mild edema at the level of his ankle, tenderness over ligaments as noted before, along with pain on external rotation of his foot, compression along his syndesmosis, and palpation over his tibiofibular joint with increased posterior translation of his proximal fibula compared to the contralateral side. His left knee exam revealed pain in the area of his fibular head with varus stress, but was otherwise unremarkable.

DIFFERENTIAL DIAGNOSIS:

- Ankle fracture
- Syndesmosis injury
- Proximal tibiofibular joint injury

TEST AND RESULTS:

Stress radiographs of left ankle at the stadium:

- no acute fracture and no obvious opening of his syndesmosis or medial joint space
- Repeat weight bearing radiographs of left ankle:
- ossification of his syndesmosis likely indicative of previous injury, as well as decreased overlap between distal tibia and fibula
- no clear evidence of medial ankle joint space widening

MRI of left calf and ankle:

- no ligamentous tear of the proximal tibiofibular joint, but changes consistent with chronic avulsion injury of the syndesmosis membrane from the distal portion of the tibia and probable injuries to his anterior inferior tibiofibular ligament and anterior talofibular ligaments

FINAL WORKING DIAGNOSIS:

Syndesmosis injury with proximal tibiofibular joint instability

TREATMENT AND OUTCOMES:

1. Non-weightbearing for the initial 10 days post injury.
2. Open reduction and internal fixation of distal syndesmosis using a single tightrope fixation, along with stabilization of the proximal tibiofibular joint using the same technique.
3. Non-weightbearing for the following 6 weeks.
4. Gradual return to physical activity.

E-17 Clinical Case Slide - Hip and Pelvis II

Hip fracture - Marathon

Title - The Piggy Back Sign

Jaimi Weber, Caroline Hu, Kelly Roberts Lane, William Roberts, Steven D. Stovitz,
Email: jweber@umn.edu

Sponsor: William Roberts FACSM

HISTORY: 25 yo woman developed R hip pain while running her 1st marathon. She first noticed R hip pain during training runs approximately 2 wks before the event. Her pain was present at the beginning of her runs, subsided during, and then ache afterwards. During the marathon, she first noticed hip pain around mile 20-21, but this didn't affect her stride until mile 24 when she began to feel cramping and her stride changed. In the last mile, which was downhill, she knew something was wrong and about 100 m from the finish line she felt a "pop" in her R hip. She was unable to weight bear and was piggy-backed over finish line about 3h:20min after the start.

PMH: History of severe GERD in 2013, currently on ranitidine 75mg daily. Avid Nordic skier and mountain biker. Suffered a mountain bike crash 1 yr prior to the race and was unable to exercise for 6 mo due to severe concussion symptoms. Started running 5 mo before the race and ramped up to the marathon distance. Reports normal menstrual cycles. Non-vegan vegetarian for 15 yrs. No iron supplementation due to GERD.

PHYSICAL EXAM: Brought to medical tent in a wheelchair, unable to bear weight on her R leg. She had no tenderness to palpation of her hip musculature. Her R leg appeared to be slightly shorter and externally rotated compared to her L leg. She had excruciating pain with internal rotation of her hip.

DIFFERENTIAL DIAGNOSIS:

1. Hip fracture
2. Stress fracture/reaction
3. SI joint dysfunction
4. Gluteal muscle strain

TEST AND RESULTS:

Hip radiographs: R transcervical femoral neck fx

Hip CT: R transcervical femoral neck fx, no pathologic fx

Pending: DEXA scan, diet and activity analysis for energy deficit

FINAL/WORKING DIAGNOSIS: R transcervical femoral neck fx

TREATMENT AND OUTCOMES:

1. R femoral neck fx CRIF
2. Weight bear as tolerated with crutches prn
3. PT started 2 wks post-operatively
4. No "pounding" activities for 6 wks
5. Stationary bike for exercise as tolerated
6. Nutrition counseling

2457 June 2 9:50 AM - 10:10 AM

Looking Beyond the Joints, An Uncommon Case of Hip Pain

Ronan Cahill, Adam pourcho. *Swedish Medical Center, Seattle, WA.*

Email: ronan.cahill@swedish.org

(No relationships reported)

History: 47 yo female presented to this clinic with more than 2 years of right anterior thigh pain. She had previously been an ultramarathon runner and cyclist but had to stop these activities secondary to pain. Her pain started the day after running a marathon in September 2014. She completed that marathon with symptoms of mild calf tightness and anterolateral thigh "giving out" during the last mile. The following day she developed right posterolateral buttock pain with radiation to anterior and mid-thigh with ambulation. She had an extensive workup prior to presentation at the sports medicine clinic and was being treated under the working diagnosis of radiculopathy. She had MRIs of her right knee, right hip, and lumbar spine. She had tried physical therapy, chiropractic care, lumbar epidural injection and watchful waiting. None of these relieved her symptoms. At initial presentation to this clinic, she complained of right anterior thigh cramping that starts with 15 minutes of running and stops within an hour after rest. The pain is severe and rated 7/10 with activity. The pain does not radiate and is located in the anterior thigh. She denies lower back pain, numbness or tingling. She has no pain with squatting and minimal periodical pain with prolonged walking. **Exam:** On exam, the patient had a normal gait, a small right knee effusion and tenderness to palpation over the distal myotendinous junction of rectus femoris and vastus lateralis. Hip ROM was full and non-painful, with negative FADIR and Stinchfield tests. Knee exam with no ligamentous laxity or point tenderness. She had bilateral weakness of hip abductors. **Differential Diagnosis:** 1 Hip labral tear 2 Femoral Acetabular Impingement 3 Iliac artery endofibrosis 4 Inflammatory Myopathy 5 Meniscal Tear of Knee **Tests and Results:** Diagnostic US of knee and hip - patellofemoral arthropathy - small knee effusion - CAM type femoral deformity - anterior acetabular calcification without labral tear Diagnostic Knee and Hip Injection without benefit Arterial Dopplers - abnormal ABI on right, normal on Left - Complete external iliac artery occlusion on right and <50% stenosis of left common iliac artery **Final Diagnosis:** Complete right external iliac endofibrosis **Outcome/Treatment:** - Right external thromboendarterectomy - Partial running on AlterG at 2 months - Full running at 3 months

2458 June 2 10:10 AM - 10:30 AM

Adolescent Track Athlete with Acute Right Hip and Groin Pain

Erin Moix Grieb, Kyle Nagle. *University of Colorado, Denver, CO.* (Sponsor: John Hill, FACSM)

(No relationships reported)

History: 11-year-old previously healthy female presents with acute-onset right hip and groin pain that started while doing hurdles at track meet. Patient led with her right foot over hurdle and felt a "pop," with immediate pain at right anterior hip and groin. Unable to bear weight without significant pain.

Physical Examination:

Gen: NAD, well-appearing.

CV: RRR, brisk pulses, <2 sec cap refill

Chest: No tachypnea, no increased WOB

Neurologic: NI muscle bulk and tone, abnormal gait with antalgia.

MSK: Right hip

-Inspection: No swelling, deformity or ecchymosis.

-Palpation: Moderate TTP over anterior hip. No tenderness over greater trochanter, iliac crest, ASIS, AIIS, adductors, distal femur, or knee. No tenderness of ischium, lumbar spine, or SI joints. No palpable joint effusion.

-Range of motion: ROM of hip limited in extension, flexion and internal rotation due to pain. External rotation intact and pain free. ROM of knee is full.

-Neurovascular: Strength 3/5 with resisted hip flexion. Distally NVI with brisk pulses, 2 sec cap refill, normal motor and sensory nerve examination.

-Special maneuvers: FABER negative. FADIR positive.

-Opposite limb: No swelling, deformity, TTP, or decreased ROM. Full strength. Skin intact.

Differential Diagnosis:

Iliopsoas tendon rupture

Femoral neck stress fracture

Greater Trochanter/Intertrochanteric/Subtrochanteric fracture

Gluteal, Hamstring, Adductor muscle tear

Labral tear

Tests & Results:

Hip/Pelvis Radiographs:

-Date of injury: Apophyseal avulsion of right lesser trochanter at iliopsoas insertion.

-1 month after injury: Increased ossification of avulsed fragment, stable positioning.

-2 months after injury: Slightly increased ossification; stable appearance.

Final/Working Diagnosis: Apophyseal avulsion fracture of right femoral lesser trochanter

Treatment and Outcomes:

-Protected weight-bearing with crutches x 5 weeks. No impact or explosive movements. Ice, Ibuprofen as needed for pain.

-After 5 weeks, started Physical Therapy and home exercise program. No ballistics or sprinting.

-After 4 weeks of PT, gradually progressed into sprinting, jumping, and ballistics under PT guidance.

-Complete resolution of pain and return to softball and track without further complications. Xrays with stable alignment, malunion with fragment displacement of ~1.7 cm.

2459 June 2 10:30 AM - 10:50 AM

Hip Pain in a Ballet Dancer

Sarah S. Jackson. *Boston Children's Hospital, Boston, MA.*

(Sponsor: Pierre d'Hemecourt, FACSM)

Email: ss.jackson25@gmail.com

(No relationships reported)

HPI

17yr old ballerina presents with bilateral hip pain, left > right that has become progressively worse over the last year. Groin pain and some posterior hip pain. She states that when standing in arabesque she has the most discomfort but also with standing in 3rd and 5th position.

PE

Normal, non-antalgic gait.

Right Hip: Negative log roll. Negative straight leg raise and Stinchfield testing.

Flexion to 150°, internal rotation 30°, external rotation 50°, abduction of 50°. Negative impingement. Minimal discomfort with extension and external rotation.

Left Hip: Negative log roll. Negative straight leg raise and Stinchfield testing. Flexion to 140° but painful from 110-140°. Internal rotation to 20°, external rotation to 50° and abduction to 50°. She has positive impingement testing. She also has a positive FABER and scour test. Significant pain with extension and external rotation.

Diff Dx

Labral tear

FAI

Psoas tendinitis/bursitis

Dysplasia

Tests/Results

AP and bilateral lateral Dunn- Prominence noted bilaterally over the posterior proximal metaphysis of both femoral heads.

MRI w/out contrast: Moderate sized sessile osteochondroma arising from the posterior proximal left femoral metaphysis. Moderate underlying bone marrow edema suggesting that this lesion is undergoing abnormal stress. There is a similar sessile osteochondroma arising on the right posterior proximal femoral metaphysis, less well pronounced. No associated bone marrow edema.

Dynamic U/S: Dynamic u/s exam of the posterior hip the bony prominence on the left femur shows significant impingement with the hip externally rotated while the patient is prone. This is less significant but still appreciated on the right posterior hip. With the patient is supine the left hip does appear to have anterior instability with the leg in extension and external rotation (position of apprehension) and the femoral head had ~3-4mm of anterior displacement.

U/S guided diagnostic IA inj (left hip): 100% relief, no pain with 3rd or 5th position and arabesque immediately s/p inj.

Final Working Dx

Posterior bony impingement with secondary anterior instability
Osteochondroma (unlikely)

Treatments

Continue PT

Modify dance, except for performances.

Surgical planning in progress - open posterior femoral osteochondroplasty, possible arthroscopy

2460 June 2 10:50 AM - 11:10 AM

Right Hip Pain in a 36 year old Ironman Athlete

Alan J. Boucher, MD, Joel Shaw, MD, Joe Simko, PT.
OhioHealth Grant Medical Center, Columbus, OH.

(No relationships reported)

HISTORY: A 36 year old female long distance runner who was training for an Ironman that presented with a 1 week history of right hip pain. Onset of pain when standing up quickly from sitting position. Pain is reported laterally and worsening with activity. She said it is progressing to the point that it has disrupted sleep for the last 2 nights. Now she is unable to weight bear on her right leg.

PHYSICAL EXAMINATION: Her hips were with no obvious deformity or effusion to inspection bilaterally. She exhibited normal ROM with severe pain with internal rotation. Strength 5/5 in hip bilaterally. Tenderness of the anterior aspect of the right hip. Pain elicited with resisted hip flexion.

TEST AND RESULTS: Xray right hip revealed a large separated bony piece at the area of the anterior inferior iliac spine (AIIS) consistent with an avulsion, initially presumed as a chronic injury. Based on the severity and concern for stress fracture of the femoral neck she was placed on crutches with no weight bearing. MRI was ordered for further evaluation and she was informed to hold off all activity until results. MRI of right hip revealed acute-to-subacute avulsion fracture of the right anterior inferior iliac spine with associated partial tearing of the rectus femoris tendon, as well as mild edema in adjacent musculature and in fascial planes about the proximal rectus femoris muscle.

FINAL WORKING DIAGNOSIS: acute-to-subacute avulsion fracture of the AIIS.
TREATMENT AND OUTCOMES: Typically, in the adolescent population where these injuries are more commonly seen, the therapy consists of complete rest and non-weight bearing then progress with light activity and running at 8-10 weeks, with a goal to return to full activity in sports at 12 weeks following the injury. This patient followed a similar course of therapy but because of age and the idea was she would not need longer to heal based on her having a fused growth plate we were more aggressive with her return to running. Therefore, she was non-weight bearing and did core and hip strengthening for one month and then gradually progressed to running using AlterG at 4 weeks and typical road jogging in 6 weeks. After 3 months she had completed a 7 mile long run and had been able to start kicking and swimming. At 16 weeks from injury, she still reports little to no pain and is currently back to training for Ironman competitions.

2461 June 2 11:10 AM - 11:30 AM

Pelvic Injury in a 60 Year Old Rollerblader

Andrew Barclay. *LECOM Sports Medicine, Erie, PA.* (Sponsor: Patrick F. Leary, FACSM)

(No relationships reported)

Clinical Case Abstract

Pelvic injury - Rollerblading

Andrew D. Barclay, LECOM Sports Medicine, Erie, PA

Email: andrew.barclay@nv.touro.edu

(Sponsor: Patrick F. Leary, FACSM)

HISTORY: A 60 year old female presented on a Friday afternoon with right groin pain for one week. Onset of pain after a fall while rollerblading. She was unable to bear weight on her right leg after the injury and during

the evaluation. After examination, she was sent for radiographs of the pelvis and bilateral hips.

PHYSICAL EXAMINATION: Examination in the office of the right pelvis and hip revealed inability to flex the hip in supine position due to pain. Special testing revealed a negative log roll and FABER test, but positive

FADIR test. Gait posture was antalgic and the patient was unable to fully bear weight on right leg.

DIFFERENTIAL DIAGNOSIS:

- 1.Hip/pelvic fracture
- 2.Hip dislocation
- 3.Hip osteoarthritis
- 4.Bone contusion

TEST AND RESULTS:

X-ray Pelvis and Bilateral Hips:

-nondisplaced fractures right superior and inferior pubic rami
-mild osteopenia

Pelvic CT:

-minimally displaced comminuted fracture right inferior pubic ramus
-nondisplaced fracture proximal right superior pubic ramus adjacent to the acetabulum
Dexa Scan:

-T-score of -2.1

Labs:

-Vit D pending

FINAL/WORKING DIAGNOSIS:

-Pelvic ring fracture
-Osteopenia

TREATMENT AND OUTCOMES:

- 1.Crutches until pain free
- 2.Ice and electrical stimulation
- 3.Vitamin D3 supplementation
- 4.Physical therapy started 3 weeks post injury
- 5.Progressed through a gradual return to activity

E-18 Clinical Case Slide - Knee I

Friday, June 2, 2017, 9:30 AM - 11:30 AM

Knee Injury- Ballet

Lindsay Ramey, Daniel Blatz. *Rehabilitation Institute of Chicago, Chicago, IL.* (Sponsor: Joseph Ihm, FACSM)

Email: lnr8t@virginia.edu

(No relationships reported)

History:

A 29-year-old male professional dancer presented with 6 weeks of right anterior knee pain after landing a jump in knee extension. His pain worsened with jumping & squatting and improved with rest. He denied systemic symptoms, other joint pain or medication use. He was evaluated by the company's physical therapist & treated for patellar tendinopathy, including eccentric strengthening, cho-pat strap & jump restrictions, without improvement.

Physical Examination:

Exam showed bilateral knee crepitus, right proximal patellar tendon tenderness and pain with right leg squat & hop. His exam was otherwise normal.

Differential Diagnosis:

- Patellar tendinopathy
- Patellar tendon tear
- Patellofemoral pain
- Avulsion fracture
- Subluxation

Tests and Results:

Knee US: Focal hypoechogenicity & fiber disruption in the right medial proximal patellar tendon

Right knee MRI: Increased signal on T2 & STIR confirming partial tear of the proximal patellar tendon

Diagnosis:

Right proximal patellar tendon tear

Treatment and Outcomes:

Initial treatment included knee immobilization, activity restriction, topical nitroglycerin & PT for 3 months without improvement. The patient pursued an US-guided platelet-rich plasma (PRP) injection without tenotomy at an outside facility. He had partial improvement but dance remained restricted. Subsequent US at 6 months showed

persistent tear. US-guided tenotomy and PRP injection were repeated, followed by activity restriction, PT and return to activity protocol. He noted limited relief at 4 weeks and pursued a third PRP injection at an outside facility.

He developed worsening, diffuse anterior knee pain. US showed new thickening and heterogeneity throughout the right patellar tendon.

MRI confirmed hypertrophic changes. Given prolonged course, he underwent open patellar tendon debridement & repair. Intra-operatively, the tendon was noted to be significantly thickened with abnormal color & texture. Post-operative follow-up is ongoing.

2466 June 2 9:50 AM - 10:10 AM

Knee Injury-jumping

Daniel P. Montero. *Mayo Clinic Florida, Jacksonville, FL.*
(Sponsor: George Pujalte, FACSM)

(No relationships reported)

HISTORY: 40 year-old female who injured her right knee jumping onto a dock. She had sudden, severe pain, 9 out of 10 in intensity. She could not bear weight or bend it initially. She had swelling the next day. She described locking and occasional "giving out". Within days, she could walk with minimal discomfort but could not exercise or lift weights. Symptoms slowly improved over the past 8 weeks as she presented for further evaluation **PHYSICAL EXAMINATION:** Thin, healthy-appearing. Normal gait. Full ROM both knees. No effusion or skin changes. Bony prominence of tibial tubercle without edema or erythema. Minimal point tenderness over patellar insertion. Nontender over origin and belly. Guarding on exam but negative anterior/posterior drawer tests, Lachman test, and patellar apprehension. Positive McMurray test.

DIFFERENTIAL DIAGNOSIS: Patellar strain/tear Meniscus tear Anterior cruciate tear Fracture of Osgood-Schlatter disease

TEST AND RESULTS: X-rays revealed hypertrophic changes of right tibial tubercle with mild associated soft tissue swelling. MRI revealed irregularity of tibial tubercle suggesting sequela of Osgood-Schlatter disease. There were surrounding inflammatory changes and edema with small amount of fluid in deep and superficial infrapatellar bursae. No internal derangement.

FINAL WORKING DIAGNOSIS: Fracture of Osgood-Schlatter disease in a 40-year-old female

TREATMENT AND OUTCOMES: 1. Modified rest for another 4 weeks (12 weeks from injury) 2. Physical therapy 3. Gradual return to jumps, squats, lunges, and weight lifting

2467 June 2 10:10 AM - 10:30 AM

Right Knee Pain - Runner

Ryan C. Kruse, Jonathan Finnoff, FACSM. *Mayo Clinic, Rochester, MN.* (Sponsor: Jonathan Finnoff, FACSM)
Email: kruse.ryan@mayo.edu

(No relationships reported)

HISTORY: A 60 year old male runner with a history of right common peroneal nerve entrapment status post-surgical decompression presented for evaluation of right lateral knee pain that had been present for 1 year. He described dull, lateral, aching knee pain, worsened by impact activity (e.g., running). He denied mechanical symptoms or effusion. Knee MRI demonstrated popliteus tendinopathy with partial-thickness intrasubstance tearing and a 10x5mm peritendinous cyst.

Ultrasound (US)-guidance was used to drain and fenestrate the cyst, and fenestrate and inject the popliteus tendon with leukocyte rich platelet rich plasma (PRP). The procedure was performed without complication. The patient used crutches for 5 days post-procedure, but on day 6 he walked 6 blocks without crutches. That evening, he developed pain and swelling with erythema in the suprapatellar region. No fever, chills, or knee drainage was present. Due to the symptoms, he returned to clinic for evaluation.

PHYSICAL EXAMINATION: Healthy appearing male in no acute distress. Mildly antalgic gait pattern. Grade 2 right knee effusion with erythema around the superolateral aspect of the knee. Well-healed injection site without erythema. Mild tenderness to palpation over the popliteus tendon insertion. Normal ligamentous and meniscal tests.

DIFFERENTIAL DIAGNOSIS: 1. Acute knee effusion secondary to overuse after recent PRP injection 2. Septic arthritis 3. Post-injection flare

TEST AND RESULTS: Right knee limited ultrasound - moderate effusion within suprapatellar recess Right knee aspiration - Appearance: straw colored - Cell count: 1283 - Neutrophils: 60 - Gram stain: negative - Culture: no growth - Crystals: intracellular CPPD crystals

FINAL WORKING DIAGNOSIS: Acute right knee pseudogout flair in a patient with no history of pseudogout, status post popliteus tendon PRP injection with peritendinous cyst aspiration and fenestration.

TREATMENT AND OUTCOMES: The patient was successfully treated with crutches, ice, compression, elevation, and NSAIDs.

2468 June 2 10:30 AM - 10:50 AM

Knee Pain - Soccer

Kenneth Y. Choi, Marissa S. Vasquez, Michael K. Fong, *Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA.*

(Sponsor: Aaron Rubin, FACSM)

(No relationships reported)

HISTORY: 18 y/o male soccer player sustained a twisting injury with direct contact of his left knee during a game. He had no immediate or delayed swelling, but continued to have persistent posterior knee pain for two months before he pursued medical care. No instability or locking. Due to the severity of the pain, he had not played at all since the injury.

PHYSICAL EXAMINATION: Examination in the office revealed a trace effusion and tenderness to palpation over the proximal posteromedial tibia. Otherwise, the patient had full range of motion, no ligamentous laxity, and no meniscal signs.

DIFFERENTIAL DIAGNOSIS:

1. Fracture/stress reaction
2. Contusion
3. Capsular sprain
4. MCL sprain
5. Medial meniscus tear
6. Maligancy

TEST AND RESULTS:

1. MRI Left Knee Without Contrast
-7 mm x 6 mm x 7 mm intracortical lesion with periostitis and periosteal reaction -bone marrow edema in the proximal tibia with medial aspect surrounding the intracortical lesion
-clinical correlation required to differentiate whether bone marrow edema is from recent trauma or intracortical lesion
2. CT Left Knee Without Contrast
-4 mm x 3 mm x 4 mm intracortical extracapsular osteoid osteoma in the proximal medial tibial metaphyseal cortex

FINAL/WORKING DIAGNOSIS:

Osteoid osteoma of the proximal tibia

TREATMENT AND OUTCOMES:

1. Initially treated with rest and non-steroidal anti-inflammatory medication as needed
2. Had continued pain for three months after diagnosis, and was referred to orthopedic oncologist
3. CT-guided radiofrequency ablation performed successfully

2469 June 2 10:50 AM - 11:10 AM

Utility of Dynamic Sonographic Evaluation of Left Knee Pain & Locking in a Softball Catcher

Allison N. Schroeder, Kentaro Onishi, *University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA.* (Sponsor: Tom Best, FACSM)

Email: aschroel@alumni.nd.edu

(No relationships reported)

HISTORY: An 18 year-old softball catcher presenting with a 3 year history of left progressive postero-lateral knee discomfort with associated knee locking when squatting or deep knee flexion. Onset was 3 years ago when she was in a squat position during a softball game. She had been avoiding aggravating activities and initially sought medical care 3 months ago, presenting to an orthopedic specialist's clinic. Following a negative MRI, she was referred to our clinic for diagnostic ultrasound of the knee. She reported no reliable way to reproduce locking, but, when locking does occur, she must manually unlock herself. Previous treatment included 8 weeks of physical therapy without benefit.

PHYSICAL EXAMINATION: No discoloration or swelling of the left knee. Non-antalgic gait. Valgus alignment with dynamic valgus on single leg squat. Posterior lateral joint line tenderness. No other focal tenderness. Full and symmetric bilateral knee active range of motion without pain, except in terminal flexion. Negative McMurray's, cruciate and collateral ligament testing and dial test. 9/9 Beighton criteria.

DIFFERENTIAL DIAGNOSIS: 1. Meniscocapsular separation 2. Lateral meniscus injury 3. Proximal tibiofibular ligament injury 4. Popliteus muscle/tendon injury 5. Anteriolateral complex sprain 6. PFL injury

TEST AND RESULTS: MRI: Subtle irregularity of posterior superior meniscocapsular fascicle deemed secondary to volume-averaging artifact. Otherwise, no discrete pathology was noted. Ultrasound: No discrete lesion of entirety of lateral meniscus on static exam. Development of a separation (3.1mm) between posterior

knee capsular tissue and posterior outermost fiber of left lateral meniscus when knee is in near full flexion. **FINAL WORKING DIAGNOSIS:** left postero-lateral meniscocapsular separation

TREATMENT AND OUTCOMES: Management options (expectant management, injection options to mitigate pain, and a surgery) were discussed. Patient elected surgical fixation of lateral meniscus. Arthroscopic fixation of lateral meniscus with 2 vertical mattress sutures using a FastFix device was performed. After 4 weeks of bracing to allow proper surgical healing, she was able to start using an elliptical at 6 weeks and jogging at 9 weeks. She remains void of pre-surgical pain and locking at 16 weeks post-operatively.

2470 June 2 11:10 AM - 11:30 AM

Knee Pain - Basketball

Nailah Coleman, FACSM, *Children's National Health System, Washington, DC.*

(No relationships reported)

HISTORY: a 12-year-old presents to clinic with left anterior knee pain for 2 to 3 years, after falling on his knee playing basketball. After his fall, someone fell on top of him and pressed further onto the back of his knee. Although his knee pain has improved, he notes it feels like someone is "pushing down on it." His pain is intermittent and associated with activity; he denies any particular functional disturbance and has been participating in sports and athletics during this time. He denies any sensation changes; he notes giving way and denies swelling, popping, or locking. For pain control he has been resting and working on some range of motion activities; he has required nothing else for pain control. In addition to the above, firm direct pressure in that same area can cause pain. He has had no other medical care for this concern. **PHYSICAL EXAM:** on physical exam he was a WDNW young man in NAD. His vital signs were WNL, and his BMI was normal for age and gender. Exam of his hips and knees was significant for symmetric appearance with intact skin and no deformities noted. He had a normal gait and was able to heel, toe, and duck walk without difficulty, although he did note mild pain with duck walk. He had full range of motion of his hips and knees. He had a negative apprehension test, negative Lachman's, negative McMurray, negative anterior and posterior drawer, and negative patellar grind. **DIFFERENTIAL DIAGNOSIS:** - Patellar contusion - Patellofemoral pain syndrome - Sinding Larsen Johansson syndrome - Osgood Schlatters disease - Osteochondral defect (OCD) **TESTS AND RESULTS:** - X-ray demonstrating a 12 x 16 mm OCD on the lateral side of the medial femoral condyle in the left knee - MRI pending **FINAL/WORKING DIAGNOSIS:** OCD **TREATMENT AND OUTCOMES:** - Continue with current comfort care measures - Avoid physical activities - Wear a hinged knee brace, locked in extension for ambulation and allowing flexion with sitting. - MRI to evaluate the extent of the lesion - Follow up with orthopedics after the MRI is completed.

E-24 Basic Science World Congress/Poster - Neurobiological Effects of Exercise

Friday, June 2, 2017, 7:30 AM - 12:30 PM
Room: Hall F

2481 Board #1 June 2 9:30 AM - 11:00 AM

fMRI Assessed Neural Activation in Blood Flow Restricted Handgrip Exercise

Aaron W. Johnson, Tiffany D. deVries, Brock Kirwan, J W. Myrer, *Brigham Young University, Provo, UT.* (Sponsor: Pat Vehrs, FACSM)

(No relationships reported)

PURPOSE: Blood-flow-restricted (BFR) exercise is reported to improve strength and elicit muscle hypertrophy, although little is known about its neural effects. The purpose of this study was to investigate brain neural responses to BFR exercise and control conditions during handgrip exercise.

METHODS: Twenty-five subjects completed dynamic handgrip exercises during BFR and control conditions on two different days separated by 72 hours. fMRI scans were acquired during both exercise conditions. The exercise protocol consisted of five 30-second sets of squeezing a non-metallic handgrip exerciser (a reported 13.6 kg resistance), doing as many repetitions as possible, with 20-second rest intervals between sets.

RESULTS: There was a significant main effect of exercise condition in the neural activity in the premotor dorsal (F = 5.71, p = 0.022), premotor ventral (F = 8.21, p = 0.007), and right ventral striatum (F = 7.36, p = 0.01) areas. When considering anatomical regions of interest, we found no significant differences between exercise conditions in the bilateral primary sensory cortex (p = 0.82), primary motor cortex (p = 0.33), supplementary motor area (p = 0.66), cerebellum (p = 0.70), insular cortex (p = 0.45), anterior cingulate cortex (p = 0.24), or thalamus (p = 0.66). Significant linear trends (p = 0.001) over the five exercise sets were found in the bilateral anterior

cingulate cortex, right middle frontal gyrus, and the right primary sensory cortex. The right primary sensory cortex, left primary sensory cortex, and the right anterior cingulate cortex showed a main effect of set ($p = 0.02$).

CONCLUSIONS: Less total work was completed during BFR exercise with similar brain neural activation as a higher volume control exercise. BFR exercise has direct effects on the central nervous system.

2482 Board #2 June 2 9:30 AM - 11:00 AM
Functional Brain Activation During Lower Extremity Neuromuscular Fatigue In Older Women

Ranjana K. Mehta, Joohyun Rhee. *Texas A&M University, College Station, TX.*
 Email: rmehta@tamu.edu
 (No relationships reported)

Fatigue is more than tiredness; it is a symptom that can cause disrupted behavior, disability and even mortality. Although the relationship between aging and fatigue is somewhat controversial, functional deficits such as increased incidents of falls, limitations of mobility and mortality rates are related to fatigue in the elderly. Understanding brain function changes during fatigue development is important because both central and peripheral fatigues are associated with an exhausted nervous system, particularly in the elderly. However, existing motor neuroscience investigations of fatigue are limited to upper and/or distal muscle groups due to physical constraints of the neuroimaging methods.

PURPOSE: Lower extremity muscles of the quadriceps are responsible in maintaining balance and preventing older adults from falling, however very little is known on brain function changes with fatigue of these large muscles. **METHODS:** We measured neural activity of frontal and motor brain areas from 13 older females (72.5 ± 4.7 years) during submaximal fatiguing leg exercise using functional near infrared spectroscopy (fNIRS). Physiological measures of joint force and electromyography measuring muscle activity of the vastus lateralis and rectus femoris, along with ratings of perceived exertion (RPE) were recorded simultaneously. Paired t-tests were used to test the effects of fatigue phases (early vs late) on force steadiness, muscle activity, RPE, and hemodynamic responses of each neural channel. **RESULTS:** As expected, the later phases of fatigue were associated with ~35% lower force steadiness, 20-23% increase in quadriceps muscle activity, and 137% higher perceived effort ratings (all $p < 0.05$). Increases in hemodynamic responses of right medial-lateral prefrontal cortex, left and right medial primary motor area, and left posterior medial sensory area was observed over the course of fatigue development, indicating distinct spatio-temporal pattern changes with fatigue development. **CONCLUSIONS:** These findings provide important insights on age-related changes in the neuromuscular control of large leg muscles that can inform innovative training or rehabilitative strategies in improving falls recovery or preserving mobility capabilities in older adults. Supported by NIH grant 1R15AG047553 - 01A1

2483 Board #3 June 2 9:30 AM - 11:00 AM
Fatigue Modulates The Effect Of Group III/IV Muscle Afferents On GABA_B-Mediated Inhibition And Corticospinal Excitability

Simranjit K. Sidhu¹, Joshua C. Weavil², Taylor S. Thurston², Eivind Wang³, Dorothea S. Rosenberger², Jacob E. Jessop², Russell S. Richardson², Chris J. McNeil⁴, Markus Amann².
¹The University of Adelaide, Adelaide, Australia. ²University of Utah, Salt Lake City, UT. ³Norwegian University of Science and Technology, Trondheim, Norway. ⁴University of British Columbia, Kelowna, BC, Canada.
 Email: simran.sidhu@adelaide.edu.au
 (No relationships reported)

PURPOSE: To investigate the influence of group III/IV muscle afferents on GABA_B-mediated long-interval inhibition (LII) during cycling exercise in the absence and presence of locomotor muscle fatigue. **METHODS:** Nine recreationally active males performed brief, non-fatiguing (NFC; 30 s) and fatiguing (FC; 5 min) cycling exercise ($80\% W_{peak}$) under control-conditions (CTRL) and with lumbar intrathecal fentanyl (FENT) impairing feedback from group III/IV leg muscle afferents. Single and paired transcranial magnetic stimulation (TMS, TMS-TMS) and single and paired TMS-cervicomedullary stimulation (CMS, TMS-CMS) were used during NFC and at the start and end of FC to evaluate cortical versus spinal contributions to LII (LII_{TMS} , LII_{CMS}). **RESULTS:** While fentanyl blockade did not alter motor-evoked potentials (MEPs) during NFC, cervicomedullary-evoked motor potentials (CMEPs) were $15 \pm 10\%$ higher ($P < 0.05$), resulting in a $7 \pm 5\%$ decrease in MEP/CMEP in FENT compared to CTRL ($P < 0.05$). Furthermore, fentanyl blockade during NFC increased LII_{TMS} by $26 \pm 15\%$ ($P < 0.05$) without affecting LII_{CMS} ($P = 0.3$). During FC in CTRL, MEPs remained unchanged during the 5 minutes of exercise whereas CMEPs increased by $12 \pm 6\%$ ($P < 0.05$) resulting in an $8 \pm 3\%$ decrease in MEP/CMEP ($P < 0.05$). This paralleled a $33 \pm 11\%$ increase in LII_{TMS} ($P < 0.05$), but no change in LII_{CMS} . During FC in FENT, MEPs, CMEPs, LII_{TMS} and LII_{CMS} remained unchanged ($P > 0.2$).

CONCLUSION: These findings suggest that in the absence of fatigue, group III/IV muscle afferents may facilitate the excitability of motor cortical cells by limiting the activation of GABA_B intracortical inhibitory interneurons. In contrast, in the presence of fatigue, these afferents may disfacilitate the excitability of motor cortical cells by enhancing the activation of GABA_B intracortical inhibitory interneurons.

2484 Board #4 June 2 9:30 AM - 11:00 AM
Effects of Alternating Standing and Sitting Compared to Prolonged Sitting on Cerebral Blood Flow Velocity

Sophy J. Perdomo, Bethany Barone Gibbs, Robert J. Kowalsky, John M. Taormina, Jeffrey R. Balzer. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: John M Jakicic, FACSM)
 Email: SJP80@pitt.edu

Reported Relationships: S.J. Perdomo: Contracted Research - Including Principle Investigator; This research was funded by the Humanscale company.

Preliminary evidence suggests that prolonged sitting may acutely reduce cerebral blood flow velocity (CBFv). Whether alternating bouts of standing and sitting while performing deskwork can attenuate decreases in CBFv is currently unknown. **Purpose:** To compare CBFv recorded at multiple time points during a simulated workday of alternating standing and sitting vs. prolonged sitting. **Methods:** This randomized crossover study enrolled working adults ($N=25$) with pre-to-Stage 1 hypertension, body mass index (BMI) from 25 to < 40 kg/m², and not using antihypertensive medications. Subjects participated in two 8-hr simulated workdays: 1) sitting continuously (SIT), and 2) alternating standing and sitting every 30 min (SS). Beat-to-beat peak systolic, mean systolic and diastolic CBFv were recorded bilaterally for 1 min via insonation of the middle cerebral artery using transcranial Doppler ultrasonography before (morning), between (midday) and following (afternoon) two 4-hr work periods. **Results:** Mean (SD) age was 42 (12) years, blood pressure (BP) was 132 (9)/83 (8) mmHg, and BMI was 32 (5) kg/m². Repeated measures ANOVA revealed a significant effect of time for peak systolic ($F = 4.08$, $P = 0.023$), mean systolic ($F = 6.76$, $P = 0.003$), and diastolic ($F = 5.67$, $P = 0.006$) CBFv. Post-hoc testing with Bonferroni adjustment revealed significant decreases from morning to midday in mean systolic ($P = 0.048$) and diastolic ($P = 0.024$) CBFv in SIT but not SS ($P \geq 0.14$). The only change from midday to afternoon was an increase in mean systolic CBFv ($P = 0.048$) in SIT. No significant effects were observed by condition or for the condition x time interaction ($P \geq 0.20$) (Figure). **Conclusions:** In individuals with elevated BP and BMI, CBFv differed across an 8-hr workday but not across sitting and alternating posture conditions. However, significant midday declines were observed only during prolonged sitting. Future studies should study trajectories and factors that influence CBFv during the workday.

Change in Cerebral Blood Flow Velocity

2485 Board #5 June 2 9:30 AM - 11:00 AM
Changes in Cerebral Oxygenation Following Anaerobic Exercise

Jeff Leiter¹, Travis J. Hrubeniuk². ¹Pan Am Clinic Foundation, Winnipeg, MB, Canada. ²University of Manitoba, Winnipeg, MB, Canada.
 (No relationships reported)

Currently there is a plethora of research identifying the fluctuations in cerebral oxygenation during aerobic exercise. Such alterations have been associated with respiratory compensation threshold (RCT), fatigue, and exercise cessation. However, there is a paucity of research investigating the effects of anaerobic exercise in this regard.

PURPOSE: To identify how cerebral oxygenation (Cox) changes throughout the recovery from a bout of maximal anaerobic exercise in comparison to baseline levels. **METHODS:** Twenty-eight physically active, healthy participants aged 18-35 were recruited, each partaking in two sessions. At the first session anthropometric measures were documented. During the second session, participants connected to a cerebral oximeter and 5 minutes of baseline measurements were recorded, followed by a 30-second Wingate test while connected to a metabolic cart. Responses to the

anaerobic test were monitored using both devices for 15-minutes post-test, with values noted at 0-, 60-, 90-, 120-, 300-, 600- and 900-second time points. Means and standard deviations were generated for all variables. Repeated measures ANOVA was used to determine differences between time points for Cox, end-tidal carbon dioxide (P_{ETCO_2}), heart rate (HR) and respiratory rate (RR). Significance was set at ($p < 0.05$).

RESULTS: Baseline Cox was $66.96 \pm 5.79\%$. Throughout recovery, Cox did not differ from baseline until 600s post-test, where it significantly increased to $68.73 \pm 7.22\%$. At exercise cessation, $PETCO_2$ was 25.84 ± 4.58 mmHg before a sudden influx at 60s, achieving 33.37 ± 4.18 mmHg; which was followed by a gradual decline through the 900s time point. As expected, both HR and RR peaked at exercise cessation and gradually declined throughout recovery.

CONCLUSION: Cox following anaerobic exercise did not deviate from baseline until a sudden rise approximately 600s post-test. This differs from previously outlined responses to aerobic exercise, which have found drastic reductions and consequential inlapses following maximal exercise. $PETCO_2$ and RR readings indicate that RCT was not achieved despite a rise in CO_2 levels, which may have prevented the drastic changes in oxygenation that are observed with aerobic exercise.

Differences in Cerebral Oxygenation Following Aerobic and Resistance Exercise

Travis J. Hrubeniuk¹, Jeff Leiter². ¹University of Manitoba, Winnipeg, MB, Canada. ²Pan Am Clinic Foundation, Winnipeg, MB, Canada.

(No relationships reported)

Cerebral blood flow and oxygenation are important variables to consider for concussion diagnosis and treatment. As a result, monitoring these variables throughout progressive aerobic exercise has emerged as a potential concussion management tool, as well as an indicator for return to sport, school or work. However, such a mechanism may not be specific to the sport or workplace to which the individual is returning. Understanding how a healthy brain responds to various types of exercise has the potential to create more individualized methods of concussion management.

PURPOSE: To identify the differences in cerebral oxygenation recovery following bouts of maximal resistance and aerobic exercise.

METHODS: Twenty-eight physically active, healthy participants aged 18-35 were recruited, each partaking in two sessions. At the first session anthropometric measures and leg press 1-RM were determined. During the second session participants completed a maximal leg press resistance training protocol, followed 30 minutes later by a maximal aerobic protocol. Participants were connected to a cerebral oximeter and metabolic cart for monitoring. As such, cerebral oxygenation and ventilatory gas exchange variables were documented throughout the duration of exercise and for 15-minutes of passive recovery post-test.

RESULTS: Maximal aerobic exercise resulted in a progressive increase in cerebral oxygenation following cessation of exercise until peaking at $70.61 \pm 7.41\%$, 300-seconds post-test. This represents a significant rise from a baseline value of $66.00 \pm 5.48\%$. The rise in oxygenation following aerobic exercise differed from resistance exercise from 90-seconds onwards, as resistance exercise did not result in a significant change from its $66.89 \pm 5.62\%$ baseline value.

CONCLUSION: While maximal aerobic exercise resulted in significant increases in cerebral oxygenation from baseline levels throughout recovery, maximal resistance exercise did not elicit the same response. This indicates that aerobic exercise results in a metabolic strain on the brain which differs from the strain experienced as a result of resistance exercise. As such, expecting equivalent outcomes and utility as concussion management tools from both exercise methods may be misguided and requires additional research.

Cognitive Function After Exhaustive Exercise: Effects Of Cerebral Oxygenation

Soichi Ando¹, Mizuki Sudo², Takaaki Komiyama³, Ryo Aoyagi³, Yasuki Higaki³. ¹The University of Electro-Communications, Tokyo, Japan. ²Physical Fitness Research Institute Meiji Yasuda Life Foundation of Health and Welfare, Tokyo, Japan. ³Fukuoka University, Fukuoka, Japan.

(No relationships reported)

It has been suggested that low to moderate exercise has beneficial effects on cognitive function. In contrast, less is known about the effects of exhaustive exercise on cognitive function, and the findings are still controversial. Furthermore, specific mechanisms by which exhaustive exercise affects cognitive function remain largely unclear. **PURPOSE:** The purpose of this study was to examine cognitive function after exhaustive exercise, and to identify physiological factors that determine cognitive function after exhaustion. **METHODS:** Thirty-two participants were assigned into Exercise (N = 18) and Control (N = 14) groups. The participants completed cognitive tasks that require working memory and executive function before and after an incremental exercise until exhaustion or resting period. Cerebral oxygenation was

continuously monitored during the cognitive task over the frontal cortex. Venous blood samples were collected before and after the exercise or resting period, and blood catecholamine, insulin-like growth hormone factor 1 (IGF-1), serum brain-derived neurotrophic factor (BDNF), blood lactate concentrations were analyzed.

RESULTS: In the Exercise group, reaction time (RT) of the cognitive task tended to decrease after exercise (Pre: 875 ± 312 ms vs. Post: 771 ± 168 ms, $p=0.07$). Number of error trials in the cognitive tasks increased after exercise (Pre: 1.2 ± 0.8 vs. Post: 2.6 ± 2.3 ms, $p<0.05$). Delta RT was negatively correlated with delta cerebral oxygenation ($r = -0.61$, $p<0.01$). Counterintuitively, delta number of error trials was negatively correlated with delta noradrenaline ($r = -0.56$, $p<0.05$) and dopamine ($r = -0.65$, $p<0.001$) concentrations. Alterations in IGF-1, BDNF, blood lactate concentrations were not associated with altered cognitive performance. In the Control group, cognitive performance and all physiological parameters were not altered.

CONCLUSIONS: The present results suggest that recovery of cerebral oxygenation affects response speed of the cognitive task after exhaustion. Impairments in accuracy may be ascribed to increased arousal level beyond the optimal level. However, venous blood samples appear not to reflect the arousal level directly.

Cerebral Pulsatility and Habitual Exercise

Adam T. Corkery¹, Kathleen B. Miller¹, Ronée E. Harvey², Anna J. Howery¹, Jill N. Barnes¹. ¹University of Wisconsin-Madison, Madison, WI. ²Mayo Clinic College of Medicine, Rochester, MN. (Sponsor: Michael J. Joyner, FACSM)

(No relationships reported)

Increased pulsatility of the cerebral arteries has been correlated with an increased risk of developing cerebral pathology. Previous research has suggested that a 16-week endurance training intervention does not alter middle cerebral artery (MCA) pulsatility in young athletes; however, the effects of long-term habitual exercise on cerebral pulsatility have not been evaluated. **PURPOSE:** To compare MCA pulsatility in sedentary adults and habitual exercisers. **METHODS:** We evaluated 49 subjects, including 28 habitual exercisers (EX; age = 38 ± 16 y, women = 11, $VO_{2max} = 44 \pm 7$ ml/kg/min, BMI = 24.2 ± 3.0 kg/m²) and 21 sedentary controls (SED; age = 46 ± 20 y, women = 12, $VO_{2max} = 27 \pm 6$ ml/kg/min, BMI = 24.9 ± 2.0 kg/m²). Mean arterial pressure (MAP) and middle cerebral artery velocity (MCAv) were continuously recorded during rest. Pulsatility index (PI) was calculated by subtracting diastolic MCAv from systolic MCAv and dividing the result by the mean MCAv. **RESULTS:** Habitual exercisers had a lower MCAv compared to sedentary controls (EX = 57.2 ± 3.5 cm/s vs. SED = 68.3 ± 4.0 cm/s; $p<0.05$), and MAP was similar between the two groups (EX = 88 ± 2 mmHg vs. SED = 89 ± 2 mmHg; $p=0.69$). Habitual exercisers tended to have a lower PI (EX = 0.75 ± 0.03 vs. SED = 0.83 ± 0.04 ; $p=0.09$), and VO_{2max} was inversely associated with PI ($r = -0.341$, $p<0.05$) when evaluating all subjects. **CONCLUSIONS:** Habitual exercisers tended to have a lower PI, although the results did not reach statistical significance. The inverse association between VO_{2max} and cerebral PI suggests that individuals with a higher fitness may have a lower risk of developing cerebrovascular-related pathology. Supported by NIH grant HL118154

Cerebral Autoregulation and Habitual Exercise in Young Healthy Adults

Kathleen B. Miller¹, Ronée E. Harvey², Anna J. Howery¹, Athena E. Goffinos¹, Alexa E. Carl¹, Jill N. Barnes¹. ¹University of Wisconsin-Madison, Madison, WI. ²Mayo Clinic College of Medicine, Rochester, MN. (Sponsor: Michael J. Joyner, FACSM)

(No relationships reported)

Cerebral autoregulation is the ability of the brain to maintain constant cerebral perfusion despite oscillations in systemic blood pressure. Exercise training improves cerebral vasomotor function; however, the impact of habitual exercise on cerebral autoregulatory function is unknown. **PURPOSE:** To evaluate static cerebral autoregulation in habitually exercising and sedentary young adults. We hypothesized that young adults who habitually exercise would show enhanced measures of cerebral autoregulation compared to sedentary controls. **METHODS:** We evaluated 20 habitual exercisers (EX; age = 28 ± 1 y; women = 6; $VO_{2max} = 47 \pm 1$ ml/kg/min) and 11 sedentary controls (CON; age = 29 ± 2 y; women = 7; $VO_{2max} = 31 \pm 2$ ml/kg/min). Middle cerebral artery velocity (MCAv), mean arterial pressure (MAP), heart rate (HR), and end-tidal carbon dioxide were recorded during three minutes of rest. Cerebral autoregulatory variables were assessed offline. **RESULTS:** HR was lower in habitual exercisers compared to sedentary controls (EX: 51 ± 3 bpm vs. CON: 58 ± 3 bpm; $p<0.05$). Habitual exercisers also had a lower MCAv (EX: 55 ± 4 cm/s vs. CON: 74 ± 4 cm/s; $p<0.05$) and no significant differences were found in MAP (EX: 94 ± 3 mmHg vs. CON: 98 ± 4 mmHg; $p=0.42$). Habitual exercisers displayed a significantly higher low-frequency coherence value (EX: 0.62 ± 0.04 vs. CON: 0.45 ± 0.05 ; $p<0.05$); however, no difference was found in low-frequency gain (EX: 0.63 ± 0.08 cm/s/mmHg vs. CON: 0.59 ± 0.07 cm/s/mmHg; $p=0.67$), or low-frequency phase (EX:

51 ± 6 degr. vs. CON: 46 ± 8 degr.; $p=0.64$). **CONCLUSIONS:** Our results indicate that low frequency cerebral autoregulatory function is not different between habitually exercising and sedentary young adults, as the higher coherence was not accompanied with a difference in phase or gain. Future studies may further examine if mode of exercise might influence cerebral autoregulation. Supported by NIH grant HL118154.

Association Between Habitual Physical Activity and Mechanical Pain Sensitivity in Healthy Adults
 Katrina Maluf, Jaime Zinn, Luisa Davila-Pablo, Paige Kettenburg, San Diego State University, San Diego, CA.
 Email: kmaluf@mail.sdsu.edu
 (No relationships reported)

Routine engagement in physical activity is recommended for the prevention and management of chronic musculoskeletal pain. Previous studies have compared pain sensitivity between active and sedentary groups categorized based on self-reported levels of physical activity. However, the extent to which pain sensitivity varies with individual differences in objectively assessed habitual physical activity is not known. **PURPOSE:** To quantify associations between mechanical pain sensitivity and physical activity outcomes measured by accelerometry. **METHODS:** Healthy young (21.5 (2.2) years) adults wore an accelerometer (ActiGraph Model wGT3X-BT) on the waist while performing their usual activities for 7 consecutive days. Published calibration equations were used to classify each 1-min epoch of activity count data as sedentary behavior (SB, <100 cpm), light intensity physical activity (LPA), and moderate-to-vigorous intensity physical activity (MVPA). The amount of time spent in each category was expressed as a percentage of total daily wear-time, and was averaged across days with at least 10 hours of valid activity data. Mechanical pain sensitivity was quantified by applying a 1-cm² algometer probe to the ventral forearm at 50 kPa/sec. Pressure pain threshold (PPT_{hr}) was recorded as the pressure at which the stimulus first became painful, and pressure pain tolerance (PPT_{ol}) was recorded as the pressure above which the painful sensation could no longer be tolerated. Associations between physical activity and pain sensitivity outcomes were assessed with Pearson's correlation. **RESULTS:** On average, 74(SD 6)% of total daily wear time was spent engaged in SB. LPA and MVPA comprised 23(5)% and 4(2)% of daily wear time, respectively. PPT_{hr} ranged from 34 to 287 kPa, and PPT_{ol} ranged from 536 to 1576 kPa. PPT_{hr} was not associated with physical activity outcomes. PPT_{ol} was negatively associated with SB ($r = -0.60$), and positively associated with LPA ($r = 0.56$) but not MVPA. **CONCLUSION:** Healthy young adults who engage in less sedentary behavior and more light intensity physical activity have greater tolerance of mechanical pain. Future work should determine whether this relationship reflects activity-related adaptations in pain processing, or the effects of pain tolerance on willingness to engage in physical activities.

Effect of Exercise Training on Cerebral Microcirculation in Men with and without Type 1 Diabetes
 Antti-Pekka E. Rissanen¹, Heikki O. Tikkanen², Anne S. Koponen¹, Jyrki M. Aho³, Juha E. Peltonen¹. ¹University of Helsinki, Helsinki, Finland. ²University of Eastern Finland, Kuopio, Finland. ³Foundation for Sports and Exercise Medicine, Helsinki, Finland.
 Email: antti-pekka.rissanen@helsinki.fi
 (No relationships reported)

PURPOSE: Effects of regular exercise on cerebral microcirculation in diabetes are unknown. We examined if exercise training leads to similar adaptations in cerebral microcirculation in men with and without type 1 diabetes (T1D). **METHODS:** Eight men with T1D (33±6 yrs) and eight healthy men (HC; 38±7 yrs) matched for age, anthropometry, and peak O₂ uptake (VO_{2peak}) ($p>0.05$), completed a 1-year individualized exercise training intervention. Individually collected data on training were similar in T1D vs. HC (mean±SD per month; $p>0.05$): 13±4 vs. 15±6 endurance training sessions, 3±1 vs. 3±3 resistance training sessions, 57±5 vs. 55±8 % of heart rate reserve, 16:58±6:07 vs. 16:52±4:39 h:min, 7759±4540 vs. 7762±3812 kcal, respectively. Before and after the intervention, the subjects performed step incremental cycling exercise to volitional fatigue. During exercise, alveolar gas exchange (mass spectrometry) and normalized relative concentration changes in deoxygenated hemoglobin (%Δ[HHb]) in the prefrontal cerebral cortex (near-infrared spectroscopy) were monitored; %Δ[HHb] reflects imbalance between local O₂ delivery and utilization. **RESULTS:** Training increased VO_{2peak} and peak work rate similarly in T1D (45±5 to 49±6 mL/min/kg fat-free mass [FFM], $p<0.01$; 237±34 to 254±27 W, $p<0.05$) and HC (48±3 to 52±5 mL/min/kg FFM, $p<0.05$; 255±17 to 282±36 W, $p<0.05$). Training also decreased minute ventilation at 160W (in T1D and HC) and 200W (in HC) ($p<0.05$) but had no effect on end-tidal CO₂ partial pressure, which estimates arterial CO₂ pressure affecting cerebral blood flow. Cerebral %Δ[HHb] did not change at any work rate in T1D but decreased at 200W in HC ($p<0.05$). No differences were observed between T1D and HC in the reported parameters before the intervention.

ACSM May 30 – June 3, 2017

CONCLUSION: Exercise training did not improve exercise-induced imbalance between local O₂ delivery and utilization in prefrontal microcirculation in T1D but did so at high exercise intensity (200 W) in HC. This between-group difference was not due to different respiratory adaptations and must thus be explained by other diabetes-related mechanisms (e.g., impaired cerebrovascular autoregulation, CO₂ reactivity, or neocapillarization) influencing cerebral blood flow.  (No relationships reported)

Aerobic exercise training may improve cerebral blood flow (CBF) regulation and reduce the risk of dementia. Cerebral autoregulation (CA) is the unique function of the brain which maintains CBF during changes in blood pressure. **PURPOSE:** To determine 1) the effects of aerobic exercise training and improvement of cardiorespiratory fitness on dynamic CA (dCA) and 2) the reproducibility of dCA metrics in patients with mild cognitive impairment (MCI). **METHODS:** Seventy MCI patients were randomized into 12 months of aerobic exercise training or stretching. Before and after intervention, beat-by-beat CBF velocity and blood pressure were simultaneously measured by transcranial Doppler (TCD) and finger plethysmography during a seated resting condition and a repeated sit-stand maneuver. Transfer function analysis was used to estimate dCA gain, phase, and coherence. Cardiorespiratory fitness was assessed by maximal oxygen uptake (VO_{2max}) that is measured on treadmill using a modified Astrand-Saltin protocol. **RESULTS:** Clean TCD signals were available from 54 patients at baseline, of which 29 patients completed exercise training (n=14) or stretching (n=15) program. After exercise training, dCA gain, phase, and coherence measured during rest and sit-stand maneuvers were not different from stretching group. Likewise, those dCA metrics measured from the patients who improved VO_{2max} were not different from the other patients who did not make improvement. The comparison of dCA metrics measured before and after 12 months showed significant intra-class correlations of dCA gain at very low frequency (rest: $R^2=0.33$, $P=0.001$; sit-stand: $R^2=0.10$, $P=0.029$). **CONCLUSIONS:** Although dCA metrics were reproducible over 1 year (particularly the gain at very low frequency during rest), neither aerobic exercise training nor the improvement of cardiorespiratory fitness altered dCA metrics in MCI patients. Supported by the NIH (R01AG033106 and K99HL133449) and the American Heart Association (14POST20140013)

 (No relationships reported)

There is a substantial body of evidence to show that acute exercise improves cognitive function. The improvements seem to be observed irrespective of exercise mode (i.e. aerobic and resistance). However, it is unclear how aerobic and resistance exercise improves cognitive function. **PURPOSE:** To clarify the effects of acute aerobic and resistance exercise on cognitive function. **METHODS:** Sixteen subjects completed cognitive tasks before and after acute aerobic or resistance exercise in a randomized crossover design. In aerobic condition, they cycled an ergometer at the intensity corresponding to 40% peak oxygen uptake. In resistance condition, they performed resistance exercise using elastic bands. Exercise duration of each condition was 30 min. Cognitive task was a Go/NoGo task, which required executive function. Plasma catecholamine, insulin-like growth hormone factor 1 (IGF-1), serum brain-derived neurotrophic factor serum (BDNF), and blood lactate concentrations were measured before and after exercise. **RESULTS:** Compared with rest, reaction time on the Go/NoGo task tended to decreased after exercise (aerobic: 651 ± 143 vs. 586 ± 175 ms, resistance: 644 ± 212 vs. 604 ± 160 ms, $p = 0.06$). Neither exercise nor condition altered the accuracy on the cognitive task. Both aerobic and resistance exercise increased adrenaline (aerobic: 38.8 ± 14.4 vs. 71.5 ± 21.5 pg/mL, resistance: 41.8 ± 21.4 vs. 66.9 ± 30.3 pg/mL, $p < 0.01$), noradrenaline (aerobic: 341 ± 97 vs. 476 ± 142 ms, resistance: 369 ± 132 vs. 627 ± 293 pg/mL, $p < 0.01$), dopamine (aerobic: 7.8 ± 2.9 vs. 9.9 ± 3.4 pg/mL, resistance: 6.8 ± 2.1 vs. 12.7 ± 8.1 pg/mL, $p < 0.05$). In contrast,

Denver, Colorado

increases in IGF-1 (aerobic: 216 ± 62 vs. 214 ± 53 ng/mL, $p = 0.66$, resistance: 210 ± 47 vs. 223 ± 41 ng/mL, $p < 0.05$) and blood lactate concentrations (aerobic: 1.1 ± 0.3 vs. 1.4 ± 0.5 mmol/L, $p = 0.17$, resistance: 1.2 ± 0.3 vs. 2.8 ± 0.8 mmol/L, $p < 0.01$) were observed only after resistance exercise. BDNF concentrations did not change after exercise (aerobic: 25800 ± 5474 vs. 26192 ± 7048 pg/mL, resistance: 27417 ± 4668 vs. 25975 ± 7647 pg/mL, $p = 0.59$). **CONCLUSIONS:** Acute aerobic and resistance exercise improves cognitive function, probably due to increased central neurochemical activity. After resistance exercise, increases in IGF-1 and blood lactate concentrations might contribute to the improvements.

 (No relationships reported)

Purpose: Physical activity during adulthood is discussed as a major preventive factor against loss of cognitive function in old age. The present study aims at analyzing the effects of lifetime physical activity (PA) on cognitive function and brain metabolism. **Methods:** Data were obtained from 50 cognitively unimpaired elderly subjects (72±5yrs, 27♀). Lifetime leisure PA was assessed by a validated questionnaire investigating five epochs across the lifespan (age in years: 14-21, 22-34, 35-50, 51-65, 66-80). Data were analyzed as average energy consumption (MET-h/wk) per epoch. Participants individual lifespan activity profile was defined as the behavior they engaged in for at least 60% of their lifetime (≥3 epochs). Referring to current activity guidelines (7.5 MET-h/wk ≈ 75' vigorous or 150' moderate PA-min/wk) and based on the individual activity profiles, subjects were stratified in 3 groups of lifetime activity behavior (MET-h/wk: <7.5 / 7.5-15 / >15). Cognitive assessment included testing of executive function (stroop interference test), verbal and non-verbal declarative memory and crystallized intelligence (MWT-B). Brain metabolism was recorded from a transversal slice just above the corpus callosum via magnetic resonance spectroscopic imaging (MRSI), and analyzed as the ratio of N-Acetylaspartate to choline (NAA/Cho). **Results:** Compared to individuals reporting less than the recommended minimum of 7.5 MET-h/wk (460ms), ANCOVA revealed significantly ($p < .05$) higher NAA/Cho values and shorter mean response times for stroop word test among those performing the recommended minimum (-50ms) and those performing ≥2 times the minimum (-60ms). Stroop interference scores were solely higher in participants performing ≥2 times the minimum recommendation. Correlation analysis showed significant associations of overall and vigorous mean lifetime PA with stroop performance ($r = .408$; $r = .410$; $p < .05$) and NAA/Cho ($r = .303$; $r = .310$; $p < .05$). **Conclusions:** The findings suggest that lifelong adherence to the minimum recommended amount of health enhancing PA results in positive effects on executive function and neuronal metabolism in old age. Exceeding minimum guideline recommendations in terms of intensity and duration might lead to additional benefits.

 (No relationships reported)

Purpose: In aging, cerebral and systemic vascular functions (VF) decline likewise to cognitive decline. Also, reduced availability of nitric oxide (NO) in both cerebral and peripheral blood vessels results in further alterations of VF. So, changes in VF and NO availability may contribute to the development of Alzheimer's disease (AD). However, current literature lacks of evidence about the progression of AD and VF. To verify if VF is significantly reduced in AD patients compared with age-matched healthy counterparts and if VF declines further with the severity of AD. Potential correlation between VF and NO availability was also assessed. **Methods:** In 55 AD patients (severity of dementia distribution: 12 MCI, 15 AD₁, 19 AD₂, 9 AD₃), 13 healthy elderly (OLD), and 10 young (YG) subjects systemic vascular function was assessed by means of passive limb movement (PLM). NO availability was determined via plasma NO metabolites (NO₂+NO₃). **Results:** Δpeak PLM was 739 ± 150 ml/min, 284 ± 46 ml/min, 227 ± 39 , 182 ± 37 ml/min, 166 ± 22 ml/min, 155 ± 26 ml/min in YG, OLD, MCI, AD₁, AD₂, and AD₃ respectively. NO₂+NO₃ was 53 ± 9 μM, 47 ± 3 μM, 42 ± 2 μM, 40 ± 3 μM, 38 ± 3 μM, 35 ± 1 μM in YG, OLD, MCI, AD₁, AD₂, and AD₃ respectively. Correlation between Δpeak PLM and NO₂+NO₃ was $r = -0.9765$. **Conclusion:** Our results confirm that VF is reduced in aging. AD patients exhibited a further reduction of VF compared with healthy age-matched counterparts. Moreover, VF and NO availability were

progressively declined with the progression of dementia, implicating that AD and its progression might be the result of an intertwined decline of both neural and vascular functions, likely related to the NO availability.

 (No relationships reported)

Deficits to cognition and skeletal muscle strength are common in the geriatric population. These deficits worsen over time, and result in a significant decrease to one's quality of life. Thus, developing therapies that can combat these deficiencies is paramount. Beta-hydroxy-beta-methylbutyrate (HMB) is a nutritional supplement shown to enhance muscle strength with recent evidence suggesting a beneficial effect of long-term HMB supplementation on cognition. However, the specific mechanisms behind these improvements are unclear. Perivascular stem cells are located in a variety of tissue types and have substantial regenerative potential, yet the extent to which long-term HMB supplementation affects their function is unknown. **PURPOSE:** To assess the impact long-term HMB supplementation has on cognitive and skeletal muscle function in aged mice as well as the perivascular stem cell response to HMB. **METHODS:** 4 month old and 17 month old sedentary C57BL/6 mice were fed chow containing either Ca-HMB or Ca-Lactate (3.75 g/kg chow) for 24 weeks. Muscle function was measured by four-limb grip strength and body weights were recorded weekly. At 22 weeks, mice underwent rotarod testing followed by active avoidance testing. At 24 weeks, gastrocnemius muscles and brains were dissected. Half of the muscles and half of the brains were used for perivascular stem cell (muscle: CD146⁺CD31⁻CD45⁻; brain: PDGFRβ⁺CD31⁻CD45⁻) isolation via FACS. The other half was collected for histological and protein synthesis analysis. **RESULTS:** After 5 days of active avoidance testing, aged mice supplemented with HMB successfully avoided a significantly greater number of foot shocks compared to aged mice on the control diet (HMB effect, $p < 0.05$). The average time spent running on the rotarod was significantly reduced with age but unaffected by supplementation (age effect, $p < 0.05$). Neither grip strength nor muscle weight were affected. **CONCLUSIONS:** Long-term HMB supplementation beginning in middle age results in preserved cognitive function in aged mice comparable to that of young mice. These findings indicate the potential for prolonged HMB supplementation to prevent age-related declines to cognition. **Supported by Abbott Nutrition through the Center for Nutrition, Learning, and Memory at the University of Illinois at Urbana Champaign.**

Learning To Suffer: High- But Not Moderate-intensity Training Increases Pain Tolerance: Results From A Randomised Study
 Martyn G. Morris¹, Johnny Collett², Ken Howells², Thomas O'Leary². ¹Coventry University, Coventry, United Kingdom. ²Oxford Brookes University, Oxford, United Kingdom.
 Email: martyn.morris@coventry.ac.uk
 (No relationships reported)

Purpose: To compare the effect of volume-matched high-intensity interval training (HIIT) and moderate-intensity continuous training (CONT) on ischaemic muscle pain tolerance and high-intensity exercise tolerance. **Methods:** Twenty healthy adults were randomly assigned to either 6 weeks of HIIT (6-8 x 5 min at halfway between lactate threshold and maximal oxygen uptake [50%Δ]) or volume-matched CONT (~60-80 min at 90% lactate threshold) on a cycle ergometer. Immediately pre- and post-training, participants completed a tourniquet test to examine ischaemic muscle pain tolerance and two time to exhaustion (TTE) trials at 50%Δ to examine exercise tolerance; the post-training TTE trials were completed at the pre-training 50%Δ (same absolute intensity) and the post-training 50%Δ (same relative intensity). **Results:** HIIT and CONT resulted in similar improvements in all markers of aerobic fitness ($P > 0.05$). Compared with pre-training, HIIT increased TTE at the same absolute and relative intensity as pre-training (148% and 43%, respectively) to a greater extent than CONT (38% and -4%, respectively) ($P < 0.05$). HIIT increased pain tolerance (41%, $P < 0.001$), which demonstrated moderate non-significant associations with the increase in TTE at the same relative intensity as pre-training ($r = 0.50$, $P = 0.07$), however pain tolerance was unaffected by CONT (-3%, $P > 0.05$). **Conclusion:** The repeated exposure to a high-intensity noxious exercise training stimuli increases ischemic muscle pain tolerance, which is independent of the improvements in aerobic fitness induced by endurance training. This increase in ischemic muscle pain tolerance may be an important contributor to the increase in high-intensity exercise tolerance following HIIT. **Key words:** Central nervous system; endurance; exercise tolerance; high-intensity interval training; muscle fatigue; muscle pain.

Maximal Aerobic Exercise Alters Plasma BDNF And BDNF Expression In PBMCs In Obese And Non-obese
 Gabriel Pena, Arun Maharaj, Chung-Jung Huang, FACSM, Michael C. Zourdos, Aaron L. Slusher, Michael Whitehurst, FACSM. *Florida Atlantic University, Boca Raton, FL.* (Sponsor: Michael Whitehurst, FACSM)
 (No relationships reported)

Purpose: The purpose of the present study was to determine the effects of an acute bout of maximal aerobic exercise (VO_{2max}) on plasma brain-derived neurotrophic factor (BDNF) and BDNF expression in peripheral blood mononuclear cells (PBMCs) in obese and non-obese individuals. **Methods:** Anthropometric data, plasma BDNF and the BDNF expression in PBMCs as well as VO_{2max} were measured in 22 participants (9 obese, 12 non-obese). Blood samples were obtained at four time points; pre-, post-, 1-hour (R1H), and 2 hours (R2H) post-exercise. Plasma and PBMCs were isolated and analyzed for BDNF via ELISA and Western Blot techniques, respectively. A 2x4 repeated measures ANOVA was used with a Bonferroni test for post hoc comparisons. Pearson correlations were used to examine relationships between anthropometrics and VO_{2max} with BDNF measures. Significance was set at $p \leq 0.05$. **Results:** Significant group differences at pre-exercise were observed for BMI (34.5 ± 3.6 vs 21.9 ± 1.5 kg/m², $p < 0.01$), waist to hip ratio (115.5 ± 9.0 vs 94.7 ± 3.9 cm, $p < 0.01$) and V_{O2max} (31.5 ± 5.6 vs 45.7 ± 8.2 ml/kg/min⁻¹, $p < 0.01$). Post hoc comparisons revealed that plasma BDNF pre-exercise (1522.01 ± 689.18 pg/ml) was significantly ($P < 0.01$) higher than R1H (1119.52 ± 1326.40 pg/ml) and R2H (871.06 ± 815.97 pg/ml), but not post-exercise (2483.37 ± 1104.44 pg/ml) in obese individuals. Further, a significant ($p = 0.046$) group by time interaction was found from pre-exercise (0.8053 ± 0.2784 vs 0.9726 ± 0.2627 a.u.) to R1H ($1.003 \pm .4230$ vs 0.9255 ± 0.2790 a.u.) for BDNF expression in PBMCs in obese compared to non-obese individuals. A very strong correlation was observed between BMI and waist circumference ($r = 0.9$, $p < 0.01$), while moderate correlations existed between waist to hip ratio ($r = 0.51$, $p < 0.002$) and pre-exercise to R1H ($r = 0.58$, $p < 0.01$). **Conclusion:** Our results indicate a significant increase in PBMC BDNF expression from pre to R1H in obese individuals. This is consistent with other investigations suggesting a pro-inflammatory response mediated by maximal exercise. Correlations support the explanation that BDNF, both in circulation and within PBMCs is mediated by body mass, particularly when taking physical work capacity into account.

The Effect of Two Types of Suspension and Un Suspension Resistance Training on Salivary Bdnf of Preadolescence Children
 Rana Fayazmilani, aynaz pourmohamadi, Ahad abbasi. *Shahid Beheshti University, Tehran, Iran, Islamic Republic of.*
 Email: r_milani@sbu.ac.ir
 (No relationships reported)

Abstract

Force development, as a result of resistance training in children is mostly attributed to neural adaptations. According to high potential of neural plasticity in childhood, it is important to find the proper training methods to culminate this capability. On the other hand, BDNF is a member of the neurotrophins family which is engaged in neuromuscular adaptations due to increased muscular activity.

Purpose: the main purpose of this study is to investigate the effects of two types of suspension and unsuspension resistance training on salivary BDNF of prepubescent children.

Method: 24 immature boys (mean age 12.3 ± 0.55 , Tanner stage of 1 and 2) were divided into three groups of TRX suspension training (TRX), body weight training (BWT), and control (C). TRX and BWT groups completed training programs, two times a week for eight weeks. Saliva samples were collected before training and also 72 hours after last training session to measure salivary BDNF using ELISA method. One-way ANOVA test with significance level of 0.05 was used for comparison between groups.

Result: Although the effects of resistance training on muscle strength in the lower body was clearly observed in the experimental group, BDNF concentrations were not significantly different between the experimental and control groups ($F = 922$, $P = .411$). **Conclusion:** It is possible that the training protocol used in this study might not be long or intensive enough to make a significant change in BDNF concentration.

 (No relationships reported)

Acute exercise (AEX) is a promising intervention for improving learning and memory. The memory enhancing effects of AEX may be mediated by increased expression of neurotrophins, elevated catecholamine signaling, and modifications to postsynaptic glutamate receptors. Given the known memory enhancing effects of AEX in humans, it is important to explore how AEX and related noradrenergic signaling impact behavior in mice, which are commonly used to study the influence of exercise on brain plasticity and behavior. **PURPOSE:** To determine the effects of one acute bout of exercise on hippocampal *Bdnf* expression, AMPA receptor phosphorylation, and behavior in mice. **METHODS:** C57BL/6J mice were randomly assigned to 3 groups: control (CON; n=12); moderate-intensity AEX (MOD; n=12); and high-intensity AEX (HI; n=12). CON mice were placed on the stationary treadmill (TM) for 30 min and MOD and HI mice ran for 30 min at 12 m/min and 15-17 m/min, respectively. Mice were sacrificed immediately after AEX. mRNA from the hippocampus, including total *Bdnf* (exon IX), *Bdnf* exon IV (*Bdnf IV*), and glutamate receptor subunits were quantified with qPCR. Total and phosphorylated GluR1 (Ser845 and Ser831) protein were quantified with immunoblotting. Utilizing the same CON (n=15) and HI (n=15) TM protocol, object location memory following AEX was examined. Anxiety-like behavior was assessed in the open field task (OFT) in a subset of mice that were separated into 4 groups: CON - Saline (n=9); CON - DSP-4 (n=10); AEX - Saline (n=8); and AEX - DSP-4 (n=9). DSP-4 was used to lesion the central noradrenergic system. **RESULTS:** We observed higher *Bdnf IV* mRNA in hippocampus of HI compared to CON mice ($p = 0.03$). There was no effect of AEX on total *Bdnf* or any other mRNA or protein targets. There were no effects of AEX on memory performance in the object location task, though HI mice explored the testing arena significantly less (distance) during the initial phase of the task compared to CON ($p = 0.0003$). In the OFT, mice exposed to AEX traveled significantly less total distance ($p < 0.0001$) and spent more time grooming ($p < 0.0001$) than CON mice. There was no effect of DSP-4 on behavior. **CONCLUSIONS:** AEX increases *Bdnf IV* mRNA expression in an intensity-dependent manner; however, high-intensity AEX also induces behaviors suggestive of an anxious phenotype in C57BL/6J mice.

Exercise Attenuates Chronic Unpredictable Mild Stress Induced Brain Microvascular Rarefaction In Obese Zucker Rat: Role Of Stat3 Signaling
 Shinichi Asano¹, Mariah L. Dowson², Whitney J. Sheets², Ashlee N. Seldomridge², Kayla W. Branyan², Evan R. DeVallance², Jefferson C. Frisbee², Paul D. Chantler². ¹*Fairmont State University, Fairmont, WV.* ²*West Virginia University, Morgantown, WV.*
 (No relationships reported)

Metabolic syndrome (MetS) is associated with increased risk of mental illness. It is estimated over 7.6 % individuals in the US are affected by depression, however, pathophysiological mechanisms by which MetS and chronic stress interact to increase depression risk are largely unknown. Previous studies by our laboratories demonstrated exercise can improve chronic unpredictable mild stress (UCMS) associated cerebrovascular reactivity in lean and obese zucker rats (LZR/OZR), however, the effects of UCMS and exercise on brain microvascular density have not been examined. **PURPOSE:** The goals of this study were: 1) to determine how MetS affects brain vascular structure and function to increase the risk of depression 2) to investigate the efficacy of exercise to minimize MetS related brain vascular pathology. We tested the hypothesis that exercise prevents UCMS induced brain rarefaction in OZR, in part, by normalizing altered STAT3 signaling in brain. **METHODS:** LZR and OZR were assigned to the following groups: Control, Exercise (Ex), UCMS, and Ex_UCMS. After 8 weeks of each treatment, brains were isolated and serially section in 20 um for immunohistochemistry and western blot analyses. **RESULTS:** After 8 weeks of UCMS treatment, OZR had a significantly lower brain microvascular density (MVD) confirmed by CD31 immunostaining (100 ± 7 vs 75 ± 6 %, $p < 0.05$) and decreased CD31 protein expression (1.00 ± 0.10 vs 0.53 ± 0.06 AU, $p < 0.05$) compared with OZR control group. Decreased MVD in OZR+UCMS was accompanied with significantly elevated phosphorylation of STAT3 in the brain (1.00 ± 0.08 vs 2.48 ± 0.46 AU, $p < 0.05$). Exercise treatment significantly attenuated UCMS induced brain rarefaction (75 ± 6 vs 114 ± 6 %, $p < 0.05$) and normalized STAT3 activity in OZR+UCMS group (2.48 ± 0.46 vs 0.79 ± 0.14 AU, $p < 0.05$). Although STAT3 signaling was significantly elevated in LZR+UCMS group compared with LZR control, there was no changes in

brain MVD in LZr+UCMS group. **CONCLUSION:** Taken together, these results suggested that OZR is more susceptible to UCMS associated brain vascular structural alteration than LZr is. Importantly, exercise treatment appears to prevent UCMS associated brain rarefaction in OZR.

Effects of Voluntary Wheel Running Exercise on the Circadian Alterations of Neuroendocrine Induced by Chronic Unpredictable Mild Stress in Rats
 Yan Zhao, Yu Fu. *Cheng Du Sport University, Cheng Du, China.*
(No relationships reported)

PURPOSE: To investigate the effect of voluntary wheel running exercise on the circadian rhythmic alterations of plasma hormone and peptide induced by the Chronic Unpredictable Mild Stress (CUMS).

METHODS: Ninety male SD rats were divided into three groups: CUMS group, EC group (Exercise plus CUMS), and Control group. The CUMS procedure consists of a variable sequence of 12 stressors. Rats were randomly exposed to two stressors every day for 3 weeks. Rats in EC group were trained in a voluntary wheel running program for a total of 8 weeks, plus CUMS procedure during the last three weeks. Blood samples were collected at each of six time points (ZT1 and 5, 9, 13, 17, 21). Plasma concentrations of corticosterone (CORT), melatonin (MT) and vasoactive intestinal peptide (VIP) were detected by ELISA kits. Data were analyzed by one-way ANOVA, and the circadian rhythms by single cosinor method.

RESULTS: Rats in Con group showed robust circadian rhythms in plasma CORT, MT and VIP. Rats in CUMS group showed an obvious disorder in circadian rhythm of plasma CORT, including phase advance and decrease in amplitude, and markedly blunted circadian rhythm. There also showed a markedly blunted circadian rhythm and decreased levels of plasma melatonin in CUMS rats compared to Con rats. VIP still has 24-hour rhythm, but the amplitude was significantly lower than that of the Con group, peak phase also delayed for 6 hours, expression was significantly higher than that of the Con group. 8-week voluntary wheel running exercise can significantly inhibit the disturbance of MT, CORT and VIP circadian rhythm, and also the abnormal expression of these hormones secretion.

CONCLUSION: CUMS induce these peptides and hormones desynchronized from SCN and voluntary wheel running exercise can rescue the disturbed circadian rhythms of these synchronizers.

Supported by the Sports Medicine key laboratory of General Administration of Sport of China/Sports Medicine key laboratory of Sichuan province Foundation.

Long-term Treadmill Exercise Reduces Obesity-induced Tau Hyperphosphorylation In Rat Brain

Guoliang Fang¹, Ye Tian², Jiexiu Zhao¹, Zihong He¹, Liang Li¹, Xingya Yang¹, Pengfei Li¹, Tao Yu¹, Yuemeng Wen¹. ¹China Institute of Sport Science, Beijing, China. ²China Anti-Doping Agency, Beijing, China.

(No relationships reported)

PURPOSE: To investigate the effects of aerobic exercise on tau phosphorylation and PI3K/Akt pathway in the hippocampus of obese rats, and provide some theoretical basis for physical activity improving obesity-related neurological disorders.

METHODS: Male Sprague-Dawley rats aged 3 weeks were randomly assigned to either a high-fat or a normal diet protocol for 12 weeks. Animals submitted to the high-fat diet were divided into two groups: sedentary group (HF-Sed) and exercise group (HF-Ex). The rats fed the normal diet were also divided into sedentary group (ND-Sed) and exercise group (ND-Ex). The rats in the HF-Ex and ND-Ex groups were underwent a treadmill training for 8 weeks. Then the hippocampus were isolated at 48h after last exercise. The protein and phosphorylation levels of tau, GSK3β, PI3K and Akt were assayed by Western blot.

RESULTS: After 8 weeks of treadmill exercise, compared with ND-Sed group, the phosphorylation levels of tau were increased significantly in the HF-Sed group. While the phosphorylation levels of tau were decreased remarkably in the HF-Ex group compared with HF-Sed group. Furthermore, compared with ND-Sed group, the activity of GSK3β was increased in the HF-Sed group by reducing Ser9 phosphorylation and increasing Tyr216 phosphorylation. But in the HF-Ex group, the activity of GSK3β was decreased significantly compared with HF-Sed group by increasing Ser9 phosphorylation and reducing Tyr216 phosphorylation. Moreover, compared with ND-Sed group, in the HF-Sed group the PI3K/Akt pathway was inhibited by reducing the protein levels of PI3K p110 and p85 subunits and the phosphorylation levels of Akt Thr308 and Ser473. But compared with HF-Sed group, the protein levels of PI3K p110 and p85 subunits and the phosphorylation levels of Akt Thr308 and Ser473 were increased remarkably in the HF-Ex group, and the activity of PI3K/Akt pathway was enhanced.

CONCLUSIONS: Obesity induces tau hyperphosphorylation in the rats hippocampus. While long-term aerobic exercise can reduce tau hyperphosphorylation by increasing PI3K/Akt pathway activity and inhibiting GSK3β activity. It has a positive effect on delaying neurofibrillary tangles formation and improving obesity-related neurological disorders.

Role Of Neuronal Fractalkine In Reducing Diet-induced Hypothalamic Inflammation

Robby Zachariah Tom, Yuanqing Gao, Sonja C. Schriver, Dominik Lutter, Chun-Xia Yi, Matthias Tschömp, Susanna M. Hofmann. *Helmholtz Zentrum, Munich, Germany.*
 Email: robby.tom@helmholtz-muenchen.de

(No relationships reported)

PURPOSE: Persistent exposure to an energy dense diet leads to hypothalamic inflammation and is considered an early and a determining factor for the development of metabolic disorders. Hypothalamic pro-inflammatory signals activate the glial cells, resulting in various inflammatory mediators resulting in neuronal dysfunction further promoting obesity and systemic metabolic disease. It has been reported from our lab that moderate intensity treadmill training could revert the diet-induced microglial activation in the hypothalamus. Several lines of evidence suggest that chemokines are involved in the regulation of neurodegenerative and neuroendocrine disorders.

Fractalkine (CX3CL1) is a chemokine that is secreted from neurons, which then binds to its receptor CX3CR1 on the microglia. This ligand-receptor interaction confers a resting - ramified phenotype to microglia thereby reducing hypothalamic inflammation.

AIM: The aim of the present study is to investigate the role of exercise induced fractalkine in reducing high-fat diet (HFD) induced hypothalamic inflammation.

METHODS: We determined the activation status of microglia and astrocytes in hypothalamus of C57Bl/6 mice in response to high fat-diet and exercise. High fat diet exposure for sixteen weeks induced microgliosis and astrogliosis. Microgliosis and astrogliosis were quantified by immuno-histochemical staining for Iba1 and GFAP respectively. **RESULTS:** High fat diet exposure for sixteen weeks induced microgliosis and astrogliosis. Treadmill running reversed microgliosis induced by HFD. Mice underwent an acute bout of exercise to elucidate the neuronal fractalkine response to exercise. Fractalkine mRNA expression (Q-RT-PCR) as well as protein levels (chemokine array) were increased after an acute bout of exercise. Furthermore data from RNA-sequencing after acute bout of exercise indicates that Rfx4 which is a transcriptional regulator of CX3CL1 is also up regulated in response to exercise.

CONCLUSIONS: On going studies using CX3CR1 knock out mice will elucidate the role of fractalkine-receptor signaling in HFD induced hypothalamic inflammation. Hypothalamus targeted fractalkine delivery might ameliorate diet-induced hypothalamic inflammation and associated metabolic complications.

Voluntary Exercise and Expression of Energy Homeostasis-related Genes in Hypothalamus of High-fat Diet Fed Mice
 Francine P. Carvalho, Thais L. Moretto, Izabelle D. Benfato, Marcela Barthichoto, Camila A. M. Oliveira. *Federal University of Sao Paulo, Santos, Brazil.*
 Email: carvalho.franp@gmail.com
 (No relationships reported)

Several strategies have been studied to combat obesity, including physical exercise. The knowledge of whether exercise can modulate the expression of genes involved in energy homeostasis in hypothalamus of diet-induced obese mice can bring additional information about the treatment of this pathology. **PURPOSE:** Investigate the effect of voluntary exercise on the hypothalamic expression of genes related to energy homeostasis in high-fat diet fed mice. **METHODS:** C57BL/6 mice were divided into 3 groups: control (C), high-fat (H) and high-fat exercise (HE). Mice had free access to food (C, chow or H, 34% fat) and running wheel (HE, 5 days/week) for 10 weeks. Hypothalamus was collected and expression of 84 obesity-related genes was assessed by RT PCR with the gene array system. The data was analyzed in the PCR Array System Data Analysis Software (Excel & Web based - SABioscience). Results are expressed as fold change. Significance was set at $p < 0.05$. **RESULTS:** High-fat diet modulated ($p < 0.05$) the expression of 14% of the 84 analyzed targets. The anorectic genes *Bdnf* (0.53 H vs C and 0.57 HE vs C), calcitonin receptor (H 0.63 and HE 0.57 vs C) and ciliary neurotrophic factor receptor (H 0.53 and HE 0.57 vs C) were downregulated in H and HE compared to C. The adrenergic receptor beta 1 (H 0.53 and HE 0.58 vs C) and interleukin 1 receptor type 1 (H 0.54 and 0.58 HE vs C) were also downregulated by high-fat diet. Neuropeptide Y receptor Y1 (H 1.06 and HE 1.15 vs C), protein tyrosine phosphatase non-receptor type 1 (H 1.07 and HE 1.15 vs C), corticotropin releasing hormone receptor 1 (H 1.06 and HE 1.14 vs C), 5-hydroxytryptamine receptor 2C (H 1.07 and HE 1.15 vs C) and zinc finger protein 91 (H 1.07 and HE 1.16 vs C) were upregulated by high-fat diet. Interleukin-1 alpha was upregulated in H (1.06 H vs C) but downregulated in HE (0.57 HE vs C). Only calcitonin receptor was not differentially expressed in HE compared to H. Except for interleukin-1 alpha, all the other genes were upregulated in HE compared to H. **CONCLUSIONS:** High-fat diet downregulated anorexigenic and prothermogenic genes and upregulated genes linked to positive energy balance, favoring obesity. Voluntary exercise only marginally modulated (small magnitude despite significant) the expression these genes, indicating a discrete central effect.

Regulation Of Hypothalamic Expression Of Kiss-1 and Gpr54 Genes Mrna By Moderate-intensity Exercise In Diet Induced Obesity Rats
 Yi Yan, Rui Xu. *Beijing Sport University, Beijing, China.*
 Email: yanyi22@sina.com
 (No relationships reported)

More recently, kisspeptins are reported with a significant role in regulating glucose homeostasis, insulin secretion, as well as food intake and body composition. **Purpose:** To observe the effect of diet induced obesity on the hypothalamic expression of KiSS-1 and the G-protein coupled receptor (GPR) 54 mRNA and explore the modulatory role of moderate-intensity exercise in the diet induced obesity male rats. **Methods:** After 8 weeks high fat feeding, 20 obesity 11-weeks SD rats were randomly assigned to high-fat diet sedentary (FS, n=8) and high-fat diet exercise (FE, n=8) groups, 20 normal diet 11-weeks SD rats also were randomly assigned to sedentary (SS, n=8) and exercise (SE, n=8) groups. During the following 8 weeks, obesity rats were continued expose to high-fat-diet. SE and FE groups did the 60%-70% $V(\bullet)O_2$ max treadmill training (5 days/week, 1 hour/day). The $V(\bullet)O_2$ max of exercise groups were remeasured every two weeks. The hypothalamic expression of KiSS-1 and GPR54 mRNA were tested in each group. **Results:** After the first 8-weeks high fat feeding, the obesity rats were heavier than normal diet group (491.74±26.19g vs. 410.05±45.77g, $p < 0.01$). After 8-weeks training, the FE group was lighter than FS group (590.23±35.74g vs. 681±52.56, $p < 0.01$). The FS group had higher hypothalamic expression of KiSS-1 mRNA (1.51±0.66 vs 0.75±0.27, $p < 0.05$) and GPR54 mRNA (2.45±0.38 vs 0.61±0.15, $p < 0.01$) than SS group. The FE group had lower hypothalamic expression of KiSS-1 mRNA (0.69±0.13, $p > 0.05$) and GPR54 mRNA (0.58±0.10, $p < 0.01$) than FS group. **Conclusion:** There is stimulating effect of high-fat diet induced obesity on hypothalamic expression of KiSS-1 and GPR54 mRNA. 8-weeks 60%-70% $V(\bullet)O_2$ max treadmill training could cure this effect.

Hypothalamic Leptin Signaling Modulates Spontaneous Physical Activity During Ageing in Mice.
 Izabelle Dias Benfato¹, Francine Pereira De Carvalho, MSc¹, Thais Ludmilla Moretto, MSc¹, Marcela Barthichoto, MSc¹, Sandra Mara Ferreira, PhD², José Maria Costa Júnior, PhD², Carolina Martinez, MSc¹, Carolina Prado de França Carvalho, PhD¹, Camila Aparecida Machado de Oliveira, PhD¹. ¹FEDERAL UNIVERSITY OF SÃO PAULO, SANTOS, Brazil. ²STATE UNIVERSITY OF CAMPINAS, CAMPINAS, Brazil.
 Email: izabelle.benfato@gmail.com
 (No relationships reported)

Spontaneous physical activity (SPA) comprehends all daily physical activities other than volitional exercise (e.g. sports-related activities). The energy spent in SPA can represent up to 50% of the total daily energy expenditure. Little is known regarding the biological regulation of SPA, especially during ageing, when SPA is known to decline. As a mediator of energy homeostasis, hypothalamic leptin signaling may be involved. **PURPOSE:** to investigate the temporal relationship between hypothalamic leptin signaling and SPA in mice from 4 to 10 months of age. **METHODS:** Male C57bl/6 mice were divided into three groups, according to age: 4 (4M, n=10), 6 (6M, n=10) and 10 (10M, n=20) months-old mice. SPA, distance travelled (DT), average speed of locomotion (AS) and energy expenditure (EE) were measured monthly from 4 to 10 months of age in the 10M group. Hypothalamic expression of STAT3 and phosphorylated STAT3 (pSTAT3) by Western Blotting, intraperitoneal glucose tolerance test (ipGTT), and retroperitoneal (RAT) and epididymal (EAT) adipose tissue weight were determined in all the groups (4M, 6M and 10M). Results are shown as mean + standard error of the mean. Repeated measures ANOVA or One-way ANOVA were employed and the Newman-Keuls post hoc test was used when necessary. Significance was set at $p < 0.05$. **RESULTS:** Compared to the 4th month, SPA, DT and AS started to decrease in the 6th month ($p < 0.05$) and persisted reduced all over (SPA 30%; DT 25%; AS 25% decrease in the 10th month). EE decreased ($p < 0.05$) in the last three months (19% decrease in the 10th month). Hypothalamic pSTAT3 decreased ($p < 0.05$) in 6M and 10M in relation to 4M (4M: 0.83 + 0.28; 6M: 0.52 + 0.16*; 10M: 0.53 + 0.17* arbitrary units). STAT3 decreased 45% in 10M compared with 6M, but it was not statistically significant ($p = 0.09$). The area under the curve of ipGTT (4M: 31,228 + 9,875; 6M: 36,776* + 11,629 10M: 40,544* + 13,514 mg/dL x 120 minutes), and the weight of RAT (4M: 3.76 + 1.19; 6M: 9.58* + 3.03; 10M: 9.76* + 3.25 mg/g) and EAT (4M: 14.59 + 4.61; 6M: 29.28* + 9.26; 10M: 26.87* + 8.96 mg/g) increased ($p < 0.05$) in 6M and 10M groups when compared to 4M group. **CONCLUSIONS:** Decreases in SPA, DT and AS were accompanied by a reduction of hypothalamic leptin signaling. Besides, glucose intolerance and increased fat pads weight manifested when SPA declined. **Supported by: FAPESP and CAPES.**

2508 Board #28 June 2 9:30 AM - 11:00 AM
Influences Of Swimming On Learning And Memory And Expression Of Orexin And Ncam In Rat Hippocampus
 Qiongjia Yuan, Female¹, Yeting Zhang, Male², Xue Li, Female¹, Lu Wang, Female¹. ¹Chengdu Sport Institute, Chengdu, China. ²Chengdu University, Chengdu, China.
 (No relationships reported)

PURPOSE: Through the different load intensity swimming exercise intervention in rats, we observed that the movement influenced on rats spatial learning and memory ability and detected the proteins expression of rat hippocampal. **METHODS:** 30 male SD rats were selected. After acclimatization to the laboratory for 1 week, the rats were randomly divided into 3 groups: Control Group(C), Medium load Group (M), over load Group (O). Group C were feed naturally; group M did swimming exercise intervention; group O did over load swimming exercise. The Morris Water Maze test (MWM) was performed to evaluate spatial learning and memory ability. Tissue samples were collected after the MWM test. 6 whole brain samples for immunofluorescence assay, while the bilateral hippocampus of the other 6 brains for western blot and real-time PCR analysis. **RESULTS:** (1) Blood testosterone detections: there was no significantly difference between group M and C ($P > 0.05$), the blood testosterone of group O was significantly lower than group M and C ($P < 0.01$); (2) MWM detection: during the navigation experiment, group M was easier to find the platform than group C ($P < 0.01$). During the space exploration, rats in group M crossed where the platform was fixed more often than group C and O ($p < 0.05$), rats in group C crossed where the platform was fixed more often than group O ($p < 0.05$); (3) mRNA detection: the expression of NCAM mRNA and OXA mRNA of group M were significantly higher than group C ($P < 0.05$), OX1R mRNA of group M was significantly lower than group C ($P < 0.05$); (4) Protein detection: the expression of NCAM of group M was significantly higher than group C ($P < 0.05$), the group O was significantly lower than group C ($P < 0.05$). **CONCLUSION:** Medium load swimming exercise could improve the rats spatial learning and memory ability and significantly improve the expression of OXA, OX1R

mRNA and OX1R, and significantly reduce the expression of OXA, OX1R mRNA, OX1R; Over load swimming exercise could damage the spatial learning and memory ability of rats, after over load swimming exercise, the expression of NCAM, OXA and OX1R was normal. **Acknowledgments:** Supported by the National Natural Science Foundation of China (No.31371202). Supported by the Sports Medicine key laboratory of State Administration of Sports/ Sichuan province Foundation.

2509 Board #29 June 2 11:00 AM - 12:30 PM An Analysis of Female Athlete Triad Components in Elite Para-Athletes

Cheri A. Blauwet¹, Emily M. Brook¹, Adam S. Tenforde¹, Elizabeth Broad², Elizabeth G. Matzkin¹. ¹Brigham and Women's Hospital/Harvard Medical School, Boston, MA. ²United States Olympic Committee, Chula Vista, CA.
(No relationships reported)

The Female Athlete Triad (Triad) is a syndrome defined as the interaction of three interrelated conditions: low energy availability with or without disordered eating, menstrual dysfunction, and low bone mineral density (BMD). The Triad may also impact males, and may have long term health consequences if unaddressed. Although participation in elite para-sport is rapidly growing, no studies have assessed the prevalence of Triad risk factors in this population.

PURPOSE: To evaluate the prevalence of Triad risk factors in an elite para-athlete population and association to sex and para-sport type.

METHODS: Subjects were United States para-sport athletes who were training to qualify for the 2016 Summer or the 2018 Winter Paralympic Games. Participants completed an online questionnaire characterizing nutrition, menstrual status (if female), bone health, and awareness of the triad. Responses were analyzed to determine overall prevalence of Triad components, and significant differences based on sex and sport type (leanness vs. non-leanness).

RESULTS: A total of 248 (144 male, 104 female) athletes completed the survey. Of these, 137 athletes competed in leanness sports and 109 athletes in non-leanness sports. Of the cohort, 40% (53 male, 45 female) of athletes indicated that they were currently trying to lose weight, and 61% (n = 151; 90 male, 61 female) indicated they were attempting to change their body composition to improve sport performance. Only 3% (1 male, 6 female) of athletes indicated that they had been previously diagnosed with an eating disorder. For pre-menopausal women, 32% (n = 29) reported less than 9 menstrual cycles in the past year. A total of 21% (27 male, 25 female) of athletes reported a history of a bone stress injury, yet 9% (8 male, 13 female) reported a diagnosis of low BMD based on DXA scan. There were no differences in risk factor prevalence between sexes or those competing in leanness versus non-leanness sports. Only 9% of athletes were aware of the Triad.

CONCLUSIONS: Elite para-sport athletes have high prevalence of Triad components, regardless of sex or sport type. Awareness of the Triad in athletes is low. While consequences of the Triad in a para-athlete population are poorly understood, screening tools and education to increase awareness are required to optimize overall health of this population.

2510 Board #30 June 2 11:00 AM - 12:30 PM Sex Differences in Competition Volume, Club Sport Participation, Specialization, and Injury Among High School Athletes

Eric G. Post, David R. Bell, Stephanie M. Trigsted, Dan A. Schaefer, Madeline M. Miller, Adam Y. Pfaller, Scott B. Hetzel, M. Alison Brooks, Timothy A. McGuine. *University of Wisconsin-Madison, Madison, WI.*
(No relationships reported)

Female adolescent athletes are at greater risk for certain injuries, such as ACL injuries or overuse knee injuries. One theory for this increased risk is the increasing trend towards intense, year-round sport participation and specialization. However, it is unknown whether characteristics of sport participation, including competition volume, club sport participation, specialization, or history of lower extremity injury (LEI) differ between female and male athletes.

PURPOSE: To compare level of competition volume, club sport participation, sport specialization, and previous lower LEI between males and females in high school athletes.

METHODS: 1525 high school athletes (780 female, age=16.1±1.1 years old, grades 9-12) from 29 high schools were recruited to complete a pre-season questionnaire regarding their sport participation patterns and previous injury history. Sport competition volume in the previous 12 months was classified as high (>60 competitions), moderate (30-60 competitions), or low (<30 competitions). Sport specialization status was classified as low, moderate, or high using a widely utilized 3-point specialization scale. Chi-square tests were used to investigate associations of competition volume, club sport participation, specialization, and LEI by sex (a-priori p<.05). **RESULTS:** Females were more likely than males to participate in high competition volume (23.2% vs 11.0%, $\chi^2=84.7$, p<0.001), participate on a club team (61.2% vs 37.2%, $\chi^2=88.3$, p<0.001), and be highly specialized (16.4% vs 10.4%, $\chi^2=19.7$, p<0.001). A total of 487 subjects (31.5%) reported sustaining a total of 599 previous time-loss LEI. Female athletes were more likely to report a previous LEI than males when considering all sports (36.5% vs. 27.0%, $\chi^2=15.9$, p<0.001) and when the sample was restricted to sex-equivalent sports (37.3% vs. 28.2%, $\chi^2=9.0$, p=0.003). **CONCLUSIONS:** Female athletes were more likely to participate in sports at high volumes, on club teams in addition to their high school teams, be highly specialized, and report previous LEI. Female high school athletes may be at greater risk of injury due to these differences in sport participation patterns. Supported by grants from the American Medical Society for Sports Medicine and the National Federation of State High School Associations.

2511 Board #31 June 2 11:00 AM - 12:30 PM Chronic Training Load, But Not Stress Or Sleep, Is An Independent Predictor Of Illness In Female Youth Athletes

Andrew Watson, Stacey Brickson, Warren Dunn. *University of Wisconsin-Madison, Madison, WI.*
Email: watson@ortho.wisc.edu
(No relationships reported)

Although training load and subjective well-being have been suggested as risk factors for injury, their relationship with illness in youth athletes is unknown. **Purpose:** To determine whether training load, stress or sleep are independent predictors of in-season illness in female youth soccer players. **Methods:** 69 female soccer players (13-18 years) were monitored for 10 months of formal competition. Daily training load (TL) was determined by session-rating of perceived exertion (duration [min] x intensity [1-10]). Every morning, participants recorded sleep hours and rated stress from -3 to +3 (higher being better) and illnesses were recorded throughout the year. Data were aggregated weekly and 2, 3, and 4 week rolling averages were calculated as well as an acute:chronic workload ratio (A:C; weekly divided by 4-week TL). TL measures were converted to z-scores and Poisson regression analyses were used to compare the relative abilities of the different TL measures to predict the number of illnesses the following week. Based on this, 2-week TL was classified as low, moderate-low, moderate-high, high, or very high using z-scores, and the relative risk of subsequent illness was compared between the groups. Finally, a multivariable Poisson regression was developed to predict the number of weekly illnesses, using 2-week TL, sleep, and stress values as covariates. **Results:** 73 illnesses occurred during the 10 months of competition. Weekly illnesses were significantly and similarly predicted by the preceding 2-week TL (OR=1.74, p<0.001), 3-week TL (OR=1.71, p<0.001), and 4-week TL (OR=1.70, p<0.001), but not 1-week TL (OR=1.21, p=0.15) or A:C (OR=1.22, p=0.22). Compared to low 2-week TL, the risk of illness was increased following 2-week periods of high (RR=2.0) and very high TL (RR=3.5). After inclusion in the multivariable model, 2-week TL remained a significant, independent predictor of subsequent weekly illness (OR=1.81, p<0.001) while sleep (OR=0.78, p=0.80) and stress (OR=0.42, p=0.50) did not. **Conclusion:** After controlling for sleep and stress, chronic training load is a significant, independent predictor of illness risk, while weekly TL and A:C are not. Monitoring cumulative TL over 2 or more weeks during the competitive season may allow for intervention to reduce the risk of illness in adolescent female athletes.

2512 Board #32 June 2 11:00 AM - 12:30 PM Influence Of Year In School On Health-related Quality Of Life Among Collegiate Athletes

Jennifer L. Sanfilippo, Liga A. Blyholder, Timothy A. McGuine, Bryan C. Heidershceit. *UW-Madison, Madison, WI.* (Sponsor: Joseph Weir, FACSM)
(No relationships reported)

Transitioning from high school to college can be a difficult experience; freshmen must adapt to life away from home, new responsibilities, and higher academic demands. For collegiate athletes, this transition also requires adjusting to more rigorous training and greater performance pressures. Together, these stressors may negatively impact health-related quality of life (HRQoL) among freshmen collegiate athletes. **PURPOSE:** To examine changes in HRQoL over a competitive season among freshmen and senior collegiate athletes. **METHODS:** 69 freshmen (age=18.2±0.47, male=56) and 23 senior (age=21.4±0.49, male=14) collegiate athletes at a large, Division I university

completed the Short Form 12v2.0 Acute Recall (SF-12) prior to the start of the competitive season (PRE) and within 1 month following the end of the competitive season (POST). Participants included athletes who did not sustain an injury during the season or 6 months prior to PRE competing in football (freshman=36, senior=12), soccer (freshman=16, senior=3), and cross country (freshman=17, senior=8) over the 2013-2014 or 2014-2015 seasons. Raw scores were converted to norm-based scores via a linear z-score transformation. Changes (median (IQR)) in PRE to POST Mental Composite Score (MCS) and Physical Composite Score (PCS) were analyzed using Wilcoxon signed-rank tests. **RESULTS:** MCS significantly decreased ($p<0.001$) pre- to post-season among freshmen collegiate athletes (PRE=57.06 (54.79, 59.43), POST=54.67 (48.93, 57.06)). This decrease was observed in both males and females ($p<0.001$ and $p=0.027$, respectively). There was no change ($p=0.341$) in PCS among freshmen. Among senior collegiate athletes, MCS (PRE=55.34 (54.22, 58.26), POST=54.20 (49.50, 58.10)) and PCS (PRE=57.47 (54.39, 57.84), POST=56.71 (55.34, 58.40)) did not change significantly pre- to post-season ($p=0.487$ and $p=0.889$, respectively). **CONCLUSION:** Among freshmen collegiate athletes, mental aspects of HRQoL decreased over the course of the competitive season. Transitioning from high school to collegiate academics and athletics may produce high levels of psychological stress that can negatively impact HRQoL. University athletic programs should consider offering stress-management and counseling services to help incoming freshmen athletes adjust to college life.

2513 Board #33 June 2 11:00 AM - 12:30 PM
In-season Injury And Health-related Quality Of Life Among Collegiate Athletes

Liga A. Blyholder, Jennifer L. Sanfilippo, Timothy A. McGuine, Bryan C. Heiderscheid. *University of Wisconsin-Madison, Madison, WI.* (Sponsor: Joseph Weir, FACSM)
 Email: blyholder@ortho.wisc.edu
 (No relationships reported)

For many athletes, sport-related musculoskeletal (MSK) injuries result in significant time loss from activity and declines in athletic performance. These events may negatively impact health-related quality of life (HRQoL). **PURPOSE:** To determine the effect of MSK injuries sustained during the competitive season on HRQoL among collegiate athletes. **METHODS:** 160 Division I collegiate athletes (mean age=19.6±1.4, 117 males) at a large public university completed the Short Form 12v2.0 Acute Recall (SF-12) prior to the start of the competitive season (PRE) and within 1 month following the end of the competitive season (POST). Participants included athletes not injured in the prior 6 months who competed in football (n=73), soccer (n=43), cross country (n=35), and volleyball (n=9). Data on injuries sustained during the season was collected from a medical database maintained by sports medicine staff. SF-12 raw scores were converted to norm-based scores via a linear z-score transformation. Differences (median (IQR)) in PRE and POST Mental Composite Score (MCS) and Physical Composite Score (PCS) were analyzed using Wilcoxon signed-rank and Mann Whitney U tests. **RESULTS:** Among athletes who suffered an in-season MSK injury (n=55), PCS significantly decreased ($p=0.023$) over the season (PRE=56.71 (54.24, 57.76), POST=55.86 (52.14, 56.71)) while MCS remained unchanged ($p=0.208$). Athletes who underwent surgery during the season (n=10) showed no change in PCS ($p=0.097$) or MCS ($p=0.722$). Among athletes who did not sustain an injury (n=105), MCS significantly decreased ($p=0.003$) pre- to postseason (PRE=57.06 (54.10, 59.43), POST=54.79 (51.73, 57.16)) while PCS did not change ($p=0.289$). Postseason PCS was significantly lower ($p<0.001$) among athletes who underwent surgery (POST=51.63 (48.72, 54.95)) and among athletes who suffered a MSK injury (POST=55.86 (52.14, 56.71)) compared to uninjured athletes (POST=56.71 (55.09, 57.76)). **CONCLUSION:** Among collegiate athletes, in-season MSK injury negatively affected physical aspects of HRQoL. Sports medicine providers should be aware that MSK injury can impact, not only athletic performance, but also self-perceived physical health and function among collegiate athletes.

2514 Board #34 June 2 11:00 AM - 12:30 PM
The Assessment Of Body Composition In Young Athletes

Giorgio Galanti, Benedetta Tosi, Martina Bocci, Giulio Tempesti, Gabriele Mascherini, Petri Cristian. *Sport Medicine Center, Florence, Italy.*
 Email: giorgio.galanti@unifi.it
 (No relationships reported)

Purpose: In this study we have compared the body composition of elite athletes practicing two different sports, we also evaluated bone health in cyclists. **Methods:** we enrolled 64 male athletes (15-21 years old): 52 soccer players and 12 cyclists, belonging to same soccer or cycling team. The athletes were subjected to anthropometric evaluations, measurements of circumferences and skinfolds, DXA and BIA. Specifically, using Durnin & Rahaman formula we evaluated fat mass (FM) and fat free mass (FFM). With DXA we evaluated Whole Body Total Fat (WBTF), Whole Body Total Lean (WBTL), Whole Body Total Mass (WBTM) and Whole Body Total

Percentage of Fat(WBTF). Furthermore BIA allowed us to measure Body Cellular Mass (BCM); Total Body Water (TBW); intracellular water (ICW), extracellular water (ECW) and the index of hydration. Cyclists were also subjected to blood samplings. **Results:** In soccer players we observed (data expressed in Means) BMI 21.75. Waist, hip and bicep circumferences were 73,03; 91,51 and 26,69 cm respectively. Skinfolds sum was 54,57 mm. FM was 16,8% (12,0 kg) and FFM was 59,0 kg. DXA results were: 12,6 kg WBTF, 60,7kg WBTL and 17,2% WBTF. BIA results were: 63,3 kg of FFM. BCM, TBW, ICW, ECW were: 39,03kg; 46,4L; 52% and 48%, respectively. Index of hydration was 6,6. In cyclists we observed: BMI 21,79. Waist, hip and bicep circumferences were 74,08, 94,38 and 29,13 cm. Skinfolds sum was 65,28 mm. FM was 14,5% (9,9 kg) and FFM was 58,1 kg. DXA results were: 12,1 kg WBTF, 57,96 kg WBTL and 17,14% WBTF. BIA results were: 58 kg of FFM. BCM, TBW, ICW, ECW were: 33,63kg; 43,4L; 55,9%; 44,1 %, respectively. Index of hydration was 7,2. Sieric mean value of Vitamine D was 29,87 ng/ml; Z score was -2,9. **Conclusions:** In athletes playing ciclismo we observed, in addition to a minor concentration of FM, a lower percentage of FFM, mostly due to a reduction of bone mineral density (BMD), in line with former studies. Moreover, this study underlines how cycling can induce a significant reduction of BMD. Therefore we should suggest a suspension of this activity for a period of about three or four months per year.

2515 Board #35 June 2 11:00 AM - 12:30 PM
A Wellness Program for Older Female Golfers: Effects on Golf Performance and Range of Motion

Katherine James, Michael Rabel, Lorraine Lacoppola, Erin Ruest. *University of Maryland Eastern Shore, Princess Anne, MD.*
 (No relationships reported)

PURPOSE: To compare the effect of a wellness program on range of motion (ROM) and golf performance in older female golfers. **METHODS:** Twenty-five healthy, right-handed, female golfers were randomly assigned to either an intervention (N=12; mean age ± SD, 60.3 ± 6.8) or control (N=13; mean age ± SD, 65.9 ± 5.4) group. Baseline measures included shoulder, hip, and trunk rotation passive ROM using inclinometers, club head speed (CHS), and self-reported golf performance. The intervention group received a wellness program consisting of flexibility and strengthening exercises. The flexibility component incorporated one exercise for each of the following regions: shoulder, hip, and trunk. The three strengthening exercises focused on abdominal and hip musculature. A daily exercise log was used to monitor compliance with the wellness program. Subjects were reassessed after five weeks. Repeated measures ANOVAs, with age as a covariate, were performed to determine whether pre and post measures differed between groups. **RESULTS:** The intervention group demonstrated a significant increase in all shoulder rotation ROM values ($P\leq 0.03$) with the exception of right internal rotation. For the same group, self-reported golf performance scores ($P=.02$) improved significantly. No significant change in CHS was identified for either group. **CONCLUSION:** The shoulder exercise (cross-body stretch) used in the wellness program has been found to improve shoulder ROM in young adults. This study shows that the exercise may also be effective for older females. While all ROM measures improved for the intervention group, additional time may have been needed to demonstrate significant change. In general, research concerning the female golfer remains limited. This study begins to define a wellness program for female golfers that could easily be incorporated into their daily routine.

2516 Board #36 June 2 11:00 AM - 12:30 PM
Investigating the Acute Effects of Olympic-style Boxing Among Females

David R. Howell¹, William P. Meehan, III¹, Michael P. Loosemore², Joseph Cummiskey³, Jean-Paul Grabner von Rosenberg⁴, David McDonagh³. *¹Boston Children's Hospital, Waltham, MA. ²University College Hospital London, London, United Kingdom. ³AIBA, Lausanne, Switzerland. ⁴St. Olavs Hospital, Trondheim, Norway.* (Sponsor: Lou Osternig, FACSM)
 Email: david.howell2@childrens.harvard.edu
 (No relationships reported)

Although diagnosed concussions affect balance control, dual-task abilities, visual functions, and neurocognitive functions, few prospective investigations have examined how head impacts sustained during an Olympic-style boxing tournament that do not result in a concussion, so-called sub-concussive blows, affect performance. Female boxers, in particular, have received scant attention in the boxing literature to date. **Purpose:** To prospectively examine the neurocognitive, postural control, dual-task, and visual abilities of female Olympic-style boxers before and after participation in a boxing tournament. **Methods:** Sixty-one females completed the modified Balance Error Scoring System (mBESS), King-Devick test, and 3m timed-up-and-go (TUG) test in single-task and dual-task conditions. A subset (n= 31) also completed the CogState computerized neurocognitive test. Initial testing was completed prior to the 2016 Women's World Boxing Championships and each participant repeated the testing protocol within a day of elimination. Pre-tournament and post-tournament performance

variables were compared using paired samples t-tests. **Results:** Participants (mean age = 26.1 ± 4.6 years) completed a mean of 7.5 ± 4.5 rounds of Olympic-style boxing over the course of 2-8 days. Pre-tournament scores were significantly worse than post-tournament scores for total mBESS (5.5±2.9 errors vs. 2.2±1.9 errors, p<.001, d= 1.23) and King-Devick time (18.0±8.3 s vs. 14.2±3.9 s, p= .002, d= 0.53). Processing speed was significantly slower prior to the boxing tournament (maze chase task: 1.17±0.44 correct moves/second vs. 1.39±0.34 correct moves/second, p= .001, d= 0.58). No significant changes between testing sessions were detected for the other obtained outcome variables. **Conclusion:** Female boxers demonstrated either improvement or no significant change after competing in an Olympic-style boxing tournament, relative to pre-tournament performance. As many of the tasks employed in our testing battery are novel, practice effects may have contributed to improved performance. Given the relatively short time frame between assessments, clinicians should be aware of potential practice effects when using ringside tests in the diagnosis and management of concussion.

2517 Board #37 June 2 11:00 AM - 12:30 PM

The Influence Of Oral Contraceptives On Subjective Physical Condition And Athletic Performance In Japanese Female Athletes.

Mariko Nakamura, Sayaka Ogura-Nose. *Japan Institute of Sports Sciencs, Tokyo, Japan.*
(No relationships reported)

In Japan, the prevalence of dysmenorrhea and premenstrual syndrome (PMS) in elite female athletes are 25.6 % and 70.3% respectively (Ogura-Nose et al., 2014). However, the use of oral contraceptives (OC) in Japanese female athletes is low (2%)(Ogura-Nose et al., 2014). One of the reasons is because athletes are concerned about the side effects taking OC might have adverse effects on athletic performance. **PURPOSE:** To examine the influence of OC on subjective condition and athletic performance. **METHODS:** Fourteen female athletes were recruited. All subjects were examined during the follicular (F) and luteal (L) phases, OC (days 10-20 of their OC use) and withdrawal-bleeding (W) phase (days 2-5 post OC phase). Each phase of the menstrual cycle was confirmed by serum luteinizing hormone (LH), follicular stimulating hormone (FSH), estradiol, and progesterone levels. After natural menstrual cycle tests, all subjects began taking OC. Monophasic OC with ultra low-dose was used. A post-exercise cardiovascular reactivation test, lactate curve test, oxygen consumption (VO₂max) test, and Wingate test were performed during all phases. In addition, subjective fatigue, mood states and subjectively perceived daily training load were estimated on visual analog scales (100mm). All parameters were analyzed by tow-way analysis of variance for repeated measurements. **RESULTS:** There were no significant changes in subjective physical condition, post-exercise cardiovascular reactivation, VO₂max, and time to exhaustion during all phases. No significant changes in peak power, and mean power of Wingate test were observed. However, at the time of the low-intensity exercise (< 2mmol/L) in lactate curve test, lactic acid values were high during the OC and W phase (OC: 1.6.0 ± 0.4, W: 1.5 ± 0.4 mmol/L) compared with the natural cycle (F: 1.3 ± 0.3, L: 1.3 ± 0.3 mmol/L, P < 0.05). In Wingate test, maximum lactate value after the Wingate test was high during the OC and W phase (OC: 12.0 ± 2.4, W: 12.0 ± 2.6 mmol/L) compared with the natural cycle (F: 11.2 ± 2.2, L: 11.1 ± 1.9 mmol/L, P < 0.05). **CONCLUSION:** These results suggest that ultra low-dose monophasic OC had no influence on athletic performance. Further research is needed regarding the influence of OC on the glycolytic pathway. Supported by Japan Sports Agency's consignment fund.

2518 Board #38 June 2 11:00 AM - 12:30 PM

The Prevalence and Impact of Heavy Menstrual Bleeding Among Exercising Women.

Allyson L. Parziale¹, Georgie Bruinvels², Toby Richards², Charles R. Pedlar³, Kathryn E. Ackerman, FACSM¹. ¹Boston Children's Hospital, Boston, MA. ²University College London, London, United Kingdom. ³Massachusetts General Hospital, Boston, MA. (Sponsor: Kathryn Ackerman, FACSM)
Email: allyson.porziale@childrens.harvard.edu
(No relationships reported)

PURPOSE: Heavy menstrual bleeding (HMB), which includes flooding through clothes, frequent changes of sanitary products, needing extra protection, and/or passing large clots, is prevalent among exercising females in the UK. HMB has negative associations with training and performance and an increased risk of iron deficiency. The aim of this study was to identify the prevalence, associated characteristics, and the impact of HMB within an American exercising female population. **METHODS:** 532 females, ages 15-30 years, who exercise ≥ 4 hours per week and presented to a US-based Sports Medicine clinic, were invited to complete a questionnaire incorporating: a four-part diagnostic series for HMB; menstrual cycle characteristics such as typical duration and frequency; reported impacts on training and performance; cramping and bloating symptoms; and the seeking of medical advice for heavy periods. **RESULTS:** HMB prevalence was 29.7%, while 30.6% reported that their menstrual cycle impacts

their training and performance. These were significantly related, with more than half (52.5%) of those with HMB reporting that their menstrual cycle affects their training and performance (X₂= 50.687; p<0.05). However, only 41.8% with HMB reported seeking medical advice. On average, those with HMB reported longer bleeding days per cycle than those without HMB (5.3 days vs. 4.5 days, t=-5.554; p<0.05), but there was no difference in total number of periods per year (p>0.05). Those with HMB were more likely to report experiencing non-menstrual cycle related cramps (X₂= 19.562; p<0.05) and feelings of gaseous bloating (X₂= 19.072; p<0.05). **CONCLUSIONS:** HMB is linked to negative impacts on training and performance, a longer menstrual cycle, cramping and bloating among American adolescent and young adult exercising females. Further research is required to elucidate the physical and psychological effects of HMB and the clinical implications.

2519 Board #39 June 2 11:00 AM - 12:30 PM

Preliminary Evidence Of Sub-optimal Sleep Durations In Trained Middle Eastern Adolescent Soccer Players

Lee Taylor, Darren Paul, Luiz Gustavo Tomazoli, Abdulaziz Farooq, Richard Akenhead, Peter Fowler. *Aspetar – Orthopaedic and Sports Medicine Hospital, Doha, Qatar.*
Email: lee.taylor@aspetar.com
(No relationships reported)

Sub-optimal sleep durations relative to the National Sleep Foundations (NSF) guidelines of 8-10 h per night are seen in adolescents globally, with the Middle East region having specific lifestyle, environmental and cultural nuances which exacerbate these deficiencies. These deficiencies are due to general and athlete specific negotiable (eg pre-bed screen time, socialising, etc) and non-negotiable (eg schooling, travel, etc) factors. This is concerning given the proposed relationship between sleep and illness/injury risk, athletic performance/recovery and holistic athlete development. **PURPOSE:** Characterise sleep in trained adolescent Middle Eastern soccer players pre- and post-match and the influence of pre-dawn sleep interruption upon these characteristics. **METHODS:** During a 17 day training camp sleep was assessed in 20 male trained adolescent Middle Eastern soccer players prior to (PRE) and night of (POST) three discrete matches (MATCH 1, 2 and 3) on day 5, 9 and 13 of the camp. Quantitative sleep values were obtained by wrist actigraphy, with activity count interpretation determining bedtime (hh:mm), get-up time (hh:mm), time in bed (h), sleep duration (h) and sleep efficiency (%) as well as whether a player did (YES) or did not (NO) experience pre-dawn sleep interruption. In YES sleep was seen in two bouts, BOUT1 - pre-dawn intermission - BOUT2. Linear mixed models were used to analyse data. **RESULTS:** On average these players do not meet NSF endorsed minimum sleep durations PRE and POST match (6.97 ± 1.27 h vs. recommended 8-10 h) with deficits significantly exacerbated (-10% or -0.76 h) in YES compared to NO (6.49 ± 1.05 h vs. 7.43 ± 1.29 h, p<0.01). Sleep efficiencies were less than the recommended 85% on average across all players (82.13 ± 7.04), and in YES, NO, BOUT1 and BOUT2. No differences in any sleep characteristics were observed between BOUT1 and BOUT2 (p>0.05). **CONCLUSION:** Deficiencies in these players of duration and quality of sleep relative to recommendations may jeopardize athletic development/recovery and holistic adolescent maturation. Given the high inter- and intra-individual variances in sleep characteristics seen, these players require from their practitioners individualised sleep education strategies/interventions, without reliance on sleep medications.

2520 Board #40 June 2 11:00 AM - 12:30 PM

Influence of Sports Participation and Bone Stress Injury Anatomical Location on Low Bone Mineral Density in Male Athletes

Adam S. Tenforde¹, Allyson L. Parziale², Kathryn E. Ackerman, FACSM². ¹Spaulding Rehabilitation Hospital, Charlestown, MA. ²Boston Children's Hospital, Boston, MA. (Sponsor: Kathryn Ackerman, FACSM)
(No relationships reported)

PURPOSE: Sports participation can provide health benefits to male athletes, including improvements in bone mineral density (BMD) and strength. However, a subset of male athletes may experience impaired bone health associated with sports participation. The aim of this study was to identify the association of sports type and bone stress injury (BSI) location with low BMD (defined as BMD Z-scores < -1) in male athletes. **METHODS:** A retrospective chart review was performed on male athletes (ages 14 - 35 years) referred to a single tertiary-care center for evaluation of BMD following development of one or more BSI. We excluded non-athletes, fractures from trauma, medical conditions that predispose to low BMD, and athletes taking medication(s) that could negatively influence bone health. Analysis is descriptive and demonstrates proportion of athletes with low BMD by sport type (runner versus other athletes) and location of BSI using Fisher exact test with significance at P<0.05. **RESULTS:** Low BMD was observed in 16 of 37 athletes. Low BMD was more common in runners (11 of 19, 58%) compared to other sports (4 of 18, 22%, P=0.045). Of athletes sustaining BSI in regions of higher trabecular bone content (localized to lumbar spine, pelvis, femoral neck, or calcaneus) 61% (11 of 18) had low BMD. Low BMD was less

common in athletes with BSI in anatomical sites with primarily cortical bone content ($P=0.02$), including tibia (3 of 10), metatarsal (1 of 4), femur (0 of 3), tarsal navicular (0 of 1), and rib (0 of 1). **CONCLUSIONS:** A subset of athletes with history of BSI met criteria for low BMD; runners and athletes who sustain BSI in regions of higher trabecular bone content appear at increased risk. Clinicians should consider screening male athletes for low BMD and consider methods to optimize bone health in this population.

2521 Board #41 June 2 11:00 AM - 12:30 PM
Pediatric and Adult CrossFit Injuries Presenting to a Sports Medicine Clinic
 Bridget J. Quinn, Rebecca L. Zwicker, Dai Sugimoto, Andrea A. Stracciolini, FACSM. *Children's Hospital Boston, Boston, MA.*
 (Sponsor: Andrea Stracciolini, FACSM)
 (No relationships reported)

PURPOSE: To evaluate and compare both pediatric and adult CrossFit injuries presenting to a sports medicine clinic. **METHODS:** A retrospective chart review was performed of all medical records (age ranges from 8 to 54 years) in an academic tertiary hospital's sports medicine clinic between January 1, 2003 through June 31, 2016. Patients were selected if "CrossFit" was identified in their records ($n=312$) and excluded if injuries were deemed not related to CrossFit ($n=166$), CrossFit participation was questionable ($n=25$), or patient had medical conditions that could influence their risk for injury outside of CrossFit ($n=6$). Data collection included sex, age, injury site, diagnosis, diagnostic imaging, and treatment. Injury site, diagnosis, diagnostic imaging, and treatments were descriptively analyzed. Chi-square (χ^2) analyses were employed to compare CrossFit injuries based on sex and age with a significance level of 0.05. **RESULTS:** A total of 115 medical charts met inclusion criteria (male: $N=55$ female: $N=60$ age: 25.2 ± 10.4). The most common injury sites were: knee (27.0%), spine (24.3%), and shoulder (16.5%). The top five diagnoses were muscle strain (6.1%), back pain (5.2%), patellofemoral stress syndrome (PFSS) (4.3%), labral tears (4.3%) from hip (2.6%) and shoulder (1.7%) joints, shoulder pain (4.3%), and knee pain (4.3%). Diagnostics included MRI (46.0%), plain radiographs (39.2%), CT (7.4%), and ultrasound (7.4%). The most commonly prescribed treatments were PT/OT (32.3%), activity modification (23.1%), NSAIDS (13.6%), crutches/brace/splinting/compression sleeve (10.4%), and injections (7.2%). Males sustained more shoulder injuries than females (68.4% vs. 31.6%, $p=0.049$). All CrossFit athletes diagnosed with PFSS were female (100% vs. 0%, $p=0.029$). Age comparison analysis showed that injuries to the spine were more frequently documented in ≤ 19 years old compared > 20 years old (53.6% vs. 46.4%, $p=0.016$). **CONCLUSIONS:** Injuries from CrossFit appear to differ by sex and age. Males presented with more shoulder injuries than females while females had the greatest incidence of patellofemoral stress syndrome. Pediatric athletes sustained more injuries to the spine. More research is warranted regarding CrossFit injuries, particularly in the pediatric athlete.

2522 Board #42 June 2 11:00 AM - 12:30 PM
Injury Epidemiology at Multi-Day Youth Soccer Tournaments
 Ariel Kiyomi Daoud, Elyce Lamphere, Kayla Burnim, Anne Skelton, Julie C. Wilson. *Children's Hospital Colorado, Aurora, CO.*
 (No relationships reported)

PURPOSE: Sports medicine clinical teams are often employed to provide first-aid, triage, and emergency care at multi-day youth athletic tournaments. This study analyzed data collected from medical tent visits at six multi-day soccer tournaments hosted by competitive clubs in 2015 and 2016 to provide insight into frequency, distribution, injury type, and treatment. This data will enable optimal preparation of sports medicine teams for future tournaments.
METHODS: Sports medicine team members electronically captured clinical data for each medical tent encounter at six multi-day soccer tournaments. These records were assessed for completeness and excluded if date of birth, treatment, or the day of encounter were not documented. Data was sorted by 3-day, 4-day, or 5-day tournaments. Chi-squared testing within tournament types was performed for tent visit frequency, treatment, and body region probability.
RESULTS: Of 3207 encounters, 2896 were included for analysis [5-day: $n = 1655$, 4-day: $n = 1001$, 3-day $n = 240$]. Participant age ranged from 6-19 years [mean = 15.2 years, $SD = 1.8$]. Significant differences were found between tournament day and tent visit frequency. For 3-day events, most tent visits occurred on Day 2 [48.7%, $p < 0.001$]. For 4-day events, most tent visits occurred on Day 3 [41.2%, $p < 0.001$]. For 5-day events, most tent visits occurred on Day 4 [41.0%, $p < 0.001$]. No significant difference was found between treatment delivered and tournament day for 3-day, but existed for 4- and 5-day with Ice, Taping, and Injury Evaluation as the most reported treatments in that order [$p < 0.0001$]. Lower Extremity was most likely to present to the medical tent [$n = 1115$], followed by Upper Extremity [$n = 147$], and Head/Neck [$n = 136$] out of 1454 records with body region recorded [$p < 0.009$].

CONCLUSION: During multi-day youth soccer tournaments, sports medicine teams can optimize staffing and resources by preparing for increased frequency of tent visits during the middle and end of the tournament, scheduling staff capable of expected treatments, and ensuring adequate supplies for predominantly lower extremity injuries and treatments. Future data collection for multi-day tournaments should include injury time of day, games played, and non-injured player data to allow for incidence calculations and control comparisons.

2523 Board #43 June 2 11:00 AM - 12:30 PM
The Impact of Grant Funding on Physical Fitness Levels of School Children
 Michael A. Jennings, Dale D. Brown, FACSM, Kelly R. Laurson, Skip M. Williams, Mary L. Henninger, Daniel Phelps. *Illinois State University, Normal, IL.*
 Email: jenningsm@myunit5.org
 (No relationships reported)

Purpose: The purpose of this study was to evaluate the effect of a three year Carol M. White Physical Education Program (PEP) Grant on fitness levels of students in grades K-12. **Methods:** A total of 1251 students (616 female and 635 male), 5-18 years of age (mean 11.07) participated in the FitnessGram series of health related physical fitness assessments (aerobic capacity, muscular strength, and muscular endurance) in each of the 3 years of the grant project. Basic anthropometric measures of height and weight were recorded for each student and used in the calculation of body mass index (BMI). Along with BMI, the assessment scores utilized in this investigation included: the 20 meter PACER test (PACER), Push Up Test (PT), and Curl Up Test (CT). Students performed these assessments as directed by a licensed physical education teacher during the spring semester of each of the 3 years of the grant project. Upon completion of the assessments, students were classified into Fitness Zones based on FitnessGram standards. The classifications for BMI were as follows: Healthy Fitness Zone (HFZ), Needs Improvement (NI), Needs Improvement - Health Risk (NI-HR), or Very Lean (VL). The PACER, PT, and CT only classify students into 2 Fitness Zones: HFZ and NI. **Results:** The data show an increase in number of students in the HFZ for each of the assessments from year 1 to year 2, with an average increase of 8.75%. The PT garnered the greatest percentage of increase at 12%, while the percentage of students in the HFZ for BMI only increased 6%. Conversely, the data from year 2 to year 3 show decreased percentages of student in the HFZ for all assessments, except for the PACER test which remained unchanged (63%). The percent of student in the HFZ decreased 2%, 11%, and 10% for BMI, CT, and PT respectively. Even with the decrease in percent of students in the HFZ for these assessments, the year 3 percentages remained higher than the initial assessment year for both the BMI and PACER with a 4% and 7% increase respectively. **Conclusion:** The increase in overall percent of students classified in a HFZ for multiple physical fitness assessments shows that a 3-year PEP grant had a positive impact on students' physical fitness levels. This improvement coupled with the increased availability of resources and funding make the PEP grant an asset.

Effect of Yoga, Meditation or Body Awareness on Sports Performance and Attention in Futsal Players
 Marcio Cascante-Rusenhack, Gerardo Araya-Vargas, Walter Salazar-Rojas, Alejandro Salicetti-Fonseca, Jose Moncada-Jiménez. *University of Costa Rica, San José, Costa Rica.*
 Email: marcio.cascante@ucr.ac.cr
 (No relationships reported)

PURPOSE: To determine the chronic effect of yoga, meditation or body awareness practice produces significant improvements in attention and sports performance in Futsal players. A second aim was to determine the association between attention and sports performance. **METHODS:** Thirty subjects (15 men, 15 women) were randomly assigned to four groups: Meditation (MG) ($n = 8$, mean age = 20.8 ± 2.4 yr.), Yoga (YG) ($n = 8$, mean age = 21.2 ± 1.6 yr.), Body awareness (BA) ($n = 7$, mean age = 20.5 ± 1.4 yr.), and Control Group (CG) ($n = 7$, mean age = 21.0 ± 2.3 yr.). Before (pre) and after (post) nine yoga, meditation or body awareness sessions, the subjects were measured on attention with the Stroop Test, and on sports performance with the Loughborough soccer passing test. **RESULTS:** There was no significant interaction in attention and sport performance ($p > 0.05$). There were significant main effects in measurement (pre- to -post) on attention (Pre = 51.7 ± 5.7 vs. Post = 54.6 ± 4.5 hits, $p < 0.05$), and for sport performance (Pre = 65.2 ± 5.7 vs. Post = 63.6 ± 5.1 -s, $p < 0.05$).

No significant correlations were found between the change in attention scores and sport performance in experimental groups MG ($r = 0.62$), YG ($r = 0.20$), BA ($r = 0.16$), and CG ($r = 0.20$) ($p > 0.05$). **CONCLUSIONS:** Meditation, yoga and body awareness exercises do not influence attention or sport performance in Futsal players.

2525 Board #45 June 2 11:00 AM - 12:30 PM
The Utilization of Different Cues in Visual Anticipation in Skilled Table Tennis Players

Chenglin Zhou, Yingzhi Lu, Yingying Wang, Qiqi Yang.
Shanghai University of Sport, Shanghai, China.
 Email: chenglin_600@126.com

(No relationships reported)

It is reported that expert motor skill performance are superior to less skilled individuals to predict the outcome of an object in striking sport, such as table tennis, due to the ability of using advance information, such as body kinematics cue. Meanwhile, it also revealed that the accuracy would be improved with the visual information (such as the ball trajectory cue). It is unclear the utilization strategies on these two cues in striking sports between expert and novice.

PURPOSE: To investigate the utilization of body cue and ball cue in the visual anticipation and compare the utilization strategies among skilled players, less skilled players and non skilled players.

METHODS: 74 participants were grouped into Elites group (EG, $n=24$), Amateur group (AG, $n=26$) and Novice group (NG, $n=24$) based on the table tennis and skilled level. Participants were presented with short video-clips of serve that were partially occluded (racket-ball contact (T), 50ms after the contact (T+1), 100ms after the contact (T+2)) and probably congruence or incongruence (T'+1; T'+2) within the body cue and ball cue. The task was to judge whether the ball would land on left or right side and the accuracy was analyzed.

RESULTS: The results showed that the EG ($.92 \pm .07$) had a higher accuracy than the other two groups (AG: $.82 \pm .07$, $p < .001$; NG: $.78 \pm .10$, $p < .001$) when the video-clips were occluded before the ball cue showed up, while both the EG (T+1: $.98 \pm .04$; T+2: $.97 \pm .04$) and AG (T+1: $.95 \pm .05$; T+2: $.95 \pm .07$) had a better accuracy than the NG (T+1: $.88 \pm .07$; T+2: $.87 \pm .11$) when the ball cue was offered in the video-clips. Meanwhile the accuracy of EG (T'+1: $.67 \pm .16$; T'+2: $.90 \pm .17$) and AG (T'+1: $.64 \pm .16$; T'+2: $.90 \pm .14$) was sharply decreased in the incongruence video-clips, but their ability to discriminate these two cues was better, comparing with the NG (d -prime: $F(2, 68) = 10.491$, $P < .001$; EG: $-.77 \pm .41$; AG: $-.61 \pm .41$; NG: $-.52 \pm .27$).

CONCLUSIONS: This leads us to argue that experts (both elites and amateur) had the anticipatory advantage than the novice in striking sport. They mainly utilized the body cue to anticipate the outcome, while the novice needed the ball cue to do anticipation. Also, the experience levels of the experts moderated the utilization strategy in visual anticipation. Supported by NSFC (No. 31571151)

2526 Board #46 June 2 11:00 AM - 12:30 PM
Socially Prescribed Perfectionism Might Predict Enhanced Performance When Racing Against an Opponent

Lieke Schiphof-Godart¹, Marco J. Konings², Florentina J. Hettinga². ¹University of Groningen, Groningen, Netherlands. ²University of Essex, Colchester, United Kingdom. (Sponsor: Carl Foster, FACSM)
 Email: l.schiphof@umcg.nl

(No relationships reported)

Recent research has shown that racing against an opponent can improve endurance exercise performance (Konings et al, 2016). To what extent athletes can be motivated by racing against an adversary might depend at least partially on personality characteristics such as type of perfectionism.

PURPOSE: We sought to explore the relationship between self-oriented (SO) and socially prescribed perfectionism (SPP) (Hewitt & Flett, 1991) and time-trial performance. We hypothesized that SPP would be related to performance enhancements associated with the presence of an opponent, but that SO would not. **METHODS:** Twelve experienced cyclists (45.8 ± 7.0 years) completed four 4-km time trials (TT) on a VeloTron cycle ergometer. Participants performed three TTs without opponent (TT1no, TT2no, TT3no) and one TT against a virtual opponent (TTopp). Mean performance on the three trials without an opponent was calculated and the difference (Δ TTno-TTopp) between the resulting "meanTTno" and TTopp was assessed for each participant. Participants also answered the 12-item "perfectionism in sport scale" (PPS-P) (Hill et al., 2016) on a 6-point Likert scale before the first race. Spearman correlations of the participants' mean scores on the PPS-P and Δ TTno-TTopp were calculated. **RESULTS:** Overall, there was no significant difference in performances over the 4 trials: T1 = 385.86 ± 18.07 s; T2 = 380.31 ± 20.75 s; TTno = 377.66 ± 17.40 s and TTopp 378.86 ± 19.68 s. Mean score on PPS-P was 4.29 ± 0.96 for SO and 2.83 ± 0.91 for SPP. A significant positive correlation was found between SPP and Δ TTno-TTopp ($\rho = 0.867$, $p < 0.01$), but we found no relationship between SO and Δ TTno-TTopp. **CONCLUSION:** Previous studies have shown that being confronted

with a (virtual) opponent enhances endurance athletes' performance. In the present group of cyclists, overall 4-km performances with and without opponent did not differ significantly. Interestingly, our results show that the performance enhancing effect of a virtual opponent during a 4 km cycling trial is correlated to socially prescribed perfectionism in sport. These findings support current literature and our hypothesis that the positive effect of racing against an opponent might differ according to athletes' psychological characteristics.

Exploring Parental Preferences for Choosing Youth Flag or Tackle Football

Mallory McElroy¹, Katie Stephenson-Brown¹, Samantha Mohler¹, Nathan D'Amico¹, Anthony Kontos², R.J. Elbin¹.

¹University of Arkansas, Fayetteville, AR. ²University of Pittsburgh, Pittsburgh, PA.

Email: mmcelroy@uark.edu

(No relationships reported)

Youth football participation rates have decreased 27.7% over the last six years. One of the primary reasons posited for this decline is parental concerns about concussion. In an attempt to provide an alternative to tackle football, many youth leagues are offering a choice of flag or tackle football. In fact, flag football participation has risen by 8.7 percent from 2014-2015. However, there is a lack of research exploring factors associated with parental preferences for choosing flag over tackle football.

PURPOSE: To explore factors associated with parental preferences for choosing youth flag and tackle football. **METHODS:** Two youth sport leagues offering a choice of both youth tackle and flag football for players aged 5 to 15 years distributed an online survey to 859 parents of youth football participants. The 50-item online survey was administered via Qualtrix and gathered responses on several variables that included parental preference for flag or tackle, history of football participation, injury history, and concussion knowledge. A series of chi-square analyses with odds ratios (OR) and 95% confidence intervals (CI) were used to assess associations and likelihood of select variables and youth football preference. **RESULTS:** A total of 29% (245/859) of parents completed the online survey. Seventy-seven percent (157/203) of parents preferred tackle instead of flag football. Parents that previously played or had a spouse/partner that played football were 2.61 times more likely to prefer flag over tackle ($\chi^2[1, 199] = 4.87$, $p = .03$, 95% CI = 1.09 - 6.25). Parents fearful of their child getting a concussion were 2.41 times more likely to prefer flag instead of tackle football ($\chi^2[1, 199] = 6.31$, $p = .01$, 95% CI = 1.10 - 4.86). Parental history of concussion ($p = .42$), concussion knowledge ($p = .67$), perceived child size ($p = .64$), speed ($p = .51$), and strength ($p = .25$) were not associated with football preference. **CONCLUSIONS:** When given a choice between flag or tackle football for their children, a majority (77%) of parents prefer tackle football. However, parents who played football or are fearful of their child getting a concussion are more likely to prefer flag for their children. Flag football may provide children with a physically active sport that parents view as less risky than tackle football.

2528 Board #48 June 2 11:00 AM - 12:30 PM
Pain Coping Skills of Competitive High School Pole Vaulters

Joshua T. Holland, Cody M. Smart, Michael C. Meyers, FACSM. Idaho State University, Pocatello, ID.

(No relationships reported)

For competitive pole vaulters, their abilities to cope with painful challenges and subsequent injuries are crucial to overcome obstacles in sport development. In a sport with highly technical and explosive training, the failure to adapt to these competitive challenges could result in suboptimal performance and rehabilitative outcomes. Therefore, the ability to appropriately cope with pain and potential injury is essential for competitive success, especially at this young stage of development. **PURPOSE:** To quantify the coping skills of pain and injury in competitive high school pole vaulters. **METHODS:** Following written informed consent, 59 high school pole vaulters completed the Sports Inventory for Pain (SIP; Meyers et al., 1992): direct coping (COP), cognitive (COG), catastrophizing (CAT), avoidance (AVD), body awareness (BOD), and a composite score referred to as total coping resources (TCR). Data were grouped by skill level (novice, intermediate, advanced), gender, and academic classification (upperclassmen, lowerclassmen). **RESULTS:** MANOVAs (Wilks' Lambda) indicated no significant main effects across skill level ($F_{10,104} = 1.511$; $p = 0.146$), gender ($F_{5,53} = 1.128$; $p = 0.357$), or academic classification ($F_{5,53} = 1.440$; $p = 0.225$). Although no significance, there was a trend for upperclassmen to respond higher in COP, COG, CAT, BOD, and TCR. **CONCLUSION:** Although, findings may have been influenced by a limited sample size, pain coping skills among this group reflected above average responses when compared to normative values across other athletic populations. At this early stage of mental and physical development, it is imperative that coaches devote time to the psychological challenges these athletes will face during competition. Further research is warranted assessing challenges from larger populations, as well as to determine the efficacy of pain coping skills interventions.

Influence of Parent and Child Concussion History on Parental Knowledge and Attitudes Regarding Concussion

Melissa C. Kay¹, Johna K. Register-Mihalik¹, Richelle M. Williams², Jason P. Mihalik¹, Tamara C. Valovich McLeod².
¹University of North Carolina - Chapel Hill, Chapel Hill, NC.
²A.T. Still University, Mesa, AZ.
 Email: mkay@email.unc.edu
 (No relationships reported)

Parents' knowledge and attitudes towards concussions are often a vital factor affecting care for injured adolescent athlete. It is important to understand the role previous experiences play in regards to current concussion knowledge and attitudes. **PURPOSE:** To determine the influence of parental and child concussion history on parental attitudes and knowledge towards concussive injury. **METHODS:** Parents of youth sport athletes (n=234; males: n=82; females: n=144; age=44.0±6.3yrs) completed a pre-validated survey for concussion knowledge (max score possible=28) and attitudes (max score possible=49). Higher scores indicated better knowledge and attitudes towards concussive injury. Parents reported the frequency of concussion diagnosis and/or experience of concussion-related symptoms, and whether their child had a diagnosed concussion or experienced concussion symptoms (yes/no). Linear regression models were used to understand the association between concussion history variables and knowledge and attitudes (alpha level 0.05 *a priori*). **RESULTS:** Twenty-seven percent (n=63) of parents had a previously diagnosed concussion while 43% (n=101) had experienced at least one symptom of a possible concussion without reporting a history of diagnosed concussion. Only 8% (n=19) of parents reported their child having a previously diagnosed concussion while 26% (n=61) reported their child had experienced symptoms of a possible concussion. Mean parental knowledge and attitude scores were 23.3±2.5 and 46.3±3.7, respectively. Parents with no previously diagnosed concussions had significantly lower total knowledge scores (mean=23.0±2.5; p<0.001) than those with a previous concussion (mean=23.9±2.3). Those who had never experienced symptoms of a concussion trended towards significance (p=0.05). There were no associations between any of the concussion history variables (parent or child) and attitudes. **CONCLUSIONS:** Parents with no concussion history may benefit from enhanced education. However, given the multifaceted nature of recognizing and responding to concussion, it is important to look further and identify possible driving factors to improve educational efforts within this population. This study was funded in part by the National Operating Committee on Standards for Athletic Equipment.

Prevalence Of Muscle Dysmorphia In Male and Female NCAA Division III Athletes.

Greg Farnell. *John Carroll University, University Heights, OH.*
 (Sponsor: Ellen Glickman, FACSM)
 (No relationships reported)

INTRODUCTION: In society today, body image has been, and continues to be, a growing concern for individuals. Muscle dysmorphia (MD) is a preoccupation with the idea that one's body is not sufficiently lean and/or muscular. Many associated disorders and risks of muscle dysmorphia have been identified including exercise dependence and increased anabolic steroid use. To date, few studies have investigated muscle dysmorphia in both male and female college athletes. **PURPOSE:** The purpose of this study was to examine the prevalence of muscle dysmorphia characteristics in NCAA Division III male and female athletes. **METHODS:** 297 athletes (188 males and 109 females) from 16 varsity sports teams (8 men's teams and 8 women's teams) were recruited from a private NCAA Division III school in the eastern United States. Data were collected via the Muscle Dysmorphia Inventory (MDI), which is a 27-item self-report measure designed for the assessment of MD. The 27 questions are divided into 6 sub-sections that examine different areas of behavioral and psychological characteristics associated with MD. These sub-categories are 1. Diet; 2. Supplement usage; 3. Physique protection; 4. Exercise dependency; 5. Size/symmetry; and 6. Pharmacology. The questionnaire was distributed and collected at the end of a sports practice session or team meeting. A one-way ANOVA was used to determine any difference by sport and an independent *t* test was used for differences by gender using IBM SPSS 23. **RESULTS:** The results demonstrated a significant difference by sport in 5 of the 6 sub-categories of the MDI (Diet: $p < .001$; Supplement: $p < .001$; Physique: $p < .001$; Exercise dependency: $p = .049$; Size/symmetry: $p < .001$; and Pharmacology: $p = .214$). The results also demonstrated a significant difference between male and female athletes for all 6 sub-categories of the MDI (Diet: $p < .001$; Supplement: $p < .001$; Physique: $p < .001$; Exercise dependency: $p = .004$; Size/symmetry: $p < .001$; and Pharmacology: $p = .019$). **CONCLUSIONS:** The current results suggests that Division III college athletes are indeed at a risk of developing muscle dysmorphia and its characteristics. This information may be valuable in helping sport coaches, strength and conditioning coaches, athletic trainers to identify warning signs and characteristics of muscle dysmorphia.

ACSM May 30 – June 3, 2017

2531 Board #51 June 2 11:00 AM - 12:30 PM

Coach-identified Barriers To Removing Athletes With Concussion Symptoms From Play: Implications For Concussion Education

Emily Kroshus, 98121. *University of Washington, Seattle, WA.*
 (No relationships reported)

PURPOSE: Coaches play a critical role in concussion safety. At the high school level, most contact sports teams do not have an athletic trainer on the sidelines of games or practices. This means that coaches are often the adult responsible for identifying if an athlete is experiencing symptoms of a concussion that warrant removal from play for further evaluation from a medical professional. To-date, there has been little research conducted among high school coaches to determine what makes coaches more or less likely to remove an athlete with a suspected concussion from play. The present study sought to describe what coaches considered to be barriers and to determine whether coaches who experienced barriers more strongly were less likely to remove an athlete from play, independently of their concussion knowledge.

METHODS: Participants were 250 Washington state public high school coaches who completed a written survey (92% response rate). Standardized measures assessed concussion knowledge, barriers to removing symptomatic athletes from play, and removal from play intentions. Data were analyzed using structural equation modeling. **RESULTS:** The three most frequently endorsed barriers were "athletes tend to hide their symptoms so it's hard for me to know if they've sustained a concussion" (55% of coaches), "the athlete's parents might be upset if I removed their child from play" (44% of coaches) and concern that they "might make a mistake and remove an athlete who has not sustained a concussion" (36% of coaches). Coaches who more strongly experienced barriers were less likely to intend to remove a symptomatic athlete from play for medical evaluation ($B = -0.22$, $p = 0.006$). There was also a strong positive association between concussion knowledge and removal from play intentions ($B = 0.41$, $p < 0.001$).

CONCLUSION: While sports leagues are increasingly mandating concussion education for coaches, it is important that educational interventions be developed to be most impactful on behavior. The present findings indicate that in addition to addressing gaps in concussion knowledge there is a critical need to address coach-identified barriers related to removing symptomatic athletes from play for medical evaluation. Specific implications for concussion education for coaches will be discussed.

Factors That Predict Grit In Collegiate Athletes During The Competitive Season

Mindy H. Mayol¹, Urska Dobersek², K. Lee Everett¹, Matthew D. Beekley, FACSM³. ¹University of Indianapolis, Indianapolis, IN. ²University of Southern Indiana, Evansville, IN. ³DePauw University, Greencastle, IN.
 Email: mmayol@uindy.edu
 (No relationships reported)

Grit is defined as the drive, passion and persistence that one possesses to reach short- and long-term goals. Yet, few studies have measured grit in athlete populations presenting a gap within sport behavior research. **PURPOSE:** To examine possible predictors of grit among collegiate athletes during the competitive season.

METHODS: Three hundred and thirty-two NCAA Division II athletes ($n_{men} = 185$, $n_{women} = 147$) from twenty-two teams ages 18 to 23 years ($M = 19.50$, $SD = 1.36$) completed five self-report questionnaires: Short Grit Scale (GRIT-S), Short Self-Compassion Scale (SSCS), Sport Motivation Scale II (SMS II), State Self-Esteem Scale (SSES) and a demographics questionnaire. The 12-item GRIT-S was used to measure grit, the 12-item SSCS was used to measure self-compassion (having benevolence for one's self in instances of perceived inadequacy, suffering, or failure), the 18-item SMS II scale was used to measure six sport motivation types and the 20-item SSES was used to assess performance state self-esteem (the degree of fluctuations of positive or negative performance-based attitudes toward oneself). A multiple regression analysis was conducted and an alpha level of 0.05 was set for statistical significance. **RESULTS:** Results demonstrated that the following three factors statistically significantly predicted grit during the athletes' respective in-season, $R^2 = 0.34$, $F(3,329) = 55.45$, $p < 0.001$: performance state self-esteem ($\beta = 0.42$, $p < 0.001$), integrated regulation ($\beta = 0.18$, $p < 0.001$), and self-compassion ($\beta = 0.17$, $p = 0.002$). **CONCLUSIONS:** Results revealed that three predictor variables explained 34% of the variance for grit. The findings of the current study suggest that performance self-state esteem, integrated regulation (an autonomous motivation type where there is congruency between an action and an individual's identified values, goals and needs) and self-compassion are significant predictors for grit. Previous grit research in non-athlete populations has illustrated that high levels of "grittiness" predicts goal outcomes regardless of perceived or actual challenges or adversities. This study's finding on athletes, while novel and promising, warrants further investigation into grit and other psychosocial factors on goal attainment and outcomes during the competitive season.

Sport: Relationship Between Age And Skills Perceived By Children Sport Practitioners
 Inransé Oliveira-Silva, Bianca da Silva Peres, Fábio Santana.
UNIEVANGÉLICA, ANÁPOLIS, Brazil. (Sponsor: Carl Foster, FACSM)
 Email: iranoliveira@hotmail.com
 (No relationships reported)

Psychosocial aspects are factors that influence the psyche of the human being in development. Such aspects infer about the behavioral patterns of the individual, causing physical, cognitive and social changes throughout his life (Myers, 2012). One of the effective ways to experience these practices is the sport (Noble et al., 2014). **PURPOSE:** Identify the relationship between age and skills perceived by children assisted by a sports program. **METHODS:** The sample consisted of 50 children of a municipal sports center of Anápolis, who practiced sport twice a week at the school turn against for more than 6 months (30 boys and 20 girls), aged between 7 and 12 years old. The psychosocial aspects of children were assessed using the Brazilian version of the Self-Perception Profile for Children, validated by Valentini et al. (2010). The Brazilian version called Self Perception Child scale (SPCS) is configured in a questionnaire that assesses six specific areas of competence: cognitive skills, emotional skills, motor skills, physical appearance, behavioral conduct, in addition to the global self-worth. **RESULTS:** The children attending showed moderate levels of self perceived competence in the dimensions evaluated in the present study, by gender and age. Such skills are psychosocial aspects that can be influenced when compared to children who do not participate in sports programs. It was evident that the younger children, the lower the influence of the sports program on the skills perceived except in motor racing, which takes place from 9 years old. The sport seems to exert an influence on the self-perception skills (ie cognitive, social, motor and behavioral), especially when there is a longer practice. **CONCLUSIONS:** The skills perceived by children assisted by a sports program only are perceived as the children mature (i.e 11 and 12 years old). Younger children assisted by sports program have no perception of skills, as they only manifest as the action is performed for longer.

Athletic Coping Skills of the Competitive High School Pole Vaulter
 Cody M. Smart, Joshua T. Holland, Michael C. Meyers,
 FACSM. *Idaho State University, Pocatello, ID.*
 (No relationships reported)

A competitive pole vaulters' ability to cope with stressful situations during competition is crucial for optimal development. Therefore, the ability to cope under these circumstances is essential for creating a strong mental capacity that leads to competitive success. **PURPOSE:** To quantify athletic coping skills of competitive high school pole vaulters. **METHODS:** Following written informed consent, 59 high school pole vaulters completed the Athletic Coping Skills Inventory (ACSI; Smith et al., 1995): coping with adversity (COPE), peaking under pressure (PEAK), goal setting/mental preparation (GOAL), concentration (CONC), freedom from worry (FREE), confidence and achievement motivation (CONF), coachability (COAC), and a composite score referred to as personal coping resources (PCR). Data were grouped by skill level (novice, intermediate, advanced), gender, and academic classification (upperclassmen, lowerclassmen). **RESULTS:** MANOVAs (Wilks' Lambda) indicated no significant main effects across skill level ($F_{14,106}=1.146$; $p=0.329$), and academic classification ($F_{7,51}=1.524$; $p=0.180$), but indicated a significant main effect by gender ($F_{7,51}=2.575$; $p=0.024$). Univariate analyses (mean±SD) indicated that males responded higher in PEAK (7.81±3.146 vs. 5.82±2.736; $p=0.013$) than female athletes, whereas females responded higher in COAC (9.75±2.703 vs. 8.26±2.683; $p=0.038$) than males. Although no significance, there was a trend for upperclassmen to respond higher in COPE, PEAK, GOAL, CONC, CONF, COACH and PCR. **CONCLUSION:** Although findings may have been influenced by limited sample size, coping skills among this group reflected subnormal response when compared to normative values across other athletic populations. At this early stage of mental and physical development, it is imperative that coaches devote time to the psychological challenges these athletes will face during competition. Further research is warranted assessing challenges from larger populations, as well as to determine the efficacy of athletic coping skills interventions.

Adolescent Behavior Regarding Concussion
 Brent Harper, Ken Cox, Angela Mickle, Alex Siyufy, Cameron Holshouser, Adrian Aron. *Radford University, Roanoke, VA.*
 (Sponsor: Lynn Millar, FACSM)
 Email: bharper2@radford.edu
 (No relationships reported)

PURPOSE: To assess adolescent male American football players' concussion attitudes and behaviors using a modified Rosenbaum Concussion Knowledge and Attitudes Survey (RoCKAS) questionnaire. **METHODS:** Two groups (n=19) completed the questionnaire. Group 1 (YRL) included youth recreation league players (n=13; ages 11-13) and group 2 (HS) was high school players (n=7; ages 13-18). Responses were scored as "safe" or "unsafe" based on RoCKAS guidelines. Normative data was established with expected "safe" answers set at 90% and "unsafe" set at 10%. **RESULTS:** For general concussion behavior questions (i.e. I feel that concussions are less important than other injuries, and I feel that an athlete has a responsibility to return to the game even if it means playing while still experiencing symptoms of a concussion), 71.3% of responses were safe and 38.7% unsafe ($X^2=31.25$, $p=0.0001$). There was a difference between group 1 and 2 responses. Safe responses were greater for the HS subjects (Pearson chi = 4.4, $p=0.03$). Responses to the four situational questions were safe 32.5% and unsafe 67.5% ($X^2=293.9$, $p=0.0001$) with no difference between groups (Pearson chi = 0.9, $p=0.34$). When situational questions were analyzed for return to play following an early season concussion with persistent symptoms, 70% demonstrated safe behavior ($X^2=8.9$, $p=0.003$) by not returning the athlete to play with no difference between groups (Fisher $p=0.35$). If the situation posed included returning a symptomatic concussed athlete to play in a playoff game, 75% selected unsafe ($X^2=80.0$, $p=0.0001$) return to play with no difference between groups (Fisher $p=0.61$). **CONCLUSIONS:** As youth football athletes mature, they improve in concussion understanding. However, players' attitudes and behaviors regarding situational return to play decisions did not improve with age, but continue to demonstrate unsafe behavior.

2536 Board #56 June 2 11:00 AM - 12:30 PM
Assessment of Disordered Eating and Orthorexia Nervosa in Endurance Athletes Following Gluten and Wheat-free Diets
 Sarah E. Weber¹, Margaret M. Harris¹, Hattie H. Wright², Melinda M. Manore, FACSM³. ¹University of Colorado-Colorado Springs, Colorado Springs, CO. ²University of the Sunshine Coast, Australia, Sunshine Coast, Australia. ³Oregon State University, Corvallis, OR. (Sponsor: Melinda M Manore, FACSM)
 (No relationships reported)

Endurance athletes recognize that a leaner and lighter body can improve performance outcomes. Currently, there is limited data assessing disordered eating, including orthorexia nervosa, in endurance athletes choosing to adhere to gluten and wheat-free diets (GWDs). **Purpose:** The aim of this study was to assess disordered eating, including orthorexia behaviors, in endurance athletes following GWDs compared to athletes following a normal diet (ND). **Methods:** Endurance athletes (ages 18-55y) were invited to participate in a web-based questionnaire via multiple sporting websites. The survey included demographic information, questions regarding beliefs and attitudes about GWDs, and two validated disordered eating and orthorexia questionnaires: Three Factor Eating Questionnaire (TFEQ-R18) and the ORTO-15. Athletes following GWDs were combined. Descriptive statistics and independent sample t-tests comparing groups using SPSS with significance set at $p<0.05$. **Results:** Of the athletes responding (n=100), only 73 had usable data (63 females; 9 males; 1 transgender). One-third (37%; n=27) reported being on GWDs (clinically diagnosed gluten sensitivity (n=10); celiac (n=1)). ND's were significantly older (44+11 y) than GWD (39+12 y, $p=0.05$). There were no differences between groups for self-reported body mass index (GWD=22+3 vs. ND=24+4 kg/m²), orthorexia scores (GWD=37.1+6.9 vs. ND=39.0+6.3), and TFEQ subscale scores for emotional eating (GWD=8.2+2.1 vs. ND=8.2+2.2), dietary restraint (GWD=14.4+4.1 vs. ND=15.8+3.9) and uncontrolled eating (GWD=24.7+5.3 vs. ND=25.1+4.8). Athletes classified with orthorexia (75.3%; n=55) had significantly lower TFEQ scores in restrained, emotional, and cognitive disordered eating than those not categorized as having orthorexia (24.7%; n=18) ($p<0.001$). **Conclusion:** This sample of endurance athletes displayed high levels of orthorexia and disordered eating behaviors but there were no differences between GWD and ND groups. Further studies are needed to determine the extent of nutritional and behavioral risk in endurance athletes presenting with orthorexia.

Psychological Follow-up of 6 Months Training for a Half Ironman Triathlon
 Vincent Gosselin Boucher, François Lalonde, Alain Steve Comtois. *Université du Québec à Montréal, Montréal, QC, Canada.* (Sponsor: Jean-Pierre Boucher, FACSM)
 Email: vincent.gosselin.boucher@gmail.com
 (No relationships reported)

Preparation for an endurance event amongst amateur athletes requires a major investment in time as well as a proper physical and mental training. Even if there is an increase of participation for endurance events in the country, there are few studies that have reported the psychological effects of such a demanding training for age groups athletes. **PURPOSE:** The aim of this study was to characterise the psychological state of recreational athletes during a six months training prior to a half Ironman triathlon. **METHODS:** Thirty-one amateur athletes were recruited for this observational study. Participants were 40 ± 9.1 years old; and had a body weight of 74 ± 12.7 kg and a height of 172 ± 10.12 cm. All participants underwent a physical fitness assessment in January and two weeks prior to the half ironman event, held in June. They followed a training program supervised by a registered kinesiologist based on the Ironman University™ annual planning. The training volume was 410.4 ± 201.48 min per week. For each month of training, participants received an email with a link to complete a monthly series of questionnaires that included: Facets Mindfulness Questionnaire Short Version (FFMQsv), Profile mood scale (POMS), Positive and Negative Affect Schedule (PANAS) and Sport Motivation Scale 2 Revised (SMS-2R). **RESULTS:** Vigour, anxiety and fatigue, POMS sub scale, significantly changed during training ($p < 0.05$). Positive emotions increased over 3 months to stabilise until the competition. Participants felt different types of motivation regulation: intrinsic (15.9 ± 1.76), integrated (15.9 ± 1.98), identified (15.7 ± 1.87) and a little less ($p < 0.05$) for introjected regulation (13.3 ± 1.62). They were significantly different ($p < 0.01$) from external (4.9 ± 1.08) regulation motivation and non-regulation (3.6 ± 0.73). Mindfulness sub scale, Observation and Describe factors, were the only factors that significantly increased or decreased during the 6-months training ($r^2 = 0.35$ and $r^2 = 0.30$, respectively). **CONCLUSIONS:** Athletes who engages in this type of event have a high intrinsic motivation. We also noted that motivation, mindfulness and mood state follow the macrocycle of training. Thus, specific interventions and mental training could be structured around these important elements.

2538 Board #58 June 2 11:00 AM - 12:30 PM
Vitamin D, Serum Ferritin, and College Athlete Burnout: A Pilot Study
 Brigid Byrd¹, Jeffrey Martin¹, Kristin Landis-Piwowar², Carrie Aprik², Tamara Hew-Butler, FACSM². ¹Wayne State University, Detroit, MI. ²Oakland University, Rochester, MI. (Sponsor: Tamara Hew-Butler, FACSM)
 (No relationships reported)

PURPOSE: To examine the relationship between serum 25 hydroxyvitamin D concentration ([Vit D]), serum ferritin concentration ([Fe]) and athlete burnout (AB) in Division I (D1) collegiate athletes. **METHODS:** Seventy-two (males = 24) DI college athletes (cross-country, swimming, basketball, women's soccer) completed blood draws and psychosocial measurements both pre- and post-competitive season. Serum was analyzed for 25 hydroxyvitamin D and ferritin at a certified hospital laboratory. The athlete burnout questionnaire (ABQ) was completed post-competitive season (Raedeke & Smith, 2001). Subscales of ABQ include devaluation of sport, emotional and physical exhaustion, and reduced sense of accomplishment. **RESULTS:** Linear regression analyses on the entire cohort (male and female athletes combined) revealed no statistically significant relationships between pre-to post-competitive season change (Δ) for either Δ [Vit D] ($p = .78$) or Δ [Fe] ($p = .69$) with regards to any subscale variable within the ABQ. When separated by gender, Δ [Vit D] ($p = .57$) and Δ [Fe] ($p = .57$) did not significantly predict AB in females. However, a significant decrease in pre to post competition Δ [Vit D] ($Mean \pm SD = -8.45 \pm 4.33$) did significantly predict and explain 20.6% of the variance of male athlete perceptions of devaluation of sport ($p < .05$). Another linear regression showed that pre-season [Fe] ($Mean \pm SD = 68.53 \pm 31.49$) predicted and explained 16% of the variance of male athlete perceptions of physical and emotional exhaustion from sport ($p \leq .05$). Additionally, medium to large correlations were noted in male athletes between [Fe], [Vit D], and AB including pre-season [Fe] and AB ($r = .41; p < 0.05$), post-season [Fe] and AB ($r = .36; NS$), and Δ [Vit D] and AB ($r = .41; p < 0.05$). **CONCLUSION:** These preliminary findings support a proposed interplay between mood and chemistry, with respect to Δ [Vit D], Δ [Fe], and AB, particularly in male collegiate athletes who live and train in latitudes above 37 degrees north (Vitamin D winter). Although significant negative relationships were found in male athletes only (the lower [Vit D] and [Fe], the greater chance of AB) we will continue exploration in both genders with randomized (supplement) trials, greater number of subjects, and extended testing time through the winter.

2539 Board #59 June 2 11:00 AM - 12:30 PM
Role Of Stressors In Physiological And Psychological Parameters Associated With Golf Playing
 Samantha Bernardi. *University of Pavia, Pavia, Italy.*
 Email: samantha.bernardi01@universitadipavia.it
 (No relationships reported)

PURPOSE: A 31-year-old Italian professional golfer shows alteration in putting performance: lack consistency of putting performance; low ability to manage different situation and unexpected events; inability to quiet himself; low awareness about causes and motivation of his emotional states. The aim was to understand how variables related to anxiety affects athletic movements in different stressful situations. **METHODS:** Study consists in: baseline - paper and pencil questionnaire + training (T_0); Experimental Phase - task with goal (T_1), Experimental Phase - task with public (T_2); Post-training (T_3). It was administered STAI-X1 (T_0 and T_3) and STAI-X2 (T_0). The heart rate (bpm) was recoding by a heart rate monitor. The swing analysis was performed by SAM PuttLab. **RESULTS:** Data shown an improvement in the movement consistency at T_1 and T_2 than T_0 and T_3 . The percentage obtained at T_1 (72%) is similar to that obtained by PGA professional golfers (75%) and exceeds at T_2 (81.8%). Also, in this two sessions there was an increase of accuracy due to an acceleration of the forward swing time ($T_1 = 890$ ms; $T_2 = 820$ ms). The score of STAI X2 was 31/80 (anxiety of lower middle level) and the scores of STAI-X1 was 25/80 at baseline and 23/80 to post-test (no state anxiety). These results agree with the presence of a normal bpm at T_0 and T_2

CONCLUSIONS: Putting analysis shown an unexpected improvement of performance in the presence of stressors. These data shown that psychological variables are not sufficient to explain the observed phenomenon. An emotional state is not in the head, but is rather the elementary manifestation of our being situated. Being emotionally situated corresponds to a tension which is born and which is continually renewed in the sphere of social and practical engagement but which, at the same time, reflects and actualizes the story of the individual. There are two affective dispositions: *Inward* and *Outward*. Unlike classic construct of anxiety, this emotional disposition may vary across different periods of life and in accordance with contextual factors that can contribute to determine the interplay between established traits and present experience. This case suggests that you need to incorporate different parameters that take into account the active and continuous interaction with the environment.

Psychophysiological Stress In Women Athletes Elite Tennis Players
 Ivete Balen¹, Maressa P. Krause¹, Birgit Keller², Carla Cristina Tagliari³, Cintia L. N. Rodacki¹, Ricardo W. Coelho². ¹UTFPR, Curitiba, Brazil. ²UFPR, Curitiba, Brazil. ³FAFES, Curitiba, Brazil.
 Email: ivetebalen@gmail.com
 (No relationships reported)

PURPOSE: To analyze psychophysiological stress by saliva cortisol in female tennis athletes, 16 and 18 years-old, during a circuit of an international tournament.

METHODS: Forty-eight female tennis players, enrolled in the Copa Guga-Kuerten. Cortisol samples were collected by saliva, using a Salivette® tube, and analyzed by ELISA method. Samples were collected during the meeting (C-pre) and immediately post-game (C-post). Data are described by mean and standard deviation, and analyze by an ANCOVA (2x2): categories: 16 and 18 years; and, winners and losers), using C-pre measures as covariant ($p < 0.05$).

RESULTS: C-pre (8.0 ± 3.6 nmol/L) differed from C-post (13.0 ± 6.2 nmol/L) when the two categories were analyzed simultaneously ($t = -7.526; p < 0.000$), indicating an elevation of cortisol during the sportive event. There were not differences of cortisol concentrations between winners and losers ($F_{1,98} = 2.686; p = 0.104$). There were not significant associations between athletes' ranking with C-pre ($0.083; p = 0.602$) and C-post ($-0.037; p = 0.818$), which may indicates that athletes' rank position do not influence on cortisol concentration.

CONCLUSIONS: This study showed that female tennis athletes had a higher cortisol concentration after the game. However, only a few studies evaluated the influences of sportive competition on cortisol reporting controversial results. Therefore, it is suggested that further studies quantifying other factors related to stress, purposing a better understanding of its influences on athletes' performance.

Modifications Of Negative Attitudes Toward Obesity In Pre-professionals Of Exercise Sciences.
 Edda Lorenzo-Bertheau¹, Francisco Cruz-Quintana², Athanasios Pappous³, Yaira Barranco-Ruiz, 060150¹, Emilio Villa-González¹, Jacqueline Schmidt-RioValle, 18015⁴. ¹Faculty of Health Sciences, National University of Chimborazo, Riobamba, Ecuador. ²Faculty of Psychology, University of Granada, Granada, Spain. ³University of Kent, Kent, United Kingdom. ⁴Faculty of Health Sciences, University of Granada, Granada, Spain.
 Email: elorenzo@unach.edu.ec
 (No relationships reported)

PURPOSE: To investigate the effect of short intervention programs for changing negative attitudes towards obesity through strategies of dynamics intergroup contact in pre-professionals of exercise sciences and determine the most effective strategy. **METHODS:** A total of 56 students of exercise sciences (23.95 ± 4.70-years; 75% male) from Ecuadorian universities participated in this study. The sample was randomly divided into a control group (CG: without intervention, n = 14) and three experimental groups with different dynamics intergroup contact interventions (DC: Direct-Contact, n=14, IC: Imagined Contact, n=13 and CTP: Contact to Take-Perspectives, n=15). Participants were assessed before and after interventions through the AFA (Antifactor Attitudes Questionnaire) for explicit attitudes toward obesity in three dimensions (aversion, fear of gaining weight and unwillingness), and the IAT (Implicit Association questionnaire Antifactor, electronic version) for measuring implicit attitudes. The body mass index was normal (22.5 ± 1.75) for the participants. Statistical comparisons between groups before and after the interventions were analyzed using the Mann-Whitney U test for the AFA, and Chi-square test for the IAT. **RESULTS:** AFA questionnaire revealed that the implementation of short intervention programs decreased attitudes toward obesity with significant differences among all groups in aversion subscale (p=0.06) and unwillingness (p=0.007). In addition, DC group showed the lowest ranges whereas the CG showed the highest ranges for both subscales. The IAT questionnaire showed that DC group significantly decreased the number of participants with implicit negative attitudes towards obesity ($\chi^2 = 0.04$). The CG showed the smallest decrease compared to the rest of study groups. **CONCLUSIONS:** Social psychology programs of short intervention, and in particular by dynamics direct contact programs could modify the implicit and explicit attitudes towards obesity in pre-professionals of exercise sciences.

2542 Board #62 June 2 11:00 AM - 12:30 PM
Perceived Stress has a Negative Impact on Variables Related to Exercise Recovery in Adolescent Athletes
 Katelyn A. Born, Erin E. Dooley, Andy Cheshire, John B. Bartholomew, FACSM. University of Texas, Austin, Austin, TX.
 (Sponsor: John Bartholomew, FACSM)
 Email: katelynborn@utexas.edu
 (No relationships reported)

PURPOSE: Psychological stress has been shown to impair recovery in laboratory settings, but no study has done so in field settings. This study was designed to test the impact of perceived stress on variables related to recovery in an adolescent athlete population who were participating in a 6-wk Summer training program. **METHODS:** Participants included 100 high school athletes (M age = 15.1; 78% Male; 46% African American). Data were collected during 4 consecutive days in the middle of the training program. Recovery was indicated by measures of feeling states and arousal, fatigue, and soreness. These were collected prior to each day's training. The Perceived Stress Scale was used to assess stress. Growth curve analysis was used to examine change in these variables throughout the week. We hypothesized stress to be associated with greater soreness to begin the week, and greater decrements in all variables throughout the week. **RESULTS:** Stress had a significant ($p < .05$) impact on the reference value of the feeling scale ($\beta_{00} = 1.2$) and soreness ($\beta_{00} = 1.4$). As stress increases by 1 SD, there was a .7 decrease in average feeling scale response and a .4 increase in reported soreness. In addition, stress had a significant impact the change in both felt arousal ($\beta_{10} = -.1$) and soreness ($\beta_{10} = .3$) during the week, with each 1 SD increase in stress associated with a daily .14 drop in felt arousal, and a daily increase of .16 in soreness. **CONCLUSION:** Stress appears to be associated with reduced recovery during a week of intense, Summer training in high school athletes. Not only was stress associated with reduced mood and increased soreness overall, it was also associated with a greater increase in soreness and reduction in felt arousal across the week. It may be important to help athletes better cope with stress to enhance their response to training. **Research reported in this publication was supported by Dairy MAX: UTA16-000534.**

Sex Differences in Perceived Achievement after an ACL Injury Prevention and Yoga Program
 Kirsten R. Buchanan¹, Carly A. Keafer¹, Alison E. Newell¹, Karissa M. Wells¹, Irene S. Davis, FACSM². ¹University of New England, Portland, ME. ²Harvard Medical School, Cambridge, MA. (Sponsor: Irene Davis, FACSM)
 Email: kbuchanan@une.edu
 (No relationships reported)

Females are more likely to tear their ACL than their male counterparts. A preponderance of ACL injury prevention programs (ACL IPP) have shown that these interventions are effective in decreasing the risk of ACL injuries. Research has shown that girls have a lower general perception of achievement in sports than boys. Little research has investigated sex-specific perceived achievement on lower extremity alignment, flexibility, strength or performance after an ACL IPP. **PURPOSE:** The purpose of this study was to investigate the perceived achievement after 8 weeks of an ACL/yoga IPP between male and female high school soccer players. **METHODS:** 98 high school soccer players (45 girls, 53 boys; 14-19 yrs) participated. Intervention included a 30 minute ACL IPP followed by yoga once a week for 8 weeks. Athletes reported if they injured their ACL and/or had any injuries during the season. An 11 point Likert scale (anchors: -5= worse, 0=no change, 5=better) was used to determine perceived outcomes on lower extremity alignment, flexibility, strength, and performance. An independent t-test ($p=0.05$) was used to determine significant differences between male and female responses. **RESULTS:** There were no ACL injuries in either group. Males reported over twice the number of overall injuries (22) than females (10). Males exhibited significantly greater perceived improvement in lower extremity alignment ($p=0.03$), flexibility ($p=0.01$) and performance ($p=0.05$), however, not for strength ($p=0.45$) (Figure 1). **CONCLUSIONS:** While there were no ACL injuries in either group, and lower overall injuries in the female group, males had a significantly higher perceived improvement than females on lower extremity alignment, flexibility, and performance.

Lived Experiences of College Athletes Misuse of Drinking Alcohol with their Teams: A Phenomenological Study
 Debra L. Fetherman, Joan A. Cebrick-Grossman. The University of Scranton, Scranton, PA.
 Email: debra.fetherman@scranton.edu
 (No relationships reported)

This work describes college athletes' shared experiences of the misuse of drinking alcohol with their teams. **PURPOSE:** To explore the essential meaning that college athletes use to characterize their experiences of alcohol misuse when drinking with their teams. **METHODS:** The modified Van Kaam Method of Analysis was used in this psychosocial phenomenological study. Participants (n=15) represented a convenience sample of Division III athletes. The majority of participants (67%) were female. Eight out of 18 (44%) of the campus, intercollegiate teams were represented. Freshmen (27%, n=2), sophomore (20%, n=3), junior (32%, n=5) and senior athletes (20%, n=3) were represented. Over a 7-week period, data was collected during in-depth, semi-structured interviews. Two questions guided the inquiry: What have you experienced when drinking with your team? and What has influenced or affected your experience of drinking with your team? Interviews were recorded and transcribed verbatim. Saturation and validity were confirmed through triangulation of data, bracketing and peer debriefing. **RESULTS:** College athletes characterize the misuse of drinking alcohol with their teams as a primary mechanism for navigating college social life. The four interrelated, interdependent, and embedded themes included acceptance, comradery, safety and protection, and a gateway to college social life. **CONCLUSION:** This examination highlighted the important role that participants' psychosocial development played in their alcohol misuse behaviors. The reported changes in participants' motives throughout college acted as a moderator of alcohol

misuse. The interplay of multiple factors and the malleability of athletes' identities (team identity, student identity) also influenced changes in alcohol misuse behaviors. Participants identified teammates as having the greatest potential to moderate their team's culture of alcohol misuse. Health promoters ought to target transitions in psychosocial development by creating prevention strategies based on the malleability of athletes' social identities.

Supported by a NCAA CHOICES Grant.

The Psychological Parameters of Sports Related Injuries in Female Collegiate Athletes

Courtenay Stewart-Reiner. *Valparaiso University, Valparaiso, IN.*

Email: courtenaystewartreiner@gmail.com

(No relationships reported)

PURPOSE: To determine if psychological parameters previous to injury had any impact on injury in female collegiate athletes.

METHODS: Participants were female athletes (n=51) from four various sports teams (basketball, golf, soccer, and softball) at a Division I college. Five questionnaires were completed, an injury report, The Life Events Coping Scale for Collegiate Athletes (LESCA), The Sport Anxiety Scale (SAS), The Sport Competition Anxiety Test (SCAT), and The Athletic Coping Skills Inventory-28 (ASCI-28). Data collection and analysis were completed to calculate mean, median, mode, range, standard deviation, and a t-test for injury and non-injury by each team and overall.

RESULTS: Seventy-one percent of respondents suffered at least one injury in the previous 18 months. There was a statistically significant correlation found between life events and injury ($P < .05$, $P = .03$) and no significant correlation between the SAS and injury ($P > .05$, $P = .12$), the SCAT and injury ($P > .05$, $P = .12$), and coping skills and injury ($P > .05$, $P = .47$). In basketball, a correlation between injury and non-injury for life events, anxiety, and coping could not be found due to the fact that there was only one non-injured athlete. In golf, there was no significant correlation found between life events and injury ($P > .05$, $P = .35$), anxiety and injury ($P > .05$, $P = .32$, $P = .22$), and a somewhat significant correlation found between coping skills and injury ($P > .05$, $P = .08$). For soccer, there was a definite significant correlation found between life events and injury ($P < .05$, $P = .01$), and no significant correlation found between anxiety and injury ($P > .05$, $P = .20$, $P = .27$), and coping skills and injury ($P > .05$, $P = .32$). For softball, there was a somewhat significant correlation found between life events and injury ($P > .05$, $P = .09$), and no significant correlation found between anxiety and injury ($P > .05$, $P = .43$, $P = .29$), and coping skills and injury ($P > .05$, $P = .20$). **CONCLUSIONS:** The findings show that almost all athletes, non-injury or injury have a history of negative life events and a large amount of sport anxiety, but a increased amount of coping skills. The findings suggest that certain psychosocial variables moderated the relationship between life stress and injury, supporting the components of Williams and Andersen's model for stress and athletic injury.

Health and Well-being Mindset and Behavior Patterns: A Qualitative Analysis of Swim Coaches

Krista M. Kezbers¹, Bridget M. Miller¹, Jamie C. Clark¹, Suraj Vadhul Sivakumar². ¹Oklahoma State University, Stillwater, OK. ²Barry University, Miami Shores, FL.

Email: krista.kezbers@okstate.edu

(No relationships reported)

Full-time sports coaches face a unique, challenging, and constantly changing work environment. Understanding the experiences and perceptions of individual coaches is paramount to appreciating the implications of the profession on a coach's behavior and ultimately their health and well-being.

PURPOSE: The purpose of this interpretative phenomenological analysis is to understand in-depth the individual perceptions and experiences of health and well-being for swim coaches. **METHODS:** Six focus groups were conducted at an annual worldwide swim coaching clinic. Twenty-three participants, aged 23-70, were asked a series of open-ended questions to gain a better understanding of participants' experiences, perceptions, and beliefs related to health and well-being in their profession. Questions aimed to address three research questions: (1) How do swim coaches perceive their health and well-being? (2) What are the lived experiences of swim coaches pertaining to health and well-being? (3) If a coach is a former athlete, how are health and well-being experienced in coaching? All audio files were transcribed verbatim and coded separately by 3 coders. The 3 coders thoroughly discussed each transcript before coming to consensus on finalized codes and developing major and minor themes. **RESULTS:** A number of major themes emerged including the notion that (1) coaches experience some of the same challenges of maintaining a healthy lifestyle that the general adult population also faces (lack of motivation and limited supporting infrastructure from employer), but also that (2) the profession of coaching is distinctive in the way the job becomes a lifestyle which presents unique challenges to maintaining work/life balance, regular physical activity,

and healthy nutrition. **CONCLUSION:** Swim coaches have a complex occupation that directly influences their health and well-being. Many coaches express interest in learning how to improve their health and well-being suggesting that targeted programming on the topic could be quite popular. The findings presented here can be instrumental in the development of such programs and motivating professional organizations to support such endeavors.

(No relationships reported)

Underserved boys' Self-Efficacy, PACER Performance and Ethnicity in a Summer Sports Camp

Yiyu Wang, Jiling Liu, Ping Xiang, Ron E. McBride

Texas A&M University, College Station, TX

Childhood obesity is prevalent in the United States. It occurs with a higher rate among minority children and particularly during the summer time. Physical activity (PA) participation is vital in curbing obesity epidemic. To promote PA, it is crucial to understand its underlying psychological factors such as self-efficacy (SE). Research indicates SE is related to children's fitness performance. However, few studies have examined the association among minority children.

PURPOSE: This study investigated the relationship between underserved boys' SE and PACER performance and whether these variables differed by ethnicity in a summer sports camp. **METHOD:** Participants included 94 boys (13.1 ± 2.1 yrs) enrolled in summer sports camp in 2015. The boys came from low-income families and were 20.2% African American, 20.2% Caucasian, and 59.6% Hispanic American. Their social self-efficacy (SSE) and physical activity self-efficacy (PASE) were measured using a previously validated questionnaire on a 5-point Likert scale during the first week of the camp, and fitness performance was assessed by PACER in the third week of the camp. **RESULTS:** SSE was significantly correlated with PASE ($r = 0.52$, $p < 0.01$), while PASE was significantly correlated with PACER performance ($r = 0.26$, $p < 0.01$). A MANOVA yielded a significant main effect for ethnicity ($\lambda = .81$, $F(6, 178) = 3.32$, $p < .01$, $\eta^2 = .10$). Follow-up tests revealed significant ethnicity differences in the mean scores of PASE only ($F(2, 94) = 6.86$, $p < .01$, $\eta^2 = .13$), with African American boys scoring the highest ($M = 4.16$), followed by Hispanic American boys ($M = 3.82$) and Caucasian boys ($M = 3.51$). **CONCLUSION:** Similar to previous research, boys in this study believing in their physical activity ability had better PACER performance than boys who did not. This finding provides additional evidence for the importance of physical activity self-efficacy in physical activity settings. Observed ethnicity differences support the notion that ethnicity is related to children's self-efficacy.

This study was funded by the Sydney and J.L. Huffines Institute for Sports Medicine and Human Performance at Texas A&M University.

E-27 Free Communication/Poster - Blood Flow Restriction

Friday, June 2, 2017, 7:30 AM - 12:30 PM

2548 Board #68 June 2 9:30 AM - 11:00 AM

Are Higher Blood Flow Restriction Pressures More Beneficial When Lower Loads Are Used?

Jeremy P. Loenneke, Scott J. Dankel, Matthew B. Jessee, Samuel L. Buckner, J Grant Mouser, Kevin T. Mattocks. *The University of Mississippi, University, MS.*

(No relationships reported)

Low load (~20% one repetition maximum (1RM)) exercise in combination with blood flow restriction (BFR) produces robust increases in muscle size and strength. However, little is known about relative loads less than 20% 1RM.

PURPOSE: To determine the effect of BFR in combination with very low loads on acute changes in electromyography (EMG) amplitude, muscle thickness (Mth), and torque; all variables associated with long term muscle growth.

METHODS: Fourteen participants completed four visits. The 1RM was determined during visit 1. Visits 2-4 involved the same procedures but differed based on the load (10%, 15%, or 20% of their 1RM) lifted and level of restriction (40% or 80% of arterial occlusion). Each condition (i.e. load (% 1RM)/pressure (% arterial occlusion)) began with a measure of arterial occlusion. Measurements of Mth and torque were taken before and after exercise. EMG amplitude of the last 3 reps was analyzed and expressed relative to the value obtained during a maximal isometric contraction

(%MVC). Both arms were exercised each visit. A repeated measures ANOVA was used to identify differences in the dependent variables. Data represented as means (95% CI) and mean (SD) for EMG.

RESULTS: There was an interaction with torque and Mth ($p < 0.001$). There were no differences across Pre ($p = 0.312$) but there were for Post ($p < 0.001$) with torque. Increasing load [e.g. 10/40: -5.2 (-7.2, -3.2) Nm vs. 20/40: -24.4 (-32.9, -15.8) Nm] and pressure [e.g. 15/40: -15.1 (-22.3, -7.9) Nm vs. 15/80: -20.7 (-29.2, -12.2) Nm] resulted in a gradient pre-post decrease in torque ($p < 0.001$). Increasing load [e.g. 10/40: 0.18 (0.1, 0.25) cm vs. 20/40: 0.38 (0.29, 0.47) cm] and pressure [e.g. 15/40: 0.31 (0.23, 0.4) cm vs. 15/80: 0.43 (0.37, 0.48) cm] resulted in a gradient pre-post increase in Mth ($p < 0.001$). For EMG amplitude there was a condition ($p = 0.002$) and time ($p = 0.019$) effect. EMG amplitude increased across time [e.g. 1st set: 40 (12.6) %MVC vs. 4th set: 45 (14.4) %MVC, $p = 0.033$] and was augmented by increasing the load to 20% 1RM [15/80: 40 (9) %MVC vs. 20/40: 55 (15) %MVC, $p = 0.003$] with no effect of pressure [20/80: 54 (20) %MVC].

CONCLUSIONS: These acute findings provide important information for implementing BFR with very low loads. We wish to suggest that higher pressures may be useful when implementing BFR with loads less than 20% 1RM.

2549 Board #69 June 2 9:30 AM - 11:00 AM

The Acute Muscular Responses to Blood Flow Restricted Exercise Using Low and High Relative Pressures

Matthew B. Jessee¹, Kevin T. Mattocks¹, Brittany R. Counts², Samuel L. Buckner¹, J Grant Mouser¹, Scott J. Dankel¹, Gilberto C. Laurentino³, Jeremy P. Loenneke¹. ¹The University of Mississippi, University, MS. ²University of South Carolina, Columbia, SC. ³University of Sao Paulo, Sao Paulo, Brazil.

(No relationships reported)

The efficacy of an exercise modality to increase muscle size has been linked to increased muscle activation, fatigue, and muscle swelling. With low load exercise in combination with blood flow restriction (BFR), a range of moderate (40%) to high (90%) pressures made relative to arterial occlusion pressure (AOP) have been investigated, but no studies have examined the acute muscular responses to even lower relative BFR pressures.

PURPOSE: To determine how a muscle responds to low relative BFR pressures. **METHODS:** Participants ($n = 26$) performed elbow flexion with 30% of one repetition maximum (1RM) while undergoing BFR with one of six BFR pressures: 0%, 10%, 20%, 30%, 50%, 90% of AOP. Muscle thickness and maximal voluntary isometric contraction (MVC) of the elbow flexors were assessed prior to exercise as well as 0, 15, and 30 minutes after exercise. Electromyography amplitude (EMG) was assessed during each set of exercise and normalized to the first 3 repetitions of set 1.

RESULTS: Data presented as mean (95% confidence intervals). There was a main effect of time for muscle thickness ($p < 0.001$), which increased from pre to 0 minutes post-exercise [+0.47 (0.40, 0.54) cm] and trended back toward baseline. Decrements in MVC from pre to 0 minutes post-exercise were greater in higher pressure conditions compared to lower pressures ($p = 0.015$) [e.g. 10% AOP: -20.7 (-15.5, -25.8) Nm vs. 90% AOP: -24 (-19.1, -28.9) Nm]. For each set of exercise EMG amplitude relative to the first 3 reps of set 1 was greater for the last 3 repetitions compared to the first 3 repetitions of sets 2-4 ($p \leq 0.003$) [First 3 reps of Set 2-4: 130 (122, 138) % vs. Last 3 reps of Set 2-4: 151 (137, 165) %]. Repetitions decreased across sets ($p < 0.001$), with most participants unable to complete all repetitions, indicating volitional failure. Repetitions were lower with increasing pressures ($p < 0.05$) [e.g. 10% AOP sets 2-4: 13 (12, 14), 11 (10, 13), and 11 (9, 12) reps vs 90% AOP: 9 (7, 11), 6 (4, 7), and 5 (3, 7) reps].

CONCLUSIONS: When exercising to volitional failure with 30% of 1RM the application of BFR does not seem to augment the acute muscular responses indicative of a hypertrophic stimulus. However, increasing BFR pressure reduced the number of repetitions required to reach failure which may be beneficial for certain populations contraindicated to higher volumes of exercise.

2550 Board #70 June 2 9:30 AM - 11:00 AM

Effects of Different Levels of Blood Flow Restriction on Arterial Occlusion Pressure and Perceptual Responses

Kevin T. Mattocks¹, Matthew B. Jessee¹, Brittany R. Counts², Samuel L. Buckner¹, J Grant Mouser¹, Scott J. Dankel¹, Gilberto C. Laurentino³, Jeremy P. Loenneke¹. ¹The University of Mississippi, University, MS. ²University of South Carolina, Columbia, SC. ³University of Sao Paulo, Sao Paulo, Brazil.

(No relationships reported)

Low load exercise with blood flow restriction (BFR) increases muscle size similar to high load exercise. Studies have investigated relative restriction pressures ranging from 40% - 90% of resting arterial occlusion pressure (AOP) during BFR exercise, however, no studies have investigated relative restriction pressures below 40% AOP.

PURPOSE: To characterize the cardiovascular and perceptual responses to pressures below 40% AOP and compare them to a moderate (50% AOP) and higher (90% AOP) relative pressure.

METHODS: Twenty-six participants performed four sets of unilateral elbow flexion using 30% of their one-repetition maximum (1RM) while a 5cm wide nylon cuff was placed at the proximal portion of their upper arm. The cuff was inflated to one of six relative restriction pressures (0%, 10%, 20%, 30%, 50%, 90% AOP). AOP was measured before (pre) and immediately after four sets (post) of exercise at the radial artery. Ratings of perceived exertion (RPE) and discomfort were taken prior to (pre) and following each set of exercise. A repeated measures ANOVA determined differences in AOP. A Friedman test was used to determine differences for perceptual responses. Data presented as mean (95% CI) except for perceptual responses represented as the 25th, 50th, 75th percentiles. Statistical significance was set at $p \leq 0.05$.

RESULTS: AOP increased from pre to post ($p < 0.001$) in all conditions but was augmented further with higher pressures [e.g. 0%: 36 (30 - 42) mmHg vs. 10%: 39 (34 - 44) mmHg vs. 90% 46 (41 - 52) mmHg]. For RPE and discomfort, there were significant differences across conditions for all sets of exercise ($p < 0.01$) with RPE [e.g. 0%: (13, 14.5, 17) vs. 10%: (12, 13.5, 17) vs. 90%: (14.7, 17.0, 19.0) during last set] and discomfort [e.g. 0%: (1.5, 3.5, 6.2) vs. 10%: (1, 3, 6) vs. 90%: (4.5, 7.0, 9.0) during last set] generally being greater at higher restriction pressures.

CONCLUSIONS: The results provide additional information to the BFR literature by categorizing the cardiovascular and perceptual response to pressures $< 40\%$ AOP. The cardiovascular response is different depending on the relative restriction pressure applied. These findings may guide future studies to provide a safer and more tolerable stimulus for the individual who still wants to increase muscle size while concomitantly minimizing the cardiovascular response.

2551 Board #71 June 2 9:30 AM - 11:00 AM

Cardiovascular And Perceptual Responses To Various Blood Flow Restriction Pressures And Exercise Loads

Scott J. Dankel, Matthew B. Jessee, Samuel L. Buckner, J Grant Mouser, Kevin T. Mattocks, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*

(No relationships reported)

Blood flow restriction (BFR) allows individuals to exercise with lower loads while producing similar increases in muscle size as high load training. Most studies implement moderate to high pressures with loads corresponding to 20-30% of their one-repetition maximum (1RM). No study has examined perceptual or cardiovascular responses using loads lower than 20% 1RM, which may provide a more widely inclusive and palatable stimulus.

PURPOSE: To determine the cardiovascular and perceptual response to very low load BFR exercise using both moderate (40%) and high (80%) relative arterial occlusion pressures (AOP).

METHODS: 14 participants came to the lab on four separate days to complete six exercise protocols (2 per visit on visits 2-4) consisting of 4 sets (1 set of 30 followed by 3 sets of 15) of BFR elbow flexion exercise with either a 10%, 15% or 20% 1RM load, each of which was performed with a moderate (40% AOP) and high (80% AOP) relative pressure. A repeated measures ANOVA was used to determine differences in AOP pre and post exercise and a Friedman test was used to determine differences in discomfort and ratings of perceived exertion (RPE) following each set. AOP is expressed as [mean (95% confidence interval)] with RPE and discomfort expressed as [median (25th, 75th percentile)].

RESULTS: There was an interaction for AOP ($p = 0.002$) with higher pressures and loads producing a gradient increase. The pre to post changes ranged from 21 (95% CI: 10-32) mmHg in the 10% 1RM/40% AOP condition to 62 (95% CI: 45-78) mmHg in the 20% 1RM/80% AOP condition.

Ratings of discomfort were primarily dependent on the level of restriction pressure applied, with higher pressures resulting in greater discomfort ($p < 0.001$) ranging from 2.5 (1, 5) in the 15% 1RM/40% AOP condition to 6.5 (5.5, 7.25) in the 15% 1RM/80% AOP condition. Additionally, a gradient increase in RPE accompanied higher pressures and loads which ranged from 8.5 (7, 12) at the conclusion of the 10% 1RM/40% AOP condition to 15.5 (12.75, 17.25) at the conclusion of the 20% 1RM/80% AOP condition.

CONCLUSIONS: Increases in load and restrictive pressure resulted in elevated AOP and RPE, but higher pressures were primarily responsible for increased discomfort. Individuals experiencing discomfort during low load BFR exercise may wish to decrease the applied pressure and increase the exercise load.

Global And Regional Cardiac Function In Lifelong Endurance Athletes With And Without Myocardial Fibrosis

Thijs M. Eijvogels, L8 9RU¹, David Oxborough¹, Rory O'Hanlon², Sanjay Sharma³, Sanjay Prasad⁴, Greg Whyte, FACS¹, Keith George, FACS¹, Mathew Wilson⁵. ¹Liverpool John Moores University, Liverpool, United Kingdom. ²St. Vincent's University Hospital, Dublin, Ireland. ³St. Georges Hospital, London, United Kingdom. ⁴Royal Brompton and Harefield National Health Service Trust, London, United Kingdom. ⁵ASPETAR, Doha, Qatar.
Email: t.m.eijvogels@ljamu.ac.uk
(No relationships reported)

PURPOSE: The aim of the present study was to compare cardiac structure as well as global and regional cardiac function in athletes with and without MF.
METHODS: Cardiac magnetic resonance imaging with late gadolinium enhancement was used to detect MF and global cardiac structure in 9 lifelong veteran endurance athletes (58±5 years, 43±5 years of training). Transthoracic echocardiography using tissue-Doppler and myocardial strain imaging assessed global and regional (18 segments) longitudinal left ventricular function.
RESULTS: MF was present in 4 athletes (range 1-8 g) and not present in 5 athletes. MF was located near the insertion points of the right ventricular free wall on the left ventricle in 3 athletes and in the epicardial lateral wall in 1 athlete. Athletes with MF demonstrated a larger end diastolic volume (205±24 vs 173±18 ml, p=0.06) and posterior wall thickness (11±1 vs 9±1 mm, p=0.03) compared to those without MF. The presence of MF did not mediate global tissue velocities or global longitudinal strain (-22.0±4.3 vs -21.7±1.8) and strain rate (S': -0.97±0.19 vs -1.02±0.11; E': 0.95±0.20 vs 0.90±0.15; A': 0.61±0.16 vs 0.66±0.17), however, regional analysis of longitudinal strain demonstrated reduced function in 5 out of 8 wall segments associated with the presence of MF in 3 athletes (Figure).
CONCLUSIONS: MF is associated with larger cardiac dimensions, normal global cardiac function but evidence of co-localised regional cardiac dysfunction in lifelong veteran endurance athletes. Given the heterogeneous phenotype of MF, we propose that follow-up studies and a case-by-case approach are needed for appropriate risk assessment in athletes with MF.

Figure: Regional left ventricular longitudinal strain data from co-localised MRI derived myocardial fibrosis segment. Data is presented per case (black bars) and compared to the average strain value in the same segment of athletes without myocardial fibrosis (white bars). Data is presented as mean ± SD. 4CH1, apical 4 chamber view, APLAX, apical parasagittal long axis view.

2553 Board #73 June 2 9:30 AM - 11:00 AM

Accuracy Of Mobile HRV Devices For Measuring RMSSD: A Systematic Review And Meta-analysis

Michael R. Esco, FACS¹, Michael V. Fedewa, Hayley V. MacDonald. University of Alabama, Tuscaloosa, AL.
(No relationships reported)

There are a number of commercially available heart rate variability (HRV) mobile devices that provide a measure of root mean square of successive R-R differences (RMSSD). However, their accuracy compared to electrocardiography (ECG) remains questionable. **PURPOSE:** To compare a range of mobile devices to ECG for measuring RMSSD under a variety of conditions. **METHODS:** This review was

conducted in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) statement guidelines. Articles published before July 22, 2016 were located using searches of the Physical Education Index (n=1,007), PubMed (n=1,145), Scopus (n=1,562), and SPORTDiscus (n=2,137) online databases using combinations of the terms: *heart rate variability, HRV, valid, and validity*. Duplicate publications were removed, yielding 4,686 original records for review. In addition, three publications were identified through a manual reference search. All studies included in the meta-analysis were peer reviewed and published in English. Each study effect size (ES) was calculated as the difference between the RMSSD measures recorded from the mobile device compared to ECG, divided by the pooled standard deviation and adjusted for small sample bias. Random-effects models were used to aggregate a mean ES and 95% confidence intervals (CI). In addition, a multi-level model was used to account for the nesting of multiple effects within a single study. **RESULTS:** The cumulative results from 35 effects extracted from 14 articles published between 2005 and 2016 indicate no difference between the mobile devices and ECG for RMSSD measures (ES = -0.0040, 95% CI = -0.0687, 0.0608, p = 0.9039). The multi-level model yielded similar results (ES=-0.0040, 95% = -0.0687, 0.0608, p=0.9059). The number of effects obtained from each studied ranged from 1 to 12 (mean=2.92, standard deviation=3.00). We observed minimal heterogeneity among our effects (Q = 4.516, p=0.99; I²=0%), with 100% of the observed heterogeneity explained by sampling error. **CONCLUSIONS:** These results suggest that mobile HRV devices provide similar measures of RMSSD compared to ECG.

Tumor Necrosis Factor-alpha Adversely Influences Myocardial Oxygen Demand and Exercise Tolerance in Postmenopausal Women

Stephen J. Carter, David R. Bryan, William H. Neumeier, Stephen P. Glasser, Gary R. Hunter, FACS¹. University of Alabama at Birmingham, Birmingham, AL. (Sponsor: Gary R. Hunter, FACS¹)
(No relationships reported)

Oxidative stress-mediated arterial stiffening is related to the pathophysiological progression of vascular dysfunction with advancing age. However, the functional implications concerning the involvement of tumor necrosis factor-alpha (TNF-α), a marker of oxidative stress, on hemodynamic responses at rest and during physical exertion are unclear. **PURPOSE:** The aims of this investigation were to examine the independent effects of TNF-α on myocardial oxygen demand at rest and during submaximal exercise, while also evaluating the influence of TNF-α on exercise tolerance. **METHODS:** Forty, postmenopausal (65 ± 3 years) women, provided blood samples and completed a modified-Balke protocol to measure maximal oxygen uptake. Local pulse contour analyses were used to assess large artery compliance while rate-pressure product (RPP), a reliable index of myocardial oxygen demand, was measured at rest and during two submaximal workloads. RPP was calculated by dividing the product of heart rate and systolic blood pressure (via auscultation) by 100. Exercise tolerance corresponded with the cessation of the graded exercise test. P-values ≤ 0.05 were considered statistically significant for all analyses. **RESULTS:** Multiple linear regression revealed a positive association between TNF-α and RPP during submaximal exercise (partial r = 0.43; p = 0.015) adjusted for maximal heart rate, maximal oxygen uptake, large artery compliance, and percent body fat. Path analyses revealed a significant indirect effect of large artery compliance on exercise tolerance through TNF-α, β = 0.13, CI [0.03, 0.35] such that heightened levels of TNF-α translated to poorer exercise tolerance. **CONCLUSIONS:** These data indicate that TNF-α is independently associated with myocardial oxygen demand during submaximal exercise equating to 5 METs but not at rest and TNF-α mediates the indirect effects of large artery compliance on exercise tolerance. Future studies should explore differential responses to standardized exercise tasks among older adults and consider the influence of exercise training on myocardial oxygen demand and activity-related energy expenditure.

2555 Board #75 June 2 9:30 AM - 11:00 AM

Absence of Cardiac Drift during a Prolonged, Submaximal Swim Bout

Curtis S. Goss¹, Joel T. Greenshields¹, Chris L. Brammer¹, Kosuke Kojima¹, Brian V. Wright², Joel M. Stager, FACS¹. ¹Indiana University - Bloomington, Bloomington, IN. ²DePaul University, Greencastle, IN. (Sponsor: Joel M. Stager, FACS¹)
(No relationships reported)

PURPOSE: Cardiovascular (CV) factors undergo progressive time-dependent changes beginning approximately 10 min into a bout of prolonged, submaximal exercise. One expected response is a gradual rise in heart rate (HR) throughout a prolonged sustained exercise bout. The purpose of this study was to examine whether or not CV drift occurs in trained swimmers during a typical early season repetition training session. **METHODS:** Thirteen swimmers (n=2 women; n=11 men) were asked to perform 60 repetitions of 91.4 m of freestyle swimming in 26.6 C water with a 5-10

sec rest interval between each repetition. HR was collected in 15 second epochs using a commercially available cardio-tachometer (Actiheart) for the entire bout. During the 60 min and after each swimmer achieved "steady state" (10 min after the beginning of the bout), the HR data were averaged each minute. A series of 6 one-tailed paired t-tests were used to compare the group mean HR at 10 min to each of the subsequent 10 min time interval of group mean HR. Standard deviations, and the subsequent average of those standard deviations, were calculated for each subject's HR data. **RESULTS:** Significant differences were found between the group mean HR at 10 min (165.2 ± 8.2 bpm; baseline) and minutes 11-20, 21-30, 31-40, and 41-50 (166.1 ± 9.0 bpm, 169.1 ± 7.9 bpm, 169.8 ± 8.2 bpm, 169.4 ± 7.0 bpm, respectively; $p < 0.05$). No significant differences were found between the group mean HR at 10 min and minutes 51-60 and 61-70 (167.8 ± 6.3 bpm, 166.4 ± 6.1 bpm, respectively). The range of standard deviations for each subject's HR was 2.7-9.5 bpm (mean = 5.9 ± 1.8 bpm). **CONCLUSIONS:** The swimmers in this study experienced a small increase in HR from their first 10 minute value through minute 50 of the prolonged bout. However, HR then returned to baseline suggesting either CV drift did not occur or the results were related more to athlete pacing than any CV response per se.

Cardiovascular Structure and Function in Lifelong Competitive Swimmers

Wesley J. Manz¹, Michael S. Emery², Joel T. Greenshields¹, Lawrence D. Rink³, Joel M. Stager, FACSM¹. ¹Indiana University, Bloomington, IN. ²Indiana University School of Medicine, Indianapolis, IN. ³Premier Healthcare, Bloomington, IN. (Sponsor: Joel M. Stager, FACSM)
Email: manzwesleyj@gmail.com
(No relationships reported)

It is known that intense aerobic exercise elicits physiological adaptations of the cardiovascular system. However, it is unclear whether these adaptations exist over a lifetime of training. Little published data exists quantifying such adaptations in older competitive athletes, & even less data exists on populations engaged in long-term interval training, such as swimmers.

Purpose: To assess & compare the cardiovascular remodeling status of chronically trained Master's swimmers to age-matched, inactive reference values. **Methods:** Chronically trained (20.0 ± 14.5 yrs), competitive men (M, n=7) & women (F, n=21) Master's swimmers (age 55.2 ± 6.0 yrs) were studied just prior to competing in the 2009 US Masters Swimming Long Course Nationals. Demographics, anthropometrics, training history & resting hemodynamics were recorded. Subjects then underwent 2D transthoracic echocardiography with Doppler. Septal wall thickness (IVS), posterior wall thickness (PWT), left ventricular internal diastolic & systolic dimensions (LVIDd/s), end diastolic & systolic volumes (EDV/ESV), relative wall thickness (RWT), LV mass measured via truncated ellipsoid method (LVM), & left atrial volume (LAV) were assessed & indexed to body surface area where appropriate. RWT & LVMi were used to characterize remodeling status per American Society of Echocardiography (ASE) guidelines. Sex-specific means as well as individual values were compared to ASE published normal values (mean + 2SD = ULN, upper limit of normal). A one-sample T-test was used to compare published ASE values to subject sex-specific means ($p < 0.05$). **Results:** 64% of all athletes demonstrated normal geometry (M 57%, F 67%), 21% concentric remodeling (M 14%, F 24%), 14% eccentric hypertrophy (M 29%, F 10%), & 0% concentric hypertrophy. No statistical difference was shown between sex-specific means for LVIDd, LVIDs, EDV, EDVi, ESV, ESVi, LAVi & ASE reference values. However, 29% of men displayed LVEDVi above age-specific ASE ULN, compared to only 5% of women. **Conclusions:** Compared to inactive reference values nearly a third of the active men showed signs of exercise-induced cardiac remodeling. This trend was not observed in women suggesting a difference in physiological response to training, or a difference in long-term training parameters.

Heart Rate Variability During Acute Recovery from Maximal Exercise; Utility of a Nonlinear Dynamics Approach

Nathaniel Berry¹, James Janssen¹, Jessica Dollar¹, Cheryl Lovelady¹, Susan Calkins¹, Susan Keane¹, Lilly Shanahan², Laurie Wideman, FACSM¹. ¹University of North Carolina at Greensboro, Greensboro, NC. ²University of Zurich, Zurich, Switzerland. (Sponsor: Laurie Wideman, FACSM)
Email: nberry11@gmail.com
(No relationships reported)

The non-stationary trend of the heart rate (HR), response immediately following the cessation of exercise mathematically biases traditional measures of heart rate variability (HRV), during acute recovery. Fitness-induced alterations in resting HR, HRV and heart rate recovery (HRR) are observed in response to changes in cardiac autonomic nervous system modulations. **PURPOSE:** To pilot the utility of nonlinear

dynamics to characterize the patterns of fluctuation and complexity surrounding the non-stationary drift in HRV during acute recovery from exercise. **METHODS:** HR data was collected throughout exercise and into recovery following an incremental treadmill test to exhaustion in young adults [age range=19-21 yrs (male: n=14, Ht=173±7cm, Wt=71.7±11.4kg, BF=16.8±6.7%, VO_{2max} =48.0±6.0ml/kg/min, HR_{max} =200±11; female: n=18, Ht=162±5cm, Wt=67.8±15.9kg, BF=32.9±9.4%, VO_{2max} =33.3±9.5 ml/kg/min, HR_{max} =195±12)]. Nonlinear regression techniques were used to fit the first 5-min of R-R interval data following the cessation of exercise. Residuals were calculated from individual-specific regressions and used to create a secondary time-series. Detrended fluctuation analysis (DFA_a) and sample entropy (SampEn) were used to characterize self-similar patterns and the complexity of fluctuation in HRV-R, respectively. **RESULTS:** We successfully removed the non-stationary trend associated with post-exercise HRV data. Preliminary analyses show a significant interaction between VO_{2max} and HR_{max} as predictors of complexity (SampEn) surrounding the post-exercise HR response ($p=0.03$). A significant interaction between gender and HR_{max} predicted DFA_a ($p=0.02$); after controlling for HR_{max} , DFA was greater in women than men during acute recovery. **CONCLUSIONS:** Nonlinear dynamics provide an additional perspective on HRV during acute exercise recovery. The complexity surrounding the nonlinear trend of HRV during recovery may provide additional context for the role of fitness on cardiac autonomic nervous system modulation which has been previously described during resting HRV data. Future analyses should investigate the utility of this residual approach to examine the relationships across pre-, during-, and post-exercise HRV measures.

Repeatability Of Impedance Cardiography In The Measurement Of Cardiovascular Hemodynamics During Exercise.

Daniel S. Valcicak, Lindsey M. Rodriguez, Michael J. Saunders, FACSM, Christopher J. Womack, FACSM, Trent A. Hargens, FACSM. James Madison University, Harrisonburg, VA.
(No relationships reported)

Impedance cardiography (IC) is a non-invasive method for measuring cardiovascular hemodynamics during exercise. However, the consistency of measurements obtained via IC across different exercise modes has not been investigated.

PURPOSE: To investigate whether hemodynamic measures assessed via IC are consistent between treadmill (TM) and cycle (C) exercise at a given intensity. **METHODS:** Ten men (age = 21.2 ± 2.2 y; BMI = 24.8 ± 3.3) completed three exercise tests, two TM and one C. Within each test, a five minute, steady-state stage was completed with a target intensity of 5 METs. Oxygen consumption (VO_2) was measured by indirect calorimetry. Hemodynamic measures were obtained via IC (PhysioFlow, PF07 Enduro) and included stroke volume (SV), heart rate (HR), cardiac output (CO), cardiac index (CI), end diastolic volume (EDV), end diastolic filling ratio (EDFR), ejection fraction (EF), ventricular ejection time (VET), and systemic vascular resistance (SVR).

RESULTS: There were no significant differences in VO_2 and hemodynamic measures between repeated TM tests ($P > 0.05$). Steady-state VO_2 (19.2 ± 1.1 vs 19.1 ± 1.2 ml·kg⁻¹·min⁻¹) and HR (112 ± 14 vs 113 ± 16 beats·min⁻¹) did not differ between exercise modes (TM vs C). There were no significant differences between TM and C in SV, CO, CI, EDV, EF, and SVR, but EDFR and VET differed between trials. Significant intraclass correlation coefficients ($r = 0.70 - 0.90$, $p < 0.05$) were observed between modes for SV, HR, CO, EDV, EF, and SVR, but not for CI, VET, and EDFR. Bland-Altman analyses indicated good agreement between TM and C for in SV, HR, CO, CI, EDV, EF, and SVR.

CONCLUSION: The majority of hemodynamic measurements obtained via IC during moderate exercise showed moderate-strong consistency between TM and C modes. Future research utilizing IC during exercise should be conducted across a greater range of exercise intensities. In addition, hemodynamic variables obtained with IC should be compared with invasive methods to confirm their validity.

Comparison of Heart Rate Variability in Intercollegiate Explosive Power vs. Sustained Power and Endurance Athletes

Alex Claiborne, Helaine M. Alessio, 45056, FACSM, Eric Slattery, Emma Nilsson, Ron H. Cox, Edwin Barth. Miami University, Oxford, OH. (Sponsor: Helaine Alessio, FACSM)
Email: claiboa@miamioh.edu
(No relationships reported)

Heart rate variability (HRV) provides valuable feedback about heart function by measuring the RR interval change over time (Poincaré SD1 and SD2, RMSSD, PNN50), sympathetic activity with low frequency (LF) Power, and parasympathetic activity with high frequency (HF) Power. **PURPOSE:** To investigate HRV and autonomic activity in intercollegiate explosive power (EXP) vs. sustained power and endurance athletes (SEN). **METHODS:** A standard operating procedure was created

to assess resting HRV and autonomic activity over 10-15 minutes in 27 Intercollegiate athletes (EXP n=17, SEN n=10). Data were sorted and analyzed by sport type using t-tests. **RESULTS:** Despite a 43% variation, EXP athletes' LF Power did not differ significantly from SEN athletes ($p=0.08$); however, EXP had a significantly higher HF Power (56%) than SEN ($p=0.03$). EXP did not differ significantly in HRV via Poincaré SD1 compared with SEN athletes ($p=0.09$). LF:HF ratio was similar in all athletic types.

HRV in Explosive Power Vs. Sustained Power and Endurance Athletes		
HRV Measure	Explosive Power (n=17)	Sustained Power and Endurance (n=10)
LF Power ($\text{ms}^2 \pm \text{SEM}$)	3863 \pm 847	2191 \pm 352
HF Power ($\text{ms}^2 \pm \text{SEM}$)	3107 \pm 725	1366 \pm 192
Mean LF:HF \pm SEM	1.64 \pm 0.25	1.69 \pm 0.21
Poincaré SD1 (ms) \pm SEM	61.6 \pm 7.7	46.9 \pm 3.6
Poincaré SD2 (ms) \pm SEM	114.6 \pm 11.5	115.5 \pm 10.1
RMSSD (ms) \pm SEM	87.1 \pm 10.9	66.3 \pm 5.1
PNN50 (%) \pm SEM	26.8 \pm 5.4	20.1 \pm 5.0

CONCLUSION: Differences in HRV were observed between EXP and SEN athletes, with the major significance in HF Power indicating EXP athletes demonstrated greater parasympathetic activity at rest compared with SEN athletes. Most HRV studies have focused on endurance trained athletes. This finding is of interest as cardiovascular variability studies in explosive athletes have potential to elucidate autonomic and cardiovascular regulation.

Effect of the Muscle Metaboreflex on Heart Rate Kinetics during the Exercise Transient Spanning the Entire Moderate Intensity Domain

Dana S. Lahti¹, Natasha G. Boyes¹, Josie T.J. Fries¹, Paul J. Fadel², Corey R. Tomczak¹. ¹University of Saskatchewan, Saskatoon, SK, Canada. ²University of Texas at Arlington, Arlington, TX. (Sponsor: Paul J Fadel, FACSM)

(No relationships reported)

Recent data from our laboratory has shown that increasing sympathetic activity to the heart via muscle metaboreflex activation speeds heart rate kinetics during transitions in the lower moderate intensity domain (from 20W to ~60% of the ventilatory threshold, VT). Whether the magnitude of the exercise transient and heart rate change influences the effects of elevated sympathetic activity on heart rate kinetics is not known.

PURPOSE: We tested the hypothesis that increasing sympathetic activity to the heart via muscle metaboreflex activation would speed heart rate kinetics throughout the entire moderate intensity exercise transient. **METHODS:** Five healthy and active, but not trained, adults ($m/f = 3/2$; age = 22 ± 2 yrs; peak $\text{VO}_2 = 46 \pm 8$ ml/kg/min) performed square-wave moderate intensity exercise transitions from 20W to 90% VT. Each subject was tested in 2 conditions. Condition 1 was a control (CTL) condition. In condition 2, the muscle metaboreflex activation was induced by 2 min of handgrip at 40% maximal voluntary contraction during the pre-transition 20W baseline followed by 5 min of circulatory occlusion (OCCL) during the transition to 90% VT. Trials were randomized and three repetitions of each condition were completed, time-aligned, and averaged by condition. Heart rate kinetics were determined using mono-exponential curve fitting and data was analysed with non-parametric tests. $P < 0.05$ was significant.

RESULTS: The pre-transition baseline heart rate was not different between CTL (93 ± 8 beats/min) and OCCL (90 ± 10 beats/min), $P = 0.138$. Heart rate amplitude was not different between CTL (29 ± 6 beats/min) and OCCL (29 ± 5 beats/min), $P = 0.500$. Finally, the heart rate time constant, tau, was not different between CTL (34 ± 10 s) and OCCL (36 ± 16 s), $P = 0.686$. **CONCLUSIONS:** Heart rate kinetics are not altered by sympathetic activation via the muscle metaboreflex during the exercise transition from 20W to 90% VT. These findings suggest that the magnitude of step-change in exercise intensity and/or the magnitude of change in heart rate plays an important role in heart rate kinetics under a sympathetically elevated condition.

Email: awong@marymount.edu

(No relationships reported)

Increased blood pressure (BP) and autonomic dysfunction are independent risk factors for cardiovascular disease. Heart rate variability (HRV) is used as a measure of cardiac autonomic function in many research settings, including the evaluation of the autonomic control during and after physical activity. A prolonged sympathetic predominance and a slow parasympathetic reactivation contribute to a delayed BP and heart rate (HR) recovery after exercise which is thought to be associated with increased risk of acute cardiac events. Therefore, understanding the impact of various exercise modalities on the post-exercise autonomic modulation and BP would allow for appropriate exercise prescription in susceptible populations. Kettlebell (KB) training has become an extremely popular training modality for improving both muscle strength and aerobic fitness. However, the HRV and BP responses induced by an acute KB exercise session are currently unknown. **PURPOSE:** To evaluate the effects of an acute session of KB exercise on HRV and BP responses in healthy young adults. **METHODS:** 17 young healthy adults ($M=10, F=7$) completed a KB exercise or a no-exercise control trial in a randomized order. During the KB trial, participants completed twelve-30s sets of KB swings followed by 30 seconds of rest. Men and women used a 16kg and 8kg KB, respectively. Low-frequency power (LF), high-frequency power (HF), the LF to HF ratio (LF/HF), HR and BP were collected in the supine position at baseline, 3, 10 and 30 min after each trial. LF and HF were normalized to total power resulting in nLF, nHF and nLF/nHF. **RESULTS:** There were significant group-by-time interactions ($P < 0.05$) for nLF (sympathetic activity), nHF (vagal tone), nLF/nHF (sympathovagal balance), HR, systolic and diastolic BP. There were significant increases ($P < 0.01$) in nLF, nLF/nHF and HR as well as significant decreases ($P < 0.01$) in nHF, systolic (~4mmHg) and diastolic (~3mmHg) BP for 30 min after KB compared to no changes after control. **CONCLUSIONS:** Our findings indicate that KB exercise increases sympathovagal balance 30 min post-exercise which is concurrent with a sustained hypotensive effect in young healthy adults. Further research is warranted to evaluate the potential clinical application of KB in populations that might benefit from post-exercise hypotension.

Acute Resistance Exercise Effects on Autonomic Modulation Between Resistance-Trained Men and Women

Alaina Glasgow, Erica Marshall, Yu Lun Tai, J. Derek Kingsley. Kent State University, Kent, OH. (Sponsor: Ellen L. Glickman, FACSM)

(No relationships reported)

While it has been reported that women have greater vagal withdrawal during aerobic exercise and supramaximal exercise compared to men, the sex-specific responses to an acute bout of resistance exercise are unknown. **PURPOSE:** To determine the effects of an acute bout of free-weight resistance exercise consisting of the squat, bench press, and deadlift on heart rate variability (HRV) and heart rate complexity (HRC) between the sexes. **METHODS:** Twenty-three resistance-trained (aged 23 ± 3 yrs; mean \pm SD) men ($n=13$) and women ($n=10$) with a minimum of 1 year of resistance training volunteered for the study. Autonomic modulation was assessed at rest as well as 15-20 minutes (Rec1) and 25-30 minutes (Rec2) after an acute bout of resistance exercise utilizing 3 sets of 10 repetitions at 75% 1-repetition maximum on the squat, bench press and deadlift. Two minutes of rest was given between sets and exercises. A quiet control condition of the same duration was also utilized for each participant. Measures of HRV were analyzed in the frequency domain and included measures of vagal modulation (normalized high frequency (HFnu)), sympathetic modulation (normalized low frequency (LFnu)), and sympathovagal balance (LF/HF ratio). Sample Entropy (SampEn), indicative of vagal modulation, was used as a measure of HRC. A repeated measures ANOVA was used to compare the effects of sex (men and women) across the two conditions (resistance exercise and control) and time (rest, Rec1 and Rec2). T-tests were used for post-hoc testing if the ANOVA was significant with a Benjamini-Hochberg correction factor. **RESULTS:** There were no significant sex differences at rest for any of the variables. Furthermore, there were no significant sex \times condition \times time interactions for any variable. Compared with Rest LFnu (Rest: $35.5 \pm 15.3\%$; Rec1: 73.0 ± 18.0 ; Rec2: $66.0 \pm 25.1\%$, $p=0.0001$), LnLF/HF (Rest: $4.0 \pm 0.9\%$; Rec1: $5.1 \pm 1.1\%$; Rec2: $5.2 \pm 1.1\%$, $p=0.002$) were augmented at Rec1 and Rec2. HFnu (Rest: $61.2 \pm 17.1\%$; Rec1: $40.3 \pm 22.3\%$; Rec2: $38.4 \pm 21.8\%$, $p=0.0001$) and SampEn (Rest: 1.5 ± 0.3 units; Rec1: 1.2 ± 0.3 units; Rec2: 1.3 ± 0.5 units, $p=0.0001$)

were decreased at Rec1 and Rec2 compared to Rest after the acute resistance exercise. **CONCLUSIONS:** These data suggest that acute RE using free-weights has a profound impact on autonomic modulation that is similar between the sexes.

2563 Board #83 June 2 9:30 AM - 11:00 AM
The Effects Of Ultra-endurance Event Participation On Biomarkers Of Cardiac Damage - A Systematic Review And Meta-analysis

Steven E. Safille¹, Hayley V. MacDonald², Michael V. Fedewa², James M. Smoliga¹. ¹High Point University, High Point, NC. ²University of Alabama, Tuscaloosa, AL. (Sponsor: Gerald Zavorsky, FACSM)
 Email: jsmoliga@highpoint.edu
 (No relationships reported)

Meta-analysis has not yet collectively evaluated biomarkers of cardiac damage following ultra-endurance races or factors which modulate these biomarkers.

PURPOSE:

To quantify the response of creatine kinase MB (CK-MB) and cardiac troponin (cTn) isoforms following a single ultra-endurance event and determine whether patient and ultra-endurance race characteristics modulated changes in these markers of cardiac damage.

METHODS:

A systematic review was conducted and reported according to PRISMA guidelines. A generic search strategy using PubMed, CINAHL, and SportsDiscus was employed to comprehensively identify all peer-reviewed publications which evaluated health-related effects of participating in an ultra-endurance event. Data from observational studies which reported pre- and post-race measurements of CK-MB (k=16 studies), cTnI (k=8), and cTnT (k=6) were analyzed following random-effects assumptions.

RESULTS:

On average, ultra-endurance participants were middle-aged males who competed in running, cycling, or triathlon race distances ~156-235 km and ~20 h duration. Overall, ultra-endurance events significantly increased CK-MB ($d = 11.29$; 95% CIs: 7.90, 14.69) and cTn levels ($d = 2.18$; 95% CIs: 1.39, 2.97) post- compared to pre-race. Collectively, these effect sizes lacked homogeneity (I^2 [95% CI]: CK-MB=94.4% [92.2, 95.9]; cTn=90.9% [86.4, 93.8]). Bivariate moderator analyses revealed that older versus younger samples experienced greater increases in CK-MB following a single ultra-endurance event ($\beta = 0.543$, $p = 0.030$). Ultra-endurance running events elicited greater increases in CK-MB compared to cycling and triathlon events ($\beta = 0.583$, $p = 0.018$). In contrast, greater increases in cTn levels were observed among younger compared to older samples following a single ultra-endurance event ($\beta = 0.659$, $p = 0.020$). Furthermore, cycling and triathlon events elicited greater increases in cTn compared to running events ($\beta = 0.472$, $p = 0.036$). Effects were similar whether cTn isoforms were analyzed separately or combined.

CONCLUSIONS: Cardiac biomarkers were consistently elevated following ultra-endurance events and dependent on age and race type. Further research is necessary to determine the long-term clinical significance of repeated ultra-endurance races.

2564 Board #84 June 2 9:30 AM - 11:00 AM
Influence of Exercise Mode on Post-Exercise Indices Reflecting Cardiac Parasympathetic Reactivation and Sympathetic Withdrawal

Scott W. Michael¹, Ollie Jay, FACSM¹, Kenneth S. Graham², Glen M. Davis, FACSM¹. ¹University of Sydney, Sydney, Australia. ²New South Wales Institute of Sport, Sydney, Australia. (Sponsor: Prof. Glen Davis, FACSM)
 Email: scott.michael@sydney.edu.au
 (No relationships reported)

PURPOSE: This study investigated indirect measures of post-exercise parasympathetic reactivation (using heart rate variability, HRV) and sympathetic withdrawal (using systolic time intervals, STI) following upper- and lower-body dynamic exercise. **METHODS:** 13 males (age 26.4±4.7 y) performed maximal incremental arm-crank and leg cycling exercise tests (MAX-ARM and MAX-LEG, respectively). Subsequently, participants performed separate 8-min bouts of submaximal HR-matched exercise of each mode (SUBMAX-ARM and SUBMAX-LEG). HRV (including the natural-logarithm of root mean square of successive differences, Ln-RMSSD) and STI (including the pre ejection period, PEP) were assessed throughout 10-min seated recovery. **RESULTS:** Peak HR was higher ($p = 0.001$) during MAX-LEG (182±7 b.min⁻¹) compared with MAX-ARM (171±12 b.min⁻¹), while HR ($p < 0.001$) and Ln-RMSSD ($p = 0.010$) recovered more rapidly following MAX-ARM. PEP recovery was similar between maximal exercise bouts ($p = 0.106$). HR during submaximal exercise was 146±7 and 144±8 b.min⁻¹ for SUBMAX-LEG and SUBMAX-ARM, respectively ($p = 0.139$). The recovery of HR and Ln-RMSSD was also similar between submaximal modes ($p = 0.219$ and 0.110, respectively), although these variables did not return to resting levels ($p < 0.001$). PEP was similar at end-exercise (SUBMAX-LEG 70±6 ms; SUBMAX-ARM 72±9 ms;

$p = 0.471$), however PEP recovery was slower following SUBMAX-ARM ($p = 0.021$), with differences between modes apparent over 1 to 10-min recovery ($p \leq 0.036$). By 10-min post-exercise, PEP had recovered to near-resting levels (132±21 ms) following SUBMAX-LEG (130±21 ms; $p = 0.143$) but not after SUBMAX-ARM (121±17 ms; $p = 0.001$). **CONCLUSION:** Compared with submaximal HR-matched lower-body exercise, upper-body dynamic exercise elicited a similar recovery of HR and HRV indices of parasympathetic reactivation, but a delayed recovery of PEP (index of sympathetic withdrawal). These data indicate that exercise mode influences post-exercise parasympathetic reactivation and sympathetic withdrawal in a manner that is moderated by exercise intensity. These results may be of practical relevance to multi-discipline athletes, as well as for clinical monitoring applications where the mode of exercise testing may vary.

Early Life Nutrition Alters the Electrocardiogram of Adult Mice with Dobutamine Stimulation

Joseph R. Visker, David P. Ferguson. Michigan State University, East Lansing, MI.
 Email: viskerjo@msu.edu
 (No relationships reported)

PURPOSE: Under nutrition in early life has been shown to increase the risk of cardiovascular disease (CVD) in adult life. Thus, the purpose of this study was to determine if early life undernutrition at various windows of development (Postnatal days [PN] 1-21) produced cardiac arrhythmias at rest and when pharmacologically stressed (PST) with dobutamine. **METHODS:** Mouse FVB/N dams were fed a semi-purified diet (CON: 20% protein), or a low-protein (LP: 8%) diet beginning 1 week prior to mating. In order to evaluate the phases (N=16/group) of early life undernutrition (early-EUN; PN1-10, late-LUN; PN11-21, E+L-PUN, PN1-21) a cross fostering model was used where pups suckled to dams fed a LP diet received a global reduction in caloric intake (~18% as compared to CON) during the designated window prior to weaning. After weaning all mice were fed the control diet until PN80. At PN80 body composition (BC) was measured by MRI, and then evaluated for cardiac function via electrocardiogram (ECG) under 1% isoflurane anesthesia. After baseline measure, the mouse was administered an intraperitoneal injection of dobutamine (1.5 µg/g BW) and measurements repeated. Quantitative ECG analysis was performed using EMKA Tech. software. **RESULTS:** At PN80 Undernutrition significantly ($P < 0.05$) reduced weight in the LUN (22.68±0.88g) and PUN (19.96±0.32g) but there was no difference between CON (25.05±0.96g) and EUN (25.28±0.92g). Similarly fat mass was reduced ($P < 0.05$) in all groups compared to controls (CON: 8.00±1.2g, EUN: 6.32±0.65g, LUN: 5.11±1.1g, PUN: 3.90±0.25g), however lean mass was only significantly reduced ($P < 0.05$) in the PUN group (CON: 17.99±0.26g, EUN: 17.78±0.39g, LUN: 17.34±0.33g, PUN: 15.85±0.28g). Heart weight when standardized to body surface area was only significantly ($P < 0.05$) reduced in the EUN group (.001288±.000031 kg/cm²) as compared CON group (.001405±.000089 kg/cm²), with LUN (.00135±.00004 kg/cm²) and PUN (.001342±.000031 kg/cm²) not different from CON. ECG analysis showed that with dobutamine, EUN group had a 6.25% increase in 1st degree AV block and PUN group had a 43.75% increase in wide QRS complex. **CONCLUSION:** Thus, EUN reduces heart size with a predisposition for conduction delays to left ventricle but ischemia is primarily associated with prolonged undernourishment in postnatal life (PUN).

Cardiac Autonomic Response to Handgrip Exercise Performed with and without Blood Flow Restriction

Kimberly E. Allen, Edward T. Kelley, Jeffrey D. Miller, Daniel P. Credeur. University of Southern Mississippi, Hattiesburg, MS.
 Email: kimberly.e.allen@usm.edu
 (No relationships reported)

Recent studies examining blood flow restriction (BFR) training, utilizing low-intensity leg exercise, demonstrate that the cardiac autonomic stress is lower in comparison to high-intensity leg exercise without BFR. Whether or not this response occurs for upper-body exercise performed with and without BFR is unclear. **PURPOSE:** To examine the heart rate variability (HRV) response to low- and high-intensity unilateral handgrip exercise performed with and without BFR. **METHODS:** Six college-aged males (Age=23±1 yrs; BMI=31±3 kg/m², handgrip max voluntary contraction-MVC=53±4 kg) underwent three 5-min bouts (10 mins rest between, counterbalanced design) of exercise consisting of rhythmic handgrip (20 contractions/min, 1-2 sec duty cycle) performed at a low- (40% MVC) and high-intensity (60% MVC) with and without a proximally placed occlusion cuff (80-100mmHg, 50-80% arterial occlusion assessed via radial artery Doppler-ultrasound). Using Lead-II surface electrocardiography, heart rate (HR) and HRV data [time and frequency domain (power-spectral analysis)] were analyzed at baseline, and also during the last 2 mins of each exercise bout. **RESULTS:** High-intensity handgrip performed with and without BFR produced a greater HR increase from baseline as compared to the low-intensity handgrip with BFR (60% with BFR=+8±2, vs. 60% without BFR=+9±2, vs. 40%

with BFR=+6±2 bpm; $P=0.001$). Compared to baseline, the standard deviation of R-R intervals was lower during high-intensity handgrip without BFR (baseline=58±8, vs. 60% without BFR=37±3 ms; $P=0.035$), but similar to baseline for low- and high-intensity BFR (40% with BFR=40±4, $P=0.071$; 60% with BFR=44±6 ms, $P=0.3$). A similar finding was noted for root mean square of R-R standard deviations ($P=0.01$). The low and high frequency HRV components (markers of sympathetic and parasympathetic activity, respectively) were lower during exercise ($P<0.05$), but comparable across all handgrip bouts ($P>0.05$). **CONCLUSIONS:** These preliminary findings suggests that both low- and high-intensity handgrip exercise performed with BFR produce a comparable cardiac autonomic stress (i.e., parasympathetic withdrawal) as high-intensity handgrip exercise without BFR.

Multi-layer Myocardial Mechanics In The Athlete's Heart

Glenn Stewart¹, Surendran Sabapathy², Bryce Balmain², Bruce Johnson¹. ¹Mayo Clinic, Rochester, MN. ²Griffith University, Gold Coast, Australia.

Email: stewart.glenn@mayo.edu

(No relationships reported)

Introduction: Endurance exercise training provokes numerous adaptive changes to the morphology, structure and function of the human heart that are chamber and region specific. Accordingly, regional non-uniformity of the human heart may play an important role in ventricular contraction and relaxation, and contribute to myocardial efficiency during exercise. **Purpose:** This study examined regional and transmural myocardial tissue deformation (strain) in a cohort of endurance trained (active >10h/week) and untrained (active <2h/week) men to characterize multi-layer myocardial tissue mechanics in the athlete's heart. **Methods:** Echocardiography was used to measure biventricular strain in 12 endurance trained men (ET; Age: 27.4±1.6yr, BMI: 23.2±0.7m², $VO_{2\text{peak}}$: 4.4±0.3L·min⁻¹) and 12 healthy untrained men (UT; Age: 26.5±1.0yr, BMI: 22.6±0.8m², $VO_{2\text{peak}}$: 3.1±0.2L·min⁻¹). **Results:** Left ventricular global longitudinal strain (ET: -18.8±0.8% vs UT: -18.5±0.5%) was similar in trained and untrained men, while right ventricular global longitudinal strain (ET: -18.3±0.8% vs UT: -23.5±1.8%, $p<0.01$) was lower in trained men. Left ventricular transmural strain increased from the epicardium to the endocardium in trained (Epi: -16.6±0.4%; Mid: -18.4±0.5%; Endo: -21.1±0.5%, $p<0.01$) and untrained (Epi: -16.0±0.6%; Mid: -18.7±0.7%; Endo: -21.2±0.8%, $p<0.01$) men. Right ventricular transmural strain was similar across myocardial layers in untrained men (Epi: -23.2±1.7%; Mid: -23.4±1.8%; Endo: -23.9±1.8%), while right ventricular transmural strain increased from the epicardium to the endocardium (Epi: -16.9±0.8%; Mid: -18.3±0.7%; Endo: -19.7±0.6%, $p<0.01$) in trained men. **Conclusion:** Functional non-uniformity is more pronounced in the left ventricle than the right ventricular free wall; however, right ventricular functional changes develop following endurance training. Differences in myocardial architecture and exercise-induced wall stress in the left and right ventricles are possible explanations for the marked functional non-uniformity throughout the myocardium, and in response to exercise training.

Cardiac Autonomic Modulation and High Intensity Interval Training in Physically Inactive Men

Jamie M. O'Driscoll, Steven Wright, Katrina A. Taylor, Damian D. Coleman, Jim D. Wiles, Jim D. Wiles. Canterbury Christ Church University, Canterbury, United Kingdom.

Email: jamie.odriscoll@canterbury.ac.uk

(No relationships reported)

Purpose: Cardiac autonomic dysfunction and physical inactivity are associated with increased risk of cardiovascular disease. Short duration high intensity interval training (HIIT) has been shown to improve aerobic capacity; however, adaptations of the cardiac autonomic nervous system are less clear. Therefore, the aim of the present study was to assess cardiac autonomic adaptations to HIIT.

Methods: In a randomised crossover controlled trial, 40 physically inactive males (21 ± 1.7 years; 179.9 ± 5.4 cm; 82.6 ± 11.5 kg; mean ±SD) completed 2-weeks of HIIT and a matched duration control period. The HIIT protocol consisted of 3 x 30-second maximal cycle ergometer sprints against a resistance of 7.5% body weight, interspersed with 1-minute of active recovery (50 rev·min⁻¹ with no resistance). In total 6-sessions were performed. Cardiac autonomic function was measured pre and post-training and control period using a plethysmographic device (Task Force® Monitor). Total power spectral density (PSD) and associated low-frequency (LF) and high-frequency (HF) power spectral components were recorded in absolute (ms²) and normalised units (nu).

Results: Each participant completed 18-maximal cycle ergometer sprints over a 2-week period. The HIIT intervention produced an improvement in cardiac autonomic function with significant increases in total PSD (361.8 ± 200.1 vs. 19.8 ± 141, $p<0.001$), HF (ms²) (210.6±159.3 vs. 15.6±86.9, $p<0.001$) and HF (nu) (3.6 ± 2.5 vs. 0.23 ± 1.7,

$p<0.001$), coupled with a significant decrease in LF (nu) (-3.6 ± 2.5 vs. -0.23 ± 1.7, $p<0.001$) and LF/HF ratio (-0.3 ± 0.3 vs. 0.01 ± 0.2, $p<0.001$) compared to the control period. There was no significant change in the LF (ms²) power spectral component. **Conclusion:** A short-term programme of HIIT was associated with a significant increase in cardiac autonomic modulation, demonstrated by a residual increase in cardiac vagal activity. Further research is required to establish whether these adaptations are sustained with regular HIIT training and any impact this may have on long-term cardiovascular disease risk.

Post-exercise Heart-rate Recovery Correlates To Resting Parasympathetic Modulation In Apparently Healthy Men

Guilherme E. Molina¹, Keila E. Fontana¹, Giliard L. Garcia¹, Carlos J. G. da Cruz², Edgard M. K. V. K. Soares¹, Luiz G. G. Porto¹, Luiz F. Junqueira Jr¹. ¹University of Brasilia - UnB, BRASILIA, Brazil. ²UniEuro - University Center - Brasilia, BRASILIA, Brazil.

(No relationships reported)

Post-exercise heart rate (HR) recovery (HRR) has recently been considered to be a powerful and independent predictor of risk for cardiovascular disease and mortality. The short-term post-exercise cardiovascular adaptation is associated to simultaneous rapid increase in parasympathetic and a progressive decrease in sympathetic activity. However, the relationship between HRR and rest parasympathetic modulation is not yet fully understood. **PURPOSE:** We aimed to correlate HRR with resting parasympathetic status. **METHODS:** We evaluated 70 apparently healthy men, aged 27.5 ± 6.3 years showing BMI 24.4 ± 2.3 kg/m². All participants underwent a sub-maximal exercise testing (SET). At 85% of the maximal predicted HR, the recovery protocol started. The HRR was calculated as the absolute difference from the peak HR to the HR at the 1st min to 5th min during 5-min period of active recovery at 2.4km/h and 2.5% grade. HRR at the 1st min to 5th min following SET were correlated with 5 min time domain (pNN50 and rMSSD), frequency domain (HF_{nu}) and Poincaré Plot (SD1) indices of heart rate variability (HRV) at rest in supine position. Due to non-normal distribution of variables (*Shapiro-Wilk test*) we used the Spearman correlation at the 5% level of significance. **RESULTS:** We observed positive correlation of HRR from the 1st to 5th min with parasympathetic indices in the supine position, as shown in Table 1.

Table 01- Spearman correlation coefficients and p value (in parenthesis) of the correlation of heart rate recovery (HRR), at different post exercise times, with the parasympathetic indices in resting supine position, in 70 healthy men

Variables	1 st min	2 nd min	3 rd min	4 th min	5 th min
pNN50 (%)	0.18 (0.05)	0.29 (<0.01)	0.25 (<0.01)	0.35 (<0.01)	0.36 (<0.01)
rMSSD (ms)		0.25 (0.01)	0.23 (0.02)	0.35 (<0.01)	0.35 (<0.01)
HF _{nu} (%)		0.29 (<0.01)	0.37 (<0.01)	0.43 (<0.01)	0.42 (<0.01)
SD ₁	0.18 (0.05)	0.24 (0.02)	0.18 (0.05)	0.27 (0.01)	0.25 (0.01)

CONCLUSIONS: HRR from the 1st to 5th min post-exercise positive correlated with parasympathetic indices in resting supine position. Our results demonstrate that the highest is the tonic (resting supine) parasympathetic modulation, the greater is the decrease of HRR after SET in apparently healthy men.

Long-term Intensive Exercise Induced Atrial Fibrillation Is Associated With Tgf-β1-Mir-21 Signaling Pathway

yun chang. china institute of sport science, beijing, China.

Email: changyun2518@vip.sina.com

(No relationships reported)

PURPOSE: To explore the long-term intensive exercise induced atrial fibrillation relates to cardiac injury and TGF-β1/miR-21 Signaling Pathway and provides experimental evidence for determine the mechanism of exercise-induced atrial fibrillation.

METHODS: 72 SD rats were grouped to control group(C), moderate intensity group (M) and high intensity group (H) with 24 animals in each group. M and H group were conditioned to run for 4, 8, and 16 weeks, 5 days/weeks, 1h/day. Rats were euthanized to obtain hearts within 24h after exercise. Right atrial were collected. Plasm cTnI was detected, hydroxyproline was measured by lkali hydrolysis method. TGF-β1 and miR-21 gene expression were evaluated by real-time PCR. TGF-β1 protein was quantified by Western Blot.

RESULTS: Compared with control and M group, rats serum cTnI increased at 8 weeks/12 weeks/16 weeks($P<0.01$). Compared with C and M group, hydroxyproline content of H group showed significant increase at 12 weeks and 16 weeks($P<0.01$).

Hydroxyproline of H group confirmed a gradual increase with training time, with significant increase from 8 weeks to 16weeks($P<0.05$). TGF- β 1 gene and protein expression of H group increased compared their control group at 8/12/16 weeks. Compared with their controls, miR-21 expression of H group showed a significant increase($P<0.05$). miR-21 of H group significantly decrease from 8 weeks to 16weeks($P<0.05$).

CONCLUSIONS: Long-term Intensive exercise induced sustained myocardial damage, resulted in sustained collagen increase which induced myocardial fibrosis. TGF- β 1/miR-21 signaling pathway, upregulated by long-term intensive exercise, may involve in the pathology of intense exercise -induced myocardial damage and atrial fibrillation.

Muscle Metaboreflex Modulation of Heart Rate Kinetics During the Transition to Low-Moderate and High-Moderate Exercise Intensities

Natasha G. Boyes¹, Josie T.J. Fries¹, Stephanie Fusnik¹, Paul J. Fadel, FACSM², Corey R. Tomczak¹. ¹University of Saskatchewan, Saskatoon, SK, Canada. ²University of Texas at Arlington, Arlington, TX. (Sponsor: Paul J Fadel, FACSM) (No relationships reported)

Our classical understanding of heart rate kinetics is that a sympathovagal balance favouring parasympathetic tone at rest or during low level exercise contributes to a rapid heart rate adaptation (i.e. fast kinetics) during low level exercise transitions. Conversely, higher-level exercise transitions elicit slower heart rate kinetics, due in part to a sympathovagal shift to greater sympathetic tone. **PURPOSE:** To test the hypothesis that increasing sympathetic activity to the heart via muscle metaboreflex activation would slow heart rate kinetics during lower vs higher level exercise transitions. **METHODS:** Twelve healthy, active, and untrained adults (m/f = 6/6; age = 23 ± 3 yrs; peak $\dot{V}O_2 = 40 \pm 3$ ml/kg/min) performed square-wave moderate intensity exercise transitions in two equal step changes between 20W to 90% ventilatory threshold (VT). The first transition was in the low moderate domain (LMD: 20W to 55 \pm 13 W) and the second transition in the high moderate domain (HMD: 55 \pm 13 W to 90 \pm 27 W). These transitions were performed without (control; LMD-CTL and HMD-CTL) and with muscle metaboreflex activation induced by 2 min of handgrip at 40% maximal voluntary contraction during the pre-transition baseline followed by 5 min of brachial occlusion (OCC) during either the LMD (LMD-OCC) or HMD (HMD-OCC) transition. Trials were randomized and three repetitions of each condition were completed, time-aligned, and averaged by condition. Heart rate kinetics were determined using mono-exponential curve fitting. Data was analysed with non-parametric tests. $P < 0.05$ was significant. **RESULTS:** Heart rate amplitude was lower during LMD-OCC vs LMD-CTL (15 ± 5 vs 17 ± 6 beats/min; $P = 0.012$) and the heart rate time constant, tau, was faster during LMD-OCC vs LMD-CTL (18 ± 9 vs 26 ± 11 s; $P = 0.01$). Heart rate amplitude was not different between HMD-OCC vs HMD-CTL (18 ± 6 vs 19 ± 8 beats/min) and heart rate tau was not different between HMD-OCC vs HMD-CTL (49 ± 28 vs 45 ± 24 s; all $P > 0.05$). **CONCLUSIONS:** Contrary to our hypothesis, an increase in sympathetic activity induced by the muscle metaboreflex speeded heart rate kinetics during LMD but not HMD exercise transitions. Our data suggests that elevating sympathetic activity can speed heart rate kinetics to a certain point, beyond which heart rate kinetics via sympathetic activity may already be maximized.

Test-retest Reliability of Female Heart Rate Variability
 Meghan Murley, Charles R.C. Marks, Jacqueline S. Drouin. Oakland University, Rochester, MI. (Sponsor: Steven Keteyian, FACSM) (No relationships reported)

PURPOSE: The study purpose was to evaluate the test-retest reliability of our heart rate variability (HRV) assessment method in: cancer survivors; and healthy-active and healthy-inactive females. The study also determined the impact on reliability of the body position and of the time compared to frequency domains. **METHODS:** Subjects were 25 females, 18 years or older. Testing was on two different days 2-7 days apart. Each day had exactly the same protocol. Participant started in the sitting or supine position (order randomized) and breathed in rhythm with a metronome (12 br/min). Following 10 minutes of rest, ECG data were collected for 10 minutes. Blood pressure and then cardiac output (Q, by CO_2 rebreathing) were then measured. Finally, the participant switched positions and repeated the protocol. A time domain [Standard Deviation of Normal beat to beat (SDNN)] and a frequency domain [Low to High Frequency ratio(LF/HF)] were analyzed for five minute intervals. Intra Class Correlation Coefficients (ICC) were calculated between each consecutive five minute interval. Also, data for a given position were pooled for ICC determinations. Stroke volume (SV) was calculated from heart rate (HR) and Q. **RESULTS:** For the LF/HF ratio two outliers (values 5 x or more than others) were not used. Repeated Measures ANOVAs found no significant day effect or interaction for HR ($p = .424, p = .230$) and SV ($p = .899, p = .108$) but significant ($p < .001$) position effect for HR and SV.

	Sit			Supine		
	Pooled	Day 1	Day 2	Pooled	Day 1	Day 2
SDNN	0.92	0.91	0.96	0.96	0.97	0.98
LF/HF	0.74	0.65	0.86	0.88	0.74	0.91
HR min ⁻¹	Mean + SD	73.5 + 14.5	75.6 + 18.1		64.0 + 12.8	64.1 + 14.2
SV mL* ^b -1	Mean + SD	53.2 + 15.1	51.5 + 16.6		65.5 + 19.2	66.7 + 20.2

CONCLUSION: It appears that the time domain and supine position are more reliable than the frequency domain and sitting position, respectively. Frequency domain itself may be more reliable on the second day of testing.

2573 Board #93 June 2 9:30 AM - 11:00 AM
Left Atrial Enlargement is Related to Diastolic Dysfunction in Obese Individuals

Norman N. Aiad, Michinari Hieda, Satyam Sarma, Benjamin Levine, FACSM. UT Southwestern Medical Center, Dallas, TX. (Sponsor: Benjamin Levine, FACSM) Email: Norman.Aiad@utsouthwestern.edu (No relationships reported)

Purpose: Obesity is linked to diastolic dysfunction and left atrial enlargement (LAE). The mechanisms responsible for LAE in obesity are unknown. We hypothesize that diastolic dysfunction, which is common in obesity, is the mechanism through which LAE occurs.

Methods: 37 middle-aged, obese patients (8M: 29F, 49 \pm 6years) with an average body mass index (BMI) of 38 ± 5 kg/m² were compared to age and sex matched non-obese healthy controls. Diastolic function (IVRT; isovolumic relaxation time, Vp: propagation velocity) was assessed using echocardiography. Left atrium (LA) size was measured using 3D echocardiogram, and normalized to height to account for the effects of body size.

Results: Obese individuals had a significantly enlarged atrial volume when compared to healthy individuals (52.5 ± 31.2 vs. 23.1 ± 10.5 mL/m; $p<0.01$). Obese patients had a significantly faster IVRT when compared to non-obese patients (68 ± 11 vs 100 ± 16 msec; $p<0.01$). Obese patients also had a significantly faster Vp when compared to non-obese patients (75 ± 19 vs 56 ± 13 cm/sec; $p<0.01$). In obese subjects, there was a significant negative-relationship between LA volume index and IVRT ($R^2=0.27$; $p<0.05$) as well as a significant positive-relationship between LA volume index and Vp ($R^2=0.18$; $p<0.05$). (Figure 1)

Conclusions: Obese patients had larger LA and markers of elevated LA filling pressures (faster IVRT and Vp) compared to age matched controls. LAE in obesity may be a driven by sub-clinical elevations in left atrial filling pressures.

Doppler Measurement of Parasternal Aortic Blood Flow Velocity: A Pilot Study

Evan L. Matthews, Stephanie A. Guarino, Jennifer M. Masiddo, Peter A. Hosick. Montclair State University, Montclair, NJ. Email: matthewse@mail.montclair.edu (No relationships reported)

Echocardiographic Doppler is capable of continuously measuring blood velocity, and stroke volume at rest and during exercise. Doppler measurements require a near parallel angle between the flow of blood and the ultrasound signal necessitating apical cardiac views to obtain accurate absolute values. However, apical cardiac views are technically challenging during long serial recordings. Parasternal views

are less challenging, but do not provide a parallel angle to the aorta. If a relationship exists between the aortic Doppler measurements from these two cardiac windows, a correction calculation can be established to estimate stroke volume from the parasternal view. **PURPOSE:** To determine if a relationship exists between Doppler measurements made at the aorta in the parasternal long axis and apical three chamber echocardiographic views. **METHODS:** Healthy college age participants underwent Doppler ultrasound measurements at the aorta in the parasternal long axis and apical three chamber view. Linear cross sectional analysis was performed to assess aortic annulus area and Teichholz stroke volume estimates in the parasternal long axis. Only participants with complete data sets are included in this analysis. Bivariate correlations and t-test were used as appropriate to analyze the data. **RESULTS:** Of the 18 participants studied, only 12 (66.7%; 6 males, 6 females, age 25.5±1.1yrs, height 156±14.2cm, weight 69.8±4.5kg, body fat 20.6±2%) had adequate Doppler signal strength in the parasternal long axis view for software automated signal tracing. No relationship was found between the time averaged mean blood flow velocity measurements obtained in the parasternal long axis and apical three chamber views ($r=-0.216$, $p=0.498$). Parasternal long axis Doppler based stroke volume (25.9±4.9mL/beat) measurements were lower than parasternal long axis Teichholz estimated stroke volume (57.8±4.9mL/beat) measurements ($p<0.001$), with no correlation between the two ($r=0.402$, $p=0.190$). **CONCLUSIONS:** While this data is preliminary, it suggests that aortic Doppler measurements in the parasternal long axis view suffer from low Doppler signal strength, and are inaccurate when compared to more conventional measurements.

Cardioprotective Benefits Associated With Routine Physical Activity In Middle Aged Population
 Stephen Gagnon, Benjamin Skutnik, Joel Greenshields, Maleah Holland, Joel Stager, FACSM. *Indiana University, Bloomington, IN.* (Sponsor: Joel Stager, FACSM)
 Email: sgagnon@indiana.edu
 (No relationships reported)

Purpose: It is well known that routine intensive physical activity (PA) will result in positive cardiovascular adaptations. Similarly, it is known that aging will cause decrements in similar common measures of cardiovascular health. However, there is only limited data on the cardiovascular performance of an older, presumably healthy, physically active population who have remained active for decades. **Methods:** Thirteen masters level swimmers (MS) and eight controls (IC) (54.3 ± 12.7yrs and 57.5 ± 7.9yrs; respectively) were asked to wear an ambulatory heart rate monitor (Actiheart) for seven consecutive days. Subjects were partitioned based upon self-reported long-term physical activity and asked to maintain their normal daily activities for the entirety of the data collection period. Heart rate was collected during waking hours (14.8 ± 3.2 hrs). All HR data was verified via accelerometer. To measure HR_{peak} and estimate cardiovascular fitness level, subjects completed a 1-mile timed walk. Independent two-sample t-tests were used for all comparisons, significance set at $p<0.05$. **Results:** Mean daily HR_{min} and HR_{avg} was lower in MS than IC (54 ± 5 vs 67 ± 8bpm, 72 ± 8bpm vs. 83 ± 9bpm; $p<0.05$, respectively) while mean daily HR_{max} was higher in MS (139 ± 18bpm vs. 131 ± 19bpm; $p<0.05$). Mean daily HR_{max} was higher than HR_{peak} during the 1-mile test for MS (139 ± 19 vs. 123 ± 20bpm; $p<0.05$) but not for IC (131 ± 18 vs. 135 ± 18; $p = 0.69$). **Conclusions:** Persistent participation in routine physical activity at any age appears to result in training induced changes consistent with improved cardiovascular health. Results from the present study, however, suggest that a 1 mile walk may not be an appropriate test for the physically active as it tends to underestimate maximum values for heart rate.

Measurement of Myocardial Microvascular PO₂: Impact of Sumatriptan
 Sarah E. Dobard, Scott A. Cammack, William L. Sexton, FACSM. *A.T. Still University, Kirksville, MO.*
 Email: sdobard@atsu.edu
 (No relationships reported)

Triptan drugs (e.g., sumatriptan) are 5-HT_{1B/1D} receptor agonists that are prescribed for treatment of migraine. However, triptans may cause coronary vasoconstriction and increase the risk of adverse cardiac events. The balance between oxygen delivery (QO₂) and oxygen consumption (VO₂) at the tissue level is reflected in the microvascular partial pressure of oxygen (PO_{2,mv}). **PURPOSE:** To determine whether sumatriptan decreases coronary QO₂ and decreases PO_{2,mv} in a beating rat heart preparation. **METHODS:** Female Sprague-Dawley rats (n=22, 262 ± 4 g) were anesthetized with pentobarbital sodium (50 mg/kg ip). A tracheal cannula was inserted and the carotid artery and jugular vein were cannulated. A left lateral thoracotomy exposed the heart and mechanical ventilation was initiated (4-6 ml at 60 bpm; PaO₂ 74 ± 2, PaCO₂ 43 ± 2). PO_{2,mv} was measured by phosphorescence quenching. The fiber

optic probe of the phosphorometer was positioned over the left ventricular free wall to measure PO_{2,mv} during steady-state conditions and after the following interventions; 1) bolus infusion of sumatriptan (1 mg, n=7), 2) infusion of dobutamine (9 and 18 µg/min, n=5), 3) infusion of sumatriptan (37.5 and 75 µg/min, n=5), and 4) infusion of both dobutamine and sumatriptan (n=5). **RESULTS:** Left ventricular PO_{2,mv} averaged 75 ± 2 mmHg and mean arterial pressure (MAP) averaged 93 ± 5 mmHg. With a bolus infusion of sumatriptan, PO_{2,mv} fell 5 ± 1 mmHg and MAP fell 25 ± 4 mmHg, whereas infusion of an equivalent volume of saline vehicle had no effect. Dobutamine infusion caused PO_{2,mv} to fall 25 ± 3 mmHg and MAP to fall 39 ± 8 mmHg. Sumatriptan infusion did not impact PO_{2,mv} (0 ± 1 mmHg) or MAP (2 ± 2 mmHg). Simultaneous infusion of dobutamine and sumatriptan caused PO_{2,mv} to fall 19 ± 1 mmHg and MAP to fall 14 ± 5 mmHg. Isoproterenol was infused as a positive control (10 µg) at the end of each experiment to ensure responsiveness of the system. **CONCLUSION:** Bolus infusion of sumatriptan caused a small transient fall in left ventricular PO_{2,mv} suggesting a decrease in QO₂. In contrast, slow infusion of a low dose of sumatriptan did not impact PO_{2,mv} and did not exacerbate the effect of dobutamine. These findings do not support the notion that sumatriptan may elicit a profound vasoconstriction that would compromise cardiac function. Supported by a grant from the Graduate Program, KCOM-ATSU.

 (No relationships reported)

INTRODUCTION In heart failure with preserved ejection fraction (HFpEF), the underlying systemic inflammatory state is related to myocardial stiffening. However, optimal treatment remains largely undefined. **PURPOSE:** To investigate the effect of exercise training (ExT) on left ventricle (LV) stiffness in a rat model of HFpEF. **METHODS:** The study was performed with nine-week old ZSF1 obese rats (Ob n=20). At the 16th week, they were randomly divided in sedentary (ObSED, n=10) and exercised (ObEX, n=10; treadmill ExT during 4 weeks, 5 days/week, 60 min/day, at a speed of 20m/min). In the 18th week, all animals underwent echocardiographic evaluation. In the 20th week, animals were sacrificed and samples from heart and LV were collated for: i) histological analysis (cross-sectional area (CSA), collagen content; ii) passive tension analysis in skinned cardiomyocytes; iii) assessment of expression on matrix metalloproteinases (MMP-2,-9) and its tissue inhibitors (TIMP-1 and 2) by western blot analysis and iv) zimography assessment of proteolytic activity. **RESULTS:** Both groups presented preserved ejection fraction (>70%). ExT improved diastolic function evidenced by E/E' ratio (14.81±2.27 vs 16.53±1.47 $p<0.05$). Moreover, in skinned cardiomyocytes, the ObEX showed decreased passive tension, which suggests a reduction in myocardial stiffness ($p<0.05$). No significant differences were observed between the groups in body mass, heart and LV weight, CSA, and MMPs and TIMPs expression and activity ($p>0.05$). However, the ratio collagen/muscle was significantly reduced in ObEX, compared to ObSED (0.08 vs. 0.12 $p<0.05$). **CONCLUSION:** ExT improves diastolic function mainly due to the decrease on collagen deposition and diminished cardiomyocyte stiffness. **FUNDING:** Grant from the European Commission FP7-Health-2010; MEDIA-261,409. CIAFEL is funded by European Regional Development Fund through the Operational Competitiveness Programme, and by FCT (UID/DTP/00617/2013). Schmidt, C.: CAPES (BEX 0554/14-6). Global Longitudinal Strain And Left Ventricular Remodelling In Young Black Athletes
 Benedetta Tosi, Melissa Orlandi, Chiara Giannelli, Loira Toncelli, Laura Stefani, Giorgio Galanti. *Sport Medicine Center, Florence, Italy.*
 Email: giorgio.galanti@unifi.it
 (No relationships reported)

Purpose: Cardiac adaptation to intense physical training is determined by many factors including age, gender, body size, load training and ethnicity. ECG analysis investigating the impact of ethnicity has shown a higher presence of marked repolarization changes and left ventricular (LV) hypertrophy in black compared to

white athletes. Despite the wide availability of ECG analysis, echocardiographic studies on young black and white athletes are lacking in literature. We aimed to assess the secondary LV remodelling to load training in young black players compared to matched white players. **Methods:** 77 young black soccer players (BP) and 53 white matched soccer players (WP) (mean age = 17.35±0.50 and 18.25±0.77 yo in BP and WP, respectively) were enrolled. The athletes, training with the same load and having the same lifestyle, were evaluated with echocardiography. 30 BP and 27 WP were followed up for 4 years (mean age at the first evaluation: 12.47±0.60 and 13.90±0.50 yo in BP and WP, respectively). Contractile function was determined using speckle-tracking echographic global longitudinal strain (GLS). **Results:** No significant differences in basal anthropometric parameters were found in both groups. BP showed higher level of LV remodelling, consisting in higher interventricular septum (IVS) and posterior wall (PW) thickness (IVS: 10.04±0.14 and 9.35±0.10mm, p<0.001; PW: 9.70±0.20 and 9.19±0.10mm, p<0.05; in BP and WP respectively). Strain data showed no significant differences between the two groups (-22.35±0.48 and -23.38±0.69% in BP and WP, respectively). At the beginning of the follow up period, BP showed a significantly higher LV remodelling (IVS= 9.29±0.3 and 8.53±0.12mm, p<0.002; PW= 9.01±0.2 and 8.40 ±0.20, p=0.1; in BP and WP respectively). A regular parallel increase in LV wall thickness and diameters, proportionally with body-size and LV mass, was observed in both groups during the follow-up period (IVS=10.52±0.17 and 9.03±0.22mm, p<0.001; PW: 10.06±0.17 and 8.26±0.19mm, p<0.001; in BP and WP respectively). **Conclusion:** LV remodelling in BP seems to be a specific and normal phenotype already present in pre-adolescent period, suggesting the central role that ethnicity plays in it since the first years of life in elite athletes and the need for echocardiographic specific ethnic criteria.

Effects Of Endurance Exercise Training On Doxorubicin-induced Changes In Cardiac Insulin-like Growth Factor-1 Expression
 Nicole R. Wood, Reid Hayward, David S. Hydock. *University of Northern Colorado, Greeley, CO.*
 Email: nicole.wood@unco.edu
 (No relationships reported)

Doxorubicin (DOX) is a highly effective chemotherapeutic agent used in the treatment of cancer; however, its clinical use is limited due to a dose-dependent cardiotoxic side-effect. Insulin-like growth factor-1 (IGF-1) signaling regulates contractility, metabolism, hypertrophy, apoptosis, and many other process related to optimal cardiac function. DOX treatment has been shown to decrease IGF-1 expression and down-regulate other markers in the IGF-1 signaling pathway. Although exercise training has been shown to mitigate the cardiotoxic side-effects of DOX, it is unclear whether exercise may mediate its effects via IGF-1 expression. **PURPOSE:** The purpose of this study was to examine the effects of endurance exercise on DOX-induced changes in cardiac IGF-1 expression. **METHODS:** Male Sprague-Dawley rats (n = 12) were randomly assigned to either sedentary (SED) or treadmill (TM) exercise groups. The TM protocol included 10 weeks of running, 5 days/week, with progressive increases in intensity and duration on a motorized treadmill, while SED animals were limited to normal cage activity for 10 weeks. Following the 10-week treatment period, animals were further randomized to receive saline (SAL) or a 12.5 mg/kg bolus dose of DOX. Cardiac IGF-1 was quantified in all hearts three days following injection. **RESULTS:** Cardiac IGF-1 expression decreased 22% in the SED/DOX group when compared to SED/SAL (Cohen's d = 0.774). Results also indicate a 22% increase in IGF-1 expression in the TM/SAL group when compared to the SED/SAL group (Cohen's d = 0.843) and a 16% increase in IGF-1 expression in the TM/DOX group when compared to SED/DOX (Cohen's d = 1.131). **CONCLUSIONS:** These pilot studies show that the cardioprotective effects of exercise may be mediated, at least in part, through preservation of IGF-1 expression. Initial data from these studies show a large effect size across all comparisons and warrants further exploration with larger sample sizes. While several mechanisms may explain exercise-induced protection against chemotherapy cardiotoxicity, IGF-1 and IGF-1 signaling pathways may be involved.

Effect of Cardiac Resynchronization Therapy on Arterial-Ventricular Coupling during Exercise in Heart Failure with Reduced Ejection Fraction
 Corey R. Tomczak¹, Mark J. Haykowsky², Ian Paterson³.
¹University of Saskatchewan, Saskatoon, SK, Canada.
²University of Texas at Arlington, Arlington, TX. ³University of Alberta, Edmonton, AB, Canada.
 Email: corey.tomczak@usask.ca
 (No relationships reported)

Exercise intolerance in heart failure with reduced ejection fraction (HFrEF) is mediated, in part, by an impairment in arterial-ventricular coupling. Cardiac resynchronization therapy (CRT) improves resting and paced arterial-ventricular coupling. The effect of chronic CRT on arterial-ventricular coupling during exercise

in HFrEF has not been studied. **PURPOSE:** To study the effects of 6 months of CRT on arterial-ventricular coupling during exercise in patients with HFrEF. **METHODS:** Seven patients with HFrEF (59 ± 9 yrs; m/f: 5/2; NYHA III/IV = 6/1; EF = 18 ± 3%; peak VO₂ = 12.5 ± 3.6 ml/kg/min) were studied pre-CRT and 6 months following (post-CRT). After resting measurements, subjects performed cycle ergometry at 22 ± 8 W (70 ± 13% of peak VO₂) for 4 min. Left ventricular volumes were determined using contrast enhanced echocardiography. Blood pressure was measured manually at the brachium. End-systolic pressure (ESP) was approximated as 0.9 × systolic blood pressure. Effective arterial elastance (Ea) was calculated as ESP/stroke volume and end-systolic elastance (Ees) was calculated as ESP/end-systolic volume. Arterial-ventricular coupling was calculated as Ea/Ees. Comparisons were made with a 2 (rest, exercise) × 2 (pre-CRT, post-CRT) repeated measures factorial ANOVA and *t*-tests. Data are mean ± SD and P < 0.05 was significant. **RESULTS:** There was a main effect of CRT on Ea, where the pre-CRT Ea increased 0.28 ± 0.45 mmHg/mL during exercise and the post-CRT Ea decreased 0.12 ± 0.25 mmHg/mL (P < 0.05). There was no main effect of CRT on Ees, as both the pre-CRT (0.04 ± 0.03 mmHg/mL) and post-CRT (0.08 ± 0.04 mmHg/mL) increase in Ees from rest to exercise was not significant (P > 0.05). However, resting and exercise Ees tended to be higher post-CRT. Lastly, there was a main effect of CRT on Ea/Ees, where Ea/Ees increased 0.40 ± 1.35 mmHg/mL from rest to exercise pre-CRT and Ea/Ees decreased 0.69 ± 0.35 mmHg/mL from rest to exercise post-CRT (P < 0.05). **CONCLUSION:** The improvement in arterial-ventricular coupling during exercise following chronic CRT in HFrEF can be attributed to improvements in arterial loading on the left ventricle, as contractility changes related to CRT were modest.

Adequate reference values for cardiopulmonary exercise testing (CPET) is crucial for accurate interpretation and prognostic purposes for children with a chronic disease. Current reference values in healthy children have been developed using heterogeneous exercise protocols and often incomplete adjustment for body size. **PURPOSE:** To update current reference values from CPET and provide new reference values for several parameters previously unstudied in children using a prospectively recruited cohort of healthy children. **METHODS:** In this cross-sectional multicenter study, we prospectively recruited 269 healthy children (♂=107; ♀=162) between the ages of 12-17 years old (14.8 ± 1.5) in local schools. We measured height, weight, waist circumference, pubertal development and fat free mass (FFM) and performed a symptom-limited CPET (Vmax Encore Metabolic Cart, SensorMedic, San Diego, CA) on an electronically-braked ergocycle using a progressive ramp protocol. Reference values and Z score were computed by testing several regressions models for each CPET measurement. Variation around the predicted mean was modeled to account for heteroscedasticity and residual association with growth-related parameters was assessed. **RESULTS:** Using currently published reference values, up to 31.2% of children were classified as having abnormal CPET results despite being free of chronic disease. Our weighted non-linear parametric modeling allowed more precise and well-adjusted Z scores and percentiles limits. The table shows a selection of our predicting equations as well as the percentage of children below the 3rd percentile. Selection of prediction equations for males

Parameters	Z score equation (Measured parameter - Predicted mean) / Predicted SD	% of children below the 3 rd percentile
Peak VO ₂	$Z \text{ score} = \frac{\text{Peak VO}_2 - [(-0.52 \times \text{FFM}^2) + (100.2 \times \text{FFM}) + (-970.38)]}{(3.95 \times \text{FFM}) + 152.6}$	5.6%
Peak O ₂ pulse	$Z \text{ score} = \frac{\text{Peak O}_2 \text{ pulse} - [(0.002 \times \text{FFM}^2) + (0.47 \times \text{FFM}) + (-3.91)]}{(0.03 \times \text{FFM}) + 0.64}$	6.7%
OUES	$Z \text{ score} = \frac{\text{OUES} - [(-0.17 \times \text{FFM}^2) + (62.4 \times \text{FFM}) + (162.11)]}{(6.37 \times \text{FFM}) + 91.67}$	2.8%
VE/VO ₂ slope	$Z \text{ score} = \frac{\text{VE} / \text{VO}_2 - [(0.005 \times \text{FFM}^2) + (-0.56 \times \text{FFM}) + (43.79)]}{(-0.03 \times \text{FFM}) + 4.86}$	0.9%

CONCLUSION: The use of weighted non-linear regression model resulted in a decreased false-positive rate. These updated and new reference values provide an accurate lower limit of normal thus improving their value for prognostic and risk-stratification in children with chronic diseases.

Abstracts were prepared by the authors and printed as submitted.

(No relationships reported)

Children after the Fontan operation have reduced heart rate variability (HRV) and altered blood pressure control, consistent with autonomic dysfunction. We tested the hypothesis that increasing sympathetic nerve activity via the muscle metaboreflex may improve post exercise blood pressure responses in children after the Fontan operation. **PURPOSE:** To determine resting HRV and the mean arterial pressure (MAP) response to post-handgrip exercise muscle metaboreflex activation in children after the Fontan operation compared to age- and sex-matched healthy controls. **METHODS:** Five children after the Fontan operation and 10 controls (12 ± 2 yrs) underwent resting electrocardiography and continuous finger arterial plethysmography. Children then completed 2 min of isometric handgrip exercise at 30% of maximal voluntary contraction, followed in random order by either (1) 3 min of rest with no occlusion or (2) 3 min of brachial cuff occlusion to produce post exercise ischemia and increased sympathetic nerve activity via the muscle metaboreflex. Post-handgrip MAP changes were calculated as the 1 min average value after 3 min of recovery minus the pre-handgrip resting 1 min average value. Comparisons were made using unpaired *t*-tests. *P* < 0.05 was significant. **RESULTS:** Resting heart rate was higher in children after the Fontan operation vs. controls (78 ± 14 vs. 67 ± 5 beats/min; *P* = 0.041). HRV spectral analyses were similar in the low frequency domain (24 ± 10 vs. 22 ± 13%; *P* = 0.720), but increased in the high frequency domain (23 ± 15 vs. 52 ± 16%; *P* = 0.005) and low/high frequency domain ratio (1.5 ± 1.3 vs. 0.6 ± 0.4; *P* = 0.046) for children after the Fontan operation vs. controls, indicating autonomic dysfunction. Following isometric handgrip exercise with no occlusion, the change in heart rate (-2 ± 5 vs. -3 ± 5 beats/min; *P* = 0.646) was similar, but children after the Fontan operation had greater lowering in MAP (-5 ± 1 vs. 0 ± 5 mmHg; *P* = 0.024) vs. controls. With brachial occlusion, changes in heart rate (0 ± 5 vs. -1 ± 6 beats/min; *P* = 0.701) and MAP (6 ± 7 vs. 6 ± 7 mmHg; *P* = 0.980) were similar between children after the Fontan operation vs. controls. **CONCLUSION:** Our findings suggest that increasing sympathetic nerve activity via the muscle metaboreflex helps to improve post exercise blood pressure responses in children after the Fontan operation.

Race Effect On Improved Aerobic Efficiency In Pediatric Obese Patients After A Weight Management Program

Sandra K. Knecht, Wayne A. Mays, Michelle A. Amos, Yvette M. Gerdes, Clifford Chin. *Cincinnati Children's Hospital, Cincinnati, OH.*

Email: sandy.knecht@cchmc.org

(No relationships reported)

BACKGROUND: Studies have shown that obesity may be influenced by measurable racial differences in metabolism. The current study aims to establish the effect of race on aerobic efficiency in obese patients participating in a weight management program. **METHODS:** We evaluated 60 African American (AA) and 135 Caucasian (C) pediatric patients using a Modified Balke protocol before (Pre) and after (Post) a 16-week weight management program. Oxygen consumption (VO₂), indexed maximal oxygen consumption (IMVO₂), carbon dioxide production (VCO₂), expiratory volume (VE), respiratory quotient (RQ) and heart rate (HR) were obtained at all submaximal and maximal stages. The VE/VO₂ slope (SLOPE) was calculated across all stages for each subject. VE/VO₂ and VE/VCO₂ equivalents (AT VE/VO₂ and AT VE/VCO₂) were calculated at anaerobic threshold for each subject. Maximal oxygen pulse (O2Pulse) was calculated by dividing maximal oxygen consumption (MVO₂) by maximal HR (MHR) and used as an indicator of maximal stroke volume.

	AA Pre	AA Post	C Pre	C Post
Weight (kg)	98 ± 30	99 ± 30	85 ± 29	82 ± 28**
IMVO ₂ (cc/kg/min)	23 ± 3	26 ± 4**	26 ± 5	31 ± 6**
ET (minutes)	10.9 ± 3.0	13.2 ± 3.4**	13.3 ± 3.7	16.5 ± 4.0**
MHR (BPM)	190 ± 13	190 ± 12	192 ± 9	194 ± 9*
SLOPE	26 ± 9	24 ± 5	24 ± 3	23 ± 4*
O2Pulse	11.6 ± 3.4	13.0 ± 3.4**	11.4 ± 3.4	12.7 ± 3.8**
MRQ	1.02 ± 0.06	1.05 ± 0.08**	1.06 ± 0.08	1.06 ± 0.07
AT VE/VO ₂	22.8 ± 3.6	22.0 ± 3.2	22.2 ± 4.1	20.9 ± 3.5**
AT VE/VCO ₂	25.4 ± 3.5	25.2 ± 3.3	24.7 ± 3.8	24.6 ± 3.9

Pre versus Post: * *p* < 0.05, ** *p* < 0.01

RESULTS: There was no significant difference in mean age between AA and C groups (12.4 ± 2.8, 11.8 ± 2.9 years pre-program). The C group had a significant decrease in weight (84.9 ± 28.8 vs 81.7 ± 27.7 kilograms (kg)) pre and post program. IMVO₂, exercise time (ET), and O2Pulse was significantly increased post program in both groups with a significant increase in MHR in the C group. Aerobic efficiency improved in the C group only, noted by a decrease in SLOPE and VE/VO₂ equivalent. **CONCLUSION:** These data suggest that a 16-week weight management program increases aerobic capacity in both AA and C obese pediatric patients. Improved aerobic efficiency, however, was only seen in the C group. Further investigation into racial disparity effecting weight loss and aerobic efficiency is warranted.

Relationship between Self-Reported Physical Activity Levels and Exercise Capacity in Pediatric Fontan Patients

Kelli Teson, David White, Jessica Hall, Suma Goudar. *The Children's Mercy Hospital, Kansas City, MO.*

Email: kmteson@cmh.edu

(No relationships reported)

Cardiopulmonary exercise testing is routine in the care of children with cardiac disease. Those with single ventricle physiology after Fontan completion have limitations in cardiac function and exercise tolerance. Hemodynamic adaptations may be affected following surgery, and it is unclear if this alters the relationship between leisure time physical activity (PA) and peak oxygen consumption (VO₂). **PURPOSE:** To examine the relationship between self-reported leisure time PA and peak VO₂ in pediatric Fontan patients. **METHODS:** Twenty-six youth with Fontan physiology (age 14.2 ± 2.1 yrs, male 57%) underwent routine cardiopulmonary exercise testing. Peak VO₂ (ml/kg/min), respiratory exchange ratio (RER), VE/VCO₂ slope, oxygen pulse (ml/beat), and maximal heart rate (bpm) were measured. Subjects exercised to volitional fatigue on a cycle ergometer using the Modified James protocol. Subjects were excluded if RER at peak VO₂ was < 1.0. Self-reported leisure time PA was assessed using the interviewer administered Modifiable Activity Questionnaire for Adolescents (MAQ-A). Relationships were assessed using Pearson partial correlations and nonparametric Kruskal-Wallis tests. **RESULTS:** Significant positive relationships were found between VO₂ peak (24.44 ± 5.8 ml/kg/min) and self-reported hours per week of PA (1.36 ± 1.15 hrs) (*r* = 0.534, *p* < 0.05) and MET hours per week of PA (7.71 ± 6.66 MET hrs) (*r* = 0.483, *p* < 0.05). Significant negative relationships were found between VE/VCO₂ slope (35.78 ± 7.08) and hours per week of PA (1.36 ± 1.15 hrs) (*r* = -0.481, *p* < 0.05) and MET hours per week of PA (7.71 ± 6.66 MET hrs) (*r* = -0.483, *p* < 0.05). Days per week of light exercise was associated with VE/VCO₂ slope (*X*² = 9.57, *p* < 0.05) and O₂ pulse (*X*² = 12.9, *p* < 0.05). **CONCLUSIONS:** Greater self-reported hours per week and MET hours per week of leisure time PA were associated with higher peak VO₂ and lower VE/VCO₂ slopes. Despite the hemodynamic compromises in single ventricle Fontan physiology, routine leisure-time PA appears to have a beneficial effect on both aerobic capacity and ventilatory efficiency, thus improving their prognosis in cardiac mortality risk.

Adolescent Children Born Preterm Have An Inhibited Stroke Volume And Cardiac Output Response To Exercise

Kristin Haraldsdottir, Andrew Watson, Arij Beshish, Laura Tetri, Kara Goss, Mari Palta, Marlowe Eldridge. *University of Wisconsin, Madison, WI.*

Email: haraldsdotti@wisc.edu

(No relationships reported)

Purpose: Young adults born preterm exhibit lower ejection fractions and higher right ventricular mass but little is known about the consequences of premature birth on cardiac performance during exercise, particularly in children. The aim of the present

study was to compare the cardiac response to maximal exercise between adolescent children born preterm and age-matched controls. **Methods:** Seven children born preterm (PT) (age 12-13, birthweight <1500 g, gestational age 24-31 weeks) and 6 age-matched children born full term (CT) (gestational age 38-40 weeks) underwent progressive maximal exercise testing on a cycle ergometer, with continuous measurement of O_2 consumption (ml/kg/min), and cardiac output (Q), stroke volume (SV) and heart rate (HR) using thoracic bioimpedance. SV and Q were indexed to body surface area (BSA (m^2)), SVi and Qi, respectively). HR was recorded for two minutes following exercise, and HR recovery (HRR_{2min}) was calculated as decrease in HR at 2 minutes after maximal exercise. Statistical analysis was done using multiple t-tests. **Results:** PT had lower relative maximal oxygen consumption (VO_{2max}) compared to CT (38.3 ± 9.3 v 51.5 ± 7.3 ml/kg/min, $p=0.03$). SV did not increase in PT from rest to maximal exercise (51.7 ± 9.0 v 53.3 ± 8.3 ml/ m^2 , $p=0.77$), while SV significantly increased in CT (47.4 ± 4.0 v 67.7 ± 14.4 ml/ m^2 , $p=0.01$). The change in SV from rest to maximal exercise was significantly smaller in PT compared to CT (1.6 ± 6.5 v 20.3 ± 17.0 ml/ m^2 , $p=0.04$). The increase in Qi from rest to exercise was also significantly smaller in PT than CT (5.6 ± 1.1 v 9.0 ± 2.6 L/min/ m^2 , $p=0.02$). There was no difference in resting or maximal HR between the groups ($p>0.05$ for all). HRR_{2min} was lower in PT than CT (54 v 64 beats, $p=0.01$). Maximal arterio-venous O_2 difference was not different in PT compared to CT (13.2 ± 6.5 v 13.2 ± 2.3 ml/dL, $p=0.98$). **Conclusion:** Adolescent children born preterm exhibit lower maximal aerobic capacity and significantly smaller maximal SVi and Qi than age-matched controls. PTs also demonstrated slower HRR after maximal exercise. This data suggests that PTs may not be able to increase SV in response to increasing metabolic demand, and this may reduce their ability to exercise at higher intensities. National Institutes of Health: 1R01 HL086897 (ME) and R01 HL38149 (MP), and UW CVRC T32- HL 07936 (KH).

Activity Levels and Caloric Expenditure in Obese Youth Before, During and After Weight Management Camp.
 Christopher Kist, Amanda Gier, Shelley Kirk, Philip Khoury, Robert Siegel. *Cincinnati Children's Hospital, Cincinnati, OH.*
 Email: christopher.kist@cchmc.org
 (No relationships reported)

PURPOSE: To compare the physical activity levels and caloric expenditure of participants before, during and after a weight management camp for youth with obesity. **METHODS:** Fifteen obese youth, ages 9 to 13 years, were recruited at an open house for an overnight weight management camp. Informed consent/assent was obtained. Subjects wore GENEActiv accelerometers 24 hours/day for approximately one week before, during, and after camp. Data were analyzed to determine the amount of time each participant spent in sedentary (SED), moderate (MPA) and vigorous (VPA) activity, as well as calories expended (EE). The participants' activity levels and caloric expenditure and other subject characteristics were compared during the week of camp and weeks at home. **RESULTS:** Complete usable data was obtained from 10 (67%) participants (6 boys, 4 girls). Mean age (\pm SD) was 11.7 ± 1.2 years. Mean BMI was 32.25 ± 5.1 kg/ m^2 . Overall, there were no significant differences between the weeks at home for SED, MPA, VPA or EE. During camp, participants averaged less daily SED than at home (428.38 ± 63.20 minutes, $p=0.0003$) and more MPA (363.4 ± 38.63 , $p=0.0001$) and VPA (55.05 ± 33.96 , $p=0.0055$). Average EE was also higher during camp (3.00 ± 0.57 kcal/min, $p=0.0004$). A higher BMI was strongly associated with more SED and less MPA and VPA before ($r=0.87$, $r=-0.83$ and $r=-0.71$) and during ($r=0.75$, $r=-0.69$ and $r=-0.78$) camp. **CONCLUSION:** Obese youth exercise at higher intensities and expend significantly more energy while participating in a summer weight management camp versus on their own at home. BMI of the participants also plays a key role in determining caloric expenditure and intensity of activities they participate in at home and while attending camp. Campers were no more or less active in the week following camp as the week prior to camp, indicating camp did not have an impact on motivation or self-selected exercise at home.

2587 Board #107 June 2 11:00 AM - 12:30 PM
Accuracy of Cardiorespiratory Fitness and Adiposity to Discriminate Elevated Cardiometabolic Risk Among Prepubertal Children
 Tuomo Tompuri¹, Jarmo Jaaskelainen¹, Eero Haapala², Tomi Laitinen¹, Timo A. Lakka². ¹*Kuopio University Hospital, Kuopio, Finland.* ²*University of Eastern Finland, Kuopio, Finland.*
 (No relationships reported)

The measures of cardiorespiratory fitness scaled by lean mass (LM) have physiological rationale for assessing aerobic capacity as the scaling by body weight introduces confounding by adiposity.

PURPOSE: To investigate differences in the accuracy to discriminate elevated cardiometabolic risk between the measures of adiposity and cardiorespiratory fitness when using alternative methods to perform body size related scaling of maximal workload (Wmax).

METHODS: Altogether 448 children (214 girls) aged 6-8 years participated in the study. We assessed fat mass (FM), percent body fat (%BF) and LM by dual-energy X-ray absorptiometry, and Wmax by incremental bicycle ergometer exercise test. Absolute and by body weight, FM and LM scaled Wmax were used in the analysis. We used age and sex-specific criteria (Ahrens et al. *Int J Obes*, 2014;38:S4-S14) to define dyslipidemia (elevated triglycerides or high density lipoprotein cholesterol), elevated blood pressure and elevated insulin resistance (HOMA-IR), and 90th percentile for cardiometabolic risk score (CMS) to define elevated cardiometabolic risk. We used area under the curve (AUC) by receiver operating characteristics to investigate the accuracy of the measures of cardiorespiratory fitness and adiposity to discriminate elevated cardiometabolic risk, and the Youden index to assess the thresholds discriminating elevated CMS.

RESULTS: In boys, %BF and Wmax/FM were able to discriminate CMS (AUC 0.86, $P<0.001$), HOMA-IR (AUC 0.79-0.80, $P<0.001$), elevated blood pressure (AUC 0.73-0.74, $P<0.001$) and dyslipidemia (AUC 0.64, $P<0.05$). While Wmax/body weight had AUC 0.82 ($P<0.001$) for CMS, and AUC 0.71 ($P=0.001$) for HOMA-IR and AUC 0.64 ($P<0.05$) for elevated blood pressure, Wmax/LM had AUC 0.65 ($P<0.05$) for CMS and the absolute Wmax had AUCs <0.6 . In girls, %BF, Wmax/FM and Wmax/body weight were able to discriminate CMS (AUC 0.75-0.78, $P<0.001$) and HOMA-IR (AUC 0.69-0.71, $P<0.01$). Proposed thresholds in girls and in boys were 2.3 and 2.6 W/kg of body weight (sensitivity 67 and 64%; specificity 80 and 85%) and 3.9 W/kg of LM in boys (sensitivity 82%; specificity 45%).

CONCLUSIONS: Measures representing adiposity (%BF; Wmax/FM; Wmax/body weight) were the best discriminators for cardiometabolic risk, and Wmax/LM showed ability to discriminate elevated CMS only in boys.

2588 Board #108 June 2 11:00 AM - 12:30 PM
High-intensity Interval Training in Children With A Chronic Disease Or Condition
 Maremka Zwinkels¹, Tim Takken², Anne Visser-Meily², Olaf Verschuren¹. ¹*De Hoogstraat Rehabilitation, Utrecht, Netherlands.* ²*University Medical Center Utrecht, Utrecht, Netherlands.* (Sponsor: Thomas Janssen, FACSM)
 Email: m.zwinkels@dehoogstraat.nl
 (No relationships reported)

High-intensity interval training (HIT) is superior compared to moderate-intensity continuous training for improving anaerobic fitness, agility and aerobic fitness. However, for children and adolescents with a chronic disease or condition the effects of HIT as a training modality is relatively unknown. **PURPOSE:** To investigate the effect of eight weeks of HIT on physical fitness in children and adolescents with a chronic disease or condition who 1) are able to run, 2) walk independently but are not able to run, and 3) propel a manual wheelchair. **METHODS:** A total of 68 children and adolescents were recruited from schools for special education in the Netherlands (mean age 13.5 ± 2.8 , range 8-19 years, 56% boys). They had various chronic diseases: cerebral palsy (41%), spina bifida (8%), other neuromuscular diseases (34%), musculoskeletal (4%), cardiovascular (4%) and metabolic diseases (9%). The sample consisted of 35 runners, 24 independent walkers, and 9 wheelchair users. All subjects performed HIT twice a week for 45 minutes. Every session consisted of 8-12 intervals containing a 30 seconds all-out exercise followed by 90 or 120 seconds of active recovery. Anaerobic fitness was measured by the Muscle Power Sprint Test (MPST), agility with the 10x5 meter sprint test and a shuttle run/ride test (SRT) was performed to determine aerobic performance (shuttles) and aerobic capacity (VO_{2peak}). **RESULTS:** Exercise attendance was 85%. A significant improvement in respectively mean and peak power on the MPST was only found for children and adolescents who are able to run ($p=.043$; $p=.028$). Both agility and aerobic performance on the SRT showed a significant training effect in all groups; runners ($p=.001$; $p<.001$), independent walkers ($p=.024$; $p=.006$) and wheelchair users ($p=.024$; $p=.012$). However, VO_{2peak} (ml/kg/min) did not change significantly in all groups of functional mobility. **CONCLUSION:** HIT is feasible in children and adolescents independent of mode of mobility. Agility and aerobic performance, both parameters containing motor-skills, improved. However, since anaerobic fitness improved only in children and adolescents who are able to run, the 30s all-out HIT principle is probably not applicable for independent walkers and wheelchair users. Future studies about HIT protocols to improve VO_{2peak} as well are warranted.

An Assessment of Cardiovascular Health in Southern Maine Children and Comparison to National Normative Values
 Katherine Wallingford. *University of New England, Biddeford, ME.*
 Email: kwallingford1@une.edu
 (No relationships reported)

Childhood obesity has been on the rise, with an increase in obesity from 7% to 18% from 1980 to 2012. Along with the rise in obesity, the onset of coronary artery disease

(CAD) risk factors has become more prominent in children. **PURPOSE:** The purpose of this study was to assess current CAD risk factors in Southern Maine (SM) children and compare to National norms. **METHODS:** A total of 691 children participated in the Cardiovascular Health Intervention Program (368 females, 323 males, 9.2 ± .41 years old). Assessment included a fasting blood lipid/glucose profile, height, weight, and blood pressure (BP). Surveys were used to assess physical activity (PA) level. **RESULTS:** Females had higher values for total cholesterol (TC) ($p < .00$) and triglycerides ($p < .00$), while males had higher values for HDL-C ($p < .05$) and glucose ($p < .00$). In respect to the number of risk factors, 12.3%, 36.03%, 28.36%, 18.67%, 3.91%, and 0.72% had 0, 1, 2, 3, 4, or 5 risk factors, respectively for females and males combined. In comparison to National norms, 8% of children 6-11 years old nationally had high total cholesterol (> 170 mg/dl), versus 35% for SM children. Nationally and in SM, 14% of children had low levels of HDL-C (< 45 mg/dl). In SM, 51.23% of children reported they were physically inactive (< 60 min/day), in comparison to 58% nationally. Nationally, 16.5% and 17.7% of children were overweight ($> 85^{\text{th}}$) or obese ($> 95^{\text{th}}$), versus 20.47% and 22.8% of children in SM, respectively. Only 1.6% of children nationally had high blood pressure ($> 95^{\text{th}}$), versus 5.93% of children in SM. In SM, 26.34% of children reported a family history of heart disease, versus 33% nationally. **CONCLUSION:** The observed CAD risk factors at this age differ between sex and may be related to one's maturation status. The number of CAD risk factors at this age is somewhat alarming, in that more than 25% of the subjects had at least two CAD risk factors. Lastly, in comparison to National norms, SM children had higher BMIs, which may reflect the observed higher lipid and blood pressure values, whereas PA appears to be greater. Funding provided by Clark Charitable Foundation (Subcontract from Children's National Medical Center, Washington, DC)

2590 Board #110 June 2 11:00 AM - 12:30 PM
Exploring the Relationships of Body Composition, Aerobic Fitness and Physical Activity Levels with Arterial Stiffness in Healthy Children with Children with Congenital Heart Disease

Shayne Hayward¹, Natasha G. Boyes¹, Michael K. Stickland², Stephanie Fusnik¹, Elizabeth Hogeweide¹, Josie TJ Fries¹, Mark J. Haykowsky³, Shonah Runalls¹, Ashok Kakadekar¹, Scott Pharis¹, Charissa Pockett¹, Kristi D. Wright⁴, Timothy J. Bradley¹, Marta Erlandson¹, Corey R. Tomczak¹. ¹University of Saskatchewan, Saskatoon, SK, Canada. ²University of Alberta, Edmonton, AB, Canada. ³University of Texas Arlington, Arlington, TX. ⁴University of Regina, Regina, SK, Canada. (Sponsor: Paul J Fadel, FACSM)
 (No relationships reported)

Physical activity is a key modulator for arterial health and greater arterial stiffness increases mortality risk. Children with congenital heart disease (CHD) are often less physically active compared to healthy children and this may predispose them to greater arterial stiffness. **PURPOSE:** To explore the relationships of body composition, aerobic fitness and physical activity levels with arterial stiffness in children with CHD and healthy age- and sex-matched controls. **METHODS:** Nineteen children with CHD (m/f: 9/10; mean ± SD; age 11 ± 3 years) and 22 age-matched healthy controls (m/f: 12/10; age 11 ± 3 years) were studied. Carotid-radial pulse-wave velocity (PWV) was assessed with applanation tonometry (foot-to-foot method) to determine arterial stiffness. Average daily minutes of moderate-to-vigorous physical activity (MVPA) was assessed by 7-days of accelerometry. Total lean body mass (LBM) was measured via dual-energy x-ray absorptiometry. Aerobic fitness was determined by 6-minute walk test (6MWT). Data were analyzed with linear correlations and stepwise multiple regressions, with significance accepted at $P < 0.05$. Analyses were performed across all participants pooled, split into CHD and control groups only, and split into high MVPA ($N = 21$; 64 ± 19 minutes/day) and low MVPA ($N = 20$; 23 ± 11 minutes/day) groups. **RESULTS:** There was a significant correlation of LBM with PWV in all participants pooled ($R = 0.536$, $P < 0.001$) and in controls only ($R = 0.668$, $P < 0.001$), but not in CHD only. There was no significant correlation of 6MWT or MVPA with PWV in pooled analyses or when split into CHD and control groups. When split by physical activity level, in the high MVPA group, LBM significantly predicted PWV ($R^2 = 0.224$, $P = 0.03$), and in the low MVPA group, LBM and 6MWT distance significantly predicted PWV ($R^2 = 0.571$, $P = 0.001$). **CONCLUSIONS:** In children with CHD and healthy controls, body composition predicts arterial stiffness independent of physical activity levels. Aerobic fitness further predicts arterial stiffness only in children with low physical activity levels. Our findings suggest that interventions to improve body composition and aerobic fitness may be especially important for arterial health in less physically active children, independent of health status.

2591 Board #111 June 2 11:00 AM - 12:30 PM
Muscle Strength and Power Deficits in Children with Type SS Sickle Cell Disease

Kelly A. Dougherty¹, Chiara Bertolaso², Joan I. Schall³, Kim Smith-Whitley⁴, Virginia A. Stallings⁴. ¹Stockton University, Galloway, NJ. ²University Hospital Umberto I, Sapienza University, Rome, Italy. ³The Children's Hospital of Philadelphia, Philadelphia, PA. ⁴The Children's Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA. Email: Kelly.Dougherty@stockton.edu
 (No relationships reported)

We previously showed (Dougherty et al., 2011) that muscle strength and power adjusted for body size and composition deficits, were attenuated in children with type SS sickle cell disease (SCD-SS) compared to healthy African-American children. However, in today's SCD clinical care environment, hydroxyurea is considered a "standard of care" treatment and is introduced at a young age. It is unclear if this change in treatment may have corrected these body size and muscle performance deficits. **PURPOSE:** To compare muscle strength and power, adjusted for body size and composition, in a contemporary group of 5- to-20-yr-old African-American children with and without SCD-SS. **METHODS:** Anthropometry and DXA for body composition were measured and associated Z-scores generated. Maximum muscle strength with a handgrip dynamometer and peak power via 3 squat jumps on a force plate were assessed. **RESULTS:** Twenty-one children with SCD-SS and 23 healthy control children did not differ by age (11 ± 1 vs. 10 ± 1 yrs), sex (male, female: 9, 12 vs. 13, 10) or maturation stage (Tanner 1, 2, 3, 4, 5: 10, 4, 3, 4, 0 vs. 11, 2, 5, 3, 2), respectively. Children with SCD-SS compared to healthy controls had significantly lower (all $P < 0.05$) height Z (-0.5 ± 0.3 vs. 0.4 ± 0.2), weight Z (-0.7 ± 0.3 vs. 0.8 ± 0.2), BMI Z (-0.6 ± 0.2 vs. 0.7 ± 0.2), arm circumference Z (-0.9 ± 0.3 vs. 0.8 ± 0.3), upper arm muscle area Z (-0.6 ± 0.3 vs. 1.0 ± 0.4), and whole body lean mass-for-height Z (-1.9 ± 0.2 vs. -0.9 ± 0.3). Unadjusted dominant hand maximum handgrip strength (16 ± 2 vs. 23 ± 2 kg, $P < 0.01$) and peak power (1054 ± 107 vs. 1488 ± 169 W, $P < 0.04$) were significantly reduced in children with SCD-SS compared to healthy controls. Performance decrements persisted when handgrip strength was adjusted for lean body mass and fat mass explaining 66% of the variance and power was adjusted for age, lean body mass, fat mass, height explaining 91% of the variance. **CONCLUSIONS:** Body habitus adjusted muscle strength and power are reduced in children with SCD-SS compared with healthy children beyond expectation for growth and body composition deficits suggesting that additional factors contribute to attenuation in anaerobic performance. Is The Acsm Recommendations For Exercise Prescription For Obese Adolescents In Accordance With Ventilatory Threshold?

WAGNER L. PRADO¹, Mara C. Lofrano-Prado², Daniel Calado³, Antonio Henrique G. Soares³, James O. Hill⁴, João Paulo Botero¹, Raphael M. Ritti-Dias⁵. ¹Universidade Federal de São Paulo, Santos, Brazil. ²Universidade de São Paulo, São Paulo, Brazil. ³Universidade de Pernambuco, Recife, Brazil. ⁴University of Colorado, Denver, CO. ⁵Hospital Israelita Albert Einstein, São Paulo, Brazil. Email: wagner.prado@unifesp.br
 (No relationships reported)

Purpose: To compare heart rate (HR) and oxygen uptake ($\dot{V}O_2$) among ACSM recommended intensities for obese adolescents (70% of maximum heart rate - HR_{max}, 60% of maximum oxygen uptake - $\dot{V}O_{2max}$) and ventilatory threshold 1 (VT_1). **Methods:** One-hundred and twenty-seven obese adolescents (age=15.2±1.5yrs.; BMI=34.6±3.9 kg/m²; Fat mass=48.8±5.3%) performed an incremental treadmill test. The initial load was set at 3 km/h (3 minutes) and increased 1km/h each minute until exhaustion, while the grade was kept constant at 1%. $\dot{V}O_2$ was measured directly in an open circuit respiratory metabolic system (Quark, PFT, Cosmed, Italy). VT_1 was determined by visual inspection using Wasserman's criteria by two independent researchers. ANCOVA adjusted for gender, age and fat percentage was used to compare HR and $\dot{V}O_2$ among the three intensities (70%HR_{max}, 60% $\dot{V}O_{2max}$ and VT_1), with Tukey test for post-hoc comparisons. **Results:** VT_1 was achieved at 67 ± 9% of $\dot{V}O_{2max}$ (ranging from 45 to 93%). HR at VT_1 was higher than HR at 60% $\dot{V}O_{2max}$ and 70%HR_{max} ($p < 0.05$). HR at 60% $\dot{V}O_{2max}$ was higher than at 70%HR_{max} ($p < 0.05$). $\dot{V}O_2$ was also higher at VT_1 compared to 70%HR_{max} ($p < 0.05$), with no differences in further comparisons ($p < 0.05$) (Figure 1). **Conclusion:** In obese adolescents, an aerobic exercise prescription based on ACSM recommendations requires lower cardiorespiratory effort than VT_1 intensity. The exercise prescription at 60% $\dot{V}O_{2max}$ induces higher cardiorespiratory stimulus than at 70%HR_{max}.

Supported by CNPq (grant 477955/2009-6) and FACEPE (grant 0928-4.9/08)
 Figure 1. Heart rate and oxygen uptake responses at different recommendations for aerobic exercise prescription for obese adolescents

The GPS data were used to determine the total distance and velocities performed, and to examine for pacing affects. Summary statistics of mean ± SD are provided. **RESULTS:** High total running speeds for the initial 150 s ($S_{150s} = 5.79 \pm 0.59$ m/s) and total distance (3 MT distance = 871.5 ± 71.9 m) were observed. A total of 13 of 30 subjects surpassed the 300 m D' value (mean $D' = 288.2 \pm 49.1$ m). The CS of the total group was 3.87 ± 0.55 m/s. Skewing of CS and D' was observed between forwards and backs, therefore between-group differences in neither CS nor D' were observed ($p > 0.05$). **CONCLUSION:** Comparisons with previous literature indicate male rugby players have higher CS values than female rugby players. Using referent data on male Olympic distance runners, male rugby players have markedly higher D' values and markedly lower CS values. Feature utility of the CS concept is anticipated as we begin to understand norms for CS and D' of different athletes and different running conditions (e.g., load carriage, shuttle running).

Physiological & Anthropometric Profiles Of Elite Collegiate Rugby Union Players

Robert C. Pritchett¹, Todd T. Thornley¹, Kelly L. Pritchett¹, Matt J. Green, FACSM². ¹Central Washington University, ELLENSBURG, WA. ²University of North Alabama, Florence, AL.
 Email: pritchettr@cwu.edu
 (No relationships reported)

PURPOSE: To Investigate physiological and anthropometric characteristics of Elite US College Rugby Union Players (ECP).
METHODS: Thirty-six elite US college rugby union players (20 forwards, 16 backs) was measured for height (cm), body mass (kg), percentage of body fat (3 sites), muscular power (vertical jump, power Clean), speed (10m and 40m sprint), strength (back squat, bench press) and maximal aerobic power (Yo-Yo test).
RESULTS: Forwards were significantly taller (183.8±6.0cm vs. 176.8 ±4.9cm) ($p < 0.01$), more massive (110±13.9kg vs. 86.4 ±8.1kg), had higher percent body fat than the backs (17.0 ± 5.9 vs. 11.7 ± 4.3) ($p < 0.01$). Scores for vertical jump (27.4±4.3 cm vs. 29.5±2.4cm), power clean 1RM (112.0±10.4kg vs. 93.4±24.5kg), back squat 1RM (177.4±29.9kg vs. 150.1±21.8kg), bench press 1RM (132.0 ±19.5kg vs. 110.7 ±16.3kg) and pull-up (10±7 reps vs. 14 ±4reps) were all found significantly different between forwards and backs ($p < 0.01$). However, there was no significant difference for power clean, back squat and bench press when scaled to body weight. Scores for 10m (1.9±0.13sec vs. 1.78 ±0.1sec) and 40m sprint (5.55±0.30 vs. 5.21±0.22), Yo-Yo test (865 ±312m vs. 1240±360m) performance and estimated VO_{2max} (43.7±2.6 ml/kg/min vs. 46.8±2.6 ml/kg/min) were significantly different between forwards and backs ($p < 0.01$).
CONCLUSION: Certain physiological characteristics (muscular strength & power) of ECP are of the same level when compared to other competitive rugby union players. These finding suggest that position specific training is effective in ECP. A greater importance should be placed on developing ECP's aerobic power and enhancing anthropometric characteristics to aid success in the future at higher competitive levels of rugby union.

2594 Board #114 June 2 11:00 AM - 12:30 PM

Positional Norms For Critical Speed And D' Of High-level Male Rugby Athletes

Robert Pettitt, FACSM¹, Ida E. Clark², Nicholas A. Jamnick³, Cody J. Strom¹, Mark Kramer⁴. ¹Minnesota State University, Mankato, Mankato, MN. ²University of Exeter, Exeter, United Kingdom. ³Victoria University, Melbourne, Australia. ⁴Nelson Mandela University, Port Elizabeth, South Africa.
 Email: robert.pettitt@mnsu.edu
 (No relationships reported)

The critical speed (CS) concept helps characterize the aerobic and anaerobic fitness of an athlete. Rugby players should hypothetically have modest CS values but extremely high curvature constant (D') values, yet, normative data are unavailable. **PURPOSE:** To gather normative data of CS and D' on high-level male rugby athletes. **METHODS:** A total of 30 male rugby players, were recruited from the Eastern Cape of South Africa. All subjects performed the running 3-min all-out exercise test (3 MT) using global positioning system (GPS) technology to determine CS and D' .

2595 Board #115 June 2 11:00 AM - 12:30 PM

An Interdisciplinary Athlete Development Program Aimed at Improving Skills and Physical Attributes in Elite Athletes

Tracy A. Dierks¹, Vincent C. Nittoli², Jason Pociask³, Erin E. Angle¹. ¹Indiana University, Indianapolis, IN. ²St. Vincent Hospital, Indianapolis, IN. ³Community Health Network, Indianapolis, IN.
 Email: tdierks@iupui.edu
 (No relationships reported)

While strength and conditioning training can improve athlete skills and physical attributes, little is known on how effective an interdisciplinary approach can be when focused on additional factors (medical, psychological, nutrition) shown to influence such variables. **PURPOSE:** to evaluate the effectiveness of an interdisciplinary athlete development program for improving skills and physical attributes related to the NFL combine. **METHODS:** Retrospective review (2008-2016) of 108 elite level football athletes that completed the St. Vincent Sports Performance NFL Pre-Draft Program. Sports health and fitness professionals created 6-week individualized training programs based on 4 disciplines: 1) Physical Training (strength, speed, position skills), 2) Medical (diagnostic, treatment, corrective exercises), 3) Nutrition (dietary analysis, meals), and 4) Psychological (mental preparation, composure). Anthropometric and skill measurements for strength, power, speed, and agility were obtained pre- and post-program. Paired t-test ($p < 0.05$) was used to assess pre to post differences for all athletes and for subgroups of position demands (speed, hybrid, power). Independent t-test was used to compare both pre- and post-program to NFL combine averages. **RESULTS:** All variables significantly improved pre- to post-program (Table 1), which moved our athletes from worse than combine averages at pre-program, to the same or better at post. Subgroup outcomes showed the same general pattern of improvements, except for fat weight where hybrid (tight end, quarterback, linebacker) showed significant change (38.4 to 36.8 lbs, $p = 0.03$). **CONCLUSION:** While our athletes were of elite status pre-program, thus little room for gains, all outcomes improved post-program and were the same or better than the NFL combine averages. This was likely due to the interdisciplinary approach focused on the total athlete. Future studies should assess how such gains translate to performance.

Table 1. Pre- and post-program outcomes and NFL Combine averages for anthropometrics (percent body fat, fat weight, lean weight) and skill tests for bench press (maximum repetitions of 225 lbs), vertical and broad jumps, and linear and multidirectional speed.

	Weight (lb)**	% Body Fat*	Fat Weight (lb)	% Lean*	Lean Weight (lb)**
Pre	236.3† (45.5)	16.1% (7.9%)	40.8 (26.5)	83.9% (7.9%)	194.6 (23.1)
Post	241.0 (43.3)	15.5% (7.4%)	39.9 (25.3)	84.5% (7.4%)	200.6 (22.4)
Combine	243.8 (45.4)				

	225 Bench (reps)**	Vertical Jump (in)**	Broad Jump (in)**	20 Yard Shuttle (s)**	60 Yard Long Shuttle (s)**
Pre	15.4†† (6.7)	29.1†† (4.3)	106.8†† (9.1)	4.56†† (0.26)	12.23†† (0.58)
Post	20.9 (7.0)	32.3 (4.4)	112.1† (9.1)	4.31†† (0.24)	11.91†† (0.58)
Combine	21.1 (6.5)	32.5 (4.3)	114.3 (9.1)	4.40 (0.30)	11.58 (0.37)

	40 Yard Dash (s)**	20 Yard Dash (s)**	10 Yard Dash (s)**	3 Cone Drill (s)**

A Comparative Study of Shoulder ROM, Proprioception and Balance Ability between General People and Pro Golfers

Deuk-Su Park, Moo-Yeop Ji, Shun-Zhe Piao, Da-Woon Park, Dong-Woo Kim, Tae-Yeon Kim, Hyeong-Jun Park, Jae-Keun Oh. *Korea National Sport University, Seoul, Korea, Republic of.* (No relationships reported)

PURPOSE:

The purpose of this study is to identify the differences of shoulder range of motion, proprioception and balance ability between general peoples (28±3 yrs, n=9) and pro golfers (members of Korea Professional Golfers' Association, 26±4 yrs, n=9).

METHODS:

Data of the results was analyzed by using the SPSS/PC Window version 21.0 statistics program. To verify differences between the groups, Independent T-test was conducted. All the statistical significance level was set at $\alpha=0.05$.

RESULTS:

1. In shoulder range of motion (ROM), pro golfers group showed higher shoulder range of motion in flexion, abduction, internal rotation than the general people, but there was no significant difference. Pro golfers group showed significant higher range of motion than general people in external rotation ($p<0.05$).
2. In shoulder passive joint position sense (PJPS) test, there was no significant difference between the groups, but in shoulder active joint position sense (AJPS) test, pro golfers group showed significant low error angle than general people ($p<0.05$).

CONCLUSION:

As a result of this study, pro golfers were identified that they have higher shoulder ROM in external rotation and they were showed a low error angle of AJPS than general people. This results might come from the superior motor ability of the pro golfers, however to improve athletic performance and prevent injury & rehabilitation, exercises to improve shoulder range of motion and proprioceptive sense should be included.

For balance ability, there was no significant difference between the groups, but pro golfers group showed the tendency of higher scores than general people, exercise to increase balance ability also considered to be included. However, this study has the limitations of range of motion and proprioception ability measurement for single joint, balance ability test was conducted by the movement of supported plate not by the active movement of the subjects. Therefore, further study is a assessment through a more various and segmentation study are needed.

2597 Board #117 June 2 11:00 AM - 12:30 PM
Comparison of Agility and Approach Jump in Elite Sand and Indoor Collegiate Volleyball Athletes

Morgan H. Kocher, Heather C. Boyan, Matthew E. Niesen, Ronald K. Hetzler, FACSM. *University of Hawaii at Manoa, Honolulu, HI.* (Sponsor: Ronald Hetzler, FACSM)
 Email: morganhk@hawaii.edu
 (No relationships reported)

The differences between sand and indoor volleyball courts can affect an athlete's performance, most notably jumping and agility performance. Maximal jumps have been reported to be lower when performed on sand compared to rigid surfaces similar to a wood-flooring court. **PURPOSE:** To examine the performance of elite female sand and indoor collegiate volleyball players in agility and approach jump testing in sand and on an indoor surface; including heart rates and ratings of perceived exertion. **METHODS:** Participants (n=21, age 19.8±1.1yrs, height 1.78±0.08m, body mass 73.62±9.63kg) were members of NCAA Division I women's indoor and sand volleyball teams who finished their seasons ranked in the top 8 nationally. Two thirty minute sessions (one sand, one indoor) were completed, consisting of the approach jump test and the 4 Cone Star Drill with a five minute rest between tests. At least three trials were completed for each test and the outcome measures were the participant's approach jump (cm) and agility time (sec), as well as their ratings of perceived exertion (RPE) and heart rate recovery (HRR) following agility testing. **RESULTS:** There was a significant difference between surfaces for both approach jump (57.57±6.28cm indoor vs. 51.03±5.47cm sand, mean difference 6.5±4.3cm, $p<0.001$) and agility trials (6.66±0.52sec indoor vs. 6.96±0.60sec sand, mean difference 0.30±0.46sec, $p=0.021$), but not in HRR (36.4±10.2bpm indoor vs. 36.3±9.9bpm sand, $p>0.05$), peak HR (139.5±12.1bpm indoor vs. 142.3±11.9bpm sand, $p>0.05$), and RPE (9.6±2.1 indoor vs. 9.4±2.2 sand, $p>0.05$). There were no significant differences in approach jump or agility time for athletes who competed in sand, indoor, or both ($p>0.05$ for all), although the difference in RPE trended towards significance ($p=0.082$). Although not significant, sand athletes and hybrid (compete in sand and indoor) athletes consistently performed better than indoor athletes on both surfaces (mean difference 0.593±0.238 sec and 0.553±0.79 sec, respectively). **CONCLUSIONS:** Significant differences exist between sand and indoor surfaces when performing approach jump and agility drills, but not between sand and indoor volleyball athletes.

2598 Board #118 June 2 11:00 AM - 12:30 PM
Salivary Cortisol Responses After A Women's Basketball Match In Elite Athletes

Athanasios Moustogiannis¹, Anastassios Philippou¹, Nikolaos Kostopoulos². *¹Medical School, National and Kapodistrian University of Athens, Goudi-Athens, Greece. ²Faculty of Physical Education and Sport Science, National and Kapodistrian University of Athens, Dafni-Athens, Greece.*
 Email: moustogi@gmail.com
 (No relationships reported)

Cortisol can negatively affect athletic performance, potentially causing fatigue and inflammation, and high levels of this hormone have been associated with impaired performance in elite athletes. Monitoring hormones in saliva has distinct advantages over doing it in other biological fluids. However, little is known about the salivary cortisol responses in female athlete and particularly after a basketball match.

PURPOSE: The purpose of this study was to examine the salivary cortisol responses in elite female athletes after a women's basketball final match. **METHODS:** Fifteen elite female basketball players participated in the study. Unstimulated mixed saliva samples were collected in salivate swabs before and immediately after the basketball match. Specifically, the swab was placed in the mouth for one minute, then it was transferred into plastic tubes, centrifuged and the resulted saliva sample was analyzed. Saliva samples were assayed in duplicate using a commercially available ELISA kit for cortisol. Differences between the cortisol levels before and after the match were analyzed using student's T-test, while Pearson correlation coefficient (r) was used to reveal potential relationship between post-match cortisol levels and participation time in the match. **RESULTS:** Salivary cortisol levels were significantly higher after the completion of the basketball match compared to the baseline levels (2425.6±1927.6 pg/ml vs. 1014.5 ± 548.8 pg/ml; $p=0.003$). No significant correlation was revealed between the participation time (in minutes) of the elite basketball players and their salivary cortisol levels ($r=0.22$; $p>0.05$). **CONCLUSIONS:** The findings of the present study suggest that monitoring cortisol in saliva can be a useful, non-invasive and sensitive method to assess this hormonal response in female athletes after a basketball match. The increased cortisol levels appear not to be associated with the total participation time of the elite basketball players. However, the possible negative effects of these cortisol responses on the female elite athlete's performance needs to be further investigated.

Profiling Inflammatory Markers During The Competitive Season And Post Season In Collegiate Wrestlers

Mary Moore, Joe Roth, Taylor Szczygiel, Ryan Pettit-Mee, Micah Zuhl. *Central Michigan University, Mount Pleasant, MI.*
 Email: moore8m@cmich.edu
 (No relationships reported)

PURPOSE: Collegiate wrestling is a highly demanding sport, requiring hours of training, intense competition, combined with periods of poor nutrition and weight loss. The purpose of this study was to profile inflammation in collegiate wrestlers during a competitive season and post season. **METHODS:** Subjects were recruited from the Central Michigan University Division I collegiate wrestling team (N=7). Subjects reported in a fasted state on six separate occasions throughout the competitive season and post season; each time point was separated by 2-weeks up to 2-months. The following measurements were made each time: body fat, hydration, blood profiles (Hct, Hgb, %ΔPV), fatigue (questionnaire), and inflammatory plasma proteins (creatinine kinase, IL-6, TNF α , IL-1 β , IL-10). **RESULTS:** The wrestlers trained 3-4 hours per day during the season. The self-reported level of muscle soreness and fatigue was significantly higher from pre-season through mid-season, but leveled off late into the season ($p<0.05$). Creatine Kinase levels peaked early into the season at time point 2 versus pre-season (391.32 ± 48.46 vs. 220.75 ± 54.18, $p<0.05$), but decreased at the end of season versus pre-season (158.11 ± 44.23 vs. 287.79 ± 44.34, $p<0.05$). Plasma TNF α levels increased late into season (time point 4) compared to pre-season (5.26 ± 0.38 vs. 3.34 ± 0.36, $p<0.05$). Plasma IL-8 followed a similar trend and peaked at time point 4, however this value was not significant ($p=0.08$). Sleep quality correlated with plasma levels of IL-8 ($r^2=0.120$, $p<0.05$). No other plasma cytokine data was statistically significant ($p>0.05$). **CONCLUSIONS:** Muscle soreness and fatigue values peaked early in the competitive season and decreased as the season progressed, without a reduction in training volume; suggesting an adaptive response to training load. Low grade systemic inflammation increased late into the season (measured by plasma cytokines), and correlated with poor sleep quality. Sleep quality may be a simple marker to track inflammation among wrestlers. Based on these data, wrestlers may benefit by additional recovery time early into the season to prevent fatigue and muscle damage. As the season progresses, low-grade inflammation may be prevented by tracking the quality of sleep. Combined these measures may prevent injury and improve performance.

The Retention Potential of the 2016 U.S. Olympic Track and Field Team
 Tyler J. Noble, Robert F. Chapman, FACSM. *Indiana University-Bloomington, Bloomington, IN.*
 Email: tynoble@indiana.edu
(No relationships reported)

In 2016, USA Track & Field (USATF) fielded a team of 129 athletes to compete at the Olympic Games in Rio de Janeiro. Trends in the retention rates of athletes on past USATF national teams may help to better direct future USATF funding and support. **PURPOSE:** To assess the retention potential of the 2016 U.S. Olympic Track and Field team for future World Championships and Olympic Games teams. **METHODS:** USATF rosters from 13 World Championships and Olympic national teams dating back to 2000 were analyzed in terms of athlete retention rates at subsequent national team events. The relationship between the mean retention rates of national teams and subsequent national team events was modeled using non-linear regression. Data from this model were used to make inferences regarding the future retention rates of the 2016 Olympic team and its athletes with the significance level set at $P < 0.05$. **RESULTS:** The retention rate of a given national team falls logarithmically ($y = -0.0203 \ln(x) + 0.5443$) with time as athletes attempt to make subsequent teams ($R = 0.98$). Furthermore, individual athlete retention rates decayed exponentially ($y = 1.354e^{-0.424x}$) with time as athletes attempted to make subsequent teams ($R^2 = 0.99$). Using these models to assess the 2016 Olympic team, the model predicts that only 65 of the 129 members will make the 2017 World Championships team (95% CI, [58-73]). Additionally, the model suggests that only 39 athletes from the 2016 Olympic team will make the 2020 Olympic team (95% CI, [32-46]). Finally, when applied to the 48 first time national team athletes in 2016, the model projects that 19 (41.2%) will never make another national team (95% CI, [17-22]). **CONCLUSIONS:** The large amount of turnover from one national team to another is likely a reflection of the highly competitive and objective nature of national track & field team selection in the United States. From an athlete funding standpoint, national governing organizations with limited resources may be able to optimize their return on investment by funding athletes on a year to year basis as opposed to making long term commitments.

Metabolic Approach in Canoeing Olympic Medalist Athletes in Rio 2016 Summer Olympic Games
 PEDRO RODSTEIN, RAFAEL FERREIRA, RODRIGO MANDA, OKESLEY TEIXEIRA, SALETE COELHO, FRANZ BURINI, ROBERTO BURINI, FACSM. *UNESP MEDICAL SCHOOL, BOTUCATU, Brazil.* (Sponsor: ROBERTO CARLOS BURINI, FACSM)
 Email: pimrodstein@alunos.fmb.unesp.br
(No relationships reported)

Olympic athletes are overexposed to training and daily routine, and the training log should be matched with multifactorial issues, such as nutrition, physiotherapy, psychologic, and health, focusing on improvement of performance. Evaluate how the athletes is responding to each period of preparation is challenging, specially on a 4 year Olympic cycle. Interdisciplinary approach is mandatory and any mismatch may lead to injury or decrement of performance. Canoeing has specific demands and methods for evaluation, and multifactorial analysis such as biomechanical, metabolic and clinical aspects should be encouraged. **PURPOSE:** The aim of this study was to evaluate athletes participating in Rio 2016 Summer Olympics Games on a multidisciplinary and multifactorial aspect. **METHODS:** 2 male athletes (Bronze Medalists) were evaluate during a 1.000m sprint on an ergometer, analyzing aerobic capacity (VO_2), Heart Rate (HR) and Power (W) on every 250m. Blood samples were collected for muscle-damage biomarkers: Creatine-Kinase (CK) and Lactate Dehydrogenase (LDH); Electrolytes: Sodium (Na) and Potassium (K) levels. **RESULTS:** Descriptive data demonstrate that VO_2 (mL/kg/min), HR (bpm), W (watts) were, during 250m: 39.3/172/113 x 39.2/159/107, 500m: 31.2/176/105 x 37.1/160/109, 750m: 36.7/178/110 x 34.9/168/100, and 1.000m: 43.5/184/182 x 45.1/178/118, respectively. CK levels (mg/dL) and LDH (U/L) were, pre vs post protocol, 835 vs 1081 and 548 vs 682 for the first athlete, and 255 vs 340 and 488 vs 492 for his teammate. Electrolytes, Na (mEq/L) and K (mEq/L) were 143 vs 151 and 5.8 vs 5.6; and 141 vs 151 and 5.4 vs 5.9. The time for completing the 1.000m protocol were 5m12s06ms vs 5m02s92ms. **CONCLUSIONS:** The protocol described evidences multidisciplinary variables that should be focused when detailing improvement in performance, on cardiorespiratory and metabolic approach.

Differences Among Kinetics, Kinematics, Performance, and Elbow Varus Torque in Professional Versus High School Pitchers
 Micheal J. Luera¹, Mitchel A. Magrini¹, Tyler W.D. Muddle¹, Ryan J. Colquhoun¹, Jason M. DeFreitas¹, Brittany Dowling², Nathaniel D.M. Jenkins¹. ¹Oklahoma State University, Stillwater, OK. ²Motus Global, Massapequa, NY.
(No relationships reported)

PURPOSE: The purpose of this study was to compare ball velocity (BV) and elbow varus torque (EVT), as well as kinematic and kinetic differences between high school (HS) and professional (PRO) baseball pitchers. **METHODS:** Seventy-eight HS ($n = 39$; 16 ± 1 yrs; 74 ± 10 kg; 178 ± 7 cm) and PRO ($n = 40$; 21 ± 2 yrs; 94 ± 9 kg; 189 ± 4 cm) baseball pitchers were analyzed while throwing fastball pitches using an eight-camera 3D motion capture system. Following a warm-up, participants threw ~8 maximal effort fastballs. The 6 pitches with the greatest BV were used for analysis. Independent samples t-test were used to examine differences between the HS and PRO pitchers. Pearson correlation coefficients were used to assess potential relationships between BV, EVT and several kinetic and kinematic variables during phases of the throwing motion. **RESULTS:** BV (86.3 ± 2.2 vs 70.4 ± 6.5 mph; $p < 0.001$) and EVT (79.2 ± 14.9 vs 44.4 ± 16.0 Nm; $p < 0.001$) were greater in PRO than HS. In HS, BV was related to EVT ($r = 0.77$) and BV and EVT were related to elbow flexion torque, elbow flexion and extension velocity, shoulder anterior and elbow medial shear force at arm acceleration, shoulder rotation torque at arm cocking, and elbow and shoulder proximal force at arm deceleration ($r = 0.35 - 0.98$, $p < 0.05$). However, in PRO, BV and EVT were not related to each other ($r = 0.01$) but were related to elbow flexion torque and shoulder anterior shear force at arm acceleration ($r = 0.32 - 0.52$, $p < 0.05$). In Pro, EVT, but not BV, was related to elbow medial shear force at arm acceleration, shoulder rotation torque at arm cocking, and elbow and shoulder proximal force at arm deceleration ($r = 0.69 - 0.96$, $p < 0.05$), and was inversely related to upper trunk rotation at foot contact ($r = -0.31$, $p < 0.05$). **CONCLUSION:** The results of this study indicated that PRO achieve higher fastball velocities and experience greater elbow varus torques than HS pitchers. However, in PRO pitchers, those who achieved the highest fastball velocities did not necessarily experience the greatest EVTs; whereas in HS pitchers, those who threw harder generally experienced higher EVTs. The inverse relationship seen in PRO, but not HS, pitchers for EVT and upper trunk rotation may suggest that PRO pitchers have a greater ability than HS pitchers to utilize their trunk to generate the forces necessary to achieve higher fast ball velocities.

Comparisons Between Adiposity Indexes In The Association With Postural Instability In Older Women
 Juscelia C. Pereira, Silvia G.R. Neri, André B. Gadelha, Ana L. M. Correia, Ana C. David, Ricardo M. Lima. *University of Brasilia, Brasilia, Brazil.*
(No relationships reported)

PURPOSE: To compare adiposity indexes in the association with postural instability in older women. **METHODS:** A cross-sectional study was conducted on 147 elderly women, aged 60 to 84 years. Participants underwent body fat distribution assessment using dual-energy X-ray absorptiometry (DXA) and five anthropometric indexes were measured (waist circumference, WC; waist-to-height ratio; body mass index; and concity index). Balance control (BC) was evaluated using a force platform and all participants performed the following trials: opened base, eyes open (OBEO) and opened base, eyes closed (OBEC). Center of pressure (CoP) speed and the range of displacement on the anteroposterior (AP) and mediolateral (ML) axes were obtained from the average of three measurements. Pearson's and Spearman's correlation were conducted to identify the relationship between adiposity indexes and stabilometric measures. Volunteers were stratified in tertiles according to adiposity index; one-way ANOVA followed by Bonferroni post-hoc and Kruskal-Wallis with the Mann-Whitney test were used to compare the stabilometric variables between groups. **RESULTS:** WC was the index that best correlated with the range of displacements, showing significant relationships in the following conditions $OBEC_{AP}$ ($r = 0.337$; $p < 0.001$), $OBEO_{AP}$ ($r = 0.240$; $p = 0.003$), $OBEO_{ML}$ ($r = 0.222$; $p = 0.007$), $OBEC_{ML}$ ($r = 0.266$; $p = 0.001$). Moreover, volunteers in the highest tertile of WC had a greater range of displacements compared with lowest tertile in conditions $OBEO_{AP}$ (2.30 ± 0.51 vs. 1.99 ± 0.48 cm, $p = 0.011$), $OBEO_{ML}$ (1.47 ± 0.45 vs. 1.23 ± 0.44 cm, $p = 0.005$), $OBEC_{AP}$ (2.85 ± 0.68 vs. 2.35 ± 0.65 cm, $p = 0.001$), $OBEC_{ML}$ (1.60 ± 0.50 vs. 1.29 ± 0.48 cm, $p = 0.010$). Participants

in the lowest tertile showed smaller displacements compared with middle tertile in conditions OBE_{AP} (1.99±0.48 vs. 2.29±0.53 cm, $p=0.012$), OBE_{ML} (1.23±0.44 vs. 1.52±0.47 cm, $p=0.001$), OBE_{AP} (2.35±0.65 vs. 2.72±0.66 cm, $p=0.022$), and OBE_{ML} (1.29±0.48 vs. 1.56±0.55 cm, $p=0.034$). **CONCLUSION:** WC was the adiposity index the best correlated with postural instability, and subjects with greater WC also exhibited the poorest BC in older women. These results suggest that WC, an easy and low cost measure, might be associated with the risk of falling in the elderly, and support the concept that obesity impairs BC.

Gait And Pelvic Angle Symmetry As A Function Of Age In Women 55 And Older

Courtney B. Kirkeide, Chi Na Moua, Nicole S. Szyszka, Marcella J. Myers. *St. Catherine University, St. Paul, MN.* (Sponsor: Dr. Mark Blegen, FACSM)
 Email: cbkirkeide@stkatc.edu
 (No relationships reported)

Serious injuries due to falls in people 65 years and older is a critical cost and quality of life issue in our society; slowed and degraded gait is of particular concern in older women. Falling often correlates with impaired gait and balance caused by loss of muscular strength and/or sensory impairments. Gait and pelvic angle symmetries (between left and right sides of the body) are key measures of gait quality. **PURPOSE:** The goal of this study, an initial phase in a larger project, was to characterize the relationship between age and several gait symmetry measures in women 55 and older. **METHODS:** 20 healthy female participants (ages 55-83) walked along a hallway while their gait characteristics were monitored; each participant walked 4 times at their self-selected pace. Data on pelvic tilt, obliquity, and rotation symmetry, as well as overall gait symmetry (similarity of trunk accelerations on the left and right sides) were assessed using an inertial sensor (BTS-G Walk) placed on the low back (L5). **RESULTS:** Pelvic tilt symmetry, which ranged from 30-98%, showed a statistically significant relationship with age in these older women walkers ($p=0.009$); age explained 33% of the variation in pelvic tilt symmetry. Neither pelvic rotation ($p=0.33$), pelvic obliquity ($p=0.99$), or gait symmetry ($p=0.46$) showed significant relationships to age. **CONCLUSIONS:** These initial findings reveal a particular focus of gait impairment as a function of age in older women -- pelvic tilt symmetry. Interventions to address this aspect of gait may improve walking patterns, and thus dynamic stability, in older walkers.

Variability and Stability of 13-19 Month Old Infants' Gait Affected by External Perturbation

Sally-Marie Futch, Sydney Wilhoite, Brandon Harris, Barry M. Munkasy, Li Li, FACSM. *Georgia Southern University, Statesboro, GA.* (Sponsor: Li Li, FACSM)
 (No relationships reported)

Although there has been research conducted on motor development, children's walking behavior, differences between adult and children's gait with perturbation, and the effect of diaper perturbation versus unclothed on gait, there has been little to no research on different diaper perturbations on gait. **PURPOSE:** The purpose of this study was to examine how a physical perturbation (a dry and a wet diaper versus underwear) affect 13 to 19 month old children's gait. **METHODS:** The project was approved by the University's IRB, and participation was granted with written consent from a legal guardian. Sixty children ranging from 13 to 19 months in age were recruited for this study. Each child completed five trials for three conditions in a single session. Each trial consisted of the child walking on an instrumented walkway (GaitRite CIR Systems, Sparta, NJ) for at least five continuous steps wearing a dry diaper, a wet diaper, and underwear, all of which were provided to the participants. Diapers were wet using a 100 ml syringe of room temperature water. Step length (m/step), step rate (steps/s), and left and right support base (m) were analyzed using a 7x3 MANOVA. **RESULTS:** Significant main effects for age and condition, but no significant interaction were observed. For step length and rate, 13 and 19 months deviate from the means of each other and all the other ages. Step length: 0.21±0.04, 0.332±0.034, Step rate: 3.0±0.4, 3.7±0.6, 13 and 19 month respectively. Significant age difference was observed for left and right support base. Significant differences were also observed for left and right support base (1.4±.36, 1.5±.36 for wet diaper and underwear, respectively), but not for step length and rate. **CONCLUSION:** A wet diaper did not affect step length or step rate. However, there was an effect that occurred between age group and step length, step rate, left and right support base. These factors are impacted by maturation. Further research needs to address whether these conditions influence other gait parameters.

Relationship Between Body Fat And Selected Gait Parameters

Alec Russell, Spencer Petersen, Michael Bohne, Tyler Standifird, Andrew Creer. *Utah Valley University, Orem, UT.* (Sponsor: Scott Drum, FACSM)
 (No relationships reported)

Over the years obesity has become a widespread pandemic that has affected many people. Obese persons experience difficulty ambulating and conducting daily activities. While body mass indexing is typically used to identify obese individuals percent body fat was preferred for this study because body mass index presents as an inaccurate obesity classification (Shah, 2012). It has been proposed that as percent body fat increases joint mechanics of the hip, knee, and ankle will increase as well on all three planes. **PURPOSE:** The purpose of this study is to show the correlation between body percent fat and lower extremity joint mechanics. **METHODS:** 54 participants (24 male, 30 female; Height: 170.9±9.2 cm, Weight: 74.4±18.8 kg) were fit with reflective markers on the bony landmarks of the lower extremity and asked to walk across Bertec force plates (Bertec, Inc, Columbus, OH) a total of 10 times. Kinematic data were collected and normalized to body weight and collected with Vicon Nexus 2.4 (Vicon, Inc., Oxford, UK) and processed through Visual 3D software (C-Motion, Inc., Germantown, MD). Body composition was measured using a Bod Pod (CosmedUSE, Inc., Chicago, IL). Data were analyzed using a Pearson correlation coefficients ($\alpha=0.05$). **RESULTS:** The data revealed a significant relationship between percent body fat and stride width ($r^2=0.368$) as well as peak ankle plantarflexion moment ($r^2=0.373$) ($p=0.032$ and $p=0.005$ respectively). No other significant relationships were observed. **CONCLUSIONS:** Based on this data, step width and peak plantar flexor moments were increased with increased body fat percentage, suggesting that persons with a larger percent body fat require more force to propel themselves forward to toe off. Strengthening plantar flexors, or reducing body fat percentage, may allow those with high percent body fat to ambulate and perform other daily tasks efficiently. Further research is needed to examine non-normalized data to show practical effects. Additionally, the current study used primarily active individuals, a comparison to sedentary individuals is needed.

2607 Board #127 June 2 9:30 AM - 11:00 AM

High Capacity Older Adults Exhibit More Biomechanical Plasticity than Low Capacity Older Adults

Daniel Kuhman, Victoria Price, Blake Schnurr, Dyshone Jordan-Brown, John Willson, Chris Mizelle, Paul DeVita, FACSM. *East Carolina University, Greenville, NC.* (Sponsor: Paul DeVita, FACSM)
 Email: kuhmand15@students.ecu.edu
 (No relationships reported)

Old compared to young adults exhibit increased hip and decreased ankle joint work during level walking. This distal-to-proximal redistribution of joint work is known as biomechanical plasticity and is a successful strategy for maintaining walking performance into old age. It is unknown however whether high-functioning adults, (e.g. those with relatively fast walking speed) exhibit larger magnitudes of plasticity enabling them to walk well or whether low-functioning adults exhibit larger magnitudes of plasticity to simply enable them to walk. The literature weakly suggests that "low-performing" compared to "high-performing" old adults exhibit larger magnitudes of biomechanical plasticity. We seek to more precisely identify the nature of biomechanical plasticity with age and its relationship with physical capacity. **PURPOSE:** To compare magnitude of biomechanical plasticity between high and low capacity old adults during level walking. **METHODS:** 3D motion capture gait analyses were conducted on 30 old adults (n = 19 females; age = 74.7 yrs.) walking at self-selected speeds. Short Form Health Survey (SF-36) physical component scores were used as measures of physical capacity. Ratios of positive hip work to positive ankle work and peak positive hip extensor power to peak positive plantarflexor power were used as measures of biomechanical plasticity. Student's t-tests were used to compare the top 10 (n = 8 females; age = 76.5 yrs.) and bottom 10 (n = 5 females; age = 72.8 yrs.) individuals based on their SF-36 PC scores. **RESULTS:** High capacity adults exhibited larger ratios of both hip/ankle positive work (0.948 vs 0.613, $p=0.01$) and hip/ankle peak positive power (0.599 vs 0.375, $p=0.003$) compared to low capacity adults. High capacity adults exhibited faster self-selected walking speed (1.39 vs 1.22 m/s, $p=0.01$) and longer stride lengths (1.46 vs 1.29 m, $p=0.002$) compared to low capacity adults. **CONCLUSION:** Old adults with high physical capacity exhibited a larger magnitude of biomechanical plasticity compared to old adults with low physical capacity. This allowed the high capacity individuals to maintain faster self-selected walking speeds and longer stride lengths compared to the low capacity individuals – two variables that may help these individuals maintain higher capacities.

Test-retest Reliability Of The Walk-to-run Transition Stride Frequency Predicted From Behavioral Attractors
 Ernst A. Hansen, Lasse AR Kristensen, Andreas M. Nielsen, Pascal Madeleine, Michael Voigt. *Aalborg University, Fredrik Bajers Vej 7D, Denmark.*
 Email: eah@hst.aau.dk
 (No relationships reported)

We recently showed that the observed walk-to-run transition stride frequency agrees with a transition stride frequency predicted in a novel way by the two stride frequencies applied during treadmill walking and running at freely chosen velocities and freely chosen stride frequencies. The two latter stride frequencies are defined as behavioral attractors. **PURPOSE:** To test the day-to-day reliability of the predicted walk-to-run transition stride frequency determined by this novel approach. **METHODS:** Healthy individuals ($n=25$, 19 men and 6 women of age, height, and body mass of 26.6 ± 4.2 years, 1.77 ± 0.08 m, and 76.4 ± 11.6 kg, respectively) were recruited for a laboratory test of treadmill walking and running. The two behavioral attractors were determined during walking and running at freely chosen velocities and stride frequencies. Subsequently, the walk-to-run transition stride frequency was predicted to occur at the point where the walking stride frequency starts to get closer to the running attractor than to the walking attractor. The laboratory test was repeated after 4-8 days. Intraclass correlation coefficient ($ICC_{3,1}$), standard error of measurement (SEM), and smallest real difference (SRD) were calculated as measures of reliability. **RESULTS:** The freely chosen stride frequency during walking was 57.7 ± 4.1 and 59.1 ± 4.8 strides min^{-1} in test 1 and 2, respectively ($p=0.03$). The freely chosen running stride frequency was 81.8 ± 3.7 and 81.9 ± 3.1 strides min^{-1} in test 1 and 2, respectively ($p=0.67$). The predicted walk-to-run transition stride frequency was 69.7 ± 3.3 and 70.5 ± 3.4 strides min^{-1} in test 1 and 2, respectively ($p=0.08$). The $ICC_{3,1}$ of the predicted walk-to-run transition stride frequency was 0.89, the SEM was 1.1 strides min^{-1} , and the SRD was 3.1 strides min^{-1} . **CONCLUSION:** The predicted walk-to-run transition stride frequency showed almost perfect relative reliability and high absolute reliability.

Hip Moment Prediction with a Subset of Inverse Dynamics Components
 Nicole A. Batrouny¹, Brecca M. Gaffney¹, Craig J. Simons¹, Cory L. Christiansen², Bradley S. Davidson¹. ¹University of Denver, Denver, CO. ²University of Colorado Denver, Aurora, CO.
 Email: nabatrouny@yahoo.com
 (No relationships reported)

Purpose Joint moments, calculated via inverse dynamic (ID) analyses, represent the net effect of all forces spanning a joint, and are used as a surrogate to represent joint demand and are used to describe movement patterns. However, because excessive instrumentation is required, ID analyses are rarely used outside of a laboratory setting. Insight into joint moments using simply collected quantitative measures has the potential to impact a variety of settings (e.g. movement retraining, sports performance, etc.). Therefore, the objective of this study was to determine if hip moment could be predicted using a subset of ID analysis components. **Methods** Kinematic and force platform data were captured for 12 healthy subjects (9M/3F, age: 59.8 ± 7.8 yrs, BMI: 25.1 ± 2.9) walking at 1m/s. Sagittal-plane hip moment during stance period was calculated using ID analysis. Pearson correlations (r) were calculated at every percentage of the stance period between the hip moment and the kinetic components ($M_{MK}, M_{Kx}, M_{Kz}, M_y$) and inertial components (M_{Iy}, M_{Ix}, M_{Iz}) of the thigh from the ID calculations (Fig. 1a). 95% confidence intervals that did not cross zero were considered to be significant, and mean correlations throughout stance were calculated. **Results** Hip moment was highly correlated ($r = 0.93$) with M_{Kx} , the moment due to vertical joint reaction force at the knee for 94.4% of the stance period and highly negatively correlated ($r = -0.83$) with M_g , the moment due to gravity. Inertial components of the thigh were not correlated with hip moment. **Conclusions** The results indicate that hip moment can be predicted with vertical knee joint reaction force and thigh orientation. Because the moment due to the vertical reaction force at the knee is dominated by the ground reaction force, this can be estimated using instrumented insoles. In summary, the hip moment during stance shows promise for being predicted with simple regression equations and minimal instrumentation.

Milton⁶. ¹Harvey Mudd College, Claremont, CA. ²Claremont McKenna College, Claremont, CA. ³Scripps College, Claremont, CA. ⁴Pitzer College, Claremont, CA. ⁵College of Osteopathic Medicine, Michigan State University, East Lansing, MI. ⁶Claremont Colleges, Claremont, CA.
 (No relationships reported)

Developing computer algorithms to reliably estimate stride times is an important first step for applying wearable devices for assessing gait outside a laboratory setting. The fundamental problem for identifying heel strikes using numerical techniques is multiple local maxima in fore-aft accelerations. Thus, when stride times vary, algorithms that use a fixed sampling interval cannot identify those accelerations associated with heel strike. **PURPOSE:** We assess the ability of wearable devices that measure both 3D accelerations and 3D angular velocities to measure stride times during solo treadmill and paired subject 3-legged walking. **METHODS:** Acceleration was measured in the plane parallel to the walking surface (a_x) using a Shimmer3 (Dublin, Ireland) attached to the shin. The angular velocity in the sagittal plane (or pitch) (Ω_p) provided a measure of heel strike. The algorithm identified heel strike as the first a_x maxima that occurs after the maximum in Ω_p . The stride times calculated using this method were compared to stride times measured using a force sensitive resistor (FSR; Interlink Electronics, Camarillo, CA) placed under the heel. The two methods were compared at various walking speeds on a treadmill (1.25, 1.5, 1.75, and 2.0 $m s^{-1}$). Three-legged walking speeds ranged from 1.0 to 3.0 ms^{-1} included 55 stumbles ($N = 25$ pairs of subjects). **RESULTS:** The identified heel strike using the wearable unit occurred $\approx 28 \pm 5$ ms after heel strike measured using an FSR. The stride times calculated using the algorithm differed from the FSR by an average of 2.0 ± 0.16 ms. Less than 0.1% of the strides were not identified by the algorithm. **CONCLUSION:** The wearable unit and algorithm is suitable for use in gait studies measuring stride times during solo and 3-legged walking. Supported by HHMI grant number 52007536 and 52007544.

 (No relationships reported)

Soldiers are fielded with a wide range of loads to carry including battery powered electronic devices. An energy harvesting backpack (EHB) was developed to convert gait kinetic energy into electrical power, providing a power source to recharge batteries and reduce the load of extra batteries carried in standard backpacks. Little is known about the kinematic effects of carrying the EHB compared to the military standard assault pack (AP). **PURPOSE:** To determine if trunk lean changes when carrying the EHB compared to the AP and whether these changes are affected by pack, load, and speed. **METHODS:** Sixteen subjects (28.6 ± 4.7 years; 173.9 ± 10.1 cm; 76.9 ± 16.1 kg) walked on an instrumented treadmill under 8 combinations of pack, load, and speed conditions each for 5 minutes. Conditions included 1) pack: AP and EHB, 2) load: 7.9 kg (light) and 15.9 kg (heavy), and 3) speed: 1.34 m/s and a self-selected faster speed. Due to its design, the empty EHB mass was 4.4 kg greater than the AP. Kinematic data

were collected to calculate trunk lean relative to the vertical axis (degrees). A 3-way repeated measures ANOVA was used to determine effects of pack, load, and speed on trunk lean with an alpha level set a priori at $p < 0.05$. Post-hoc pairwise comparisons were performed with Bonferroni corrections. **RESULTS:** A significant main effect of speed on trunk lean ($F_{1,13}=44.1$, $p < 0.001$) was observed where forward lean was greater at faster speeds (Slow: 3.8 ± 0.6 ; Fast: 7.5 ± 0.7 , $F_{1,13}=44.1$, $p < 0.001$). There was a significant pack x load interaction on trunk lean (AP-Light: 1.4 ± 2.1 ; AP-Heavy: 4.6 ± 2.3 ; EHB-Light: 5.5 ± 2.9 ; EHB-Heavy: 10.9 ± 3.4 ; $F_{1,13}=15.5$, $p = 0.002$). Subjects using the EHB walked with greater increase in forward lean when carrying the heavy load. **CONCLUSION:** Walking with heavy loads and carrying the EHB produced greater increase in forward lean when compared to the AP. This suggests a potential nonlinear effect of pack and load on trunk lean. The weight cost or oscillation of the EHB may also contribute to these changes in gait. Phase relationships between the user and EHB centers-of-mass could be examined in future research to study the effects on gait biomechanics. Further analysis is also warranted to determine tradeoffs in power generated from the EHB and Soldier biomechanics while walking with the system.

Test-retest Reliability of Spatial-temporal Characteristics In Novice Walkers

Sydni Wilhoite, Sally-Marie Futch, Nicholas Murray, Li Li, FACSM. *Georgia Southern University, Statesboro, GA.*

(No relationships reported)

Infant walkers have immature gait patterns. Small perturbations to gait, such as a dry diaper, could impact their already unstable spatial-temporal gait characteristics. However, little is known regarding the test-retest reliability of spatial temporal measurements as measured by the GAITRite of novice walkers in dry diapers.

PURPOSE: To determine the reliability of spatial-temporal gait characteristics, such as Velocity, Cadence, Stride length, and Base of Support in 13-16 month old novice walkers wearing a dry diaper. **METHODS:** The project was approved by local IRB board and participated with written consent from legal guardians. 18 novice walkers, 9 males and 9 females, (14.4 ± 1.0 months of age) participated in a series of 5 walking trials at a self-selected pace in a dry diaper on the GAITRite System (sampling rate 120Hz) on two separate testing sessions one week apart (Day 1 and 2). During each session, participants were fitted with the dry diaper and encouraged to walk 5 or more steps continuously for each trial, five trials total, over the GAITRite. Upon completion of each testing session, the raw data was exported and averaged across five trial for each day. Average gait velocity (cm/s), cadence (step/s), stride length (cm) and base of support (cm) were calculated at each time point. Intraclass Correlations were employed to assess between-day reliability. **RESULTS:** Gait Velocity, 92.3 ± 25.0 and 93.6 ± 20.0 , for Day 1 and 2 respectively, ICC = 0.848 (95% CI = 0.594 to 0.943); Cadence, 208.6 ± 34.7 and 209.9 ± 25.8 , for Day 1 and 2 respectively, ICC = 0.836 (95% CI = 0.561 to 0.939); Stride Length = 53.0 ± 9.0 , and 53.5 ± 7.8 , for Day 1 and 2 respectively, ICC = 0.916 (95% CI = 0.777 to 0.969), Base of support, 10.9 ± 2.6 , 10.9 ± 1.6 , for Day 1 and 2 respectively, ICC = 0.767 (95% CI = 0.376 to 0.913). **CONCLUSION:** The results of the study demonstrated excellent test-retest reliability for Gait Velocity, Cadence, and Stride Length and good test-retest reliability for Base of support when testing 13-16 month old novice walkers in a dry commercially available diaper on the GAITRite. Future research needs to address the test-retest reliability of infants wearing a wet diaper since wet diapers introduce great perturbation to walking.

2613 Board #133 June 2 9:30 AM - 11:00 AM

Altered Locomotive Hip Joint Patterns in Patients with Chronic Ankle Instability

James Mitchell¹, Hyunsoo Kim², S. Jun Son¹, Jordan Read¹, Matthew K. Seeley¹, J. Ty Hopkins, FACSM¹. ¹Brigham Young University, Provo, UT. ²West Chester University, West Chester, PA. (Sponsor: J. Ty Hopkins, FACSM)

Email: jamitchenor@gmail.com

(No relationships reported)

Lateral ankle sprains are common among athletes and often times lead to chronic ankle instability (CAI). Altered hip joint biomechanics during functional activity has been noted in CAI patients. However, few studies have comprehensively examined locomotive hip joint movement strategies in subjects with CAI. **PURPOSE:** To examine gait patterns of frontal and sagittal hip kinematics, kinetics, and muscle activation in those with and without CAI. **METHODS:** 100 CAI patients ($M=49$, $F=51$; 22 ± 2 yrs, 174 ± 10 cm, 71 ± 14 kg, $82 \pm 9\%$ FAAM ADL, $62 \pm 13\%$ FAAM Sports, 4.5 ± 2.6 ankle sprains) and 100 controls ($M=56$, $F=44$; 22 ± 3 yrs, 172 ± 13 cm, 72 ± 18 kg, 100% FAAM ADL & Sports, no previous sprains) performed five walking trials, while hip joint angles, moments and muscle activation were collected during the stance phase. Functional analyses ($\alpha = .05$) were used to compare the entire stance phase of gait between groups. Functions of each group as well as 95% confidence intervals (CI) were plotted to determine significant differences. If functions and associated 95% confidence intervals did not cross zero, group differences existed. **RESULTS:** Figure

1. CAI subjects demonstrated increased hip flexion and extension, likely a result of greater hip joint moments during stance. CAI patients decreased hip adduction during 45-70% and increased hip abduction between 90-100% of stance. CAI subjects decreased hip abduction moment during 10-14% of stance. Gluteus maximus and medius activation decreased during mid-and terminal stance of gait. **CONCLUSION:** Lack of EMG activation combined with altered biomechanics at the proximal joint may alter the position and loading of distal joints in the chain, potentially affecting injury risk.

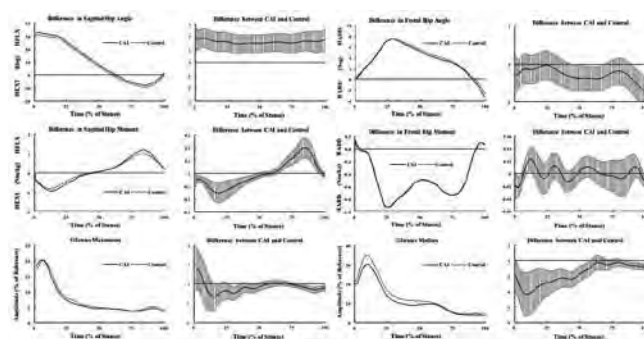

Figure 1. Hip flexion/extension (HFLX/EXT) and hip adduction/abduction (HAD/HAB) angle, HFLX/EXT and HAD/HAB moment, and hip joint EMG amplitudes for gluteus maximus and gluteus medius during stance phase of walking trials. Mean differences (solid black curve) and corresponding 95% CI (shaded area) are plotted as a function of time. When the shaded area does not overlap with the zero line (red horizontal line), a significant difference ($p < 0.05$) is indicated between groups.

Effect Of Activity-related Pain On Gait Characteristics During 4-meter Usual-pace Walking Across The Lifespan

Duane B. Corbett¹, Amal A. Wanigatunga¹, Vincenzo Valiani¹, Matin Kheirkhahan¹, Kelly M. Naugle², Eileen M. Handberg¹, Christopher M. Janelle¹, Todd M. Manini, FACSM¹. ¹University of Florida, Gainesville, FL. ²Indiana University – Purdue University Indianapolis, Indianapolis, IN. (Sponsor: Todd Manini, FACSM)

Email: dcorbett@ufl.edu

(No relationships reported)

Purpose: Recent literature suggests activity-related pain in older adults may play a role in gait impairment and lead to declines in mobility that pose threat to older adult independence. While research shows this to be a function of adopting slower but more variable physical movements, the underlying mechanism is unclear. The purpose of this study was to test whether activity-related pain during walking plays a role in gait impairments that may be responsible for slower, more varied walking typically experienced by older adults.

Methods: 16 young (26.7 ± 6.2 yrs), 44 middle-aged (54.5 ± 6.7 yrs), and 40 older adults (72.6 ± 6.1 yrs) were asked to walk 4-meters at a usual pace over a computerized gait analysis system. Gait characteristics were averaged over three trials. Self-reported pain was measured using the Borg CR10 pain scale immediately following four separate walking tasks of various intensity (5-8 min duration each). Average scores were then used to categorize people into either a pain ($n=57$) or no pain category ($n=43$). Among those reporting pain, the average self-reported scores across all activities ranged from 0.1 to 4.3 with a mean of 1.0 ± 1.0 . Regression models were used to estimate the difference of gait characteristics between those with and without pain during different walking scenarios.

Results: In middle-aged adults, individuals with pain had a faster gait cycle time than individuals without pain (1.2 ± 0.1 vs 1.1 ± 0.1 s, $p = 0.036$), but there was no difference between those reporting pain and those not in young ($p = 0.622$) or older adults ($p = 0.668$). Additionally, no difference was found in walking speed, step length differential, or average base of support between individuals with and without pain across all age categories ($p > 0.05$).

Conclusion: While individuals with pain did have faster gait cycle than individuals without pain in middle-aged adults, this effect was not observed among older adults. However, the similarity in walk speed between individuals with and without pain in older adults may suggest the use of strategies to compensate for the walking-related pain and maintain gait characteristics. Future work is needed to investigate mid-age differences in gait cycle due to pain and possible gait-maintenance strategies as aging with pain occurs.

2615 Board #135 June 2 9:30 AM - 11:00 AM
Altered Gait Characteristics In Individuals With Medial Knee Osteoarthritis
 Keyi Yin, Cui Zhang, Donghai Wang, Yu Liu. *Shanghai University of Sport, Shanghai, China.*
 Email: yky0504@outlook.com
 (No relationships reported)

Knee osteoarthritis (KOA) is one of the most predominant causes of pain, functional decline and disability in elderly. In China the prevalence of radiographic KOA was 42.8% in women and 21.5% in men. Medial KOA has been shown to affect a multitude of biomechanical and gait parameters.

PURPOSE:

The objective of study were to investigate the multi-joint of lower extremity motor coordination during walking in individuals with KOA, and then supplies biomechanics theoretical basis for the prevention and rehabilitation of KOA.

METHODS:

Motion analysis system and force platforms were used to measure biomechanical data of medial KOA individuals and age-matched controls during walking. Each participant walked at a self-selected, comfortable pace on a 10-m walkway. All biomechanical variables characterizing sagittal-plane joint function were compared between two groups using Independent-Samples T test. The level of significance was set at $\alpha=0.05$.

RESULTS:

Significant reductions were observed for medial KOA group compared to control group in terms of the left, right step length ($0.62\pm 0.05\text{m}$ vs. $0.70\pm 0.02\text{m}$, $P<0.05$; $0.61\pm 0.05\text{m}$ vs. $0.68\pm 0.05\text{m}$, $P<0.05$) and gait speed ($1.28\pm 0.12\text{m/s}$ vs. $1.39\pm 0.13\text{m/s}$, $P<0.05$).

Significant differences were obtained in the peak flexor ($0.77\pm 0.13\text{Nm/kg}$ vs. $1.00\pm 0.23\text{ Nm/kg}$, $P<0.05$) and extensor muscle torque ($-0.58\pm 0.16\text{Nm/kg}$ vs. $-0.88\pm 0.20\text{ Nm/kg}$, $P<0.05$) of left hip between medial KOA and controls; Ankle joint angle at the heel-strike portion in medial KOA individuals were greater than controls ($-5.11\pm 5.22^\circ$ vs. $-1.03\pm 3.75^\circ$, $P<0.05$). Besides, peak dorsiflexor moment ($0.19\pm 0.05\text{Nm/kg}$ vs. $0.29\pm 0.07\text{ Nm/kg}$, $P<0.05$) were different between two groups. During the heel-strike portion, midstance portion and terminal portion of stance phase, Significant differences were obtained in the peak angle of left knee between two groups ($-6.9^\circ \pm 1.9^\circ$ vs. $-2.2^\circ \pm 1.6^\circ$, $P<0.05$; $-16.6^\circ \pm 2.5^\circ$ vs. $-18.0^\circ \pm 2.6^\circ$, $P<0.05$; $-9.2^\circ \pm 2.3^\circ$ vs. $-5.5^\circ \pm 1.9^\circ$, $P<0.05$). Besides, knee extensor muscle torque of heel-strike in KOA group are less than that in control group.

CONCLUSION:

The biomechanical changes of knee induced by disease will alter the angle, muscle torque of adjacent joints. So in future rehabilitation and prevention of medial KOA, we should not only do focus on knee joint alone, but also other joints motion.

2616 Board #136 June 2 9:30 AM - 11:00 AM
Obesity Is Associated with Altered Plantar Pressure Distribution in Elderly Women
 Silvia G. R. Neri, André B. Gadelha, Juscélia C. Pereira, Ana L. M. Correia, Ana C. David, Ricardo M. Lima. *University of Brasilia, Brasilia, Brazil.*
 Email: silvia_grn@hotmail.com
 (No relationships reported)

Increased plantar pressure has been found to be related with higher incidence of foot pain, reduced physical activity and a greater risk of falling. Although there is evidence suggesting that obesity is linked to foot disorders, the association between obesity and plantar pressure of older adults has been poorly investigated. **PURPOSE:** To examine the association between obesity and plantar pressure distribution and to evaluate its relationship with body fat distribution in older women. **METHODS:** 211 volunteers (67.99 \pm 6.25 years; 27.86 \pm 4.4 kg/m²) took part in this cross-sectional study. Anthropometric measures were taken for body mass index calculation. The cut-off values for overweight and obesity were 25 kg/m² and 30 kg/m², respectively. Whole body, android and gynoid fat percentage was assessed using dual-energy X-ray absorptiometry. Peak plantar pressure at six anatomical regions (hindfoot, midfoot, forefoot, hallux, lesser toes and whole foot) was evaluated during gait using an Emed AT-4 pressure platform. Kruskal-Wallis test was conducted to compare peak pressure between obese, overweight and normal weight volunteers. Spearman's correlation was used to examine its relationship with body fat distribution. Significance level was set at $p<0.05$. **RESULTS:** Obese volunteers generated increased peak pressure at midfoot (187.26 \pm 54.24 kPa) compared to both normal weight (128.52 \pm 39.47 kPa, $p<0.001$) and overweight (165.74 \pm 58.42 kPa, $p=0.001$). Peak plantar pressure was also increased in overweight compared to normal weight ($p<0.001$). At forefoot, peak pressure was higher in the obese (498.15 \pm 177.08 kPa) compared to normal weight volunteers (420.41 \pm 138.14 kPa, $p=0.007$). Whole body, android and gynoid fat percentage were significantly associated with peak pressure at midfoot ($p=0.411$, $p<0.001$; $p=0.536$, $p<0.001$; and $p=0.358$, $p<0.001$, respectively) and forefoot ($p=0.220$, $p=0.001$; $p=0.167$, $p=0.015$; and $p=0.188$, $p=0.006$, respectively). **CONCLUSIONS:**

Overweight and obesity are associated with increased peak pressure in older women, regardless of body fat distribution patterns. Therefore, clinicians dealing with foot problems should consider the effect of increased bodyweight on plantar pressure.

The Kinematic Effects Of KT Flex And Knee Sleeves On The Hip And Knee
 Brian Burton, Jordan Peterson, Jordan Eatough, J. Brent Feland. *Brigham Young University, Provo, UT.* (Sponsor: J Ty Hopkins, FACSMM)
 Email: btbjr89@gmail.com
Reported Relationships: B. Burton: Contracted Research - Including Principle Investigator; Study Funded by KT Tape, PI - J. Brent Feland.

Knee sleeves and similar products are often used by runners and walkers to ameliorate knee pain and provide support during exercise. A new product, KT Flex (a kinesio style tape with an integrated stabilizing plastic stay) is purported to add more support than KT tape strips or knee sleeve with stabilizer springs. Limited studies exist on Knee kinematics using sleeves and/or tape.

Purpose: To determine the effect of the prototype KT Flex product, knee sleeve with stabilizing springs and two other KT Tape conditions on lower extremity hip and knee kinematics and ground contact time during running and walking.

Methods: 23 Healthy College aged individuals (18 men, 5 women) (age 23.42 \pm 2.66, 177.04 cm \pm 7.72, 68.73 kg \pm 12.95) served as their own control and completed all 5 conditions in random order. All subjects walked (3 mph) and jogged (7 mph) on an instrumented treadmill for 30 seconds under 5 separate conditions: 1) Normal (no intervention), 2) KT Flex on lateral knee, 3) KT Flex on lateral and KT Tape on medial knee, 4) KT Tape on medial and lateral knee, and 4) Knee sleeve with medial and lateral support springs. 18 reflective markers were used with 12 Vicon motion analysis cameras. Peak knee flexion during both stance and swing, peak hip flexion during swing, and peak knee and hip rotation were measured. Motion capture data was processed using Visual 3D. The results were evaluated using a General linear model ANOVA with pairwise comparisons for both walking and jogging conditions.

Results: The only significant difference was found in Peak knee flexion angle during stance phase of walking between the knee sleeve and KT Flex with Medial KT Tape ($p=.034$). The knee sleeve kept the knee in 3° more flexion. No other significant ($p>0.05$) differences were found between any of the measured variables within walking or jogging conditions.

Conclusion: The KT Flex prototype product and generic knee sleeve with spring support do not alter gait kinematics during running and the effect on measured variables were similar. The knee sleeve caused more flexion in stance during walking. Both types of equipment can be used without interfering with normal running mechanics. These findings are significant to serious runners considering using knee support products which have been reported in the literature to help reduce various pain related syndromes.

Functional Patterns of Knee Neuromechanics during Stance in Subjects with Chronic Ankle Instability
 Jake Roush¹, Hyunsoo Kim², S. Jun Son¹, Trevor Fuhrman¹, Matthew K. Seeley¹, J. Ty Hopkins, FACSMM¹. ¹Brigham Young University, Provo, UT. ²West Chester University, West Chester, PA. (Sponsor: J. Ty Hopkins, FACSMM)
 Email: ajaker94@gmail.com
 (No relationships reported)

Patients with chronic ankle instability (CAI) have been shown to display altered gait mechanics. While many studies have focused on the ankle joint, knee-gait mechanics are not well documented. **PURPOSE:** To examine knee biomechanics and muscle activation patterns during walking in those with and without CAI. **METHODS:** 100 CAI patients (M=49, F=51; 22 \pm 2 yrs, 174 \pm 10 cm, 71 \pm 14 kg, 82 \pm 9% FAAM ADL, 62 \pm 13% FAAM Sports, 4.5 \pm 2.6 ankle sprains) and 100 controls (M=56, F=44; 22 \pm 3 yrs, 172 \pm 13 cm, 72 \pm 18 kg, 100% FAAM ADL & Sports, no previous sprains) performed five walking trials, while knee joint angles, moments, and EMG activation were measured. Functional analyses were used to compare variables between groups across the stance phase of gait ($\alpha=.05$). If functions and associated 95% confidence intervals did not cross zero, group differences existed. **RESULTS:** Figure 1. Compared to controls, CAI patients increased valgus angle during initial loading and reduced valgus angle during pre-swing. The valgus moment decreased during loading response and terminal stance. The CAI group reduced knee flexion angle during mid-stance, likely a result of a reduced knee extension moment tied to decreased vastus lateralis activation. Medial hamstring activation was decreased during initial loading and mid-stance. **CONCLUSIONS:** CAI patients demonstrated altered knee neuromechanic patterns in a way that reduced knee flexion; likely a result of less knee extension moment and vastus lateralis and medial hamstring activation. Changes in knee joint mechanics may increase injury risk during functional movement. More data are needed to link these findings to injury risk.

Figure 1. Knee flexion/extension (Flex/Ext) and knee varus/valgus (Var/Val) angle, Flex/Ext and Var/Val moment, and EMG amplitude for vastus lateralis and medial hamstring during stance phase of walking tasks. Mean differences (bold solid curve) and corresponding 95% CI (shaded area) are plotted as a function of time. When the shaded area does not overlap with the zero line (red horizontal line), a significant difference ($p < 0.05$) is indicated between groups.

2619 Board #139 June 2 9:30 AM - 11:00 AM
Comparison Of Absolute Gait Parameters Between Breast Cancer Survivors And Healthy Controls During Forward And Backward Walking

Emily H. Harrison, Takudzwa A. Madzima, Caroline D. Deaterly, Srikant Vallabhajosula. *Elon University, Elon, NC.* (Sponsor: Dr. Stephen Bailey, FACSM)
 Email: eharrison6@elon.edu
 (No relationships reported)

Older breast cancer survivors (BCS) report more falls and less stability than older adults with no cancer history. Spatio-temporal gait parameters are often used as indicators of fall risk in older adults. **PURPOSE:** To assess the differences in forward, backwards, and accelerated forward walking in BCS in comparison to a control group. **METHODS:** 13 postmenopausal BCS (mean age: 58.5±8.5 years) and 8 control (mean age: 60.8±6.1 years) participated. Four BCS had surgery, chemo and radiation done. Gait was measured on the 16x4' Zeno walkway. Participants completed 5 trials each of forward, backward, and accelerated forward walking conditions. Participants had a lead and follow-up distance of 1m to capture steady-state gait. Gait speed, step length, step time, and stride width were used as dependent variables. A mean of five trials was used to run a Group X Condition ANOVA. **RESULTS:** Significant group main effect indicated that BCS (59.63±1.38cm) had significantly shorter step length compared to healthy controls (64.42±1.76 cm) across all conditions ($P=0.045$). Significant condition main effect was observed for all the variables (all post hoc tests $P < 0.001$). All participants walked significantly slower during backwards condition (0.91±0.03m/s), followed by forward (1.24±0.03m/s) and accelerated forward (1.76±0.06m/s) conditions. All participants walked with significantly shorter step length during backwards condition (48.43±1.47cm), followed by forward (64.38±1.01cm) and accelerated forward (73.26±1.29cm) conditions. All participants took significantly step time during accelerated forward condition (0.42±0.01s) compared to forward (0.52±0.01s) and backward (0.54±0.02s) conditions. All participants walked with significantly wider stride during backwards condition (16.07±0.77cm) compared to forward (7.65±0.47cm) and accelerated forward (7.31±0.50cm) conditions. No significant interaction was observed. **CONCLUSION:** Shorter step length irrespective of forward or backwards walking could indicate a more conservative gait approach among BCS. Overall, spatio-temporal gait parameters among BCS seem to be similar compared to healthy controls. Whether these results hold true based on exposure to surgery and/or radiation and/or chemo therapy needs to be determined.

Concussion Recovery: Gait Characteristics In Collegiate Student-athletes

Caroline J. Ketcham, Briana N. O'Grady, Jeanine J. Grabowski, Brighton E. Summers, Lauren A. Brown, Srikant Vallabhajosula, Kirtida Patel, Eric E. Hall, FACSM. *Elon University, Elon, NC.* (Sponsor: Eric E. Hall, FACSM)
 Email: cketcham@elon.edu
 (No relationships reported)

BACKGROUND: Sports-related concussions have recently become one of the highest profile injuries in the athletic community. Concussions result from significant force to the brain that induces pathophysiological processes that affect its function. These effects can often present themselves through different combinations of physical, cognitive, emotional, and sleep symptoms. While neurocognitive computerized evaluations can provide useful information regarding self-report symptoms as well as quantitative measures of neurocognitive performance, they may not be sensitive to alterations in balance and gait which may last longer. **PURPOSE:** To assess gait characteristics in concussed NCAA Division 1 collegiate student-athletes at various time periods following a concussion. **METHODS:** 47 participants completed an

assessment of gait at baseline ($n=24$), while symptomatic ($n=13$) and/or when cleared to return-to-play ($n=10$). The gait protocol (10m walk under single and dual task conditions) was assessed through the use of the Mobility Lab software using ADPM sensor system. Gait measures included cadence, gait speed, step length, step duration and double stance time. **RESULTS:** A 2 (cognitive load) x 3 (phase assessment) MANOVA was conducted. There was a significant overall cognitive load main effect ($p < 0.05$), assessment phase main effect ($p < 0.05$) and a cognitive load x assessment phase interaction ($p < 0.05$). Univariate analysis showed there were significant differences for all variables when a cognitive load was added ($p < 0.05$). There were no significant differences found for gait speed ($p > 0.05$), but significant differences were found between assessment phase groups for double support ($p < 0.05$), step duration ($p < 0.05$) and cadence ($p < 0.05$). **CONCLUSIONS:** Time point in recovery and cognitive load affects gait patterns and will overall speed may not show differences in recover, underlying mechanisms of control still remain affected even when student-athletes are returned to play. This has implications for concussion recovery and susceptibility to injuries if not fully recovered.

Shorter Distance In 6-minute Walk Test In People With Multiple Sclerosis Demonstrating Leg Strength Asymmetries

Felix Proessler, Matt J. Carnal, Nathan B. Ketelhut, John H. Kindred, Brian L. Tracy, FACSM, Thorsten Rudroff, FACSM. *Colorado State University, Fort Collins, CO.* (Sponsor: Thorsten Rudroff, FACSM)
 Email: fproessler@colostate.edu
 (No relationships reported)

One of the early signs of Multiple Sclerosis (MS) is weakness on one side of the body, which is experienced by more than 75% of people with MS (PwMS). In addition, up to 92% of PwMS are affected by fatigue. Our previous findings indicate that leg strength asymmetries are associated with imbalanced muscle activity during walking. **Purpose:** To determine the association between leg strength asymmetries and walking characteristics, as indicated by total distance covered and step count, during a 6-minute walk test in PwMS. **Methods:** PwMS (aged 46-52 yrs) with self-reported asymmetries (2-5 on a 1-5 scale) and moderate disability (PDDS score 2-6) completed a series of maximal voluntary contractions of the knee extensors on each leg. Subsequently, participants walked as quickly, and safely as possible during a 6-minute walk test in a hallway with 2 cones placed 29 m apart. iPods with built-in accelerometers were strapped on both ankles to detect steps. In addition, ratings of perceived exertion (RPE) and distance covered were recorded every minute. Stride length was then calculated by dividing total distance by step count. **Results:** The distance covered by the PwMS was 391 ± 110 m with 572 ± 86 steps. The average increase in stride length from minute 1 to minute 6 was 8 ± 4 %. The average difference in leg strength was 27 ± 12 %. The subject with the greatest leg strength asymmetry (37%) demonstrated the shortest distance during the 6-minute walk test (307 m) and the greatest change in stride length (12%). Furthermore, RPE and distance covered each minute remained constant during the 6 minutes. **Conclusion:** These preliminary data indicate that leg strength asymmetries may result in altered walking strategies during a 6-minute walking test in PwMS. While previous studies have used the 6-minute walking test as a measurement of fatigue, in this sample, fatigability, defined as a decline in performance over time, appears to rather manifest itself as changes in walking characteristics.

2622 Board #142 June 2 9:30 AM - 11:00 AM
Changes In Healthy Old Adults' Gait Biomechanics Following Short-term Lower Extremity Power Training

Azusa Uematsu¹, Tibor Hortobagyi, FACSM², Kazushi Tsuchiya³, Norio Kadono³, Hirofumi Kobayashi⁴, Tomoya Ogawa³, Shuji Suzuki³. ¹Dokkyo Medical University, Shimotsuga-gun, Japan. ²University of Groningen, Groningen, Netherlands. ³Waseda University, Tokorozawa, Japan. ⁴The University of Tokyo, Meguro-ku, Japan. (Sponsor: Tibor Hortobagyi, FACSM)
 Email: auematsu@dokkyomed.ac.jp
 (No relationships reported)

PURPOSE: Age-related slowing of walking speed predicts many clinical conditions later in life. A variety of exercise programs can increase old adults' habitual and fast gait speed. However, the biomechanical mechanism of how old adults make use of the newly acquired physical abilities during gait is still unknown. Here, we examined the kinematic and kinetic mechanisms of how lower extremity power training increases healthy old adults' gait speed. **METHODS:** 12 males and 10 females (age 70-81 y) were randomly assigned to a control ($n = 7$) and training group ($n = 15$). The training intervention consisted of 16 sessions, administered over 8 weeks to improve lower extremity muscle power by

having participants explosively leg press progressively increasing loads of 30-40% of 1-repetition maximum (1RM). We measured participants' leg muscle strength in five muscle groups and gait biomechanics before and after the training intervention. **RESULTS:** Training increased maximal leg press load by ~40% ($P < 0.05$) and maximal voluntary force in five groups of leg muscles by ~32% ($P < 0.05$) but not in the no-exercise control group. Training (12.3%) vs. control (7.4%) tended to increase habitual and fast gait speed (21.1 vs. 8.9%) more (all $P < 0.05$). In the training group only, these increases in gait speed correlated with increases in stride length (habitual: $r^2 = 0.84$, fast: $r^2 = 0.89$). Training made old adults' gait more erect, as hip and knee extension increased in the stance phase of gait. Training increased ankle joint power by 3.3 J (control: -0.4 J, Group by Time interaction: $P < 0.05$), which correlated $r^2 = 0.58$ and $r^2 = 0.67$ with increases in habitual and fast gait speed without changes in hip and knee joint powers. **CONCLUSION:** After the intervention, old adults walked with a more erect gait due to increases in hip and knee extension in the stance phase of gait. The small but significant increase in ankle joint but not in hip and knee joint power correlated with increases in gait speed. The present results provide the first mechanistic insights into how short-term lower extremity power training improves healthy old adults' gait biomechanics. Supported by JSPS KAKENHI Grant Number 16K21320.

High Intensity Cycling Improves Spatiotemporal and Kinematic Gait Parameters in Parkinson's disease Patients
 Elise Baron. *Cleveland Clinic, Cleveland, OH.*
 Email: barone@ccf.org
 (No relationships reported)

Purpose: Gait dysfunction is a cardinal symptom of Parkinson's disease (PD). Alterations in gait are more pronounced during dual-task conditions where a cognitive and motor task are performed simultaneously. We have demonstrated that high-intensity aerobic exercise programs improve gait function under single-task (ST) conditions, however its impact on gait function while dual-tasking (DT) is unknown. A fundamental gap exists in understanding how high intensity exercise may impact DT performance. The aim of this project was to determine the changes in gait performance under ST and DT conditions following an 8-week cycling program. **Methods:** Eleven individuals with idiopathic PD were recruited to participate in an 8-wk stationary cycling intervention. Participant's gait was analyzed before and after the intervention using the Computer Assisted Rehabilitation Environment (CAREN) virtual reality system to assess upper and lower extremity kinematics. Participants walked on a treadmill at a self-selected speed while performing three cognitive tasks: N-back, Serial 7's and Verbal fluency. **Results:** MDS-UPDRS scores significantly improved from pre to post testing (-4.72 ± 5.54). Participants demonstrated significant increases in velocity (0.169 ± 0.61 m/s) ($p=0.01$), arm swing path length, hip joint range of motion (ROM), and knee joint ROM during both ST and DT conditions after the cycling intervention when compared to baseline. The ST condition was significantly greater than DT conditions for all parameters. Change in path length during ST conditions from pre to post testing (0.086 ± 0.135 m) was significantly greater than the N-Back (0.020 ± 0.136 m), Serial 7's (0.018 ± 0.130 m), and Verbal fluency (-0.002 ± 0.119 m) ($p=0.005$). Hip and knee ROM for single task were also found to be significantly greater ($p < 0.05$) when compared to DT. **Conclusions:** High-intensity cycling can improve gait dysfunction in PD. Changes occurred in both ST and DT conditions, with greater improvements seen under ST conditions. The increases found after the 8-wk cycling intervention suggest that high-intensity exercise elicits centrally mediated changes in the brain, allowing participants to allocate fewer cognitive resources to gait performance. This study was supported by a grant through the National Institute of Health R01NS673717.

The Effect of a Backpack Hip Strap on Energy Expenditure While Walking.
 Peter A. Hosick¹, Jamie Pigman², William Sullivan¹, Steven Leigh³. ¹Montclair State University, Montclair, NJ. ²University of Delaware, Newark, DE. ³Marshall University, Huntington, WV.
 Email: hosickp@mail.montclair.edu
 (No relationships reported)

Previous studies have demonstrated that the energy cost of carrying a backpack increases as the mass of the load carried increases. Conflicting results have been found when research examined the effect of duration on energy expenditure while carrying a backpack. A potential confounding variable could be the design of the backpack, particularly the use of a backpack hip strap. **PURPOSE:** To examine the effect of backpack hip strap use on walking energy expenditure while carrying a loaded backpack.

METHODS: A crossover design was used in which fifteen young, healthy male subjects walked at a self-selected pace for two 10-minutes in two backpack loading conditions: with a hip strap (strapped) and without a hip strap (non-strapped). Oxygen consumption (VO_2), rating of perceived exertion (RPE), respiratory exchange ratio (RER), and heart rate (HR) were monitored throughout each 10-minute trial. Change scores from the 4th to 10th minute were calculated for each variable. A t-test was used to evaluate the difference between conditions for each variable. **RESULTS:** The change in VO_2 (-0.62 ± 0.40 vs. 0.33 ± 0.23 , $p = 0.04$) and change in RPE (1 ± 0.25 vs. 2 ± 0.21 , $p < 0.01$) from the 4th to the 10th minute were different for the strapped versus non-strapped condition, respectively. There was no difference in the change in RER (0.04 ± 0.01 vs. 0.03 ± 0.01 , $p > 0.05$) or HR (3.53 ± 0.93 vs. 4.07 ± 1.39 , $p > 0.05$) for the strapped versus unstrapped condition, respectively. **CONCLUSIONS:** Wearing a hip strap reduced the energy expenditure and perceived exertion in as little as 10 minutes of walking compared the non-strapped condition. Future work should consider the effect of a hip strap on these variables while hiking for extended periods.

Altered Lower Extremity Joint Energetic Patterns in Patients with Chronic Ankle Instability during Walking
 Trevor Fuhriman, Hyunsoo Kim, S. Jun Son, Jake Roush, Matthew K. Seeley, J. Ty Hopkins, FACSM. *Brigham Young University, Provo, UT.* (Sponsor: J. Ty Hopkins, FACSM)
 Email: trevorfuhriman@gmail.com
 (No relationships reported)

A lateral ankle sprain is among the most common sports-related injuries often leading to chronic ankle instability (CAI). Identification of energetic patterns in patients with CAI may clarify underlying injury pathomechanics of CAI. **PURPOSE:** To examine the effect of CAI on energetic patterns of the lower extremity joints during walking. **METHODS:** 100 CAI patients (M=49, F=51; 22 ± 2 yrs, 174 ± 10 cm, 71 ± 14 kg, $82 \pm 9\%$ FAAM ADL, $62 \pm 13\%$ FAAM Sports, 4.5 ± 2.6 ankle sprains) and 100 controls (M=56, F=44; 22 ± 3 yrs, 172 ± 13 cm, 72 ± 18 kg, 100% FAAM ADL & Sports, no previous sprains) performed five walking trials, while ankle, knee and hip joint powers (W/kg) were measured during the stance phase of walking tasks. Functional analyses ($\alpha = .05$) were used to evaluate difference in joint power between groups. If functions and associated 95% confidence intervals did not cross zero, group differences existed. **RESULTS:** Figure 1. CAI subjects had less ankle eccentric power and concentric power during early to mid and late stance phase respectively. CAI demonstrated decreased eccentric knee joint power during the initial phase and increased eccentric knee joint power during pre-swing phase. Both concentric and eccentric hip joint power were increased throughout the entire stance phase in patients with CAI. **CONCLUSIONS:** The CAI group increased proximal joint energy absorption and generation to compensate for decreased distal joint power during walking compared to a control group. More data are needed to determine if joint power redistribution in CAI patients is a risk factor for further ankle injury.

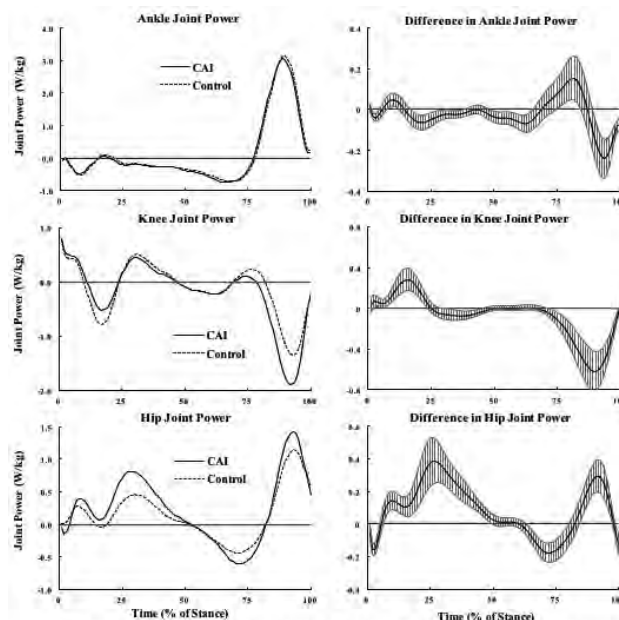

Figure 1. Ankle, knee and hip joint power during stance phase of walking tasks between groups (CAI vs. Control). Mean differences (bold solid curve) and corresponding 95% CI (shaded area) are plotted as a function of time. When the shaded area does not overlap with the zero line (bold horizontal red line), a significant difference ($p < 0.05$) is indicated between groups.

Effects of Strength and Proprioceptive Exercises on Walking Energetic Patterns in Chronic Ankle Instability Patients

Sunku Kwon¹, S. Jun Son¹, Hyunsoo Kim², Alyssa Evans¹, Dustin Bruening¹, Matthew Seeley¹, J. Ty Hopkins, FACSM¹.
¹Brigham Young University, Provo, UT. ²West Chester University, West Chester, PA. (Sponsor: J. Ty Hopkins, FACSM)
 Email: sunkukwon@gmail.com
 (No relationships reported)

Chronic ankle instability (CAI) patients often exhibit altered walking mechanics, due to strength and proprioceptive deficits associated with CAI. Reduced strength and proprioception function may decline a gait energetic efficiency, which can reduce shock absorption and power generation. It is unclear whether strength and proprioceptive training can affect walking energetics for CAI patients. **PURPOSE:** To examine the effect of a 6-week ankle and hip rehabilitation program on ankle, knee, and hip joint energetic patterns during walking in CAI patients. **METHODS:** 15 CAI patients (23±2 yrs, 178±8 cm, 76±9 kg, 83±7% FAAM ADL, 56±10% FAAM Sports, 3.6±1.1 MAII, 4.7±2.0 ankle sprains) performed ankle and hip strength and proprioceptive exercises (i.e., theraband, wobble board, etc.) 3 times per week, for 6 weeks (this was the rehab group). 14 CAI patients (22±2 yrs, 177±9 cm, 75±12 kg, 81±9% FAAM ADL, 56±12% FAAM Sports, 3.4±1.2 MAII, 5.9±3.3 sprains) performed no rehabilitative exercises (this was the control group). We measured ankle, knee, and hip joint power during walking for all patients before and after the exercises. Functional statistics ($\alpha=.05$) were used to evaluate the influence of the rehab exercises on joint power for both groups across the entire stance phase of walking. **RESULTS:** Figure 1. The rehab intervention resulted in up to 0.07 W/kg more positive ankle power (concentric) between 19 and 26% of stance and up to 0.06 W/kg more positive knee power (concentric) between 40 and 48% of stance. No changes were detected in hip joint power during the stance phase of walking. **CONCLUSION:** Data suggest that the strength and proprioceptive training results in an improved gait energetic efficiency through the increased ankle and knee power generation during mid-stance. As greater muscular strength can lead to an increase in power absorption and generation, the intervention focusing on strength should be beneficial in improving walking energetics in a CAI population.

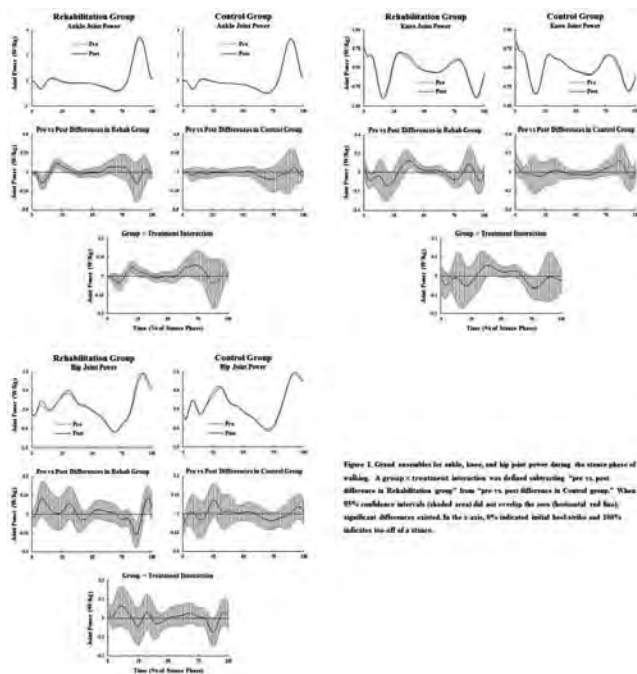

Figure 1. Grand averages for ankle, knee, and hip joint power during the stance phase of walking. A group x treatment interaction was defined subtracting "pre vs post" differences in Rehabilitation group from "pre vs post" differences in Control group. When 95% confidence intervals (shaded area) did not overlap the zero (horizontal red line), significant differences existed. In the x-axis, 0% indicated initial heelstrike and 100% indicates toe-off of a stance.

Performing The Six-minute Walk Test Is Linked To Increased Risk Of Falling For Persons With Ms

Collin D. Bowersock¹, Corey Rynders², Jake Sosnoff³, Steven Morrison¹. ¹Old Dominion University, Norfolk, VA. ²University of Colorado, Boulder, CO. ³University of Illinois, Champaign, IL.
 Email: cdbowersock@gmail.com
 (No relationships reported)

A major health concern for individuals with MS is the likelihood of suffering a fall. The cause of any fall is often multifaceted, given the numerous physiological changes linked to this disease process. For this population, tiredness and fatigue are prominent factors linked to increased falls risk, given that these metrics have been linked to a decline in balance, walking ability, sensation and general muscle function. **PURPOSE:** To assess the effect of performing a standardized endurance task (the six-minute walk test, 6MWT) on gait, balance, strength and falls risk in older adults with MS. **METHODS:** Twenty-three persons with MS (mean 55.1±9.1 yr) participated in this study whereby their walking ability, balance and falls risk was assessed prior to and after performing the 6MWT. Each person's falls risk was assessed using the Timed Up and Go (TUG) test and the Physiological Profile Assessment (PPA). The PPA incorporates physiological measures related to falls including vision, sensation, posture, reaction time and muscle strength. Walking ability was assessed using a 20 ft GAITRite mat. **RESULTS:** At baseline, the MS persons had an increased falls risk reflected by higher PPA values (2.4±0.4), slow TUG times (13.9±0.4 s) compared to age-matched normative adults. Following the 6MWT, the MS group exhibited no significant changes in gait performance from baseline (velocity 1.07 to 1.04 ms, p=0.284; Cadence 15 to 17 steps/min, p=0.645). In contrast, significant declines in knee extension strength (from 27.3 to 23.2 kg, p<0.05) and increases in postural sway (from 8.3+3 to 11.5+3 cm, p<0.05) and falls risk (2.8+0.3, p<0.05) were for the MS group. **CONCLUSION:** Compromised balance control leading to the increased likelihood of suffering a fall is a major problem for persons with MS. For the current study, we assessed the impact of performing the standardized clinical assessment of endurance on gait, balance and overall falls risk. Interestingly, the immediate effects of the 6MWT were not reflected by any notable change in gait performance. However, declines in balance control, knee extension strength, and increased falls risk were seen following the 6MWT. Overall, it would appear that while mobility (i.e. gait) of the person with MS was not affected by this endurance task, general stability and balance were compromised.

Individuals with Chronic Ankle Instability Exhibit Altered Ground Reaction Force Patterns during Walking

Jordan R. Read¹, Hyunsoo Kim², S. Jun Son¹, James Mitchell¹, Matthew K. Seeley¹, J. Ty Hopkins, FACSM¹. ¹Brigham Young University, Provo, UT. ²West Chester University, West Chester, PA. (Sponsor: J. Ty Hopkins, FACSM)
 Email: jordanread31@gmail.com
 (No relationships reported)

Lateral ankle sprains frequently occur and often lead to chronic ankle instability (CAI). CAI has been shown to alter neuromuscular function and walking mechanics which impact ground reaction force (GRF). **PURPOSE:** To examine patterns of ground reaction forces across the stance phase of gait in those with and without CAI. **METHODS:** 100 CAI patients (M=49, F=51; 22±2 yrs, 174±10 cm, 71±14 kg, 82±9% FAAM ADL, 62±13% FAAM Sports, 4.5±2.6 ankle sprains) and 100 controls (M=56, F=44; 22±3 yrs, 172±13 cm, 72±18 kg, 100% FAAM ADL & Sports, no previous sprains) performed five walking trials. Three dimensional GRFs (anterior-posterior, medial-lateral, and vertical) were measured during the stance phase of gait (0-25%: initial stance, 25-50%: loading response, 50-75%: midstance, and 75-100%: terminal stance). Functional linear models were used to compare difference in GRFs between the groups during walking ($\alpha=.05$). If functions and associated 95% confidence intervals did not cross zero, group differences existed. **RESULTS:** Figure 1. CAI subjects demonstrated greater vertical GRF during 0-10% and 67-95% of stance. Patients with CAI also increased posterior and anterior GRFs during 10-20% and 70-95% of stance respectively. Lateral GRF was greater in CAI subjects during 65-75% of stance compared to controls. **CONCLUSION:** CAI subjects may compensate for ankle instability with a more rigid walking strategy by increasing anterior-posterior, lateral and vertical GRFs during the stance phase of gait. The greater GRF of the CAI group indicates altered gait mechanics which could increase loads on lower extremity joints and potentially increase re-injury risk.

Figure 1. Anterior (+) / posterior (-), lateral (+) / medial (-), and vertical ground reaction force (GRF) during stance phase of walking tasks. Mean differences (bold solid curve) and corresponding 95% CI (shaded areas) are plotted as a function of time. When the shaded area does not overlap with the zero line (bold horizontal red line), a significant difference ($p < 0.02$) is indicated between groups.

Does the Polar FT60 Fitness Test™ Accurately Predict Maximal Oxygen Consumption in Healthy Subjects?

Kent D. Johnson, FACSM, Jenny Beadle. *Lipscomb University, Nashville, TN.*
Email: kent.johnson@lipscomb.edu
(No relationships reported)

Accurately predicting maximal oxygen consumption ($\dot{V}O_{2max}$) in healthy individuals as part of a fitness assessment is a common practice in some fitness and wellness centers where maximal testing is not practical. One system used to predict $\dot{V}O_{2max}$ is the Polar FT60 Fitness Test™ which predicts maximal oxygen consumption based on an individual's resting heart rate and prior three month activity level. While these systems are somewhat popular, the question remains concerning their validity and accuracy in predicting $\dot{V}O_{2max}$ in healthy subjects. **PURPOSE:** To determine the validity of the Polar FT60 Fitness Test™ in accurately predicting $\dot{V}O_{2max}$ in healthy individuals. **METHODOLOGY:** Thirty-one subjects volunteered for the study (males=13; females=18; age=27.61±5.46yrs; WT=71.50±15.00kg; HT=169.32±14.00cm; BMI=24.09±3.84kg/m²; BF%=20.58±10.00). Volunteers reported to the lab where their predicted maximal oxygen consumption was assessed using the Polar FT60 Fitness Test™ following manufacturer's recommendation. Maximal oxygen consumption was then determined using a standard maximal treadmill protocol where $\dot{V}O_{2max}$ was assessed with a calibrated Parvo Medics' TrueOne® 2400 metabolic system. **RESULTS:** Results indicate that the Polar FT60 Fitness Test™ significantly overestimates maximal oxygen consumption by ~9.75% (predicted $\dot{V}O_{2max}$ =49.77±10.74ml/kg/min; actual $\dot{V}O_{2max}$ =44.92±8.12ml/kg/min; $p < 0.001$; 95% CI=2.188, 7.515). **CONCLUSION:** These results indicate that the Polar FT60 Fitness Test™ significantly overestimates maximal oxygen consumption in this population of healthy subjects.

Accuracy And Practicality Of A NIRS Device On Blood Lactate Levels

John Abbott, Melissa A. Whidden. *West Chester University, West Chester, PA.*
(No relationships reported)

Historically, cyclists have relied upon blood lactate analysis and/or metabolic testing to determine their fitness level and training zones. However, these methods are now being challenged by Near Infrared Spectroscopy (NIRS). The BSX Insight is a wearable NIRS device that claims to predict lactate threshold by analyzing changes in muscle oxygenation. **PURPOSE:** The purpose of this study was to compare the accuracy of the BSX Insight against blood lactate and ventilatory threshold analyses. **METHODS:** Nine highly trained cyclists (18-55 years of age) performed a graded exercise test while wearing the Insight and data was simultaneously collected via the TrueOne 2400 metabolic cart and Lactate Plus analyzer. Lactate threshold heart rate (HR) and power as predicted by the Insight was compared with blood lactate threshold (LT) as determined by the Dmax method and with the ventilatory threshold (VT) as determined by the respiratory exchange ratio (RER) method, V-slope method, and ventilatory equivalency (VEQ) method. **RESULTS:** Average LT power output as determined by the BSX Insight was not significantly different when compared to Dmax, RER, VEQ, and Vslope ($P = 0.811$). Average LT power output from the Insight showed a positive correlation with Dmax ($r = 0.869$), RER ($r = 0.964$), VEQ ($r = 0.970$), and Vslope ($r =$

0.949). Average LT HR as determined via the BSX Insight device was not statistically different when compared to Dmax, RER, VEQ, and Vslope ($P = 0.386$). The average percent difference of LT HR from the Insight compared with all other methods was within 5% (Dmax = 2.29%, RER = -2.56%, VEQ = -2.74%, Vslope = 0.545). **CONCLUSIONS:** The wearable BSX Insight device is good at predicting LT HR and power output during a cycling test and muscle oxygenation can be used to estimate LT. The BSX Insight device may be an extremely helpful tool for those cyclists who do not have the ability or access to utilize more expensive testing protocols.

Reliability Of An On-court Basketball-specific Protocol

Kelly A. Barnes, Melissa L. Anderson, Lindsay B. Baker.
PepsiCo, Inc., Barrington, IL.
Email: kelly.barnes1@pepsico.com
Reported Relationships: K.A. Barnes: Salary; PepsiCo, Inc. Ownership Interest (Stocks, Bonds); PepsiCo, Inc.

There is limited information available on sport-specific performance protocols in basketball, particularly where reliability has been assessed. **Purpose:** To determine the reliability of a set of drills designed to assess a wide variety of skills related to basketball-specific performance. **Methods:** Seventeen (8 guards, 9 posts) competitive, male basketball players (17±1 y, 72.6±11.9 kg) completed a familiarization visit followed by two identical experimental trials. Subjects ate a consistent diet 24 h before each trial and consumed 500 ml water and a granola bar 3 h before each trial. The protocol began with a 10-min warm up, followed by four ~20-min quarters consisting of 13 basketball drills; involving sprinting, vertical jumping (VJ), shooting, dribbling, passing, pre-planned agility, reactive agility, and a basketball-specific cognitive task (recall of a mock scouting report and game plan). Heart rate (HR) was measured continuously. Subjects received the same volume of a carbohydrate-free, electrolyte beverage to maintain euhydration during both trials. Paired samples t-tests and coefficient of variation (CV) were used to assess the reliability of each drill (between mean values of the two trials). **Results:** There were no differences between trials in mean HR (160 ± 11 bpm vs. 161 ± 10 bpm, $p=0.77$). There were no differences in performance between trials for any of the drills ($p > 0.05$). Between-trial CV's by drill were as follows: 15-s VJ max height (11.5%) and mean height (6.8%), pre-planned agility (3.9%), passing accuracy (9.8%), dribbling speed (3.7%), mid-range shooting accuracy (13.1%), lay up accuracy (3.3%), reactive agility (7.0%), lane slides (3.5%), 3-point shooting accuracy (14.7%), sprints (4.3%), rebounding (7.9%), free throw accuracy (15.8%), and accuracy on the cognitive task (8.8%). Shooting accuracy was more reliable in the guards vs. posts; mid-range (9.0% vs. 15.4%), 3-point (8.5% vs. 19.4%), and free throw (9.4% vs. 18.7%). **Conclusion:** The reliability of the basketball drills in 14-19 y players ranged from 3 to 16% and varied by player position. Future research is needed to determine the validity (e.g., identifying different skill levels) and sensitivity (e.g., measuring the efficacy of nutritional interventions) of this novel basketball-specific protocol.

2632 Board #152 June 2 11:00 AM - 12:30 PM
Time of Day and Leg Dominance Influence Estimated and Actual Maximal Single Leg Hop Performance

David MacDonald¹, Stephane Desjardins², Kylie Tucker².
¹Griffith University, Gold Coast, Australia. ²The University of Queensland, Brisbane, Australia.
Email: david.macdonald@griffith.edu.au
(No relationships reported)

PURPOSE: To determine whether time of day and leg dominance influence estimated and/or actual maximal single leg hop (SLH_{max}) performance. **METHODS:** 22 healthy participants (mean age 21.7 ± 2.5 years, 16 males and 6 females) estimated their SLH_{max} performance and performed a SLH_{max} (on dominant and non-dominant legs) during a morning (6-8am) and an evening (6-8pm) experimental session. All outcome measures were analysed using separate two-way repeated measures analysis of variance (ANOVA) with Leg Dominance (DOM vs NONDOM) and Time of Day (AM vs PM) as within subject factors. **RESULTS:** There was no difference in estimated SLH_{max} between the morning and evening sessions ($p=0.58$). Participants had a mean estimated SLH_{max} distance of 137 ± 32.2 cm in the morning and 139.5 ± 33.4 cm in the evening. Actual SLH_{max} was greater in the evening session than in the morning ($p < 0.05$). Participants achieved an actual SLH_{max} distance of 166 ± 34.9 in the morning and 171.3 ± 31.8 cm in the evening. Participants did estimate a greater SLH_{max} on their dominant compared to non-dominant leg ($p < 0.01$) but there was no difference in SLH_{max} performance between legs ($p=0.55$). When using their dominant leg, participants estimated they could hop a SLH_{max} distance of 141.9 ± 32.9 cm and performed an actual hop distance of 169.3 ± 34.2 cm. When using their non-dominant leg, participants estimated they could hop a maximal SLH distance of 134.6 ± 32.3 cm and performed an actual hop distance of 168 ± 32.7cm. **CONCLUSION:** The SLH_{max} is a functional outcome measure that evaluates lower limb muscular power and is used clinically to track progress of lower limb musculoskeletal injury. Like other tests of lower limb power there are differences in SLH_{max} between time of day. However,

unlike other tests of lower limb performance, individuals were not able to accurately estimate those time of day differences in performance or the lack of differences in performance between dominant and non-dominant legs. Overall, it is interesting that for time of day and leg dominance, participants either did not perceive differences that were present or perceived differences that were not present.

2633 Board #153 June 2 11:00 AM - 12:30 PM
Resting and Post-exercise Heart Rate Detection from Fingertip and Facial Photoplethysmography Using a Smartphone Camera

Bryan P. Yan¹, Christy K. Chan¹, Olivia T. To¹, Christien K. Li², William H. Lai¹. ¹The Chinese University of Hong Kong, Hong Kong, China. ²Newcastle University, Newcastle, United Kingdom.
 Email: bryan.yan@cuhk.edu.hk
 (No relationships reported)

Modern smartphones allow measurement of heart rate (HR) via detection of pulsatile photoplethysmographic (PPG) signals from the fingertips or the face without physical contact by extracting subtle beat-to-beat variations of skin color that is similar to HR fluctuations with built-in cameras.

PURPOSE: To evaluate HR measurements at rest and after exercise using a smartphone based PPG detection application.

METHODS: Forty healthy subjects (50% males; mean age 24.7 ± 5.2 years; Von Luschan skin color range 14-27) underwent treadmill exercise using the Bruce protocol. Simultaneous PPG signals were recorded per subject by (i) facing the front camera and (ii) placing index fingertip over the back camera of iPhone 6Ss and analyzed by the *Cardio-Heart Rate Monitor + 7 Minute Workout Exercise Routine for Cardio Health and Fitness* (Cardio Inc., Cambridge, MA) smartphone application for HR compared to continuous ECG as reference. Recordings of 20 seconds duration each were acquired at rest, immediately post moderate (50-70% maximum HR) and vigorous (70-85% maximum HR) intensity exercise and repeated successively until return to resting HR. Bland-Altman plots were used to examine agreement between ECG and PPG estimated HR. HR monitors are considered accurate if the correlation coefficient (r) is ≥ 0.93 and root mean square error (RMSE) is ≤ 5 beats per minute (bpm) or $< 6.8\%$.

RESULTS: Mean HR was 73 ± 13 bpm (range 53-114) at rest and 97 ± 21 bpm (51 to 157) post exercise. 477 fingertip and 582 facial PPG measurements were recorded and analyzed. Fingertip PPG estimated HR were strongly correlated with both resting ECG HR ($r = 0.997$ and RMSE = 1.025 bpm or 1.404%) and post-exercise HR ($r = 0.995$ & RMSE = 2.074 bpm or 2.220%). Correlation of facial PPG estimated HR were stronger with resting ECG HR ($r = 0.997$ & RMSE = 1.020 bpm or 1.428%) and was also strong with post-exercise HR ($r = 0.984$ & RMSE = 3.673 bpm or 3.931%). Bland-Altman plots showed better agreement between ECG with fingertip than facial PPG estimated HR.

CONCLUSIONS: HR detection by the Cardio smartphone application is considered accurate at rest and after moderate and vigorous intensity exercise in a healthy young adult sample. Although touchless facial PPG detection is convenient, it may not be able to consistently detect a HR when body motion is excessive after exercise.

2634 Board #154 June 2 11:00 AM - 12:30 PM
Repeatability of Heart Rate Variability Across Exercise Modes

Trent A. Hargens, FACSM, Daniel S. Valcicak, Lindsey M. Rodriguez. *James Madison University, Harrisonburg, VA.*
 Email: hargenta@jmu.edu
 (No relationships reported)

Heart rate variability (HRV) is a common method for assessing autonomic nervous system function. Little research has explored the repeatability of HRV during exercise, particularly with differing exercise modes.

PURPOSE: To compare HRV variables during steady-state exercise at the same intensity during treadmill (TM) and Cycle (C) exercise.

METHODS: Eleven men (Age = 21.4 ± 2.2; BMI = 24.7 ± 3.1 kg/m²) completed 3 maximal graded exercise tests, 2 TM and 1 C. During each test, a 5-minute, steady-state stage was completed, with a target of 5.0 METs. Oxygen consumption (VO₂) was measured via indirect calorimetry. HRV was measured using the Polar V800 watch, and analyzed with Kubios HRV software. Time [Standard deviation of RR intervals (SDNN) and mean squared difference of successive RR intervals (RMSSD)] and frequency [high frequency power (HF), low frequency power (LF), normalized HF (HFnu), normalized LF (LFnu), and the LF/HF ratio] measures of HRV were analyzed, with non-normally distributed data Log transformed for analysis.

RESULTS: Heart rate, VO₂ and HRV measures did not differ between TM trials. Heart rate (111.4 ± 14.1 vs. 112.0 ± 15.8 bpm for TM and C, respectively) and VO₂ (19.2 ± 1.1 vs 19.1 ± 1.2 ml·kg⁻¹·min⁻¹) did not differ between TM and C trials. Minute ventilation (38.1 ± 13.9 vs 38.5 ± 13.7) also did not differ. Respiratory exchange ratio was lower during the TM trial (0.80) compared to the C trial (0.86, P < 0.01).

No significant mean differences were noted any HRV variable. Intraclass correlation coefficients were significant for SDNN (0.87), RMSSD (0.78), LF (0.83), HF (0.76), but not for HFnu (0.38), LFnu (0.38), or the LF/HF ratio (0.43). Bland-Altman analysis showed good agreement for all HRV variables (P > 0.05).

CONCLUSION: Results suggest that HRV variables measured during steady-state exercise at moderate exercise intensity were repeatable, particularly those associated with parasympathetic function. Future research is needed at higher intensities, when parasympathetic withdrawal has occurred, and sympathetic control of heart rate is the dominant factor.

Maximal Heart Rate Varies Across Laboratory, Field Testing, and Competition Among Collegiate Female Hockey Athletes.

Zoe R. Ziegler, Andrew Watson, Stacey Brickson, Jennifer Sanfilippo. *The University of Wisconsin-Madison, Madison, WI.*
 (No relationships reported)

In order to prescribe training intensities based on maximal heart rate (MHR), it is important to determine the potential differences in MHR using a variety of different testing conditions. Systematic differences in MHR across testing and competition conditions are poorly defined. **PURPOSE:** To determine if MHR varies between laboratory testing, field testing, practice, games and an age-prediction equation in collegiate female hockey athletes. **METHODS:** MHR was measured in 16 NCAA Division 1 female hockey athletes during a progressive, graded maximal treadmill test (MHR_{GXT}), on-one fitness testing (MHR_{FIELD}), one season of practices (MHR_{TRAIN}) and games (MHR_{MATCH}), and estimated by an age prediction equation (208-0.7 x age; MHR_{PRED}). Participants were excluded if they failed to obtain 2 out of 3 criteria during MHR_{GXT}: 1) RER ≥ 1.1 , 2) plateau in VO₂ and 3) attainment of $\geq 90\%$ of MHR_{PRED}. MHR measures were compared across different methods by Kruskal-Wallis tests and Pearson correlation coefficients were determined between the different methods. **RESULTS:** MHR_{GXT} (194.5 ± 6.0bpm) was significantly higher than MHR_{FIELD} (192.3 ± 4.9bpm, $p = 0.037$) and lower than MHR_{TRAIN} (200.1 ± 8.3bpm, $p = 0.0018$) and MHR_{MATCH} (201.1 ± 11.0bpm, $p = 0.01$), but not significantly different from MHR_{PRED} (193.8 ± 0.9bpm, $p = 0.64$). Significant correlations were found between MHR_{GXT} and MHR_{FIELD} ($r = 0.79$, $p < 0.001$) but not MHR_{TRAIN} ($r = 0.41$, $p = 0.11$) or MHR_{MATCH} ($r = 0.10$, $p = 0.70$). MHR_{PRED} was not correlated with any other methods ($r = 0.15$ to 0.22, $p > 0.05$ for all). **CONCLUSIONS:** Among elite female hockey athletes, MHR_{GXT} and MHR_{FIELD} were significantly lower than practices and games. This suggests that MHR from competition may overestimate the heart rate that is representative of maximal aerobic capacity. Use of this value as a reference to prescribe training volume could result in unintentionally higher training loads with potentially increased risk of overtraining or injury.

Validation Of The Bruce Versus A New Customized Submaximal Treadmill Protocol For Determining "True" Vo2max

Cody J. Strom¹, Robert W. Pettitt, FACSM¹, Luke M. Krynski¹, Nicholas A. Jamnick², Charles J. Hein¹, Cherie D. Pettitt¹.
¹Minnesota State University, Mankato, Mankato, MN. ²Victoria University, Melbourne, Australia. (Sponsor: Dr. Robert Pettitt, FACSM)
 Email: Cody.strom@mnsu.edu
 (No relationships reported)

A customized submaximal exercise test for cycle ergometry was reported as a superior estimate of maximum oxygen uptake (VO_{2max}) in comparison to the YMCA bike test.

PURPOSE: Following similar methodology, we sought to evaluate a custom submaximal treadmill test (MSET) with the widely used Bruce submaximal protocol. **METHODS:** Participants (29 women and 21 men; age = 31.37 ± 11.44 y, BMI = 24.02 ± 3.03) performed a graded exercise test (GXT) with a subsequent exhaustive, square-wave bout for the verification of "true" VO_{2max}. In counterbalanced-order, subjects then completed submaximal protocols. The MSET consisted of two 3-min stages estimated at 35% and 70% of VO_{2max}, where VO_{2max} was estimated with a linear regression equation utilizing gender, BMI, age, and self-reported physical activity. **RESULTS:** VO₂ values from the GXT and verification bout were 47.2 ± 7.7 and 47.0 ± 7.7 ml·kg⁻¹·min⁻¹, respectively (ICC = 0.99, CV = 2.0%, TE = 0.83 ml·kg⁻¹·min⁻¹), with the highest value used as "true" VO_{2max} (47.7 ± 7.7 ml·kg⁻¹·min⁻¹). Neither the Bruce (45.95 ± 6.97 ml·kg⁻¹·min⁻¹) nor the MSET (47.3 ± 9.4 ml·kg⁻¹·min⁻¹) differed from "true" VO_{2max}. The MSET had a "very large" measurement agreement with "true" VO_{2max} (ICC = 0.78, CV of 9.1%, TE = 4.07 ml·kg⁻¹·min⁻¹). Bruce had a "large" measurement agreement with "true" VO_{2max} (ICC = 0.62, CV of 10.0%, TE = 4.51 ml·kg⁻¹·min⁻¹). **CONCLUSION:** Our findings indicate that the MSET is superior to the Bruce protocol because it yields a better measurement agreement for "true" VO_{2max}, is more time efficient, and can be used to prescribe exercise.

Sex Differences In The Optimal Intensity For Cycle Ergometer Verification Of VO₂max
 Brandon J. Sawyer, Janie C. Unkefer, Kaiti A. Freeberg, Stephanie D. Gagnon, Nicholas McMahon, Kai Pattison, Jennifer M. Beers, Brett B. Baughman. *Point Loma Nazarene University, San Diego, CA.* (Sponsor: Robert Pettitt, FACSM)
 Email: bsawyer@pointloma.edu
 (No relationships reported)

PURPOSE: Using a verification phase test (VP) following a graded exercise test has been shown to be superior to secondary criteria to determine a "true" VO_{2max}. It has not been determined if a sex difference in the optimal intensity for cycle ergometry VP testing exists. **METHODS:** 31 participants (16 females, age: 21±1.5 yrs, BMI: 23.2±3.3 kg/m²; 15 males, age: 22±1.5 yrs, BMI: 24.5±2.2 kg/m²) completed a ramp VO_{2max} test, then on 4 subsequent days, in random order, completed VP tests at 80, 90, 100, and 105% of the peak wattage achieved during the initial ramp test. **RESULTS:** The VO_{2max} values for each test (Ramp, 80, 90, 100, and 105%) for women were 2.36±0.35, 2.29±0.34, 2.34±0.33, 2.35±0.31, 2.32±0.32 L/min and for men were 3.65±0.66, 3.67±0.71, 3.67±0.67, 3.56±0.51, 3.49±0.48 L/min. For males VO_{2max} at 105% was significantly lower than Ramp (P=0.02), 80% (P<0.01), and 90% (P=0.02). Also VO_{2max} at 80% (P=0.07) and 90% (P=0.08) was marginally higher than at 100%. Females showed no significant differences between VO_{2max} values for any VP or Ramp test. 10 of the 16 female subjects had their highest VO_{2max} during the 100 or 105% VP, while 12 of 15 male subjects had their highest from a VP at a submaximal wattage. When comparing all VPs a significant sex x test interaction (P=0.01) was observed. **CONCLUSIONS:** Submaximal VP intensities of 80% and 90% of max wattage achieved on the ramp test produce the highest VO_{2max} values in males. In females the maximal and supramaximal intensities most frequently produced the highest VO_{2max} values whereas the 80% led to excessive time to exhaustion (9.23±4.99 min). In order to obtain the highest VO_{2max} values in the most optimal test time we recommend using 90% of max wattage in males and 100 or 105% of max wattage in females.

Determining The Optimal Work Rate For Cycle Ergometer Verification Phase Testing In Males With Obesity
 Jennifer M. Beers¹, Brett B. Baughman¹, Ailish C. Sheard², Jeff A. Sullivan¹, Brandon J. Sawyer¹. ¹*Point Loma Nazarene University, San Diego, CA.* ²*California State University Los Angeles, Los Angeles, CA.* (Sponsor: Robert Pettitt, FACSM)
 Email: jennybeers100@pointloma.edu
 (No relationships reported)

PURPOSE: The applicability of verification phase (VP) testing as a means to confirm the attainment of a 'true' VO_{2max} in males with obesity is widely unknown due to only two previous published studies on this population. The aim of the present study was to assess the validity of verification phase testing on separate days in males with obesity and determine the optimal work rate at which the highest VO_{2max} can be elicited. **METHODS:** Nine healthy males with obesity between the ages of 18 and 35 (age = 24.1 ± 6.1 years; body mass index [BMI] = 33.2 ± 4.2 kg/m²) performed a ramp-style VO_{2max} test on the cycle ergometer followed by four randomly assigned constant power (verification phase) tests on separate days. VP tests were set at 80, 90, 100 and 105% of maximal wattage (W_{max}) attained during the ramp test. **RESULTS:** All participants but one attained a higher, but not significant, VO_{2max} (L/min) during a VP test to values elicited during the initial ramp test. A trend (p=0.06) was shown for VO_{2max} during the 90% (3.61 ± 0.54 L/min) VP to be higher than the ramp (3.37 ± 0.39 L/min). A trend (p=0.06) was also seen for VO_{2max} during the 90% VP (3.61 ± 0.54 L/min) to be higher than the 105% (3.41 ± 0.53 L/min) test. HR_{max} was significantly lower/ during the 105% VP (170 ± 17 b/min) compared to the 80% (177 ± 16 b/min, P=0.02) and 90% (176 ± 14 b/min, P=0.02) VP tests. **CONCLUSION:** Verification phase tests at submaximal work rates, of 90% of W_{max} attained during the ramp test, may elicit the highest VO_{2max} and HR_{max} in males with obesity. Using a verification test in this population may provide more accurate VO_{2max} results as well as more accurate HR based exercise prescriptions.

Breathing Valve Resistance Alters Physiological Responses During a Graded Exercise Test
 Sewan Kim, Eric P. Homestead, William C. Byrnes, FACSM. *University Colorado Boulder, Boulder, CO.* (Sponsor: William C. Byrnes, FACSM)
 (No relationships reported)

The graded exercise test (GXT) is a fundamental tool in the field of exercise physiology, which requires the use of a two-way breathing valve to direct inspiratory and expiratory airflow. These two-way breathing valves impose resistances to airflow and can increase the work of breathing, thus altering an individual's physiological response to a GXT. **PURPOSE:** To examine the physiological responses during a GXT when using two-way breathing valves with differing resistances to airflow. **METHODS:** Forty healthy subjects participated in this study (10 endurance trained males (ETM), 10 endurance trained females (ETF), 10 recreationally active males (RAM), and 10 recreationally active females (RAF)). On two separate occasions, subjects performed identical GXTs using either the Rudolph 2700 (high resistance) or the Daniels' (low resistance) breathing valve. The GXTs were completed on a treadmill and consisted of a submaximal and a maximal phase. During the submaximal phase, running economy (RE), energy expenditure (EE), ventilation (V_E), heart rate (HR) and respiratory exchange ratio (RER) were measured. During the maximal phase, peak oxygen consumption (VO_{2peak}), V_E, HR, RER and time to exhaustion (TTE) were measured. **RESULTS:** When using the Daniels' valve, all groups had significantly better RE (-2.7, -3.5, -1.9, and -1.8% for ETM, ETF, RAM and RAF, respectively, p<0.05) and lower EE (-2.4, -3.4, -2.7, and -2.0% for ETM, ETF, RAM, and RAF, respectively, p<0.05) across all submaximal speeds. The ET group also had lower V_E (4.6 and 3.8% for ETM and ETF, respectively, p<0.05) when using the Daniels' valve across all submaximal speeds. During the maximal phase, TTE was significantly longer when using the Daniels' valve for all groups (6.0, 10.9, 6.2 and 9.8% for ETM, ETF, RAM and RAF, respectively, p<0.05). There were no other differences between valves in all groups for the submaximal or maximal portions of the GXT. **CONCLUSION:** These findings indicate that higher resistance two-way breathing valves alter the assessment of an individual's RE, V_E and EE during submaximal exercise. Although breathing valve resistance altered TTE, VO_{2peak} was unchanged. Therefore, airflow resistance of a breathing valve must be considered when comparing physiological responses to a GXT in the applied and research settings.

Correlation Between Mock-nba Combine And Laboratory Measures In Ncaa Dii Men's Basketball Players
 Bethany L. Bouvrette, Adam M. Coughlin, Jeremy L. Knous. *Saginaw Valley State University, University Center, MI.*
 Email: blbouvre@svsu.edu
 (No relationships reported)

Combine style field-testing and laboratory-testing are commonly used to assess and track changes in fitness levels in athletes. **Purpose:** The purpose of this study was to examine the relationship between combine tests and changes in aerobic markers and anthropometrics during off-season conditioning in men's Division II basketball players. **Methods:** Anthropometrics were obtained on 12 NCAA Division II men's basketball players (20.5 ± 1.0 yrs; 190.2 ± 8.5 cm; 95.3 ± 15.9 kg) during the post-season (Post) and again during pre-season (Pre). All players completed a discontinuous, incremental maximal treadmill protocol with alternating 3 min run and 90 sec rest stages. Expired respiratory gases and heart rate (EKG) were measured continuously (ParvoMedics, Provo, UT). Oxygen consumption (VO₂) and heart rate (HR) measurements were obtained at stage 3, stage 4, and volitional exhaustion. Body composition values were obtained via Bodpod (Cosmed, Rome, Italy). During the off-season an NBA-style combine fitness protocol was implemented, testing: standing vertical jump, maximum vertical jump, lane agility, three-quarter court sprint speed, 3-RM squats, and 185lbs bench press repetitions. Statistical analysis included dependent t-tests for Post versus Pre lab-based measures. Pearson correlations were run between off-season changes (Pre minus Post) and combine data. **Results:** No significant changes were found for height, weight, or body composition. Significant differences (p ≤ 0.05), via t-tests, were found for VO_{2max} (Post: 57 ml/kg/min; Pre: 53 ml/kg/min), VO₂ stage 4 (Post: 58 ml/kg/min; Pre: 54 ml/kg/min) and HR maximum (Post: 193 bpm; Pre: 182 bpm). Correlations were observed between 185lbs bench press repetitions and changes in fat mass (r = -0.845, p ≤ 0.05) and fat-free mass (r = 0.882, p ≤ 0.05). Additional significant correlations included changes in percent of HRmax at stage 3 with maximal vertical jump (r = -0.864, p ≤ 0.05) and changes in percent of HRmax at stage 4 with lane agility (r = 0.967, p ≤ 0.05). **Conclusion:** Combine fitness data correlated minimally with changes observed in aerobic kinetics and anthropometrics between post and pre-season testing. Thus, various fitness assessment measures must be used when assessing fitness levels in basketball players due to the diverse physical demands of the sport.

Biomechanical Comparison Of Countermovement Jumps On Land And In Water: Age Effects
 Dennis Dolny, Talin Louder, Eadric Bressel. *Utah State University, Logan, UT.*
 Email: dennis.dolny@usu.edu
 (No relationships reported)

The use of a reduced impact, aquatic environment for physical activity and rehabilitation in older adults has become a focus of recent literature. **PURPOSE** The present study sought to evaluate the mechanical specificity of countermovement jumps performed on land and in water in older adults. **METHODS** Fifty-six young (22.0 ± 3.9 years) adults and twelve healthy older (57.3 ± 4.4 yr) adults were asked to perform maximal countermovement jumps on land and in chest-deep water. Kinetic and kinematic measures of jump performance were obtained using a tri-axial force platform and two dimensional videography, respectively. **RESULTS** As expected, peak (PP) and mean mechanical power (MP) outputs were greater ($p < .001$) for jumps performed by young vs older adults (PP: 7322 ± 4035 W; MP: 3049 ± 1771 W) and for jumps performed by all subjects in water (PP: 9387 ± 3981 W; MP: 3781 ± 1864 W) vs land. Compared to young adults, older adults experienced less of an increase in bodyweight normalized PP and MP for jumps performed in water vs land ($p < 0.05$). Peak movement velocities in older adults tended to be slower, with older adults spending 55% greater time in body unweighting. Compared to land, unweighting time increased more in the water for older adults (Land: 0.5 ± 0.3 s; Water: 1.2 ± 0.7 s) than young adults (Land: 0.4 ± 0.1 s; Water: 0.7 ± 0.2 s). Across ages, amortization rate was 26% greater for jumps performed in water and, in comparison with younger adults, amortization time in older adults was 20% longer in duration. A 1444% increase in peak dorsiflexion velocity for jumps performed in water ($66 \pm 34^\circ/s$ vs. $4 \pm 7^\circ/s$), suggests that loading strategy during amortization is likely unique from land-based jumping. **CONCLUSION** The aquatic environment produces jumping movements that are mechanically distinct from jumping movements performed on land. The results of the present study suggest that jumping in an aquatic environment may be beneficial in older adults training to improve mechanical power output and lower-extremity neuromuscular function.

Talk Test As A Marker For Maximal Lactate Steady State In Athletes
 Carl Foster, FACSM, Danielle Kolman, Sarah Ault, John P. Porcari, FACSM, Richard P. Mikat, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*
 Email: cfoster@uwlax.edu
 (No relationships reported)

The Talk Test (TT) is a simple surrogate of standard methods of exercise prescription. **Purpose:** To evaluate if the TT can identify Maximal Lactate Steady State (MLSS) in athletes. **Methods:** Well-trained triathletes ($m=7$, $f=5$) performed two incremental cycle tests to identify stages of the TT (101 words, with stages of Last Positive (LP), Equivocal (EX) and Negative (NEG) relative to speech comfort) and respiratory markers (VT, RCT, VO_{2max}). They also performed multiple constant power output (PO) rides to identify MLSS. During the steady-state rides HR, RPE, TT, and blood lactate were measured. **Results:** The PO at steady-state MLSS (201 ± 48 W) was significantly different than at incremental LP-1 (173 ± 57 W), EQ (223 ± 51 W) and NEG (250 ± 52 W). It was not significantly different than incremental LP (195 ± 52 W). During the course of the steady-state rides, HR was $\sim 75\%$ HRR, blood lactate was ~ 4.5 mmol, l^{-1} , RPE was $\sim 5-6$, and speech comfort was constant at EQ. **Conclusions:** In well-trained athletes, the LP stage of the TT yields a PO that approximates MLSS during steady-state exercise.

2643 Board #163 June 2 11:00 AM - 12:30 PM
Comparison of the Talk Test and Percent Heart Rate Reserve for Exercise Prescription
 John P. Porcari, FACSM, Carl Foster, FACSM, Katelyn Falck, Samantha Suckow, Jillian Turek, Anna Wargowsky, Maria L. Cross, Scott T. Doberstein. *University of Wisconsin - La Crosse, La Crosse, WI.*
 Email: jporcari@uwlax.edu
 (No relationships reported)

Exercise intensity is traditionally prescribed using %HRmax, %HRR, %VO_{2max} or %VO_{2R}. Recently, the Talk Test (TT) has been proposed as an alternative method to guide exercise intensity. However, it is unknown if prescribing exercise intensity solely using the TT can provoke training responses that are comparable to traditional guidelines. **PURPOSE:** To compare the training responses consequent to training using either the TT or %HRR. **METHODS:** Forty-four subjects (17 males and 27 females: age= 20.4 ± 3.02 yrs; ht= 170.5 ± 9.79 cm; wt= 71.9 ± 13.63 kg) completed an incremental maximal cycle ergometer test, were stratified by VO_{2max} and gender, and randomly assigned to training groups guided by either %HRR ($n=20$) or the TT ($n=24$). Both groups completed 40-minute training sessions 3 days per week for 10 weeks. In the HRR group, exercise intensity was targeted at 40-59 %HRR for weeks 1-4, 50-59 %HRR for weeks 5-8, and 60-79 %HRR for weeks 9-10. In the TT group, exercise intensity was targeted at the highest power output that still allowed for comfortable speech. Changes in VO_{2max}, peak power output (PPO – watts and watts/kg), ventilatory threshold (VT); and PO at VT, were compared between groups using two-way ANOVA with repeated measures. **RESULTS:** There were significant ($p < .05$) pre vs. post increases in VO_{2max} (TT= $+10.6\%$; HRR= $+11.5\%$), PPO – watts (TT= $+18.5\%$; HRR= $+14.1\%$), PPO – watts/kg (TT= $+19\%$; HRR= $+14\%$), VT (TT= $+56.9\%$; HRR= $+32.7\%$), and PO at VT (TT= $+39\%$; HRR= $+43\%$) in both groups as a result of training, with no significant differences ($p > .05$) in the magnitude of improvement between groups. **CONCLUSION:** Guiding exercise prescription using the TT is a simple and effective method for prescribing exercise intensity and elicits improvements in exercise performance that are comparable to traditional %HRR guidelines.

Repeatability Of 5-km Time Trials On A Non-motorized Treadmill
 Chandon L. Hines, Emily P. Kennedy, Hunter S. Waldman, Alex J. Heatherly, Gavin W. Hall, Eric K. O'Neal. *University of North Alabama, Florence, AL.* (Sponsor: Matt Green, FACSM)
 (No relationships reported)

Non-motorized treadmills (NMT) allow for continuous self-selection of pace during time trials (TT). Belt resistance of NMT results in reduction in time-trial performance versus treadmill or road running, but the repeatability between NMT TT is not well-documented. **PURPOSE:** This study examined variability across three, 5-km time trials on a NMT (Curve 3.0, Woodway Inc., Waukesha, WI). **METHODS:** Eleven male runners (30 ± 10 y) with no previous experience running on the NMT, were instructed to cover 5-km on the NMT as quickly as possible on 3 occasions. Time was not expressed, but runners were informed of distance at each km and when 0.3 km remained. RPE, velocity, and power were assessed/averaged for each kilometer. **RESULTS:** There was no main effect ($p = 0.48$) for trial number based on completion time, but mean finishing time was 22 s slower during the TT2 versus TT1. Intraclass correlation was high for TT1-TT2, (ICC = 0.95), but improved for TT2-TT3 (ICC = 0.99). Bland-Altman plots reveal the 95% upper and lower levels of agreement were -173 to 217 s for TT1-TT2, but drastically improved for TT2-TT3 (-116 to 63 s). Main effects were found for time but not trial on RPE, velocity, or power based on trial when data was broken down into 1-km intervals. **CONCLUSION:** Despite a lack of statistical significance between time trials, there was a trend in the data for runners to start TT2 with a more cautionary pace for the first 2-km. Multiple participants anecdotally reported posterior leg muscle fatigue that they were unaccustomed to experiencing during road or motorized treadmill running, possibly explain the pacing modification. When NMT are used for performance testing of 5-km distance, we suggest a familiarization TT be initiated before experimental treatment sessions.

The Validity Of A Ruler-Based Alternative To The Sit And Reach Test In Females
 Mark G. Cullum, Justin R. Bland, Ken R. Turley, FACSM.
Harding University, Searcy, AR. (Sponsor: Ken R. Turley, FACSM)
 Email: mcullum@harding.edu
 (No relationships reported)

Previous research on male subjects demonstrated the validity and reliability of a new ruler-based protocol as an alternative to the Modified Sit and Reach test (Cullum and Turley, 2016 MSSE Abstract). In contrast to the Sit and Reach test, which requires specialized equipment and a person to administer the test, the new protocol only requires commonly available tools and can be administered by the subject without assistance. To date, however, this protocol has not been validated for a female population.

PURPOSE: The purpose of this study is to assess the validity and reliability of the ruler-based protocol as an alternative to the Modified Sit and Reach test for a female population.

METHODS: Sixty-two females participated in the research project. Following a measurement of height and weight, subjects completed in a randomized order the modified Sit and Reach test using the standard measurement device and the new ruler-based protocol. This procedure had subjects stand with a 12-inch ruler extended from between their hands, bend over at the waist, and allow the floor to push the ruler into their hands as far as possible. The remaining length beyond their fingertips was recorded as their score. A Pearson correlation was utilized to compare the results from the two protocols. A second group of 32 subjects performed both tests in a randomized order on two separate occasions to establish the test-retest reliability of the protocols, as indicated by Intraclass Correlation.

RESULTS: The analysis comparing the two protocols resulted in an r value of -0.826 . The two trials for the test-retest analysis of the Sit and Reach protocol yielded a mean and standard deviation of 15.35 ± 3.03 inches and 15.95 ± 3.16 inches, while trials for the new protocol resulted in values of -3.76 ± 3.28 inches and -3.48 ± 3.41 inches. The test-retest analysis determined Intraclass Correlation values of 0.950 for the Sit and Reach test and 0.956 for the new protocol.

CONCLUSIONS: There was a strong correlation between the ruler-based protocol and the sit and reach test, in conjunction with very high high test-retest reliability for both protocols, suggesting that a valid measurement of an individual's hip and lower back flexibility can be obtained with the new protocol.

2646 Board #166 June 2 11:00 AM - 12:30 PM
The Effect of Cadence on Muscular Activity and Performance During the Push-Up Exercise
 Chris Pitsikoulis¹, David Cesario¹, Hae Ryong Chung². ¹*Aurora University, Aurora, IL.* ²*Clayton State University, Morrow, GA.*
 Email: cpitsikoulis@aurora.edu
 (No relationships reported)

The push-up is a classic exercise that is used to strengthen the upper body. It is popular because it is a body weight exercise which can be modified to accommodate different ability levels. The push-up is also used to assess muscular endurance during fitness testing. Though several standardized protocols have been established, there are still execution related issues that have not been fully examined to date, which may affect interpretation of testing and training outcomes. **PURPOSE:** To study the effects of cadence on performance and electromyographic (EMG) activity of the pectoralis major and triceps brachii during a push-up exercise to failure in young and healthy college males. **METHODS:** Thirteen subjects (age = 22.5 ± 3.4 years) recruited for this study. Height, weight and body composition were measured. Subjects completed one-set of push-ups to failure at the following cadence during 5 randomly assigned sessions: (1) 120 beats per minute (bpm), (2) 60 bpm, (3) 40 bpm, (4) 30 bpm, (5) self-selected pace (SSP). EMG activity of the right pectoralis major and right triceps brachii were recorded during each session. Repeated measures ANOVA were used to determine differences between sessions. **RESULTS:** Subjects completed $35.15 (+17.70)$ push-ups at the self-selected pace, $23.15 (+13.99)$ at the 30 bpm, $25.23 (+12.83)$ at 40 bpm, $28.31 (+12.89)$ at 60 bpm and $31.31 (+15.04)$ at 120 bpm. The total number of completed repetitions was significantly different between sessions. SSP, which equated to 98 bpm ($+20.75$) was greater than 30 bpm ($p=.000$), 40 bpm ($p=.001$), and 60 bpm ($p=.019$). Push-ups performed at 120 bpm was greater than 30 bpm ($.033$) and 40 bpm ($p=.015$) and push-ups performed at 60 bpm was greater than 40 bpm ($p=.002$). There were no differences in the EMG activity of the pectoralis major or triceps brachii between the 5 cadence sessions. **CONCLUSIONS:** Young and healthy college-age subjects performed more push-ups to failure at a self-selected pace compared to slower cadences without differences in EMG activity in the pectoralis major or triceps brachii. Self-selected pace appears to be optimal in terms of push-up performance compared to slower cadences and supports self-selected for testing purposes. However, additional work is necessary to investigate higher cadences, additional muscles, and energy costs at different speeds.

Estimation of the Lactate Threshold Using a New Wireless Near-Infrared Spectroscopy System
 Shara Perry¹, Lindsay Davis¹, Paul Bender¹, John Thistlethwaite¹, Craig Broeder, FACSM², Jakob D. Lauver³, Trent E. Cayot¹. ¹*Ohio Dominican University, Columbus, OH.* ²*Exercising Nutritionally, LLC, Lisle, IL.* ³*Adrian College, Adrian, MI.* (Sponsor: Craig Broeder, FACSM)
 (No relationships reported)

Lactate threshold (LT) is an important variable to consider for aerobic training programs and has traditionally been analyzed by measuring blood lactate concentration ([La]) during maximal exercise tests. Previously, near-infrared spectroscopy (NIRS) techniques have been used to non-invasively estimate the LT during maximal exercise tests by assessing the microvascular oxygenation (SmO_2) response. **PURPOSE:** To determine the validity and reliability of a new wireless NIRS system in estimating the LT during a maximal exercise test. **METHODS:** 10 subjects with minimal cycling experience (29 ± 3 yrs, 1.8 ± 0.1 m, 79.1 ± 12.6 kg, 35.8 ± 5.6 mL/kg/min) performed two exercise sessions, separated by 7 d, of a step protocol ($+25$ W / 3 min) to volitional fatigue on a Monark 839E cycle ergometer. During session 1, arterialized venous blood samples were collected during the last 15 s of each stage to assess [La]. Additionally, the SmO_2 response (NIRS1) was continuously recorded at a sampling rate of 2 Hz using a wireless NIRS sensor placed on the vastus lateralis. To assess reliability of the NIRS system, the SmO_2 response was measured again during session 2 (NIRS2) as the subjects repeated the same cycling step protocol from session 1. All SmO_2 data were averaged over the last 15 s of each stage. Thresholds based upon the [La], NIRS1, and NIRS2 responses to the increasing work rate were detected via visual inspection, by 3 experienced investigators blinded to the subjects and conditions, and computer modeling (Dmax, Modified Dmax). One-way, repeated measures ANOVA was used to test for significant differences ($p < 0.05$) between threshold detection methods ([La], NIRS1, NIRS2). **RESULTS:** Moderate-good inter-rater reliability between visual inspection raters was observed (ICC = 0.58-0.80). Visual inspection of the thresholds displayed no difference between threshold detection methods ([La] = 114 ± 12 W, NIRS1 = 114 ± 21 W, NIRS2 = 109 ± 26 W). No difference was detected between threshold detection methods when analyzed using the Dmax ([La] = 130 ± 44 W, NIRS1 = 120 ± 28 W, NIRS2 = 138 ± 32 W) or modified Dmax ([La] = 130 ± 44 W, NIRS1 = 119 ± 28 W, NIRS2 = 136 ± 32 W). **CONCLUSIONS:** The new wireless NIRS system may be able to accurately and reliably estimate the LT during maximal exercise tests performed on a cycle ergometer in a healthy, adult population.

Effectiveness of a Student-Led Worksite Wellness Project Addressing Health-Related Physical Fitness
 Jeffrey M. Hartman. *Gardner-Webb University, Boiling Springs, NC.*
 Email: jhartman@gardner-webb.edu
 (No relationships reported)

Individuals who are not regularly physically active are at a greater risk for developing chronic diseases, with at least 1.9 million annual deaths attributed to physical inactivity, making it the fourth leading cause of global mortality.

PURPOSE: To measure the impact of a 14-week student-led wellness project aimed at increasing physical activity while also addressing four components of health-related physical fitness: cardio-respiratory fitness, musculoskeletal fitness, body composition, and flexibility. **METHODS:** 46 apparently healthy adults volunteered to participate in this study. Week 1 and 14 were devoted to pre- and post-fitness assessment data collection utilizing The President's Challenge Adult Fitness Test. Weeks 2-13 were dedicated to addressing the participants' goals, as well as any strengths/weakness identified in the first fitness assessment. Data were compared using paired t-tests.

RESULTS: There were statistically significant ($p < .05$) improvements in the following variables from pre- to post-assessment: resting heart rate (73.6 vs. 68.3 bpm), weight (88.7 vs. 86.6 kg), waist circumference (91.1 vs. 86.8 cm), BMI (30.1 vs. 29.3 kg/m²), VO_{2max} (29.7 vs. 34.7 mL/kg/min), musculoskeletal fitness (push-ups: 17.1 vs. 27.6; sit-ups: 28.3 vs. 42.7), flexibility (37.1 vs. 41.5 cm), and overall fitness score (38.5 vs. 58.4%). **CONCLUSIONS:** Exercise Science students were effective at improving overall physical fitness and decreasing overall mortality risk in an apparently healthy adult population. Colleges and Universities with Exercise Science programs should aim to decrease physical inactivity on campus by implementing student-led worksite wellness initiatives.

Validation Of A 10-point OMNI Rating Of Perceived Exertion Colored Scale
 Nien Xiang Tou, Govindasamy Balasekaran, FACSM, Dianna Thor, Ivyna Tan, Jolene Lim. *Nanyang Technological University, Singapore, Singapore.*
 Email: nienxiang.tou@nie.edu.sg
 (No relationships reported)

Using visual cues such as colors along with the standardized numerical and verbal descriptors in OMNI scales may be more appealing to an exercise cohort to measure perceived exertion accurately. **Purpose:** To examine the concurrent and construct validity of a newly developed 10-point OMNI Ratings of Perceived Exertion (RPE) Colored Scale (OMNI-Color) in young adult women and men. **Methods:** 40 subjects (age (yrs): 22.75 ± 1.79 ; weight (kg): 60.05 ± 10.67 ; height (cm): 167.12 ± 5.87) participated in a cross-sectional, perceptual estimation paradigm to assess exertional perception via two exercise protocols: a load-incremented cycle ergometer protocol ($n = 20$) and a progressive graded treadmill protocol ($n = 20$). Equal number of participants of each gender were recruited for each study and all participants undertook the respective protocols on two separate trials, one week apart. Oxygen uptake (VO_2 ; $\text{ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$), heart rate (HR; $\text{beats} \cdot \text{min}^{-1}$) and RPE were recorded at each exercise stage. RPE was estimated with the OMNI-Color and either the OMNI Adult Walk/Run Scale (OMNI-WS) or the Adult OMNI Scale of Perceived Exertion for Cycle Ergometer Exercise (OMNI-Cycle) in a counterbalanced and randomized manner for respective studies. Correlations between the scales were used to examine the construct validity. Concurrent validity was evaluated with correlations between the RPE values of OMNI-Color, and both VO_2 and HR. **Results:** Linear regression analyses showed that the RPE derived from the OMNI-Color distributed as a positive linear function for both VO_2 and HR ($r = .97$ to $.99$; $p < .05$) for total cohort. In the cycle ergometer protocol, RPE derived from the OMNI-Color distributed as a linear function of the OMNI-Cycle ($r = 0.996$ to 0.998 ; $p < .01$) for both genders. In the progressive graded treadmill protocol, RPE derived from the OMNI-Color distributed as a linear function of the OMNI-WS ($r = .998$ to $.999$; $p < .05$) for both genders. Independent sample t test found no significant differences between OMNI-Color and OMNI-Cycle or OMNI-WS. **Conclusion:** Both concurrent and construct validity were established for the OMNI-Color. OMNI-Color may be used as an alternative scale to measure RPE during exercise, regardless of modality. Future research can further explore the scale's validity and applicability to other populations.

Validation Of Heart Rate Sensor And Phone App In Lab Versus Home-based Environment
 Galen Morton¹, Carmine Greico², Ann Gibson, FACSM¹.
¹University of New Mexico, Albuquerque, NM. ²Colorado Mesa University, Grand Junction, CO. (Sponsor: Dr. Ann L. Gibson, FACSM)
 Email: gmorton@unm.edu
 (No relationships reported)

Purpose: Heart rate variability (HRV)—beat-to-beat changes in the time interval between consecutive cardiac cycles—is a manifestation of the autonomic nervous system. The existing literature reflects validation studies of HRV using portable devices as compared to data generated by an electrocardiogram. In view of this agreement the present investigation, using a portable system, sought to establish if HRV measurements taken in the laboratory and home environments were equivalent. **Methods:** Twenty men (Age 24.4 ± 3.9 year; Height 179.3 ± 8.0 cm; Weight 86.9 ± 19.4 Kg) volunteered to obtain six HRV readings on separate days, three in a controlled laboratory (L) environment and three days at home (H). A coin toss determined the environment in which three HRV recordings would occur first. A commercially available heart rate (HR) sensor coupled to a cell phone app was used to record all data; the results were analyzed by a downloaded HRV software package. Subjects were familiarized with the HR sensor and phone app prior to data collection. All data were recorded in the morning with subjects resting in the supine position and breathing normally. No device was used for pacing purposes. The phone app recorded 60 sec of coronary electrical signals for analysis. **Results:** Nonsignificant environmental differences in grand mean HR ($H=62.9$, $L=61.2$), mean RR ($H=1008.8$, $L=1024.8$), RMSSD ($H=86.06$, $L=79.41$), pNN50 ($H=39.72$, $L=42.72$), and LF/HF ($H=2.151$, $L=2.386$) were found. A subject-to-subject r^2 coefficient of determination analysis contrasting environments yielded a variance for HR (.61), mean RR (.70), RMSSD (.85), pNN50 (.54), and LF/HF (.07). **Conclusion:** For our sample, a commercial heart rate sensor and phone app provided a valid system for recording morning HRV at rest in a home-based setting; these findings consequently open the door for future field research using this monitor and phone app system.

2651 Board #171 June 2 11:00 AM - 12:30 PM
Ventilatory Thresholds Differ Between Bruce And Self-paced Vo2Max Tests
 Cory M. Scheadler¹, Gabriel Sanders¹, Heather Mello¹, Anthony Couch¹, Nicholas Hanson². ¹Northern Kentucky University, Highland Heights, KY. ²Western Michigan University, Kalamazoo, MI.
 Email: scheadlerc1@nku.edu
 (No relationships reported)

Self-paced $\text{VO}_{2\text{max}}$ tests (SPV) are a fairly recent development in cardiorespiratory testing. SPV's have been considered valid for measuring $\text{VO}_{2\text{max}}$, however, other measurements such as ventilatory threshold (VT) are also important when completing such cardiorespiratory testing and have not been adequately studied. It has been suggested that VT cannot be measured during SPV. **PURPOSE:** The purpose of this study was to determine whether the first VT (VT1) and second VT (VT2) could be identified during an SPV and how it compared to VT1 and VT2 determined during a Bruce protocol. It was hypothesized that VT1 and VT2 could be determined during SPV and would not be different than the VT1 and VT2 identified during the Bruce protocol. **METHODS:** 10 healthy, recreationally active subjects (9 male, 1 female, 25.4 ± 9.0 years) completed SPV and Bruce protocols on the same treadmill in random order. Gas sampling was processed as 15 breath moving averages. VT1 and VT2 were determined by identifying breaks in the VE , VE/VO_2 , $\text{P}_{\text{ET}}\text{O}_2$, VE/VCO_2 and $\text{P}_{\text{ET}}\text{CO}_2$ versus time slopes as well as the VE versus VCO_2 slope. The researcher analyzing VT was not involved in testing and was blind to the protocol. VT1 and VT2 was expressed as a percentage of the maximal VO_2 ($\% \text{VO}_{2\text{max}}$) attained during the respective protocol. Paired t -tests were used to identify differences between protocols for $\text{VO}_{2\text{max}}$, VT1 and VT2. **RESULTS:** $\text{VO}_{2\text{max}}$ was not different between Bruce and SPV protocols (55.5 ± 5.5 vs 56.6 ± 4.5 $\text{ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$, respectively, $p = 0.15$). Five tests (4 during SPV) produced atypical slopes and VT2 identification was difficult. VT1 occurred at a higher $\% \text{VO}_{2\text{max}}$ in SPV (41.1 ± 8.1 SPV vs 32.2 ± 7.4 Bruce, $p = 0.005$) as did VT2 (86.4 ± 7.5 SPV vs 67.8 ± 8.9 Bruce, $p < 0.001$). **CONCLUSIONS:** SPV allowed subjects to alter their pace and their ventilatory responses making it more difficult to identify VT. Higher VT in SPV is in contrast to recent research. The magnitude of difference in VT may be due to both the difficulty in identifying VT in SPV and also the potential for SPV to allow subjects to alter their metabolic requirements and postpone anaerobiosis. Measurement of blood lactate throughout testing is needed to aid in the validation of VT in SPV.

Relationship Between Physiological Lab Tests and On-Ice Measures Among NCAA DIII Collegiate Hockey Players
 Devon J. Erps¹, Adam Coughlin², Andrea Workman¹, Joe Williams¹, Stephen McGregor¹. ¹Eastern Michigan University, Ypsilanti, MI. ²Saginaw Valley State University, University Center, MI. (Sponsor: Mark Peterson, FACSM)
 Email: derps@emich.edu
 (No relationships reported)

Previous scientific studies have examined the connection between physical fitness tests and NHL draft success (Burr, 2008). Others examined correlation of physiological lab test results and measures such as plus/minus score and skating speed in collegiate hockey players (Peyer, 2011). **PURPOSE:** To determine if laboratory physiological test results correlate to on ice measures obtained from a wearable sensor including accelerations, heart rate and breathing rate. **METHODS:** Seven NCAA division III hockey players consented to procedures approved by Adrian College Human Subjects Committee. Lab tests including the Wingate, treadmill running $\text{VO}_{2\text{max}}$ and lactate threshold were performed four times periodically throughout the five-month hockey season. The Wingate was used to determine mean power (MP), peak power (PP), and anaerobic fatigue (AF) values. Treadmill $\text{VO}_{2\text{max}}$ tests were performed using procedures previously validated (Peyer, 2011), which provided $\text{VO}_{2\text{max}}$ and time on treadmill variables. Aside from $\text{VO}_{2\text{max}}$ and lactate threshold, V2 Lac (Lactate levels at end of $\text{VO}_{2\text{max}}$ test) and V2 Lac P1 (levels one minute after test) were also determined. On-ice measures were obtained from wearable sensors (Zephyr, MD), which consisted of a triaxial accelerometer, as well as HR and breathing rate (BR) monitor. Accelerations were used to calculate Mechanical Intensity (MI), which reflected instantaneous accelerations and Load (ML), which reflected cumulative accelerations over time. HR and BR were used to calculate instantaneous physiological intensity (PI) and physiological load (PL) an accumulation of these physiological values over the session. Statistical analyses were performed using SPSS 21.0 (IBM, NY) **RESULTS:** The strongest correlations were observed between Wingate variables AF and MI (.60, $p < .001$), PP and ML (.54, $p < .001$), AF and ML (.58, $p < .001$). Strong inverse correlations were observed between ML and both V2 Lac (-0.512 , $p = .001$) and V2 Lac P1 (-0.544 , $p < .001$). **CONCLUSION:** There are positive correlations between laboratory measures of anaerobic fitness and on-ice accelerations. Further,

lower lactate accumulation following a VO₂max test is associated with the ability to generate higher cumulative accelerations during on-ice sessions among NCAA DIII hockey players.

Comparison Of Pre- And Post-season Laboratory And On-ice Measures Among NCAA Division III Hockey Players

Dakota Burke¹, Stephen McGregor¹, Andrea Workman¹, Joe Williams¹, Adam Coughlin², Martin Urbaniak¹. ¹Eastern Michigan University, Ypsilanti, MI. ²Saginaw Valley State University, Grand Rapids, MI. (Sponsor: Mark Peterson, FACSM)

(No relationships reported)

PURPOSE: The purpose of this study was to compare on-ice physiological measures to pre- and post- season off-ice physiological laboratory tests to determine i) the relationship between off-ice tests and on-ice performance and ii) changes over the course of a season among collegiate ice-hockey players. **METHODS:** Seven NCAA D III male ice hockey players (age 22 ± 0.5, weight 87.89kg ± 6.1kg, height 185.4cm ± 3.4 cm) participated in procedures approved by the Adrian College Human Subjects Committee. Laboratory tests including the Wingate anaerobic test, treadmill VO₂max test, and lactate threshold tests, were performed at the beginning and end of the 5 month hockey season. Peak power output (PP), mean power output (MP), and anaerobic fatigue (AF) were assessed by the Wingate test. A VO₂max test, previously validated among ice hockey players, was used to obtain VO₂max values and time on treadmill. Lactate levels were also measured at the end of the VO₂max test (V2 Lac) and one minute after the completion of the test (V2 Lac P1). Subjects wore a Zephyr bioharness (Zephyr, MD) to measure on-ice physiological exertions during all practices and games. The sensor measured triaxial accelerations, breathing rate, and heart rate. Statistics were performed using SPSS 21.0 (IBM, NY). Season-long measures were divided into quartiles to correspond to laboratory testing. Data from the sensors from the first and last quartiles was compared to pre- and post-season lab tests. **RESULTS:** There were no significant differences from pre- to post-season among any laboratory tests. In contrast, there were significant decreases in average on-ice accelerations at 10, 20, 30 and 60 seconds (p < .05). There were non-significant changes in average accelerations over 20 minutes, while average accelerations over 45 minutes significantly increased (p < .05). **CONCLUSION:** The increase in average accelerations over 45 minutes from pre- to post- season suggest an increase in on-ice aerobic fitness. The decrease in average accelerations during anaerobic measures at 10 to 60 seconds suggest decreased anaerobic capacity of the subjects that were not identified by Wingate tests. Wearable sensors may provide additional information to laboratory testing for the assessment of physiological changes across a season among collegiate hockey players.

Determination of Trials Needed for Measurement Consistency of Standing Long Jump in Collegiate Volleyball Players

Robert Ah Sue¹, Chad Harris, FACSM², Kent J. Adams, FACSM³, Joseph Berning, FACSM⁴, Mark DeBeliso, FACSM¹. ¹Southern Utah University, Cedar City, UT. ²Metropolitan State University of Denver, Denver, CO. ³California State University Monterey Bay, Seaside, CA. ⁴New Mexico State University, Las Cruces, NM.

(No relationships reported)

Lower body power is an important physical attribute of competitive volleyball athletes. In order to best evaluate such an attribute, it is important that the test reliability is established using a sport specific athlete group and used in a realistic application to the particular sport. Furthermore, identification of the appropriate number of trials to use during assessment, insures accuracy of scores and time efficiency for coaches. **PURPOSE:** This aim of this investigation was to establish the minimum number of trials needed for reliability of the standing long jump (SLJ) in female collegiate volleyball players. **METHODS:** Nine female athletes (age: 18.3 ± 0.5 yrs, height: 179.2 ± 5.3 cm, mass: 68.8 ± 7.9 kg) completed five trials of a SLJ. Jumps were performed at 2, 6, 10, 14 and 18 minutes following a dynamic warm-up. In an attempt to simulate the active nature of sport, the athletes alternated between walking and jogging the length of a basketball court between successive trials. For the SLJ, subjects performed a standard countermovement SLJ and distance in centimeters was measured from the starting line to the rear-most heel upon landing. Pearson (PCC) and Intraclass (ICC) Correlation Coefficients were calculated between successive trials. **RESULTS:** Means for the for the successive trials were as follows: Trial 1: 191.4 ± 10.1 cm; Trial 2: 196.1 ± 10.2 cm; Trial 3: 200.0 ± 10.3; Trial 4: 200.0 ± 11.8 cm; Trial 5: 200.7 ± 9.6 cm. Mean difference between successive trials (i.e. Trials 2 to 1, 3 to 2, 4 to 3 and 5 to 4) were; 4.8 ± 6.9, 3.8 ± 5.5, -0.40 ± 5.6 and 1.1 ± 5.4. PCC and ICC for successive trials were: 0.77 and 0.82; 0.86 and 0.89; 0.88 and 0.91; 0.89 and 0.91. **CONCLUSIONS:**

Given the parameters of this study, adequate assessment of SLJ performance is best achieved using three trials. Enhanced consistency was not realized with application of additional trials. Therefore, when testing female collegiate volleyball athletes for lower body power using the SLJ, three trials are sufficient.

2655 Board #175 June 2 11:00 AM - 12:30 PM
Comparison Of Cardiorespiratory Responses During Body Weight-supported Treadmill And Standard Treadmill Exercise

Kyle D. Biggerstaff, Kaitlyn Abruzzese, Desiree Patterson, Christopher Irvine, Matthew F. Brisebois. Texas Woman's University, Denton, TX.

(No relationships reported)

Treadmills that partially support body weight are used in some rehabilitation settings. Cardiorespiratory responses to this type of exercise have been reported in very few published studies.

PURPOSE: To determine the cardiorespiratory response to graded exercise on a standard treadmill (ST) and body weight-supported treadmill (BWST). **METHODS:** In random order, 20-36 yr old adults (n = 6 males, 4 females) performed BWST and ST trials. Identical exercise sessions were performed on each treadmill except 25% of body weight was supported by the BWST. On each treadmill a two-minute warm up was performed at 2 mph and 0% grade, followed by 6 minutes of exercise at 3% grade at each of the following treadmill velocities: 3, 4.5, and 6 mph. Expired respiratory gases were analyzed each minute. Steady state heart rate, VO₂, VCO₂, and RER were calculated as the average value during the final three minutes of each 6 min exercise stage. Blood pressure and RPE were recorded during the final minute of each stage. A 2x3 repeated measures ANOVA was used to determine significant differences at the p < .05 level, and the LSD method for post hoc analyses. **RESULTS:** There was a significant difference (p < .05) in absolute VO₂ between ST and BWST at 4.5 mph (2.14 ± .39 v 1.42 ± .27 l·min⁻¹) and 6 mph (2.75 ± .58 v 1.79 ± .40 l·min⁻¹). Relative VO₂ was significantly different (p < .05) at each exercise intensity between treadmills (ST v BWST: 16.0 ± 1.1 v 13.6 ± 1.2; 31.2 ± 2.0 v 20.6 ± 2.4; 39.8 ± 1.9 v 25.8 ± 2.9 ml·kg⁻¹·min⁻¹). There was a significant difference (p < .05) in VCO₂ between the ST and BWST at 4.5 mph (2.10 ± .43 v 1.32 ± .26 l·min⁻¹) and 6 mph (2.88 ± .63 v 1.68 ± .39 l·min⁻¹). There was a significant difference (p < .05) in RER between the ST (1.05 ± .08) and BWST (.94 ± .06) at 6 mph. The HR was significantly different (p < .05) between ST and BWST at 4.5 mph (162 ± 17 v 128 ± 17 bpm) and 6 mph (182 ± 13 v 146 ± 17 bpm). There was a significant increase (p < .05) in SBP on the ST (144 ± 20 v 163 ± 25 v 175 ± 22 mmHg) and BWST (128 ± 11 v 143 ± 13 v 155 ± 16 mmHg) at each exercise intensity. There were no significant differences in DBP at any point during exercise. There was a significant difference (p < .05) in RPE on the ST at 6 mph (15 ± 1), 4.5 mph (12 ± 1), and 3 mph (9 ± 1). **CONCLUSION:** There appears to be a lower cardiorespiratory response during body weight-supported exercise and traditional treadmill exercise.

Agreement Between Electromyographic Fatigue And Ventilatory Thresholds During Taekwondo Specific Test

Marcus Paulo Araujo, Pedro Paulo Soares, Matheus Hausen, Débora Esteves, Hilbert Julio, Roberto Tauli, Jonas Gurgel. Fluminense Federal University, Niterói, Brazil.

(No relationships reported)

PURPOSE: The aim of the present study is to compare electromyographic fatigue and ventilatory thresholds during taekwondo specific test.

METHODS: 10 male taekwondo athletes (20 ± 2 yrs, body mass 67.5 ± 6.3 kg, height 176 ± 9 cm) participated in the study. The University ethics committee approved this study (opinion #765.698). At first visit, anthropometric assessment and TKDet were performed. TKDet were constituted by 1-min progressive stages of kicking sequences, and kicking interval started from 4,6s and reduced 0,4s every minute until participant's fatigue. Expired gases were measured continuously with portable analyzer VO2000 (MedGraphics, Saint Louis, USA). Ventilatory thresholds were determined with the ventilatory equivalents method. EMG acquisition was performed with the wireless EMG system connected to a pair of surface electrodes placed in the rectus femoris, according to SENIAM recommendations. EMG signal was recorded continuously during the tests with a frequency of 2000 Hz. EMG was filtered by third order Butterworth band-pass filter. RMS values were calculated during every non-superimposing windows with 1s duration. EMG thresholds were detected by piecewise regression (two inflections - three segments line). Parametric data were described by mean and standard deviation, 95% confidence interval of mean and compared with Paired T-test (effect size Cohen's d). Non-parametric data were described by median and interquartile range, 95% confidence interval of median and compared with Wilcoxon test (effect size z/√n). The coefficient of variation and standard error of measure were reported to describe data variability, and intraclass correlation coefficient was calculated to determine the agreement. P < 0.05 was adopted for all tests.

RESULTS: Detailed results were present in table 1.

CONCLUSIONS: Although the $\dot{V}O_2$ values are similar, these methods may not be interchangeable to determine training zones. Supported by CAPES, CNPq, and FAPERJ.

Table 1 – Comparison of cardiopulmonary exercise tests' electromyographic fatigue and ventilatory thresholds (n=10)

		Mean (SD) or Median (IR)	95% CI	CV (%)	SEM	β (ES)	ICC (ICC's 95% CI)
1st Thresholds	Stage ^{NP}	Vt1	3 (3)	1 – 4	38.8	0.3	0.001* (-0.88)
		EMGt1	1 (1)	3 – 4	22.2	0.3	
	VO ₂ (mL.kg ⁻¹ .min ⁻¹)	Vt1	38.7 (1.4)	37.7 – 39.7	3.7	8.5	0.53 (0.21)
		EMGt1	37.9 (3.6)	35.3 – 40.5	9.6	15.7	
	VO ₂ (%)	Vt1	74.8 (5.8)	70 – 79	7.8	10.4	0.55 (0.23)
		EMGt1	72.7 (8.6)	67 – 79	11.9	11.4	
2nd Thresholds	Stage	Vt2	8 (1)	8 – 8	9.6	38.9	0.10 (0.57)
		EMGt2	7 (1)	7 – 8	13.7	22.2	
	VO ₂ (mL.kg ⁻¹ .min ⁻¹)	Vt2	47.1 (4.8)	43.8 – 50.6	10.4	3.7	0.02* (0.84)
		EMGt2	44.1 (5.0)	40.5 – 47.7	11.4	9.6	
	O ₂ (%)	Vt2	90.1 (3.6)	88 – 93	4.0	7.8	0.03* (0.86)
		EMGt2	84.3 (7.3)	79 – 89	8.6	11.9	

Absence of ^{NP} denotes parametric data, presented as mean (standard deviation) and 95% confidence interval of mean (inferior limit – superior limit). CI – Confidence Interval. CV – Coefficient of Variation. SEM – Standard Error of Measure. ES – Effect Size. ICC – Intraclass Correlation Coefficient. ^{NP} Denotes non-parametric data, presented as median (interquartile range) and 95% confidence interval of median (inferior limit – superior limit). Parametric data compared through Paired T-test (Cohen's d effect size). Non-parametric data compared through Wilcoxon signed rank test (z/vn effect size). EMGt – Electromyographic threshold. VO₂ – Oxygen uptake. Percentage variables (%) were calculated with the peak value observed at each test. * Denotes significant T-test's p or Intraclass Correlation Coefficient.

Reliability and Smallest Worthwhile Difference in Reactive Strength Index Modified in Male and Female Athletes

J. Bryan Mann¹, Scott Bird¹, Mike Larson¹, Rusty Burney¹, Jerry L. Mayhew², William F. Brechue, FACSM³. ¹University of Missouri, Columbia, MO. ²Truman State University, Kirksville, MO. ³A. T. Still University, Kirksville, MO.
Email: mannjb@health.missouri.edu
(No relationships reported)

Reactive strength index modified (RSImod) has gained awareness as a means of assessing and monitoring explosive movement performance among athletes. RSImod utilizes time-to-take-off (TtT) and vertical jump height (VJ) to assess the explosive power of an athlete. Despite its wide spread use, the degree of improvement in RSImod necessary to mark a real improvement versus random variation has not been well established. **PURPOSE:** To determine reliability and smallest worthwhile difference (SWD) in RSImod in college athletes. **METHODS:** Seventy-three NCAA Division-I male (n = 59) and female (n = 16) athletes volunteered to participate. Two countermovement VJ trials were recorded from dual force plates with data processed using METLAB. To control arm movement, hands grasp a PVC tube placed across shoulders behind the neck. VJ height was calculated from flight time. TtT was estimated as the duration from the start of the jump (first negative deflection greater than 10N of the force record associated with the countermovement) to take-off from the force plate. RSImod was calculated as the VJ height divided by TtT. Peak force (PF/kg) and peak power (P/kg) relative to body mass was determined from force recordings. Rate of force development (RFD) was determined from peak force per unit time during the vertical movement and the peak (PRFD) was recorded. **RESULTS:** TtT, PF/kg, P/kg, and PRFD were not significantly different between trials. Interclass correlation coefficients ranged from 0.83 for PRFD to 0.92 for PF/kg. Men had significantly higher RSImod (0.41 ± 0.08) and PP/kg (55.3 ± 14.4 N/kg) than women (0.34 ± 0.08 and 46.2 ± 6.7 N/kg), but TtT was significantly shorter in women (0.79 ± 0.13 s) than men (0.96 ± 0.10). RFD/kg was not significantly different between men (137.0 ± 80.8 N/kg) and women (99.9 ± 39.7 N/kg). CV% ranged from 3.4% for PF/kg to 18.3% for RFD/kg with RSImod being 7.9%. SDW% ranged from 10.8% for PF/kg to 59.5% for PRFD, with RSImod being 22.4%. CV% and SWD% for RSImod were 7.7% and 21.9%. **CONCLUSIONS:** Given the variation and relatively high SWD% and the between trial difference in RSImod, the novelty of the test protocol may warrant familiarization sessions prior to actual measurement to insure more consistent values among trials despite ICC values that appear acceptable.

(No relationships reported)

Assessment of barbell velocity during resistance training is an effective tool to gauge progress in strength and power and to manage intra-session fatigue. The criterion measurements of velocity are 3D motion capture or force plate systems; however, the cost of these implements is extraordinary and impractical. Therefore, linear position transducers (LPTs) are commonly used for velocity calculation. Specifically, the TENDO Weightlifting Analyzer System (TWAS), which costs >\$1,000 is widely used. However, the Open Barbell System (OBS) LPT was recently developed for a cost of <\$300. **PURPOSE:** To investigate if average concentric velocity calculations during the barbell back squat via the TWAS and OBS were valid compared to the Optotrak Certus 3D (OC3D) motion capture system. **METHODS:** Twenty-Five males (Age: 25±3yrs, Body Mass: 89.0±14.7kg, Body Fat Percentage: 12.9±4.5%) performed a one-repetition maximum (1RM) back squat followed by one set of maximum repetitions at 70% of the established 1RM. Average velocity (AV) was calculated on every 1RM attempt and every repetition at 70% of 1RM with the OC3D, TWAS, and OBS. For OC3D, AV was calculated from the observed y-coordinates (i.e. vertical position) via post-process coding in the MATLAB program. Both LPTs were attached to the right side of the barbell via a Velcro strap, and AV was displayed immediately upon completion of the lift for the LPTs. Independent samples t-tests between each LPT and OC3D were used to compare AV differences between devices. To assess agreement between LPTs and OC3D, intraclass correlation coefficients (ICCs) and 95% confidence intervals (CI) were calculated. Significance was set at p<0.05. **RESULTS:** The number of usable samples from all 1RM squat attempts and repetitions at 70% of 1RM were as follows: OC3D-522, TWAS-573, and OBS-558. There was no difference for AV between OC3D vs. TWAS (p=0.54) or OC3D vs. OBS (p=0.48). Regarding ICCs the OBS had an ICC of 0.936 in comparison to OC3D with a 95% CI of 0.914-0.952; while TWAS had an ICC of 0.870 compared to OC3D with a 95% CI of 0.830-0.899. **CONCLUSION:** Our results indicate that ICC values and CIs associated with the OBS show better validity in comparison to the criterion OC3D for AV than does TWAS. Therefore, the OBS is an effective low-cost option to assess AV during resistance training.

The portable metabolic analyzer (MA) has been commonly utilized in assessing sport- or physical activity related energy expenditure. However, little is known about the validity of the portable MA. **PURPOSE:** To determine the accuracy of oxygen consumption (VO₂) and carbon dioxide (VCO₂) production measured by the portable MA, Oxycon Mobile 5.0 (OM) using the Parvo Medic TrueOne 2400 metabolic cart (MC) as a criterion measure. **METHODS:** A total of 19 participants (age: 19-45 yrs) completed the same exercise protocols during the two separate visits. The metabolic analyzers (i.e., OM and MC) were randomly assigned for the visit. The exercise protocol included 15 mins for resting (laying down), 5 mins for sitting, standing, 3 mph, 4 mph, 5 mph, 6 mph running, and 2.5 mph cool down with a minute break between each activity. Measures of VO₂ and VCO₂ from OM were statistically compared to the values from the MC. Pearson correlation was calculated to identify the measurement relationship between the OM and the MC. Mean absolute percentage error (MAPE) was calculated to examine the measurement error of OM. Cohen's D was calculated to investigate the effect size of the measurement difference. **RESULTS:** The strong overall agreements of VO₂ and VCO₂ between the OM [r=0.94 (p<0.01)] and MC [r=0.96 (P<0.01)] were observed. For each stage of the exercise protocol, Pearson r of VO₂ and VCO₂ measurement between the OM and MC were 0.33 and 0.34 for resting, 0.26 and 0.31 for sitting, 0.28 and 0.33 for standing, 0.57 and 0.30 for 3mph, 0.68 and 0.53 for 4mph, 0.74 and 0.63 for 5mph, 0.78 and 0.76 for 6mph, 0.70 and 0.47 for 2.5mph cool down. Calculated MAPEs of VO₂ and VCO₂ for each stage are as follow: 19.22%, 13.06% for resting, 14.49%, 7.53% for sitting, 6.32%, 0.19% for standing, 10.78%, 8.70% for 3mph running, 7.49%, 5.23% for 4mph running, 4.23%, 1.22% for 5mph running, 3.87%, 0.47% for 6mph running, 3.34%, 4.34% for 2.5mph cool down. Effect size for VO₂ and VCO₂ were 0.78 and 0.43 for resting, 0.54 and 0.23 for sitting, 0.27 and 0.01 for standing, 0.44 and 0.33 for 3mph, 0.34 and 0.22

for 4mph, 0.19 and 0.04 for 5mph, 0.19 and 0.02 for 6mph, 0.11 and 0.11 for 2.5mph cool down. **CONCLUSIONS:** VO₂ and VCO₂ measured in walking and running (running 3, 4, 5, 6mph) were more valid than the light physical activities (i.e., laying down, sitting, and standing).

 (No relationships reported)

The power push-up (PPU) is an explosive upper-body test performed on a force plate and has recently replaced the bench press test in high school football combines such as the U.S. Army National Combine and Under Armour All-American Combine. **PURPOSES:** Compare the PPU test performed from the knees versus the toes across 3 age groups (6-9, 10-11, and 12-15 yr) of young male athletes and report the test-retest reliability. **METHODS:** Sixty-eight boys (mean±standard deviation (SD); height=154±14 cm; mass=47±16 kg) were tested twice over 5 days. The PPU was performed on a force plate from the knees and from the toes. Measurements included peak force (PF, N), peak rate of force development (pRFD, N·s⁻¹), average power (AP, W), and peak power (PP, W). Two-way ANOVAs (position x age) were performed, while intraclass correlation coefficients (ICC_{2,1}), standard errors of measurement (SEM), coefficients of variation (CV), and minimum detectable changes (MDC) were calculated. **RESULTS:** PF, pRFD, and PP were greater (p ≤ 0.05) from the knees for the 10-11 and 12-15 yr groups, whereas AP was greater (p ≤ 0.05) from the knees for all age groups. PF and pRFD were greater (p ≤ 0.05) in 12-15 yr than 6-9 and 10-11 yr from the knees and the toes. Table 1 shows the mean values and test-retest reliability metrics. **CONCLUSIONS:** PF, pRFD, AP, and PP were greater from the knees than the toes, and the oldest age group (12-15 yr) demonstrated the highest PF and pRFD values. However, the only consistently reliable measure was PF when the PPU test was performed from the knees in 10 to 15-year-olds; pRFD was also reliable from the knees in 12-15-year-olds. None of the measures from the youngest age group were reliable, and neither of the power measures (AP or PP) were reliable across all ages.

Table 1. Mean values (± 95% confidence intervals, CI), intraclass correlation coefficients (ICC_{2,1}), standard errors of measurement (SEM), coefficients of variation (CV), and minimum detectable changes (MDC) for each age group

Tracking Of Blood Lactate Response Across Eight Sessions Of Muscular Endurance Resistance Training
 John W. Farrell III, David J. Lantis, Gregory S. Cantrell, Debra A. Bembem, FACSM, Rebecca D. Larson. University of Oklahoma, Norman, OK. (Sponsor: Dr. Debra A. Bembem, FACSM)
 Email: John.W.Farrell-1@ou.edu
 (No relationships reported)

Muscular endurance resistance training (MERT) has been shown to improve the onset of blood lactate accumulation (OBLA). It has been speculated that improvements in OBLA following MERT is related to metabolic adaptations associated with continued exposure to increased blood lactate concentrations. **PURPOSE:** The purpose of this study was to investigate metabolic responses during each training session of a 4 week MERT program in aerobically trained males. **METHODS:** 17 males, ages 18-45, participated in this study. Subjects were randomly assigned to either an experimental (EX) or control (CON) group, 9 EX and 8 CON. Baseline measures included VO_{2max} and OBLA using a cycle ergometer, and 1 repetition maximum (1RM) for: leg press (LP), leg curl (LC), and leg extension (LE). The EX group performed MERT (4 sets of 12-15 repetitions at 50% of 1RM for LP, LC, and LE) for 4 weeks with 2 sessions per week. Resistance was increased after 4 sessions to accommodate any potential strength gains. Pre and post blood lactate concentrations were measured for each MERT session. Both groups were instructed to maintain current aerobic training throughout the study with participants returning to the lab to repeat all baseline measures. T-tests were used to determine if significant between group differences existed using delta scores (post-pre). **RESULTS:** No significant differences in baseline measurements were observed (p>0.05). No significant group differences were observed for VO_{2max}, OBLA, LP, and LE. However, significant group differences were observed for LC (kg) (EX 9.21±5.35 vs. CON: -0.142±5.08). The average blood lactate response (mmol/L) for the first 4 MERT sessions ranged from 7.0±0.716 to 13.8±1.76 and the last 4 sessions ranged 8.23±0.956 to 13.8±0.763. **CONCLUSIONS:** 4 weeks of MERT did not significantly improve VO_{2max}, OBLA, LP, and LE but did improve LC. Although subjects performed all MERT at the same percentage of 1RM a large range of lactate responses were observed between subjects. The range in lactate responses suggests that the relative intensity of the exercise and metabolic responses were not the same between subjects. It may be more appropriate to assign training load with MERT based on lactate response to ensure similar metabolic responses between subjects.

Varying Exercise Intensities: The Accuracy of Three Self-Monitoring Heart Rate and Physical Activity Wearable Devices

Erin E. Dooley, Natalie M. Golaszewski, John B. Bartholomew, FACSM. University of Texas at Austin, Austin, TX. (Sponsor: John B. Bartholomew, FACSM)
 Email: erin.dooley@utexas.edu
 (No relationships reported)

Physical activity tracking wearables have emerged as a popular method for consumers to assess their daily activity, calories expended and heart rate. However, less is known if these health measures are valid at various levels of exercise intensity.

PURPOSE: To examine heart rate (HR) and energy expenditure (EE) validity of three popular wrist-worn activity monitors at different exercise intensities.

METHODS: 62 participants (36 females, 46.8% non-white) wore the Apple Watch (AW), Fitbit Charge HR (FCHR) and Garmin Forerunner 225 (GF). Validity was assessed by 2 criterion devices: HR chest strap and a metabolic cart. Participants completed a 10-min seated baseline; separate 4-min stages of light, moderate and vigorous-intensity treadmill exercises; and a 10-min seated recovery. Data from devices were compared to each criterion via two-way RM-ANOVA and Bland-Altman analysis. Differences were expressed in mean absolute percentage error values (MAPE).

RESULTS: AW - HR MAPE between 1.14-6.70%. HR not significantly different at the start (p = .13), baseline (p = .76) or vigorous intensity (p = .84). Lower HR readings during light (p < .05), moderate (p < .01) and recovery (p < .01). EE MAPE between 14.07-210.84%. Measured higher EE at all stages (p < .01). FCHR - HR MAPE between 2.38-16.99%. HR not significantly different at start (p = .43) or moderate intensity (p = .34). Lower HR readings during baseline, vigorous and recovery (p < .001) and higher HR in light (p < .001). EE MAPE between 16.85-84.98%. Measured higher EE at baseline (p < .05), light (p < .001) and moderate (p < .001). GF - HR MAPE between 7.87-24.38%. HR not significantly different

at vigorous intensity ($p = .35$). Measured higher HR readings start, baseline, light, moderate ($p < .001$) and recovery ($p < .05$). EE MAPE between 30.77-155.05%. Measured higher EE at all stages ($p < .001$).

CONCLUSION: This study provides one of the first validation assessments for the Fitbit Charge HR, Apple Watch and Garmin Forerunner 225. An advantage and novel approach of the study is the examination of HR and EE at specific PA intensities. Establishing validity of wearables is of particular interest as these devices are being used in weight loss interventions and could impact findings. Future research should investigate why differences between exercise intensities and the devices exist.

Sex and Age Differences in Wrist and Hip Accelerometry in Adults

Shannon Merkle¹, Dana Dailey², Kathleen Sluka², Laura Frey Law². ¹United States Army Research Institute of Environmental Medicine, Natick, MA. ²University of Iowa, Iowa City, IA.
Email: shannon.l.merkle.mil@mail.mil
(No relationships reported)

INTRODUCTION: While hip accelerometry has traditionally been considered the gold standard in the measurement of physical activity, wrist-worn devices have gained popularity in both research and consumer markets. The relationships between these measurements are not well characterized.

PURPOSE: To compare acceleration measurements between hip- and wrist-worn devices in younger (Y) and middle-aged (MA) men and women.

METHODS: 37 healthy, non-smoking, Y (18-39 years; 10M,10F) and MA (40-65 years; 8M,9F) adults participated in this one-visit, observational study. Participants wore a triaxial accelerometer on their non-dominant wrist and corresponding hip during a series of 14 well-defined, but varied-intensity common activities. Three-way mixed repeated measures ANOVAs (age by sex by device location) were used to assess cohort differences in accelerations for each activity, with movement speed as a covariate when appropriate (e.g. self-selected walking velocity). Significance was set at $p \leq 0.005$ to adjust for multiple comparisons.

RESULTS: After correcting for self-selected walking speed, over-ground walking wrist accelerations were approximately 50% greater in women compared to men in both age groups ($p = 0.004$, effect size, $d = 1.2$) despite no difference in hip accelerations ($p = 0.15$). Accelerations for other activities did not differ by sex ($p > 0.03$). MA adults demonstrated greater accelerations than Y adults ($p = 0.005$; $d = 0.82$) with sweeping but no other tasks ($p > 0.05$). Wrist accelerations were often measured to be greater than hip but not consistently so.

CONCLUSIONS: Hip and wrist accelerations demonstrated few sex and age differences and were not consistently related to each other. The sex difference in wrist accelerations suggests lifestyle physical activity may be overestimated in women using wrist accelerometry. The inconsistent relationship between hip and wrist accelerations suggests previous hip cut points cannot be reliably used for wrist assessments.

The Degree Of Tracking Of Physical Fitness And The Possibility Of Anti-tracking

Kosho Kasuga¹, Takahiro Nakano², Kazuo Oguri³, Tomoaki Sakai². ¹Gifu University, Gifu, Japan. ²Nagoya Gakuin University, seto, Japan. ³Gifu Shotoku Gakuen University, Gifu, Japan. (Sponsor: Kiyoji Tanaka, FACSM)
(No relationships reported)

PURPOSE: The purpose of this study was to ascertain the degree of tracking of physical fitness by examining the relationship of physical fitness in children at 5 and 12 years of age using longitudinal data. In addition, anti-tracking was investigated in children who were classified into the low physical fitness group at the age of 5 years and belonged to a sports club at the age of 12 years.

METHODS: Subjects included 126 children who performed the physical fitness test when they were 5 and 12 years old. To determine the amount of tracking, we calculated the Pearson correlation coefficient between assessments at 5 and 12 years. Children who were classified into the low physical fitness group at 5 years of age were further divided into the group that belonged to the sports club (SG) and the group that did not belong to the sports club (CG) at the time of 12 years of age.

RESULTS: Among boys, physical fitness assessment at 12 years showed a significant correlation with that at 5 years in terms of overall physical fitness ($r=0.671$), throwing ($r=0.766$), and jumping ($r=0.467$). Among girls, physical fitness assessment showed a significant correlation with overall physical fitness ($r=0.559$), jumping ($r=0.338$),

running ($r=0.680$), and throwing ($r=0.524$). The significant difference in the overall physical fitness between SG and CG was observed in girls. The overall physical fitness was significantly higher in SG than in CG ($t=2.751$, $p=0.005$).

CONCLUSIONS: These results suggest that characteristics of physical fitness at the age of 12 were strongly influenced by the overall physical fitness at the age of 5 in both boys and girls. Analysis of anti-tracking results did not show a big effect. In particular, it was remarkable in boys. Supported by Grant-in-Aid for Scientific Research (B) (No.16H03271) from Ministry of Education, Culture, Sports, Science and Technology in Japan.

GPS Analysis of Elite Chinese Male Hockey Players During Competition: Based on New IHF Rules

Xudan Cai¹, Wayne Lombard², Niansheng Zhou¹, Xiaoping Chen³. ¹Ningbo University, Ningbo, China. ²University of Cape Town, Cape Town, South Africa. ³China Institute of Sport Science, Beijing, China.
Email: caixudan1993@yahoo.com
(No relationships reported)

PURPOSE: The aim of this study was to investigate the physiological demands of a match under the new rules as compared to the old rules.

METHODS: Four matches analyzing 16 elite Chinese field hockey players (Height: 178 ± 4.41 cm.; Weight: 76.50 ± 6.12 kg) were recorded by using global positioning system (SPI Elite, GPSports, Australia) and analyzed using Team AMS (v2014.11) software during 2015 Chinese National Tournament. All the matches were filmed by using two high definition cameras (HDR-SR12E, Sony, Japan), which were placed on the top of the stadium and filmed each half field respectively. Exact timing, including beginning and ending of each quarter, timing and details of substitutions, playing time of each player and positional changes, were reviewed post-match and used to edit the GPS data. Multiple paired t-tests were used to compare data between different positions and different quarters. Significance was set at $P \leq 0.05$. Average values were used to compare differences between new rules' and old rules' hockey matches.

RESULTS: The mean total distance covered by each player was 5788 ± 1710 m, and overall mean playing time was 37.8 ± 14.0 min. Compared with other positions, strikers had a significantly greater high-intensity activity (>14 km/h) percentage (strikers: $29.7 \pm 4.8\%$; midfielders: $25.6 \pm 5.8\%$; defenders: $17.9 \pm 3.3\%$; $P < 0.01$). Average sprint (defined as speed >19 km/h, interval of at least 1 second) counts for each player was 25.5 ± 9.9 per match, with an average duration of 2.5 ± 0.3 s. About 75% of sprint distances were between 5-20m, with recovery times varying greatly, however the two most frequently observed recovery times were >120 s (36%) and 0-40s (35%). The average repeated-sprint (defined as time interval between two sprints was less than 60s) counts were 11.4 ± 6.9 , and the average percentage of repeated-sprint counts and average recovery interval of repeated-sprints were $40.1 \pm 16.8\%$ and 23.0 ± 8.3 s respectively.

CONCLUSIONS: These results suggest that players are required to complete more high intensity bouts in a shorter time period (37.8 ± 14.0 vs. 51.9 ± 17.8 min) however average total distance was less under the new IHF rules.

Supported by NSSFC and Xinmiao Project through key project 13BTY049 and 2016R40593.

An Examination of Body Mass Index Influence on Activity Tracker Accuracy

Chris Dondzila, Holly Johnson, McKayla Steckel. Grand Valley State University, Allendale, MI. (Sponsor: Steve Glass, FACSM)
(No relationships reported)

A variety of activity trackers with evolving technology are commercially available, yet it remains uncertain the influence body size has on these devices' accuracy (as previous activity trackers have been), which would compromise their generalizability.

PURPOSE: To examine the accuracy of consumer-grade activity trackers in quantifying steps and moderate-vigorous physical activity (MVPA) engagement in free-living conditions in a diverse sample of body mass index (BMI) categories. **METHODS:** Sixty individuals (21.1 ± 1.5 years, 2.3 ± 0.2 ft stride length) across three BMI categories ("Normal" [$n=25$]: $20-24.9$ kg/m²; "Overweight" [$n=22$]: $25-29.9$ kg/m²; "Obese" [$n=13$]: ≥ 30 kg/m²) wore four activity trackers during one 24-hour day (wear time 12.7 ± 1.9 hours). On the non-dominant side of the body, the Fitbit Charge HR (Charge) and Jawbone UP3 (UP3) were worn on the wrist and the Fitbit One (ONE) on the waist, with the NL1000 activity tracker (NL; serving as the criterion device) worn on the dominant side of the waist. Mixed between-within ANOVA analyses were performed to examine differences in steps and MVPA for the activity trackers across three BMI categories. **RESULTS:** There were no differences in steps or MVPA for the individual devices across BMI categories. In the Normal group, the UP3 (6667 ± 3366 steps) and ONE (7400 ± 8135 steps) underestimated steps ($p=0.000$), compared to the NL (8135 ± 3562 steps). Similarly, in the Overweight group, the UP3 (8799 ± 3986 steps) and ONE (9019 ± 3841 steps) underestimated steps (NL 9312 ± 3986 steps, both $p < .05$). In the Obese group the Charge overestimated

steps (8847 ± 4168 , $p < .05$) and the ONE underestimated steps (7726 ± 3791 , $p < .05$), compared to the NL (8224 ± 4264 steps). The UP3 overestimated MVPA in the Normal group (67.7 ± 44.3 minutes), compared to the NL (27.6 ± 16.3 , $p = .000$). In both the Overweight and Obese groups, the UP3 overestimated MVPA (Overweight: 81.5 ± 44.3 minutes, Obese: 77.5 ± 39.4 minutes, both $p = .000$), whereas the ONE underestimated MVPA (Overweight: 25.9 ± 26.5 minutes, Obese: 19.5 ± 25.3 minutes, both $p < .05$), compared to the NL (Overweight: 36.6 ± 19.2 minutes, Obese: 31.6 ± 27.3 minutes). **CONCLUSION:** Within BMI groups, the UP3 underestimated steps and overestimated MVPA, the ONE underestimated steps and MVPA, whereas the Charge performed relatively well for both measures.

Accuracy of Garmin and Polar Smart Watches to Predict VO₂max

Nikolas C. Snyder, Courtney A. Willoughby, Bryan K. Smith.
Southern Illinois University Edwardsville, Edwardsville, IL.
(No relationships reported)

Smart watches have greatly evolved since their first release. With advancements in technology, many smart watches can now estimate aerobic capacity. These watches are user-friendly and affordable but there are no current investigations that have reported accuracy to predict VO_{2max}. **PURPOSE:** The purpose of this study was to compare actual VO_{2max} values (AMax) to predicted VO_{2max} values obtained from the Garmin Forerunner 230 (230Max) and 235 (235Max) smart watches as well as the V800 Polar smart watch (PMax). The Garmin watches predict VO_{2max} based upon heart rate values obtained during a 10 min, self-paced outdoor run. The Polar watch predicts VO_{2max} based upon resting heart rate variability. **METHODS:** Eighteen females (BMI=24.9 \pm 3.3 kg/m², age=24.7 \pm 3.8, AMax=42.9 \pm 4.8 ml/kg/min) and 24 males (BMI=26.6 \pm 3.3 kg/m², age=24.2 \pm 4.4, AMax=49.5 \pm 5.8 ml/kg/min) participated in this study. PMax values for each individual were obtained following a 10 min supine rest and were based upon the different training ranges that can be programmed into the watch. Participants then completed a treadmill VO_{2max} test. Within 48 hours of completing the treadmill VO_{2max} test, individuals completed a 10 min, self-paced outdoor run using both Garmin smart watches. Paired sample T-tests were used to determine if there were differences between AMax and the predicted VO_{2max} of each watch. **RESULTS:** There were significant differences between AMax and PMax (2.5 \pm 6.8 ml/kg/min, $p = 0.029$), 230Max (-0.3 \pm 3.4 ml/kg/min, $p = 0.02$) and 235Max (-1.1 \pm 4.0 ml/kg/min, $p = 0.026$) in females. In males there were significant differences between AMax values and PMax (-6.0 \pm 7.7 ml/kg/min, $p = 0.001$), 230Max (-1.1 \pm 3.4 ml/kg/min, $p = 0.149$) and 235Max (-3.2 \pm 4.2 ml/kg/min, $p = 0.002$). **CONCLUSION:** In females, predicted VO_{2max} values were significantly different from AMax values and the differences ranged from an overestimation of 2.5 ml/kg/min to an underestimation of 1.1 ml/kg/min. In males, predicted VO_{2max} values were significantly different from AMax values and the watches consistently overestimated VO_{2max} (range -1.1 to -6.0 ml/kg/min). Caution should be taken when using these predicted values for exercise prescription especially in men.

2668 Board #188 June 2 9:30 AM - 11:00 AM

Comparison Of Vo2Max Values Obtained From The Garmin Forerunner 230 And 235

Courtney A. Willoughby, Nikolas C. Snyder, Bryan K. Smith.
Southern Illinois University Edwardsville, Edwardsville, IL.
(No relationships reported)

The use of optical sensing technology has provided exercise watches with the ability to assess heart rate without the need of a chest strap. The Garmin Forerunner 230 (G230) and 235 (G235) are identical watches with the exception that the G230 uses a chest strap to measure heart rate (HR) and the G235 measures HR via an optical sensor built into the watch. The use of a chest strap to measure exercise HR is a proven and reliable technology whereas the use of an optical sensor to measure exercise HR is still a developing technology. Both watches provide an estimate of VO_{2max} (PMax) based upon distance ran and HR during a self-paced 10 min outside run. Average HR (AHR), maximal HR (MHR), cadence, and kcals are also recorded. **PURPOSE:** The purpose of this study was to compare PMax, AHR, MHR, distance, kcals, and cadence values obtained from the G230 and the G235 during a self-paced 10 min outside run. **METHODS:** Eighteen females (BMI=24.9 \pm 3.3 kg/m², age=24.7 \pm 3.8, VO_{2max}=42.9 \pm 4.8 ml/kg/min) and 24 males (BMI=26.6 \pm 3.3 kg/m², age=24.2 \pm 4.4, VO_{2max}=49.5 \pm 5.8 ml/kg/min) reported to a paved trail, free of any GPS interference to complete a self-paced 10 min run while wearing both watches and the HR strap associated with the G230. Participant's gender, age, height, and weight were also entered into each watch before the run. **RESULTS:** In females, AHR was significantly higher in the G230 (4.3 \pm 4.8 bpm, $p = 0.004$) but there was no significant differences in PMax (-0.8 \pm 1.86 ml/kg/min, $p = 0.118$) when compared to the G235. In males, AHR was significantly higher in the G230 (8.1 \pm 15.2 bpm, $p = 0.028$) and the PMAX was significantly lower in the G230 (2.1 \pm 2.0 ml/kg/min, $p = 0.000$) when compared to the G235. There were no significant differences between watches for MHR, distance, cadence, or kcal in females or males. **CONCLUSION:** The AHR values from the

G230 were significantly higher than the values from the G235 in both males and females. The PMax values from the G230 were significantly lower than the values from the G235 in men. In males, the differences in AHR are responsible for differences in PMax between watches since there are no differences between the other variables measured during the run. Caution should be taken when using exercise HR values obtained from an optical sensor.

The Validity And Agreement Of Running Distance Measurements By A Consumer Accelerometer And Gps

Andrew J. Carnes¹, Jacob E. Barkley², Jennifer L. Petersen³.
¹Bellarmine University, Louisville, KY. ²Kent State University, Kent, OH. ³Walsh University, North Canton, OH. (Sponsor: Ellen Glickman, FACSM)
(No relationships reported)

Distance running is a tremendously popular sport/fitness activity amongst US adults. Individualizing training volume (i.e., distance) is necessary to optimize training responses and reduce injury risk. While personal global positioning satellite (GPS) devices are a validated means of accurately measuring distance, the validity of distance measurements by accelerometer-based physical activity monitors is unknown.

PURPOSE:

Assess the concurrent validity and agreement of distance measurements by a commercially-available physical activity monitor to those of a personal GPS device during self-paced running.

METHODS:

Twenty-four recreational runners ($n = 12$ females) wore a personal GPS (Garmin ForeRunner 10, GPS) and commercially-available physical activity monitor (MOVband accelerometer, MB) on the dominant wrist during three separate outdoor training runs. Participants followed their normal training schedules, such that the pace and duration of each run was voluntarily determined by the participant. The association between MB and GPS distance measurements was determined using Pearson's correlation analysis. The 95% limits of agreement between MB and GPS were calculated according to the method of Bland and Altman. Specifically, the upper and lower limits of agreement were calculated as the mean of the differences (d) between GPS and MB \pm (1.96 x the standard deviation of the differences), expressed as: $d \pm 1.96s$.

RESULTS:

There was a significant, positive association of a large effect size between measurements of distance by GPS and the commercially-available physical activity monitor (MB) ($r = 0.763$, $p < 0.001$). However, the calculated limits of agreement (-1.946 to 2.025km) between GPS and accelerometer measurements suggest that individual MB measurements may be up to 2km above or below GPS.

CONCLUSION:

We suggest that non-GPS distance measurements by commercially-available physical activity monitors may be useful for monitoring overall, cumulative volume for health and fitness purposes. However, these measurements fall short of GPS when high accuracy is needed, as in training programs designed to enhance performance. These findings cannot be generalized to all accelerometer devices.

Accuracy of Wearable Devices for Determining Physiological Measures during Different Physical Activities

Benjamin D. Boudreaux, Corinne L. Cormier, Brian M. Williams, Edward P. Hebert, Robert R. Kraemer, FACSM.
Southeastern Louisiana University, Hammond, LA. (Sponsor: Robert R. Kraemer, FACSM)
Email: benjamin.boudreaux@selu.edu
(No relationships reported)

PURPOSE: Wearable technology is ACSM's number one 2016-2017 fitness trend. The accuracy of these devices has yet to be firmly established. The objective of the study was to determine the validity of wearable devices' assessment of step count, heart rate (HR) and caloric expenditure (KCAL) during various physical activities.

METHODS: Thirty college students (19 female, 11 male) engaged in 3 activity sessions (sweeping with a broom and dustpan, climbing stairs, and walking 1/4 mile) while wearing an Apple Watch Sport, Fitbit Charge HR, Accusplit Hip Pedometer, and iPhone 6 Plus. Step counts from devices were compared to those objectively recorded using a tally counter. Subjects also completed a treadmill graded exercise test during which HR and KCAL were reported by an Apple Watch Sport, Fitbit Charge HR, and Polar T-31. Values were compared to those from a six-lead ECG and metabolic analyzer. HR was recorded at rest and during each stage. KCAL was determined at the end of the protocol.

RESULTS: Correlations between objective step counts and from the devices were: walking (.08 to .84), stair climbing (.12 to .90), and sweeping (.12 to .70). No device

was accurate across all activities. The most accurate devices for activities were: walking (Apple Watch, $r=.84$); stair climbing (iPhone, $r=.90$); sweeping (Fitbit, $r=.70$). During the treadmill test, correlations between HR assessed via ECG and devices were: Apple Watch (.76 to .99), Polar T-31 (.72 to .94), and Fitbit (.19 to .98). Heart rate accuracy across the session was highest in the Apple Watch. KCAL from neither the Apple Watch ($r=.63$) nor Fitbit ($r=.48$) had a high correlational value to that from the metabolic analyzer.

CONCLUSIONS: Fitness-related values provided by wearable devices had varying levels of accuracy when compared to objective step counts, HR and KCAL assessed by calibrated scientific equipment. Accuracy of step counts varied by activity and was higher across activities in the iPhone. HR reported from wearable devices, similarly, had varying levels of accuracy, with the Apple Watch being most accurate across a graded exercise test. Fitness-related information from wearables that are not medical devices and should be considered as estimates and used for motivation. Further validation of these devices should include a variety of physical activity modalities.

Validity Of The Diagnostix™ 2100 And Fitbit Charge HR™ In Assessing Heart Rate

Paige Hardekopf, Charles Fontaine. *University of Minnesota Duluth, Duluth, MN.* (Sponsor: John R. Keener, FACSM)
 Email: hard0365@du.umn.edu
 (No relationships reported)

The importance of exercise intensity is an important factor when maximizing the health benefits that result from exercise. New innovations in consumer based activity trackers and electronic healthcare monitoring devices have been able to quantify the level of exercise intensity based on heart rate (HR) values. However, there is limited research assessing the validity of these devices. **PURPOSE:** To assess the validity of the Fitbit Charge HR (FB) and ACSC Diagnostix 2100 Fingertip Pulse Oximeter (PO) in assessing heart rate during exercise in comparison to the heart rate from an electrocardiogram (EKG).

METHODS: Healthy college students ($n=30$, 18 females) performed 1 min of standing rest, 10 min of the standard Bruce Protocol test on a treadmill, and a 2 min cool-down walk. Each participant simultaneously wore the FB on the right wrist, the PO on the right index finger, and had 10 electrodes placed on their chest for the 12-lead EKG. HR was recorded from each device every minute. Absolute differences between the 3 HR monitors were compared using repeated measures ANOVA. Pearson r correlation coefficients and Standard Error of Estimate (SEE) were calculated to determine the relationships between each HR monitor vs. EKG.

RESULTS: Repeated measures ANOVA indicated a significant difference in HR between the 3 monitors, $F(2,58)=16.876$, $p<0.001$. Post hoc tests indicated a significant difference between EKG and FB (132.1 ± 13 vs. 120.5 ± 13.7 bpm, $p<0.001$), and EKG and PO (132.1 ± 13 vs. 121.9 ± 15.5 bpm, $p<0.001$). The correlation between the EKG and FB was $r=0.64$, $p<0.001$, SEE 10.2 bpm, whereas the correlation between EKG and PO was $r=0.63$, $p<0.001$, SEE 10.2 bpm.

CONCLUSIONS: Large absolute differences and modest correlation values do not indicate a strong agreement between the FB or PO vs. EKG. Therefore, the extent of each device's validity to monitor HR is questionable when compared to the gold standard EKG.

2672 Board #192 June 2 9:30 AM - 11:00 AM
Validity of the Fitbit® Distance Traveled Feature Among Multiple Speed Trials

Christina J. Marton. *Gustavus Adolphus College, Saint Peter, MN.*
 Email: cmarton@gac.edu
 (No relationships reported)

A science review by Delago (2014) suggested that the distance-traveled feature on Fitbit® was an accurate measurement. However, as speed increased the accuracy of the Fitbit® decreased, meaning the faster the pace, the greater the error for distance measured. Whereas a systematic review conducted by Evenson et al. (2015) reported only one study that measured the distance-traveled feature. This study concluded that the Fitbit® over-estimated at lower speeds and underestimated at faster speeds. **PURPOSE:** To examine whether the fitness device, Fitbit® Charge, provides an accurate measurement of the distance-traveled feature at various speeds and to expand on the research regarding the distance-traveled feature. **METHODS:** Twenty-eight healthy students from a Division III college participated in this study. A repeated measure ANOVA experimental design compared the Fitbit® distance-traveled output under three dependent variable speeds of 2.5mph (76.1m/min), 4.5mph (120.7m/min), and 6mph (160.9m/min) to a Quinton MedTrack ST55 treadmill distance-traveled measurement. All participants completed a six-minute trial for each of three different speeds on a treadmill while wearing the Fitbit® Charge. Following each six-minute trial, the distance-traveled was compared between the treadmill and the Fitbit® output. A repeated measure ANOVA analysis was used to test for significant differences ($p < .05$) among the three speeds between the Fitbit® and the treadmill. **RESULTS:**

Results did not detect significant differences in distance-traveled between the Fitbit® Charge compared to the treadmill at 2.5mph ($F(1,27) = 0.67$, $p = .42$), 4.5mph ($F(1,27) = 2.45$, $p = .13$), or 6mph ($F(1,24) = .66$, $p = .43$) speeds. **CONCLUSION:** It seems reasonable to conclude that the distance-traveled feature on the Fitbit® Charge is valid when compared to treadmill output at these three speeds. Future research could look at a wider range of speeds to ensure further accuracy. IRB# 1516-0099

2673 Board #193 June 2 9:30 AM - 11:00 AM

Measuring Acceleration of a Trampoline Circus Act during Training and In-Show Using Wearable Technology

Leland Barker, 89120, John Mercer, FACSM. *UNLV, Las Vegas, NV.*
 Email: barkell@unlv.nevada.edu
 (No relationships reported)

Circus performance acts incorporate a variety of unique movements. Professional artists are often performing these acts in multiple shows a day and/or week on top of completing regular training of the acts. However, there is limited understanding of the mechanical demands of the acts. The emergence of wearable technology has allowed for measuring some mechanical aspects of these highly complicated acts.

PURPOSE: Compare acceleration profiles of a trampoline circus act recorded during training and in-show. **METHODS:** Seven acrobats (1.75 ± 0.05 m; 78.83 ± 4.49 kg; 28.93 ± 3.3 years) performed 3 training acts on separate days and 2 show acts on one day. Following the completion of the show, participants reported their rating of perceived exertion (1-10 scale). Tri-axial accelerations were measured using a commercial accelerometer system (Hexoskin, Carre Technologies Inc, Montreal, CA) with the accelerometer located on the lateral aspect of the right hip. Average resultant acceleration (AVG) was calculated each trial during training (3 trials) and show (2 trials). Time based acceleration data were also classified into 5 ranges: $0 \leq$ Very Low < 0.1 g; $0.1 \leq$ Low < 0.3 g; $0.3 \leq$ Moderate < 0.6 g; $0.6 \leq$ High < 1 ; $1 \leq$ Very High ≤ 16 g. Relative time spent in each range was averaged during training and in-show. Dependent variables were compared using paired-sample t-tests and a repeated-measures ANOVA. **RESULTS:** AVG was significantly higher during training vs. in-show (0.525 ± 0.12 g vs. 0.467 ± 0.098 g; $p=0.030$, effect size= 0.53). RPE was significantly lower during training vs. in-show (2.757 ± 0.53 vs. 3.429 ± 1.10 ; $p=0.027$). RM ANOVA revealed no interaction between acceleration ranges and environment ($p>0.05$), and no main effect for environment ($p>0.05$). Time spent in acceleration ranges was influenced by level ($p<0.05$) such that there was a both a linear and cubic trend across bin levels. **CONCLUSION:** The lower AVG may reflect that the show environment promotes less intense movements to maintain synchronization with co-artists. Wearable technology may be useful for analyzing show movements in a way to better develop effective training programs.

Equivalence Of Self-report And Accelerometer Measures Following A Physical Activity Intervention.

Kathryn J. Southard¹, Yang Bai², Greg Welk, FACSM¹, Laura Ellingson¹. ¹Iowa State University, Ames, IA. ²University of Vermont, Burlington, VT. (Sponsor: Greg Welk, FACSM)
 Email: kjsouth@iastate.edu
 (No relationships reported)

The International Physical Activity Questionnaire (IPAQ) is a validated and widely used self-report physical activity (PA) measure, however findings about validity have been somewhat equivocal.

Purpose: This study evaluated the agreement of the IPAQ measure with a novel and objective activity monitoring method known as Sojourns Including Posture (SIP). The SIP method is based on the same bout detection method as the more established Sojourn method but incorporates data from the ActivPAL to provide more robust information about transitions between Sedentary and Light activity. The aim was to investigate differences between self-reported moderate (MPA), vigorous (VPA), and sedentary (SED) minutes to SIP data, to inform whether participants were able to accurately self-report PA and SED time.

Methods: A sample of 93 inactive adults (53% female; 42 ± 9.1 mean age) participated in this study. Participants received a wearable device to track PA. Post-intervention, individuals wore accelerometers for 1 week, and self-reported PA and SED via the IPAQ. Minutes of MPA, VPA, and SED from each measure were compared using Pearson correlations, equivalence testing, and Bland-Altman plots, with the SIP method as the criterion.

Results: The overall Pearson correlation between the measures was low to moderate ($r = 0.37$, $P < .05$). The mean MPA via IPAQ was 96.9 ± 87.8 minutes per day compared to 57.3 ± 24.4 minutes per day measured by SIP. Mean VPA from the IPAQ was 8.99 ± 6.76 minutes, while the SIP method reported 14.44 ± 9.51 minutes. The mean SED via the IPAQ was 456.6 ± 156.93 minutes compared to 546.13 ± 104.42 minutes measured by SIP. Equivalence testing demonstrated that the MPA, VPA, and SED methods were

not equivalent at the $\pm 10\%$ equivalence zone. A Bland Altman plot was constructed to visualize the MPA data using 95% limits of agreement that are between -121.1 and 200.4. More data points trended below the mean of 39.65, suggesting proportional bias that self-report overestimated activity.

Conclusions: This study provides some support for the use of the IPAQ, but confirms the common observation in self-report instruments with participants tending to overestimate their participation in MPA and underestimate sedentary time. The use of measurement error modeling and calibration methods may be needed to address this error in future studies.

Validation of Three Wearable Fitness Trackers for Measuring Physical Activity in College Students

Chad Witmer¹, Peng Zhang¹, Steven Godin², Dongsheng Che¹.
¹East Stroudsburg University, East Stroudsburg, PA. ²University of Utah, Salt Lake City, PA.
Email: cwitmer@esu.edu
(No relationships reported)

Many wearable fitness trackers have a function measuring physical activity such as energy expenditure but the accuracy of the measures is unclear. **PURPOSE:** The aim of the study was to validate the energy expenditure estimation of three fitness trackers: LT, FB, and AW for treadmill walking and running. **METHODS:** The participants of the study were 30 college students (17 males and 13 females) from a public university in Pennsylvania. All participants completed six trials of 10-minute walking and running activities on a treadmill at speeds of 54, 80, 107, 134, 161, & 188 m²min⁻¹. Participants were wearing all the fitness trackers and connected to indirect calorimetry during the exercise protocol. All devices provided caloric expenditure while the indirect calorimetry was used as a criterion measure. Resting Metabolic Rate was collected along with a familiarization trial prior to the execution of the exercise protocol. Two-way ANOVA with repeated measures and Pearson Correlation were used to compare the caloric expenditure estimates between the criterion and three fitness trackers. **RESULTS:** There were no significant differences in energy expenditure estimates between the criterion and AW (mean difference 4.6 kcal, $p > 0.05$), nor criterion and LT (mean difference 0.8 kcal, $p > 0.05$). However there was a significant difference between the criterion measure and FB (mean difference 18.2 kcal, $p = 0.001$). Pearson correlation coefficients (r): the criterion of indirect calorimetry-derived activity energy expenditure yielded the strongest positive correlations with activity energy expenditure estimated from the AW at all speed levels (range from .55 to .85, all $ps < 0.01$). FB was positively correlated to the criterion measure at five speed levels (range from .46 to .67, $ps < 0.05$). No positive correlation was found between the criterion and LT measures (range from -.40 to .26). **CONCLUSION:** AW and FB demonstrated a moderate to high level of validity on measuring physical activity while LT had a low level of validity.

Accuracy of Activity Monitors During Treadmill Tests

Edward J. Sinovich, David Q. Thomas, FACSM, Kristen Lagally, FACSM, Daniel J. Dodd, Samantha Ward, Austen Bozarth, Tom Atiyeh, Jady N Chipman. *Illinois State University, Normal, IL.* (Sponsor: David Q. Thomas, FACSM)
Email: ejsinov@ilstu.edu
(No relationships reported)

A number of monitors that provide estimates of physical activity have flooded the market recently. These monitors, worn at the hip, wrist, arm or around the chest, claim to measure step count, heart rate and/or energy expenditure. **PURPOSE:** To compare physical activity estimates among several of the most popular new monitors during physical activity performed at different intensities. **METHODS:** Forty-six participants were fitted with four physical activity monitors. Subjects walked, jogged and ran on a treadmill at 3, 5, and 7 mph, each for 3 minutes. Heart rate, step count, and rate of perceived exertion (RPE) were recorded during the last minute of each stage from each device that assesses that variable. Actual step count was recorded via a hand-held clicker device. Step count from all monitors was compared to the step count from the clicker. Individual two-way t-tests were used to check for significant differences. **RESULTS:** The results of this study are mixed. For stages 1 (3 mph) and 2 (5 mph), the wrist and arm worn monitors produced significantly different ($p < .05$) step counts than the clicker, while the waist worn monitor produced non-significant differences. For stage 3 (7mph), both wrist worn monitors produced non-significant differences in comparison to the clicker, while the arm and waist worn devices produced significant difference ($p < .05$). **CONCLUSIONS:** The four physical activity monitors produced conflicting results. The waist worn monitor was accurate at the slower speeds, but inaccurate at the higher speed. The wrist worn monitors were inaccurate at the slower speeds, but accurate at the high speed. The arm band monitor was inaccurate under all conditions. Caution should be used when electing to utilize physical activity monitors to estimate physical activity.

(No relationships reported)

Assessing the physiological responses to exercise at high altitude in real time or using cloud-based data storage has important implications for remote monitoring of human health and well-being in challenging environments. **Purpose:** To determine the feasibility of using real-time monitoring to assess the cardiovascular responses to a simulated climb for military operations. **Methods:** Seventy-four male (age = 21.9 \pm 2.2 yrs, height = 1.78 \pm .02 m, weight = 78.2 \pm 9.7 kgs) sea level (SL) residents volunteered to participate in this study after giving informed consent and completing the Army Physical Fitness Test. Subjects were flown from SL to high altitude (HA) and completed a 5.9-km hike with a 35-pound rucksack that began at 3239 m and finished at 3840 m the morning after arrival at HA. They were instructed to complete the course as fast as possible. Heart rate (directly from ECG), breathing rate and depth, and step count (cadence) were assessed using a shirt with built-in sensors (Carre Technologies inc., Hexoskin). In 73 out of 74 of the subjects, the Hexoskin was effective at collecting all of the hike data. For analysis, the 5.9 km course was divided into four equal segments (Segment 1 = 0-25%, 2 = 25-50%, 3 = 50-75%, 4 = 75-100%) based on step count. Elevation gain for each of the segments was determined from topographical maps (Segment 1 = 123 m, 2 = 178, 3 = 142 m, and 4 = 262 m). Average and maximal heart rates were calculated for each of the segments. **Results:** Average heart rates were 140.1 \pm 18.1 bpm, 161.9 \pm 5.8 bpm, 159.2 \pm 6.4 bpm, and 161.5 \pm 6.2 bpm respectively for the four segments corresponding to 74.5%, 86.1%, 84.6%, and 85.9% of estimated heart rate max. The heart rates reflected the elevation gain except for Segment 4 which had the greatest elevation gain but similar heart rates to Segment 3. Further analysis of the Hexoskin data indicate that subjects had more stops during this segment (73% of all stops occurred in Segment 4) which resulted in an overall lower average. **Conclusions:** These results suggest that real-time monitoring for multiple variables simultaneously (heart rate, ECG, step count) in the field is a viable means of assessing physiological function and simulating a military operation with a 610 m elevation gain results in relatively high heart rates that generally reflect elevation gain.

Accuracy of Smart Phone Application to Monitor Heart Rate

A. Page Glave, Jennifer J. Didier, Mary L. Williams, Christina Waters, Emily Ferens, Megan Cole. *Sam Houston State University, Huntsville, TX.*
Email: apglave@shsu.edu
(No relationships reported)

Smart phones applications to monitor heart rate are very popular. The application examined in this study has millions of installs, with one application boasting of 35 million plus users (application store info). However, there is limited research available on the validity of these applications. An earlier study found a camera-based application to be accurate (McCurley, et al., 2013), but the study examined a single smart-phone platform. **PURPOSE:** The purpose of this study was to examine the accuracy of a popular heart rate application on two smart phone platforms while resting and during moderate exercise. **METHODS:** The same heart rate monitor application was chosen for two different technology platforms. The application was required to be free and allow multiple heart rate readings per day. Participants were split into two groups based on technology platform. Both groups were monitored using electrocardiograph (ECG) and the smart phone application seated pre-exercise and during an exercise session on an elliptical machine. Measurements were recorded every minute. Data were analyzed using correlations and t-tests between platforms. All data were analyzed for both seated and exercise heart rate averages. **RESULTS:** For technology platform 1, heart rate while seated correlation for the application was $r = 0.98$ (11% missing data) and for platform 2 was $r = 0.60$ (21% missing data). For platform 1, heart rate during exercise correlation for the application was $r = 0.30$ (44% missing data) and for platform 2 was $r = 0.20$ (6% missing data). There was not a significant difference in heart rate while seated, t -test (-1.33), $p = .197$ nor exercise heart rate, t -test (-1.54), $p = .142$ when comparing means of the two platforms. **CONCLUSIONS:** Smart phone applications to monitor heart rate appear to be fairly accurate, particularly at rest. Although these should not be used as a replacement for constant heart rate monitoring tools, they may be useful to allow home monitoring or a quick check of heart rate,

particularly when the individual is not moving. Introducing movement reduced the accuracy of the applications and care should be taken when interpreting readings taken during exercise.

The Validity Of A Novel, Low-cost, Wearable Physical Activity Monitor In A Laboratory Setting

Andrew Newton¹, Ellen Glickman, FACSM¹, Curtis Fennell², John Gunstad¹, Jacob Barkley¹. ¹*Kent State University, Kent, OH.* ²*University of Montevallo, Montevallo, AL.*
 (No relationships reported)

Low-cost, consumer-grade, wearable physical activity monitors are increasingly popular for personal use and may provide a more accurate measure of physical activity than subjective methods (e.g., self-report) while being less expensive than research-grade accelerometers. Because of their popularity in individuals wishing to monitor their personal physical activity behavior and their potential merits in a research setting, assessments of the validity of these devices is warranted. **PURPOSE:** To assess the validity of a novel, low-cost, wearable physical activity monitor (Movband 3) relative to established measures physical activity intensity during treadmill exercise. **METHODS:** Participants ($N = 19$) completed four, ten-minute treadmill stages (1.5, 3.0, 4.0, 6.0 MPH) while wearing the Movband 3 on their wrist and the previously-validated Actigraph GT1M monitor around their waist. During each treadmill stage, relative oxygen consumption (VO_2 ml/kg/min) and heart rate (beats/min) were recorded via indirect calorimetry and telemetry monitoring, respectively. The relationship between Movband counts and Actigraph counts, VO_2 , and heart rate were then assessed via Pearson's correlation analyses. The relationship between miles traveled as reported via the Movband and actual miles traveled on the treadmill was assessed via correlation and tests of agreement as established by Bland and Altman.

RESULTS: There were large, positive effect sizes for the associations between Movband counts and Actigraph counts ($r = 0.72$), VO_2 ($r = 0.59$), and heart rate ($r = 0.63$). There was also a large, positive association between Movband miles and actual miles traveled ($r = 0.97$). These correlations would support the validity of the Movband. However, the difference (Δ) between Movband miles and actual miles was greater than a null hypothesis of zero ($\Delta = 0.3 \pm 0.4$ miles, $t = 8.4$, $p < 0.001$) and there was a significant positive association between Δ and the mean of the Movband and treadmill miles ($\beta = 0.54$, $p < 0.001$). This indicates a lack of agreement.

CONCLUSIONS: There was evidence to support the validity of the Movband 3 for the assessment of physical activity intensity in a laboratory setting. However, while this device is associated with measures of exercise intensity it does not provide an accurate measure of miles traveled.

E-34 Free Communication/Poster - Muscle Adaptations, Atrophy, and Hypertrophy

Friday, June 2, 2017, 7:30 AM - 12:30 PM

Differentiating Swelling and Hypertrophy Following Repeated Bouts of Resistance Exercise

Samuel L. Buckner¹, Scott J. Dankel¹, Kevin T. Mattocks¹, Matthew B. Jessee¹, J Grant Mouser¹, Brittany R. Counts², Gilberto C. Laurentino³, Jeremy P. Loenneke¹. ¹*The University of Mississippi, University, MS.* ²*University of South Carolina, Columbia, SC.* ³*University of Sao Paulo, Sao Paulo, Brazil.*
 (No relationships reported)

Previous studies have examined the swelling response following a single bout of exercise; however, no study has looked at the muscle swelling response across several bouts of resistance exercise.

PURPOSE: To examine the muscle swelling response over an 8-day period consisting of four separate traditional resistance exercise bouts.

METHODS: Nine untrained males visited the lab on nine occasions. Visit 1 consisted of one repetition maximum (1RM) testing. Participants then visited the lab for eight consecutive days separated by 24 hrs. During visits 2, 4, 6, and 9 participants performed 4 sets of 10 repetitions of biceps curls (or time matched rest on control arm) at 70% of their 1RM. Muscle thickness (MTH) was measured at 50, 60 and 70% the distance from the acromion process to the lateral epicondyle before and after exercise. During Visits 3, 5, 7, and 8 there were measures of MTH taken but no exercise.

RESULTS: There was an interaction ($p < 0.003$) for MTH at all sites. MTH at the 50% site increased from 3.1 (0.2) to 3.4 (0.2) cm immediately following the first exercise bout, returning back near baseline by visit 4 pre [3.2 (0.2) cm]. Similar increases were noted immediately post exercise on visit 4 [3.5 (0.1) cm], 6 [3.4 (0.1) cm], and 9 [3.5 (0.2) cm]. MTH at the 60% site increased from 3.3 (0.3) to 3.7 (0.3) cm following

the first exercise bout, decreasing near baseline by visit 4 pre [3.4, (0.3) cm]. Similar increases were noted immediately post exercise on visit 4 [3.8 (0.3) cm], 6 [3.8 (0.3) cm], and 9 [3.8 (0.3) cm]. MTH at the 70% site increased from 3.6 (0.4) to 4.1 (0.4) cm following the first exercise bout, decreasing near baseline by visit 4 pre [3.8 (0.3) cm]. Similar increases were noted immediately post exercise on visit 4 [4.2 (0.4) cm], 6 [4.2 (0.3) cm], and 9 [4.2 (0.3) cm]. The control arm displayed a slight baseline shift (non-significant at most time points $p > 0.05$). Differences between the exercise and control arm were only observed immediately post exercise, except at the 50% site during visit 6.

CONCLUSIONS: Resting levels of MTH do not appear to change appreciably beyond what occurs following the first naïve bout of resistance exercise. We suggest that naïve resistance exercise appears to produce a baseline shift in MTH, which may represent the threshold needed to be surpassed in order to assume real muscle growth has occurred.

AMPK Subunit Isoform Expression Differs Between Human Skeletal Muscle Fiber Types

Irene S. Tobias¹, James R. Bagley², Lee E. Brown, FACSM¹, Andrew J. Galpin¹. ¹*California State University, Fullerton, Fullerton, CA.* ²*San Francisco State University, San Francisco, CA.*
 (No relationships reported)

AMP-activated protein kinase (AMPK) is an energy-sensing regulator of cellular metabolism that is activated during acute exercise and mediates long-term adaptations through initiation of gene expression programs. Previous studies on AMPK in human skeletal muscle have analyzed protein expression and activation in whole muscle biopsy samples, though more recent studies show AMPK protein expression is highly dependent on myosin heavy chain (MHC) fiber type. Additionally, transgenic animal studies indicated AMPK regulates exercise-induced MHC fiber type conversion. **PURPOSE:** Evaluate methods of detecting human skeletal muscle fiber type-specific expression for all known AMPK subunit isoforms. **METHODS:** Individual fibers from a tissue sample (biopsy) of the vastus lateralis were mechanically isolated under a microscope. Each fiber was partitioned with tweezers such that portions were available for both fiber typing (SDS-PAGE) and protein quantification (western blotting). Analyses of signaling kinases from single fibers present challenges regarding detection of protein from small sample sizes. To address this technical issue, we pooled several fibers (10-20) of the same type together following fiber type identification. **RESULTS:** AMPK of subunit isoform $\gamma 2$ (regulatory subunit) and $\beta 1$ (scaffolding subunit) expression is noticeably elevated in MHC I vs. MHC IIa fibers (Figure 1). This concurs with previous results for $\beta 1$, but represents the first fiber type-specific identification of $\gamma 2$. **CONCLUSIONS:** AMPK expression is detectable through our fiber type-specific method. Moreover, subunit isoform concentrations appear to differ between MHC I and MHC IIa fibers in human skeletal muscle, thus emphasizing key metabolic signaling differences between fiber types. These pilot methodological studies support future larger scale investigations of AMPK subunit isoform adaptations in single fibers at rest and in response to acute and chronic stimulations.

Western blot of AMPK subunit isoforms $\gamma 2$, $\gamma 3$ and $\beta 1$. Each lane is loaded with 10-21 fibers of the same type (MHC I or MHC IIa as identified by SDS-PAGE).

Effects Of Resistance Training During 8-week Bed-rest On Intramuscular-fat And Muscle-tissues Of The Thigh Muscle Groups

Madoka Ogawa¹, Akito Yoshiko¹, Gabriele Armbrrecht², Tanja Miokovic², Dieter Felsenberg², Daniel Belavý³, Hiroshi Akima¹.
¹Nagoya University, Nagoya, Japan. ²Freie und Humboldt Universitäten, Berlin, Germany. ³Deakin University, Burwood, Victoria, Australia. (Sponsor: Katsumi Asano, FACSM)
 Email: d0c0dem0.mad020@gmail.com

(No relationships reported)

We know that muscle tissue size is inversely associated with the amount of intramuscular fat (Akima et al. 2015). In prolonged bed-rest, atrophy of lower-limb muscle occurs, implying that an increase of intramuscular fat may occur in parallel. Successful countermeasures, such as resistance training, may also affect the amount of intramuscular fat. Given that muscles atrophy at different rates in disuse (Belavý et al. 2009), the adaptation in intramuscular adipose tissues may also muscle specific. **PURPOSE:** The purpose of this study was to quantify the effect of exercise during 8-week bed-rest on intramuscular fat and muscle tissue in individual thigh muscle groups. **METHODS:** Twenty-one men were randomized to either 8-week bed-rest with resistance exercise (TR-group, n = 13) or no exercise (CTR-group, n = 8). The training was performed 3 days a week and consisted of bilateral leg press, single and double leg heel raises, and back and forefoot raise. Axial images of the mid-thigh were taken before and after the bed-rest using magnetic resonance imaging. Intramuscular fat cross-sectional area (CSA) and muscle tissue CSA were measured in quadriceps femoris (QF), adductors (AD) and hamstrings (HM). We calculated the percent change of intramuscular fat CSA between before and after the bed-rest. **RESULTS:** After bed-rest, muscle tissue CSA in CTR was significantly decreased compared to before bed-rest in all muscle groups (p < 0.05), whereas muscle tissue CSA did not change in the TR-group. Intramuscular fat CSA in individual muscles did not change after bed-rest in either group (QF: CTR 7.3 ± 20.6 % vs. TR -38.0 ± 31.4 %, AD: CTR -3.8 ± 19.7 % vs. TR -34.2 ± 26.1 %, HM: CTR -9.6 ± 26.8 % vs. TR -33.6 ± 30.1%). However, for intramuscular fat of all muscle groups pooled a significant difference between the groups was observed with a reduction of intramuscular fat in the TR group (CTR 1.0 ± 13.9 % vs. TR -36.2 ± 28.2 %, P=0.004). **CONCLUSION:** Resistance training during 8-week bed-rest reduces thigh muscle atrophy and results in a reduction in intramuscular fat. No evidence was seen on the impact of bed-rest itself, in inactive subjects, on intramuscular fat in the thigh muscle groups.

Influence Of Dpp-iv And Cd26+ T-cells On Il-6 Following Doms Protocol In College-aged Participants

Leslie E. Neidert, Elise K. Mann, Zachary B. Rightmire, Anna M. La Mantia, Heidi A. Kluess, FACSM. Auburn University, Auburn, AL. (Sponsor: Heidi A. Kluess, FACSM)

(No relationships reported)

PURPOSE: To determine the influence of delayed onset muscle soreness (DOMS) on the relationship between dipeptidyl peptidase IV (DPP-IV), CD26+ T-cells, and interleukin 6 (IL-6) over time.

METHODS: Six college-aged participants (male n=3, female n=3) underwent an established bicep brachii DOMS protocol. Blood was collected on the DOMS induced arm via venipuncture to measure local plasma DPP-IV activity, plasma IL-6, and CD26+ activated T-cells. Plasma DPP-IV activity was measured on the contralateral arm via finger stick. DOMS was assessed with a soreness assessment scale and an algometer. All measurements were taken before, immediate post, 3, 24, and 48 hours post completion of the DOMS protocol.

RESULTS: Participants reported significantly increased soreness at 24 and 48 hours post (both p<0.05). This was supported by a decrease in pressure sensitivity at 24 hours post (p<0.05). IL-6 was significantly increased 166.1±124.3% immediately post and 164.9±91.26% 3 hours post before returning to baseline by 24 hours post. DPP-IV significantly increased 9.9±5.7% at 24 hours post and 9.3±9.6% at 48 hours post from baseline, but was not increased in the contralateral arm. No significant change in CD26+ activated T-cells over time was measured.

CONCLUSION: Following DOMS, inflammatory IL-6 may be hydrolyzed by the local release of the myokine, DPP-IV. Overall, this interaction of IL-6 and DPP-IV appears to be localized to the site of damaged muscle fibers and does not appear to be influenced by the activation of CD26+ T-cells.

Exercise-Induced Muscle Damage Reduces Critical Torque and Impulse Above End Test Torque

Darshit S. Patel. The University of Oklahoma, NORMAN, OK.
 (Sponsor: Kevin K McCully, FACSM)
 Email: darpatel7@ou.edu

(No relationships reported)

Exercise-induced muscle damage (EIMD) has been shown to reduce endurance exercise performance. However, the mechanism(s) underlying this reduction remain unclear. **PURPOSE:** This study sought to examine the effects of EIMD on critical torque (CT) and impulse above critical torque (IACT). **METHODS:** Eight participants performed a 5-minute all-out isometric knee extension test with a duty cycle of 3:2 (3 seconds of contraction followed by 2 seconds of rest) prior to and 48-hours following EIMD. EIMD was induced by performing electrically stimulated eccentric knee extensions (in sets of 10) until maximal voluntary isometric strength (MVC) was reduced by 40%. The magnitude of EIMD was assessed 48-hours following eccentric exercise by changes in MVC and ratings of quadriceps muscle soreness (using a 100mm VAS scale). Surface EMG and near-infrared spectroscopy (NIRS) were collected from the vastus lateralis and vastus medialis, respectively during the CT test to assess muscle activation and microvascular circulation. **RESULTS:** MVC decreased 22% from baseline (p = 0.006) and soreness increased from 2.1 ± 1.9 mm to 50.4 ± 31.5 mm (p = 0.002) confirming EIMD occurred. CT was declined from 61.6 ± 17.8 Nm to 52.0 ± 14.1 Nm (-16%; p = 0.005) post EIMD. IACT declined 31% (p = 0.0006) post EIMD. No changes were observed in EMG assessed muscle activation between bouts (p ≥ 0.28) and NIRS assessments of tissue saturation (p > 0.05) and deoxyhemoglobin (p > 0.05). **CONCLUSIONS:** CT was significantly impacted by EIMD. CT has been shown to be a strong predictor of endurance exercise performance—thus the previously observed decrements in endurance performance following EIMD may be attributed to a decline in CT. Interestingly, EIMD affected IACT to a much greater extent than CT (-31% vs. -15%). IACT is thought to represent a finite energy store, likely anaerobic in nature, that can be used to perform exercise above CT. Our findings indicate EIMD significantly reduces this energy store—potentially through impairments in excitation-contraction coupling.

2685 Board #205 June 2 11:00 AM - 12:30 PM
Myogenic And Atrophic Signaling In The Progression Of Cancer-cachexia

Thomas A. Blackwell¹, Jacob L. Brown¹, David E. Lee¹, Megan E. Rosa-Caldwell¹, Richard A. Perry Jr¹, Lemuel A. Brown¹, Wesley S. Haynie¹, Michael P. Wiggs², Tyrone A. Washington¹, Nicholas P. Greene¹. ¹University of Arkansas Fayetteville, Fayetteville, AR. ²University of Texas-Tyler, Tyler, TX. (Sponsor: Stephen F. Crouse, FACSM)

Email: thomasallenblackwell@gmail.com

(No relationships reported)

Cancer is a major public health problem in the U.S. and the world. In 2013 there were an estimated 1,660,290 new cases of cancer in the U.S. Severe weight and muscle loss in cancer (cancer-cachexia [CC]) is accepted as a common effect of many cancers, and is directly responsible for 20-40% of cancer-related deaths. The mechanisms that control the development of CC are not well understood. In order for muscle wasting to occur, there must be either a decrease in myogenic factors or an increase in catabolic factors. Most investigations of CC focus on the post-cachectic state and do not examine the progression of the condition. **PURPOSE:** The purpose of this study is to determine the roles of classical myogenic factors (Pax7, MyoD and Myogenin; markers of satellite cell content and regulators of myocyte proliferation and differentiation, respectively), and catabolic factors (Atrogin and MuRF; E3 ubiquitin ligases regulating ubiquitin-mediated protein degradation) in the onset of CC. **METHODS:** : 1x10⁶ Lewis Lung Carcinoma cells (LLC) or Phosphate Buffered Saline (PBS, control) were injected into the hind-flank of normal wildtype C57BL6/J mice at 8 wks of age, and tumor allowed to develop for 1, 2, 3, or 4 wks, gastrocnemius muscle weights were measured to assess CC. MyoD, Myogenin, Atrogin, MuRF, and Pax7 were analyzed using RT-PCR for all 5 groups (1, 2, 3, 4 wk LLC and PBS). Data were analyzed by one-way ANOVA, Student-Newman-Keuls test was used to determine differences among means, significance was set at P<0.05. **RESULTS:** Gastrocnemius muscle weights were only lower than PBS control at 4 wk post tumor-implantation. Pax7 was ~30% lower at all timepoints following tumor implantation. MyoD and Myogenin were ~50% lower in wks 1 and 2 post-tumor implantation, and returned to baseline for wks 3 and 4. Atrogin was ~3.5-fold greater in wk 4, while MuRF was ~2.3-fold higher in wk 3 and ~3.8-fold in wk 4 post-tumor implantation. **CONCLUSIONS:** Our data suggest a reduction in satellite cell content shortly after tumor implantation in mice which is tied to an early reduction in markers of myogenic differentiation and proliferation though muscle loss is not evident until 4 wk post tumor implantation; while MuRF and atrogin mediated protein degradation does not seem to be altered until later in tumor progression.  Email: marcosmoniconeto@gmail.com
 (No relationships reported)

Sleep deprivation (SD) increase catabolic hormone concentrations and decrease growth factors, which may impair the muscle regeneration. **PURPOSE:** Evaluate the influence of SD on the muscle regeneration, cellular proliferation and muscular insulin-like growth factor-1 (IGF-1) concentration after cryolesioning in rats. **METHODS:** Forty male rats, Wistar, 3 month, were distributed into 4 groups: Control (CTL), submitted to SD for 96h (SD96), CTL plus sleep recovery period (CTL+R), submitted to SD for 96h plus 96h of sleep recovery (SD96+R). Previously, the animals were submitted to cryolesioning of *Tibialis anterior* (TA) from left leg. After 3 days of recuperation, SD96 and SD96+R groups were sleep deprived for 96h by modified multiple platform method, following of sleep recovery for 96 h to SD96+R group. TA of both legs were excised (intact and injured) to histopathologic analysis (with HE, 40x), PCNA (western blot) and muscular IGF-1 (ELISA) analysis. The data were analyzed by one way ANOVA. **RESULTS:** The concentration of IGF-1 in intact leg was reduced in SD96 compared to CTL (356±27 vs 816±105 ng/dL respectively; $P<0.05$), and the basal values were reestablished in SD96+R group (776±69 ng/dL). In injured leg, the concentration of IGF-1 increased in all groups, but with less magnitude in SD96 compared to CTL (1442±256 vs 3851±249 respectively; $P<0.001$) and SD96+R compared to CTL+R (1605±260 vs 2307±182 ng/dL respectively; $P<0.001$). PCNA protein not change with SD, but injury increased its concentration proportionally in all groups when compared to intact leg (CTL - 1.88±0.22 vs 0.46±0.13 AU respectively; SD96 - 2.4±0.6 vs 0.62±0.12 AU respectively; CTL+R - 1.68±0.35 vs 0.55±0.08 AU respectively; SD96+R - 1.4±0.13 vs 0.71±0.05 AU respectively; $P<0.05$ for all). The qualitative histopathologic analysis showed a delay in process of muscle regeneration, with higher amounts of fibrous tissue, inflammatory process and muscle atrophy in SD96+R group compared to CTL+R. **CONCLUSION:** SD reduced muscular IGF-1 concentration and delayed the muscle regeneration stimulated by cryolesioning in TA of rats. Supported by CEPID/SONO-FAPESP (#98/14303-3), CNPq, CAPES, and FAPESP (#2011/15962-7; 2013/00152-5)

Effects Of Muscle Specific Pgc-1a Overexpression At The Onset Of Muscle Regeneration
 Wesley S. Haynie, Richard A. Perry, Lemuel A. Brown, David E. Lee, Jacob L. Brown, Megan E. Rosa-Caldwell, Nicholas P. Greene, Tyrone A. Washington. *University of Arkansas, Fayetteville, AR.*
 (No relationships reported)

Peroxisome proliferator-activated receptor- γ coactivator-1 α (*PGC-1 α*) is a transcriptional activator shown to stimulate mitochondrial biogenesis. Impaired muscle regeneration is associated with down-regulation of *PGC-1 α* . However, in healthy muscle *PGC-1 α* expression is unaltered. Therefore, the role of *PGC-1 α* at the onset of skeletal muscle regeneration needs further elucidation. **PURPOSE:** To examine the effects of overexpression of *PGC-1 α* on gene expression of lactate dehydrogenase (*LDH*), *TNF- α* , and myogenesis markers *MyoD* and *Myogenin* at the onset of muscle regeneration. **METHODS:** 23 C57BL/6 (WT) and 24 Transgenic (A1) mice were used for this study, with A1 mice overexpressing the protein *PGC-1 α* . Mice were injected with either PBS or Bupivacaine (MAR) at 12 weeks of age. *Tibialis anterior* (TA) muscle and tibia were excised 3-days post injection. Tissue was immediately frozen for gene expression analysis using RT-qPCR. **RESULTS:** There was no difference between TAmass/Tibia length ratio in any mice 3-days post injection. *PGC-1 α* gene expression was 13-fold greater in the A1-PBS group compared to the WT-PBS group ($p<0.05$). The A1-MAR group however, expressed approximately 4-fold less *PGC-1 α* compared to the A1-PBS group 3-days post injection ($p<0.05$). In WT mice, *MyoD* gene expression was 1.5 fold greater in the MAR group compared to the PBS group ($p<0.05$), with no difference between A1 mice. There was a main effect of MAR to increase *Myogenin* gene expression in both WT and A1 mice. There was a main effect of genotype to decrease *LDH-A* expression ~50% in both A1 groups ($p<0.05$). There was a 4-fold increase in *LDH-B* expression in the A1-PBS group compared to the WT-PBS group ($p<0.05$). In WT mice, there was no effect of MAR on *LDH-B* gene expression. However, in A1 mice there was a 50% decrease in the A1-MAR group compared to the A1-PBS group ($p<0.05$). *TNF- α* increased approximately 2-fold as a main effect of genotype in both A1 groups ($p<0.05$). **CONCLUSION:** A surplus of mitochondria may result in more ROS production and higher levels of *TNF- α* , resulting in altered expression of *MyoD*. With *TNF- α* possibly activating *NF- κ B*, a nuclear

factor shown to negatively regulate myogenesis. The differential response in *LDH-B* expression suggests *PGC-1 α* is involved in altering glycolytic energy metabolism at the onset of muscle regeneration.

Reliability and Comparison of Measurements of the Tibialis Posterior Cross-Sectional Area Via Ultrasound Imaging
 Victoria A. Violette, Sarah T. Ridge, Dustin Bruening, J W. Myrer, A. W. Johnson. *Brigham Young University, Provo, UT.*
 (Sponsor: Pat Vehrs, FACSMS)
 (No relationships reported)

PURPOSE: The tibialis posterior is a key muscle in controlling the medial longitudinal arch. Being able to assess the strength, activity and size of the muscle is crucial in understanding its role in controlling the functions of the foot. Difficulties exist in directly imaging this muscle due to the depth of its origin within the leg. This study's purpose was to evaluate techniques used to image the TP muscle size using ultrasound. **METHODS:** 10 legs of 5 healthy college students were imaged via ultrasound (12ML probe, GE Logiq P6) and the cross-sectional area and thickness of the TP was recorded. To measure the TP the probe was held at the 30% and then the 50% point from the knee joint line to the inferior tip of the lateral malleolus. Subjects inverted their foot and videos of the contraction cycle were recorded. 2 separate still-shots of the muscle at rest were saved from the recorded videos to make size measurements. This process was performed on both anterior and posterior sides of the leg. To assess reliability intraclass correlation coefficients (ICC) were calculated. A correlation was performed to compare anterior to posterior measurements. **RESULTS:** Excellent reliability was seen when comparing repeated measurements for anterior and posterior area and thickness measurements at the 30% point (ICC>0.96). There was a strong significant correlation between anterior and posterior measurements at the 30% mark ($r=0.91$, $p<0.001$). There was a non-significant weak correlation between anterior and posterior measurements at the 50% ($r=0.31$, $p=0.19$). The means and standard deviations of the cross-sectional area from the posterior view TP were 4.35 ± 0.49 cm² (30%) and 3.78 ± 0.47 cm² (50%). While the anterior view cross-sectional areas were 4.18 ± 0.49 cm² (30%) and 3.42 ± 0.46 cm² (50%). **CONCLUSION:** Repeated measurements showed excellent reliability. At the 30% point, the anterior and posterior measurements were highly correlated, thus either position could be used to image the TP. The anterior view, at the 50% should generally not be used because portions of the TP were often hidden behind bone which decreased accuracy of the measurement.

Thigh Muscle Architecture Changes During a Soccer Season in Previously Injured and Non-injured Female Athletes
 Alexa Kasl¹, Kazuma Akehi², Whitney Ryan², Scott Unruh², Matthew Bice². ¹University of Nebraska Medical Center - Kearney, Kearney, NE. ²University of Nebraska at Kearney, Kearney, NE.
 Email: kasla2@loppers.unk.edu
 (No relationships reported)

Very little research has investigated muscle morphological and architectural characteristic changes on the individual thigh muscles during a competitive season in previously injured and non-injured collegiate athletes. Such research may provide important insight into sport-induced anatomical changes, which could have a significant impact on muscle performance and injury risks. **PURPOSE:** To examine the influence of competitive women's college soccer participation on thigh and hamstring muscles' morphological and architectural characteristics. **METHODS:** Eighteen soccer players (Previously injured n=8, age=20.43±0.90 yrs; Non-injured n=10; age=20.31±1.38 yrs) volunteered to participate in the study. Participants reported a total of 4 times separated by 4 weeks during the season and underwent ultrasound testing to assess changes in muscle thickness (MT; cm), subcutaneous tissue thickness (ST; cm), pennation angle (PA; °), and echo intensity (EI) of the rectus femoris (RF), vastus medialis (VM), vastus medialis oblique (VMO), vastus lateralis (VL), vastus intermedius (VI), and biceps femoris (BF) muscles and thigh circumference measures using a tape measure. A 3-way (dominant side of the leg x injury history x time) ANOVA with repeated measure was used to analyze each variable. When interactions were present, Tukey-Kramer multiple comparison post-hoc tests were used. **RESULTS:** MT of the RF, VI, VM, and VMO muscles increased between 4.4 and 14.5% at week 4 and 8 during the season ($P<0.02$) regardless of the dominant side of the leg or injury history. EI of RF, VL, and VM muscles decreased between 3.1 and 8.1% at week 4 and 8 during the season ($P<0.01$). **CONCLUSION:** These results indicated that, muscle size and quality had improved in non-injured athletes but had diminished in those who were previously injured. Because no time-related differences in thigh circumference measures were observed it is possible that these measures may not be sensitive enough for detecting morphological changes. Given the relationship between muscle size and quality, it is possible that these

unique morphological and architectural adaptations over time may influence athletic performance and/or potential risks of musculoskeletal injuries; however, future studies are needed to test these hypotheses.

Muscle Volume Is A Critical Determinant Of Rowing Performance In Olympic Rowers

Stephan van der Zwaard¹, Guido Weide¹, Koen Levels¹, Michelle Eikelboom¹, Dionne A. Noordhof¹, Mathijs J. Hofmijster¹, Willem J. van der Laarse², Cornelis J. de Ruiters¹, Jos J. de Koning, FACSM¹, Richard T. Jaspers¹. ¹Vrije Universiteit, Amsterdam, Netherlands. ²VU University Medical Center, Amsterdam, Netherlands. (Sponsor: Jos de Koning, FACSM)
Email: s.vander.zwaard@vu.nl
(No relationships reported)

BACKGROUND: Rowing races challenge rowers to combine high sprint and endurance capacity. Muscle morphology is an important determinant of sprint and endurance capacities and as such may also be a critical determinant of rowing performance.

PURPOSE: To determine how much of the rowing performance of Olympic rowers is explained by sprint and endurance capacity and by muscle morphology.

METHODS: 18 elite rowers (12 male, 6 female and 17 competed in different disciplines at the 2016 Olympics) performed a maximal incremental rowing test to obtain $\dot{V}O_{2max}$, reflecting the endurance capacity. Sprint capacity was assessed by a 30-second Wingate cycling test and maximal isometric knee extension torque. Morphology of m. vastus lateralis (volume, physiological cross-sectional area (PCSA), fascicle length and pennation angle) was derived from a 3D ultrasound reconstructed voxel array. 13 rowers completed a 2000m time trial on a rowing ergometer to assess rowing performance. Coefficients of determination were obtained from multiple and single regression analyses.

RESULTS: Rowing performance was largely explained by absolute maximal oxygen uptake combined with peak power output obtained during the Wingate test ($R^2=0.98$, $p<0.001$). Muscle volume largely explained rowing performance ($r^2=0.85$, $p<0.001$) and was strongly related to Wingate peak power output ($r^2=0.82$, $p<0.001$), $\dot{V}O_{2max}$ ($r^2=0.65$, $p<0.0001$) and maximal isometric knee extension torque ($r^2=0.60$, $p<0.001$). Less variance in rowing performance was explained by PCSA ($r^2=0.68$, $p<0.001$) and fascicle length ($r^2=0.43$, $p<0.05$) and none by pennation angle ($r^2=0.00$, $p=0.774$).

CONCLUSION: Rowing performance of Olympic rowers is excellently explained by $\dot{V}O_{2max}$ and Wingate peak power output ($R^2=0.98$). Muscle volume, of all morphological properties, is the most important determinant of rowing ergometer performance, and endurance and sprint capacity in Olympic rowers.

Effects Of Time-of-day Specific Resistance Training On Muscle Strength And Muscular Il-6-associated Signaling In Male Rats

Szu-Hsien Yu¹, Shueh-I Lin¹, Shih-Chang Cheng¹, Chung-Pu Chi², Chia-Hua Kuo, FACSM³. ¹National ILan University, Yilan City, Taiwan. ²Taipei Medical University, Taipei, Taiwan. ³University of Taipei, Taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)

(No relationships reported)

PURPOSE: Muscle mass and strength play an important role in athletic sports and health promotion. Although resistance training (RT) is known to be effective for muscle mass improvement, the optimal daily timing of RT and feeding has not yet been determined. The purposes of the present study are to investigate the best daily timing of RT for the muscle hypertrophy in male rats.

METHODS: In study I, SD rats were divided into Control (C, non-exercise), Early (E, beginning of active phase, 8:00) and Late (L, end of active phase, 17:00). Rats of exercise groups (E and L) were asked to perform RT by climbing for 10 weeks in beginning and end of active phase respectively. Climbing strength and weight of flexor hallucis longus (FHL) and flexor digitorum profundus (FDP) was determined after 10 weeks training. In study II, rats were divided into E (Early) and L (Late) groups and were performed an acute RT by climbing. FDP muscle samples were obtained 2, 6 and 24 hours after RT.

RESULTS: In study I, we observed that 10 weeks RT improve muscle strength, muscle mass and myofiber cross sectional area (CSA), but these training effects do not show any significant difference between E and L groups. In study II, acute RT in the evening induced more plasma testosterone/cortisol and IL-6, and muscular IL-6 associated signaling such as phosphorylation of STAT1 and STAT3 compared to training in the morning.

CONCLUSIONS: we suggest that resistance exercise-induced IL-6 signal in skeletal muscle is not the main source of 10 weeks resistance training adaptation.

Characterization of Protein Metabolism in Undifferentiated and Differentiated Murine Muscle Tissue

Jessica M. Cardin, J. William Deaver, Colleen L. O'Reilly, Stephen F. Crouse, FACSM, James D. Fluckey. *Texas A&M University, College Station, TX.* (Sponsor: Stephen F. Crouse, FACSM)
(No relationships reported)

The emergence of cell culture experiments have greatly expanded the understanding of skeletal muscle physiology. However, there is a paucity of data regarding the behaviors of cells grown in culture at various stages versus in vivo. This preliminary set of studies was designed to assess alterations of anabolic responses between undifferentiated and differentiated muscle tissue.

Purpose: Determine if there is a disparity in fractional synthesis rates (FSR) between C2C12 myoblasts and myotubes.

* 100

Methods: C2C12 cells were plated at 200,000 cells per T25 flask and 600,000 cells per T75 flask with 5 mL and 12 mL DMEM (respectively) supplemented with 20% Fetal Bovine Serum and 1% gentamycin. Cells were cultured in an environment at held at a constant 37°C and 5% CO₂. Once cells reached confluence, media was changed to DMEM supplemented with 2% horse serum 1% gentamycin, 5% HEPES, 0.75% transferrin, and 0.75% insulin. Myoblasts were plated after the 4th passage. Deuterium oxide was applied 24 hours prior to harvest of the cells at a level of 4%. Media containing deuterium oxide was reserved for analysis. Cells were washed with multiple applications of PBS. Norris buffer was then applied to the flasks at 100 uL for T-25's and 300 uL for T-75's. Flasks were then placed on ice for 5 minutes. Cells were harvested and deposited into centrifuge vials. Vials were spun at 14,000 G for 30 minutes to separate cytosolic and myofibrillar fractions. The supernatant (containing the cytosolic fraction) from the vial was decanted into another vial and saved for analysis. 2H-alanine and plasma enrichment was determined by GC-MS and FSR was calculated by:

Results: Preliminary data demonstrates that differentiated murine myotubes have ~76% FSR of the undifferentiated murine myoblasts ($P < 0.005$).

Conclusion: Future investigators must be aware of the ratio of undifferentiated cells and differentiated myotubes as this ratio could confound results as myoblasts are still present even at later stages of differentiation.

Partial or Complete Unloading of Skeletal Muscle Leads to Specific Alterations of Anabolic Signal Transduction

Colleen L. O'Reilly¹, J William Deaver¹, Michael P. Wiggs², Florence Lima¹, Joshua M. Swift³, Elizabeth S. Greene⁴, Susan A. Bloomfield, FACSM¹, James D. Fluckey¹. ¹Texas A&M University, College Station, TX. ²UT-Tyler, Tyler, TX. ³USUSH, Bethesda, MD. ⁴University of Arkansas, Fayetteville, TX. (Sponsor: Susan A Bloomfield, FACSM)
(No relationships reported)

Consequences of disuse atrophy of skeletal muscle observed during spaceflight on astronaut health and performance are a focal point of space research. Decrements of both muscle mass and protein synthesis rates have been observed with exposure to varying muscle loading environments (1G > partial loading > 0G), and most of the reduced muscle mass can be attributed to diminished rates of synthesis. However, specific mechanisms behind unloading-dependent reductions of protein synthesis are not well defined. **PURPOSE:** To determine whether or not alterations of anabolic signal transduction was responsible for the changes previously observed in fractional synthesis rates with specific gravitational loading paradigms. **METHODS:** Female BALB/cByJ were normalized by bodyweight and assigned to normal cage ambulation (1G), partial weight bearing suspension titrated to approximately 33% bodyweight (G/3), partial weight bearing titrated to 16% bodyweight (G/6) and full unloading of hind limbs (0G) in specially designed cages. All mice were subjected to that loading environment for 21d prior to tissue harvest, and monitored daily. Immunoblotting of the gastrocnemius (n=23) was carried out to analyze alterations of anabolic signal transduction. Although numerous signaling intermediates were assessed, the focus of this abstract will be on ribosomal protein S6 kinase (p70-S6K). This important protein has served as a marker of protein synthesis signal transduction as well as the anabolic capacity in skeletal muscle. **RESULTS:** Regardless of loading paradigm, no differences were detected among groups for the activation of p70-S6K (as indicated by the phospho: total protein content). Total protein content, however, was ~27% lower than control in 0G and G/6 ($P=0.008$) with G/3 not being different from control ($P>0.05$). **CONCLUSION:** In combination with previous data (unpublished

observations), ambulation at G/3 is sufficient to maintain anabolic signaling capacity when compared to G/6 or 0G, suggesting that a threshold level of stimulus is necessary to maintain anabolic capacity in muscle. These results may have important implications towards the development of strategies designed to counter the effects of partial/complete unloading on skeletal muscle based on how the anabolic capacity of muscle is affected.

Age-Based Developmental Comparison of Phase Angle and Ultrasound-Derived Echo Intensity

David H. Fukuda, Eliott Arroyo, Kyle S. Beyer, Jay R. Hoffman, FACSM, Jeffrey R. Stout, FACSM. *University of Central Florida, Orlando, FL.* (Sponsor: Jeffrey Stout, FACSM)
 Email: david.fukuda@ucf.edu
 (No relationships reported)

Phase angle, determined from resistance and reactance via bioelectrical impedance analysis (BIA), provides an indication of cellular function and hydration. Ultrasound-derived echo intensity (EI) is often used to evaluate the relative variation in the composition of underlying tissue. Assessment of these non-invasive methods may allow for characterization of age-based developmental changes related to body composition. **PURPOSE:** To examine phase angle and EI amongst children, adolescents, and adults. **METHODS:** A total of 36 male children (n=11; age=12.7±1.4y), adolescents (n=13; 16.7±1.0), and adults (n=12; 25.8±3.8y) were compared. Whole body (PhA_{WB}) and leg (PhA_{DL}) phase angle were determined using 50kHz BIA. Greyscale analysis was used to determine EI from ultrasound-derived images of the cross-sectional area of the vastus lateralis. Phase angle and EI between age-based developmental groups were compared by 1-way ANOVA, while stepwise linear regression was used to evaluate relationships between these measures and the potential influence of age and body mass index (BMI). **RESULTS:** Significant differences were demonstrated between age-based developmental groups for PhA_{WB} (p<0.001), PhA_{DL} (p=0.002), and EI (p<0.001). Post-hoc analysis showed lower phase angle (p<0.05) in children (PhA_{WB} =5.4±0.6°; PhA_{DL} =5.9±0.8°) compared to adolescents (PhA_{WB} =6.4±0.8°; PhA_{DL} =6.8±0.9°) and adults (PhA_{WB} =6.9±0.6°; PhA_{DL} =7.2±0.7°). EI was greater (p<0.001) in children (57.2±10.6 au) compared to adolescents (40.0±6.8 au) and adults (41.4±7.9 au). PhA_{WB} was identified as the strongest predictor variable for EI ($r^2=0.211$; p=0.005), while age and BMI were identified as the strongest predictor variables for PhA_{WB} ($r^2=0.442$; p<0.001) and PhA_{DL} ($r^2=0.384$; p<0.001), respectively. **CONCLUSION:** Phase angle and EI appear to distinguish changes in body composition between childhood and adolescence; however, further developmental changes were not apparent into adulthood. Each measure was found to be uniquely influenced by other factors, including age and BMI. Longitudinal evaluation of phase angle and EI amongst children and adolescents may provide much needed insight into the process of maturation.

 (No relationships reported)

Age-related changes in sleep are broadly documented and complaints of sleep difficulties are more common among older adults. Although sleep disorders are viewed as a health threat in several physiological systems, it is unclear how high lean mass and muscle attenuation, markers of sarcopenia, are affected by sleep.

PURPOSE: This study aimed to examine the association between 24-hour sleep duration and mid-thigh muscle composition.

METHODS: 2,438 men and 3,326 women aged 66 to 96 years, residents in the Reykjavik area (Iceland), were included in this cross-sectional study. Mid-thigh muscle area (cm²) and muscle attenuation (Hounsfield units, HU) were assessed with a four-row detector computed tomography system. The muscle attenuation was used as an indicator of muscle fat infiltration; lower HU indicates greater fat infiltration. Sleep and nap habits were assessed using a questionnaire. Total 24-hour sleep duration was estimated as the sum of nighttime sleep hours and daytime nap hours. Statistical analysis was performed using multivariable linear regression.

RESULTS: We found that after adjustment for age and body mass index (BMI) long sleep duration (>8 h/day) was negatively associated with thigh lean area in both men (B=-2.2, 95% confidence interval (CI)=-4.0, -0.4) and women (B=-2.9, 95% CI=-3.8, -1.0) and with muscle attenuation (B=-1.0, 95% CI=-1.5, -0.4) only in women.

After adjustments for all relevant covariates (including age, BMI, health and lifestyle factors) the association between long sleep duration and thigh lean area was attenuated and became non-significant. In women, the associations between long sleep duration and muscle attenuation were significant in both the age and BMI- and the full-adjusted model. In men these associations were not significant. No associations were observed for short sleep duration (<6 h/day) and both muscle parameters.

CONCLUSIONS: Long sleep duration, particularly in old women, is associated with thigh muscle attenuation. Whether optimization of sleep can ameliorate age-associated intramuscular adipose tissue warrants further studies.

 (No relationships reported)

PURPOSE: We reported in a previous study (ACSM's 62th Annual Meeting) that the transcutaneous vacuum (dermal suction) increased range of motion of voluntary movement and induced the smoothness of movement. No study has reported that transcutaneous vacuum improved the gliding function and flexibility of muscle and fascia. This study aimed to show that fascial gliding occurs during transcutaneous vacuum treatment and to investigate whether the transcutaneous vacuum treatment improved fascial gliding function of the vastus lateralis muscle using ultrasound.

METHODS: Seven volunteers (age: 21-60) participated in this study. Transcutaneous vacuum treatment (vacuum and rolling) was applied to both left and right vastus lateralis muscle. Deep fascial motion when the knee joint was moved passively from 0 to 45 degree was measured by B-mode ultrasound before and after treatment. Deep fascial motion during this treatment was measured for five volunteers. Measurement was performed at the deep fascia between the vastus lateralis and vastus intermedius muscles. Data were statistically evaluated using two-way ANOVA (subject, [left or right] side, treatment effect [before or after treatment]) and post hoc test.

RESULTS: Motion of deep fascia (mean ± SD, mm) before treatment was 26.8 ± 7.57, the same as the result of the previous study (28.5 ± 4.3). Motion of deep fascia after transcutaneous vacuum treatment was 32.2 ± 7.39, the same as the motion after myofascial release treatment of the previous study (32.4 ± 4.0; Ichikawa et al., 2015). There was no interaction between either side (left or right). However, the treatment effect was significant, and motion after was longer than motion before (F=28.78, p<.01, effective size = 2.19, power = 1.000) analysed by ANOVA. Deep fascial motions during treatment were 5.6±2.35 mm superficial layer and 6.3 ± 2.19 deep layer.

CONCLUSIONS: In this study, the effects of transcutaneous vacuum treatment on improvement of fascial gliding function, and fascial gliding during transcutaneous vacuum were demonstrated. Transcutaneous vacuum provided mild myofascial stimulation without requiring articular movement. We concluded that transcutaneous vacuum treatment effectively improved fascial gliding function and increased range of joint motion and flexibility of muscle and fascia.

 (No relationships reported)

PURPOSE: Effects of exercise on the disease phenotype in neuromuscular disease mouse models is not systematically evaluated. Therefore, we have designed a preclinical trial in the mdx mouse model of Duchenne muscular dystrophy to specifically investigate the effects of forced downhill and horizontal treadmill exercise as well as voluntary wheel exercise. We assessed effects of exercise intervention on the muscle function and pathology using a comprehensive set of phenotyping measures. **METHODS:** This study involved a group of 12 week old wild-type BL10 (dystrophin sufficient) mice and a group of mdx (dystrophin deficient) mice. Each group was

divided into 4 exercise regimen groups (n=5): No exercise, downhill treatment (DT), horizontal treatment (HT), and voluntary wheel exercise (VW). The groups were subjected to exercise 3x per week for 13 weeks. Skeletal muscle function (grip strength) was evaluated at 12, 17, and 25 weeks of age and cardiac function was evaluated using echocardiography at 25 weeks of age.

RESULTS: Exercise intervention did not show a change in bodyweights of the BL10 mice. However, these mice showed significant improvement in hindlimb (HL) but not forelimb (FL) grip strength in comparison to non-exercised group. Analysis of the serum showed that the creatine kinase (CK) levels in the VW group significantly increased compared to the non-treated group. All three exercise interventions showed significant decreases in body weight at 25wks of age of mdx mice. Dystrophin deficient mdx mice showed different effects on muscle function depending on the exercise regimen. DT exercise was significantly detrimental to HL grip strength, while VW exercise showed significant improvement on HL grip strength over time. Evaluation of cardiac function (% ejection fraction and fraction shortening) showed that HT and VW but not DT interventions showed significant improvement. Analysis of CK levels showed that the VW group significantly increased compared to the non-treated group.

CONCLUSIONS: Our study demonstrates that type of exercise intervention significantly affects dystrophin deficient skeletal and cardiac muscle function. Our study highlights that mild but not strenuous (DH) exercise regimen show benefits in DMD muscle therefore caution must be taken when prescribing exercise regimes to DMD patients.

Cancer-cachexia Upregulates Autophagy Machinery

Jacob L. Brown, 72701¹, Megan E. Rosa-Caldwell¹, David E. Lee¹, Thomas A. Blackwell¹, Richard A. Perry¹, Lemuel A. Brown¹, Wesley S. Haynie¹, Michael P. Wiggs², Tyrone A. Washington¹, Nicholas P. Greene¹. ¹University of Arkansas, Fayetteville, AR. ²University of Texas-Tyler, Tyler, TX. (Sponsor: Stephen F. Crouse, FACSMD)
 Email: jlb024@email.uark.edu
 (No relationships reported)

Cancer is associated with severe weight and muscle loss (cancer-cachexia). Cancer-cachexia is the most common manifestation of the advanced malignant disease, leading to death. Underlying mechanisms of cancer-cachexia are not well understood. Muscle wasting is associated with an imbalance of protein turnover favoring protein breakdown. Autophagy is a mechanism for protein breakdown that has not been adequately studied throughout the progression of cancer-cachexia. **PURPOSE:** Assess autophagy machinery and flux throughout the progression of cancer-cachexia. **METHODS:** 1x10⁶ Lewis Lung Carcinoma cells (LLC) or Phosphate Buffered Saline (PBS, control) were injected into the hind-flank of C57Bl6/J mice at 8 weeks age, and tumor allowed to develop for 1, 2, 3 or 4 weeks. Muscle size was assessed by muscle wet weights. Immunoblot was utilized to measure protein content of Beclin1, LC3, LC3 2:1 ratio and p62. A One-Way ANOVA was utilized to detect statistical significance with a Student-Newman-Keuls post hoc analysis to delineate differences between groups significance was set at P=0.05. **RESULTS:** Protein content of Beclin1 and total LC3 increased by 2 fold 4 weeks following tumor implantation when compared to the PBS control group. There was no difference in the protein content of p62 or the LC3 2:1 ratio throughout the progression and cancer-cachexia. **CONCLUSIONS:** Our results indicate autophagy machinery is dramatically upregulated 4 weeks following tumor implantation suggesting autophagy may be a key regulator of cancer-cachexia. Autophagy flux does not appear to be influenced by cancer-cachexia; however, steady rates of autophagy flux with an increase in autophagy machinery may suggest an increase in protein/organelle breakdown via autophagy. Mechanisms behind the upregulation of autophagy machinery in cancer-cachexia are not fully understood; however, energy stress instigated by mitochondrial degeneration may be involved. Estimation of Critical Torque Using Neuromuscular Electrical Stimulation of the Quadriceps in Humans.

Natalie R. Janzen, Christopher D. Black. University of Oklahoma, Norman, OK. (Sponsor: Kevin McCully, FACSMD)
 Email: natalie.r.janzen-1@ou.edu
 (No relationships reported)

Critical torque (CT) is an integrative measure/concept that represents the “critical” or upper boundary of steady-state work that can be performed without leading to exhaustive fatigue. While this concept has been observed across multiple voluntary exercise modalities, it has not been tested using neuromuscular electrical stimulation (NMES). **PURPOSE:** The purposes of this study were 1) to determine if NMES exercise results in hyperbolic work-duration pattern that plateaus at the end of exercise and 2) determine if NMES exercise performed below CT results in no fatigue. **METHODS:** Participants (n = 9) were tested. Following familiarization, participants

completed 2 identical testing sessions each consisting of four separate 5-minute NMES bouts separated by 20 minutes of rest. The NMES protocol consisted of 3-seconds of stimulation, followed by 2-seconds of rest, for 60 total isometric contractions. Current and pulse duration (200- μ s) were held constant among all tests. Initially 100 Hz NMES was used. During the second test a frequency that elicited a torque value below the end test torque during the 100 Hz test (under CT) was used. The third and fourth tests were at 50 Hz and 25 Hz, applied in a random order. The second testing session was performed 2-7 days later. **RESULTS:** End-test torque (ETT) was calculated as the mean of the last 6 contractions expressed relative to peak torque. Torque values did not differ over the final 6 contractions within each exercise bout—100 Hz (p = 0.49), 50 Hz (p = 0.15), 25 Hz (p = 0.31), and under CT (p = 0.15). Torque declined from 93 \pm 18% to 22 \pm 7% of peak torque at 100 Hz, from 60 \pm 24% to 22 \pm 8% at 50 Hz, and from 29 \pm 13% to 20 \pm 6% at 25 Hz. These ETT values did not differ from each other (p > 0.05). Initial torque and ETT for the under CT bout did not differ (12 \pm 8% vs 11 \pm 5% of peak torque; p = 0.48), but ETT was lower than the ETT values from the 100, 50, and 25 Hz bouts (p < 0.05). **CONCLUSIONS:** Intermittent isometric NMES results in a hyperbolic work-duration relationship similar to what is observed during voluntary isometric exercise. NMES exercise above CT declined to a similar torque value regardless of stimulation frequency, while exercise under CT showed no declines in torque. These findings suggest the NMES exercise protocol can be used to determine CT.

The Effect of Myostatin SNP on Muscle Fiber Properties in Thoroughbred Horses during Training Period

Hirofumi Miyata¹, Fumio Sato², Tetsuro Hada², Teruaki Tozaki³. ¹Yamaguchi Univ., Yamaguchi, Japan. ²Japan Racing Horse Association, Hidaka, Japan. ³Laboratory of Racing Chemistry, Utsunomiya, Japan.
 Email: hiro@yamaguchi-u.ac.jp
 (No relationships reported)

PURPOSE: Variants of the myostatin gene (MSTN) have been shown to have an influence on muscle hypertrophy phenotypes in a wide ranges of mammalian species. Recently, a thoroughbred horse with a C-Allele at the g.66493737C/T single nucleotide polymorphism (SNP) has been reported to be suited to short distance racing. In this study, we examined the effect of the MSTN SNP on muscle fiber properties in young horses during a training period. **METHODS:** To investigate the effect of the MSTN SNP on muscle fiber before training, several mRNA expressions were relatively quantified in biopsy samples from the middle gluteal muscle of 24 untrained male thoroughbred horses (1.5-year old, C/C: n = 8, C/T: n = 8, T/T: n = 8) using real-time RT-PCR analysis. Furthermore, the remaining muscle samples were used for immunohistochemical analysis to determine the number of satellite cells (SC), as well as the population and area of each fiber type. All measurements were reevaluated in biopsy samples of the same horses after a 5-month period of conventional training. **RESULTS:** As compared to values before training, although there were not significant differences, cross sectional areas of all muscle fiber types increased (12-17%) in all SNP groups after training. Although the expressions of MSTN mRNA decreased in all SNP groups, a significant decrease was found in only the C/C group after training. However, the expressions of mRNA related to SCs activation and proliferation (HGF, Pax7, MyoD, and Myogenin) were identical among all SNP groups after training. While, expression of VEGFa, PGC1 α , and SDHa mRNAs, which relate to the biogenesis of mitochondria and capillaries, was significantly higher (54-82%) in the T/T group than the C/C group after training. **CONCLUSION:** It is suggested that hypertrophy of muscle fiber is directly associated with a decrease in MSTN mRNA expression in the C/C group, and that increased expressions of VEGFa, PGC1 α , and SDHa in the T/T group might be indirectly caused by the MSTN SNP. These results indicate that the C/C and T/T groups with the MSTN SNP have an advantage in short and long distance races, respectively.

Muscle Regeneration after Anterior Cruciate Ligament Reconstruction - Effects of Strength Training Regime and Different Autocrafts

Francesca Profit¹, Thomas Gwechenberger², Nadine Weiberg¹, Marc-André Weber¹, Nikolaus Streich³, Alexander Barić¹, Birgit Friedmann-Bette¹. ¹University Hospital, Heidelberg, Germany. ²University Hospital/Olympic Training Center, Heidelberg, Germany. ³Clinic St. Elisabeth, Heidelberg, Germany.
 Email: francesca.profit@med.uni-heidelberg.de
 (No relationships reported)

Quadriceps muscle atrophy is regularly observed after anterior cruciate ligament reconstruction (ACL-R) **PURPOSE:** To test the hypothesis that muscle regeneration after ACL-R can be augmented by quadriceps strength training with eccentric overload (CON/ECC+) **METHODS:** Biopsies from the vastus lateralis muscle were

obtained from 37 recreational athletes (25±4 yrs, 181±7 cm, 83.5±15 kg) after 12 weeks (wks) of regular rehabilitation following ACL-R (quadriceps tendon autograft, n=22 or semitendinosus tendon autograft, n=15) and again after 12 wks with 2x/wk either conventional (CON/ECC, n=16) or CON/ECC+ (n=21) supervised leg press training (random assignment). Immunohistochemical analyses were used to determine myosin heavy chain (MyHC) I, II and hybrid fibers to quantify fiber type specific satellite cells (SCs, Pax7+) and active SCs (Pax7+/MyoD+). Magnetic resonance imaging was performed to measure quadriceps cross sectional area (CSA) **RESULTS:** After 12 wks of one-legged quadriceps strength training CSA was significantly (p=0.000) increased with a significantly (p=0.003) greater increase after CON/ECC+ compared to CON (81.7±13.1 to 96.3±14.7 cm² vs. 78.5±12.1 to 87.0±11.8 cm²). MyHC I fiber number significantly (p=0.002) increased only after CON/ECC+ (35.7±17.1 to 41.7±15.8 %). The change was significantly (p=0.022) different from CON/ECC (36.6±13.0 to 35.1±10.4 %). MyHC I/II hybrid fibers showed a significant (p<0.001) similar decrease after CON/ECC+ (7.1±6.5 to 4.0±4.5 %) and CON/ECC (7.7±4.9 to 4.8±3.6 %). MyHC II fiber number did not change significantly. While no significant change in SC content was observed (SCs related to MyHC I or II fibers 0.15±0.08 and 0.14±0.07 before, 0.14±0.09 and 0.14±0.07/fiber after training) the number of active SCs per biopsy section was significantly (p=0.007) greater after training (2.42±2.09 vs. 1.08±1.38) without significant difference between the training regimes. No significant differences occurred with regard to the different autografts **CONCLUSION:** Strength-training induced muscle regeneration after ACL-R lead to an increase in activated SCs and a decrease in MyHC I/II hybrid fibers. After CON/ECC+ the gain in muscle mass was greatest and was accompanied by a significant increase in MyHC I fibers. Supported by the Dietmar Hopp Foundation (23011193)

Thigh Muscle Cross-sectional Area by pQCT: Precision of Two Software Programs

Samuel R. Buchanan¹, Christopher Poole², Daniel Schiferl³, Debra Bembem, FACSM¹, Michael Bembem, FACSM¹. ¹The University of Oklahoma, Norman, OK. ²Southern Methodist University, Dallas, TX. ³Bone Diagnostic Inc., Spring Branch, TX. (Sponsor: Dr. Debra Bembem, FACSM)

(No relationships reported)

Scans performed by pQCT produce images with voxels, each with a density value that is the average of all the tissue densities contained within the voxel. Software programs differentiate between bone and soft tissues within the human limb using contour/peel modes and threshold ranges. Subtle calculation differences of voxel partial volumes by software may lead to variations in tissue density and area values. **PURPOSE:** The purpose of the investigation was to compare the precision of two software programs, Stratec v6.00 (STC) and ImageJ (IMJ), for thigh muscle cross-sectional area (mCSA) in college age men. **METHODS:** pQCT scans (XCT 3000, Stratec) performed at the 50% femur site for 10 male subjects (18-30 years) on 3 different days, were used to measure femur mCSA using STC and IMJ. Loops were created within STC with thresholds set at -100, 40, and 710 to separate and calculate air, subcutaneous fat, bone, and muscle. Contmodes 3 and 31 were used to delineate bone from muscle. Filter F01F06U01 was used to smooth the image, incorporating intramuscular fat (IMAT) into mCSA. IMJ thresholds and filters for IMAT were similarly set. Intraclass correlation coefficients (ICC), coefficient of variation % (CV%), and least significant change (LSC) were calculated across trials to determine the precision for each method. The relationship between the two methods was determined by Pearson's r. **RESULTS:** The ICCs for STR and IMJ were 0.995 and 0.996, respectively. CVs were 2.5% for STR and 2.44% for IMJ. The LSCs for STR and IMJ were 10.955 cm² and 10.833 cm², respectively. High positive correlations (r=0.999, p<0.001) were found between methods. Repeated measures ANOVA showed significant differences between STR and IMJ, with IMJ having a significantly higher mCSA than STR (p=0.032). There was a significant trial effect with trial 1 being higher than trial 3 (p=0.05). **CONCLUSION:** The two software programs had similar precision values for mCSA, however, there was a small but significant mean difference between STR and IMJ. The higher trial 1 mean compared to trial 3 for both methods may be attributed to technical error. Both programs appear equally capable of deriving mCSA with IMAT included. ImageJ may be advantageous, as it does not require expertise for loop creation or user-created equations to derive mCSA, both being possible sources for human error.

Regional Differences in Musculoskeletal Adaptation Following 16-Weeks of High-Intensity Functional Training.

Wade Hoffstetter, Paul Serafini, Gerald Mangine, Yuri Feito, FACSM. *Kennesaw State University, Kennesaw, GA.* (Sponsor: Yuri Feito, FACSM)
 Email: wadehoffstetter@gmail.com

(No relationships reported)

High-Intensity Functional Training (HIFT) continues to gain traction in the fitness world; however, many questions remain about its effect in musculoskeletal adaptations. **PURPOSE:** We sought to investigate what musculoskeletal regions of interest (ROI) were affected following a 16-week HIFT program among a group of recreationally active adults. **METHODS:** Nine men (34.2±9.12 yrs, 1.78±0.05 m, 91.5±17.7 kg) and 17 women (36.3±7.84 yrs, 1.63±0.07 m, 68.5±12.8 kg) completed 16-weeks (2-5 sessions · wk⁻¹) of HIFT. Prior to training (PRE; < 2 weeks), measures of bone mineral density (BMD), bone mineral content (BMC), and lean mass (LM) were collected in the arm, leg, and axial (skeletal measures only) regions via dual-energy X-ray absorptiometry. Post-testing (POST) measurements were collected within two weeks following the conclusion of the 16-wk training program. **RESULTS:** Analysis of variance with repeated measures revealed a significant ROI x time interaction for LM (F = 436.967, p < 0.001, η² = 0.95), where greater improvements were observed in the legs (133.2%) compared to the arms (50.9%). A tendency was noted for changes in BMC across ROI's (F = 2.86, p = 0.067, η² = 0.11), where improvements occurred in the legs (1.6%, p = 0.002) but not the arms (0.14%, p = 0.689) or axial region (-0.48%, p = 0.167). **CONCLUSION:** Our data suggests that a 16-wk HIFT intervention focusing on general physical preparedness is particularly beneficial for stimulating adaptations in lower limb BMC and lean mass.

Effects of Doxorubicin Treatment and Exercise on Skeletal Muscle Function and Myogenic Regulatory Factors

Michael J. Capps, Nicole R. Wood, Raquel B. Busekrus, Reid Hayward, David S. Hydock. *University of Northern Colorado, Greeley, CO.*

(No relationships reported)

Doxorubicin (DOX) is used to treat a wide range of cancers, but its use is limited due to its toxicities. DOX treatment causes myotoxicity leading to skeletal muscle dysfunction and impairments in activities of daily living for cancer patients. Maintenance and repair of skeletal muscle involves myogenic regulator factor (MRF) signaling, and evidence suggests that DOX inhibits MRF expression. Exercise, however, attenuates many of the toxicities associated with DOX treatment, and including exercise with DOX treatment may have a positive effect on MRF expression. **PURPOSE:** To determine the effects of exercise and DOX treatment on skeletal muscle function and MRF expression. **METHODS:** Male rats were randomly assigned to sedentary+saline (SS), sedentary+DOX (SD), treadmill+DOX (TMD), resistance training+DOX (RSD), or combined endurance and resistance training+DOX (COMD). DOX groups received 1 mg/kg DOX daily for 12 consecutive days and SS received 0.9% NaCl at an equivalent volume as a placebo. TMD then trained on a motorized treadmill 5 days per week for 2 weeks, RSD animals were then housed in cages where food and water were progressively raised to force a bipedal stance for 2 weeks, and COMD rats were then housed in raised cages and treadmill trained for 2 weeks. Sedentary rats were restricted to normal cage activity during this time period. Twenty-four hours after the activity intervention, grip strength (GS) was measured, and the soleus was extracted and analyzed for expression of the primary MRFs MyoD and Myf5 using Western blotting. **RESULTS:** SD had a 29% lower GS than SS (p < 0.05), but this significant GS decline was not observed in TMD, RSD, or COMD (-10%, -5%, -2% vs. SS, respectively, p>0.05). MyoD expression was 61% lower in SD when compared to SS, but none of the activity interventions attenuated this decline (-56%, -65%, -65% vs. SS in TMD, RSD, and COMD, respectively, p < 0.05 for all comparisons). A similar Myf5 decline was observed with SD, TMD, RSD, and COMD expressing 44%, 40%, 65%, and 56% lower Myf5 than SS, respectively (p<0.05). **CONCLUSIONS:** Activity interventions protected against the DOX-induced reduction in GS, but this does not appear to be the result of changes in MRF expression suggesting that exercise-induced protection against DOX myotoxicity may not be due to mitigating decreases in primary MRF expression.

Regional Differences in Bone Mineral Density in Male Collegiate Runners with Different Foot-strike Patterns
Kevin S. Ryan, Alec C. Miller, Toni D. Uhrich, Kristof Kipp.
Marquette University, Milwaukee, WI. (Sponsor: Paula E Papanek, FACSM)
Email: kevin.ryan@marquette.edu
(No relationships reported)

There are two main running foot-strike patterns; heel striking (HEEL) and mid-foot striking (MID). Given that people who run with different gait patterns likely experience different loading profiles, it would be of interest to analyze regional differences in bone mineral density (BMD) in order to characterize foot-strike specific injury risk. **PURPOSE:** To investigate the differences in hip and foot BMD of male collegiate runners with different foot-strike patterns. **METHODS:** Thirteen NCAA D1 athletes were recruited for the study (Age: 20±1 yrs; Height: 179 ± 5 cm; Weight: 70 ± 6 kg; Body Fat: 10.8 ± 4 %). Ground Reaction Force (GRF) data was collected with an instrumented treadmill while the subjects ran at two different paces; threshold pace (TP: 5:00 min/mi) and long-slow distance pace (LSD: 6:58 min/mi). Femurs and foot bones of the left (L) and right (R) leg were scanned with dual-energy x-ray absorptiometry (DXA). Foot-strike patterns were categorized based on the presence of an initial impact transient in the GRF profile and confirmed with video analysis. DXA scans were used to analyze BMD of the femoral neck, first metatarsal, and the average of metatarsals 2-5. Three separate 2x2 Analyses of Variance were used to determine the effects of foot-strike pattern (HEEL, MID) and side (L, R) on regional DEXA data. Data are presented as Mean±SD. **RESULTS:** A significant interaction indicated that BMD of the first metatarsals were affected by foot-strike pattern and leg side (F = 12.60, p = 0.004). Post-hoc testing, however, failed to show significant differences during follow-up testing (Table 1). Bone mineral density (mean±SD) of the first metatarsals from the left and right side in the heel and mid-foot strike groups.

	Foot-Strike Pattern	
Leg Side	Heel n=7	Mid n=6
Left	0.641±0.095	0.564±0.127
Right	0.640±0.098	0.606±0.128

CONCLUSION: Although foot-strike pattern and leg side both appear to affect BMD of the first metatarsal, the exact nature of this effect is not known.

Individuals with Sacroiliac Joint Dysfunction Display Fewer Muscle Synergies When Walking
Daniel F. Feeney¹, Robyn A. Capobianco¹, Jana R. Jeffers¹, Joseph Morreale², Alena M. Grabowski¹, Roger M. Enoka¹.
¹University of Colorado Boulder, Boulder, CO. ²Center for Spinal Disorders, Thornton, CO.
(No relationships reported)

Sacroiliac joint (SI) joint dysfunction is present in 15-30% of individuals with low back pain. Pain in the SI joint often disturbs typical gait patterns. One hypothesis regarding the cause of SI joint dysfunction is a lack of coactivation between the latissimus dorsi and contralateral gluteus maximus, which together provide force closure between the sacrum and ilium. Latent muscle synergies during movement can be identified with a principal component analysis on EMG signals. Components with eigenvalues (EV) greater than 1.0 significantly explain a portion of the covariance of the constituent signals.

PURPOSE: To identify differences in muscle synergies during walking between individuals with SI joint dysfunction and healthy controls. **METHODS:** Six individuals diagnosed with SI joint dysfunction (4 right side) and six age-matched controls walked at 1 m/s on a dual-belt force treadmill Bertec. Muscle activity was recorded with wireless electrodes (Noraxon) for tibialis anterior, medial gastrocnemius, biceps femoris, rectus femoris, gluteus maximus (GM), internal obliques, erector spinae, and latissimus dorsi (LD) bilaterally. The EMG signals during 10 strides were bandpass filtered between 10-490 Hz and rectified. Each stride began at right heel strike and was resampled to 1000 time points, then averaged at each time point. Principal component analysis (PC) was performed on each individual's averaged EMG data and on the group ensemble EMG (averaged across individuals at each time point).

RESULTS: Individuals with SI joint dysfunction exhibited fewer muscle synergies than healthy controls (mean EV for the 5th PC (range): SI = 0.89 (0.74-1.02), control = 1.04 (0.9-1.10)). The first PC for the ensemble EMG for controls included a contribution from contralateral GM and LD (Pearson r with 1st PC of ensemble EMG: right GM = -0.20, left LD = -0.22, left GM = 0.29, right LD = 0.25), whereas this synergy was absent from left LD to right GM for individuals with SI joint dysfunction (right GM = -0.11, left LD = 0.05, left GM = 0.36, right LD = 0.37).

CONCLUSION: Individuals with SI joint dysfunction exhibit fewer synergies than healthy controls when walking. Our results support the hypothesis that individuals with SI joint dysfunction do not exhibit a synergy between contralateral gluteus maximus and latissimus dorsi when walking.

Vest-borne Loads Increase Bending Moments at the Distal Tibia
Nathaniel I. Smith¹, Timothy R. Derrick², Joseph F. Seay¹, Peter N. Frykman¹, Rebecca E. Fellin¹. ¹U.S. Army Research Institute of Environmental Medicine, Natick, MA. ²Iowa State University, Ames, IA.
Email: nathaniel.i.smith2.ctr@mail.mil
(No relationships reported)

Tibial stress fractures are a substantial issue among active duty military personnel. Previous research found that walking with heavy loads increased joint moments and contact forces to a greater degree than the relative increase in load. However, the effect of added load on tibial bending remains unclear. **PURPOSE:** Determine the relationship between added load and tibial bending moment (M_{bend}) while walking with heavy loads. **METHODS:** 26 active duty male volunteers (20.7 ± 3.3 yrs; 1.77 ± 0.87 m; 85.3 ± 13.9 kg) walked on a treadmill for 10 minutes unloaded and with each of five vest-borne loads (15, 25, 35, 45 and 55 kg) while force and motion data were collected. pQCT scans were used to obtain volunteers' mid-distal tibial geometry (38% from distal end). A musculoskeletal model was used to estimate muscle forces necessary to match joint moments. At the instant of peak tibia axial force (75.5 ± 1.9% of stance phase), M_{bend} at the mid-distal tibia were calculated as the product of joint reaction and muscle forces and their respective moment arms and summed to create a total moment. Vest-borne loads were expressed as a percentage of body mass. **RESULTS:** M_{bend} caused by muscle were consistently greater in magnitude and opposite in direction from moments caused by joint reaction forces. Total moments caused bending in the concave posterior direction placing the anterior tibia in tension. Moments were correlated with added loads when normalized to body mass (Figure 1) as well as when moments were expressed as increases relative to the unloaded condition (all p < .01). For each 10% increase in added load, M_{bend} increased 8.3% relative to unloaded walking. **CONCLUSION:** At this injury prone site on the tibia, the increase in bending moment with added loads was linear and slightly less than proportional to the loads added.

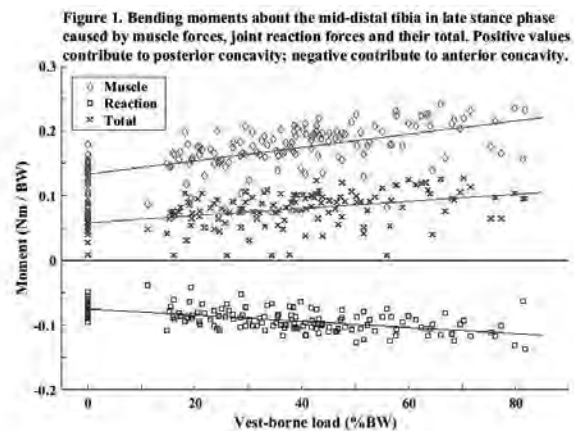

Figure 1. Bending moments about the mid-distal tibia in late stance phase caused by muscle forces, joint reaction forces and their total. Positive values contribute to posterior concavity; negative contribute to anterior concavity.

Peak Patellofemoral and ACL/PCL Forces While Performing the Forward Lunge Exercise With Varying Techniques

Rafael F. Escamilla, FACSM¹, Naiquan Zheng², Toran D. MacLeod¹, Rodney Imamura¹, Shangcheng Wang², Glenn S. Fleisig³, Kevin E. Wilk⁴, James R. Andrews⁵. ¹California State University, Sacramento, Sacramento, CA. ²University of North Carolina, Charlotte, Charlotte, NC. ³American Sports Medicine Institute, Birmingham, AL. ⁴Champion Sports Medicine, Birmingham, AL. ⁵Andrews Institution, Gulf Breeze, FL.
 Email: rescamil@csus.edu

(No relationships reported)

PURPOSE: To compare peak patellofemoral and ACL/PCL forces among varying lunging techniques involving lunging with a long and short stride both on flat ground and up to a 4 inch platform. **METHODS:** Sixteen male and female subjects (mean bodyweight 678N, 69.1 kg mass; 175.9 cm height; 28.9 years old) using bodyweight only performed a forward lunge with a long stride (shank vertical at bottom position) and a short stride (1/2 the long stride distance) on flat ground and up to a 4 inch platform. Force platform and video data were collected and input into a biomechanical model, and peak patellofemoral and ACL/PCL were calculated as a function of knee angle. A One-Way Repeated measures ANOVA assessed significant differences among lunging techniques ($p < 0.05$). **RESULTS:** Peak patellofemoral force occurred between 79°-96° knee angles and was significantly greater ($p < 0.001$) with a short stride lunge on flat ground (1668±479N) and up to a 4 inch platform (1553±580N) compared to lunging with a long stride lunge on flat ground (1193±512N) and up to a 4 inch platform (1061±523N), but no significant differences in peak patellofemoral force were found between the two short stride lunges ($p = 0.99$) and between the two long stride lunges ($p = 0.99$). Peak ACL force occurred between 7°-12° knee angles and was not significantly different ($p = 0.70$) among any of the lunging techniques. Peak PCL force occurred between 62°-83° knee angles and was significantly greater ($p < 0.001$) with a long stride lunge on flat ground (554±220N) and up to a 4 inch platform (609±265N) compared to lunging with a long stride lunge on flat ground (402±114N) and up to a 4 inch platform (458±145N), but no significant differences in peak PCL force were found between the two short stride lunges ($p = 0.99$) and between the two long stride lunges ($p = .99$). **CONCLUSIONS:** Lunge technique variations did affect peak patellofemoral and cruciate ligament forces. Compared to a long stride lunge, lunging with a short stride, which caused the knees to translate forward approximately 8 cm beyond the knees at bottom lunge position, resulted in greater peak patellofemoral force but less PCL force. Lunging technique variations did not affect peak ACL force. There were no patellofemoral or PCL differences in peak force between the two long stride lunges or between the two short stride lunges.

2709 Board #229 June 2 9:30 AM - 11:00 AM
Slope of Time-to-maximum Intensity of the Mechanomyograph in the Calf Muscles During Incremental Electrical Stimulation

W. Jeffrey Armstrong. Western Oregon University, Monmouth, OR.

(No relationships reported)

PURPOSE: In previous analysis of the mechanomyogram (MMG) obtained during incremental electrical stimulation using the von Tscherner "intensity analysis" suggested a possible decrease in time-to-maximum total intensity (TTMax) for the soleus with increasing stimulus intensity. In the present study, the slopes of TTMax were analyzed for the medial gastrocnemius (MG) and soleus (SOL) muscles. **METHODS:** 9 (7M, 2F) moderately active college-aged (21-28 y, mean = 22 ± 2 y) persons with measurable H-reflexes participated. The tibial nerve was stimulated in increments of 5V from 10-100 V with with a 10-second rest interval between stimuli. To minimize the interference of the H-wave contraction on the MMG, data from 50 to 100V were analyzed. Normalized MMG (NormMMG) data were subjected to the intensity analysis, and total intensity (sum of the intensities over the set of 11 Cauchy wavelets for each sample in time), the peak total intensities, and corresponding TTMax were determined. The slopes of the TTMax by NormMMG were determined, and correlation coefficients were analyzed. In addition, the TTM data for the SOL and MG were compared using the paired t-test. It was hypothesized that the slopes of the TTMax data would be negative and greater for the MG. **RESULTS:** TTMax was significantly different between SOL and MG ($p < 0.001$). There was a significant negative correlation between TTMax_SOL and NormMMG_SOL [-0.335 ($p < 0.001$, CI: -0.501 to -0.145); range: -0.961 to 0.878]. The correlation between TTMax_MG and NormMMG_MG was not significant [0.117 ($p = 0.252$, CI: -0.804 to 0.310); range: -0.679 to 0.936]. Overall, slopes varied among participants and muscles. **CONCLUSIONS:** The hypothesis that TTMax intensity would decrease with increasing stimulus (i.e., would reflect the rate of muscle shortening, Vmax) was not supported. Variation among muscles and participants suggest that there may be information in the MMG TTMax that reflect other characteristics of the muscle fiber recruitment (muscle composition, motor unit depth, etc.). Further study is warranted.

A Bi-Kinetic Technique To Assess Fatigue

Jenna E. Link, James C. Martin, FACSM. University of Utah, Salt Lake City, UT.

(No relationships reported)

Fatigue during maximal cycling is often quantified as relative change in torque (T) or power (P) as Fatigue Index (FI). FI however, does not account for changes in cadence (C) which impacts both P and FI. We investigated a method, Bi-Kinetic cycling, to quantify fatigue and account for changes in C. We then tested the validity of our results by using rested and fatigued T-C relationships to predict P throughout a Wingate test. **PURPOSE:** To evaluate fatigue using Bi-Kinetic cycling and develop a P model for short term maximal trials.

METHODS: Four cyclists completed six 25s maximal Bi-Kinetic cycling trials. For the first 18s C was held constant at 90, 125, or 160 rpm. C was then changed to one of the other values for the final 7s. The 6 C combinations produced three T-C relationships representing fatigue states resulting from pedaling at 90, 125, and 160rpm. Linear regression of T-time data was used to estimate the T that would have been produced during the C transition period. Slopes of the fatigued T-C relationships were compared to the rested state. Rates of changes in maximum T and C with respect to time (dTmax/dt and dCmax/dt) were evaluated. dTmax/dt and dCmax/dt were used to model the T-C relationship as a function of time and C and thereby predict P during a Wingate test. Finally, those T-C relationships were used to determine optimized maximum P throughout the Wingate test.

RESULTS: Slopes of the rested and fatigued T-C relationships differed ($p < 0.05$). dCmax/dt was significantly influenced by the fatiguing cadence ($p < 0.05$) but dTmax/dt was not. Modeled P was highly correlated with actual P during the Wingate test ($p < 0.001$, $r^2 = 0.96$). Maximum optimized P was greater than actual P during most of the Wingate test.

CONCLUSIONS: We used Bi-Kinetic cycling to quantify fatigue while accounting for C. Our results show that fatigue is influenced by C. Our model accurately predicted P during maximal fatiguing exercise. The constant load Wingate test results in less than optimal P.

Bilateral Correlations between Peak Ground Reaction Forces and Bone Mineral Density in Male Collegiate Runners

Alec C. Miller, Kevin S. Ryan, Toni D. Uhrich, Kristof Kipp. Marquette University, Milwaukee, WI. (Sponsor: Paula E Papanek, FACSM)

Email: alec.miller@marquette.edu

(No relationships reported)

Overuse injuries are prevalent in distance runners due to the repetitive nature of the sport. Some runners exhibit speed dependent asymmetries in their running mechanics, which may play into the fact that these injuries often occur unilaterally. Analyzing correlations between ground reaction forces (GRF) and bone mineral density (BMD) may help elucidate whether the risk of overuse injuries differs between legs.

PURPOSE: To investigate the bilateral correlations between peak GRF at two different speeds and left and right femoral neck BMD in male, NCAA Division I distance runners.

METHODS: Fifteen male collegiate runners participated in this study (Age: 20 ± 1 year; Height: 179 ± 9 cm; Weight: 70 ± 15 kg; Body Fat: 10.75 ± 4 %). Ground reaction forces (N) were collected with Noraxon SciFit (Scottsdale, AZ) instrumented treadmill as participants ran at two different speeds; threshold pace (TP: 19.3 km/hr or 5:00 min/mi) and long-slow distance pace (LSD: 13.8 km/hr or 6:58 min/mi). The femoral necks were scanned with dual-energy x-ray absorptiometry (DXA) using Norland Elite (Fort Atkinson, WI). Peak stance-phase GRF of the left and right leg

Denver, Colorado

were extracted from the TP and LSD condition. Femoral neck BMD (g/cm³) values for right and left leg were extracted from the DXA scans. Bivariate correlations were used to analyze the correlations between femoral neck BMD and peak GRF at the two running speeds. Separate correlation analyses were run for the left and right leg.

RESULTS: During the LSD condition, peak GRF and BMD data were correlated only for the right leg (Right: $r = 0.539, p = 0.03$; Left: $r = 0.412, p = 0.127$). Similarly, peak GRF and BMD were correlated only for the right leg during the TP condition (Right: $r = 0.53, p = 0.042$; Left: $r = 0.506, p = 0.054$).

CONCLUSIONS: Peak stance-phase GRF of the right leg were positively correlated with BMD of the right femoral neck, regardless of running speed. The fact that significant correlations between peak GRF and BMD data were only observed on one side suggests that side-to-side differences could influence the risk of sustaining unilateral overuse injuries in runners.

Motor Units Discriminated From High-density, Surface Electromyography Require Careful Scrutiny.

Leah A. Davis¹, Awad Almklass¹, Landon Hamilton¹, Taian Vieira², Alberto Botter², Roger M. Enoka¹. ¹University of Colorado Boulder, Boulder, CO. ²Politecnico di Torino, Torino, Italy.

Email: leah.davis@colorado.edu

(No relationships reported)

High-density, surface electromyography (EMG) allows concurrent recording of motor unit (MU) activity by increasing the recording area and the number of recording sites. The recorded signal comprises overlapping MU action potentials, some of which can be identified with a decomposition algorithm. However, such analyses often produce results that contradict the classical findings on motor unit discharge characteristics. **PURPOSE:** To evaluate the quality of the interspike intervals (ISIs) extracted from a high-density surface EMG recording by a decomposition algorithm. **METHODS:** Muscle activity was recorded using high-density, surface EMG (4x8 grid with a 10 mm interelectrode distance) in 10 persons with multiple sclerosis during steady, isometric dorsiflexor contractions on their less-affected limb. The target force was 10% of maximum. Custom Matlab software was used to perform a convolution kernel compensation model and a blind-source separation algorithm to discriminate individual MUs from EMG recordings. The discharge times (DT) from the discriminated MUs were used to calculate the ISIs ($ISI = DT_n - DT_{n-1}$). For each MU, the average ISI, average coefficient of variation for ISI (ISI_{CV}), kurtosis for the distribution of ISIs, and skewness for the distribution of ISIs was calculated. ISIs outside of the range of 25 ms - 400 ms were deemed inaccurate and removed from the data and the same analyses were repeated. Data are reported as mean [95% CI]. **RESULTS:** The ISIs ($n = 33,980$; 303 [285-321] per MU) of 113 MUs were examined. Before removing ISIs that did not meet the inclusion criteria (25 - 400 ms), the average ISI was 136 ms [123 - 151 ms], the average ISI_{CV} was 72% [50 - 95%], the average kurtosis was 53.5 [39.1 - 67.8], and the average skewness was 4.4 [3.5 - 4.3]. On average, 3.34% (range 0 - 31%) of the ISIs per MU were outside the acceptable range. After ISI removal, the average ISI was 120 ms [114 - 125 ms], the average ISI_{CV} was 28% [26 - 31%], the average kurtosis was 11.0 [8.9 - 13.2], and the average skewness was 1.95 [1.70 - 2.20]. Most removed ISIs were <25 ms. **CONCLUSION:** The findings quantify the extent to which MU discharge times extracted from high-density, surface EMG recordings with an automatic decomposition algorithm can be confounded by discrimination errors.

Blood Flow Restricted Exercise Alters Motor Unit Recruitment And Firing Rate

Pedro Fatela¹, Goncalo V. Mendonca², Janne Avela³, Pedro Mil-Homens¹. ¹Faculdade de Motricidade Humana, Lisboa, Portugal. ²Faculdade de Motricidade Humana; PTCD/DTP-DES/5714/2014, Lisboa, Portugal. ³University of Jyväskylä, Jyväskylä, Finland.

(No relationships reported)

Purpose: Despite suggestions that low-intensity (LI) blood flow restricted exercise (BFRE) may be as effective as high intensity (HI) resistance exercise for the purpose of enhancing the recruitment of type II motor units (MU); individual MU acute response to LI BFRE has never been observed and/or reported. Recently, the decomposition of the surface electromyographic (EMG) signals introduced new analysis methods to assess single MU properties. Through these methods we aimed to observe LI BFRE effects on the behavior of the individual MU.

Methods: Eight men (26.0 ± 3.8 yrs) performed 5 sets of 15 reps of knee extensions at 20% 1RM (with and without BFR). BFR condition was set at 60% of the individual absolute arterial occlusion value. Torque was determined during pre- and post-exercise maximal voluntary contractions (MVC). Surface EMG activity was recorded from the vastus lateralis (VL) at pre- and post-exercise time point measurements. In each of these time points, isometric voluntary contractions were performed, matching

trapezoidal target-force trajectories at 40% pre-MVC. Resulting surface EMG signals were decomposed and MU recruitment threshold, firing rates and MU action potential (MUAP) amplitudes were further analyzed.

Results: Torque only decreased after the LI BFRE condition (-20.5%; $p < 0.05$). In the regression lines between MU recruitment threshold and firing rate, LI BFRE induced higher decrements in the linear slope coefficient (-165.1% ± 120.4, $p < 0.05$) when compared to LI condition (-44.4 ± 33.1, $p < 0.05$). Also, the MU firing rate vs. MUAP amplitude relationship had a notable shift to higher firing rate and MUAP amplitude values after the BFRE condition, reinforcing the evidence that new MUs with higher MUAP amplitude are recruited and MUs with similar MUAP amplitudes are activated at higher firing rates.

Conclusion: LI BFRE induced a significant change in the MU recruitment pattern, with higher-threshold and lower-firing rate MUs being recruited earlier to compensate muscle failure. Moreover, there were strong evidences about an elevated firing rate in similar MUAP amplitude after LI BFRE condition.

The Effect of Real-Time Haptic Feedback on Kinesthetic Awareness and Motor Skill Performance

Jo T. Shattuck, Mateusz Mittek, John Ransone, FACSM.

University of Nebraska, Lincoln, NE.

Email: joshattuck@huskers.unl.edu

Reported Relationships: J.T. Shattuck: Intellectual Property; Jo Shattuck (owner).

PURPOSE: Kinesthetic awareness is an individuals' knowledge of their own body position and movements in space. Sensory integration is the process of combining inputs from proprioceptive receptors in muscles, mechanoreceptors in skin, and visual motor/visual spatial systems is critical to motor skill acquisition. We proposed that kinesthetic awareness training (KAT): the addition of haptic feedback in real time, to introduce secondary discriminatory system information into kinesthetic processing. We hypothesized that input will reinforce proprioceptive skills by merging a non-native input with native proprioceptive and visual system information, and subsequently cause an increase in accuracy in a single session of motor skill practice. **METHODS:** We assessed torso angle, a crucial control element that are common to many multi-joint, complex actions. Three subjects (19.7 ± 0.58 yrs) performed static and dynamic torso control movements with and without real-time haptic feedback. A wearable mini motion-capture-feedback device with embedded accelerometer, magnetometer, gyroscope and proximity sensors recorded continual positional data in 8 axes. The device provided haptic feedback (vibrations via tiny motor) when the target parameters were achieved. After 5 repetitions of practice, alternating sets with and without real-time haptic feedback were measured, (2 sets of 5 and 10 repetitions). **RESULTS:** We analyzed posture control in 2 conditions in the beginning and end of a training session. An ANOVA was performed on normalized differences from the target means was significant in the initial training sets, ($p < 0.01, F = 4.2$), and not significant in the final sets, ($p = 0.09, 4.00$). The results suggest a significant learning effect with KAT training after 30 repetitions. **CONCLUSION:** The results of this study suggests KAT training with haptic feedback could be a valuable teaching tool for improving somatosensory proprioception and kinesthetic awareness. Further investigations should examine if the KAT training leads to neural adaption and improved motor performance.

A 6-week Strength Training Increases Muscle Size in Patients with Chronic Ankle Instability: MRI Analysis

Hyeri Gonzales¹, S. Jun Son¹, Hyunsoo Kim², Kade Eppich¹, Neal K. Bangerter¹, Matthew K. Seeley¹, J. Ty Hopkins, FACSM¹. ¹Brigham Young University, Provo, UT. ²West Chester University, West Chester, PA. (Sponsor: J. Ty Hopkins, FACSM)

Email: Hyeri.gonzales@gmail.com

(No relationships reported)

Patients with chronic ankle instability (CAI) have shown strength deficits in ankle and hip musculature. Little is known whether strength deficits are associated with muscle size in this patient population, and if strengthening can improve muscle size.

PURPOSE: To examine the effect of a 6-week ankle and hip strength program on peroneus longus (PL) and gluteus medius (GM) muscle size in CAI patients.

METHODS: 14 CAI subjects in a strength group (22±1 yrs, 173±9 cm, 73±12 kg, 82±8% FAAM ADL, 58±13% FAAM Sports, 3.7±1.5 ankle sprains) completed a series of 5 ankle and hip strength exercises (isometric, concentric, and eccentric contraction with theraband) 3 times/week for 6 weeks under supervision. 14 CAI subjects participated in a control group (22±2 yrs, 177±9 cm, 75±12 kg, 81±9% FAAM ADL, 56±12% FAAM Sports, 5.9±3.3 sprains). A Siemens Trio MRI scanner with a large flex coil was used to acquire images using a 3D multi-slice spiral gradient echo sequence with TE: 7.48 ms, TR: 17 ms, slice thickness: 5 mm. Images were acquired

at pre- and post-intervention. Axial cross-sectional area (CSA) from each muscle was segmented using Analyze 12.0 software. PL muscle belly was consistently defined at 15th/96 slices (7.5 cm) from the superior head of the fibula. GM muscle belly was defined at 15th/64 slices (7.5 cm) from the superior greater trochanter of the femur. ANCOVA analyses (covariate: pre-intervention value) were used to detect group x time differences.

RESULTS: ANCOVA analyses confirmed between-group differences in PL ($F_{1,25}=36.232$; $p < .05$) and GM CSA ($F_{1,25}=13.389$; $p < .05$) over time. The strength training resulted in a 5% increase in PL (pre: 6.0 ± 1.31 cm², post: 6.3 ± 1.3 cm²; $p < .05$) and a 5.7% increase in GM CSA (pre: 47.7 ± 6.7 cm², post: 50.4 ± 6.6 cm²; $p < .05$). No changes were detected in PL (0.7% reduction; pre: 6.96 ± 1.7 cm², post: 6.91 ± 1.6 cm²; $p > .05$) and GM CSA (0.6% increase; pre: 47.5 ± 7.9 cm², post: 47.7 ± 7.8 cm²; $p > .05$) in the control group.

CONCLUSIONS: Relative to the control group, a 6-week strength program is beneficial in increasing ankle evorator and hip abductor muscle size. As muscle size is proportional to strength, increased muscle size would result in greater muscle strength, which can have positive effects on movement and dynamic stability during functional movement.

(No relationships reported)

Many studies have investigated the reliability of measuring isometric ankle strength using isokinetic dynamometer. However, hip position and body position may influence the participant's ability to generate torque during the test. **Purpose:** To investigate the effect of body position on isometric ankle plantarflexor (PF) and dorsiflexor (DF)-strength measurement in pre and post fatigued conditions. **Methods:** Fifteen healthy subjects (age: 20.5 ± 1.5 yrs) participated. Subjects required a total 2 of visits with a week period between visits. Subjects were initially assigned one of two test positions (seated and supine). The order of test positions were randomized and counterbalanced. Subjects performed the Bruce protocol on a treadmill until they reached volitional exhaustion. Before and after the Bruce protocol, subjects performed a total of 3 maximum voluntary isometric contractions (MVIC) in PF and DF directions. Data were analyzed using peak torque in each direction from the 3 trials of the MVIC. Separate two-way analysis of variance with repeated measures was used to assess the effect of fatigue (pre-fatigue and post-fatigue) and test position (seated and supine) for PF and DF. **Results:** There were significant differences between both pre and post-fatigue (PF; pre: 103.1 ± 17.2 Nm vs post: 82.4 ± 14.4 Nm, p -value $<.001$, DF; pre: 21.7 ± 4.9 vs post: 18.3 ± 6.3 , p -value $<.001$) and supine and seated positions (PF; supine: 84.7 ± 15.6 Nm vs seated: 101.5 ± 18.8 Nm, p -value $<.001$, DF; supine: 17.9 ± 5.4 vs seated: 22.2 ± 5.6 , p -value $=.026$) for PF and DF torques. There was no significant interaction between time and position for any variables. **Conclusions:** Body position affected isometric ankle PF and DF strength but fatigability was not influenced by body position. Specifically, subjects were able to produce more torque in the seated position compared to supine position. This may be due to the subjects ability to stabilize the back and hip against the seat back. Further, this suggests that these two positions should not be interchanged when testing individuals in pre- and post-fatigue situations.

(No relationships reported)

Chronic ankle instability (CAI) is related to strength deficits in ankle and hip musculature. Rehabilitation training improves muscular strength, but it is unclear whether strength gain results from an increase in muscle size or neuromuscular efficiency.

PURPOSE: To examine the effect of a 6-week ankle and hip strength and proprioceptive program on peroneus longus (PL) and gluteus medius (GM) muscle size in patient with CAI.

METHODS: 15 CAI subjects in a rehab group (23 ± 2 yrs, 178 ± 8 cm, 76 ± 9 kg, $83 \pm 7\%$ FAAM ADL, $56 \pm 10\%$ FAAM Sports, 4.7 ± 2 ankle sprains) completed a series of 10 ankle and hip strength and proprioceptive exercises (theraband, wobble board, ankle

disk, etc.) 3 times/week for 6 weeks under supervision. 14 CAI subjects participated in a control group (22 ± 2 yrs, 177 ± 9 cm, 75 ± 12 kg, $81 \pm 9\%$ FAAM ADL, $56 \pm 12\%$ FAAM Sports, 5.9 ± 3.3 sprains). A Siemens Trio MRI scanner with a large flex coil was used to acquire images using a 3D multi-slice spiral gradient echo sequence with TE: 7.48 ms, TR: 17 ms, slice thickness: 5 mm. Images were acquired at pre- and post-intervention. Axial cross-sectional area (CSA) from each muscle was segmented using Analyze 12.0 software. PL muscle belly was consistently defined at 15th/96 slices (7.5 cm) from the superior head of the fibula. GM muscle belly was defined at 15th/64 slices (7.5 cm) from the superior greater trochanter of the femur. ANCOVA analyses (covariate: pre-intervention value) were used to detect group x time differences.

RESULTS: ANCOVA analyses confirmed between-group differences in PL ($F_{1,26}=39.087$; $p < .05$) and GM CSA ($F_{1,26}=22.965$; $p < .05$) over time. The rehabilitation intervention resulted in a 3.9% increase in PL (pre= 5.9 ± 1.5 cm², post= 6.1 ± 1.5 cm²; $p < .05$) and a 5.1% increase in GM CSA (pre= 42.0 ± 7.1 cm², post= 44.2 ± 7.3 cm²; $p < .05$). No significant changes were detected in PL (0.7% reduction; pre= 6.96 ± 1.7 cm², post= 6.91 ± 1.6 cm²; $p > .05$) and GM CSA (0.6% increase; pre= 47.5 ± 7.9 cm², post= 47.7 ± 7.8 cm²; $p > .05$) in the control group.

CONCLUSIONS: Relative to the control group, a 6-week strength and proprioceptive program is effective in increasing muscle size of ankle and hip musculature. As muscle size is proportional to muscular strength, increased muscle size might have a positive impact on dynamic functions at the ankle and hip.

(Sponsor: Dr. Terry J. Housh, FACSM)

Email: ethan.hill@unl.edu

(No relationships reported)

PURPOSE: It is well known that muscle fatigue is manifested uniquely between men and women. Electromechanical efficiency has been used to examine various aspects of muscle function, but has not been applied to examine sex-specific fatigue responses. Therefore, the purpose of the present study was to examine electromechanical efficiency between men and women during a fatiguing task. **METHODS:** Twenty-two resistance-trained men and women performed 50 submaximal (65% of concentric peak torque), concentric muscle actions of the dominant forearm flexors at $60^\circ \cdot s^{-1}$. Concentric peak torque was determined prior to and immediately after the fatiguing protocol. Surface electromyographic and mechanomyographic signals were simultaneously recorded from the biceps brachii muscle and electromechanical efficiency was calculated as the ratio of mechanomyographic amplitude to electromyographic amplitude. An independent samples t -test was used to compare the percent decreases in concentric peak torque between the men and women. Polynomial regression analyses were used to examine the composite patterns of responses for electromechanical efficiency for the men and women. In addition, to allow for the comparison of slope coefficients, composite electromechanical efficiency values were natural log transformed and fitted with a linear model. **RESULTS:** Concentric peak torque decreased to a greater extent in the men (30.5%) compared to the women (22.3%). In addition, electromechanical efficiency decreased for both the men (quadratic, $p = 0.016$, $r = -0.919$) and women (quadratic, $p = 0.006$, $r = -0.605$), but the natural log transformed slope coefficients indicated that the decrease was greater ($p = 0.026$) for the men (-0.009) than the women (-0.003). **CONCLUSION:** Like concentric peak torque, electromechanical efficiency decreased for both the men and women, but the decrease was greater for the men. These findings indicated that men exhibited decreased electromechanical efficiency compared to their female counterparts which may have contributed to the greater decrease in concentric peak torque for the men. Thus, electromechanical efficiency may provide additional insight regarding the potential mechanisms mediating sex-specific responses to fatiguing exercise.

MMAX Normalisation of Voluntary EMG Removes the Confounding Influences of Electrode Location and Body Fat.

Marcel B. Lanza, Tom B. Balshaw, Jonathan P. Folland, FACSM. Loughborough University, Loughborough, United Kingdom.

Email: marcel.lanza@gmail.com

(No relationships reported)

The evoked maximal M-wave (M_{MAX} peak-to-peak [P-P]) is frequently used to normalise surface electromyography (sEMG) during voluntary contractions. However, it is unknown if M_{MAX} normalization: (i) accounts for the variation in electrode position over a muscle, potentially removing the need for precise and yet imperfect electrode placement between measurement sessions; and (ii) removes the documented influence of body fat on sEMG amplitude during voluntary contractions.

PURPOSE: The first aim of the study was to assess the influence of electrode positioning on sEMG measurements, using multiple recordings sites over the vastus lateralis (VL), during maximum voluntary contractions (MVCs) and evoked M_{MAX} , and examine if any site differences in these parameters were proportional. The second aim was to investigate if M_{MAX} normalization removes the confounding influence of body fat, quantified by skin-muscle distance (SMD), on sEMG during MVCs.

METHOD: Young healthy males completed both experiments. Experiment 1 (n=10; 22 ± 2 y; 1.78 ± 0.07 m; 73.6 ± 5.0 kg) involved simultaneous sEMG measurements from 8 different VL sites during knee extension isometric MVCs and twitch contractions. Experiment 2 (n=41; 24 ± 2 y; 1.76 ± 6 m; 69 ± 6 kg) involved the same contractions with sEMG recordings from one location over the VL, vastus medialis and rectus femoris, and measurements of SMD at each sEMG site using B-mode ultrasonography. **RESULTS:** Experiment 1 demonstrated that absolute sEMG at maximal voluntary torque (EMG_{MVT}) differed between the VL recording sites (P<0.001) with lower values at more proximal sites (P<0.030). However, when EMG_{MVT} was normalised to M_{MAX} P-P between sites no differences were found (P=0.929). Experiment 2 showed that absolute EMG_{MVT} was negatively related to SMD (P<0.001, r= -0.786) but when EMG_{MVT} was normalised by M_{MAX} P-P the relationship with SMD was not significant (r= -0.007, P=0.966).

CONCLUSION: The present study suggests voluntary sEMG and M_{MAX} P-P amplitude vary proportionally across the surface of the VL muscle and that normalising voluntary sEMG to M_{MAX} P-P removes the confounding influence of body fat. Therefore, M_{MAX} P-P normalisation is recommended to overcome the issues of both sensor re-positioning between test sessions and variable body composition between participants.

H-Reflex Plasticity Following Cast Immobilization Of Distal Radius Wrist Fractures

Peter Yee, Natasha G. Boyes, Geoffrey H. Johnston, Joel L. Lanovaz, Jonathan P. Farthing. *University of Saskatchewan, Saskatoon, SK, Canada.*
 Email: peter.yee@usask.ca
 (No relationships reported)

The Hoffmann (H)-reflex has been used as a recovery marker in disuse-immobilization models. The data is limited on the effects of forearm immobilization on the H-reflex, especially in clinical populations. **PURPOSE:** To determine H-reflex changes following a distal radius wrist fracture requiring cast immobilization. **METHODS:** Five fracture (FX) patients (4 W; 1 M; age: 45.2±18.9 yrs; ht: 164.1±7.0 cm; wt: 64.4±4.9 kg) and five uninjured age-matched controls (CON) (4 W; 1 M; age: 44.6±17.3 yrs; ht: 171.5±5.5 cm; wt: 68.9±8.8 kg) were enrolled. FX group was measured four times up to 12-weeks post fracture; the CON group was tracked over the same period, with measures taken at least three weeks apart. H_{max} and M_{max} were elicited in the flexor carpi radialis (FCR) of each arm via stimulation of the median nerve (0.5 ms pulse) under a 10% maximal voluntary contraction (MVC). A recruitment curve was built using 0.5 mA increments. Measures included wrist flexion (WF) torque (dynamometer), peak electromyography (EMG) amplitude normalized to M_{max} , grip strength, range of motion (ROM; goniometry), muscle thickness (MT; ultrasound), and function via Patient-Rated Wrist Evaluation (PRWE). **RESULTS:** In the fractured limb, $H_{max}:M_{max}$ amplitude ratio (23.0±16.1 to 23.1±12.0%) did not change over time (p > 0.05), but $H_{max}:M_{max}$ stimulation ratio significantly decreased: 70.5±2.9% to 63.1±4.5% (p < 0.05). WF increased during recovery (6.4±1.2 to 8.5±2.3 Nm; p < 0.05), but normalized EMG during MVC showed a decreasing trend from 18.3±6.4 to 13.8±9.6% M_{max} (p = 0.054). Time main effects were also evident for MT (2.7±0.5 to 3.2±0.5cm; p < 0.05), grip strength (6.0±6.8 to 19.6±8.5kg; p < 0.001), wrist ROM (87.9±18.7 to 119.4±20.5°; p < 0.05), and PRWE (84±24 to 28±32 score; p < 0.001), all reflecting incomplete recovery up to 12-weeks post fracture. No significant differences were shown for the uninjured arm of FX group or in any measures for CON, except WF MVC (24.7±7.2 to 22.0±6.9Nm; p < 0.05). **CONCLUSION:** Although peak amplitude of the H-reflex did not change during recovery, decreased intensity needed to evoke H_{max} could reflect changes to the excitability of spinal circuitry after wrist fracture. These data have important therapeutic implications for understanding how the nervous system is impacted after wrist fracture and cast immobilization.

Comparison of Lower Extremity Muscle Activity in Sliding Lunges versus Standard Lunges

Deborah King, Dan Drill, Adam Fong, victoria Voorhees, Rumit Singh Kakar. *Ithaca College, Ithaca, NY.*
 (No relationships reported)

Lunges are a functional exercise used in lower body neuromuscular training programs. Lunges are typically performed on the floor stepping forward, sideways, or backwards, but can be performed on a slide board or with foot sliders. Sliding allows partial weight bearing and may improve stability. Differences in neuromuscular challenges, specifically hip and knee muscle activity, between sliding and standard lunges are unknown. **PURPOSE:** To compare hip and knee muscle activity between sliding and

standard reverse lunges (RL) and side lunges (SL). **METHODS:** Sixteen healthy active subjects performed 3 types of RLs and SLs: slide board (SB), foot sliders (FS), and standard lunges (ST). After skin preparation, surface electrodes were placed over the muscle bellies of the gluteus maximus (GMX), ipsi- and contra-lateral gluteus medii (iGM, cGM), vastus lateralis (VL), and vastus medialis (VM). Muscle activity of the weight bearing leg was measured at 1000 Hz with a wireless EMG system. Lunges were performed at a standardized tempo (44 bpm) and subject specific standardized length. Maximum voluntary isometric contractions (MVIC) were used to normalize peak EMG (pEMG) and average EMG (aEMG) to percent MVIC for 4 lunges of each subject all conditions. One-way repeated measures ANOVAs (α=0.05) were used to determine differences between the 3 lunge types for SL and RL. **RESULTS:** RL cGM aEMG was greater for ST (22 ± 21%) versus FS (16 ± 17%), p = .012. RL VM aEMG was lower for SB (30 ± 12%) versus FS (34 ± 14%), p = .016. SL VL aEMG was greater for ST (230 ± 150%) versus SB (198 ± 121%), p = .049. SL GMX aEMG was greater for ST (192 ± 137%) versus SB (159 ± 123%) and FS (162 ± 103%), p = .001 and .035. SL VM aEMG was greater for ST (135 ± 14%) versus SB (26 ± 11%) and FS (25 ± 9%), p = .009 and .004. SL iGM pEMG was greater for ST (79 ± 44%) versus SB (52 ± 32%) and FS (50 ± 37%), p = .019 and .003. SL cGM pEMG was greater for ST (79 ± 41%) versus SB (59 ± 34%), p = .027. SL VM pEMG was greater for ST (92 ± 46%) versus SB (63 ± 28%) and FS (60 ± 18%), p = .031 and .01. **CONCLUSION:** Hip and knee muscle activity is similar for RL with minor differences in cGM and VM based on lunge type. Standard SL had consistently greater peak and average muscle activity compared to sliding lunges. Sliding SL may require different neural control which could be important in rehabilitation settings.

Change Of Lower Limb Muscle Strength Of Older OA Adult After 24 Weeks Tai Chi Intervention

Cui Zhang, Keyi Yin, Donghai Wang, Yunqi Tang, Yu Liu. *Shanghai University of Sport, Shanghai, China.*
 Email: 1510302016@student.sus.edu.cn
 (No relationships reported)

The incidence of knee osteoarthritis (OA) increases with age. Epidemiological studies have shown a high prevalence of knee OA among older Chinese. Tai Chi exercise as a traditional Chinese practice has long been used to enhance fitness. Research increasingly shows that many OA signs and symptoms, such as reduced joint mobility, pain, and increased joint stiffness, can be ameliorated by Tai Chi exercise. However, the lower limb joint torque of OA patients were less reported after long term Tai Chi exercise. **PURPOSE:** To determine whether the Tai Chi exercise intervention would improve lower limb joint power of OA older adult or not. **METHODS:** 20 older women (65ys - 79ys, Kellgren-Lawrence 3 grade, having no lower limb surgery, no orthopedic problems of the hip, knee, or ankle, no neurological disease, no regular exercise.) with clinically diagnosed knee OA were recruited in this study, 9 finished this at last. Participants practiced Tai Chi exercise which include eight Tai Chi forms of 24 forms Yang Style 24 weeks, 3 times/week, 1 hour/time. Hip, knee and ankle extensor/flexor muscle peak torque of older adult before and after intervention were tested by Contrax (Swissland) at 90°/s angular velocity. A paired Student's t test was used to compare pre-post differences. Written informed consent was received from all participants.

RESULTS: The hip, knee and ankle peak extensor torque were 38.67 ± 15.08N·M, 51.28 ± 13.77N·M and 10.06 ± 1.36N·M, the peak flexor torque were 27.41 ± 8.97N·M, 47.02 ± 9.88N·M, and 19.89 ± 6.75N·M before training. The hip, knee and ankle peak extensor torque were 26.81 ± 16.08N·M, 48.71 ± 6.91N·M and 26.4 ± 22.11N·M, the peak flexor torque were 23.84 ± 7.57N·M, 48.28 ± 9.09N·M, and 26.81 ± 10.00N·M after training. The hip/knee extensor/flexion torque did not change after training (p > 0.05), the ankle extensor/flexor torque increased after training (p_e = 0.05, p_f = 0.007). **CONCLUSIONS:** 24 weeks Tai Chi training will help OA older adults to improve the strength of ankle joint and it was related to the characteristics of Tai Chi movement.

Although acupuncture is a common pain relief treatment, it may also be effective in range of motion, joint position sense, and muscle function. **PURPOSE:** To examine the immediate effects of electro- and traditional-acupuncture on hip flexion range of motion (HROM), knee joint position sense (KJPS), and maximal voluntary isometric contraction (MVIC) and central activation ratio (CAR) in quadriceps. **METHODS:** Fifty healthy adults participated in this randomized controlled laboratory study. Baseline measurements (HROM, KJPS, MVIC, and CAR) were obtained before a

treatment. An acupuncturist performed three physical examinations (SLR test, Thomas test, and hip abduction manual muscle test) to determine one of three acupuncture options (option A: SP9, SP10, and SP11; option B: ST34, ST36, and GB 42; option C: GB33, GB34, and GB27). Afterwards, one of three treatments (control: no treatment, n=16; electro-acupuncture, n=19, and traditional-acupuncture, n=15) was randomly assigned to each participant for 15-min. Measurements were assessed at baseline, 0-, 20-, and 40-min post treatment. At each time point, HROM was measured using a goniometer on a supine position. KJPS on two knee flexion angles (15° and 45°) were randomly assessed. Quadriceps MVIC and CAR were measured on a dynamometer with superimposed bursts (knee locked at 90°). To test treatment effect over time, 3 × 4 mixed model ANOVAs and Tukey-Kramer post hoc tests were performed ($p < 0.05$). **RESULTS:** Either electro- (4.2°, $p < 0.0001$) or traditional-acupuncture (5.8°, $p < 0.0001$) immediately increased HROM ($F_{6,141} = 4.27, p < 0.001$) at 0-min post treatment. There was no difference between acupuncture types ($p = 0.41$). Regardless of treatments (time main effect: $F_{3,141} = 12.57, p < 0.0001$), quadriceps MVIC was reduced at 0- (5.2 %, $p < 0.001$), 20- (5.0 %, $p < 0.001$), and 40-min post treatment (7.1 %, $p < 0.0001$), compared to the baseline values. KJPS ($F_{6,141} = 1.81, p = 0.10$) and CAR ($F_{6,141} = 0.42, p = 0.87$) did not change at any time point. **CONCLUSIONS:** A single session of electro- or traditional-acupuncture treatment is beneficial for flexibility but not for kinesthesia and muscle activation. Changes in blood flow volume, overlap between actin and myosin filaments, and viscoelastic properties of muscle-tendon units may explain an increase in flexibility.

Effects of Marijuana Use on Lower Extremity Isokinetic Strength and Core Endurance

Brian C. Garcia, Grace Rhodehouse, Jonathon Lisano, Laura K. Stewart, Jeremy D. Smith. *University of Northern Colorado, Greeley, CO.*

(No relationships reported)

Marijuana use among athletes is becoming more widely reported, particularly as more states legalize the drug. Anecdotal, supporters suggest that marijuana aids in recovery and improves performance. Unfortunately, the effect of marijuana use on muscle function is not currently understood. **Purpose:** To determine whether muscle strength and endurance are altered by marijuana use. **Methods:** All participants were physically active, defined by at least 150 minutes of moderate-intensity exercise per week via the I-PAQ Short Format, and were either marijuana users (MU, $n = 10$, mass = 81.4 ± 20.0 kg; ht = 1.75 ± 0.08 m; age = 25 yrs ± 6 yrs) or non-marijuana users (NU, $n = 15$, mass = 73.5 ± 13.5 kg; ht = 1.80 ± 0.08 m; age = 25 yrs ± 6 yrs). Marijuana use habits were quantified through the Marijuana Use Measure. MU were described as those consuming marijuana products at least once a week for the past 6 months and NU were described as not having used any form of marijuana in the past 12 months. Hip ($90^\circ \cdot s^{-1}$), knee ($30^\circ \cdot s^{-1}$), and ankle ($30^\circ \cdot s^{-1}$) isokinetic strength was assessed in the dominant leg of each participant using a Biodex dynamometer. Leg dominance was determined by asking which leg the person would choose to kick a ball with for maximum velocity and distance. Core endurance (back extension, left side plank, right side plank, and trunk flexion) was also assessed by holding the position until failure. The time it took to reach failure for each condition for each participant was recorded. All conditions were randomized across participants and groups to avoid any order effects. A single factor MANOVA ($\alpha < 0.05$) was used to determine differences between groups.

Results: There were no statistically significant differences between groups for any strength or core endurance measures ($\lambda^* = 0.657$; $DF = 10, 15$; $F = .730$; $p = .687$). **Conclusion:** Marijuana use in a healthy, young, active population does not appear to enhance or suppress core endurance or lower extremity strength. It is possible that exercise may be mediating potential detrimental effects of marijuana use. Future research should also focus on inactive populations using marijuana to assess if exercise is providing a protective effect.

Comparison of Electromyographic Responses Across Handle Types During Seated Row Exercise

Tyler F. Meckes¹, Sam Meske¹, Daniel G. Drury, FACSM², Swapan Mookerjee¹. ¹Bloomsburg University, Bloomsburg, PA. ²Gettysburg College, Gettysburg, PA. (Sponsor: Daniel G. Drury, FACSM)

(No relationships reported)

Handle design and wrist position can affect the muscular performance during resistance exercises. **Purpose:** This study compared the electromyographic (EMG) responses during seated row exercise in the Latissimus Dorsi (LD), Biceps Brachii (BB), and Flexor Carpi Radialis (FCR) using a cylindrical handle versus a MAG® handle. **Methods:** Ten males (aged 21.1 ± 1.4 years) with prior resistance training experience (6.3 ± 1.9 years) performed the exercise protocol on a cable machine. Participants completed a one-repetition maximal lift (1-RM) followed by one set at 85% 1-RM until failure, using both handle types in randomized order. Root mean square EMG (EMG_{RMS}) recordings from the BB, LD, and FCR were normalized to

the 1-RM values. **Results:** Two-way repeated measures ANOVA was used to analyze differences between handle types and EMG activity. EMG_{RMS} values (%) are presented in the table below:

	Cylinder	MAG(R)
Biceps Brachii	66.6 ± 8.9	72.9 ± 2.6*
Latissimus Dorsi	86.6 ± 13.3	84.2 ± 4.6
Flexor Carpi Radialis	57.9 ± 4.1	67.3 ± 4.3

* Sign. Diff. ($p < 0.001$)

The 1-RM lifts were significantly greater ($p < 0.003$) with the MAG® handle (115.2 ± 17.4 kg) versus the cylindrical handle (112.5 ± 17.6 kg). However, there were no significant differences between handles for the total number of repetitions completed (cylindrical 11.9 ± 3.67 ; MAG® 11.2 ± 2.4). **Conclusions:** These findings showed significantly higher maximal lifts and greater EMG activity in the BB using the MAG® handle. Possible mechanisms for these differences may be related to actin and myosin overlap of the forearm flexors, grip comfort and differences in handle contact surface area.

2726 Board #246 June 2 9:30 AM - 11:00 AM

Effect of Movement Speed on Pattern Matching for a Continuous Activity with Visual Feedback

Matthew E. Holman, Benjamin J. Darter. *Virginia Commonwealth University, Richmond, VA.*
 Email: holmanme@vcu.edu

(No relationships reported)

Providing visual feedback (VF) during a task is a common strategy to enhance patient success. However, the speed of the targeted movement may impact one's ability to use feedback toward matching a desired outcome. **Purpose:** 1) To determine the effect of target pattern speed on matching the movement pattern of a continuous activity with VF. 2) To determine if different speeds produce different task normalized muscle activation patterns. **Methods:** Ten young healthy subjects were recruited. Participants completed a non-resisted continuous wrist flexion (FLEX) and extension (EXT) activity. The task involved matching wrist angular motion with a target sine wave (0.7 or 1.0 Hz). VF of wrist movement and the target pattern were provided concurrently on a monitor. An electrogoniometer captured wrist movement while EMG was used to record forearm muscle activation. Five 20s trials with 2min rest periods were completed at each target speed. Cross-correlation (CC) was used to calculate temporal lag between movement and target patterns. Discrete Fourier Transformation (DFT) was used in calculating pattern frequencies to determine movement-target speed. Muscle activation on/off time (ON, OFF), total activation time (TAT), total movement time (TMT), and total co-contraction time (TCoT) were calculated to assess movement characteristics. Paired samples t-tests compared variables between the tested speeds. **Results:** Different wrist movement speeds and muscle activity (TMT and TAT) were found for each target speed ($p < .05$). Further analysis revealed movement and target patterns were similarly matched regardless of target speed, and wrist movement lagged behind target patterns by a similar amount at each speed (0.7 Hz, .007s; 1.0 Hz, .013s). Muscle activation in early EXT was similar between speeds for EXT ON (.03s) and FLEX OFF (.01s). At the start of FLEX, EXT OFF (.04s; $p < .05$) and FLEX ON (.07s; $p < .05$) occurred later at 0.7 Hz. No differences between speeds for TCoT were found. **Conclusions:** Despite lagging behind the target, movement speed did not alter one's ability to match target patterns. Furthermore, movement characteristics were similar between speeds, except for activation during initial FLEX. Greater elastic energy stored during wrist EXT at the higher speed may have delayed agonist activation during early wrist FLEX.

2727 Board #247 June 2 9:30 AM - 11:00 AM

Acute Effects of Unilateral Static Stretching On Handgrip Strength in the Stretched and Non-Stretched Limb

Jacob D. Jelmini, Andrew Cornwell, Nazareth Khodiguian, Jennifer Thayer. *California State University, Los Angeles, Los Angeles, CA.*

Email: jjelmin2@calstatela.edu

(No relationships reported)

Scientific Abstract:

Previous research has demonstrated that an acute bout of static stretching can reduce force and power output from the muscles undergoing the stretching treatment. Although the mechanism for this effect remains unclear, evidence has been presented for both neural inhibition and a decrease in musculotendinous stiffness. To further investigate the presence of a neural inhibitory mechanism, the current study focused on the impact of stretching just one limb on both the stretched limb and the contralateral non-stretched limb. It was reasoned that any decrease in force output from the non-stretched side could only be accounted for by neural inhibition as no mechanical adaptation would have occurred.

PURPOSE: To observe the effects of an acute bout of unilateral static stretching on handgrip strength and to discern whether a neural cross-over inhibitory effect is present to cause a decrease in force output and associated electrical activity from the non-stretched limb. **METHODS:** Thirty participants (15 males, 15 females) performed maximum voluntary unilateral handgrip contractions of both limbs before and after stretching the finger flexors of the strength-dominant side only. Each trial was assessed for peak force and associated muscle activity (iEMG), as well as rate of force generation values. **RESULTS:** Peak force ($p = 0.002$) and associated iEMG ($p = 0.000$) decreased by 4.2% and 6.5% respectively in the stretched limb only. However, rate of force generation was significantly impaired in both the stretched (-15.2%; $p = 0.000$) and non-stretched limbs (-9.4%; $p = 0.006$) one-minute post-stretch, and remained similarly depressed for both limbs 15 minutes later. **CONCLUSION:** We conclude, therefore, that acute stretching negatively impacts rate of force generation more than peak force. Moreover, a reduced rate of force generation from the non-stretched limb indicates the presence of a cross-over inhibitory effect through the nervous system, which provides additional evidence for a neural mechanism.

The Epidemiological Evidence of Cardiometabolic Disease Risk Factors in College-Aged Subjects: A Cross-Sectional Investigation

Michael J. Carper¹, Hillary Dickey², Derek A. Crawford¹, Jessica Heinz¹. ¹Pittsburg State University, Pittsburg, KS. ²University of Oklahoma, Norman, OK.
Email: mcarper@pittstate.edu
(No relationships reported)

PURPOSE: The purpose of this 5-year cross-sectional investigation was to collect basic body composition and fitness data on college-aged males and females to determine cardiometabolic disease risk throughout the college years. **METHODS:** A total of 3,388 college aged males ($n = 1919$) and females ($n = 1469$) age 18 - 25yrs participated in this investigation. Subjects performed the following tests: height; weight; body composition; muscular strength and endurance; cardiopulmonary function; flexibility; waist and hip circumferences; and resting blood pressure. **RESULTS:** Females demonstrated a significant increase, from 18-19 yrs to 20-25 yrs, respectively, in weight (67.1 to 70.8 kg), % body fat (27.9 to 30.4%), waist (80.5 to 83.3 cm) and hip (95.1 to 98.9 cm) measurements, fat mass (19.9 to 24.3 kg), BMI (24.4 to 25.8 kg-m²), diastolic blood pressure (75.8 to 77.4 mmHg), waist-to-height ratio (0.48 to 0.51), and total overweight and obese status (33.9 to 39.1%). These subjects demonstrated a significant decrease, from 18-19yrs to 20-25yrs, respectively, in sit-and-reach (15.4 to 14.6 in.) and total push-ups (15.2 to 13.3). Males demonstrated a significant increase, from 18-19yrs to 20-25 yrs, respectively, in weight (80.8 to 85.3 kg), % body fat (15.1 to 17.6%), waist-to-hip ratio (0.88 to 0.90), waist (85.9 to 89.4 cm) and hip measurements (97.3 to 99.7 cm), waist-to-height ratio (0.48 to 0.50), fat mass (13.3 to 17.1 kg), BMI (25.1 to 26.3), total overweight and obese status (38 to 48.5%), diastolic blood pressure (76.7 to 79.3 mmHg), and right (49.1 to 51.1 kg) and left (46.8 to 48.3 kg) grip strength. These subjects demonstrated a significant decrease, from 18-19yrs to 20-25 yrs, in sit-and-reach (14.5 to 13.9 in), total sit-ups (52.7 to 50.9), and total push-ups (33.6 to 32.1). All data was analyzed using independent sample t-tests (SPSS, v. 23; $p < 0.05$). **CONCLUSIONS:** We have demonstrated that there is a continuous decline in basic health and fitness outcomes in college-aged students that may lead to the development of co-morbid conditions and the development of cardiometabolic diseases such as diabetes, hypertension, and cardiovascular disease.

Physical Activity and Perceived Stress Among Student Physical Therapists

Eric Arguello. University of North Texas Health Science Center, Fort Worth, TX.
(No relationships reported)

Physical activity is often suggested for managing stress. However, it is not known if there is a relationship between perceived stress and physical activity among student physical therapists.

Purpose: To determine the percentage of student physical therapists that meet the national recommended guidelines for aerobic and muscle strengthening physical activity and to describe the relationship between physical activity, perceived stress levels, and time spent in sedentary activities.

Methods: Doctor of Physical Therapy Students ($n=113$) were grouped according to their year in the academic program as Grad I's, Grad II's, and Grad III's. Perceived Stress Scale and Exercise Activities Scale were combined in a questionnaire to describe student physical therapist's perceived stress levels and to determine the average amount of aerobic and muscle strengthening physical activity performed on a weekly basis. Sedentary activities questions were also included in the questionnaire. Data were analyzed for mean perceived stress levels, percentages of student who met the exercise activity guidelines and the mean time spent in sedentary activities. **Results:** Perceived stress was lower for the Grad III's (9.1 ± 4.2) compared to Grad I's (15.1 ± 6.1 $p < .05$) and Grad II's (18.79 ± 8.4 $p < .05$). Perceived stress was lower for the Grad I's compared to Grad II's ($p < .05$). Perceived stress was higher in Grad II's among all physical therapy students. Aerobic physical activity guidelines were met by 65% of Grad I's, 54% of Grad II's, and 93% of Grad III's. Muscle strengthening activity guidelines were met by 33% of Grad I's, 25% of Grad II's, and 72% of Grad III's. Time spent in sedentary activities was lower for Grad III's (867 ± 765 min) compared to Grad I's (2884.4 ± 1531.1 min, $p < .05$) and Grad II's (3741.5 ± 2092.3 $p < .05$). There was a negative correlation between perceived stress and meeting the aerobic ($r_{pb} = -.326$, $n = 113$, $p < .001$) and muscle strengthening ($r_{pb} = -.326$, $n = 113$, $p < .001$) physical activity guidelines for all cohorts. **Conclusion:** Student physical therapists in this Doctor of Physical Therapy program experiencing higher levels of perceived stress also demonstrate overall decreased physical activity and increased sedentary levels. In addition, perceived stress and activity levels appear to fluctuate during their education.

2730 Board #250 June 2 11:00 AM - 12:30 PM

Association of Physical Activity and Sedentary Behavior with Hyperuricemia

DooYong Park¹, YeonSoo Kim¹, SeungHo Ryu², DuckChul Lee, FACSM³, YoungHwan Choi¹. ¹Seoul National University, SEOUL, Korea, Republic of. ²Sungkyunkwan University, SEOUL, Korea, Republic of. ³Iowa State University, IOWA, IA.
(No relationships reported)

PURPOSE: The purpose of this study was to identify the associations of sedentary behavior and physical activity level with hyperuricemia in South Korean men and women. **METHODS:** This study includes 161,064 healthy men and women with completed health examination between March 2011 and December 2013. Physical activity level and sitting time were assessed by a validated Korean version of International Physical Activity Questionnaire Short Form (IPAQ-SF). The presence of hyperuricemia was determined by examining serum uric acid (SUA) concentration (≥ 7 mg/dL). Multivariable logistic regression analysis was conducted to investigate the associations of sedentary behavior and physical activity level with hyperuricemia. **RESULTS:** Participants who spent ≥ 10 hours/day was more likely to have hyperuricemia than participants spending < 5 hours/day (Odds Ratio [OR]=1.10, 95% confidence interval [CI]=1.05-1.16) after adjusting for age, sex and risk factors of hyperuricemia. Participating in health enhanced physical activity (HEPA) defined as 'vigorous-intensity activity on at least 3 days achieving a minimum Total physical activity of at least 1500 MET-minutes/week or 7 more days of any combination of walking, moderate-intensity or vigorous-intensity activities achieving a minimum Total physical activity of at least 3000 MET minutes/week' was associated with decreased prevalence of hyperuricemia, compared to in active group, defined as 'not meet physical activity criteria' (OR=0.92, 95% CI= 0.87-0.96). In gender stratified analyses, sitting time ≥ 10 hours/day was associated with increased prevalence of hyperuricemia (OR=1.09, 95% CI= 1.04-1.15) compared to sitting time < 5 hours/day, and participating in HEPA was associated with decreased prevalence of hyperuricemia (OR=0.91, 95% CI= 0.87-0.96) compared to the minimal activity in men, but it was not significantly associated with prevalence of hyperuricemia in women (sitting time, OR=1.27, 95% CI= 0.97-1.67; HEPA, OR=0.91, 95% CI= 0.77-1.39). **CONCLUSIONS:** This study identified that the prevalence of hyperuricemia was associated by decreased physical activity and prolonged sedentary behavior, especially in men. Thus, participating in regular physical activity and reducing sedentary time are recommended to reduce the prevalence of hyperuricemia.

2731 Board #251 June 2 11:00 AM - 12:30 PM

Associations Between Impaired Fasting Glucose, Hypertriglyceridemia, And Hyperinsulinemia In US Adults: 2007-2012 Nhanes

James R. Churilla, FACSM, Michael R. Richardson. University of North Florida, Jacksonville, FL.
Email: j.churilla@unf.edu
(No relationships reported)

PURPOSE: Examine the gender stratified associations between combinations of impaired fasting glucose and hypertriglyceridemia and the odds of hyperinsulinemia using a nationally representative sample of U.S. adults. **METHODS:** Study sample included male ($n=3109$) and female ($n=3433$) adult (≥ 20 years of age) participants in the 2007-2012 National Health and Nutrition Examination Survey. Hyperinsulinemia

was defined using the 75th percentile of fasting insulin as the cutoff value. Logistic regression analysis was used to examine the associations among impaired fasting glucose, hypertriglyceridemia, and hyperinsulinemia. Logistic regression models were adjusted for age, race, moderate-intensity physical activity (MIPA), and waist circumference (WC). **RESULTS:** Demographic adjusted analyses revealed significantly greater odds of hyperinsulinemia in euglycemic men (OR 3.09, 95% CI 1.96-4.85) and women (OR 3.13, 95% CI 2.12-4.63) with hypertriglyceridemia ($P < 0.0001$ for both). Additionally, women with impaired fasting glucose and normal triglycerides had significantly greater odds of hyperinsulinemia (OR 5.62, 95% CI 3.61-8.75, $P < 0.0001$). A similar relationship was not revealed in men (OR 1.09, 95% CI 0.23-5.13, $P = 0.92$). Following adjustments for MIPA and WC, the odds of hyperinsulinemia in euglycemic men (OR 2.42, 95% CI 1.45-4.05) and women (OR 1.49, 95% CI 1.01-2.18) with hypertriglyceridemia were attenuated, but remained statistically significant ($P < 0.05$ for both). However, the odds of hyperinsulinemia in women with impaired fasting glucose and normal triglycerides were no longer statistically significant ($P = 0.12$). **CONCLUSION:** Our findings revealed greater odds of hyperinsulinemia in euglycemic men and women with hypertriglyceridemia regardless of MIPA or WC.

2732 Board #252 June 2 11:00 AM - 12:30 PM
Association Of Resistance Exercise With The Incidence Of Hypercholesterolemia In Men

Esmée A. Bakker¹, Duck-Chul Lee, FACSM², Xuemei Sui³, Thijs M.H. Eijssvogels¹, Carl J. Lavie⁴, Steven N. Blair, FACSM⁵.
¹Radboud university medical centre, Nijmegen, Netherlands.
²Iowa State University, Ames, IA. ³University of South Carolina, Columbia, SC. ⁴John Ochsner Heart and Vascular Institute, New Orleans, LA. (Sponsor: Dr. Duck-Chul Lee, FACSM)
 Email: Esmee.Bakker@radboudumc.nl

(No relationships reported)

Hypercholesterolemia is a significant risk factor for cardiovascular disease. Although the beneficial effects of aerobic exercise (AE) are well-documented, evidence for the effects of resistance exercise (RE) on the development of hypercholesterolemia is still scarce. **PURPOSE:** To examine the associations of RE, independent of and combined with AE, with the risk of developing hypercholesterolemia in men.

METHODS: Men, aged 18-83 years (mean age 46), who received comprehensive preventive examinations at the Cooper Clinic in Dallas, Texas, were included in this study. Baseline RE, AE, and meeting the 2008 US Physical Activity Guidelines (RE ≥ 2 days/week; AE ≥ 500 MET-minutes/week) were determined by self-reported frequency and minutes of exercise. Hypercholesterolemia was defined as total cholesterol of ≥ 240 mg/dL or physician-diagnosed hypercholesterolemia during follow-up examinations. Hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated using Cox proportional hazards regression.

RESULTS: Among 7,317 participants, 1,430 men (20%) developed hypercholesterolemia during a median follow-up of 4 years. Individuals meeting the RE guidelines had a 13% lower risk of developing hypercholesterolemia (HR 0.87; 95% CI 0.77 to 0.996) after adjustment for potential confounders and AE. In addition, after full adjustment, less than 1 hour/week and 2 sessions/week of RE were associated with 32% and 31% lower risks of hypercholesterolemia (HR 0.68; 95% CI 0.54 to 0.86 and HR 0.69; 95% CI 0.54 to 0.88), respectively, compared to no RE. Higher levels of RE did not show additional benefits. Further, meeting guidelines for both RE and AE lowered the risk of hypercholesterolemia by 21% (HR 0.79; 95% CI 0.68 to 0.92), compared to meeting neither of the guidelines. **CONCLUSIONS:** Even less than 1 hour/week and 2 sessions/week of RE, independent of AE, were associated with significantly lower risk of developing hypercholesterolemia in men. This finding suggests that RE should be added to habitual physical activity to prevent hypercholesterolemia.

Health Behaviors and Dietary Supplement Use among Military Personnel: A Latent Class Analysis

Xiaying Zheng¹, Josh B. Kazman², Tzuheg Kao³, Krauss Stephen², Diana Jeffery³, Patricia A. Deuster, FACSM².

¹University of Maryland, College Park, MD. ²Uniformed Services University, Bethesda, MD. ³Defense Health Agency, DoD, Falls Church, VA.

Email: xyzheng86@gmail.com

(No relationships reported)

Dietary supplements (DS) are commonly used to increase muscle mass and/or lose weight, even though many are ineffective and linked to adverse events. DS use is particularly common among military personnel and athletes, correlating with both health-promoting and risky/deleterious behaviors. Latent class analysis (LCA) identifies and classifies people into separate groups based on combinations of categorical responses. **PURPOSE:** To extend the current literature focused on individual relations among DS use and health behaviors, the present study used LCA to: (1) characterize military personnel with respect to health behaviors related to the performance triad, and (2) describe differences in body building (BB) and weight loss (WL) DS use across the classes constructed in (1). **METHOD:** Data from the 2011 DoD Health Related Behaviors Survey of Active Duty Military Personnel for 39,877 service members were assessed. Variables related to diet, activity and sleep were used in a sample weighted LCA to identify a best-fitting model and number of classes, and then relate class membership to BB and WL use. **RESULTS:** The best-fitting model identified four latent classes: 1) Balanced: balanced performance class (30%), characterized by healthy diet, high-to-moderate activity, and adequate sleep; 2) Active: highly active class (31%), characterized by poor diet, very high activity, and low-to-moderate sleep; 3) Unhealthy: weak performance class (34%), characterized by poor diet, low activity, and moderate-poor sleep; and 4) Inconsistent: careless responding class (5%), characterized by extreme and inconsistent responses. BB and WL supplements were most prevalent in the Active class (BB: 38%; WL: 37%) and least prevalent in the Unhealthy class (BB: 22%; WL: 28%). Females were less likely to use BB (17% female vs. 37% male) but more likely to use WL (23% female vs. 20% male) supplements. Class membership and WL/BB use also varied by military service branch. **CONCLUSION:** Among military personnel, BB and WL use are related to distinct patterns of positive and deleterious health behaviors. Educational DS campaigns should be tailored towards these latent classes of health behaviors. BB and WL use may be more common among individuals who engage in otherwise healthy behaviors than among those who engage in deleterious behaviors.

Characterizing the Relationship between Physical Activity and Osteoporosis in the Greater Philadelphia Hispanic Population

Allison R. Altman-Singles, Eliana Bolano, Pennsylvania State University, Berks Campus, Reading, PA. (Sponsor: Mary Jane De Souza, FACSM)

Email: ara5093@psu.edu

(No relationships reported)

The Hispanic population in the United States has increased 9-fold since 1960, and currently accounts for 20% of the total population. While the incidence of osteoporosis in this population is similar to the national average, the literature exploring the connection between physical activity and osteoporosis incidence in Hispanic Americans is limited. **PURPOSE:** To determine the relationship between physical activity and osteoporosis in the Philadelphia Hispanic population. **METHODS:** 49 postmenopausal Hispanic women were recruited from community centers in the greater Philadelphia area. Surveys obtained self-reported osteoporosis status, which was used to separate women into healthy and osteoporosis groups. Both groups were queried regarding their physical activity level and type in childhood, adulthood, and late adulthood. Subject characteristics, fractures, nutrition, and socioeconomic status were also obtained. **RESULTS:** Groups (healthy $n = 25$, osteoporosis $n = 24$) were similar in height, weight, and age of menopause, but the osteoporosis group (67.6 \pm 10.0 yr) was older than the healthy group (73.8 \pm 6.2 yr). The osteoporosis group reported 25 total fractures (9 at hip), versus 8 in the healthy group (0 at hip). In both groups, activity levels decreased with aging from 3.2 hr/wk during childhood to 2.3 hr/wk during late adulthood. Physical activity levels at all stages of life were 33-37% higher in the healthy group (Fig 1). Impact exercise was more widely practiced in the healthy group at all stages. The osteoporosis group reported more meals containing starch, but fewer meals containing meat, vegetables, fruit, and dairy. Education level was lower in the osteoporosis group. **CONCLUSION:** The results display a positive relationship between increased physical activity and bone health in Hispanic women. This study suggests more education may encourage better habits, potentially reducing osteoporosis incidence in this Hispanic American population.

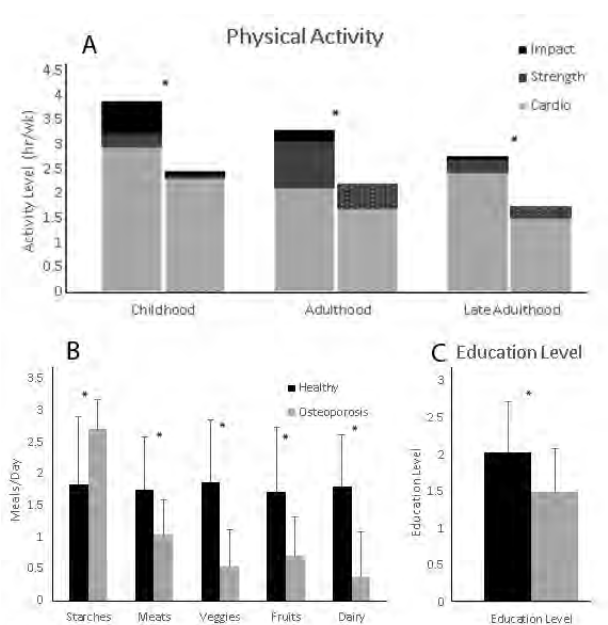

Figure 1. A. Summary of physical activity during childhood, adulthood, and late adulthood shown in bars with solid bars for healthy and dotted bars for osteoporosis group. B. Nutritional breakdown by number of meals/day containing each element. C. Education status – 1 indicates 9th grade, 2 indicates 12th grade, 3 indicates 2 year college, and 4 indicates 4 year college. Bars represent means+standard deviation. Significant difference $p<0.05$ denoted by *.

Healthy Lifestyle Behaviors Related to Cardiovascular Risk among Young Adults

Melissa A. Napolitano¹, Jessica A. Whiteley², Meghan Mavredes¹, Laura L. Hayman², Samuel Simmens¹, Loretta DiPietro, FACSM¹. ¹The George Washington University, Washington, DC. ²University of Massachusetts Boston, Boston, MA. (Sponsor: Loretta DiPietro, FACSM)
 Email: mnapolitano@gwu.edu
 (No relationships reported)

Purpose: Participation in healthy lifestyle behaviors is associated with decreased risk for CVD across the lifecourse. Examining clustering of healthy lifestyle behaviors among young adults at increased risk due to elevated BMI could provide insight into CVD preventive interventions that could be implemented during this developmental transition. **Methods:** Young adults (ages 18-35) enrolled in a healthy body weight clinical trial (n=210; % female=79.5%; M age=22.1 ±3.9; M BMI=31.4±3.7) completed surveys: demographics, the International Physical Activity Questionnaire (IPAQ) and the Population Assessment on Tobacco and Health (PATH) questions. **Healthy Lifestyle Behaviors included:** 1) meeting guidelines for moderate-to-vigorous physical activity (MVPA; >150 minutes); 2) never cigarette user 3) never e-cigarette user; 4) low sedentary behavior (<4 hours/day). Participants were scored for the presence of up to 4 healthy lifestyle behaviors. **Results:** Participants reported engaging in 122.7±103.6 minutes/week of MVPA and 8.5±3.4 hours/day of sedentary behavior. Approximately 6.2% met criteria for MVPA, 60.9% reported never smoking cigarettes, 83.2% reported never using e-cigarettes, and 17.6% had low sedentary behavior time. In terms of clustering of healthy lifestyle behaviors, 11.0%, 29.9%, 50.5%, 7.6%, 1.1% had 0, 1, 2, 3, 4 healthy behaviors, respectively. The distribution of number of health behaviors varied little by age, gender or BMI status (overweight vs. obese). **Conclusions:** Young adults with elevated BMIs are at increased risk for CVD, given their weight status. Results indicate that few were engaging in the maximum number of recommended health behaviors to mitigate risk. Understanding healthy lifestyle and CVD risk behavior is essential for both prevention and intervention efforts. Recommendations are for future studies to assess health behaviors to identify young adults at risk such that targeted multi behavior interventions can be implemented. **Funding source:** NIH/NIDDK #DK100916

2736 Board #256 June 2 11:00 AM - 12:30 PM
Effects Of Changes in Depressive Symptoms and Cardiorespiratory Fitness on All-cause Mortality: The HUNT Study

Trude Carlsen¹, Øyvind Salvesen¹, Ulrik Wisløff¹, Carl J. Lavie², Steven N. Blair, FACSM³, Linda Ernsten¹. ¹Norwegian University of Science and Technology, Trondheim, Norway. ²John Ochsner Heart and Vascular Institute, Ochsner Clinical School, The University of Queensland School of Medicine, New Orleans, LA. ³Arnold School of Public Health, University of South Carolina, Columbia, SC.
 Email: trude.carlsen@ntnu.no
 (No relationships reported)

PURPOSE: Depression and cardiorespiratory fitness (CRF) are positively and negatively associated with mortality, respectively. Studies examining the relationship between depressive symptoms (DS) and mortality seldom account for the possible effect of CRF. We investigated the independent and combined associations of changes in DS and CRF with all-cause mortality. **METHODS:** 14 799 participants (mean age 63 years, 51.8% women) from the second (1995-97) and third (2006-08) wave of the Nord-Trøndelag Health Survey (HUNT) were included. DS were measured with the validated Hospital Anxiety and Depression Scale (HADS-D). A HADS-D score ≥8 indicated high DS. CRF was estimated (eCRF) using a validated non-exercise model. eCRF above median value indicated high eCRF. Change in HADS-D score was classified into persistently high DS, increased DS, decreased DS, and persistently low DS. Change in eCRF was classified into persistently high eCRF, increased eCRF, decreased eCRF and persistently low eCRF. Deaths were ascertained using The Norwegian Cause of Death Registry. **RESULTS:** During a mean follow-up period of 7.2 years after baseline (HUNT3), 1101 all-cause deaths (7.4%) were registered. A multivariate analysis adjusted for baseline age, sex, marital status, education, physical activity, body mass index, smoking status, alcohol consumption, ischemic heart disease, cancer, stroke/brain hemorrhage, hypercholesterolemia, diabetes, systolic blood pressure and change in eCRF; showed having persistently low DS was associated with a 29% risk reduction of all-cause mortality (hazard ratio (HR) 0.71; 95% CI 0.55-0.91) compared to persistently high DS. Persistently high eCRF independently predicted lower risk of all-cause mortality (HR 0.62; 95% CI 0.50-0.77), compared to persistently low eCRF. In the combined analyses, test for trend ($p<0.001$) suggests a linear relationship between the worst (persistently high DS and persistently low eCRF) and the best (persistently low DS and persistently high eCRF) combinations of DS and eCRF. **CONCLUSION:** Maintaining low levels of DS and maintaining high levels of eCRF are associated with a lower risk of all-cause mortality in middle aged and older people.

New Get-up Test As an Indicator Of Sarcopenia, Sarcopenic Obesity, And Cardiovascular Disease Risk Factors

Duck-chul Lee, FACSM, Nathan F. Meier. Iowa State University, Ames, IA.
 Email: dclee@iastate.edu
 (No relationships reported)

PURPOSE: To investigate the associations of get-up test time with sarcopenia, sarcopenic obesity (SO), and cardiovascular disease (CVD) risk factors. **METHODS:** This cross-sectional study included 269 older adults (56% female) aged ≥65 years (mean age 72, ranged 65-95). The get-up test was newly developed as a physical function test in which the participant should lie down to the floor and back up to standing as fast as possible, and categorized into three tertiles (fast, moderate, and slow) based on the get-up test time in seconds. Sarcopenia was defined as low appendicular lean mass index (men, ≤7.23 kg/m²; women, ≤5.67 kg/m²) plus either slow gait speed (≤0.8 m/s) or weak handgrip strength (men, <30 kg; women, <20 kg), according to the European Working Group on Sarcopenia in Older People. SO was defined as the coexistence of sarcopenia and obesity based on % body fat (men, ≥25%; women, ≥30%) using Dual Energy X-Ray absorptiometry. **RESULTS:** Mean (SD) get-up test time was 7.2 (3.2) seconds, and 29 (11%) and 27 (10%) older adults had sarcopenia and SO, respectively. Each one second increase (slow) in get-up test time was associated with unfavorable sarcopenia variables and CVD risk factors, specifically with 0.02 m/s slower gait speed, 0.67 kg weaker handgrip strength, 0.87% increased body fat, 0.64 mg/dl increased fasting glucose, and 0.71 kg/m² increased body mass index (all $p<0.05$) in the linear regression after adjusting for age, sex, smoking status, and alcohol intake. Compared to the fast get-up test group, odds ratios (95% confidence intervals) in moderate and slow get-up test groups were 4.42 (1.17-16.74) and 5.86 (1.60-21.41) for sarcopenia, and 4.00 (1.04-15.34) and 5.41 (1.47-19.92) for SO, respectively, in the multivariable logistic regressions. Although mostly not statistically significant, older adults in the moderate and slow get-up test groups had increased odds ratios for the prevalence of hypertension, diabetes, hypercholesterolemia, and obesity, compared to the older adults in the fast get-up

test group. **CONCLUSIONS:** This study suggests that faster get-up test physical performance in older adults is associated with lower prevalence of sarcopenia, SO, and CVD risk factors. Get-up test can be used as a significant indicator of sarcopenia, SO, and CVD risk factors in older adults.

Active Transportation And C-reactive Protein In U.S. Adults

Nicholas F. Diaz, Michael R. Richardson, James R. Churilla, FACSM. *University of North Florida, Jacksonville, FL*. (Sponsor: James R Churilla, FACSM)
(No relationships reported)

PURPOSE: Examine the associations between self-reported use of active transportation and elevated C-reactive protein (CRP) using a nationally representative sample of U.S. adults.

METHODS: The study sample (n=9937) included male and female adults (≥ 20 years of age) who participated in the 2007-2010 National Health and Nutrition Examination Survey. Elevated CRP was defined using the current Centers for Disease Control and Prevention and the American Heart Association recommendations. Active transportation included walking or use of a bicycle to and from work, for shopping, or to school for at least 10 minutes continuously.

RESULTS: Compared to a referent group of U.S. adults reporting no use of active transportation, analysis revealed significantly lower odds of having an elevated CRP concentration in those reporting more than two days per week (d/wk.) of active transportation (Odds Ratio [OR] 0.83; 95% Confidence Interval [CI], 0.72-0.94, $P=0.0064$). A similar relationship was not revealed in those reporting less than two d/wk. of active transportation (OR 0.87; 95% CI, 0.61-1.24, $P=0.4267$).

CONCLUSIONS: In a nationally representative sample of U.S. adults, increased use of active transportation (>2 d/wk.) was associated with significantly lower odds of elevated CRP independent of waist circumference.

Impact Of Race And Non-exercise Estimated Cardiorespiratory Fitness On Incident Stroke: The Regards Study

Xuemei Sui¹, Virginia Howard², Michelle McDonnell³, Linda Ernstsens⁴, Carl Lavie⁵, Steven Hooker, FACSM⁶. ¹*University of South Carolina, Columbia, SC.* ²*University of Alabama at Birmingham, Birmingham, AL.* ³*University of South Australia, Adelaide, Australia.* ⁴*University of Science and Technology, Trondheim, Norway.* ⁵*John Ochsner Heart and Vascular Institute, New Orleans, LA.* ⁶*Arizona State University, Phoenix, AZ.* (Sponsor: Steven P. Hooker, FACSM)
Email: msui@mailbox.sc.edu
(No relationships reported)

Routine utilization of cardiorespiratory fitness (CRF) in cardiovascular disease risk assessment is limited due to cost and the need for exercise equipment and skilled personnel. Estimated CRF (eCRF), based on non-exercise algorithms utilizing readily available clinical and self-reported data, is a promising alternative though its role as a predictor of incident stroke remains unclear, especially in an African American (AA) population. **Purpose:** To study the association between eCRF and incident stroke as well as the impact of race on the associations. **Methods:** This population-based U.S. cohort study included 24,465 participants (54.8% women, 39.6% AA, mean age 64.6 years) from the REasons for Geographic And Racial Differences in Stroke (REGARDS) study who were free of stroke at enrollment 2003-2007. Participants were telephoned every 6 months to assess potential stroke, with retrieval and central physician adjudication of medical charts of suspected strokes through March 31, 2016. Baseline eCRF in maximal metabolic equivalents (METs) was determined using non-exercise sex-specific algorithms and further grouped into age-, and sex-specific tertiles of the METs distribution. Hazard ratio (HR) and 95% confidence interval (CI) for incident stroke and its subtypes (ischemic and hemorrhagic stroke) was estimated using Cox proportional hazards regression. **Results:** After an average of 8.3 years of follow-up, 961 (3.9%) participants developed stroke (856 ischemic, 105 hemorrhagic subtype). Compared to the lower tertile eCRF, those in the middle and upper eCRF groups had 6% (HR, 95% CI: 0.94, 0.81-1.10) and 25% (HR, 95% CI: 0.75, 0.63-0.90) lower risk of developing stroke, respectively. Findings were similar findings for ischemic stroke (middle: 7% (HR, 95% CI: 0.93, 0.79-1.10) and upper 28% (HR, 95% CI: 0.72, 0.60-0.88). No association was observed, however, for hemorrhagic stroke. The pattern of the association between eCRF and stroke incidence was similar in women and men. However, eCRF was not associated with stroke among AAs. **Conclusion:** Estimated CRF using non-exercise algorithms is a useful predictor of ischemic stroke, in both men and women. The null finding in AAs has important potential public health and clinical implications regarding primary stroke prevention among different ethnicity groups.

Exercise Cardiac Power And Coronary Artery Calcification In Men

Sae Young Jae¹, Kanokwan Bunsawat², Eun Sun Yoon¹, Hyun Jeong Kim¹, Won Hah Park³, Bo Fernhall, FACSM². ¹*University of Seoul, Seoul, Korea, Republic of.* ²*University of Illinois at Chicago, Chicago, IL.* ³*Samsung Medical Center, Seoul, Korea, Republic of.*
Email: syjae@uos.ac.kr
(No relationships reported)

PURPOSE: Low exercise cardiac power (ECP), defined as a ratio of peak oxygen consumption with peak systolic blood pressure during exercise, is associated with adverse cardiovascular events, but the underlying mechanisms remain unclear. Coronary artery calcification (CAC) as a surrogate marker of atherosclerosis is associated with an increased risk of cardiovascular outcomes. We tested the hypothesis that lower levels of ECP may be associated with the prevalence of CAC, independent of conventional risk factors, in a cross-sectional study of 2165 (age 53 \pm 6 yrs, range 40-78 yrs) men. **METHODS:** We measured CAC using multidetector computed tomography using the Agatston coronary artery calcium score. The prevalence of CAC was defined as dichotomous variables of CAC score >0 . ECP was calculated by a ratio of peak oxygen consumption with peak systolic blood pressure and classified into quartiles. **RESULTS:** The presence of CAC was inversely associated with ECP quartiles (both, $P < .001$ for trend). After adjusting for age, BMI, SBP, HDL-C, hsCRP, glucose, heart rate, smoking, hypertension and diabetes, men in the lowest quartile of ECP had a significantly elevated odds ratios for having CAC (odds ratio (OR) 1.43, 95% CI 1.06-1.93), compared with men in the highest quartile of ECP. Each ECP unit increment as a continuous variable was associated with 4% (OR 0.96, 95% CI 0.93-0.99) lower prevalence of CAC after adjusting for established risk factors. **CONCLUSIONS:** Our findings demonstrate that lower levels of ECP are associated with the prevalence of coronary artery calcification, which could contribute to increased risk of cardiovascular events.

Isotemporal Substitution Models For Associations Between PA And Health Outcomes In Overweight/obese Adults

Jaemyung Kim¹, Hyo Lee², Munchong Choi¹, Jaegyun Jung¹, Eunhyung Cho³, Miyoung Lee¹. ¹*Koomin University, SEOUL, Korea, Republic of.* ²*Sangmyung University, SEOUL, Korea, Republic of.* ³*Sungkyunkwan University, SUWON, Korea, Republic of.* (Sponsor: Ulf Ekelund, FACSM)
(No relationships reported)

PURPOSE: Purpose: To examine the effects of reallocating sitting time to moderate- or vigorous-intensity physical activity on health outcomes in a population-representative sample of overweight/obese Korean adults. **METHODS:** Data were retrieved from a subsample (N=1,420; Age=52.35 \pm 16.64yrs; BMI=27.57 \pm 2.37) of the KNHANES 2014. Time spent on moderate-intensity physical activity (MPA), vigorous-intensity physical activity (VPA), and sitting (ST) were measured utilizing the GPAQ. Health outcomes were 1) the metabolic syndrome (having 3+ risk components: elevated fasting glucose, central obesity, systemic hypertension, elevated triglycerides, and low HDL-C, defined according to AHA/NHLBI criteria), and 2) self-reported health measured by the EuroQol-5D Questionnaire (EQ5D; count variable). Age-group-specific (i.e., middle-age vs. older adults) Logistic and Poisson regression models were used to determine the associations when substituting a specific amount of ST with an equal amount of MPA, and VPA, respectively on metabolic and self-reported health outcomes. Analyses were adjusted for gender, smoking, drinking, education, and household incomes. **RESULTS:** In middle aged (30-64yrs), replacing ST with an equal amount of time in VPA was significantly associated with reduced odds for self-reported health problems (OR=0.86, 95%CI:0.76-0.98). Similarly, in older adults (65+yrs), substituting sitting time with MPA was significantly associated with lower odds for self-reported health problems (OR=0.96, 95%CI:0.92-0.99). In opposite, replacing ST with MPA or VPA was not associated with the metabolic syndrome. **CONCLUSIONS:** Substituting sitting time with VPA or MPA appears beneficially associated with self-reported health in overweight/obese middle-aged and elderly Korean men and women, respectively. The different associations between age groups may be explained by low participation in VPA in the older age-group. *This study was supported by NRF-2014R1A1A3049992. Corresponding: Miyoung Lee

Change in Cardiorespiratory Fitness and Ideal Cardiovascular Health in the Aerobics Center Longitudinal StudyJacob L. Barber, Leanna M. Ross, Xuemei Sui, Steven N. Blair, FACSM, Mark A. Sarzynski, FACSM. *University of South Carolina, Columbia, SC.**(No relationships reported)*

PURPOSE: To examine the relationship between changes in cardiorespiratory fitness and changes in ideal cardiovascular health (CVH) score over time. **METHODS:** The association between change in fitness and change in ideal CVH score was examined in 2,555 adults who had at least two clinic visits in the Aerobics Center Longitudinal Study. Fitness was measured as duration in minutes from a maximal treadmill test. Ideal CVH score was calculated on a 14 point scale using the AHA's simple 7 criteria of smoking status, BMI, physical activity (MET-min/wk), healthy diet, total cholesterol, blood pressure, and fasting plasma glucose. Participants were grouped into categories of loss, stable, or gain, by tertiles of change in cardiorespiratory fitness and also by tertiles of change in ideal CVH score between baseline and last follow-up visit. **RESULTS:** After a mean follow up of 3.3 ± 2.4 years, the average change in ideal CVH score was 0.14 ± 1.9 and the average change in treadmill time was -0.25 ± 2.7 minutes for the total sample. After controlling for age, sex, and time between exam dates, the gain in fitness group ($n=851$) significantly ($p<0.0001$) increased their ideal CVH score by an average of 0.71 ± 1.9 , while the stable and loss of fitness groups ($n=830$ and 873 respectively) significantly ($p<0.0001$) decreased their scores by -0.07 ± 1.9 and -0.55 ± 1.9 , respectively ($p<0.0001$ for difference between groups). Change in treadmill time per year explained 6.5% of the change in ideal CVH score. For every minute increase in treadmill time per year, the ideal CVH score increased by 0.09 per year. **CONCLUSIONS:** Improving cardiorespiratory fitness during middle age is associated with higher scores and greater improvement in ideal cardiovascular health.

2743 Board #263 June 2 11:00 AM - 12:30 PM

Screen-time, Physical Activity And Bmi: Confounding By Socioeconomic Status Among Young AdultsJonathan M. Miller, Theresa L. Osypuk, Richard F. MacLehose, Katie A. Loth, Dianne Neumark-Sztainer. *University of Minnesota, Minneapolis, MN.* (Sponsor: Matthew Buman, FACSM)

Email: mill5687@umn.edu

(No relationships reported)

PURPOSE: Observational studies often adjust for confounding by socioeconomic status (SES) but rarely report the magnitude of confounding bias. Also, different indicators of SES may not meet the definition of a confounder for some associations. This study will determine whether different measures of SES have different confounding effects on the associations of screen time with BMI and of moderate/vigorous physical activity (MVPA) with BMI.

METHODS: In a 15 year prospective cohort study, 1830 young adults (age 25 - 36) reported height and weight (used to calculate BMI in kg/m^2), hours/day of screen time, hours/week of MVPA and nine measures of SES in 2015. SES at baseline (2000) was based on parent education and employment. BMI, screen time and MVPA were regressed with linear regression on each SES measure and a composite measure that combined young adults' income and education. Crude associations of screen time with BMI and of MVPA with BMI were assessed with linear regression. The SES measures were added individually to these models to determine the percent change in the associations (percent confounding).

RESULTS: Seven measures of SES were associated with BMI; eight with screen time; and four with MVPA. Education, income, financial strain and living with parents all confounded the association of screen time with BMI by more than 10%. No measure confounded the relationship of MVPA with BMI by more than 10%. The composite measure was significantly associated with screen time ($\beta = -0.39$, 95% CI $[-0.47$ to $-0.31]$) and BMI ($\beta = -1.29$, 95% CI $[-1.58$ to $-0.99]$), but not with MVPA. This composite substantially confounded the association of screen time with BMI (29%) but not of MVPA with BMI (3%).

CONCLUSIONS: The composite SES measure had similar properties to individual SES measures: it was associated with screen time and BMI but not with MVPA and it had substantial confounding bias effect on the association of screen time with BMI, but not on the association of MVPA with BMI. Knowing the magnitude of confounding can help assess results from other studies that do not adjust for SES. A composite measure may be useful for the varied analyses done with data from large cohort studies. However, because of the potential for over fitting models, associations with measures of SES should be carefully considered before using them to adjust for confounding.

2744 Board #264 June 2 11:00 AM - 12:30 PM

Change In Knee Extensor Strength And All-cause Mortality In Japanese Elderly Individuals: A Cohort StudyNaofumi Yamamoto¹, Hideo Miyazaki², Hiroshi Nagayama³, Mieko Shimada⁴, Naoki Nakagawa⁵, Susumu S. (Sponsor: Susumu S. Sawada, FACSM)

Email: yamamoto.naofumi.mk@ehime-u.ac.jp

(No relationships reported)

Previous epidemiologic studies have shown that a low level of lower extremity strength is associated with a high risk of mortality among elderly individuals. However, most of these studies only measured lower extremity strength once, at baseline, and limited data are available on the association between changes in the lower extremity strength and mortality in the elderly, particularly in Asian populations. **PURPOSE:** The purpose of this study was to examine the association between changes in knee extensor strength (KES) over four years and all-cause mortality in Japanese elderly individuals.

METHODS: The participants were 338 (185 males and 153 females) physically independent, community-dwelling Japanese individuals 70 years of age at baseline. KES was measured annually from 1998 (baseline) to 2002. We included participants with KES measured at baseline and at least two more times from 1999 to 2002. We estimated the change per year in KES for each person using simple linear regression. Participants were then divided into quartiles based on the regression coefficient (first quartile, $<-3.54\%$ per year; second quartile, -3.53% to -0.82% per year, third quartile, -0.81% to 2.31% per year; fourth quartile, $>2.32\%$ per year), and were followed up for 8 years (2002-2010). The hazard ratios and 95% confidence intervals (CIs) for death across the baseline quartiles of KES trend were obtained from a Cox proportional hazards model while adjusting for sex, body mass index, smoking status, alcohol intake, medication use, functional capacity and initial KES value.

RESULTS: Forty-six (13.6%) participants died during the follow-up period. The hazard ratios for death across the quartiles of KES trend (lowest to highest) were 1.0 (referent), 0.55 (95% CI 0.25-1.21), 0.61 (95% CI 0.28-1.31), 0.33 (95% CI 0.12-0.86) (P for trend=0.033). Participants in the highest quartile had a significantly lower risk of death than those in the lowest quartile.

CONCLUSIONS: These results indicate that, among physically-independent Japanese elderly individuals, 4-year change in KES among 70-year-olds is associated with lower risk of all-cause mortality over 8 years of follow-up, independent of the KES value at baseline.

2745 Board #265 June 2 11:00 AM - 12:30 PM

Estimated Cardiorespiratory Fitness And Incident Cognitive Impairment: Results From The Regards StudyLinda Ernsten¹, Xuemei Sui², Virginia J. Howard³, Virginia G. Wadley³, Evan Thacker⁴. ¹Norwegian University of Science and Technology, K.G. Jebsen Center of Exercise in Medicine, Trondheim, Norway. ²University of South Carolina, South Carolina, SC. ³University of Alabama at Birmingham, Birmingham, AL. ⁴Brigham Young University, Provo, UT. Email: linda.ernsten@ntnu.no*(No relationships reported)*

Purpose: Clinical studies suggest that higher cardiorespiratory fitness (CRF) is associated with better global and domain-specific cognitive function. Estimated CRF (eCRF), based on non-exercise algorithms from clinical and self-reported data, is feasible and practically useful in primary care. However, whether eCRF is an appropriate predictor for increased risk for cognitive impairment in the general population remains unclear. **Methods:** This prospective study included 21,220 participants (55.9% women, 37.1% African American, mean age 64.2 years) from the REasons for Geographic And Racial Differences in Stroke (REGARDS) study without cognitive impairment and no history of stroke at baseline. Participants' global cognitive status was assessed annually with the validated Six-Item Screener

(SIS) (range from 0 to 6) where a score ≤ 4 indicates cognitive impairment. Incident cognitive impairment was defined based on the most recent SIS, obtained an average of 7.6 years after baseline. Baseline eCRF in METs was determined using non-exercise algorithms based on gender, age, body mass index, waist circumference, heart rate, physical activity, and smoking status. Baseline eCRF was further grouped into age- and sex-specific categories of the METs distribution. Logistic regression models were used to calculate odds ratio (ORs) and 95% confidence intervals (CIs) for the association between baseline eCRF and incident cognitive impairment. The multivariable analyses were adjusted for race, residence in stroke belt, education, income, alcohol use, depressive symptoms, hypertension, dyslipidemia, diabetes, atrial fibrillation, and coronary artery disease. **Results:** During follow-up, 2,300 (10.8%) of the participants experienced incident cognitive impairment. In fully adjusted models comparing with lower category of eCRF, those in the middle and upper eCRF groups had 8% (OR: 0.92, 95% CI: 0.83-1.04) and 23% (OR: 0.77, 95% CI: 0.68, 0.62-0.87) lower odds of incident cognitive impairment, respectively. **Conclusion:** Estimated CRF using non-exercise algorithms is a useful predictor of incident impairment in the general population, and the protective effect is more pronounced for those with highest eCRF.

2746 Board #266 June 2 11:00 AM - 12:30 PM
Physical Activity, Life's Simple 7, and Health-Related Quality Of Life In Older Rural U.S. Adults
 Peter D. Hart, Gabriel A. Benavidez. *Montana State University - Northern, Havre, MT.*
 Email: peter.hart@msun.edu
 (No relationships reported)

PURPOSE: The American Heart Association (AHA) has developed a new metric representing ideal cardiovascular health. The Life's Simple 7 (LS7) consists of four health behavior and three health factor metrics: 1) smoking, 2) body mass index (BMI), 3) healthy diet, 4) physical activity (PA), 5) cholesterol, 6) blood pressure, and 7) diabetes mellitus. Currently, the AHA promotes meeting all seven components of the LS7 metric, considering each component equal in terms of its impact. The aim of this study was to examine specifically the contribution of PA to the LS7 metric and its relationship to health-related quality of life (HRQOL). **METHODS:** Data for this study came from a large national survey conducted in 2015. A total of N=46,498 adults 50+ years of age and residing in a rural U.S. county were included. HRQOL was assessed using the CDC Healthy Days Index and dichotomized to represent good or poor health. A modified LS7 metric was assessed to include: 1) not smoking within past year, 2) BMI less than 25, 3) consumption of 5+ fruits and vegetables per day, 4) obtaining 150+ minutes of moderate PA per week, and not being diagnosed with 5) high cholesterol, 6) hypertension, or 7) diabetes. One set of analyses were performed with those meeting the PA metric excluded and one set with those meeting the PA metric included. Multiple logistic regression was used to compute odds ratios (ORs) and 95% confidence intervals (CIs) while adjusting for age, sex, race, and income. **RESULTS:** Prevalence of good HRQOL increased linearly (59.0%, 68.9%, 75.1%, 80.4%, 84.2%, 89.6%, & 90.0%, $p < .001$) across adult groups meeting 0 to 6 LS7 metrics, respectively. Adjusted models with those meeting PA excluded showed increased odds of reporting good HRQOL in adults meeting 1 (OR=2.16; 95% CI: 1.74-2.67), 2 (2.40; 2.01-2.88), 3 (2.61; 2.13-3.21), 4 (3.08; 2.32-4.08), and 5+ (4.56; 2.67-7.78) LS7 metrics. Adjusted models with those meeting PA included showed mostly greater odds of reporting good HRQOL in adults meeting 1 (1.71; 1.55-1.87), 2 (3.78; 3.03-4.73), 3 (4.69; 3.72-5.93), 4 (6.66; 5.01-8.86), and 5+ (6.76; 5.22-8.74) LS7 metrics. **CONCLUSIONS:** Results from this study show that the LS7 metric is a stronger predictor of HRQOL when PA is met in older rural U.S. adults. Health promotion programs should emphasize the importance of PA to the LS7 metric.

Novel Predictors of Age-Related Changes in Lung Function: An Analysis of the Fels Longitudinal Study
 Shilpa Dogra¹, Andrew W. Froehle², Peterson J. Matthew².
¹University of Ontario Institute of Technology, Oshawa, ON, Canada. ²Wright State University, Dayton, OH.
 Email: shilpa.dogra@uoit.ca
 (No relationships reported)

Smoking and air pollution exposure are modifiable predictors of age-related declines in lung function. There is some evidence to suggest that physical inactivity may be a predictor of age-related changes in lung function; however, the independent contribution of sitting time, physical activity, and cardiorespiratory fitness have not been investigated to date. **PURPOSE:** To determine the association between age-related declines in lung function with sitting time, physical activity and cardiorespiratory fitness in a population of healthy adults. **METHODS:** Data from the Fels Longitudinal Study (1999-2015) were used for analysis (n=996), with serial data available for up to five study visits. Forced expiratory volume in 1 second (FEV₁) and forced vital capacity (FVC) were measured using a metabolic cart (SensorMedics VMax). Physical activity was measured using the Baecke questionnaire and TV time was self-reported as either never, seldom, sometimes, often, and very often.

Cardiorespiratory fitness was determined by calculating VO_{2max} from a submaximal treadmill test. Data were analyzed using repeated measures hierarchical linear models in SAS. **RESULTS:** The sample was middle-aged (45.0 ± 17 years), overweight (BMI: 27.1 ± 5.6 kg/m²), and their VO_{2max} was 36.6 ± 9.8 ml/kg/min. Approximately 53% of the sample reported watching TV often and only 3% of the sample reported engaging in regular physical activity often. In models adjusted for age, BMI, physical functioning and smoking status, there was a significant TV time x sex interaction ($p < 0.0001$) when modeling FEV₁, such that higher TV time in females was associated with worse FEV₁ compared to males. A physical activity x sex interaction ($p < 0.0001$) was also observed in adjusted models of FEV₁. When TV time, physical activity and cardiorespiratory fitness were included in the same model, only the association between cardiorespiratory fitness and FEV₁ remained significant ($p < 0.001$). **CONCLUSION:** Cardiorespiratory fitness is a predictor of age-related changes in lung function. Among deconditioned adults, particularly in females, reducing sedentary time and increasing physical activity may lead to an increase in cardiorespiratory fitness and thus may attenuate the age-related decline in lung function.

Adiposity Parameters As A Full Mediation Of The Influence Of Muscular Fitness And Cardiometabolic Risk Clustering In Adults From Colombia
 Lorena E. Benavides-Rodríguez¹, Jorge E. Correa-Bautista¹, Andres Vivas², Daniel H. Prieto-Benavidez¹, Javier Martínez-Torres³, Katherine Gonzalez-Ruiz², Hugo Alejandro Carrillo⁴, Hector Reynaldo Triana-Reina³, Jeison Alexander García-Hermoso⁵, Robinson Ramírez-Vélez¹. ¹Centro de Estudios para la Medición de la Actividad Física «CEMA». *Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá D.C, Co, Bogota, Colombia.* ²Grupo de Investigación en Ejercicio Físico y Deporte. *Vicerrectoría de Investigación, Universidad Manuela Beltrán, Bogotá, D.C, Colombia.* ³Grupo GICAEDS. *Facultad de Cultura Física, Deporte y Recreación, Universidad Santo Tomás, Bogota, Colombia.* ⁴Grupo GRINDER, *programa de Educación Física y Deportes, Universidad del Valle, Cali, Colombia.* ⁵Facultad de Educación a Distancia y Virtual. *Institución Universitaria Antonio José Camacho, Cali, Colombia.*
 Email: robin640@hotmail.com
 (No relationships reported)

PURPOSE: Studies in the adult's population have shown an inconsistent association between musculoskeletal fitness (MF) and cardiometabolic risk clustering independent of adiposity. The purpose of this study was two-fold: to analyze the association between MSF and cardiometabolic risk clustering, and to determine the influence of adiposity parameters on the association between MF and cardiometabolic risk clustering in adults from Colombia.

METHODS: The cross-sectional study included a total of 886 (51.9% women) healthy children and adolescents. Standing broad-jump and isometric handgrip dynamometry were used as indicators of lower and upper body muscular fitness, respectively. Also, a MF was computed by summing up the standardised values of both standing broad-jump and handgrip strength. We assessed the following adiposity parameters: fat mass, body mass index, waist-to-height ratio and abdominal visceral fat. A MetSyn z-score was calculated for each subject from triglycerides, HDL cholesterol, fasting glucose, waist circumference, and arterial blood pressure (MAP). Linear regression models fitted for mediation analyses examined whether the association between MF and MetSyn z-score was mediated by adiposity parameters according to Baron and Kenny procedures. **RESULTS:** Findings revealed that lower levels of MetSyn z-score were associated with the best adults profiles (high MF + low adiposity) (p for trend < 0.001 in the four adiposity parameters), compared with unfit strength and obese (low MF + high adiposity) counterparts. Linear regression models suggest a full mediation of adiposity parameters in the association of MF with MetSyn z-score, for both men and women alone. **CONCLUSIONS:** Our findings seem to emphasize the importance of obesity prevention in adults, suggesting that having high levels of MF may not counteract the negative consequences ascribed to adiposity.

Physical Activity and not Sedentary Time Influence on Metabolic Risk in Older Community-dwelling Women
 Andreas Nilsson, Britta Wählin-Larsson, Fawzi Kadi. *Örebro University, Örebro, Sweden.*
 Email: andreas.nilsson@oru.se
 (No relationships reported)

The risk of developing the metabolic syndrome increases by older age, where older women typically engage in less health-enhancing physical activity (PA) than men. Whether sedentary behaviors influence on metabolic risk and related components

in older adults, and if so to what extent such relationships are independent of PA behavior, remain unclear. **PURPOSE:** To examine cross-sectional associations of objectively assessed PA and sedentary behaviors on metabolic syndrome components and clustered metabolic risk in a sample of older community-dwelling women.

METHODS: Components of the metabolic syndrome including waist circumference (WC), systolic and diastolic blood pressures, fasting levels of plasma glucose, HDL-cholesterol and triglycerides were assessed in 120 community-dwelling older women (65-70 yrs). Total amount of PA (total counts per day), accumulated time spent in different intensities (sedentary, light (LPA), and moderate-to-vigorous PA (MVPA)), continuous bouts of sedentary time and breaks in sedentary time were assessed with accelerometers. Isotemporal substitution models were used to examine influence of PA and sedentary behavior on each component of the metabolic syndrome and on a clustered metabolic risk score.

RESULTS: All associations between variables of sedentary behavior and metabolic risk were lost once variation in total accelerometer counts per day was adjusted for. Replacement of a 10-min time block of MVPA with either LPA or time in sedentary behaviors was related to an increase in WC and clustered metabolic risk score (zMS) (WC: $\beta = 1.78$ to 2.19 $p < 0.01$; zMS: $\beta = 0.06$ to 0.08 , $p < 0.05$).

CONCLUSIONS: Detrimental influence of a sedentary lifestyle on metabolic health is likely explained by variations in amounts of PA rather than sedentary time per se. Given our findings, increased amounts of PA with an emphasis on increased time in MVPA should be recommended in order to promote a favorable metabolic health profile in older women.

(No relationships reported)

Oral red complex bacteria, including *Porphyromonas gingivalis*, *Treponema denticola*, and *Tannerella forsythia*, were significantly associated with the severity of chronic periodontal disease. Previous studies indicated that engaging in physical activity is associated with lower periodontitis prevalence. However, the association between physical activity and periodontal bacteria was not clear. **PURPOSE:** To determine whether physical activity is associated with red complex bacteria among Japanese adults. **METHODS:** We studied 226 adult employees aged 20-69 years. Analysis of bacterial species in saliva was conducted using 16S rRNA gene cloning and sequencing. Physical activity was assessed using the International Physical Activity Questionnaire. Total physical activity was calculated based on intensity and duration of physical activity and divided into three categories according to the Japanese guideline as follows: none (0 METs hours/week), low (0.1-22.9 METs hours/week), and high (≥ 23.0 METs hours/week). The association between physical activity and prevalence of saliva red complex bacteria was tested with multivariate logistic regression analysis after adjusting for sex, age, smoking, alcohol use, breakfast skipping, and body mass index. Data were expressed as odds ratios (OR) and 95% confidence intervals (CI). **RESULTS:** The prevalence of red complex bacteria was 46.0% for *Porphyromonas gingivalis*, 67.7% for *Treponema denticola*, and 78.3% for *Tannerella forsythia*, respectively. Multivariate analysis showed that physical activity was not associated with red complex bacteria (*Porphyromonas gingivalis*: low, 0.79 [0.40-1.55]; high, 1.13 [0.57-2.24]; P for trend = 0.717; *Treponema denticola*: low, 1.09 [0.48-2.48]; high, 0.76 [0.33-1.75]; P for trend = 0.816; *Tannerella forsythia*: low, 1.43 [0.69-2.97]; high, 1.09 [0.52-2.29]; P for trend = 0.520). On the other hand, participants with higher physical activity tended to have a better self-reported oral health than those with lower physical activity (low, 1.85 [0.88-3.89]; high, 2.20 [1.02-4.77]; P for trend = 0.044). **CONCLUSION:** This cross-sectional study demonstrated that physical activity was not associated with periodontal bacteria, such as *Porphyromonas gingivalis*, *Treponema denticola*, and *Tannerella forsythia* in Japanese adults.

2751 Board #271 June 2 11:00 AM - 12:30 PM
Met-minutes Of Activity And Telomere Length In 5,823 Men And Women: An NHANES Investigation

Larry A. Tucker. Brigham Young University, Provo, UT.
Email: tucker@byu.edu
(No relationships reported)

PURPOSE: The primary aim was to determine the extent to which physical activity (PA) accounts for differences in telomere length in a large random sample of U.S. men and women. A secondary purpose was to assess the extent to which multiple demographic and lifestyle factors affect the relationship between PA and telomere length. **METHODS:** A total of 5,823 adults from the National Health and Nutrition

Examination Survey (NHANES) were studied cross-sectionally. Blood samples were used for DNA analysis. Employing the quantitative polymerase chain reaction method, leukocyte telomere length was compared to standard reference DNA. Individuals in the lowest sex-specific quartile were defined as having short telomeres. PA was indexed using MET-minutes, calculated using self-reported frequency, intensity, and duration of participation in 62 physical activities. Age, gender, race, education, smoking, body mass index, and alcohol use were controlled statistically. **RESULTS:** Telomeres were 15.6 base pairs shorter for each year of chronological age ($F=723.2$, $P<0.0001$). PA was inversely related to telomere length, after adjusting for all the covariates together ($F=8.3$, $P=0.0004$). Specifically, base pair differences between adults with High PA and those in the Sedentary, Low, and Moderate groups were 140, 137, and 111, respectively. Therefore, adults with High PA were estimated to have a biologic aging advantage of 9 yrs (140 base pairs \div 15.6) over Sedentary adults. The difference in cell aging between those with High and Low PA was also significant at 8.8 yrs (137 base pairs \div 15.6), as was the base pair difference between those in the High and Moderate PA categories (7.1 yrs; 111 base pairs \div 15.6). Additionally, adults in the Sedentary, Low, and Moderate PA categories had 1.95 (95% CI: 1.38-2.75), 1.66 (95% CI: 1.21-2.30), and 1.73 (95% CI: 1.24-2.40) times greater odds of possessing short telomeres than adults with High PA, after adjusting for the covariates. **CONCLUSIONS:** PA was significantly and meaningfully associated with telomere length in 5,823 men and women representing U.S. adults. Evidently, adults who engage in high levels of PA tend to have longer telomeres, accounting for up to 9 yrs of reduced cellular aging compared to their sedentary counterparts. They are also much less likely to have short telomeres than other adults.

2752 Board #272 June 2 11:00 AM - 12:30 PM
Disparities Between BMI And BFR To Evaluate Obesity Rate In Chinese Urban White-collar Population: A Cross-section Study

WanMei Cheng, YuHua Jia, DongLiang Zhang, YunXin Luo, Bin Liang, Gang Bei, QiHua Huang, Xue Huang, XiaoLing He, Fei Xiao. Cinkate Corporation, Shanghai, China.
Email: hemolly@cinkate.com.cn
(No relationships reported)

Overweight and obesity (OO) are risk factors of metabolic syndrome. Body Mass Index (BMI) is commonly used to evaluate OO rates. However, even though the OO rates by BMI in Chinese population are significantly lower than in other ethnics, the incidence of metabolic syndrome remain same. Therefore, it's critical to find alternative methods to evaluate true obesity base on Body Fat Rate (BFR).

PURPOSE: To compare the difference between BMI and BFR on the assessment of the obesity rate in Chinese urban white-collar population and to explore a rational of BFR in justifying the true OO rates.

METHOD: From June 5, 2015 to August 14, 2016, a total of 2,195 white-collar employees (male 1049, female 1146) participated in this study in Zhangjiang InnoPark of Shanghai, China. The mean age was 33.69 ± 9.26 (18 to 66) years. BMI was obtained from each participant. BMI between 24 (kg/m²) and 27.9 (kg/m²) is defined as overweight and over 28 (kg/m²) as obese. BFR was obtained from Inbody 320 body composition analyzer based on the method of Direct Segmental Multi-frequency-Bioelectrical Impedance Analysis (DSM-BIA) and calculated the muscle weight and fat weight. Categorized by BFR, male over 20% and female over 28% are defined as body fat overweight rate (BFOR), respectively.

RESULTS: Applying BMI, the overall OO rates are 30.30%, 47.18% in men and 14.84% in women. While applying BFR, the overall BFOR are 52.67%, 57.58% in men and 48.17% in women. There are significant differences in three pair comparisons ($X^2=410.431$, $X^2=244.644$ and $X^2=160.277$, $p<0.01$). 588/2195 (26.79%) of the BMI-defined normal weight and underweight subjects were defined overweight by BFR, including 194/1049 (18.49%) males and 394/1146 (34.38%) females.

Conclusions: The BFOR of Chinese urban white-collar population is higher than the OO rates with BMI, especially in women. The BMI severely underestimates the true obesity incidence among Chinese population, BFR may replace BMI as a better method for obesity measurement.

2753 Board #273 June 2 11:00 AM - 12:30 PM

Objective And Self-reported Measures Of Physical Activity And Sex Hormones: Women's Lifestyle Validation Study.

Marquis S. Hawkins¹, Deirdre K. Tobias², Hala B. Alessa³, Andrea K. Chomistek⁴, Walter C. Willett³, Sue E. Hankinson¹.
¹University of Massachusetts Amherst, Amherst, MA. ²Harvard Medical School and Brigham and Women's Hospital, Boston, MA. ³Harvard School of Public Health, Boston, MA. ⁴Indiana University-Bloomington, Bloomington, IN. (Sponsor: Lisa Chasan-Taber, FACSM)
 Email: mshawkins@schoolph.umass.edu
 (No relationships reported)

Physical activity (PA) has been associated with reduced breast cancer risk, which may be partially mediated through an effect on sex hormones. Prior studies of PA and sex hormones relied on self-reported measures of PA, thus the impact of PA duration and intensity remains unclear. **PURPOSE:** To evaluate the association of both objective (o-PA) and self-reported measures of PA (sr-PA) with circulating sex hormones. **METHODS:** This cross-sectional analysis was conducted within the Women's Lifestyle Validation Study, a sub-study of the Nurse's Health Study I and II cohorts (n=525). A triaxial accelerometer was used for 7 days to assess average counts per day (CPD), minutes of light intensity PA (o-LPA), and moderate-vigorous intensity PA (o-MVPA). A modified Paffenbarger PA questionnaire was used to assess self-reported minutes of total, LPA (sr-LPA) and MVPA (sr-MVPA). Dehydroepiandrosterone sulfate (DHEAS), testosterone, and sex hormone binding globulin (SHBG) were assayed among all women; estradiol was measured in postmenopausal women not currently on hormone therapy (n=426). Multivariable linear regression models analyzed each PA measure with each biomarker adjusted for age, race, parity, age at menarche, oophorectomy status and BMI. **RESULTS:** In general, the associations between PA and sex hormones appeared stronger with o-PA than sr-PA. For example, women in the 4th (vs. 1st) quartile of CPD and o-MVPA had 13% and 19% lower SHBG levels respectively (p<0.001), whereas women in the 4th (vs. 1st) quartile of sr-PA (i.e., total, LPA, and MVPA) had 10% lower SHBG levels (p<0.05). Further, women in the 4th (vs. 1st) quartile o-MVPA had 14% higher testosterone levels (p<0.001). There were no statistically significant relationships between any sr-PA measure with testosterone. CPD had the strongest impact on DHEAS and estradiol. Specifically, women in the 4th (vs. 1st) quartile CPD had 13% higher DHEAS levels (p<0.001) and 22% lower estradiol levels (p<0.01). There were no statistically significant relationships between any sr-PA measure with DHEAS. Women in the 4th (vs. 1st) quartile sr-MVPA had 10% lower estradiol levels (p<0.01). **CONCLUSIONS:** PA was modestly related to sex hormones in women. CPD and o-MVPA showed the strongest and most consistent relationships with sex hormones.

Muscle Strengthening Activity, C-reactive Protein, And Diabetes: 1999-2006 Nhanes

Brandi S. Rariden, Adrian J. Boltz, Bethany D. Williams, Michael R. Richardson, Tammie M. Johnson, James R. Churilla, FACSM. University of North Florida, Jacksonville, FL.
 (Sponsor: James R. Churilla, FACSM)
 Email: n00774738@unf.edu
 (No relationships reported)

PURPOSE: Examine the associations between muscle strengthening activity (MSA) and elevated C-reactive protein (CRP) using a nationally representative sample of U.S. adults (≥ 45 years of age) with Diabetes Mellitus (DM). **METHODS:** Cross-sectional analyses utilized data from the 1999-2006 National Health and Nutrition Examination Survey. A dichotomous (yes/no) MSA variable was created based on self-reported participation over the past 30 days. Elevated CRP (> 3.0mg/L) was based on current recommendations. Pairwise tests were performed to contrast potential differences when comparing measured (fasting plasma glucose [FPG] ≥ 126mg/dL, n=757) DM and self-reported physician diagnosed DM (n=1,390). **RESULTS:** The prevalence of elevated CRP concentrations was 50.1% and 50.4% in the populations with measured FPG and self-reported DM, respectively. In both groups the prevalence of elevated CRP was significantly lower in those reporting MSA compared to those reporting no MSA (FPG, 39.8% vs. 52.4%, p= 0.0142; Self-reported diagnosis, 42.9% vs. 51.9%, p= 0.0478). **CONCLUSIONS:** The prevalence of elevated CRP was significantly lower in those reporting engaging in MSA using subjective and objective measures of DM.

Impact Of The American Heart Association (AHA)'S 7 Health Metrics On Life Expectancy In The United States General Population

Chong-Do Lee, FACSM, Erin Dierickx, Tongyu Ma, Kyle Menkosky. Arizona State University, Phoenix, AZ.
 (No relationships reported)

The impact of the AHA's 7 health metrics on life expectancy in the US general population remains less explored. **PURPOSE:** We investigated the impact of the AHA's 7 health metrics on life expectancy and lifetime risk of all-cause mortality in the US general population. **METHODS:** We followed 1,5908 men and women, aged 20 to 90 years, who participated in the Third National Health and Nutrition Examination Survey (1988-1994) through December 31, 2006. All participants completed baseline health factors and lifestyle behavior questionnaires. The AHA's 7 ideal health metrics were defined as untreated blood pressure (<120/80 mmHg), untreated total cholesterol (<200 mg/dL), untreated fasting glucose (<100 mg/dL), physically active, never smoked, a healthy diet, and a normal waist girth. We further categorized these variables as having 0, 1, 2, 3, 4, 5, 6 or 7 combined ideal health metrics. Cox proportional hazards regression was used to investigate the associations of single and a combined number of 7 health metrics and all-cause mortality. Survival analysis was used to compute lifetime risk of all-cause mortality. **RESULTS:** During an average of 13.2 years of follow-up (217,404 person-years), there was a total of 3,352 all-cause deaths (1,413 CVD, 658 cancer, 299 respiratory diseases, 107 diabetes mellitus). After adjustment for multiple risk factors, men and women with all 6 or 7 combined ideal health metrics had a 62% (95% CI: 43% to 75%) lower risk of all-cause mortality compared with men and women with zero ideal health metrics. The lifetime risks of all-cause mortality (at 20 years of age to 90) across 0, 1, 2, 3, 4, 5, and 6 or 7 ideal health metrics were 63.5%, 55.0%, 44.6%, 35.8%, 38.0%, 33.0%, and 17.6%, respectively. Increasing number of ideal health metrics was associated with lower lifetime risk of all-cause mortality. Men and women with 1, 2, 3, 4, 5, and 6 or 7 combined ideal health metrics had 3.1, 5.7, 7.8, 7.6, 8.7, and 11.9 years longer life expectancy, respectively, as compared with men and women with zero health metrics. Approximately 40% (95% CI: 11% to 60%) of all-cause deaths might have been avoided if men and women had adopted all 6 or 7 combined ideal health metrics. **CONCLUSION:** The AHA's 7 ideal health metrics is associated with lower lifetime risk of all-cause mortality and longer life expectancy in the US general population.

Functional Ability and Physical Activity in Urban African American and Rural White Older Adults

Haocen Wang, Carly E. Babino, Wan-chin Kuo, Randall J. Gretebeck, FACSM, Kimberlee A. Gretebeck. University of Wisconsin-Madison, Madison, WI.
 Email: hwang472@wisc.edu
 (No relationships reported)

Late-life motor impairment is a common part of aging and increasingly recognized as a barrier to the maintenance of independence and well-being in old age. Loss of motor function, such as slowed walking, is progressive, and there is increasing interest in health disparities related to activity limitations in older adults. Staying physically active is vital for maintaining physical function, but few studies have compared functional ability and physical activity in urban African American (AA) and rural white (RW) older adults. **PURPOSE:** The purpose of this investigation is to compare functional ability and physical activity in urban AA and RW older adults. **METHODS:** One group of participants included 31 self-identified older African-Americans (age= 68.2 yrs+6.5); BMI=34.5+9.2) living in an urban setting. The other group included 60 older white participants (age= 72.7 yrs+7.9); BMI=32.3+7.2) living in a rural setting. The participants completed questionnaires related to physical function (physical functioning questionnaire) (PF), physical activity (CHAMPS physical activity questionnaire) (PA), and self-regulation related to physical activity (SR). Additional measures included: 1) timed up and go (TUG), which involved rising from a chair, walking three meters, returning to the chair and sitting down, 2) gate speed (GS) over a six-meter distance, and 3) six-minute walk (6MW). Significant differences (p<0.05) between groups were identified using independent samples t-tests. **RESULTS:** For the objective physical measures, there were significant differences between AA and RW for TUG (13.1 vs 11.0 seconds) and UGS (0.990 vs 1.180 m/s) respectively. PF and PA were not significantly different. With regard to SR, significant differences between AA and RW were noted for goal setting (2.11 vs 1.55) and relapse 1.87 vs 1.456) respectively, related to being physically active. **CONCLUSIONS:** Both groups of participants had low levels of physical activity and would benefit from programs designed to improve functional ability. The differences noted for TUG and UGS as well as aspects of self-regulation can inform physical activity programming in our efforts to eliminate health disparities.

Fatness and Low Back Pain: A Cohort Study of Japanese Male Workers in the Tokyo Metropolitan Area
 Yuko Hashimoto¹, Susumu S. Sawada, FACSM², Ko Matsuda³, Yuko Gando², Ryoko Kawakami⁴, Chihiro Kinukawa⁵, Takashi Okamoto⁵, Koji Tsukamoto⁵, Motohiko Miyachi², Hisashi Naito¹, Steven N. Blair, FACSM⁶. ¹*Juntendo University, Chiba, Japan.* ²*National Institutes of Biomedical Innovation, health and Nutrition, Tokyo, Japan.* ³*University of Tokyo Hospital, Tokyo, Japan.* ⁴*Waseda University, Tokyo, Japan.* ⁵*Tokyo Gas Health Promotion Center, Yokohama, Japan.* ⁶*University of South Carolina, Columbia, SC.*
 (No relationships reported)

Low back pain is a major health problem worldwide. It is also the largest contributor to years of living with disability. Several studies have sought to explain the relationship between fatness and low back pain, especially in Western countries, but there are few studies clarifying this relationship among Japanese, for whom there is a different standard for obesity. **PURPOSE:** We evaluated whether obesity/overweight is a risk factor for chronic low back pain, by using body fat percentage (%FAT) and body mass index (BMI) as indices of fatness among Japanese male workers. **METHODS:** Participants underwent an annual health examination in 1986, and followed up in the 2009-2010 period. BMI was calculated based on height and weight. %FAT was estimated using the Brozek formula for body density, which was estimated by the Nagamine and Suzuki formula for skinfold thickness. Participants who had low back pain in 1986 or earlier were excluded. From annual health examinations in 2009-2010, participants who on our self-administered questionnaire responded "all the time" with regard to subjective back pain symptoms were considered as having chronic low back pain. These participants were divided into quartiles based on their %FAT and BMI. A logistic regression model was used to adjust the covariates and evaluate the relationship between presence of chronic low back pain and obesity. The multivariable-adjusted odds ratios and 95% confidence intervals (95%CI) were calculated for both %FAT and BMI, adjusting for age, cigarette smoking, and alcohol intake as the variables. **RESULTS:** Participants were 1,152, and median age (range) at baseline year was age 29 (18-43) years. Ninety people reported chronic low back pain in 2010. Following age, cigarette smoking, and alcohol intake adjustments, using the lowest %FAT (first quartile) group as a reference, the odds ratios (95%CI) for the second, third, and fourth quartiles were 0.86 (0.43-1.70), 1.46 (0.79-2.68), and 2.11 (1.16-3.83); *p* for linearity = 0.006. Moreover, using the BMI (first quartile) group as a reference, the odds ratios (95%CI) for the second, third, and fourth quartiles were 1.33 (0.69-2.56), 1.39 (0.71-2.69), and 1.80 (0.95-3.39), respectively; *p* for linearity = 0.011. **CONCLUSION:** Our findings suggest that both high %FAT and BMI are risk factors for chronic low back pain.

 (No relationships reported)

PURPOSE: The purpose of this study was to compare 10-year longitudinal changes in physical fitness (from age 70 to age 80 years) between older Japanese adults who did and did not take medications over the ten years period. **METHODS:** Six hundred men (n=306) and women (n=294), 70 years of age at baseline, residing in Niigata City, Japan, participated in this study. Baseline and follow-up physical fitness tests included hand-grip strength, isometric knee extensor strength, leg extensor power, stepping rate, and one-leg standing time with eyes open, and had medical examinations by physicians. Only the individuals who completed the physical fitness test at age of 80 years were grouped into no-medication or medication groups over the past decade, and divided into three groups: Group A: no medication over the 10 years period, Group B: medication at 80yr, no medication at 70yr, Group C: medication over the 10 years period. Their physical fitness at ages 70 and 80 years were compared using Paired t-test and Chi Square test. **RESULTS:** 59% of baseline data (n=354) were compared with 10 years follow-up data. Among these subjects, the rate of no medication use at 70 years old was 35.8%, which declined to 15.3% by 80 years of age. The most common chronic disease requiring medication was high blood pressure of these 80 year old men and women (n=122). The numbers of participants in each group were: A-56, B-104, and C-194. When compared the means of test results among these 3 groups at age 70 and 80 years, there were significant differences (*p*<0.05) in hand-grip

strength (A: 33.0kg, B: 30.2kg, C: 28.8kg) and knee extensor strength (A: 1.19kg/kg, B: 1.05kg/kg, C: 0.97 kg/kg). There were also significant decline over the ten years period in grip strength (A: -5.818kg B:-4.045kg C:-4.788kg), total protein (A: -0.135 g/dl, B: -0.112 g/dl, C: -0.223g/dl), and total cholesterol (A: -0.056mg/dl, B:-9.257mg/dl, C: -12.09mg/dl). Limitation of this study was significant decline of completion rate of the tests (leg extensor power, knee extensor strength) in participants in Groups B and C. **CONCLUSIONS:** The present study showed that the older adults with no medications over the ten years period had higher physical fitness level than medication groups. The findings of this study may provide interesting insight regarding the physical fitness in the elderly population.

Physical Activity In Bouts And Nonbouts: Relation To Physical Fitness And Health-related Quality Of Life
 Daniela Ciprandi¹, Filippo Bertozzi², Matteo Zago¹, Chiarella Sforza¹, Christel Galvani². ¹*Università degli Studi di Milano, Milan, Italy.* ²*Catholic University of the Sacred Heart, Milan, Italy.*
 Email: daniela.ciprandi@unimi.it
 (No relationships reported)

PURPOSE: It has been previously demonstrated that higher physical activity (PA) levels and better physical fitness (PF) were associated with higher health-related quality of life (HRQoL)¹. However, Wanderley et al. did not take the differences between PA levels calculated as overall PA (MVPA_{all}) or accumulated in bouts of at least 10 min (MVPA₁₀) into account. Therefore, the aim of this study was to compare the different effects of MVPA₁₀ and MVPA_{all} on PF and HRQoL in a population of young and older adults. **METHODS:** 21 young adults (YA: age 22.6±2.9 yrs; BMI 22.5±2.6 kg·m⁻²) and 21 older adults (OA: age 68.3±3.3 yrs; BMI 26.1±3 kg·m⁻²) wore an activity monitor for 7 consecutive days to obtain time spent in MVPA, analyzed in bouts of at least 10 consecutive min (MVPA₁₀) and in overall minutes (MVPA_{all}). To assess maximal isometric strength (iMVC), they performed a hand-grip strength test. Cardiorespiratory fitness (V'O_{2max}) was determined by indirect calorimetry using a maximal treadmill test. HRQoL was measured with the Short-Form 36 Health Status Survey (SF-36v2) that provided the physical (PCS) and the mental (MCS) component summary score. **RESULTS:** Although young adults resulted fitter than older adults (YA: V'O_{2max} 2.3±0.3 L·min⁻¹; iMVC 190.6±60.2 N; OA: V'O_{2max} 1.7±0.3 L·min⁻¹; iMVC 151.4±52.3 N; *p*<0.05), no differences were detected for MVPA (nor MVPA₁₀ neither MVPA_{all}) or HRQoL between groups. MVPA₁₀ was significantly lower than MVPA_{all} (MVPA₁₀: 28.7±35.6 min·day⁻¹; MVPA_{all}: 61.1±57.5 min·day⁻¹; *p*<0.01). The overall average PCS and MCS scores were 55.1±6.3 and 47.7±8.5, respectively. Regression analysis, adjusted for age and BMI, revealed that neither MVPA_{all} nor MVPA₁₀ were related to a higher PF or a higher HRQoL. Only V'O_{2max} was associated with a higher PCS (R²=0.095; β=4.216; *p*<0.05): each 1 L·min⁻¹ was associated with an increase of 4.5% in PCS. **CONCLUSIONS:** In contrast with Wanderley et al., this study showed that among relatively healthy, active but unfit older individuals HRQoL (PCS domain) is related only to V'O_{2max}. This observed positive association seems to be independent of age and BMI. This information will be useful for designing PA programs, aiming to improve cardiorespiratory fitness and that could also positively affect HRQoL. REFERENCES ¹Wanderley, Qual Life Res. 2011 Nov;20(9):1371-8.

Dose-Response of Light Intensity Physical Activity and Glucose Dynamics in Older Adults
 Whitney A. Welch¹, Scott J. Strath, FACSM², Renee E. Walker², Ann M. Swartz, FACSM². ¹*Northwestern University, Chicago, IL.* ²*University of Wisconsin-Milwaukee, Milwaukee, WI.*
 Email: whitney.welch@northwestern.edu
 (No relationships reported)

National data reports older adults spend about 30% of their day in light intensity physical activity (LPA). This study was designed to examine how increasing the proportion of the day spent in LPA would affect glucose control. **PURPOSE:** To determine the duration-response of proportion of time spent in LPA on post-prandial glucose response in older adults in a controlled environment. **METHODS:** Older adults (N=9), 60 y and older, completed four, three-hour treatment conditions, a seated control condition, and three subsequent randomized conditions 1) 20% (36 min) of the condition spent in continuous LPA, the remaining time seated, 2) 40% (72 min) of the condition spent in continuous LPA, the remaining time seated, and 3) 60% (108 min) of the condition spent in continuous LPA, the remaining time seated. Energy expenditure was measured continuously and glucose was measured at baseline following mixed meal ingestion and each hour thereafter. Glucose AUC was calculated and compared between conditions using RMANOVA. **RESULTS:** A significantly greater amount of energy was expended during all activity conditions when compared to the seated condition (*p*<0.05). There was a significant difference between proportion of time spent in LPA and glucose AUC (F=11.601, *p*<0.001). Post-hoc analysis showed a significant difference between the seated condition and 60% LPA condition (AUC

mean difference (Seated-60%): 35.0 mg/dL, $p=0.016$), 20% LPA condition and 60% LPA condition (AUC mean difference (20%-60%): 17.3 mg/dL, $p=0.010$), and 40% LPA condition and 60% LPA condition (AUC mean difference (40%-60%): 9.8 mg/dL, $p=0.023$) **CONCLUSION:** These results provide experimental evidence to the importance LPA may play in the overall metabolic health of an older adult population. According to national data, LPA constitutes about 30% of the active day in older adults. Therefore, the translation of the current results suggest that if older adults, who spend on average about three hours per day in LPA, increase LPA by 36 min/d they could significantly benefit glucose control.

Lower Cognition and Prefrontal Cortex Oxygenation during High Intensity Exercise in Individuals with Substance Addiction

Kell Grandjean da Costa¹, Wesley Quirino Alves da Silva¹, Daniel Aranha Rego¹, Alexandre Hideki Okano¹, Hassan Mohamed Elsangedy¹, Eduardo Caldas Costa¹, Vanessa De Paula Soares Rachetti¹, Erika Hussey², Natan Ward², Eduardo Bodnariuc Fontes¹. ¹Federal University of Rio Grande do Norte, Natal, Brazil. ²Tufts University, Boston, MA.
 Email: kellgrandjean@gmail.com
 (No relationships reported)

Substance addiction is a public health problem worldwide. Individuals with substance use disorder (SUD) have lower activity in the prefrontal cortex during resting state, which has been related to cognitive impairments and compulsive substance-seeking behavior. Exercise has shown to contribute in the treatment of SUD; however, its effects on the brain of these individuals is unclear, in particular under different intensities. **PURPOSE:** To verify the effects of an incremental exercise intervention on cognitive performance and oxygenation in the prefrontal cortex in individuals with substance use disorder (SUD). **METHODS:** The SUD group consisted of 14 patients (33.3 ± 5.6 years old) in a psychiatric hospital with substance use history (alcohol, marijuana, or crack cocaine) of 13.8 ± 5.6 years and classified as severe SUD by DSM-V. The control group (CG) consisted of 15 subjects (age: 25.3 ± 3.1 years) without addiction classification by the DSM-V. Both groups were subjected to an incremental test on a cycle ergometer accompanied by spirometry and assessments of prefrontal cortex oxygenation by near-infrared spectroscopy (oxyhemoglobin; ΔHbO_2) and cognitive performance (response time in ms on the Stroop task). Assessments were conducted at the respiratory compensation point (RCP) and maximal oxygen consumption (VO_2 peak), and effects were evaluated with two-factor mixed-design ANOVAs with post hoc Scheffé's tests. **RESULTS:** Although the groups did not differ in attained VO_2 peak ($p>0.05$), brain oxygenation increased for the SUD group (+9.1%) and the CG (+14.0%) as intensity increased during incremental exercise. Moreover, the SUD group showed lower cerebral oxygenation than the CG at high intensities (RCP ΔHbO_2 : SUD = 5.1 ± 2.4 vs. CG = 9.7 ± 3.1; VO_2 peak ΔHbO_2 : SUD = 9.11 ± 3.83 vs. CG = 14.01 ± 2.94) and demonstrated lower cognitive performance (RCP reaction time: SUD = 2583 ± 499 ms vs. CG = 1620 ± 356 ms; VO_2 peak reaction time: SUD = 2492 ± 399 ms vs. CG = 1539 ± 176 ms; $p<0.05$). **CONCLUSION:** Chronic addiction may impair prefrontal cortex oxygenation and cognition during exercise. Interestingly, exercising at high intensities promotes higher oxygenation in the prefrontal cortex, indicating its potential for treatment of individuals with SUD.

Acute And Chronic Immune Responses To Consecutive Or Non-consecutive Days Of Resistance Training

Pang Boon Bay¹, Yongtai Raymond Wang¹, Hilary Wei Jian Teo¹, Junli Huang¹, Jorming Goh², Yifan Yang¹. ¹Nanyang Technological University, Singapore, Singapore. ²National University of Singapore, Singapore, Singapore.
 (No relationships reported)

Current exercise guidelines recommend resistance training (RT) 2 to 3 days per week (wk), spaced 48-72 h apart for optimal muscle growth and strength improvement. However, shorter rest periods between RT sessions has not been well studied. In addition, the immunological effects of RT due to different recovery periods are poorly understood. **PURPOSE:** To investigate the immune responses to two identical RT programs using different recovery period. **METHODS:** Two groups of 15 recreationally active men performed RT 3 times per wk for 12 wk either on consecutive (C) or non-consecutive days (NC). Both groups performed leg press, latissimus pulldown, leg curl, dumbbell shoulder press and leg extension for 3 sets of 10 repetitions at their pre-determined 10 repetition-maximum. Blood was sampled in untrained (UT) and trained (T) state in wk 1 and 12 before 1st day of RT (UT Pre and T Pre), immediately post 3rd day of RT (UT 0h and T 0h) and 24h after the 3rd day of RT (UT 24h and T 24h). Samples were analysed for counts of total white blood cells (WBC), neutrophils (NE), lymphocytes (LY), monocytes (MO), eosinophils (EO), basophils (BA) and platelets (PL). Generalized estimating equations analyses were

performed. **RESULTS:** Both groups were similar in age [25 (SD 2) y], weight [65 (10) kg], height [1.72 (.06) m], BMI [22.2 (2.7) kg/m²], systolic and diastolic blood pressures [114 (5)/69 (8) mm Hg], fasting glucose [4.5 (.3) mmol/L] and physical activity level [2144 (1428) MET-min/wk] pre-RT. No interaction was found for all measures ($p = .065$ to $.967$). There were no group differences ($p = .103$ to $.525$) except MO, which was lower in C (.528 x 10⁹/L) than NC [.641 x 10⁹/L, 95% CI of difference (.028, .197), $p = .009$]. Significant main effects of time were found for all variables except MO ($p = 0.170$) and EO ($p = 0.236$). In wk 1, both groups increased WBC (C: +9.2%; NC: +7.0%; $p = 0.025$), LY (C: +12.4%; NC: +15.2%; $p < .001$), BA (C: +11.4%; NC: +23.1%; $p = .003$) and PL (C: +10.3%; NC: +12.1%; $p < .001$) at UT 0h compared to UT Pre. LY fell below UT Pre at UT 24h ($p = 0.002$). In wk 12, T 0h values for all measures were not significantly different from T pre values ($p = .772$ to $.999$) except for an increase in PL ($p = 0.001$). There was no difference between UT Pre and T Pre values for all measures ($p = .335$ to $.999$). **CONCLUSION:** Both groups had similar immune response to RT.

3 Week Behavioral Intervention Does Not Lower Urinary Bisphenol A Concentrations In Women With Obesity

Todd Hagobian, FACSM, Zoe Belli-Dovi, Adrian Mercado, Megan Guy, Suzanne Phelan. California Polytechnic State University, San Luis Obispo, CA.
 Email: thagobia@calpoly.edu
 (No relationships reported)

Previous studies have shown that women with obesity have higher concentrations of Bisphenol A (BPA), but an intervention to reduce BPA is lacking in women. **PURPOSE:** To determine whether a theory-based behavioral intervention designed to reduce BPA would decrease urinary BPA concentrations over 3 weeks in women with obesity. **METHODS:** Thirty college-aged, women were randomly assigned to an intervention (N=15; 31.5 ± 5.6 kg/m²; 21.6 ± 3.3 yrs) or control (N=15; 30.8 ± 5.8 kg/m²; 21.5 ± 3.1 yrs). The intervention included weekly face-to-face meetings to reduce BPA exposures from food, cosmetics, and other packaged products. Women were provided with BPA-free cosmetics, hygiene, glass food/water containers and daily self-monitored major sources of BPA. Fasting urine BPA and creatinine concentrations, and weight were assessed at baseline and after 3-weeks. **RESULTS:** BPA was non-detectable (limit of detection 0.05 µg/L) in 26% of samples at baseline. No significant (P=0.55) treatment x time interaction effect was observed on creatinine-adjusted BPA concentrations from baseline to 3-weeks in the intervention (0.41 ± 0.56, 0.77 ± 0.66 µg/g Creatinine) or control group (0.62 ± 0.92, 0.51 ± 0.81 µg/g Creatinine) using baseline BMI, age, and demographics as covariates. No significant treatment x time interaction effect (P=0.54) in weight was observed from baseline to 3-weeks in the intervention (83.9 ± 17.0, 83.9 ± 16.9 kg) or control group (81.4 ± 15.4, 81.1 ± 15.6 kg), and changes in creatinine-adjusted-BPA concentrations and weight were not significantly related (P>0.05). In sensitivity analysis, omitting subjects with non-detectable BPA concentrations at baseline, there was a trend for a significant treatment x time interaction (P=0.09). **CONCLUSION:** 3-week intervention had no effect on urinary BPA concentrations or weight in women with obesity. Future research is needed to examine intervention effects in individuals with high baseline urine BPA.

Relationship Between Oxygen Consumption, Percentage Of Muscle Mass And Risk Of Cardiovascular Disease In Adult Men

Aura C. Zea-Robles¹, Astrid Y. Rodríguez-Arboleda¹, Diana P. Sáenz¹, Henry H. León-Ariza², Marluco De Souza-Martins³, Sandra Posada-Bernal³. ¹Santo Tomás University, Bogotá, Colombia. ²La Sabana University, Chia, Colombia. ³Pontifical Javeriana University, Bogotá, Colombia.
 Email: aurazea@usantotomas.edu.co
 (No relationships reported)

Previous studies have shown that physical exercise of resistance and strength are related to cardiovascular health. **PURPOSE:** This study aims to establish the relationship between maximum oxygen consumption, percentage of muscle mass and cardiovascular risk disease in professors from the Santo Tomas University of Bogota - Colombia. **METHODS:** The population was 56 men with a mean age of 42.1 ± 9.5 years. The 10-years cardiovascular risk (10y-CVR) was calculated using the Framingham scale, considering the parameters of gender, age, presence of diabetes, smoking (cigarettes per day), total cholesterol (Total-C), HDL cholesterol (HDL-C) and systolic blood pressure (SBP). Pre-prandial blood samples were collected and blood pressure was evaluated after 15 minutes of rest. In a different session, the muscle mass percentage (MP) was evaluated by bioimpedance, a submaximal fitness test (modified Bruce protocol) was performed and the maximum oxygen consumption ($\text{VO}_{2\text{max}}$) was calculated based on the test duration. The statistical analysis was

performed using the Pearson's correlation coefficient (r) with a significance level of 0.05. **RESULTS:** In the evaluated subjects, one was diabetic and 16 men smoke up to 20 cigarettes per day. The Total-C was 5.58 ± 1.09 mmol/l, the HDL-C 1.27 ± 0.24 mmol/l and the SBP 106.7 ± 10.2 mmHg. The 10y-CVR was $5.5 \pm 5.2\%$, with a range of 0.5 - 21.3%. The average of MP was $34.7 \pm 3.1\%$ and the relative $\dot{V}O_{2max}$ 49.1 ± 11.1 ml/kg/min. A negative correlation was observed between the MP and 10y-CVR ($r = -0.38$ $p = 0.01$) as well as between $\dot{V}O_{2max}$ and RCV ($r = -0.51$ of $p < 0.01$). **CONCLUSION:** The results of this research evidence the protective effect on the risk of cardiovascular disease arising from a good aerobic capacity, especially by the reduction Total-C, lower SBP and a greater amount of MP. This work contributes to evidence the beneficial effects of combining aerobic and of strength exercise in reducing cardiovascular risk, which will be used in prevention programs within the Santo Tomas University population.

2765 Board #285 June 2 11:00 AM - 12:30 PM
Effect of Bikram Yoga on Heart Rate Variability and Associated Outcomes in Stressed and Sedentary Adults

Zoe L. Hewett¹, Kate L. Pumpa², Caroline A. Smith¹, Paul P. Fahey¹, Birinder S. Cheema¹. ¹Western Sydney University, Sydney, Australia. ²University of Canberra, Canberra, Australia. Email: zoehebett@hotmail.com

Reported Relationships: Z.L. Hewett: Ownership Interest (Stocks, Bonds); Bikram Yoga Kingston.

PURPOSE: This study investigated the effect of a 16-week Bikram yoga intervention on the high frequency (HF) power component of heart rate variability (HRV) and associated physiological and psychological outcomes in stressed and sedentary adults. **METHODS:** Eligible adults were randomized to an experimental group ($n=29$) or a no-treatment control group ($n=34$) after baseline testing. Experimental group participants were instructed to attend three to five Bikram yoga classes per week at local studios. All outcomes were collected at baseline (week 0) and completion (week 17), with psychological outcomes also collected at midpoint (week 8). Secondary physiological outcomes included additional HRV measures, blood pressure, augmentation index, body composition (via DEXA), waist circumference, fasting blood glucose, cholesterol, and C-reactive protein. Secondary psychological outcomes included the Perceived Stress Scale, the General- and Exercise Self-Efficacy Scales and health-related quality of life (HRQoL) measures (via Short-Form-36). **RESULTS:** Sixty-three adults (37.2 ± 10.8 years, 79% women) were enrolled in the study and included in the intention-to-treat analysis. The experimental group attended 27 ± 18 classes. The HF component of HRV did not significantly change between groups over time, nor did any secondary physiological endpoints. However, higher attendance to the intervention was associated with significant reductions in diastolic blood pressure ($p=0.039$), body fat percentage ($p=0.001$), fat mass ($p=0.003$) and body mass index ($p=0.05$). Further, the experimental group significantly improved several psychological endpoints versus the control group including perceived stress ($p = 0.003$), general self-efficacy ($p=0.034$), exercise self-efficacy ($p=0.003$), and HRQoL 'Vitality' ($p=0.019$) and 'General Health' ($p=0.034$). **CONCLUSIONS:** A 16-week Bikram yoga program did not increase the HF power component of HRV or any physiological outcomes evaluated. Low adherence possibly contributed to these null effects. However, participants in the experimental group significantly improved perceived stress, and measures of self-efficacy and HRQoL. Future studies are required to address barriers to adherence and elucidate the dose-response effects of Bikram yoga practice.

Association of Cardiorespiratory Fitness, Visceral Fat and Weight Cycling History in Pre-menopausal Women.

Karen Moreno, Pamela D. Swan, FACSM, Matthew Buman, FACSM, Zachary Zeigler. Arizona State University, Phoenix, AZ. (Sponsor: Pamela Swan PhD, FACSM)
 Email: kimoreno@asu.edu

(No relationships reported)

Weight cycling (WC), or repeated bouts of intentional weight fluctuations are common among overweight and obese women and have been linked to various cardiometabolic health risks such as visceral fat (VF) accumulation. Cardiorespiratory fitness (CRF), independent of weight loss, is a known counter measure to health risks and VF. Although, WC has been positively associated with increases in VF, this association may be confounded by age and/or physical activity status. **Purpose:** This cross sectional study explored the association of multiple factors (i.e., AGE, WC and CRF) on VF and investigated WC as a potential moderator on the relationship between CRF and VF among pre-menopausal women. **Methods:** 41 overweight and obese (BMI = 30.4 ± 6.2 kg/M²) pre-menopausal (age = 31.0 ± 5.6 yrs) women were assessed. Dichotomous WC groups were established from the number of self-reported WC bouts and total weight lost per bout. WC ($n = 19$) was defined as ≥ 3 cycles of ≥ 10 lb; and Non-WC ($n = 22$) was defined as not meeting WC definition. Additionally, a

weight cycling index (WCI) was constructed to form a continuous variable. WC due to pregnancy and illness were excluded from the totals. CRF was determined with indirect calorimetry using a cycle ergometer protocol to peak $\dot{V}O_{2max}$, and VF volume (cm³) was assessed with CoreScan software (iDXA, GE Lunar). Correlation and multiple regression analysis were used to examine the relationship between VF and potential predictors, and possible moderator effects. **Results:** Significant ($p < .001$) differences between WC vs. Non-WC groups were found for AGE (33.1 ± 3.7 vs. 29.3 ± 6.4 yr); BMI ($34.6.1 \pm 5.7$ vs. 26.7 ± 3.8 kg/M²); VF (1257.2 ± 1033.0 vs. 426.6 ± 547.0 cm³); and CRF (24.1 ± 5.7 vs. 31.0 ± 6.5 ml/kg/min). The strongest association was found between CRF and VF ($R = -0.718$, $p < .001$). The regression model with four factors (AGE, WCI, CRF, WC x CRF) was significant ($R^2 = .570$, $p \leq .001$); however, only CRF significantly predicted VF ($p \leq .001$). The WC x CRF interaction was not significant ($p = .150$) with a $\Delta R^2 = .026$, predicting only 2% of VF. Thus, no moderator effect was detected. **Conclusion:** These findings suggest the relationship between CRF and VF was independent of WC status and that CRF was the most influential factor predicting VF among overweight and obese pre-menopausal women with a history of weight cycling.

2767 Board #287 June 2 11:00 AM - 12:30 PM
Improvement Of Cognitive Function By dual-task Exercise

Ryuta Ito¹, Soichi Ando¹, Ryuji Takigawa¹, Sakamoto Kazunori², Ataru Kobayashi¹, Shinobu Tsurugano¹, Kiyoji Tanaka, FACSM³, Kazunori Ohkawara¹. ¹The University of Electro-Communications, Tokyo, Japan. ²National Institute of Information, Tokyo, Japan. ³University of Tsukuba, Ibaraki, Japan.

(No relationships reported)

Studies have shown that exercise improves cognitive function and that dual-task exercise, in particular, has neuroprotective effective effects in elderly individuals. **PURPOSE:** The purpose of this study was to examine the improvement of cognitive function by a dual-task exercise intervention. We also tested if the improvement of cognitive function was associated with the number of steps and exercise duration at different exercise intensity levels. **METHODS:** In all, 17 men and 25 women (mean [SD], age 73.8 [6.0] years, height 158.6 [7.0] cm, weight 56.0 [7.6] kg, and body mass index 22.2 [3.2] kg/m²) participated in square-step exercise (dual-task) once per week for 12 weeks. The number of steps was recorded from a waist-mounted accelerometer, and weekly data were classified into four levels based on the exercise intensity (inactivity, light, moderate, and vigorous). Participants performed the Cognitive Assessment for Dementia (CADI2) and Trail Making Test (TMT) before and after the exercise program to evaluate cognitive function. **RESULTS:** The total reaction time determined by CADI2 was significantly shorter in the post-exercise test than that in the pre-exercise test (post: 89.3 [25.7] vs. pre: 96.1 [28.3] s, $p = 0.025$), which suggests that cognitive function improved during the 12-week exercise program. Conversely, there was no significant change in TMT score (TMT A post: [49.4] vs. pre: [54.7] s $p = 0.19$, TMT B post: [113.0] vs. pre: [138.5] s $p = 0.05$, TMT B-A post: [63.3] vs. pre: [83.8] s $p = 0.59$). However, changes in CADI2 score did not correlate with the number of steps and exercise duration at each level of exercise intensity. **CONCLUSIONS:** These results demonstrate that the improved cognitive function was not primarily derived from increases in physical activity but, specifically, from involvement in dual-task exercise.

2768 Board #288 June 2 11:00 AM - 12:30 PM
Physical Activity and Sedentary Behavior among Hispanic Obstructive Sleep Apnea Patients in Puerto Rico

Alexis Gonzalez-Rodriguez, Lucía del R. Martinez-Colon, Marta Amaral-Figueroa, Farah A. Ramirez-Marrero, FACSM. University of Puerto Rico, Rio Piedras Campus, San Juan, Puerto Rico.

(No relationships reported)

Obstructive sleep apnea (OSA) is a chronic respiratory disease more prevalent in men compared with females, and commonly associated with obesity and poor quality of life. Few studies have reported low physical activity (PA), but none has evaluated sedentary time (ST) in this population; and these characteristics among Hispanics are unknown. **PURPOSE:** To describe PA behavior and ST, and their association with waist circumference and BMI in a group of Hispanic adults living with OSA in Puerto Rico (PR). **METHODS:** A group of 15 adults (10 men and 5 women, mean age = 44.3 ± 9.4 yrs) in treatment for OSA completed measurements of height and weight; and wore an ActiGraph GT3x+ accelerometer attached to a waist band placed in the right hip area for 7 days. Wilcoxon signed-rank tests were used to detect gender differences, and Spearman correlations to evaluate the association between PA, ST and BMI. **RESULTS:** No gender differences were observed. Participants spent 34.7 ± 46.9 min/week in moderate to vigorous physical activity (MVPA), and 8.8 ± 1.3 hrs/day in ST. Mean BMI was 34.7 ± 5.9 kg/m². No significant correlations were observed between PA

and BMI ($p = -0.39$, $P = 0.15$), ST and MVPA ($p = -0.23$, $P = 0.42$), and ST and BMI ($p = 0.05$, $P = 0.86$). **CONCLUSION:** Obesity was highly prevalent (93%) in this group of Hispanic adults living with OSA in PR, probably obscuring its association with PA and ST. In general, these participants could be classified as physically inactive and sedentary, factors associated with reduced life expectancy and poor quality of life. Clinical treatment must integrate strategies to help control body weight, improve PA, and reduce ST in this population.

2769 Board #289 June 2 11:00 AM - 12:30 PM

Effects of Short Term Detraining in Metabolic Syndrome Patients

Felix Morales Palomo, Miguel Ramirez Jimenez, Juan Fernando Ortega Fonseca, Ricardo Mora Rodriguez. *UCLM, Toledo, Spain.*

Email: felixmoralespalomo@gmail.com

(No relationships reported)

PURPOSE: Aerobic exercise training improves some of the components of metabolic syndrome (MSyn). Although it would be advisable to incorporate exercise permanently into life-style of MSyn patients, training discontinuation due to holidays, minor illness and/or musculoskeletal disorders is frequent. The aim of this study was to identify which of the metabolic syndrome factors reverses faster during short-term detraining. **METHODS:** Forty MSyn patients (54±8.9 yrs old; 32.4±1.2 BMI; 28 males and 12 females) underwent 8-wk of aerobic interval training (AIT). Then they were randomly divided into two groups, one that continued training for 3 more weeks (i.e., training group; TR, n=22) and another that stopped training during those 3-wks (i.e., detraining group; DeTR, n=18). Body composition, blood pressure and biochemistry were collected prior to start training, after 8 weeks (i.e., common training period) and 3 further weeks of either continuing training (TR group) or detraining (DeTR group). **RESULTS:** Before training started subjects in both groups were similar in body weight (90.6±3.9 vs. 93.9±4.2; $P = 0.56$) body fat (36.1%±1.4 vs. 33.1%±1.4; $P = 0.15$), number of MSyn factors (3.7±0.2 vs. 3.4±0.3; $P = 0.28$) and cardiopulmonary fitness level (2.5±0.7 vs. 2.2±0.7 L·min⁻¹). DeTR group did not increase body weight or fat mass and thus both groups remained similar in these parameters at week 11 ($P > 0.05$). Both groups reduced total cholesterol (T-CHOL), triglycerides (TG) and LDL-cholesterol (LDL-c) similarly after 8 weeks of training. However, DeTR compared to TR group showed blunted reductions TCHOL (-9.6±3.9 vs. -19.7±5.5, mg·dl⁻¹; $P < 0.05$), TG (4.3±13.9 vs. -3.2±6.8, mg·dl⁻¹; $P < 0.05$) and LDL-c (-6.0±3.6 vs. -13.1±4.7, mg·dl⁻¹; $P < 0.05$) at week 11, respectively. Furthermore, DeTR also blunted the reduction in resting heart rate (1.4±2.0 vs. -2.5±1.1, lat·min⁻¹; $P < 0.05$) although it did not affect arterial blood pressure that remained similarly reduced in both groups after 11 weeks. **CONCLUSION:** Our data suggest that short-term detraining (3 weeks) halts and tends to revert the benefits of 8 weeks of intense aerobic interval training in blood lipid profile despite no gains in body weight or body fat. In contrast, the cardiovascular benefits of training seemed more resilient to short-term detraining.

(No relationships reported)

Sex differences exist in the cardiovascular consequences of the inspiratory muscle metaboreflex in young adults. However, it is unknown if these sex differences are present in older adults. **PURPOSE:** To determine the effect of age on sex differences in the cardiovascular consequences of the inspiratory muscle metaboreflex. We hypothesized that, compared to their younger counterparts, older men and women would exhibit greater 1) increases in mean arterial pressure (MAP) and limb vascular resistance (LVR) and 2) decreases in limb blood flow (Q_L). We also hypothesized that the inspiratory muscle metaboreflex-induced cardiovascular responses would not be different between older men and women.

METHODS: Sixteen young (8 men, 8 women; 18-24 yr) and older (8 men, 8 women; 60-73 yr) adults were recruited for this study. Subjects performed inspiratory resistive breathing tasks (IRBTs) at 2% and 65% of their maximal inspiratory pressure. During the IRBTs, breathing frequency was 20 breaths min⁻¹ with a 50% duty cycle. At rest and during the IRBTs, MAP was measured via automated oscillometry, Q_L was

measured via Doppler ultrasound, and LVR was calculated. End tidal CO₂ remained at baseline levels during the IRBTs. EMG was recorded on the leg to ensure no muscle contraction occurred.

RESULTS: The 65% IRBT led to significantly greater increases in MAP from baseline in OW (15.9±8.1 mmHg) compared to YW (6.9±1.4 mmHg), but not ($p > 0.05$) between OM (12.3±5.7 mmHg) and YM (10.3±5.7 mmHg). OW (-20.2±7.2 %) had greater ($p < 0.05$) decreases in Q_L from baseline compared to YW (-9.4±10.2 %), but no differences ($p > 0.05$) were present between OM (-22.8±9.7 %) and YM (-22.7±11.3 %) during the 65% IRBT. The 65% IRBT led to greater ($p < 0.05$) increases in LVR in OW (48.2±25.5 %) compared to YW (19.7±15.0 %), but no differences ($p > 0.05$) existed among OM (54.4±17.8 %) and YM (47.1±23.3 %). No differences ($p > 0.05$) were present in MAP, Q_L , or LVR between OM and OW. The 2% IRBT resulted in no changes ($p > 0.05$) in MAP, Q_L , or LVR across time or among groups. **CONCLUSIONS:** These data suggest older women compared to younger women exhibit greater inspiratory muscle metaboreflex-induced cardiovascular consequences, while there were no differences between older and younger men. Lastly, sex differences in the inspiratory muscle metaboreflex are not present in older adults.

Respiratory muscle endurance training improves respiratory endurance and attenuates respiratory muscle-induced metaboreflex. In an animal study, it was shown that a larger increase in citrate synthase activity in the diaphragm occurred after exercise training under hypoxic conditions than under normoxic conditions. From these findings, it was hypothesized that respiratory muscle training under hypoxic conditions would lead to a greater respiratory endurance and a larger reduction of cardiovascular responses to increased respiratory muscle work. **PURPOSE:** The purpose of the present study was to clarify the effects of respiratory muscle endurance training under hypoxic conditions on respiratory muscle endurance and respiratory muscle-induced metaboreflex.

METHODS: Collegiate male endurance runners were assigned to a normoxic (n=6) or hypoxic group (n=6). Before and after 6 weeks of respiratory muscle endurance training, cardiovascular responses to an incremental respiratory endurance test were measured. The training was isocapnic hyperpnoea under normoxic and hypoxic conditions. Minute ventilation during the training was initially set at 50% of the individual MVV₁₂, and thereafter, target minute ventilation increased progressively. Target SpO₂ in the hypoxic group was set at 90% in the first and second weeks, and thereafter it was set at 80%. **RESULTS:** Respiratory endurance time was extended after the training in both groups, but there was no difference between the normoxic and hypoxic groups (norm: +45.1%, hypo: +39.6%). The changes in HR and arterial BP during the incremental respiratory endurance test were significantly reduced after 6 weeks of respiratory endurance training in both groups. There were no significant differences between the normoxic and hypoxic groups in either HR or arterial BP during hyperpnoea. **CONCLUSION:** These results suggest that respiratory muscle endurance is improved and respiratory muscle-induced metaboreflex is attenuated by respiratory muscle endurance training, but there is no additional effect when the training is performed under hypoxic conditions.

(No relationships reported)

Pulmonary function, which supplies adequate and instantaneous amounts of oxygen consumption, is associated with the exercise performance. Endurance athletes, such as triathlon and swimming, have a higher and prolonged demand than power athletes and non-athletes for gas exchange and ventilation during exercise.

PURPOSE: The purpose of this study was to analyze pulmonary function and the relationship between pulmonary function and endurance performance in triathletes. **METHODS:** Twenty-four male subjects, aged 20-25 years old, were recruited and divided into triathletes (n=12), who participated in international competition, and non-athletic control (n=12) groups. Anthropometry and body fat were measured at rest.

Pulmonary function tests were performed using a spirometry, including tidal volume (V_T), vital capacity (VC), forced vital capacity (FVC), Forced expiratory volume (FEV) in 1 second (FEV_1) and maximal voluntary ventilation (MVV). Endurance performance tests were examined during treadmill exercise testing with respiratory gas analysis, including maximal oxygen consumption (VO_2 max) and time to exhaustion (TTE). Informed consent forms had been completed by all participants before the experiments started.

RESULTS: All of baseline characteristics were not significantly different between two groups, except for the percentage of body fat ($13.59 \pm 3.30\%$ and $19.70 \pm 4.73\%$, $p < .05$ in triathletes and control groups). Triathletes had significantly higher pulmonary function in V_T (0.80 ± 0.20 vs 0.63 ± 0.13 L, $p < .05$), FVC (5.09 ± 0.50 vs 4.53 ± 0.43 L, $p < .05$), and MVV (181.72 ± 21.70 vs 157.97 ± 17.83 L/min, $p < .05$) compared with the control group. Moreover, they had greater VO_2 max (66.90 ± 4.93 vs 47.00 ± 8.43 ml.min⁻¹.kg⁻¹) and higher TTE (1074.80 ± 43.10 vs 782.40 ± 92.30 secs) compared with their counterpart ($p < .05$). We also found that FVC, FEV_1 and MVV were significantly correlated with VO_2 max in all subjects ($p < .05$).

CONCLUSIONS: This study indicated that triathletes had higher pulmonary function and some correlations existed in pulmonary function and VO_2 max, which may provide useful information for triathlon training.

 Email: sabielko@indiana.edu
 (No relationships reported)

High levels of ventilatory work have been shown to compromise locomotor muscle blood flow during endurance exercise. Inspiratory muscle training (IMT) may provide a useful technique to deal with increased ventilation during hypoxic exercise and maintain skeletal muscle blood flow.

PURPOSE: To examine if 6 weeks of IMT affects leg blood flow during endurance exercise in normobaric hypoxia.

METHODS: Ten male endurance trained athletes (VO_2 max = 61.6 ± 5.6 mL.kg⁻¹.min⁻¹) were pair matched based on pre-exercise maximal inspiratory pressure (MIP). Subjects underwent IMT for 3-d per week over a period of 6 weeks, with training set at either 80% sustained MIP (IMT group, n=5) or 30% sustained MIP (sham group, n=5), within a regimen of progressively increased work-rest ratios until task failure. Pre- and post-training, subjects completed respiratory muscle strength tests and a 20km cycling time trial (TT) in normobaric hypoxia ($F_{O_2} = 16.1\%$), where VO_2 was measured breath by breath and skeletal muscle deoxygenation (deoxygenated hemoglobin+myoglobin [HHb]) was measured via near-infrared spectroscopy. Using the change in HHb from unloaded cycling to exercise as a surrogate for a- VO_2 difference (O_2 extraction), VO_2/HHb gives an estimation for skeletal muscle blood flow.

RESULTS: The IMT group significantly improved MIP (145.3 ± 27.9 cmH₂O vs 171.7 ± 38.7 cmH₂O) following training ($p < 0.05$) while the sham group remained unchanged. During the last min of the 20km TT, VO_2 of the IMT group was at $87.4 \pm 12.5\%$ and the sham group at $91.7 \pm 8.9\%$ of normoxic VO_2 max. 20km TT mean V_E was higher post-IMT (98.9 ± 15.9 l.min⁻¹ vs 109.3 ± 22.4 l.min⁻¹, $p=0.055$) and unchanged in sham. V_E in the last min post-IMT was 133.6 ± 33.0 L.min⁻¹ compared to pre-IMT of 110.9 ± 18.2 L.min⁻¹ ($p=0.08$), and was unchanged in sham. The change in pre- to post- VO_2/HHb in the IMT group was $21.2 \pm 1.6\%$, but was not significant ($p=0.38$). There was no significant change in VO_2/HHb in the sham group and no differences were seen between groups following IMT.

CONCLUSION: Despite an increase in V_E and therefore, increased respiratory muscle work, there was no change in leg blood flow with IMT. IMT may allow for greater tolerance for increased ventilation during hypoxic exercise while maintaining leg blood flow.

Blood Pressure Response During Hyperpnoea Is Lower in Women Compared with Men

Kaori Shimizu, Keisho Katayama, Kanako Goto, Koji Ishida, Hiroshi Akima. *Nagoya University, Nagoya, Japan.* (Sponsor: Craig A. Harms, FACSM)
 Email: shimizu.kaori@h.mbox.nagoya-u.ac.jp
 (No relationships reported)

It has been reported that women exhibit less inspiratory muscle fatigue during exercise. Additionally, a recent study found a lower blood pressure response to resistive inspiratory muscle activity (high-resistance, low-speed inspiratory muscle contractions), indicating that women exhibit an attenuated inspiratory muscle metaboreflex compared to men. Another way to model the respiratory muscle metaboreflex is to measure the cardiovascular response to exercise-mimicking

hyperpnoea (low-resistance, high-speed inspiratory and expiratory muscle contractions). It is hypothesized that women will have a lower cardiovascular response to low-resistance, high-speed inspiratory and expiratory muscle contractions.

PURPOSE: To test this hypothesis, the cardiovascular response during voluntary normocapnic incremental hyperpnoea was evaluated in young women and age-matched men. **METHODS:** Healthy young subjects (8 men, 10 women) participated in this study. An incremental respiratory endurance test was performed as follows: target minute ventilation was initially set at 30% of maximal voluntary ventilation (MVV_{12}) and was increased by 10% MVV_{12} every 3 min. The test was terminated when the subject could no longer maintain the target ventilation. Heart rate and arterial blood pressure (BP) were continuously measured. **RESULTS:** There was no significant difference in respiratory endurance time between women (11.6 ± 0.6 min) and men (12.3 ± 0.5 min). The change in mean arterial BP (MBP) during the incremental respiratory endurance test was significantly lower in women compared to men (women: 105.9 ± 3.2 mmHg, men: 126.0 ± 6.0 mmHg at 9 min). **CONCLUSIONS:** The data from the present study suggests that the respiratory muscle-induced metaboreflex is blunted in women compared to age-matched men.

Exercise Breathing During Arm And Leg Cycling in Adults with Motor Incomplete Spinal Cord Injury

Khalid Alwadeai, Gino S. Panza, Jeffrey E. Herrick. *George Mason University, Fairfax, VA.* (Sponsor: Randall E. Keyser, FACSM)
 Email: kalwadea@masonlive.gmu.edu
 (No relationships reported)

INTRODUCTION: Motor incomplete spinal cord injury (iSCI) is associated with impaired ventilation at rest and during exercise and may exacerbate functional limitations from the injury. iSCI reduces overall lung capacities and volumes below predicted values and is also associated with poor respiratory control. **PURPOSE:** To characterize the breathing pattern and timing during arm- and leg-cycling in adults with motor iSCI and compare their response to a reference group. **METHODS:** 6-subjects (REF: n=3, iSCI: n=3) REF group; age: 32 ± 4.58 years; BMI: 29.3 ± 2.6 kg/m²; height: 178 ± 3.6 cm; weight: 92.9 ± 16.3 kg and iSCI group; age 31 ± 18 years; BMI: 22.1 ± 2.6 kg/m²; height: 185.6 ± 6.0 cm; weight: 75.9 ± 14.3 kg; injury level: C3-C5. Subjects completed testing on 2 separated days. Day 1: They performed a maximum voluntary ventilation test (MVV), and then 3 6-minute constant work rate (CWR) bouts randomized to either Leg and Arm cycling trials that elicited 10, 20, 30% of MVV (V_E L.min⁻¹). Day 2: The other work trial was performed. Workload was adjusted during the first 3 minutes of each 6-minute bout to establish the required V_E ($\pm 10\%$). Pedaling frequency was kept at 60 ± 5 revolutions per minute (RPM). Each bout was followed by a 5-minute seated rest. MANOVA were used to compare inspiratory time (T_I), expiratory time (T_E), and inspiratory duty cycle (T_I/T_{TOT}) within and between the groups as well as intensity. **RESULTS:** There was no significant differences in breathing pattern and timing during arm- or leg-cycling within the REF group ($F = 0.70$, $P = 0.65$) and iSCI group ($F = 0.66$, $P = 0.68$). Intensities within arm and leg trials did not reach significance in either group ($P \geq 0.17$). However, there was a significant difference between the two groups during arm-cycling: T_I , T_E , T_I/T_{TOT} (REF = $1.06 \pm 0.3s$, $1.78 \pm 0.4s$, 0.37 ± 0.02 ; iSCI = $0.78 \pm 0.2s$, $1.66 \pm 0.5s$, 0.33 ± 0.3 ; $F = 7.61$, $P = 0.002 < 0.05$, respectively), and leg-cycling (REF = $0.89 \pm 0.2s$, $1.58 \pm 0.3s$, 0.35 ± 0.02 ; iSCI = $0.78 \pm 0.1s$, $1.72 \pm 0.6s$, 0.33 ± 0.05 ; $F = 3.46$, $P = 0.036 < 0.05$, respectively). **CONCLUSION:** iSCI had a shortened T_I and prolonged T_E , reduced T_I/T_{TOT} compared to REF. Our results suggest a greater expiratory phase with a reduced inspiratory duty cycle in iSCI during both arm- and leg-cycling compared to non-iSCI, which could be associated with the injury and not to the exercise intensity.

Relation Between Inspiratory Muscle Strength and Recruitment Onset of Neck Inspiratory Muscles

Sohei Washino, Hironori Watanabe, Hiroaki Kanehisa, Yasuhide Yoshitake. *National Institute of Fitness and Sports in Kanoya, Kanoya, Japan.*
 Email: swashino.eagle@gmail.com
 (No relationships reported)

The diaphragm contributes approximately 70–90% to whole inspiratory muscle pressure generation. In contrast, the neck inspiratory muscles are not always active during quiet breathing in healthy people but frequently active in patients with respiratory disease who has lower inspiratory muscle strength, probably due to help performing inspiration for a certain lung volume. Taken together, the recruitment onset for the neck inspiratory muscles during an inspiration may depend on the inspiratory muscle strength.

PURPOSE: To test whether inspiratory muscle strength is associated with the recruitment onset for the neck inspiratory muscles during an inspiration. **METHODS:** First, eight healthy young subjects measured maximal inspiratory mouth pressure (MIP) as inspiratory muscle strength, and peak inspiratory flow rate (PIFR).

Then, subjects matched their flow rate to 20, 40, 60, 80, and 100% PIFR during volitional inspiration from residual volume (Flow rate-control task) to determine the index of recruitment onset for the neck inspiratory muscles. Flow rate-control task was performed with (W; 23cmH₂O) and without (WO) inspiratory load. Mean %PIFR and EMG amplitude (aEMG) of the sternocleidomastoid (SCM) and scalene (SC) were calculated over the duration of every 10% of maximal lung volume (MLV) ranging from 20% to 60% of MLV. The index of recruitment onset for each muscle was determined by the processed %PIFR-aEMG curves at each %MLV. Finally, a linear regression analysis was performed between MIP normalized to body weight (MIP/BW) and index of recruitment onset for each muscle across subjects, for which the Pearson product-moment correlation coefficient (*r*) was calculated at each %MLV.

RESULTS: MIP was ranged from 124 to 205 cmH₂O across subjects. When collapsed across %MLV, there were highly negative correlations between MIP/BW and index of recruitment onset for both muscles under W (SCM: *r* = -0.866; SC: *r* = -0.877, *P* < 0.01) and WO (SCM: *r* = -0.789; SC: *r* = -0.735, *P* < 0.05).

CONCLUSION: The current results indicate that the neck inspiratory muscles of a subject who has lower inspiratory muscle strength are recruited at lower flow rate with a certain lung volume, suggesting that MIP/BW becomes useful outcome for assessing not only inspiratory muscle strength but also recruitment onset of the neck inspiratory muscles.

Ventilatory Strategies Of Swimmers During Submaximal Efforts

Ben Skutnik¹, Ting Li², Christopher L. Brammer¹, Yifan Lu², Joel M. Stager, FACSM¹. ¹Indiana University, Bloomington, IN. ²Beijing Sport University, Beijing, China. (Sponsor: Joel M. Stager, Ph.D., FACSM)
 Email: bskutnik@indiana.edu
 (No relationships reported)

Background: Pulmonary ventilation while swimming is constrained by the medium (water) and the timing associated with arm mechanics. Attempts at describing ventilation have been technically complex and therefore little published data exists on ventilatory strategies and pulmonary function while swimming. This is in contrast to the considerable data available for other exercise modes.

Methods: Ten trained, competitive men swimmers (age = 24.4 ± 1.91 yrs) were asked to perform six submaximal exercise tests on separate days, three on a cycle ergometer and three while swimming in a flume. Workloads were set to elicit 70, 80, and 90% $\dot{V}_{E,peak}$ based off previous incremental tests in both modes. Tidal volume (V_T), breathing frequency (fB), peak tidal flow expired (P_{TE}), time to inspire (T_i) and expire (T_e), total tidal time (T_t), and duty cycle (T_i/T_{tot}) were assessed repeatedly in both conditions via flow-volume loops. Oxygen consumption (\dot{V}_O) and ventilation (\dot{V}_E) was measured via open flow calorimetry. All variables were recorded over the final minute of each workload. Two-way, repeated measures ANOVAs were used for all comparisons, with the level of significance set at 0.05.

Results: At 70%, subjects had a larger \dot{V}_E (79.04 ± 10.1 vs. 72.49 ± 11.2 L/min; *p* < 0.05), T_i/T_{tot} (59.1 ± 2.86 vs. 48.8 ± 1.47%; *p* < 0.05), and P_{TE} (5.92 ± 0.79 vs. 3.53 ± 0.63 L/s; *p* < 0.05), and smaller T_e (0.70 ± 0.13 vs. 1.07 ± 0.35 s; *p* < 0.05) when swimming compared to cycling. At 80%, subjects had a larger T_i/T_{tot} (58.9 ± 4.81 vs. 48.8 ± 2.78%; *p* < 0.05), P_{TE} (6.46 ± 1.16 vs. 4.31 ± 1.05 L/s; *p* < 0.05), and smaller T_e (0.62 ± 0.10 vs. 0.86 ± 0.23 s; *p* < 0.05) when swimming compared to cycling. At 90%, subjects had a larger T_i/T_{tot} (59.1 ± 2.86 vs. 48.8 ± 1.47%; *p* < 0.05) and P_{TE} (6.47 ± 0.87 vs. 5.01 ± 1.05 L/s; *p* < 0.05) but smaller \dot{V}_E (95.49 ± 20.4 vs. 103.18 ± 22.0 L/min; *p* < 0.05) and T_e (0.61 ± 0.12 vs. 0.76 ± 0.23 s; *p* < 0.05) when swimming compared to cycling. Swimming elicited a higher \dot{V}_E across all intensities (3.16 ± 0.64, 3.36 ± 0.73, 3.57 ± 0.69 vs. 2.65 ± 0.35, 2.96 ± 0.44, 3.19 ± 0.50 L/min; *p* > 0.05).

Conclusions: Unlike cycling, ventilatory strategies during swimming seem to be independent from the metabolic demand, calling for a forced hyperventilation at lower intensities but transitioning into a hypoventilation at near maximal intensities. The cause of this phenomena remains unclear.

Hypercapnia and Voluntary Activation of the Diaphragm in Healthy Humans

Hsuan-Yu Wan¹, Jonathon L. Stickford², Koichi Kitano¹, Wesley J. Manz¹, David M. Koceja¹, Robert F. Chapman, FACSM¹, Joel M. Stager, FACSM¹. ¹Indiana University, Bloomington, IN. ²Appalachian State University, Boone, NC.
 Email: hsuan-yu.wan@hsc.utah.edu
 (No relationships reported)

As a result of central fatigue, adults with severe pulmonary disease, e.g., asthma and COPD, may be unable to fully activate the respiratory muscles, eventually leading to pulmonary insufficiency. While hypercapnia is a common characteristic of pulmonary disease, the relationship between hypercapnia and voluntary activation of the diaphragm is unclear. **PURPOSE:** To examine whether or not hypercapnia

independent of ventilatory work contributes to central fatigue of the diaphragm in healthy humans. **METHODS:** Fourteen (N = 14) healthy volunteers visited the laboratory on two occasions. Following standardized pulmonary function testing and familiarization of experimental procedures on Day 1, subjects visited the laboratory on Day 2 to spontaneously breathe room air at rest (NN) and a gas mixture containing 7% CO₂ to induce hypercapnia (HH). Thereafter, subjects volitionally hyperventilated while breathing room air in an effort to match the inspired minute ventilation (\dot{V}_I) of HH while end-tidal PCO₂ (P_{ET,CO_2}) was maintained at eucapnic levels (NH). Twitch interpolation with bilateral magnetic stimulation of phrenic nerves at functional residual capacity was used to assess voluntary diaphragmatic activation (VA_{di}). VA_{di} was assessed during spontaneous breathing and the ventilatory manipulation period. Thus, the present study utilized a repeated-measures design with P_{ET,CO_2} and \dot{V}_I as the independent variables and VA_{di} as the dependent variable. **RESULTS:** Inhaling 7% CO₂ significantly increased P_{ET,CO_2} (NN = 38.6 ± 4.5, HH = 55.6 ± 2.2, NH = 39.5 ± 5.0 mmHg, *p* < 0.05). Although hypercapnia resulted in significant increases in the diaphragmatic pressure-time integral ($\int P_{di}$; NN = 349.6 ± 88.2, HH = 521.9 ± 110.4, NH = 492.5 ± 135.4 cmH₂O, *p* < 0.05) and \dot{V}_I (NN = 12.11 ± 2.95, HH = 40.27 ± 10.93, NH = 42.84 ± 12.64 L·min⁻¹, *p* < 0.05), there was no difference in VA_{di} across the experimental trials (NN = 94.5 ± 5.0, HH = 93.3 ± 7.0, NH = 94.9 ± 4.7%, *p* > 0.05). **CONCLUSIONS:** Our findings indicate that the magnitude of hypercapnia acutely imposed was not effective in inhibiting voluntary neural drives to the diaphragm in normal resting individuals. This may be due to an insufficient activation of the thin muscle afferents or a counterbalanced motor command to the ventilatory muscle.

2779 Board #299 June 2 11:00 AM - 12:30 PM
Hypoxic Preconditioning Enhances Diaphragm Function Via Erk And Akt Signaling In COPD Mice

Li Zuo, FACSM, Chia-Chen Chuang, Tingyang Zhou. *The Ohio State University, Columbus, OH.*
 Email: zuo.4@osu.edu
 (No relationships reported)

Diaphragm experiences sustained hypoxia in chronic obstructive pulmonary disease (COPD). Prolonged low O₂ exposure is linked with excessive reactive oxygen species formation, which may exacerbate muscle fatigue and compromise respiratory efficiency. Hypoxic preconditioning (HPC) represents a novel strategy that can effectively protect diaphragm against hypoxic stress caused by COPD. During HPC, muscles are treated with alternate high and low levels of O₂, which can induce certain adaptive changes to hypoxia. However, the associated mechanism remains unresolved. **PURPOSE:** To determine whether ERK and AKT signaling contribute to the protective effect of HPC during hypoxia in COPD mice.

METHODS: C57BL6 mice were exposed to cigarette smoke for two hours each day, five days a week for three months to develop COPD symptoms. When the smoking protocol was completed, mice were sacrificed, and their diaphragms were dissected out. Isolated muscle strip was mounted in a contractile chamber and treated with (n = 6) or non-treated with HPC (n = 5) or incubated with AKT inhibitor (MK 2206, 50 μM, n = 5) or ERK inhibitor (PD 98059, 100 μM, n = 5) prior to HPC. Muscle strips were electrically stimulated for five minutes during the middle of a 30-min hypoxia treatment (PO₂ = 5 Torr). The contraction force at the end of contraction protocol was recorded and normalized by the initial force to indicate muscle function. Data were expressed as mean ± SE and analyzed using multi-way ANOVA.

RESULTS: Our results show that HPC significantly improve muscle function during hypoxia (29 ± 2.8% for HPC vs. 6 ± 1.3% for control, *p* < 0.05). Either the inhibition of AKT or ERK diminished HPC protective effect on diaphragm (9 ± 2.6% for AKT inhibitor + HPC; 5 ± 1.3% for ERK inhibitor + HPC; 29 ± 2.8% for HPC, *p* < 0.05).

CONCLUSION: We propose that HPC attenuates diaphragm fatigue during hypoxia through AKT and ERK activation in COPD mice.

Effects Of Inspiring Hyperoxic Air On Excess Post-exercise Oxygen Consumption And Muscle Temperature After Exhaustive High Intensity Intermittent Exercise

Katsunori Tsuji. *University of Ritsumeikan, Shiga, Japan.*
 (Sponsor: Izumi Tabata, FACSM)
 Email: gr0055sx@ed.ritsumei.ac.jp
 (No relationships reported)

PURPOSE: The purpose of the present study is to elucidate effects of inspiring hyperoxic air (60% O₂; 40% N₂) on excess post-exercise oxygen consumption (EPOC) and muscle temperature after exhaustive high intensity intermittent exercise.

METHODS: Eight young males volunteered for this study. Means ± standard deviations (SDs) of the subjects' age (yrs), body mass (kg), and VO_{2,max} (ml/kg/min) were 23±2, 65.1±9.0, and 48.2±6.5, respectively. For normoxic experiment (N-E), the subjects entered the metabolic chamber at 10:00. After 10 min of warming up, the subjects started an exhaustive high intensity intermittent bicycle exercise (6 to 7

sets of 20-s exercise at an intensity of 170% $\dot{V}O_{2max}$ with a 10-s rest between each bout: HIIE) from 10:30. Until 14:00, the subject stayed in the metabolic chamber, and were measured oxygen uptake, rectal temperature and temperature of the vastus lateralis which is a mainly recruited muscle during the bicycle exercise. For hyperoxic experiment (H-E), the subjects followed the same protocol, except for inspiring the 60% O_2 air during the exercise. The order of N-E and H-E were randomly assigned for each subject.

RESULTS: Compared with the N-E (811.0±155.6 J/kg), total work during the HIIE was significantly higher on the H-E (880.7±141.0 J/kg). From the end of the HIIE until 10:48, oxygen uptake was significantly higher on the H-E (146.4±26.4 ml/kg) than the N-E (130.7±24.7 ml/kg). However, no differences in oxygen uptake between N-E and H-E was observed after 10:49. Compared with the N-E (36.14±0.51 °C), the muscle temperature after the HIIE was significantly higher from the end of the HIIE until 10:48 on the H-E (37.05±0.74 °C), while no difference in rectal temperature between H-E and N-E was observed after HIIE to 10:48. The Δ oxygen uptake observed in H-E over N-E (15.7±14.3ml/kg) from the end of the HIIE to 10:48 was highly correlated with the Δ muscle temperature measured in H-E over N-E during the same time period after the HIIE (0.91±0.66°C, $r=0.95$, $p<0.01$).

CONCLUSIONS: The present investigation demonstrated that hyperoxia elevates the total work during HIIE and EPOC after the HIIE. Furthermore, a significant part of the increased oxygen consumption observed until 15 min after the HIIE may be explained by the elevated muscle temperature which might enhance metabolism in the exercised muscle.

Older Women Exhibit Higher Airway 8-isoprostane Responses To Exhaustive Exercise Compared To Older Men

Stephanie P. Kurti, Sam R. Emerson, Joshua R. Smith, Sara K. Rosenkranz, Samantha A. Alexander, Garrett M. Lovoy, Craig A. Harms, FACSM. *Kansas State University, Manhattan, KS.*
 Email: stephkurti@ksu.edu
 (No relationships reported)

INTRODUCTION: Development of late-onset asthma and cardiovascular disease are associated with elevated lipid peroxidation in the airways and systemically. However, sex differences exist in development of these diseases. Using an exhaustive exercise bout as a physiological stressor may elucidate whether there is a sex difference in post-exercise lipid peroxidation in older adults. **PURPOSE:** To determine whether sex differences exist in airway and systemic 8-isoprostane responses to exhaustive exercise and establish whether changes in airway 8-isoprostane generation correlate with lung function from pre to post-exercise. We hypothesized that older women (OW) would have elevated post-exercise airway 8-isoprostane compared to older men (OM). Also, we hypothesized that airway 8-isoprostane would be negatively associated with improvements in lung function from pre to post-exercise. **METHODS:** Twenty-four subjects aged 60 years and over completed the study (12 OW/12 OM). Subjects came to the laboratory for one testing session after a 2-hour fast, with no exercise for at least 24 hours. Baseline measurements included exhaled breath condensate (EBC) for assessment of airway 8-isoprostane, a blood draw for systemic 8-isoprostane, and standard pulmonary function testing (PFTs) to assess forced expiratory volume in 1-second (FEV₁), forced vital capacity (FVC), FEV₁/FVC, and forced expiratory flow at 25-75% of FVC (FEF_{25-75%}). Participants then performed a $\dot{V}O_{2peak}$ test on a cycle ergometer. Immediately post-exercise, PFTs, a blood draw, and EBC were performed. **RESULTS:** The generation of airway 8-isoprostane from pre to post-exercise was different between OW and OM ($p=0.003$), increasing ~74±77% in OW and decreasing ~12±50% in OM. Systemic 8-isoprostane did not change over time in either group ($p=0.81$). In OW, FEV₁ increased post-exercise ($p=0.02$), but was not associated with 8-isoprostane. In OM, FEV₁, FEV₁/FVC and FEF_{25-75%} increased post-exercise ($p>0.05$), and the decreased 8-isoprostane was associated with an increased FEV₁/FVC and FEF_{25-75%} ($p<0.05$). **CONCLUSIONS:** OW had a greater airway 8-isoprostane response to exhaustive exercise compared to OM. These results suggest that sex differences in lipid peroxidation may play a role in the airway remodeling that is associated with disease development.

Gait Parameters of Individuals with Chronic Obstructive Pulmonary Disease

Haley Hawkins, Avery Wheelless, Nicole Rodgers, Stephen Bailey, FACSM, Srikant Vallabhajosula. *Elon University, Elon, NC.* (Sponsor: Dr. Stephen Bailey, FACSM)
 Email: hhawkins@elon.edu
 (No relationships reported)

Gait assessment for persons with chronic obstructive pulmonary disease (COPD) is beneficial in assessing fall risk and potentially treating limitations with ambulation associated with the disease. Some of the studies that estimated gait parameters in persons with COPD used the 6-minute walk test whose objective is to cover as much

distance as possible in 6 minutes rather than focusing on the pace at which they walk. There is a current lack of literature identifying fall risk among persons with COPD estimated using standard testing procedure for gait.

PURPOSE: To determine differences in gait parameters among individuals with COPD, healthy older adults, and older adults at high fall risk. **METHODS:** Seven persons with COPD (mean age 61.7±17.7 years), seven healthy older adults (mean age 70.4±6.8 years) and seven older adults at high fall risk (mean age 68.1±8.6 years) walked across a GAITrite walkway at their normal comfortable pace. Gait speed, stride length, % of swing phase of the three groups were compared using a one-way ANOVA. **RESULTS:** Persons with COPD had a significantly slower gait speed (75.6±17.3 cm/s) when compared to healthy older adults (132.4±14.6 cm/s; $p<0.001$) and to older adults at high fall risk (111.4±16.0 cm/s; $p=0.002$). Persons with COPD also had a significantly shorter stride length (94.3±16.9 cm) when compared to healthy older adults (138.4±17.4 cm; $p<0.001$), but not to older adults at high fall risk (116.5±17.2 cm; $p=0.08$). Persons with COPD spent less percentage of their gait cycle in swing phase (32.8±1.9%) when compared to healthy older adults (38.4±1.3%; $p<0.001$) and to older adults at high fall risk (37.2±1.8%; $p<0.001$). There were no significant differences between the healthy older adults and older adults at high fall risk. **CONCLUSIONS:** These results indicate that persons with COPD exhibit more conservative gait, walking slower, with a shorter stride length and less time spent in swing phase compared to healthy older adults and older adults at high fall risk. A gait-training program for this population may be beneficial. A randomized control trial with persons without COPD is also needed.

The Relationship between AR and ERK1/2 Pathway in Rat Skeletal Muscle During Exercise

Li Xun¹, Wang Xiaoqiang², Zeng Fanxing². ¹*Shandong Sport University, Jinan, China.* ²*Beijing Sport University, Beijing, China.*
 Email: lixun0221@163.com
 (No relationships reported)

PURPOSE: By blocking androgen receptor (AR), to investigate the effect of exercise on extracellular signal-regulated kinase 1/2 (ERK1/2) pathway in skeletal muscle, and by blocking ERK1/2 pathway, to further discuss the relationship between AR and ERK1/2 pathway during exercise.

METHODS: 48 adult male SD rats were randomly divided into control group (C), exercise group (E) that exercised on treadmill (20 m/min, 10%, 60 min/d), flutamide group (F) that implanted subcutaneously with a single 21-d release pellet of 50 mg/pellet flutamide, flutamide+exercise group (EF), blocking ERK1/2 group (P) that i.p. 5mg/kg/d of PD98059, blocking ERK1/2+exercise group (EP), sham group (S) and DMSO group (D). After 10 days, extensor digitorum longus (EDL) was isolated at 6h after the last exercise. The protein expression of MHC, AR, p-AR^{Ser210}, and the phosphorylated protein expression of ERK1/2 pathway (p-MEK1/2^{Ser217/221}, p-ERK1/2^{T202/Y204}, p-p90^{RSK Thr573}) of EDL were examined by western blotting analysis. **RESULTS:** Exercise can activate p-AR^{Ser210} ($P<0.05$) and p-MEK1/2^{Ser217/221}, p-ERK1/2^{T202/Y204}, p-p90^{RSK Thr573} (all $P<0.05$), eventually contributing to the increase of MHC ($P<0.05$). In EF group, p-AR^{Ser210}, p-MEK1/2^{Ser217/221}, p-ERK1/2^{T202/Y204} and p-p90^{RSK Thr573} were significantly decreased compared with E group (all $P<0.01$), and had no significant difference compared with F group. The MHC content in EF group decreased by 48.0% compared with E group ($P<0.01$), but had no significant difference compared with F group. In EP group, p-ERK1/2^{T202/Y204} and p-p90^{RSK Thr573} were significantly decreased compared with E group ($P<0.05$; $P<0.01$), and p-MEK1/2^{Ser217/221} and p-ERK1/2^{T202/Y204} were significantly decreased compared with P group ($P<0.01$; $P<0.01$), but AR had no significant change. The MHC content in EP group decreased by 24.2% compared with E group ($P<0.05$), but had no significant difference compared with P group. There are no significant difference between S group, D group and C group.

CONCLUSIONS: During exercise, blocking AR can lead to the phosphorylation expression of ERK1/2 pathway increasing, but blocking ERK1/2 pathway had no significant effect on AR. It is indicated that exercise can regulate ERK1/2 pathway via AR to promote protein synthesis in skeletal muscle.

Effects of Heavy Load Exercise and Acupuncture on Mitophagy in Rat Skeletal MuscleHua-yu SHANG¹, Yu Fu¹, Sheng-chao Bai², Bo-ya Gu², Zhi Xia³, Rui-yuan Wang². ¹Chengdu Sport Institute, Chengdu, China. ²Beijing Sport University, Beijing, China. ³Jinggangshan University, Ji'an, China.

Email: santanashy@hotmail.com

(No relationships reported)

PURPOSE: To examine the effects of heavy load exercise and acupuncture on mitochondrial structure and mitophagy in rat skeletal muscle.

METHODS: Male Sprague-Dawley rats were divided into 4 groups: control group (C, n=40), exercise group (E, n=40), acupuncture group (A, n=40), exercise and acupuncture group (EA, n=40). Rats in the E and EA groups ran on a rodent treadmill down a 16° grade at 16m/min for 90 min, and those in the A and EA groups received a 2-min session of acupuncture (needling of the bilateral soleus muscle). Each group was further divided into 0h, 12h, 24h, 48h and 72h sub-groups (n=8 each), and at each time point the bilateral soleus muscle was collected under anesthesia. Mitochondrial ultrastructural changes in skeletal muscle were observed by a transmission electron microscope. The content of quantitative enzyme citrate synthase (CS) was measured by ELISA. Protein expression of PTEN-induced putative kinase 1 (PINK1), mitochondrial Parkin, microtubule-associated protein 1 light chain 3 (LC3) were determined by western blot. Mitochondrial co-localization with Parkin and LC3 was measured by the immunofluorescence double labeling technique. The data of variables were all analyzed by one-way or multivariate ANOVA.

RESULTS: After heavy load exercise, the mitochondrial structure appeared to be abnormal and formed a large number of mitophagosomes; the CS content decreased 25.8%-50.1%; the expression of PINK1 (E12=2.552±0.141), Parkin (E24=2.535±0.100), LC3 (E12=2.757±0.180) significantly increased (C=1.000, p<0.05 to p<0.01). Acupuncture promoted the recovery of mitochondrial ultrastructure, alleviated the reduction of CS content, and lowered the expression of PINK1 (EA12=1.738±0.083), Parkin (EA24=2.053±0.117), LC3 (EA12=1.718±0.095) in mitochondria (C=1.000, p<0.05).

CONCLUSION: Heavy load exercise may activate the PINK1/Parkin pathway, promote the combination of LC3 and mitochondria, and result in mitophagy and mitochondrial damage within skeletal muscle. Acupuncture can decrease the expression of PINK1 and Parkin, and inhibit the combination of LC3 and mitochondria, thereby inhibiting excessive activation of mitophagy and alleviating mitochondrial damage within rat skeletal muscle. The Combined Effect of Obesity & Pulmonary Arterial Hypertension on the Gastrocnemius in Zucker Rats

Richard A. Perry, Jr, Wesley S. Haynie, Lemuel A. Brown, Jacob L. Brown, Megan E. Rosa-Caldwell, David E. Lee, Jamie I. Baum, Nan Smith-Blair, Nicholas P. Greene, Tyrone A. Washington. University of Arkansas, Fayetteville, AR.

(No relationships reported)

Pulmonary arterial hypertension (PAH) often leads to systemic hypoxic conditions promoting peripheral dysfunctions that affect skeletal muscle. Clinically, PAH is often observed concomitantly with obesity; as many as 38%-48% of PAH patients are obese. Recent studies have focused on the cellular mechanisms involved in PAH-associated skeletal muscle dysfunction; however, many of these studies have not included the additional effect of obesity. Further research into the combined effects of PAH and obesity on skeletal muscle could provide insight into unforeseen complications that arise in the PAH, obese population. **PURPOSE:** Describe the combined effect of PAH and obesity on myogenic capacity and fiber size in the gastrocnemius of Zucker rats. **METHODS:** Twenty-Four Zucker rats were divided into four groups: lean control (LC) (n=6), obese control (OC) (n=6), lean PAH (LP) (n=6) and obese PAH (OP) (n=6). At 9 weeks of age, control and PAH groups were injected with saline and mono-crotaline, respectively. Four weeks after injection, mice were sacrificed. Gastrocnemius muscles were excised. Gene expression and histochemical analysis was conducted. **summary of RESULTS:** There was a main effect of obesity to decrease cross-sectional area (CSA) (p<0.05). Cyclin D1 mRNA abundance was higher in the LP group compared to the OP group (p<0.05). The LP group also had higher CyclinD1 mRNA content compared to its control counterpart (LC) (p<0.05). MyoD mRNA abundance was higher in the LP group compared to the OP group (p<0.05). The LP group also had higher MyoD mRNA content compared to its control counterpart (LC) (p<0.05). Myogenin mRNA abundance was lower in the OC group compared to the LC group (p<0.05). The LC group also had higher Myogenin mRNA content compared to its PAH counterpart (LP) (p<0.05). **CONCLUSION:** Higher mRNA abundance of CyclinD1 and MyoD in the LP group are suggestive that skeletal muscles in LP rats may induce a compensatory effect against atrophic conditions. This is supported

by the CSA of the LP group being statistically similar to the CSA of the LC group. Additionally, this compensatory effect is lost in the OP group possibly resulting in the observed loss in CSA.

The Impact of Acetaminophen Consumption on mTOR Signaling in Human Skeletal Muscle Following Resistance ExerciseAndrew C. D'Lugos¹, Shivam H. Patel², Jordan C. Ormsby¹, Tara N. Mahmood¹, Don P. Curtis³, Glenn A. Gaesser, FACSM¹, Christopher S. Fry⁴, Chad C. Carroll², Jared M. Dickinson¹. ¹Arizona State University, Phoenix, AZ. ²Purdue University, West Lafayette, IN. ³Midwestern University, Glendale, AZ. ⁴University of Texas Medical Branch, Galveston, TX. (Sponsor: Glenn A Gaesser, FACSM)

(No relationships reported)

Resistance exercise (RE) is a powerful stimulus for skeletal muscle adaptation. Previous data have shown that cyclooxygenase (COX) inhibiting drugs may interact with the cellular mechanisms governing the adaptive responses of skeletal muscle to exercise. **PURPOSE:** Determine if prior consumption of acetaminophen (APAP) alters skeletal muscle mammalian target of rapamycin (mTORC1) signaling in response to RE. **METHODS:** In a double-blinded, counter-balanced, crossover design, healthy young men (n=8; 25 ± 1 yr, BMI: 26 ± 2 kg·m⁻²) performed two trials of unilateral knee extension (8 sets, 10 reps, 70% 1RM). For 24h prior to each trial, subjects ingested either APAP (1000mg/6h) or placebo (PLA) (final dose consumed immediately post RE). Muscle biopsies (*vastus lateralis*) were collected at rest and at 1 and 3h postexercise during each trial. Western blot was utilized to assess phosphorylation and total protein levels of mTORC1 signaling proteins. **RESULTS:** Total protein for all markers was unchanged with time or treatment (p>0.05). Relative phosphorylation (p/t) of mTOR^{Ser2448} was similarly increased from rest (p<0.05) in both trials at 1h (PLA, 1.5 ± 0.2; APAP, 1.8 ± 0.2 fold) and 3h postexercise (PLA, 1.6 ± 0.2; APAP, 1.8 ± 0.2 fold), while the relative phosphorylation of S6K1^{Thr389} was only increased (p<0.05) in APAP at 3h (PLA, 2.0 ± 0.3; APAP, 3.5 ± 1.2 fold). In contrast, absolute phosphorylation levels of mTOR^{Ser2448} and S6K1^{Thr389} were only increased from rest (p<0.05) following RE in PLA, while absolute phosphorylation levels of 4E-BP1^{Thr37/46} were reduced (p<0.05) postexercise in APAP. Absolute and relative phosphorylation of eEF2^{Thr56} were reduced (p<0.05) following RE only in APAP. **CONCLUSION:** Compared with other COX-inhibiting drugs (i.e., ibuprofen), prior APAP consumption may have a reduced impact on the relative phosphorylation of mTORC1 signaling proteins following RE. These findings further highlight the unique interaction between the consumption of different COX-inhibiting drugs and the adaptive cellular response of skeletal muscle to exercise.

Relationship Between Estimated Muscle Fiber-type And Peak Velocity For The Upper And Lower Extremity

Cameron S. Mackey, Ryan M. Thiele, Mitchel A. Magrini, Jason M. DeFreitas. Oklahoma State University, Stillwater, OK.

(No relationships reported)

Changes in muscular strength across isokinetic protocols have been used as a non-invasive method to estimate fast-twitch muscle fiber-type. However, few have determined the utility of estimated muscle fiber-typing in predicting performance. **PURPOSE:** Determine the relationship between estimated fast-twitch (FT%) muscle fiber-type and peak velocity (PV) of upper (UE) and lower (LE) extremity muscle groups. **METHODS:** Nineteen (mean ± SD: age = 23.62 ± 2.97 years, height = 178.67 ± 5.22cm, mass = 88.91 ± 13.86kg) males visited the laboratory on 2 occasions, separated by 2-3 days. During the first visit, participants were familiarized with the isokinetic protocols and maximal voluntary contractions (MVCs) of the UE [Elbow Flexors (EF) and Extensors (EE)] and LE [Knee Flexors (KF) and Extensors (KE)]. During the second visit, participants performed a maximal isokinetic protocol (50 repetitions at 180°·s⁻¹) for the UE and LE. The order of testing was randomized and a 20-minute rest period was implemented between protocols. Peak torque was calculated for each repetition of the isokinetic protocol and the average of the highest three and lowest three repetitions were used to calculate fatigue index (FI%) [FI% = (highest - lowest) ÷ highest * 100] and FT% muscle fiber-type [FT% = (FI% - 5.2) ÷ 0.90]. Prior to each protocol, isokinetic MVCs at 500°·s⁻¹ were completed in order to assess PV. The highest values recorded for PV were used for analysis. A Pearson correlation coefficient was computed to assess the relationship between FT% and PV for all muscle groups. **RESULTS:** The means ± SDs for each muscle group, as well as the results of the Pearson correlations are shown in Table 1. **CONCLUSION:** The results of the present investigation reveal that of the four muscle groups examined, only the EF showed a significant relationship between FT% and PV. These findings indicate that FT% may have a limited ability to accurately predict PV performance in various upper and lower extremity muscle groups.

Table 1. Mean \pm SD values for peak torque fatigue index (PTFI), estimated fast-twitch (FT%) muscle fiber type, and peak velocity (PV) for each muscle group. Pearson's r and p value reported from PTFI to PV for each muscle group.

	PTFI (%)	FT (%)	PV (deg·s ⁻¹)	Correlation	
				r	p
EF	46.58 \pm 10.07	45.98 \pm 11.19	422.46 \pm 32.55	0.536*	0.018
FE	57.28 \pm 15.06	57.86 \pm 16.73	410.20 \pm 25.78	0.405	0.085
KF	61.12 \pm 11.63	62.13 \pm 12.92	484.00 \pm 16.35	0.265	0.273
KF	55.35 \pm 11.77	55.73 \pm 13.08	476.81 \pm 22.96	0.218	0.369

* = significant relationship ($p < 0.05$) between FT% and PV

The Effect Of Exercise Intensity On Gene Expression And Protein Function Of Rs9939609 Gene Variant In Fto

Matthew B. Cooke¹, Jessica Danaher¹, Michael Greenwood, FACSM², Christos Stathis¹. ¹Victoria University, Melbourne, Australia. ²Texas A&M University, College Station, TX. (Sponsor: Michael Greenwood, FACSM)
 Email: matt.cooke@vu.edu.au

(No relationships reported)

Recent meta-analysis has shown the association between FTO risk allele and the odds of obesity to be attenuated by 27% in physically active adults, which may suggest a possible relationship between exercise and FTO protein function. **PURPOSE:** To examine differences in FTO gene expression and protein function following high and low intensity exercise. **METHODS:** Twenty eight apparently healthy untrained males and females were genotyped for the FTO rs9939609 (T>A) polymorphism, prior to performing continuous isocaloric (400 kcal) cycle ergometer exercise on two separate occasions at 80% (HI) and 40% (LO) VO₂peak. Skeletal muscle biopsies were sampled from the vastus lateralis at pre exercise (0 mins), 10 and 90 mins post exercise. Differences in FTO genotype, gene and protein expression, and m6A RNA methylation status before and/or after exercise were determined using an ANOVA. **RESULTS:** Distribution of the FTO variant alleles was 36% homozygous (AA), 32% heterozygous (AT) and 32% wild-type alleles (TT). No significant differences between genotypes in time to expend 400 kcal during the HI (AA: 36:45 \pm 2:00min:sec, AT: 39:29 \pm 3:07min:sec, TT: 41:21 \pm 3:02min:sec, $p = 0.511$) and LO intensity (AA: 54:28 \pm 2:58min:sec, AT: 57:59 \pm 4:06min:sec, TT: 61:04 \pm 4:19min:sec, $p = 0.472$) exercise protocol, or for average RER, glucose utilization and fat utilization (g.kgLBM⁻¹.T.I⁻¹) ($p < 0.05$) during each exercise protocol were noted. FTO mRNA expression was significantly increased at 10 mins post HI exercise (AA: 0.69-fold, AT: 0.21-fold, TT: 0.23-fold, $p = 0.003$). No genotype or genotype by time interaction was observed ($p < 0.05$). m6A on RNA was significantly decreased at 90 minutes following both LO and HI intensity exercise (Delta Change: HI - AA: -0.29 \pm 0.10ng, AT: -0.27 \pm 0.12ng, TT -0.06 \pm 0.17ng, $p < 0.05$; LO - AA: -0.07 \pm 0.12ng, AT: -0.16 \pm 0.11ng, TT: -0.20 \pm 0.06ng, $p < 0.05$). No genotype or genotype by time interaction was observed ($p < 0.05$). No main effect for time, genotype or genotype by time interaction was identified for muscle FTO protein expression in response to HI and LO intensity exercise. **CONCLUSIONS:** Physical exercise has a significant impact of FTO gene expression and possible function. The significance of these findings requires further investigation.

The Acute Effect Of Massage On Local Skeletal Muscle Perfusion And Oxygenation: A Pilot Study

Keeron J. Stone¹, Lee Stoner², James Faulkner³, Danielle Lambrick⁴, Samantha Barry-Wilson¹, Edward Brander¹, Simon M. Fryer¹. ¹University Gloucestershire, Gloucester, United Kingdom. ²University of North Carolina, Chapel Hill, NC. ³University of Winchester, Winchester, United Kingdom. ⁴University of Southampton, Southampton, United Kingdom.
 (No relationships reported)

Massage therapy is purported to hasten performance recovery, in part, through an augmentation of circulation leading to increased oxygen delivery to tissues, removal of metabolites and an earlier return to homeostasis. Despite this, existing research is equivocal, reporting little or no effect of massage on macrocirculation. However, given that perfusion of skeletal muscle can occur independently of macrocirculation, evaluating the microcirculation response may be more pertinent.

PURPOSE: To determine if massage therapy acutely increases local skeletal muscle perfusion and oxygenation.

METHODS: Twelve males (27 \pm 7 yr) attended the laboratory after an overnight fast, refraining from caffeine, alcohol and exercise for 24 h. After 15-min of prone rest, baseline oxyhaemoglobin (O₂Hb), deoxyhaemoglobin (HHb), total haemoglobin (tHb) and tissue saturation index (TSI%) of the gastrocnemius were determined using

near-infrared spectroscopy (NIRS). Subsequently, changes in NIRS variables were determined during (last minute) and 1-min, 5-min, 10-min and 15-min after massage therapy. The therapy consisted of 10-min of effleurage and petrissage techniques.

RESULTS: Repeated measures ANOVA's revealed significant 'time' main effects for tHb ($P < 0.001$, $\eta^2_p = .566$), O₂Hb ($P < 0.001$, $\eta^2_p = .472$) and HHb ($P < 0.001$, $\eta^2_p = .587$). *Post hoc* analysis revealed that tHb (MD -6.5 μ mol, 95% CI [-11.2, -1.8]), O₂Hb (MD -3.2 μ mol, 95% CI [-6.8, 0.2]) and HHb (MD -3.5 μ mol, 95% CI [-5.7, -1.2]) were reduced during massage when compared to baseline, but were unchanged at any other time point. TSI% was unchanged during and following massage ($P > 0.05$).

CONCLUSION: A reduction in muscle perfusion during massage therapy likely reflects the mechanical action of massage inhibiting capillary inflow but aiding outflow from the muscle. Whilst a lack of change in perfusion, oxygenation and TSI% following massage suggests a modest impact upon microcirculation, it is acknowledged that skeletal muscle perfusion but not blood flow was assessed. A lack of change in perfusion suggests that massage did not result in more capillaries being perfused; however, blood flow may still have been altered. Future studies should simultaneously assess blood flow through the macrocirculation, as well as microcirculation perfusion and blood flow.

In Vivo Intracellular Ca²⁺ Dynamics Over 7 Days Following Eccentric Contractions In Rat Skeletal Muscle

Ayaka Tabuchi¹, Hideki Shirakawa¹, David C. Poole, FACSM², Yutaka Kano¹. ¹University of Electro-Communications, Tokyo, Japan. ²Kansas State University, Manhattan, KS. (Sponsor: David C Poole, FACSM)
 Email: tabuchi@ecc.pc.uec.ac.jp

(No relationships reported)

In vitro studies have supported an important role for intracellular calcium ion concentration ([Ca²⁺]_i) as an intracellular signal for protein synthesis and degradation. Eccentric contractions (ECC) facilitate Ca²⁺ influx from the extracellular space via stretch-activated channels and cause high-levels of [Ca²⁺]_i accumulation. Accumulated [Ca²⁺]_i activates proteolysis-related enzymes and induces muscle damage. A few days after ECC, the damaged muscle fiber shifts from this proteolytic to a regenerative phase. Whether there is any temporal and/or spatial correspondence between [Ca²⁺]_i accumulation and structural damage/repair during recovery from ECC is unknown. **PURPOSE:** Specifically, we tested the hypothesis that there would be a dynamic pattern of [Ca²⁺]_i accumulation post-ECC that would relate temporally to the damage-recovery cycle. **METHODS:** In anesthetized adult Wistar rats, the tibialis anterior muscles (TA) were subjected to unexercised controls (CONT) and ECC (5 sets of 40 contractions). After 1 day (1D), 3 days (3D), and 7 days (7D) of ECC, the TA was loaded with ratiometric dye Fura-2 AM. We used the 340/380 nm ratio to analyze alterations in [Ca²⁺]_i by *in vivo* fluorescence imaging. After *in vivo* observations, the TA muscles were dissected to identify the histological features of the damage-to-regeneration cycle. **RESULTS:** After ECC, there was profound swelling at 1D followed by infiltration at 3D and regeneration at 7D (i.e. appearance of central nucleus). The mean [Ca²⁺]_i was significantly increased after ECC at 1D (1.48 \pm 0.09) and 7D (1.47 \pm 0.04) but not at 3D (1.34 \pm 0.05) compared with CONT (1.31 \pm 0.05). Whereas there was a heterogeneous [Ca²⁺]_i accumulation pattern evident among fibers it was interesting that [Ca²⁺]_i oscillated significantly more over the 30 minute observation period at 1D (mean variation range: 0.10 \pm 0.07) than at any other time (CONT: 0.08 \pm 0.03, 3D: 0.07 \pm 0.02, 7D: 0.08 \pm 0.02). **CONCLUSIONS:** We determined that: 1. There were peaks of [Ca²⁺]_i accumulation during both the swelling (1D) and regeneration (7D) phases. 2. The swollen and edematous fibers at 1D evidenced an oscillatory [Ca²⁺]_i pattern. These profiles of [Ca²⁺]_i accumulation may be key to controlling the extended pattern of protein synthesis and degradation that characteristically follows novel ECC.

GROWTH INHIBITION OF MESENCHYMAL STEM CELLS BY LAMINARIN, a β -D-GLUCAN: IMPACT ON CHONDROCYTE DIFFERENTIATION**ABSTRACT**

Mesenchymal stem cells (MSCs) are multipotent adult stem cells that differentiate to form cartilage, bone, tendons, muscle, and skin. Usually found in the bone marrow and can also be isolated from other tissues including cord blood or adipose tissue. Given the innate ability of MSCs to promote cellular damage recovery and tissue repair, there is rising interest in their use in a broad repertoire of cell-based therapy for the treatment of several diseases. One of the most important tasks of MSCs therapy is to control cells proliferation and differentiation. These processes model and shape tissue and organ relationships in multicellular organisms. Previous investigations showed that cell growth pathways are mediated through protein-glycan interactions. We have adopted this approach to study the effect of laminarin, a beta-(1→3)-D-glucans. **Methods:** MSCs were isolated from the bone marrow of six-week old male Wistar rats then cultured in MSC growth and chondrogenic differentiation mediums. Proliferation rate and apoptosis were explored by cell count, MTT assays and Annexin V staining. mRNA and protein expression of specific markers for MSCs and chondrocytes were studied using qPCR and immunofluorescence. **Results:** Laminarin treatment reduced cell proliferation of MSCs cultured in both growth and chondrogenic mediums. Annexin V staining showed no apoptosis. Cells in MSC growth medium showed no impact of laminarin for Thy1, nucleostemin and endoglin mRNA analysis. Conversely, in chondrogenic medium, laminarin had a negative effect on Thy1 levels and no change in nucleostemin and endoglin. Collagen II responded positively in chondrogenic medium in absence of laminarin and significantly reduced when laminarin was added. **Conclusion:** These results indicate that laminarin inhibited both cells proliferation and chondrogenic differentiation suggesting potential clinical applications in MSC therapy.

Leg Dominance and Fiber Type Composition Influence Landing Performance in Resistance-Trained Men

Jose A. Arevalo¹, James R. Bagley², Jakob J. Rosengarten¹, Scott K. Lynn¹, Lee E. Brown, FACSM¹, Pablo B. Costa¹, Andrew J. Galpin¹. ¹California State University, Fullerton, Fullerton, CA. ²San Francisco State University, San Francisco, CA.
Email: joarevalo@fullerton.edu
(No relationships reported)

Leg dominance may lead to asymmetrical performance and injuries. No study has investigated this issue at both the biomechanical and single muscle fiber level.

PURPOSE: Simultaneously investigate leg dominance, muscle fiber type composition, and landing performance in resistance-exercise trained (RE) men. **METHODS:** Fourteen men (age=24.1±2.6yrs; height=181.6±6.6cm; mass=87.8±10.9kg) answered a leg dominance questionnaire (preferred kicking leg) and performed drop-jumps (30cm) onto two independent force plates (one foot per plate), alternating the step off leg. Muscle biopsies were performed on the vastus lateralis in both dominant (D) and non-dominant (ND) legs. Individual muscle fibers (107.8±34.3/leg/person) were isolated and sodium dodecyl sulfate polyacrylamide gel electrophoresis was used to identify myosin heavy chain fiber type (MHCI, MHCI/IIa, MHCIIa, MHCIIa/IIx, or MHCIIx). **RESULTS:** Significant differences in MHCI [t ($df=13$)= 3.135, $p=0.008$] and MHCIIa [t ($df=13$)=-2.898, $p=0.012$] between legs were identified; D had a higher percentage of MHCI (33.9±11.2% vs. 24.9±15.3%) and ND had a higher percentage of MHCIIa (54.8±13.3% vs. 61.8±14.8%) fibers. Significantly more fibers containing MHC I isoforms (MHCI+MHCI/IIa) in D was present [t ($df=13$)=3.273, $p=0.006$] compared to ND (42.1±14.6% vs. 34.1±14.5%), and significantly more fibers containing MHC II isoforms (MHCIIa+MHCIIa/IIx+MHCIIx) in ND was present [t ($df=13$)=-1.923, $p=0.077$] compared to D (57.6±13.9% vs. 65.3±14.8%). A significant interaction existed between landing foot and step-off foot ($f=11.99$, $p=0.004$). ND produced a significantly higher landing rate of force absorption (RFA) compared to D ($p=0.03$) when stepping off with ND. The RFA in ND (stepping off with ND) was negatively

correlated with the percentage of fibers containing MHCI isoforms ($p=0.029$, $r=-0.581$) and positively correlated with the percentage of fibers containing MHCII isoforms ($p=0.048$, $r=0.536$). **CONCLUSIONS:** The preferred kicking leg was not preferred to absorb landing force. The greater abundance of MHCIIa fibers in the preferred force absorbing leg may provide an explanation for, or a result of, the observed asymmetry. These results enhance our understanding of leg dominance, performance, and muscle fiber type composition in RE men.

Body Weight Support Training Modulates Muscle NF- κ B p65 Expression Induced By Spinal Cord Injury

Lloyd P. Ruiz, Erika J. Hinahon, Emanuel Ruiz, Christina A. Estrada, Silvia Villanueva, Ray D. de Leon, Stefan Keslacy. California State University, Los Angeles, Los Angeles, CA.
Email: lruiz13@calstatela.edu
(No relationships reported)

Purpose: To improve the efficacy of exercise rehabilitation following traumatic spinal cord injury (SCI), a better understanding of muscle-associated cellular signaling is imperative. The transcription factor NF- κ B is a "master controller" of the inflammatory pathway with P65 being the main subunit. Thus we hypothesized that P65 is expressed in muscle of SCI rodents and that body weight supported treadmill training (BWSTT) modulates P65-related signaling cascade. **Methods:** A low-thoracic spinal cord contusion was performed on 16 Sprague Dawley rats and 8 were trained 5 days/week for 4 weeks. Proteins were extracted from soleus (Sol), gastrocnemius (GM), tibialis anterior (TA), and extensor digitorum longus (EDL) muscles. Immunoblot analysis for total NF- κ B p65, and I κ B- β was performed. Equal amounts of protein were analyzed by 4 to 12% SDS-polyacrylamide gel electrophoresis. Following transfer (TransBlot Turbo, Bio Rad), membranes were blocked in 5% milk and incubated overnight at 4°C with a primary antibody (p65, and I κ B, Santa Cruz Biotechnology, Santa Cruz, CA). Following incubation with a peroxidaseconjugated secondary antibody, bands were visualized by ECL, imaged and densitometry was determined (QuantityOne, Versadoc Bio-Rad). **Results:** P65 was strongly expressed in all muscles of untrained animals. Training significantly decreased P65 only in TA muscles ($P<.05$). P65 inhibitor I κ B- β expression increased in EDL, and GM muscles ($P<.05$) and decreased in Sol ($P<.05$) following training. The ratio of P65:I κ B- β significantly increased for Sol and decreased for EDL, GM, and TA for the trained group ($p<.05$). **Conclusion:** P65 was expressed in all muscles of SCI rodents. The BWSTT modulation of P65 expression seems to be related to I κ B interaction and is muscle-dependent.

E-39 Free Communication/Poster - Systematic Reviews and Meta-Analysis

Systematic Review Of The Association Between Physical Activity With Natural And Assisted Female Fertility

Kelly R. Evenson, FACSM¹, Shana G. da Silva², Kathryn R. Hesketh³. ¹UNC-Chapel Hill, Chapel Hill, NC. ²Federal University of Pelotas, Pelotas, Brazil. ³UCL Institute of Child Health, London, United Kingdom.
(No relationships reported)

PURPOSE: This systematic review summarized the association between physical activity (PA) and natural and assisted female fertility.

METHODS: We searched 5 databases for eligible studies through May 2016. Included studies were required to report an association between PA (exposure) and fertility (outcome) and focus on either natural or assisted fertility among women. Both observational studies and randomized controlled trials were eligible for inclusion, although none of the latter were identified.

RESULTS: The search yielded 25,168 titles. We included 21 studies from 19 unique populations: 13 cohort studies; 6 cross-sectional studies; 1 case control study; and 1 case cohort study. Fourteen distinct studies from 12 patient populations reported on the association between PA and natural fertility (in Canada, Denmark, Finland, Iran, the Netherlands, Norway, and the United States). Both PA and fertility were self-reported in all studies. Eight studies reported on the association between PA and natural fertility: 3 identified favorable associations, 1 identified unfavorable associations, and 6 identified no association between higher PA and natural fertility. Among 7 studies, findings for vigorous activity were similarly mixed. In 1 study, duration of daily standing or walking at work was not associated with pregnancy attempt duration, while another study found women with higher mean energy expenditure/working hour had

lower fecundability compared to women with lower mean energy expenditure/working hour. Seven cohort studies reported associations between PA and assisted fertility (in Brazil, Iran, Italy, Taiwan, Turkey, and the United States). Assisted fertility included in vitro fertilization (IVF) in 6 studies and intracytoplasmic sperm injections (ICSI) in 2 studies. PA was self-reported in all studies; one study also used accelerometry. Four studies found favorable associations, 1 found unfavorable associations, and two found no association between higher PA and assisted fertility.

CONCLUSION: The association between PA and natural and assisted fertility remains unclear. Future studies should incorporate objective PA measures and explore the PA volume and dose associated with fertility.

Motor Impairments in Transient Ischemic Attack and Subsequent Stroke

Neha Lodha¹, Jane Harrell², Stephan Eisenschenk², Evangelos Christou². ¹Colorado State University, Fort Collins, CO.

²University of Florida, Gainesville, FL.

(No relationships reported)

PURPOSE: Transient ischemic attack (TIA) increases the risk for a subsequent stroke. Typical symptoms include motor weakness, difficulty with speech, and loss of coordination. The association between the presence of motor impairments during a TIA and the chances of a subsequent stroke has not been systematically examined. In the current study, we examine whether the odds of a recurrent stroke are greater in TIA individuals who experience motor impairments as compared to those who don't experience motor impairments.

METHODS: We conducted systematic search of electronic databases as well as manual searches of the reference lists of retrieved articles. The meta-analysis included studies that reported an odds ratio relating motor impairments to a subsequent stroke, or the number of individuals with or without motor impairments who experienced a subsequent stroke. We examined these studies using rigorous meta-analysis techniques including random effects model, forest and funnel plots, I², publication bias, and fail-safe analysis.

RESULTS: Twenty-two studies with 11,084 participants from North America, Australia, Asia, and Europe qualified for inclusion. An odds ratio of 2.14 (95% CI, 1.66 - 2.77, p = 0.000) suggested that the chances of a subsequent stroke are increased by two-folds in individuals who experience motor impairments during a TIA.

CONCLUSIONS: The presence of motor impairments during TIA is a significantly high-risk clinical characteristic for a subsequent stroke, requiring specialist follow-up care and stringent secondary measures to prevent a further stroke. Thus, TIA prognosis warrants more robust quantification of motor impairments beyond clinically determined motor weakness.

A Meta-analytic Approach To Determine The Effectiveness Of Exercise Interventions On Abdominal Fat And Liver Enzymes In Overweight And Obese Youth.

Robinson Ramírez-Vélez¹, Katherine Gonzalez-Ruiz², Jorge E. Correa-Bautista², Antonio Garcia-Hermoso³, Mark D. Peterson⁴. ¹Centro de Estudios para la Medición de la Actividad Física «CEMA», Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogota, Bogotá D.C., Colombia. ²Centro de Estudios para la Medición de la Actividad Física «CEMA», Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogota, Bogota, Colombia. ³Laboratorio de Ciencias de la Actividad Física, el Deporte y la Salud, Universidad de Santiago de Chile, Santiago, Chile. ⁴Department of Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, MI.

Email: robin640@hotmail.com

(No relationships reported)

PURPOSE: Interestingly, despite the prevalence of obesity and the multiple position stands promoting exercise for the treatment of obesity and hepatic function, a meta-analytic approach has not previously been used to examine the effects in the paediatric population. However, several studies also show inconsistent results particularly with respect to children and adolescents, where data are scarce. Due to heterogeneity between studies in terms of results, we used a meta-analytic approach to determine the effectiveness of exercise interventions on abdominal fat and liver enzymes in overweight and obese youth.

METHODS: A computerized search was made using three databases. The analysis was restricted to studies that examined the effect of supervised exercise interventions

on abdominal fat (visceral and subcutaneous fat) and liver enzymes (alanine aminotransferase, aspartate aminotransferase and gamma-glutamyl transferase). Standardized mean difference [SMD] and 95% confidence intervals were calculated.

RESULTS: Fourteen clinical trials (1,231 youths) were eligible for inclusion in this systematic review and meta-analysis. Exercise was associated with a significant reduction in visceral ([SMD]=-0.661; 95% CI, -0.976 to -0.346; p<0.001), subcutaneous (SMD=-0.352; 95% CI, -0.517 to -0.186; p<0.001) and intrahepatic fat (SMD=-0.802; 95% CI, -1.124 to -0.480; p<0.001), as well as gamma-glutamyl transferase (SMD=-0.726; 95% CI, -1.203 to -0.249), but did not alter any other liver enzymes.

CONCLUSIONS: This meta-analysis supports current recommendation for physical exercise, mainly aerobic, as an effective intervention in the treatment of non-alcoholic fatty liver disease, through reduction on visceral and subcutaneous adipose tissue and intrahepatic fat. **Systematic review registration:** PROSPERO CRD42016042163

Effects Of Mhealth Apps On Physical Activity And Weight Loss Outcomes: A Meta-analysis

Zachary Pope, Nan Zeng, Zan Gao, FACSM. University of Minnesota, Minneapolis, MN. (Sponsor: Zan Gao, FACSM)

Email: popep157@umn.edu

(No relationships reported)

PURPOSE: Little systematic review has been conducted on mobile device health applications (a.k.a., mHealth apps) frequently used in health promotion. This meta-analysis synthesized evidence regarding the effectiveness of mHealth apps on physical activity (PA) and weight loss (WL).

METHODS: A total of 150 published articles regarding mHealth apps and PA/WL were found. Twelve studies met the following inclusion criteria: 1) empirical articles published between 2000 and 2016 in English; 2) examined the effectiveness of an mHealth app on PA or WL outcomes; and 3) each study contained ≥ 1 comparison. Data extraction for comparisons was completed for the following outcomes: 1) PA; 2) WL; and 3) body mass index (BMI). Moderator analyses were performed for studies reporting intervention fidelity frequency of: 1) greater than every two weeks; 2) less than every two weeks; or 3) not reported. Calculation of effect size (ES; Hedge's g) was completed with Comprehensive Meta-Analysis software for each entry. Analyses were run separately between mHealth apps and control (i.e., standard care or no treatment) or comparison (i.e., another experimental treatment) conditions.

RESULTS: mHealth apps were most commonly used for WL (n= 10). Compared to control and comparison, mHealth apps had no effect on WL (ES= .02 and ES= .08, respectively; all p > .05). Seven and six studies investigated mHealth apps effect on BMI and PA, respectively (one study examined both outcomes). Regarding BMI, mHealth apps had no effect versus control (ES= -.08, p > .05) or comparison (ES= -.09, p > .05). The same result was seen when using mHealth apps to promote PA outcomes. Specifically, when compared to control, mHealth apps demonstrated no effect in promoting increased step counts (ES= -.10, p > .05) and moderate-to-vigorous PA (ES= -.12, p > .05). Intervention fidelity was only reported by 4 of the included studies, with moderator analyses revealing no effect of intervention fidelity frequency on the study outcomes (all p > .05).

CONCLUSIONS: Findings indicate mHealth apps to be at least as effective as standard/no treatment or another experimental treatment condition. To improve effectiveness of mHealth apps in promoting PA and WL, future studies need to improve intervention fidelity measures and use established behavioral theory to implement the study.

2798 Board #318 June 2 9:30 AM - 11:00 AM
The Protective Role Of Physical Activity On Type 2 Diabetes: A Race/Ethnic-specific Meta-analysis

William R. Boyer¹, Scott E. Crouter, FACSM¹, Lyndsey M. Hornbuckle¹, Samantha F. Ehrlich¹, James R. Churilla, FACSM², Eugene C. Fitzhugh¹. ¹University of Tennessee, Knoxville, TN. ²University of North Florida, Jacksonville, FL.

(No relationships reported)

It is well known physical activity (PA) plays a role in the prevention of Type 2 diabetes (T2D). However, the extent to which PA may impact T2D risk among different race/ethnic groups is unknown. **PURPOSE:** To systematically examine the protective relationship between PA and T2D across five common race/ethnic groups (Caucasian, African American, American Indian, Hispanic, and Asian). **METHODS:** PubMed and Embase databases were systematically searched through June 2016. Study assessment for inclusion was conducted in three phases: 1) title review (N= 13,022), 2) abstract review (N=2,200), and 3) full text review (N=265). A total of 27 studies met the inclusion criteria and were used in the analysis. Relative risks (RRs) and 95% confidence intervals (CIs) were extracted and analyzed using the Comprehensive Meta-Analysis software. All analyses used a random-effects model. **RESULTS:** Statistically significant protective summary RRs, comparing the most active to the least active PA group, were found for Caucasians (RR 0.71, 95% CI 0.60-0.85), Asians (RR 0.76,

95% CI 0.67-0.85), Hispanics (RR 0.75, 95% CI 0.64-0.89), and American Indians (RR 0.73, 95% CI 0.60-0.88). The RR for African Americans did not attain statistical significance (RR 0.91, 95% CI 0.76-1.08). **CONCLUSIONS:** The results of this study indicate that PA (comparing most to least active groups) provides significant protection from T2D across the race/ethnic groups, with the exception of African Americans. Although the reason is not completely elucidated, this may be due to lowered fat oxidation rates at-rest and during exercise, large increases in susceptibility to diabetes with small decreases in insulin sensitivity, and higher percentages of type II muscle fibers in African Americans. The results also suggest a need for race- and ethnic-specific reporting of T2D RRs related to PA dose among prospective cohort studies.

2799 Board #319 June 2 9:30 AM - 11:00 AM

The Effect Of Exercise Training On Leptin: A Meta-analysis Of Randomized Controlled Trials

Michael V. Fedewa¹, Elizabeth D. Hathaway², Christie L. Ward-Ritacco³, Tyler D. Williams¹. ¹University of Alabama, Tuscaloosa, AL. ²University of Tennessee at Chattanooga, Chattanooga, TN. ³University of Rhode Island, Kingston, RI. Email: mvfedewa@ua.edu

(No relationships reported)

PURPOSE: Leptin is the primary energy balance hormone released from adipose cells. Lower leptin levels activate peripheral and central systems to restore energy balance; higher leptin levels inhibit feelings of hunger and are associated with increased energy expenditure. The effects of acute exercise bouts on leptin has been previously examined, however the effect of chronic exercise training on leptin is still incompletely characterized. As such, the primary aim of this study was to quantify the effect of exercise training on leptin level. **METHODS:** Articles published before April 14, 2016 were located using searches of the Physical Education Index (n=149), PubMed (n=355), Scopus (n=225), SPORTDiscus (n=54), and Web of Science (n=314) online databases using combinations of the terms: exercise, training, exercise training, leptin, randomized, randomized controlled study, and randomized controlled trial. All studies included in this meta-analysis were peer reviewed and published in English. Human participants were assigned to a non-exercise comparison group or exercise training group, with interventions lasting ≥ 2 weeks. Leptin levels were measured at baseline, during and/or after completion of the exercise training program. Each study effect size (ES) was calculated as the change in the control group subtracted from the change in the treatment group, divided by the pooled standard deviation of baseline values. Random-effects models were used to aggregate a mean ES and 95% confidence intervals (CI). A positive ES indicated a decrease in leptin following exercise training. **RESULTS:** The cumulative results from 128 effects extracted from 73 articles published between 1998 and 2016 indicate that exercise training can effectively reduce leptin levels (ES=0.2178, 95% CI: 0.1499-0.2856; $P < 0.0001$). The estimate of the effect increased slightly after accounting for the nesting of multiple effects within a single study (ES=0.2431, 95% CI: 0.1431-0.3431; $P < 0.0001$). The significant decrease in leptin following exercise training was moderately heterogeneous ($Q_{127}=218.66$, $I^2=41.92\%$; $P < 0.001$), with sampling error accounting for 64.8% of the observed variance. **CONCLUSIONS:** These results suggest that exercise training decreases leptin levels.

Current Evidence of Gait Modification Strategies to Reduce Knee Adduction Moment: Systematic Review and Meta-Analysis

Oladipo Eddo, Bryndan Lindsey, Shane Caswell, Nelson Cortes. George Mason University, Manassas, VA. Email: oeddo@gmu.edu

(No relationships reported)

Knee osteoarthritis (KOA) is a debilitating joint disease that predominantly occurs in the medial compartment due to excessive joint loads. Gait retraining using real-time biofeedback (RTB) is a conservative approach for reducing knee joint loads. While outcomes suggest moderate to large short-term treatment effects, existing evidence limits generalizability and clinical application.

PURPOSE: To determine if gait retraining interventions using RTB are beneficial for altering knee adduction moment (KAM) in KOA and asymptomatic individuals.

METHODS: An electronic search was conducted using the following databases: PubMed, EBSCO host, Embase, PROQuest, and Cochrane [1970 to January 1, 2016]. Duplicates were removed within then across databases. A total of 11 full text articles were retained that evaluated the effects of RTB on KAM. Methodological quality was assessed using the PEDro scale. Standardized mean differences (SMDs) were calculated for 1st peak KAM. Gait modification strategy (medial weight shift, lateral trunk lean, and self-selected) and mode of RTB (haptic and visual) were used as moderators for separate meta-analyses of studies with healthy participants. An inverse variance with random effects model approach was used with SMDs to account for heterogeneity between studies. Heterogeneity was quantified with the I^2 statistic with $P < 0.10$ being statistically significant.

RESULTS: Mean PEDro score was 6.0 ± 0.6 out of a possible 11 with internal validity scoring poorly across all studies. For studies including healthy participants, the I^2 index averaged 93%, with $P < 0.10$, in the two meta-analyses. Gait modifications strategies presented: $Tau^2 = 3.2644$, $Chi^2 = 180.6403$, $df = 14$ ($P < 0.0001$); $I^2 = 94.66\%$, $z = 2.4552$ ($P < 0.05$). The overall SMD was 1.18 [0.24; 2.13]. Self-selected gait modification strategies presented the greatest SMD. Mode of RTB results presented: $Tau^2 = 2.4776$, $Chi^2 = 122.8985$, $df = 12$ ($P < 0.0001$); $I^2 = 92.31\%$, $z = 3.7829$ ($P < 0.0001$) with an overall SMD of 1.19 [0.95; 1.43].

CONCLUSIONS: Evidence presented in this review suggests that gait modification via RTB is effective in reducing KAM in both symptomatic and asymptomatic individuals. However, evidence is limited and of low quality, meaning the optimal combination of gait modification strategy and mode of RTB delivery remains unclear.

Arterial Stiffness Is Reduced Regardless Of Exercise Training In Obese Paediatric Populations: A Meta-analysis Of Randomised Controlled Trials

Alejandra Tordecilla-Sanders¹, Antonio Garcia-Hermoso², Katherine Gonzalez-Ruiz³, Robinson Ramirez-Vélez³. ¹Centro de Estudios para la Medición de la Actividad Física «CEMA». Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá D.C, Co, Bogotá D.C, Colombia. ²Laboratorio de Ciencias de la Actividad Física, el Deporte y la Salud, Universidad de Santiago de Chile, Santiago, Chile. ³Centro de Estudios para la Medición de la Actividad Física «CEMA». Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá D.C, Co, Bogota, Colombia. Email: robin640@hotmail.com

(No relationships reported)

PURPOSE: In paediatric populations, the use of carotid intima-media thickness (IMT) as a marker of cardiovascular risk has increased. However, previous studies examining the effects of exercise training on arterial structure and function in obese children and adolescents have shown inconsistent findings. The primary aim of this systematic review and meta-analysis is to expand on the current body of literature by providing a quantitative estimate of the change in carotid IMT following exercise training, as well as to provide an exploratory analysis of potential moderators associated with the variation in response to an exercise training intervention in overweight and obese youth.

METHODS: A search of the literature was performed using the electronic databases CENTRAL, EMBASE, and MEDLINE. The terms used were: ['Obesity' and 'Overweight' OR], ['Exercise' and 'Training' and 'physical activity' and 'sport' OR]. All medical subject heading terms were combined with intima-media thickness* and children and adolescent as limiters. Studies reported in languages other than English were not explored. The analysis was restricted to studies that examined the effect of exercise interventions on carotid IMT in paediatric obesity (6-18-year-olds). Six randomised controlled trials (RCTs) (303 youths) were included. Hedges' g and 95% confidence intervals were calculated.

RESULTS: Exercise was associated with a small-to-moderate but significant reduction in carotid IMT ($g = -0.306$; 95% CI, -0.540 to -0.072 ; $p = 0.011$). Likewise, exercise programme duration per week significantly influenced the effect of exercise on carotid IMT ($\beta = -0.060$; $p = 0.015$). The meta-regression analysis shows that there was a greater decrease in carotid IMT in studies with a duration of more than a week. The slope regression coefficient was -0.060 [95% CI = -0.136 to -0.015] and was significant ($p = 0.015$). These data indicate that greater decrease in carotid IMT was observed in individuals that achieved larger interventions in terms of minutes per week.

CONCLUSIONS: Exercise seems to reduce carotid IMT in childhood obesity. Therefore, encouraging obese paediatric individuals to become physically active can lead to favourable changes in the arterial wall.

Exploring the Relationship between Fundamental Motor Skills & Physical Activity Levels in Children: A Meta-Analysis

Belinda Parmenter, Carolyn Broderick, Nancy van Doorn, Alexander Engel. University of NSW, Sydney, Australia.

(No relationships reported)

PURPOSE: Fundamental motor skills (FMS) are the building blocks for movements used throughout life and its proficiency is correlated with higher levels of physical activity (PA) and decreased incidence of obesity in school-aged children (SC) (5-12 years). However, it is unknown if the same relationship exists in preschool children (PC) (3-5 years). This review aims to evaluate interventions for improving FMS and PA levels in children from 3-5 and 5-12 and determine whether there is a similar relationship between a change in FMS and a change in PA across age groups.

METHOD: A systematic search of 7 electronic databases was conducted up until 20th July 2016. Controlled trials that implemented a FMS/PA intervention and qualitatively measured PA levels and FMS in healthy children between the ages of 3-12 years were included. Exclusions included intellectual/developmental delay, or a chronic disease/disability. Sub-analysis was conducted based on the type of intervention (teacher led (TL) or teacher educated (TE)), sessions/week (<3 or ≥3) and age group (PC or SC). Standardized mean difference (SMD), heterogeneity, bias and percentage change (%Δ) were calculated using RevMan 5.3.

RESULTS: Search terms yielded 16,576 articles, of which 13 met the inclusion criteria. In total 3,695 children (age 5.6±2.8 years) were studied. On average, interventions ran for 27±15 weeks, 3±2 sessions/week lasting for 41±23 minutes. Seven studies reported significant improvements in at least one measure of FMS or PA. Sub-analysis showed that TL interventions which run ≥3 sessions/week in PC were effective at increasing FMS (SMD=0.26 [0.10, 0.42]; p=0.002), PA (SMD=0.30 [0.10, 0.50]; p=0.003), and moderate-vigorous PA (SMD=0.24 [0.02, 0.46]; p=0.03). However, there was no significant correlation between the %Δ in FMS and %Δ in PA in either age group.

CONCLUSION: FMS and PA are both significantly improved by TL interventions run ≥3 sessions/week in preschools. This information should be used in designing future programs to implement in pre-schools. Further research is required on the relationship between change in FMS and PA across childhood, as research is limited.

A Systematic Review And Meta-analysis Physical Activity Intervention Fitness Of Female'S Middle Students In China

Yan Peng¹, Ming Yang¹, Yi Liu¹, Hao Guo¹, Mingxi Guan², Jindong Chang¹. ¹Southwest of University, Chongqing, China. ²Chongqing Business Vocational College, Chongqing, China. Email: 1049685056@qq.com

(No relationships reported)

Purpose: It is reported that approximately 50 % of Chinese weights are not reach the national standard. 2015 China Adolescent Weight Investigate Report. Approximately 70 % of Chinese adolescent are not physically active enough to achieve health benefits. The purpose of this study was to systematically review and meta-analyze the effect of fitness for Chinese middle students interventions on physical activity.

Methods: CNKI, Wanfang Data, Weipu Data and Web of Science Database were systematically searched to identify all relevant randomized controlled trials that evaluated the effect of fitness for Chinese middle students on physical activity from 2011 to 2015 years. According to the study design, the data of the boys were selected for analysis. The studies were described and effect size data were included in meta-analyses.

Results: Eighteen studies were included in the review and ten reported statistically significant improvements in physical activity. A meta-analysis of ten studies showed a statistically significant effect (SMD=0.24, P=0.0009<0.001) of Sit and Reach on physical activity immediately post-intervention. However, it is not statistically significant effect of Vital Capacity (SMD=0.08, P=0.24), Height(SMD=0.13, P=0.06), Weight(SMD=0.05, P=0.45) and Grip(SMD=0.10, P=0.17) on physical activity immediately post-intervention.

Conclusion: Female's daily activity is to be effective at increasing weekly duration of exercise in middle students, but the effect size is too small. Training Chinese female adolescents to encourage increased physical activity may provide an effective method for reaching their fitness health. More studies with detailed quantification of total physical activity will help to find more precise relative estimates for different levels of activity of Chinese females adolescents.

Effects Of Accumulated Short-bout Exercise On Systolic And Diastolic Blood Pressures: A Meta-analysis

Joel D. Reece¹, Heontae Kim², Minsoo Kang, FACSM². ¹Brigham Young University Hawaii, Laie, HI. ²Middle Tennessee State University, Murfreesboro, TN. Email: joel.reece@byuh.edu

(No relationships reported)

Exercise guidelines allow for the accumulation of short-bout exercise, but the effect of short-bout exercise (6-15 minute bouts) on reducing blood pressure is uncertain. **PURPOSE:** To determine the effect of accumulated short-bout exercise on systolic (SBP) and diastolic (DBP) blood pressures. **METHODS:** The mean and standard deviation of blood pressure change scores (the difference between pre- and post-intervention) were extracted to calculate effect sizes (ESs). SBP and DBP were analyzed separately. A random effects model was used to calculate an overall ES and 95% confidence interval (CI). Each ES was weighed by the inverse variance to give more weight to studies with larger samples. Moderator analyses were conducted to evaluate the effects of total intervention period (e.g., ≥12 weeks, <12 weeks) and total

exercise minutes per week (e.g., ≥150 mins, <150 mins) on overall ES. Heterogeneity was evaluated using Cochran's Q statistic. Comprehensive Meta Analysis (Version 2.2) software was used to conduct ES calculation and moderator analyses. **RESULTS:** Key search words included short, intermittent, and accumulated bouts in Ebscohost and Google Scholar databases. The searches yielded 446 articles. After initial screening of titles and abstracts, 34 potentially relevant studies were reviewed in full, 10 studies involving 163 participants were included, and 20 ESs were calculated in this meta-analysis. Overall mean ES for SBP was significant (ES = -0.324, CI = -0.59, -0.05). This indicated that accumulated short-bout exercise was effective in reducing SBP. Moderator analyses indicated that the mean ES for SBP was influenced by total intervention period, $Q_{\text{between}} (Q_b) = 5.028, df = 1, p = .025$, but not by total exercise minutes per week. Overall mean ES for DBP was not significant (ES = -0.136, CI = -0.45, 0.18). This indicated that short-bout exercise was not effective in reducing DBP. Moderator analyses indicated that the mean ES for DBP was not influenced by any of the two moderator variables. **CONCLUSION:** The accumulation of short-bout exercise can have a significant effect on decreasing SBP, especially with a longer intervention period (≥ 12 weeks). However, these changes are not seen in DBP. To better establish guidelines, more research should be conducted to understand the effects of short-bout exercise on DBP.

The Impact of Laminar and Oscillatory Shear Stress on Cellular Adhesion Molecule Expression in HUVEC

Edward B. Crabb, Daniel E. Conway, Lindsay M. LaFratta, Edmund O. Acevedo, FACSM, Robert L. Franco. Virginia Commonwealth University, Richmond, VA.

(No relationships reported)

PURPOSE: To investigate the influence of acute laminar shear stress (LSS) on the expression of VCAM-1 and fractalkine on human umbilical vein endothelial cells (HUVEC) following prolonged exposure to oscillatory shear stress (OSS) *in vitro*. **METHODS:** Cultured EC were stimulated with TNF-α for 24 hr and immediately exposed to shear experiments using a parallel-plate flow chamber: (i) 24 hr of LSS or OSS, and (ii) 24 hr of OSS followed by 30 min of LSS. Cells were collected and incubated with primary antibodies for surface VCAM-1 and fractalkine. Samples were analyzed via standard fluorescence-activated cell sorting. **RESULTS:** Prolonged LSS and OSS significantly reduced the TNF-α-induced elevation in the % of gated cells expressing VCAM-1 (p<0.001) and fractalkine (p=0.001); however, the reduction in VCAM-1 caused by LSS was shown to be significantly greater than the reduction elicited by OSS (p=0.006). Interestingly, the mean fluorescent intensity (MFI) of TNF-α-induced VCAM-1 was significantly elevated by prolonged OSS (1.60±0.01 fold [p<0.001]). Whereas, prolonged LSS had no impact on the MFI of TNF-α induced VCAM-1 (p=0.931). Prolonged LSS and OSS elicited a significant elevation in the MFI of TNF-α induced fractalkine (p=0.017). Lastly, acute LSS following prolonged OSS had no effect on the % of gated or MFI of cells expressing VCAM-1 and fractalkine. **CONCLUSIONS:** Prolonged OSS may increase markers of vascular inflammation. However, an acute period of LSS, utilized as a model of physical activity, does not appear to alter the OSS-induced inflammatory state.

Physical Activity Attenuates NLRP3 Inflammasome-associated Vascular Dysfunction in Obese Mice Heart

Jonghae Lee¹, Yang Lee², Kwangchan Kim¹, Eunkyung Park¹, Junyoung Hong¹, Yoonjung Park¹. ¹University of Houston, Houston, TX. ²Texas A&M Health Science Center College of Medicine, College Station, TX. Email: jlee88@central.uh.edu

(No relationships reported)

Activation of the NLRP3 inflammasome mediates the release of pro-inflammatory cytokine IL-1β and thereby plays a pivotal role in the inflammatory response in vascular pathology. An active lifestyle has beneficial effects on inflammation-associated vascular dysfunction in obesity. However, it remains unclear how physical activity regulates NLRP3 inflammasome-mediated vascular dysfunction in obesity. **PURPOSE:** To determine the protective effect of physical activity on NLRP3 inflammasome-associated vascular dysfunction in mice heart, and the potential underlying mechanisms. **METHODS:** C57BL/6J male mice were randomly divided into four groups: (1) control low-fat diet (LF-SED), (2) LF diet given free access to a voluntary running wheel (LF-RUN), (3) high-fat diet (HF-SED); 45% of calories

from fat), and (4) HF-RUN. Western blotting and immunofluorescence staining determined NLRP3 inflammasome-related signaling pathways and nitric oxide (NO) bioavailability-related pathways in the heart. **RESULTS:** Western blotting showed increased protein expression of NLRP3 in HF-SED (31%) compared to LF-SED, but it was reduced by voluntary wheel running. Immunofluorescence staining illustrated significantly higher expression of caspase-1 and IL-1 β in coronary endothelial cells and arterioles in HF-SED than LF-SED, LF-RUN, and HF-RUN. Compared to LF-SED, decreased expression of endothelial nitric oxide synthase (eNOS; 32%) and increased NOX2 (NADPH oxidase 2; 51%) expression in HF-SED were normalized to the level of LF-SED by voluntary wheel running. **CONCLUSION:** Our findings suggest that voluntary running would oppose high fat diet-induced vascular dysfunction in mice heart by suppressing NLRP3 inflammasome activation and possibly improving NO bioavailability via increased expression of eNOS and reduced oxidative stress.

Vigorous-Intensity Physical Activity May Improve Central Aortic Pressure Response to Glucose Loading in Overweight/Obese Men

Toru Yoshikawa, Hiroshi Kumagai, Kanae Myoenzono, Tomoko Kaneko, Takehiko Tsujimoto, Kiyoji Tanaka, FACSM, Seiji Maeda. *University of Tsukuba, Tsukuba, Japan.* (Sponsor: Kiyoji Tanaka, FACSM)
Email: yoshikawat@live.jp
(No relationships reported)

Central aortic systolic blood pressure (cSBP) decreases after a meal or glucose challenge, but the response is impaired by obesity-related disorders. We have previously reported that the blunted cSBP response to oral glucose loading in overweight/obese men was normalized after a 12-week aerobic exercise training program. However, the most effective intensity of physical activity to improve the cSBP response to glucose loading is unclear. **PURPOSE:** To evaluate the effect of intensity of regular physical activity on cSBP response to oral glucose loading in overweight/obese men. **METHODS:** Thirteen overweight/obese (body mass index, BMI ≥ 25 kg/m²) men (age, 50 \pm 8 years; BMI, 27.1 \pm 2.5 kg/m²; mean \pm SD) completed a 12-week aerobic exercise training program, involving both supervised and unsupervised walking/jogging. Physical activity time (PAT) was measured using a tri-axial accelerometer for 2-3 weeks prior to the exercise program and during 12 weeks of the exercise program, and was classified into low- (1.5-2.9 METs), moderate- (3.0-5.9 METs), or vigorous-intensity (≥ 6.0 METs). Before and after the program, cSBP was noninvasively estimated using applanation tonometry of the radial artery with a validated general transfer function at fasting and 120 min after 75 g oral glucose loading. **RESULTS:** Moderate- and vigorous-intensity PAT significantly increased during the exercise program, whereas low-intensity PAT did not change (low-intensity: 244 \pm 55 to 254 \pm 63 min/day, $P = 0.39$; moderate-intensity: 48 \pm 16 to 70 \pm 19 min/day, $P < 0.01$; vigorous-intensity: 0 \pm 1 to 12 \pm 10 min/day, $P < 0.01$). Glucose loading significantly decreased cSBP only after the exercise program (109 \pm 13 to 104 \pm 14 mmHg, $P < 0.05$), but not before (111 \pm 15 to 110 \pm 17 mmHg, $P = 0.56$). Changes in cSBP response to glucose loading after the exercise program were significantly correlated with changes in vigorous-intensity PAT, but not with changes in low- and moderate-intensity PAT (low-intensity: $r_s = 0.03$, $P = 0.93$; moderate-intensity: $r_s = -0.16$, $P = 0.61$; vigorous-intensity: $r_s = -0.78$, $P < 0.01$). **CONCLUSIONS:** Vigorous-intensity physical activity during the 12 weeks of aerobic exercise training program may have improved the cSBP response to oral glucose loading in overweight/obese men. The Impact of Repetitive Long-duration Water Immersion on Vascular Function

Erin E. Simmons, Elizabeth R. Bergeron, John P. Florian. *Navy Experimental Diving Unit, Panama City, FL.*
Email: ees06f@tamu.edu
(No relationships reported)

While physiological responses to water immersion (WI) are well-studied, the vascular responses after WI are less understood. **PURPOSE:** The objective of this study was to quantify the changes in endothelial function and vascular stiffness following repeated six-hour WIs with surface-supplied air. **METHODS:** Sixteen healthy subjects (15 male) performed six-hour resting thermoneutral water immersions (WI) at 1.35 atmospheres absolute (ATA) for four consecutive days, with follow-up on the fifth day. Measurements included endothelial function and arterial stiffness (peripheral arterial tonometry), beat-to-beat blood pressure (photoplethysmography), heart rate (HR), and plasma volume (PV) calculated from changes in hemoglobin and hematocrit. **RESULTS:** The reactive hyperemia index (RHI), a marker of endothelial function, increased with repeated immersions ($p=0.008$) as did lnRHI ($p=0.025$). By WI 3, RHI and lnRHI increased 16% and 17%, respectively, compared to WI 1 values, but no significant differences were detected between WI 4 and WI 1 for either measure.

Absolute arterial stiffness (augmentation index, AI) increased by an average of 33% ($p<0.001$) and AI normalized for HR (AI@75) by 11% ($p=0.12$) following each WI. PV decreased significantly by 13.2% ($p<0.001$) following WI and remained 6.8% lower at follow-up compared to pre-WI. Systolic blood pressure significantly decreased by an average of 2.5% following each WI ($p=0.012$). HR decreased 4.3% after each WI ($p<0.001$) but increased overall by 6.6% over the course of repeated WI ($p<0.001$). Total peripheral resistance increased by an average of 13.1% following WI ($p=0.003$).

CONCLUSION: Four consecutive days of six-hour WIs while breathing air at 1.35 ATA results in a transient increase in arterial stiffness following each WI as well as an increase in endothelial function on the third day. Additionally, in the context of acute exposure to WI, blood pressure and endothelial function diverge from their usual direct associations with arterial stiffness

2809 Board #329 June 2 9:30 AM - 11:00 AM

Serum CTRPs Levels Are Associated With Exercise Training-induced Reduction Of Arterial Stiffness In The Elderly

Natsuki Hasegawa¹, Shumpei Fujie¹, Masataka Uchida¹, Naoki Horii¹, Toshiyuki Kurihara¹, Kiyoshi Sanada¹, Takafumi Hamaoka, FACSM², Motoyuki Iemitsu¹. ¹*Ritsumeikan University, Kusatsu, Japan.* ²*Tokyo Medical University, Tokyo, Japan.* (Sponsor: Takafumi Hamaoka, FACSM)
(No relationships reported)

Habitual aerobic exercise reduces arterial stiffness and decreases fat accumulation, concomitant with an elevated serum level of adiponectin, as an adipokine of anti-inflammatory factor. Adiponectin regulates endothelial nitric oxide (NO) synthase in endothelial cells, promoting NO production. Recently, C1q/tumor necrosis factor-related proteins (CTRPs) has been identified as a novel adipokines and are paralog of adiponectin. However, the association between exercise-training effects of arterial stiffness and circulating CTRPs levels remain unclear.

PURPOSE: This study aimed to clarify whether reduction of arterial stiffness by exercise training is associated with change in serum levels of CTRPs.

METHODS: Fifty-six middle-aged and older subjects were enrolled in this study. The study subjects were randomly divided into two groups: the training group ($n = 28$, 68 \pm 1 years) and the control group ($n = 28$, 65 \pm 2 years). Subjects in the training group completed 8-week of aerobic exercise training (60-70% peak oxygen uptake [VO₂peak] for 45 min, 3 days/week). Before and after the intervention, we measured body composition by magnetic resonance imaging (MRI) and dual-energy x-ray absorption (DXA), carotid-femoral pulse wave velocity (cfPWV) as an indicator of arterial stiffness, and serum CTRPs (adiponectin, CTRP3, CTRP5, CTRP9) concentrations using enzyme-linked immunosorbent assay (ELISA) method.

RESULTS: In the training group, %body fat, abdominal visceral fat area and cfPWV were significantly decreased after the intervention ($P < 0.05$). Moreover, aerobic exercise training significantly elevated serum adiponectin and CTRP5 levels ($P < 0.05$) and tended to increase serum CTRP3 level. Additionally, the training-induced change in cfPWV was negatively correlated with training-induced change in serum adiponectin, CTRP3 and CTRP5 levels ($r = -0.46$, $r = -0.52$, $r = -0.39$, respectively, $P < 0.05$). By contrast, none of these parameters changed significantly in the control group. **CONCLUSION:** These results suggest that the exercise training induced increase in serum CTRPs levels may be associated with the reduction of arterial stiffness in middle-aged and older adults.

Evidence Suggesting Reduced Macrovascular and Microvascular Dilator Function in Well-Healed Burned Survivors

Amy N. Adams¹, Steven A. Romero¹, Daniel Gagnon², Manall F. Jaffery¹, Matthew N. Cramer¹, Ken Kouda³, Gilbert Moralez¹, Craig G. Crandall, FACSM¹. ¹*Institute for Exercise and Environmental Medicine, Dallas, TX.* ²*Montreal Heart Institute and Université de Montréal, Montreal, QC, Canada.* ³*Wakayama Medical University, Wakayama, Japan.* (Sponsor: Craig Crandall, FACSM)
Email: AmyAdams3@texashealth.org
(No relationships reported)

In healthy non-burned individuals, prolonged physical inactivity impairs vascular function and structure evidenced by reduced resting femoral artery diameter and macrovascular and microvascular dilator function. Burn survivors are exposed to prolonged physical inactivity immediately post-injury, which often persists years into recovery. Therefore, burn survivors may be at a heightened risk for vascular dysfunction. **PURPOSE:** To test the hypothesis that macrovascular and microvascular

dilator function is reduced in burn survivors compared with healthy non-burned controls. **METHODS:** Seven healthy non-burned adults (3 females; age 32 ± 10 years; mass 72 ± 22 kg; height 167 ± 9 cm; mean \pm SD) and 12 adults having sustained a burn injury covering at least 20% of their body surface area (11 ± 8 years prior to assessment (5 females; age 39 ± 16 years; mass 82 ± 20 kg; height 171 ± 11 cm; body surface area burned 53 ± 23 %) participated in this study. Macrovascular (flow mediated dilation) and microvascular (peak reactive hyperemia and area under the curve) dilator function was assessed, via duplex ultrasonography, of the brachial artery following 5 minutes of arterial occlusion. Nitroglycerin mediated dilation (0.4 mg sublingual administration) was used to assess endothelial independent vasodilation. **RESULTS:** Macrovascular dilator function tended to be reduced in burn survivors (controls $7.6 \pm 1.0\%$ vs burn survivors $5.1 \pm 0.8\%$; $P = 0.08$). Likewise, forearm vascular conductance area under the curve (controls 2.73 ± 0.34 ml mmHg^{-1} vs burn survivors 2.03 ± 0.26 ml mmHg^{-1} ; $P = 0.1$) and peak forearm vascular conductance (controls 5.27 ± 0.56 ml min^{-1} mmHg^{-1} vs burn survivors 4.07 ± 0.42 ml min^{-1} mmHg^{-1} ; $P = 0.1$) tended to be lower in burn survivors. Nitroglycerin mediated vasodilation did not differ between groups (controls $21.8 \pm 2.3\%$ vs burn survivors $21.1 \pm 2.4\%$; $P = 0.8$). **CONCLUSION:** In these preliminary data, macrovascular and microvascular dilator function tends to be impaired in burn survivors. However, endothelial independent vasodilation is well maintained in these individuals, suggesting that endothelial dysfunction contributes to their attenuated macrovascular and microvascular dilator responses. Funded by National Institutes of Health (GM-068865).

Serum Salusin- α Level Is Associated With Exercise Training-induced Reduction Of Arterial Stiffness In The Elderly
 Shumpei Fujie¹, Natsuki Hasegawa¹, Masataka Uchida¹, Naoki Horii¹, Kiyoshi Sanada¹, Takafumi Hamaoka, FACS², Motoyuki Iemitsu¹. ¹Ritsumeikan University, Kusatsu, Shiga, Japan. ²Tokyo Medical University, Tokyo, Japan. (Sponsor: Takafumi Hamaoka, FACS)
 Email: sh0017hv@ed.ritsumei.ac.jp
 (No relationships reported)

Aging-induced elevation of blood pressure and arterial stiffness is reduced by aerobic exercise training. Administration of salusin- α to healthy rats induces a decrease in mean arterial blood pressure, and circulating salusin- α level was lower in patients with hypertension or coronary artery disease compared with healthy controls. Additionally, circulating salusin- α level is significantly negative correlated with brachial-ankle pulse wave velocity (baPWV) as an indicator of systemic arterial stiffness. However, it is unclear whether circulating salusin- α level is associated with exercise training-induced reduction of risks for hypertension and arteriosclerosis. **PURPOSE:** The aim of this study was to investigate whether serum salusin- α level is associated to exercise training-induced changes in blood pressure and arterial stiffness in healthy middle-aged and older adults.

METHODS: Twenty-eight healthy middle-aged and older subjects (67 ± 1 years) were participated in this study. Subjects completed 8-week of aerobic exercise training (60-70% peak oxygen uptake [VO_{2peak}] for 45 min, 3 days/week). We measured brachial blood pressure, carotid-femoral pulse wave velocity (cfPWV) as an indicator of central arterial stiffness, and VO_{2peak} as an indicator of cardiorespiratory fitness.

RESULTS: After the exercise intervention, VO_{2peak} was significantly increased, and systolic blood pressure and cfPWV were significantly decreased (each $P < 0.05$). Serum salusin- α level was significantly increased after the exercise training ($P < 0.05$). Additionally, significant negative correlations between the training effects of serum salusin- α level and cfPWV ($r = -0.580$, $P < 0.05$) and systolic blood pressure ($r = -0.409$, $P < 0.05$) were seen.

CONCLUSIONS: These results suggest that aerobic exercise training-induced changes in serum salusin- α level may be related to the reduction of blood pressure and arterial stiffness in healthy middle-aged and older adults. Physical Fitness Protects Against Age-Related Vascular Dysfunction in the Lower Limb
 Matthew J. Rossman¹, H. Jonathan Groot², Ryan S. Garten³, Eivind Wang⁴, Jan Helgerud⁴, Jan Hoff⁴, Russell S. Richardson⁵. ¹University of Colorado, Boulder, CO. ²University of Utah, Salt Lake City, UT. ³Virginia Commonwealth University, Richmond, VA. ⁴Norwegian University of Science and Technology, Trondheim, Norway. ⁵University of Utah, salt lake city, UT.
 Email: matt.j.rossman@gmail.com
 (No relationships reported)

Vascular function is reduced with sedentary aging, which contributes to increased cardiovascular disease risk with age. Physical activity can prevent, and/or reverse, age-related vascular dysfunction. Data supporting the beneficial impact of physical activity,

however, are primarily derived from assessments of vascular function in the arm. **PURPOSE:** This study sought to examine the impact of aging and physical fitness on lower limb vascular function. **METHODS:** Flow-mediated dilation (FMD, Doppler ultrasound) of the superficial femoral and popliteal arteries (SFA and PA, respectively) was assessed in a total of 32 subjects, consisting of 8 young sedentary (Y; 23 ± 1 yrs), 8 old sedentary (OS; 73 ± 2 yrs), 8 old active (OA; 71 ± 2 yrs), and 8 old endurance trained (OT; 72 ± 1 yrs) adults. Subjects were grouped based on age, physical activity (interview and accelerometry), and maximal oxygen consumption (VO_{2max}) assessed on a cycle ergometer. **RESULTS:** FMD was reduced in the OS group relative to the Y in the SFA (Y: $4.3 \pm 0.9\%$, OS: $1.7 \pm 0.4\%$, $p < 0.05$) and PA (Y: $6.3 \pm 0.9\%$, OS: $1.9 \pm 0.4\%$, $p < 0.05$). Increasing levels of physical fitness corresponded to an increase in FMD in the SFA (OA: $2.9 \pm 0.6\%$, OT: $4.3 \pm 0.8\%$) and PA (OA: $2.3 \pm 0.8\%$, OT: $5.2 \pm 1.1\%$), such that SFA FMD was not different from the Y in the OA and OT groups, and PA FMD was not different from the Y in the OT group. Additionally, in the old subjects, both SFA ($r = 0.44$) and PA ($r = 0.48$) FMD were significantly correlated with VO_{2max}. **CONCLUSION:** Collectively, these data suggest that physical fitness diminishes the detrimental effect of aging on lower limb vascular function. Importantly, these data extend observations in the arm, in terms of the benefits of physical activity on vascular function with advancing age, to the lower limb, which, as a consequence of limb-specific vascular aging, may be at a greater predisposition for age-related vascular dysfunction.

The Acute Effect of Total Resistance Training Load on Blood Pressure: A Meta-Analysis
 Engell Quesada-Valle, Elizabeth Carpio-Rivera, Andrea Solera-Herrera. University of Costa Rica, San José, Costa Rica.
 Email: engellqv@gmail.com
 (No relationships reported)

Systemic arterial hypertension is a multifactorial disease with high prevalence in the elderly population. Resistance training has shown promising results in reducing hypertension; finding mainly explained by the post-exercise hypotensive effect. **PURPOSE:** The purpose of this meta-analysis was to determine the acute effect of the total resistance training load on blood pressure (BP). **METHODS:** A systematic search of articles evaluating post-exercise BP responses published until June 2016 was performed in 6 databases. Risk of bias was assessed using a 5 point Likert-type scale. Hedge's standardized mean difference effect size (ES) was calculated for each result; then, ESs pooled using random-effects models. Non-overlapping 95% confidence intervals (CI_{95%}) were considered statistically significant. Heterogeneity was assessed using Q and I², while funnel plots and Egger's regression test were used to assess small-study effects (potential bias). The z-test was computed to determine whether ESs were different from zero. **RESULTS:** Twelve studies were selected, representing 171 subjects for a total of 342 ESs. For systolic BP, the overall ES was -0.86 (CI_{95%} = -0.73 , -1.02 ; $z \neq 0$, $p < 0.05$), which translates to a reduction of 6.3 mmHg. For diastolic BP, the ES was -0.51 (CI_{95%} = -0.62 , -0.40 ; $z \neq 0$, $p < 0.05$), which translates to a reduction of 3.3 mmHg. Normotensive and physically-active participants who were prescribed exercise intensities based on submaximal tests showed higher reductions in BP than hypertensive, sedentary, and when one maximal repetition (1-RM) was used for exercise intensity prescription ($p < 0.05$). Significant reductions in diastolic BP following exercise were observed with higher session total training load ($r = -0.23$, $p < 0.05$). **CONCLUSIONS:** The total resistance training load is highly correlated to post-exercise BP reductions, providing significant clinical benefits for patients.

 (No relationships reported)

Recovery from severe burn injuries involves prolonged hospitalization and accompanying bed rest. Additionally, burn survivors are often physically inactive for years following the burn injury, which together with the aforementioned bed rest during hospitalization may contribute to a reduction in vascular health. **Purpose:** Using arterial stiffness as an indicator of vascular health, the purpose of this study was to test the hypothesis that arterial stiffness is greater in burn survivors compared with non-burned control subjects, indicative of a less compliant vascular bed. **Methods:** Central (carotid-femoral) and peripheral (carotid-radial) arterial stiffness were assessed via pulse wave velocity (Doppler) in eight non-burned adults (4 females; age 33 ± 10 years; height 167 ± 8 cm; mass 76 ± 24 kg; mean \pm SD) and 15 burn survivors (8

females; age 40 ± 15 years; height 170 ± 11 cm; mass 80 ± 19 kg; mean \pm SD). Burn survivors had an average of $49 \pm 23\%$ (range: 16 - 85%) body surface area burned and were at least two years post burn injury. **Results:** Neither peripheral arterial stiffness (controls: 8.3 ± 0.5 m s⁻¹; burn survivors: 7.8 ± 0.4 m s⁻¹; $P = 0.5$) nor central arterial stiffness (controls: 6.6 ± 0.6 ; burn survivors: 6.7 ± 0.5 m s⁻¹; $P = 0.9$) differed between groups. **Conclusions:** These data suggest that arterial stiffness is not altered in well-healed burn survivors.

Effect Of Topical EMLA Application On Cutaneous Sympathetic C-fiber Function

Kevin Wr Kunz, Gary W. Mack, 84602, FACSM. *Brigham Young University, Provo, UT.* (Sponsor: Gary W. Mack, FACSM) (No relationships reported)

Purpose: Activation of nociceptive afferents (small C-fibers) in the skin results in the activation of an axon reflex mediated increase in cutaneous blood flow. Topical lidocaine (EMLA) is often used to mitigate the axon reflex and its impact on the skin blood flow response to local heating. However, it is possible that EMLA would impact cutaneous sympathetic nerves which are also small C-fibers. **Methods:** To evaluate this hypothesis, we examined the effect of topical EMLA application on axon reflex mediated sweating induced by intradermal electrical stimulation in 10 subjects with and without EMLA application. Local sweat rate (SR) was measured by passing dry gas through a small sweat capsule mounted on the skin. The skin was stimulated at a constant current intensity of 2.5 mA for 30 s at frequencies of 0.2, 1, 2, 4, 8, 16, 32, and 64 Hz using two small stainless steel stimulating electrodes. This procedure produced a sigmoid shape stimulus-response curve when we plotted the area under the SR-time curve versus stimulus frequency. **Results:** In control conditions peak local SR during 64 Hz stimulation averaged 0.364 ± 0.219 mg \cdot min⁻¹ \cdot cm⁻² which was significantly ($p < 0.05$) reduced by application of EMLA to 0.078 ± 0.098 mg \cdot min⁻¹ \cdot cm⁻². The stimulus-response curves were significantly different from each other with a significant reduction in the plateau with EMLA (11.7 ± 1.3 versus 2.6 ± 0.6 , $p < 0.05$) but with a similar EC₅₀ values (7.2 ± 0.11 versus 9.9 ± 0.2 Hz). **Conclusion:** These data support the hypothesis that topical application of EMLA does impact cutaneous sympathetic C fiber function. As such, topical EMLA cream should not be viewed as an appropriate method to selectively eliminate superficial sensory fiber activity from studies of human cutaneous blood flow.

Effect Of Habitual Interval Walking On Arterial Stiffness In Older Adults

Takanobu Okamoto, Ryota Kobayashi, Yuto Hashimoto, Hiroyuki Hatakeyama. *Nippon Sport Science University, Setagaya-ku, Tokyo, Japan.* Email: tokamoto@nittai.ac.jp (No relationships reported)

Arterial stiffness that increases with aging is an independent risk factor for cardiovascular diseases. Interval walking is an effective way to prevent cardiovascular diseases.

PURPOSE: The present study aimed to determine whether habitual interval walking decreases arterial stiffness in older adults. **METHODS:** Fifty-four older adults (72.3 \pm 5 yrs) were randomly assigned to undergo interval walking (IW; n=26; male, n=14) or normal walking (NW; n=28; male, n=11). The IW group repeated five 3-min walks at $\leq 40\%$ (low intensity) and $\geq 70\%$ (high intensity) peak aerobic capacity for a total of 6 min per set. The NW group walked continuously at 50% (moderate intensity) peak aerobic capacity. Both groups repeated the walks 3-6 days/week for 20 weeks. The IW group was instructed to walk at high intensity (fast walking) for ≥ 60 min per week (total walking time per week: ≥ 120 min). The NW group walked each week for a total of ≥ 120 min. Energy expenditure during each walk was monitored using a triaxial accelerometer. Carotid-femoral (cf) and femoral-ankle (fa) pulse wave velocity (PWV), which reflects central (aortic) and peripheral (leg) arterial stiffness, were measured using an automatic oscillometric device (form PWV/ABI, Omron-Colin Co. Ltd., Komaki, Japan). Brachial systolic and diastolic blood pressure and heart rate were simultaneously measured using an automatic waveform analyzer and electrocardiography during waveform recording. The cfPWV, faPWV, brachial blood pressure, and heart rate were measured before (baseline) and at 10 and 20 weeks after both types of walking. **RESULTS:** The weekly amount of energy expended while walking was significantly lower in the IW, than in the NW group (IW vs. NW; 566 ± 37 vs. 1166 ± 147 kcal, $p < 0.05$). The cfPWV in both groups significantly decreased from baseline to 20 weeks (IW; 1283 ± 41 to 1167 ± 44 cm/sec, NW: 1214 ± 40 to 1159 ± 34 cm/sec, $p < 0.05$, respectively), whereas the faPWV in both groups did not. The degree of changes in cfPWV was significantly lower in the IW than in the NW group (IW vs. NW; 9 ± 2 vs. 4 ± 1 %, $p < 0.05$). **CONCLUSIONS:** These results suggest that central arterial stiffness was apparently reduced by IW despite a decreased energy expenditure compared with NW in older adults. Therefore, risk factors for cardiovascular diseases seemed to be decreased more effectively in IW than NW.

Post Exercise Hypotension and Blood Flow Characteristics Between Eccentric and Concentric Exercise

Jon Stavres, Stephen Fischer, John McDaniel. *Kent State University, Kent, OH.* (No relationships reported)

PURPOSE: Post exercise hypotension following resistance training has been reported in a variety of populations, though its mechanisms are not clear. The role of metabolism in post-exercise hypotension can be explored through the isolation of eccentric and concentric contraction, due to the greater metabolic cost of concentric contractions. Therefore the purpose of this study is to determine how metabolic activity, independent of mechanical work, influences post-exercise hypotension. **METHODS:** Twelve healthy participants (6 male, 6 female) completed a traditional, a concentric, and an eccentric exercise session, each matched for total work. Participants performed 3 sets of 10 repetitions in the traditional session and 3 sets of 20 repetitions in the concentric and eccentric session, all at 65% of a predetermined 1 repetition max. Blood pressure was collected at baseline, after each exercise (6), and every 15 minutes after exercise for 2 hours. Brachial and femoral blood flow were also assessed at baseline, immediately after exercise, and at 30, 60, 90, and 120 minutes after exercise. **RESULTS:** Repeated measures ANOVA results indicated a significant main effect of time ($F_{9,90} = 2407$, $P = .017$), condition ($F_{2,20} = 9.29$, $p = .001$), and a significant time by condition interaction ($F_{18,180} = 5.12$, $p < .001$) for mean arterial pressure (MAP). Results also indicated significant main effects of time ($F_{2,22} = 10.10$, $P < .001$), condition ($F_{5,55} = 32.24$, $P < .001$), and a time by condition interaction ($F_{10,110} = 9.13$, $P < .001$) for brachial blood flow; and significant main effects of time ($F_{5,55} = 2.59$, $P < .001$), condition ($F_{2,22} = 7.93$, $P = .001$), and a time by condition interaction ($F_{9,110} = 1.75$, $P = .012$) for femoral blood flow. **CONCLUSIONS:** Results from this study indicate that metabolic activity does influence post exercise hypotension independently from factors related to force production. Furthermore, these data suggest that eccentric exercise may elicit a sustained post exercise hypertensive response.

Reductions In Posterior Cerebral Blood Flow Are Susceptible To Orthostatic Stress During Post-exercise Acute Hypotension

Takuro Washio¹, Jennifer R. Vranish², Jasdeep Kaur², Benjamin E. Young², Paul J. Fadel, FACSM², Shigehiko Ogoh, FACSM¹. ¹Toyo university, Kawagoe, Japan. ²University of Texas at Arlington, Arlington, TX. (Sponsor: Shigehiko Ogoh, FACSM) Email: t.washie@gmail.com (No relationships reported)

Recent work suggests that reductions in posterior cerebral blood flow (CBF) rather than anterior CBF may be associated with orthostatic intolerance. Thus, we reasoned that the response of posterior CBF to post-exercise acute hypotension may be related to "grey- or black-out" after heavy resistance exercise.

PURPOSE: We tested the hypothesis that the response of posterior CBF to post-exercise acute hypotension is modified by orthostatic stress.

METHODS: Nine healthy subjects performed handgrip exercise (HG) for 3 min at 30% maximum voluntary contraction with and without lower body negative pressure (LBNP; -40mmHg) applied before, during and for 1 min following HG. Vertebral artery (VA) blood flow was measured throughout using duplex Doppler ultrasound.

RESULTS: At rest, there was no difference in VA blood flow between with and without LBNP ($P = 0.39$), while stroke volume was significantly decreased ($P < 0.01$). HG increased VA blood flow similarly from resting baseline with ($+31.7 \pm 6.3$ %baseline) and without ($+30.9 \pm 2.8$ %baseline) LBNP. VA blood flow and mean arterial pressure decreased immediately after HG (recovery from 0 to 15sec) with and without LBNP ($P < 0.01$). However, the reduction in VA blood flow was larger with LBNP (-35.8 ± 4.2 ml/min) than without LBNP (-20.0 ± 3.3 ml/min, $P < 0.05$). In contrast, there was no difference in VA vascular conductance between conditions at rest, during HG or recovery.

CONCLUSIONS: The application of LBNP augmented the reduction of posterior CBF to post-exercise acute hypotension. This reduction in VA blood flow appeared to be driven by the decrease in arterial blood pressure as there were no differences in VA vascular conductance with LBNP. Collectively, these findings suggest that posterior CBF is sensitive to orthostatic stress during post-exercise acute hypotension and may be associated with "grey- or blackout" after heavy resistance exercise.

Internal Laboratory Validation of Flow Mediated Dilation Analysis

Brycen J. Ratcliffe, Robert Pawlak, Francisco Morales, Caleb Harrison, Alvaro N. Gurovich, FACSM. *Indiana State University, Terre Haute, IN.* (Sponsor: Alvaro N Gurovich, FACSM)
Email: bratcliffe2@sycamores.indstate.edu
(No relationships reported)

Flow Mediated Dilation (FMD) has immense potential to become a clinical, non-invasive assessment of endothelial function. However FMD analysis techniques could deviate significantly in different laboratories if a validation process is not involved. **PURPOSE:** To provide validation to the assessment of FMD analysis in our lab and to standardize this process as a first step in every lab before reporting results of FMD. **METHODS:** Brachial and femoral arteries FMD was performed on 30 young, apparently healthy participants (15 males). For the intratester reliability study, 10 subjects were asked to come to the lab for a second brachial FMD within 48 hours. All FMD procedures were performed by the same investigator, while the FMD analyses were performed by 2 independent testers who were blind to each other analyses. FMD analyses included baseline artery diameter measurements, peak artery diameter after 5 minutes of ischemia, and FMD. Analysis was completed via Brachial Analyzer for Research Software (Medical Imaging Applications LLC, Coralville, Iowa) by both testers. Intratester and intertester reliability were determined by using coefficient of variation (CV) between first and second visit (intratester) and between results obtained by both testers (intertester). **RESULTS:** For tester 1, the intratester CVs were 4.45% ($\pm 6.31\%$) for brachial baseline artery diameter, 5.23% ($\pm 6.47\%$), for brachial peak artery dilation, and for brachial FMD was 2.42% ($\pm 1.77\%$). For tester 2, the intratester CVs were 5.08% ($\pm 6.64\%$) for baseline brachial artery diameter, 5.60% ($\pm 7.49\%$) for peak brachial artery dilation, and for FMD was 4.82% ($\pm 5.82\%$). The intertester CVs were 2.40% ($\pm 1.94\%$) for brachial baseline artery diameter, 3.16% ($\pm 3.00\%$) for brachial peak artery dilation, and 3.37% ($\pm 3.46\%$) for brachial FMD, and 4.52% ($\pm 9.42\%$) for femoral baseline artery diameter, 5.50% ($\pm 12.55\%$) for femoral peak artery dilation, and 3.46% ($\pm 3.36\%$) for femoral FMD. **CONCLUSIONS:** All CVs were under or around 5%, confirming a strong reliability of the method. Our lab has illustrated the accuracy necessary to reproduce quality results from FMD procedures results due of the significantly low coefficient of variation. It is necessary for all labs to validate FMD procedures, to obtain a reproducible and validated value for future procedures utilizing FMD.

Influence of an Acute Bout of Sitting on Leg Vascular Function

Jennifer R. Vranish¹, Benjamin E. Young¹, Brandi Y. Stephens¹, Jasdeep Kaur¹, Jaime Padilla², Paul J. Fadel, FACSM¹.
¹University of Texas at Arlington, Arlington, TX. ²University of Missouri, Columbia, MO. (Sponsor: Paul J. Fadel, FACSM)
(No relationships reported)

Following an extended sitting challenge of 1-6 hours, endothelial function measured via flow-mediated dilation (FMD) is impaired in the leg. Further, this impairment has been shown to be mediated by the reduction in shear stress that occurs in the legs with prolonged sitting. Interestingly, previous findings have demonstrated that prolonged periods of sitting result in a reduction in shear rate as early as 10 minutes into the sitting period. However, it is unknown whether this acute reduction in shear stress is sufficient to alter conduit artery endothelial function or if the decline in shear stress must be maintained for a longer period. **PURPOSE:** We tested the hypothesis that 10 minutes of sitting would result in a reduction in popliteal artery shear stress and an impairment in FMD. **METHODS:** Popliteal artery diameter and blood velocity were continuously recorded via duplex Doppler ultrasound in ten healthy men before, during, and after a 10 minute sitting period. In addition, popliteal artery FMD was performed before and after the acute sitting period. Shear rate was calculated as $[8 \times \text{mean blood velocity}/\text{diameter}]$. FMD was calculated as $[(\text{peak diameter} - \text{base diameter})/\text{base diameter} \times 100]$ and was ANCOVA-corrected for hyperemic shear rate AUC. **RESULTS:** Popliteal artery shear rate was significantly reduced with 10 minutes of sitting (PreSit: $57.1 \pm 11.2 \text{ s}^{-1}$ vs. PostSit: $37.4 \pm 5.1 \text{ s}^{-1}$; $P = 0.034$); however popliteal artery FMD was unaffected (PreSit: $4.5 \pm 0.6\%$ vs. PostSit: $4.6 \pm 0.8\%$; $P = 0.738$). ANCOVA-corrected FMD yielded similar results ($P = 0.715$). Interestingly, reactive hyperemia, a measure of microvascular dilator function, tended to be lower following the acute bout of sitting (PreSit: $59.243 \pm 9.642 \text{ a.u.}$ vs. PostSit: $41.201 \pm 6.578 \text{ a.u.}$; $P = 0.06$). **CONCLUSIONS:** These preliminary findings demonstrate that shear rate is diminished within the first 10 minutes of sitting, yet this stimulus is not sufficient to affect conduit artery endothelial function. However, microvascular function

may be more sensitive to this brief reduction in shear stress, suggestive of a distinction between sitting-induced impairments in macrovascular and microvascular responsiveness.

Habitual Endurance Exercise And Vascular Mechanical Biomarkers Derived From Arterial Reservoir Pressure Analyses

Hsin-Fu Lin¹, Takashi Tarumi², Andreama Haley³, Hao-Min Cheng⁴, Chen-Huan Chen⁴, Hirofumi Tanaka, FACSM³.
¹National Taiwan University, Taipei, Taiwan. ²University of Texas-Southwestern Medical Center, Dallas, TX. ³University of Texas at Austin, Austin, TX. ⁴Taipei Veterans General Hospital, Taipei, Taiwan. (Sponsor: Hirofumi Tanaka, FACSM)
Email: dateo.lin@gmail.com
(No relationships reported)

A number of vascular mechanical biomarkers have been developed and proposed to predict cardiovascular outcomes. Among them, systolic (SC) and diastolic rate constants (DC) of reservoir pressure waveform have recently been shown to predict future cardiovascular events in large cohort studies. Impairments in arterial reservoir functions can result in a larger reservoir pressure wave with accelerated reservoir filling rate (higher SC) and faster reservoir emptying rate (higher DC). Currently, the effects of regular exercise training on these vascular biomarkers are unknown. **Purpose:** We determined the role of habitual aerobic exercise on well-established vascular function measures and novel arterial reservoir pressure parameters by using both cross-sectional and interventional approaches. **Methods:** First, we studied 60 apparently healthy, normotensive adults who were either sedentary (SED) or endurance-exercise trained (ET). Second, we studied 16 sedentary healthy subjects before and after a 3-month endurance training, and their data were compared with a sedentary time control group (N=10). **Results:** The cross-sectional analyses showed that ET had higher aerobic fitness, carotid artery distensibility, and lower pulse wave velocity compared with SED. Of the reservoir pressure waveform analysis, ET demonstrated a lower DC, the rate of reservoir pressure decay during diastole phase, than SED. DC was negatively associated with aerobic fitness and positively associated with central systolic blood pressure (cSBP) and pulse wave velocity. In the intervention approach, regular aerobic exercise reduced cSBP and DC. Changes in cSBP were positively associated with SC. **Conclusions:** Both cross-sectional and interventional approaches consistently demonstrate that regular aerobic exercise modulates diastolic constant of reservoir pressure waveform that represents reservoir emptying. This may be one mechanism by which habitual endurance exercise lowers the risk of vascular diseases.

High Fit Older Adults Maintain a Similar Endothelial Response to Acute Inflammation as Younger Adults

Elizabeth C. Schroeder¹, Abbi D. Lane-Cordova², Sushant M. Ranadive³, Tracy Baynard, FACSM¹, Bo Fernhall, FACSM¹.
¹University of Illinois at Chicago, Chicago, IL. ²Northwestern University, Chicago, IL. ³Mayo Clinic, Rochester, MN. (Sponsor: Bo Fernhall, FACSM)
(No relationships reported)

Acute and chronic inflammation are associated with an increased risk of cardiovascular (CV) events in older adults and reduced endothelial function (flow-mediated dilation; FMD). Higher cardiorespiratory fitness levels are associated with lower risk of CV events and improved vascular function. Whether fitness plays a role in the endothelial response during acute inflammation is unknown. **Purpose:** To evaluate the role of fitness in the endothelial response to acute inflammation in younger (YA) and older (OA) adults. **Methods:** An influenza vaccine induced acute inflammation in 23 YA (12 male, 26 ± 4 yrs, $24.0 \pm 3.5 \text{ kg/m}^2$) and 60 OA (20 male, 65 ± 5 yrs, $27.8 \pm 5.0 \text{ kg/m}^2$). Blood pressure, FMD and serum inflammatory markers were measured before vaccination and 24 hours after. $\text{VO}_{2\text{max}}$ was measured via a treadmill test. Participants were divided into low and high fitness by age group. **Results:** OA with high fitness reduced FMD more than OA with low fitness ($p=0.04$) at 24h even with similar C-reactive protein and interleukin-6 responses. Both high and low fit YA similarly decreased FMD at 24 hr ($p=0.76$). YA and high fit OA had a similar reduction (relative %) in FMD. There were no differences in baseline FMD or blood pressure changes in either group. Regression analyses indicated no association between $\text{VO}_{2\text{max}}$ and change in FMD ($\beta=-0.01$, $p=0.98$) in YA, whereas an association existed in OA ($\beta=-0.36$, $p=0.04$) after adjusting for age, sex, BMI and baseline FMD. **Conclusion:** In OA, higher fitness is associated with a greater decrease in endothelial function during acute inflammation; high fit OA had a similar endothelial response compared to YA. This suggests intact reactivity of the vasculature to stress in high fit OA, which indicates a healthier vessel in high fit versus low fit OA.

Arterial Distensibility and Compliance Following Hypovolemic Challenge in Individuals with and without Down Syndrome

Sang Ouk Wee, 606071, Alexander J. Rosenberg², Kanokwan Bunsawat¹, Garrett Griffith², Tracy Baynard, FACSM², Bo Fernhall, FACSM². ¹University of Illinois at Chicago, CHICAGO, IL. ²University of Illinois at Chicago, Chicago, IL. Email: swee3@uic.edu

(No relationships reported)

Individuals with Down syndrome (DS) commonly exhibit autonomic dysfunction, which may contribute to abnormal arterial function and partially explains low exercise tolerance in this population. Arterial stiffness, reduced arterial compliance and distensibility, is a strong predictor of future CV events and all-cause mortality. Individuals with DS also have alterations in arterial function and the effect of sympathetic stimulation on arterial distensibility is unclear in individuals with DS. **Purpose:** To examine potential differences in carotid artery distensibility, arterial compliance (AC), and hemodynamics to sympathoexcitation using hypovolemic lower body negative pressure (LBNP) in individuals with and without DS. **Methods:** VO_{2peak} was measured in 20 volunteers (DS=9, 23 yrs; Control=11, 24 yrs) using an individualized treadmill protocol. Changes in hemodynamics and vascular reactivity (BP, carotid distensibility, AC and β -stiffness) were measured by ultrasonography at baseline, during and immediately after LBNP (-20 mmHg). **Results:** Compared with controls, individuals with DS have lower VO_{2peak} (24.6 ± 5.9 vs. 41.1 ± 7.1 mL/kg/min, respectively) and higher BMI (22.6 ± 2.4 vs. 33.5 ± 8.1 kg/m²) (p < 0.05). LBNP did not alter arterial stiffness, AC or distensibility for either group. Overall carotid distensibility appeared to be higher in individuals with DS with a medium effect size (partial η^2 = 0.092). In addition, AC approached a significant group effect and yielded a large effect size (p < 0.06, partial η^2 = 0.175) for those with DS. **Conclusions:** Our results indicate that individuals with DS exhibit more compliant arteries than controls, which may be due to autonomic dysfunction with reduced sympathetic tone, as well as alterations in collagen and elastin, which are commonly observed in the skeletal muscles and ligaments in this population. However, the medium effect size suggests that a larger sample size is necessary.

	DS (N = 9)			Control (N = 11)

Reliability of the Passive Leg Movement Assessment of Vascular Function

H Jonathan Groot¹, Ryan M. Broxterman², Ryan S. Garten³, Matthew J. Rossman⁴, Jayson R. Gifford², Oh Sung Kwon², Jay R. Hyden¹, Russell S. Richardson¹. ¹University of Utah, Salt Lake City, UT. ²Geriatric Research, Education, and Clinical Center, Salt Lake City, UT. ³Virginia Commonwealth University, Richmond, VA. ⁴University of Colorado Boulder, Boulder, CO. (No relationships reported)

Purpose: Although vascular function is an independent predictor of cardiovascular disease risk, and therefore has significant prognostic value, there is currently not a single clinically accepted assessment of vascular function. The recently emerged passive leg movement (PLM) assessment of vascular function appears to reflect predominantly endothelium-dependent vasodilation and can identify changes in vascular health with both advancing age and pathology. However, the reproducibility of the PLM model has yet to be examined. **Methods:** Seventeen healthy subjects (age: 24 - 37 yr) were studied on three separate experimental days, allowing five total trials of PLM to be performed on each subject, three within day (Trials 1-3) and three between day (Trials 1,4,5). The leg blood flow (LBF) response to PLM was assessed with Doppler ultrasound, and expressed as the change from baseline to peak (Δ LBF_{peak}). **Results:** The PLM-induced Δ LBF_{peak} was similar across all five trials (Trial 1: 1,030 ± 113, Trial 2: 960 ± 107, Trial 3: 909 ± 106, Trial 4: 1,000 ± 139, Trial 5: 973 ± 135 ml/min; p = 0.27) and these Δ LBF_{peak} values were significantly correlated both within (r: 0.64 - 0.88; p < 0.001) and between days (r: 0.73 - 0.85; p < 0.001). Also these repeated PLM assessments revealed high intraclass correlation coefficients (ICC) (within-day: 0.91; between-day: 0.93). Finally, despite the inclusion of all data, although some were clearly statistical outliers, PLM measurements exhibited a coefficient of variation of ~20%. **Conclusions:** The blood flow response to PLM is both consistent and reproducible between trials, whether performed repeatedly on the same day or on separate days. In combination with the growing evidence that PLM can distinguish between healthy individuals and populations with known vascular dysfunction (elderly, heart failure, sepsis, COPD, etc.), these findings support the continued movement to foster clinical acceptance of PLM as an effective assessment of vascular function and future cardiovascular disease risk.

Quantification of Sympathetic Transduction in Type 2 Diabetes Patients

Benjamin E. Young¹, Jennifer R. Vranish¹, Seth W. Holwerda², David M. Keller¹, Paul J. Fadel, FACSM¹. ¹University of Texas at Arlington, Arlington, TX. ²University of Iowa, Iowa City, IA. (Sponsor: Paul J. Fadel, FACSM) (No relationships reported)

Type 2 Diabetes patients (T2D) have been shown to have greater alpha-adrenergic sensitivity. How this impacts the transduction of muscle sympathetic nerve activity (MSNA) to arterial blood pressure under resting conditions using spontaneous fluctuations in MSNA, as well as during stressors known to elicit sympatho-excitation (e.g., cold pressor test (CPT)) is unclear.

PURPOSE: We tested the hypothesis that T2D patients would exhibit greater sympathetic transduction compared to age- and BMI-matched, healthy controls. **METHODS:** MSNA (microneurography), heart rate (ECG), and beat-to-beat arterial blood pressure (finger photoplethysmography) were continuously recorded during a 10 minute baseline period, and in response to a 2-minute CPT in six T2D patients and six age- and BMI-matched, healthy controls (CON). To quantify sympathetic transduction at rest, normalized burst heights were divided into four quartiles (smallest to largest), related to the corresponding peak change in mean arterial pressure (MAP) within those quartiles and a slope was determined. To quantify sympathetic transduction in response to a stressor, the change in MAP was related to the change in MSNA from rest to the last minute of CPT.

RESULTS: There were no differences in resting sympathetic transduction between groups (CON slope: 0.0103 ± 0.0023 mmHg/AU, T2D slope: 0.0095 ± 0.0016 mmHg/AU; p=0.78). Indeed, signal averaging of MSNA bursts indicated a similar peak increase in blood pressure in CON (+4.2 ± 0.6 mmHg) and T2D (+4.0 ± 0.9 mmHg) (p=0.66). Although the peak increase in blood pressure to CPT tended to be higher in T2D (T2D: +31.6 ± 3.4 mmHg, CON: +21.4 ± 3.7 mmHg; p=0.096), the Δ MAP/ Δ MSNA relationship during CPT was not different between groups (CON: 0.4158 ± 0.21, T2D: 0.1862 ± 0.05; p=0.36).

CONCLUSIONS: Despite clear sympathetically-mediated increases in blood pressure in T2D patients and healthy CON subjects both at rest and during the CPT, neither of the methodologies used to estimate sympathetic transduction, with respect to changes in arterial blood pressure, detected group differences.

Exercise And Vascular Function In Overweight And Obese Adults: A Meta-analysis
 Younsun Son¹, Kyungun Kim², Soeun Jeon³, Minsoo Kang, FACSM⁴, Yoonjung Park¹. ¹University of Houston, Houston, TX. ²The University of Texas at Austin, Austin, TX. ³Texas A&M University-San Antonio, San Antonio, TX. ⁴Middle Tennessee State University, Murfreesboro, TN.
 Email: xppizim@naver.com
 (No relationships reported)

PURPOSE: Obesity is strongly associated with vascular dysfunction, including a reduction in flow-mediated dilation (FMD), and evidence has shown that exercise training improves vascular dysfunction and FMD. The objective of this meta-analysis is to summarize the effect of exercise intervention on FMD in overweight and obese adults, as well as to investigate the role of age, weight, body mass index (BMI), exercise type, and intervention period on the effects observed. **METHODS:** We searched four electronic databases (Pubmed, Scopus, CINAHL, and Medline), through June 2016 for relevant studies pertaining to the effectiveness of exercise intervention on FMD. Search terms were "(obesity OR overweight) AND (Exercise OR training) AND (Flow mediated dilatation OR Flow mediated dilation OR FMD)". Inclusion criteria were as follows: 1) included value of relative FMD, 2) included exercise intervention at least 7 days, 3) studied only obesity or overweight adult subjects, and 4) published in English language peer-reviewed articles. Comprehensive Meta-Analysis version-3 software was used to compute the mean effect size (ES) and 95% CI using a random effects model. Cochran's Q statistic was also used to assess heterogeneity across individual studies. Subgroup analyses were conducted to identify moderator effects. **RESULTS:** Of 91 citations identified by the search strategy, 17 studies met the inclusion criteria and 33 ESs were calculated. The results showed that the exercise interventions had moderate effects on FMD, with an overall effect size of 0.52 (95% CI = 0.26, 0.79). The results of subgroup analyses demonstrated that BMI (Qb = 8.11, df = 2, p = 0.017) and weight change (Qb = 13.11, df = 4, p = 0.011) explained the heterogeneity of ESs. The group with highest BMI (>35) (ES = 1.98) and most weight loss (>5kg) (ES = 1.41) appeared to be most effective in increased FMD. No significant group differences were found by age, intervention period, and exercise type, but exercise interventions had significant effects on FMD for specific groups (e.g., over 12 months, aerobic training, and combined aerobic and resistance training). **CONCLUSION:** Exercise training significantly improves vascular function in overweight and obese adults as measured by increased FMD, and this benefit is dependent on the exercise modality and degree of weight loss.

Cardiorespiratory Fitness and Adiposity do not Predict Vascular Reactivity in Sedentary Men and Women
 Siddhartha S. Angadi¹, Catherine L. Jarrett¹, Wesley J. Tucker², Brandon J. Sawyer³, Zachary S. Zeigler⁴, Glenn A. Gaesser, FACSM¹. ¹Arizona State University, Phoenix, AZ. ²University of Texas at Arlington, Arlington, TX. ³Point Loma Nazarene University, San Diego, CA. ⁴Grand Canyon University, Phoenix, AZ. (Sponsor: Glenn A Gaesser, FACSM)
 Email: sangadi@asu.edu
 (No relationships reported)

PURPOSE: Prior, small-scale studies have demonstrated significant associations between endothelial function (assessed by brachial artery flow-mediated dilation; FMD) and both cardiorespiratory fitness (VO₂max) and adiposity. We examined the associations between FMD and both VO₂max and several measures of adiposity in a larger cohort of sedentary, predominantly overweight and obese men and women. **METHODS:** Sixty-one subjects (9 females; Age = 30 ± 8 yrs) with a mean body mass index (BMI) of 31.4 ± 5.7 kg/m² (range = 20.2 - 49.1) and body fat percentage of 35.3% ± 9.6% (range = 14.0% - 52.9%) were sequentially enrolled in this cross-sectional study. Subjects were weighed using a calibrated scale and abdominal circumference was recorded at the level of the umbilicus. They then underwent dual-energy x-ray absorptiometry (DXA) for determination of fat mass, % body fat and visceral adipose mass. FMD was quantified using high-resolution B-mode ultrasound and automated edge-detection software. Finally, they underwent VO₂max testing on an electronically-braked cycle ergometer with a ramp protocol. All testing was conducted at a similar time of day to rule out effects of diurnal variation, and women were examined during the follicular phase of their menstrual cycle. Pearson correlation coefficients were used to examine the relationship of VO₂max, FMD and measures of adiposity. **RESULTS:** No significant (P > 0.6) correlations were found between FMD and DXA-measured body fat % (r = 0.07) and visceral adiposity (r = -0.03). Similarly, FMD was not significantly (P > 0.15) correlated with abdominal circumference (r = 0.18) or BMI (r = -0.04). Finally, VO₂max was not significantly correlated with FMD (r = -0.06, P = 0.63).

CONCLUSIONS: Contrary to previously published data, traditional and sophisticated DXA-based anthropometric measures as well as Vo₂max were not significantly associated with brachial artery flow-mediated dilation in this cohort of predominantly overweight and obese, sedentary men and women without evidence of cardiovascular disease.

Effect of Sitting Time on Measures of Subclinical Atherosclerosis in Older Adults
 Jacob P. DeBlois, Wesley K. Lefferts, Jacqueline A. Augustine, Kayla N. Nunemacher, Kevin S. Heffernan. Syracuse University, Syracuse, NY. (Sponsor: Denise L. Smith, FACSM)
 (No relationships reported)

Increased sitting time has been associated with increased risk of cardiovascular disease and cardiovascular mortality. In young adults, sitting time was found to correlate with arterial stiffness and wave reflection, two subclinical markers of early atherosclerotic progression. **PURPOSE:** To determine if sitting time is associated with markers of subclinical atherosclerosis in older adults. **METHODS:** 99 adults between the ages of 60 and 85 yrs (mean: 68±6 yrs; 46.5% female) completed the International Physical Activity Questionnaire to assess physical activity behavior, including sitting time. Markers of subclinical atherosclerosis included common carotid intima-media thickness (IMT), carotid β stiffness, and Young's elastic modulus (ε) as measures of carotid stiffness, carotid-femoral pulse wave velocity (c-fPWV) as a measure of aortic stiffness, and aortic augmentation index (AIx) as a measure of global wave reflections. IMT, β stiffness, and ε were assessed on the left common carotid artery using ultrasound, while c-fPWV and AIx were assessed on the right side via applanation tonometry. Pearson correlations were performed to determine the strength of the relationship between sitting time and subclinical atherosclerotic measures. **RESULTS:** Older adults sat for an average of 6.3±2.8 hrs·d⁻¹ and sitting time was not different between the sexes (6.0±2.5 vs. 6.6±3.0 hrs·d⁻¹, p = 0.279, for women and men, respectively). Sitting time was not significantly correlated with IMT (r = -0.089, p = 0.193), β stiffness (r = -0.047, p = 0.324), ε (r = -0.013, p = 0.449), c-fPWV (r = 0.038, p = 0.356), or AIx (r = -0.003, p = 0.488). When exploring associations by sex, there were no associations between sitting time and any measure of arterial stiffness or wave reflection (p ≥ 0.073). **CONCLUSIONS:** Sitting time is not associated with measures of subclinical atherosclerosis in older adults. These data suggest sitting time may not further impact the structure of the aged artery. Future studies using objective measures of sedentary behavior are needed to further explore the relationship between sitting time and subclinical atherosclerotic risk. Supported by Dairy Research Institute/Dairy Management Inc.

 Email: chris.easton@uws.ac.uk
 (No relationships reported)

Rinsing the mouth with anti-bacterial mouthwash (MW) suppresses the reduction of nitrate (NO₃⁻) to nitrite (NO₂⁻) and nullifies the reduction in blood pressure (BP) often reported after dietary NO₃⁻ supplementation. Given the known interactions between the microbiome and the central nervous system, we speculated that disruption of the oral flora with MW would induce a stress response exemplified by increased BP and cortisol secretion. **PURPOSE:** To determine the effects of ingesting NO₃⁻-rich beetroot juice (BR) and using MW on BP, plasma [NO₂⁻] and [NO₃⁻] and salivary [cortisol]. **METHODS:** After a 'no treatment' control (CON), ten healthy male participants rinsed with an inert placebo mouthwash (PM) prior to ingestion of 5 x 70 ml BR (~31 mmol NO₃⁻) over the 24 h prior to the experiment (PM+BR) followed by two further experimental arms conducted in a randomised order. In one arm, participants used MW prior to ingestion of BR (MW+BR) and in the other they used MW prior to the ingestion of a NO₃⁻-depleted beetroot juice placebo (MW+PLA). Blood was collected and measurements performed after 30 min of laying supine. Plasma [NO₂⁻] and [NO₃⁻] were measured by chemiluminescence. **RESULTS:** Plasma [NO₂⁻] in PM+BR (209 ± 98 nM) was elevated in comparison to all other experimental arms (all P<0.04). Plasma [NO₂⁻] was similar between CON (95 ± 27 nM) and MW+BR (115 ± 57 nM, P=1.0) but lower in MW+PLA (41 ± 24 nM) compared to all other arms (all P<0.03). Plasma [NO₃⁻] was higher in PM+BR (382 ± 104 μM) and MW+BR (412 ± 87 μM) both compared separately to CON and MW+PLA (all P<0.001). Plasma [NO₃⁻] was not different between CON (64 ± 24 μM) and MW+PLA (43 ± 14 μM, P=0.385) or

between PM+BR and MW+BR ($P=1.0$). Diastolic BP was lower in PM+BR (63 ± 5 mmHg) compared to MW+BR (67 ± 5 mmHg, $P=0.018$) but not different between other experimental arms (all $P>0.43$). There were no differences in systolic BP, mean arterial BP, or salivary cortisol between any arms of the experiment (all $P>0.16$). **CONCLUSIONS:** As expected, MW reduced plasma $[\text{NO}_2^-]$ but not $[\text{NO}_3^-]$, with and without ingestion of BR. Contrary to our hypothesis, however, MW did not alter BP or cortisol levels suggesting that it does not induce a stress response with short-term use. Further research employing a longer intervention and more extensive assessment of stress markers is required to confirm these observations.

Aortic Reservoir Function of Lifelong Japanese Female Pearl Divers

Jun Sugawara¹, Tsubasa Tomoto¹, Keisei Kosaki², Hirofumi Tanaka, FACSM³. ¹National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan. ²University of Tsukuba, Tsukuba, Japan. ³University of Texas at Austin, Austin, TX. (Sponsor: Hirofumi Tanaka, FACSM)
 Email: jun.sugawara@aist.go.jp
 (No relationships reported)

PURPOSE: Female pearl divers in Japan, called "Ama", perform repeated breath-hold free-diving for collecting pearls in oysters, seaweeds, and shellfish in the cold sea. In a typical day, they dive 50-200 times, 4-6 days/week throughout the year. We have previously reported significantly lower systemic arterial stiffness values in Ama compared with the age-matched sedentary peers living in the same fishing villages. As a follow-up study, the primary aim of the present study was to evaluate their aortic reservoir function and segmental arterial stiffness.

METHODS: We recruited 115 female pearl divers (mean age: 65 ± 11 yr) as well as age-matched 50 physically inactive and 33 physically active female non-divers living in the same fishing villages in rural locations. Aortic reservoir and excess pressure were calculated from the synthesized aortic pressure waveforms derived from carotid arterial pressure waveforms obtained with arterial applanation tonometry. Pulse wave velocity from the heart to the brachial artery (hbPWV; partly reflecting proximal aortic stiffness) and between the brachial artery and the ankle (baPWV; reflecting stiffness of abdominal aorta and leg arteries) were measured.

RESULTS: There were no significant differences in age, body weight, and body mass index among the groups. Blood pressure and pulse pressure in the brachial artery and the aorta were not different among the groups. Aortic reservoir function, as measured by the normalized area under the curve of aortic reservoir pressure by area under the curve of aortic blood pressure, tended to be higher in physically active individuals ($P=0.06$) and significantly greater in Ama ($P<0.05$) compared with their sedentary peers. baPWV was 8-9% lower in Ama and physically active adults than in sedentary adults ($P<0.05$ for both). hbPWV was 5% lower in physically active adults and 9% lower in Ama compared with their sedentary peers ($P<0.05$).

CONCLUSIONS: Our present findings suggest that life-long repetitions of breath-hold diving are associated with proximal aortic destiffening and improved aortic reservoir function.

The Effect of a High Fat Meal on Cerebral Vascular Function

Jordan C. Patik, Wesley J. Tucker, Bryon M. Curtis, Michael D. Nelson, R. Matthew Brothers. *The University of Texas at Arlington, Arlington, TX.*
 Email: jordan.patik@uta.edu
 (No relationships reported)

It is well known that a single high fat meal (HFM) causes a robust and transient elevation in serum triglycerides (TG). This elevation in serum TG is a primary contributor to the post-prandial attenuation of peripheral vascular endothelial function, as assessed by flow-mediated dilation in the brachial artery. Whether a similar impairment in vascular reactivity can be observed in the cerebral circulation remains unknown, and was the focus of this investigation. **PURPOSE:** To test the hypothesis that cerebral vascular function is impaired following a HFM.

METHODS: End-tidal carbon dioxide partial pressure (PETCO_2), middle cerebral artery blood velocity ($\text{MCAV}_{\text{mean}}$), calculated cerebral vascular conductance index (CVCI ; $\text{MCAV}_{\text{mean}}/\text{mean arterial pressure}$) and cerebral vasodilator response to rebreathing induced hypercapnia (% increase in CVC from baseline at common maximal ΔPETCO_2) were assessed in 6 healthy young men (27 ± 5 years). Measures were assessed during fasted baseline and again at 2 and 4 h post meal consumption (HFM day) or at a similar time point in the fasted state (TC day). The two visits were separated by 2-7 days and were conducted in a randomized order. Blood lipids were assessed at baseline and at the 2 h time point into each respective condition.

RESULTS: As expected, consumption of the HFM significantly elevated serum TG concentrations relative to TC at 2 h (HFM: 101 ± 38 to 169 ± 77 mg/dL, TC: 107 ± 32 to 92 ± 31 mg/dL, $P=0.007$). However, the HFM had no effect of cerebral vasodilator

capacity during rebreathing induced hypercapnia. The maximal increase in %CVC achieved at the highest common ΔPETCO_2 during all conditions within each subject was unchanged during 2hr and 4hr post HFM or TC (condition x time interaction: $P=0.96$). Similarly, the slope of the change in %CVC per change in ΔPETCO_2 was unaffected by HFM across time ($P=0.49$).

CONCLUSIONS: Contrary to our hypothesis, and unlike the peripheral vasculature, our preliminary data suggest that the cerebral circulation appears to be protected from the acute negative effects of a high fat meal.

Vascular Peripheric Differences In Patients With Chagas Versus Ischemic Heart Failure

Alexandra C G B Lima¹, Marianne Lucena da Silva¹, Vinicius Z M da Silva², Luis Tadeu Giollo Jr³, Ana Paula Silva¹, Jose F. Vilela-Martin⁴, Gaspar R. Chiappa¹, Gerson Cipriano Jr¹. ¹University of Brasilia, Brasilia, Brazil. ²Superior School of Health Science, Brasilia, Brazil. ³State Medical School of São José do Rio Preto, São Jose do Rio Preti, Brazil. ⁴State Medical School of São José do Rio Preto, Brasilia, Brazil.
 (No relationships reported)

Purpose: Heart failure (HF) is characterized by a complex blend of central and peripheral pathophysiologic alterations, among which is vascular dysfunction and increased arterial stiffness. Applanation tonometry (AT) non-invasively assesses central blood pressure (CBP) and arterial stiffness [augmentation index (Aix)]. The presence of lower arterial compliance (higher Aix) represents an abnormal state and is a prognostic marker in HF. The influence of HF etiology on AT measures has not been explored. Thus, the aim of this study was compare AT measurements in patients with ischemic and Chagas HF.

Methods: Third-two male subjects, 11 ischemic (IS) HF, 10 Chagas (CH) HF, and 11 healthy controls (HC) matched by age and body mass index were included in this analysis. The radial artery pulse wave was measured non-invasively by resting AT.

Results: The Chagasic group had a lower peripheral systolic (SBPp) and central blood pressure (CBP). While the ischemic HF group demonstrated a higher Aix (Table 1). **Conclusion:** The ischemic HF group presented with greater arterial stiffness, reflected by a significantly higher Aix. Otherwise, chagasic patients as healthy control individuals had non increment arterial stiffness. These findings indicate assessment and treatment strategies for arterial stiffness may be more relevant in HF patients with an ischemic etiology. In conclusion, key AT differences were observed in patients with ischemic and Chagas HF, indicating these two HF etiologies present with unique pathophysiologic mechanisms.

Table 1: Applanation Tonometry Measurements.

Variables	Control (m ± sd)	Ischemic HF (m ± sd)	Chagas HF (m ± sd)	P value
SBP _p	118 ± 12.44	113 ± 16.59*	97 ± 14.23 [∞]	0.010
CSP	108 ± 13.97	108 ± 15.29	88 ± 10.10 [∞]	0.0074
Aix	80.27 ± 15.23	93.36 ± 10.74*	80.60 ± 17.91 [∞]	0.049

Legends: SBP_p = Peripheral Systolic Blood Pressure; CSP = Central Systolic Blood Pressure; Aix = Augmentation index. * = significant difference between ischemic HF and control Groups; [∞] = Significant difference between ischemic HF and Chagas HF groups; [∞] = Significant differences between Chagas HF and Control Groups.

Effect of Chronic Lower Limb Heating on Indices of Vascular Function and Functional Capacity in Aged Humans

Steven A. Romero¹, Daniel Gagnon², Amy N. Adams³, Matthew N. Cramer¹, Manall N. Jaffery³, Ken Kouda⁴, Gilbert Morales¹, Craig G. Crandall¹. ¹University of Texas Southwestern Medical Center, Dallas, TX. ²Université de Montréal, Montreal, QC, Canada. ³Texas Health Presbyterian Hospital Dallas, Dallas, TX. ⁴Wakayama Medical University, Wakayama, Japan.
 (Sponsor: Craig G. Crandall, FACSM)
 (No relationships reported)

In aged adults, acute lower limb heating increases leg blood flow, vascular shear stress, and improves macro- and microvascular dilator function. However, the effect of chronic lower limb heating on indices of vascular function and functional capacity remains unclear. **Purpose:** To test the hypothesis that chronic lower limb heating improves macro- and microvascular dilator function and functional capacity in aged adults. **Methods:** Five healthy aged adults (4 females; age 66 ± 4 years; height 163 ± 4 cm; weight 68 ± 7 kg; mean \pm SD) were exposed to 8 weeks of chronic lower limb heating. Subjects immersed their lower limbs ~33 cm into a heated (~42°C) and circulated water bath 4 days per week, for 45 min per session. Prior to and after the chronic limb heating regimen, duplex ultrasonography was used to assess macro-

(flow-mediated dilation) and microvascular (3 min reactive hyperemia area under the curve) dilator function in the superficial femoral artery following 5 min of arterial occlusion. Functional capacity was assessed via a 6 min walk test. Rating of perceived exertion (Borg scale) was also recorded immediately following the walk test. **Results:** Chronic lower limb heating improved macrovascular dilator function (pre $1.9 \pm 0.2\%$ vs. post $3.2 \pm 0.2\%$; $P = 0.01$), while microvascular dilator function tended to increase (pre 468 ± 89 ml vs. post 562 ± 131 ml; $P = 0.09$). Likewise, distance covered during the 6 min walk test tended to increase following chronic heating (pre 629 ± 36 m vs. post 665 ± 32 m; $P = 0.06$), whereas rating of perceived exertion did not differ (pre 12 ± 1 vs. post 13 ± 1 ; $P = 0.4$). **Conclusions:** Taken together, chronic lower limb heating improves macrovascular dilator function in aged adults, while perhaps improving microvascular dilator function and functional capacity, despite a similar perceived effort. These data suggest that chronic lower limb heating may be an effective therapy to reduce cardiovascular disease risk in aged adults by improving vascular health and functional capacity. Funded by National Institutes of Health (GM-068865 & GM-117693).

The Acute Effect of Aerobic and Resistance Training on Arterial Diameter: A Meta-Analysis
 Briceño-Torres José Miguel, José Moncada-Jiménez. *University of Costa Rica, San Jose, Costa Rica.*
 Email: josemiguel5692@gmail.com
 (No relationships reported)

A positive chronic effect of different exercise modalities on vascular endothelial diameter and function has been reported; however, little is known about the arterial vascular response to acute bouts of exercise. **PURPOSE:** The purpose of the study was to investigate the acute response of two exercise modes (aerobic and resistance training) on the endothelium vascular diameter. **METHODS:** A meta-analysis was planned where the inclusion criteria for studies were: 1) experimental trials; 2) only one exercise session (acute treatment); 3) aerobic (AE) or resistance training (RT) interventions; 4) studies in human adults with no heart disease; 5) studies published only in English language; and 6) studies with pre and post flow-mediated dilation (FMD) measurement. The electronic search was performed in six databases (PubMed, Springer Link, Science Direct, SAGE Journals, Sport Discus and Nature), cross-referencing, and hand searching, using the following combinations of words "Acute exercise FMD", "endothelial exercise function", "vascular exercise endothelium", and "FMD exercise". Hedge's standardized mean difference effect size (ES) was calculated for each result; then, ESs pooled using random-effects models. Non-overlapping 95% confidence intervals ($CI_{95\%}$) were considered statistically significant. Heterogeneity was assessed using Q and I^2 , while funnel plots and Egger's regression test were used to assess small-study effects (potential bias). **RESULTS:** A total of 13 studies were meta-analyzed and 40 ESs computed from 378 (245 men and 133 women) participants. Of the 40 ESs, 27 were on AE, 9 on RT and 4 on control groups (no exercise). The AE training revealed no significant effect on artery diameter ($ES = 0.26$; $CI_{95\%} = 0.00, 0.52$; $Q = 14.2$; $p = 0.11$; $I^2 = 0\%$). The RT interventions indicated no significant effect ($ES = 0.29$; $CI_{95\%} = -0.08, 0.66$; $Q = 0.38$; $p = 0.25$; $I^2 = 0\%$). **CONCLUSIONS:** Neither aerobic or resistance training elicited an acute response on vascular function. More research is needed to better understand the physiological mechanisms responsible for this response.

Dietary Nitrate and Pulse Wave Analysis: Preliminary results
 Caleb D. Harrison¹, Robert Pawlak¹, Brycen J. Ratcliffe¹, Francisco Morales¹, Colin Carriker², Alvaro N. Gurovich, FACSM¹. ¹Indiana State University, Terre Haute, IN. ²High Point University, High Point, NC. (Sponsor: Alvaro N Gurovich, FACSM)
 Email: charrison18@sycamores.indstate.edu
 (No relationships reported)

Nitric Oxide (NO) is a vasodilator naturally produced by an oxygen dependent pathway. In addition, an oxygen independent pathway may also produce NO by the digestion of a dietary nitrate. Lower than normal levels of NO are associated to an increase in central blood pressure. Thus, an increase in dietary nitrates might improve central blood pressure. **PURPOSE:** To determine the effectiveness of an acute dietary nitrate supplement in central blood pressure measured via pulse wave analysis (PWA). **METHODS:** A double-blind, cross-over study design was performed in nine young, healthy subjects (18 to 35 years old). Four lab visits were scheduled within 10 days; the first 2 visits in back to back days and the last 2 visits one week after. Subjects were asked to follow a low-nitrate diet for 3 days (NHLBI: 7 East Low-Nitrate Diet), starting two days prior to the first and third lab visits. Two hours before visits 2 and 4, subjects were asked to drink 800 mg of nitrate or placebo (solutions randomly assigned, both from Beet it, James White Drinks Limited, UK). Values of Central

Systolic Blood Pressure (cSBP), Central Diastolic Blood Pressure (cDBP), Central Augmented Pressure (cAP), Central Pulse Pressure (cPP), Augmentation Index (Aix) and Aix normalized at a heart rate of 75 bpm (Aix@75bpm) were measured with a cuff-based PWA device (SphygmoCor Xcel®). A two-way repeated measurements ANOVA (time x drink) was performed and significance was set at $\alpha = 0.05$. **RESULTS:** There was no significant interaction (time x drink) for any of the studied variables. However, a significant main time effect showing a decrease in cSBP, cAP, Aix, and Aix@75bpm (all $p < 0.05$) was observed.

	Placebo Baseline	Placebo 2 hrs post drink	Nitrate Baseline	Nitrate 2 hrs post drink	ANOVA (time effect)
cSBP (mm Hg)	106 ± 10	104 ± 10	107 ± 8	104 ± 9	< 0.05
cDBP (mm Hg)	71 ± 4	69 ± 9	73 ± 7	69 ± 4	0.12
cAP (mm Hg)	2.6 ± 5.9	3.6 ± 6.7	3.7 ± 6.1	5.5 ± 6.8	< 0.05
cPP (mm Hg)	36 ± 9	35 ± 10	34 ± 9	35 ± 9	0.75
Aix (%)	6.3 ± 13.7	7.7 ± 16.3	9.1 ± 13.3	13.8 ± 13.1	< 0.05
Aix@75bpm (%)	-1.6 ± 15.8	-0.2 ± 18.2	1.5 ± 15.1	6.2 ± 13.74	< 0.05

CONCLUSION: These preliminary results show that dietary nitrate supplement, on average, has minimal effects on central blood pressure and PWA in young healthy individuals. Trends on some decrease of cSBP, cAP, Aix, and Aix@75bpm after drinking dietary nitrate might improve if increasing the sample size.

Recent studies demonstrate that single bouts of prolonged, uninterrupted sitting (3-6 hours) can negatively impact peripheral vascular health (i.e., decreased endothelial function and reduced blood flow-induced shear stress in legs). It is unknown whether or not prolonged, uninterrupted sitting can have a similar impact on central cardiovascular hemodynamics and vascular stiffness. **PURPOSE:** To test the hypothesis that prolonged sitting will increase central blood pressure, aortic pulse wave reflection and vascular stiffness in healthy, college-aged individuals. **METHODS:** In 6 subjects (Age=23±1 yrs, BMI=30±kg/m², 3 males and 3 females), brachial artery pulse wave analysis was performed before (baseline-BL), during (10, 60, 120, and 180 mins), and immediately after 3 hours of uninterrupted sitting. Aortic pulse wave velocity (PWV, an index of vascular stiffness) was also examined before and after sitting using carotid applanation tonometry coupled with oscillometry performed on the upper-thigh. **RESULTS:** Over the course of sitting, no significant change was noted for heart rate ($P > 0.05$). Peripheral (brachial) systolic blood pressure (BP) and mean arterial pressure (MAP) were greater than central (aortic) systolic BP and MAP across all time points; however, both exhibited a biphasic response to sitting, characterized by an initial decrease at 60 mins, with a return to baseline at 180 mins (e.g., MAP at BL=90±4; vs. 60 mins=82±4, $P = 0.001$; vs. 180 mins sitting=87±3 mmHg, $P > 0.05$). No change was noted for peripheral and central diastolic BP across all time points ($P > 0.05$). Augmentation pressure (AP) and index (Aix), wave reflection height (Pb) and magnitude (RM%) all exhibited a significant decrease over the course of 3 hours sitting, most notable at 180 mins (e.g., Aix at BL=7±6, vs. 180 mins sitting=-8±3%, $P = 0.03$). No change was observed for aortic PWV in response to sitting ($P > 0.05$). **CONCLUSION:** These preliminary findings indicate that a single bout of prolonged, uninterrupted sitting results in a significant alteration in central cardiovascular hemodynamics (i.e., decreased aortic pulse wave reflection), with no change occurring in aortic vascular stiffness.

Vascular and Temperature Changes During and After Applications of Superficial Heat Therapy
 Jihong Park, Sunghoon Kang. *Kyung Hee University, Yongin, Korea, Republic of.*
 Email: jihong.park@khu.ac.kr
 (No relationships reported)

Although superficial heat treatments—such as moist heat pack (MHP) and warm whirlpool (WLP)—are common for musculoskeletal injuries, treatment effects of MHP and WLP in terms of vascular and temperature responses are not clear. **PURPOSE:** To assess changes vascular (volume, diameter, and velocity of blood flow) and temperature (skin and inner tissue—2.5 cm deep) reaction on ankle joint during and

after applications of MHP and WLP. **METHODS:** Nineteen healthy adults underwent one of three treatment sessions (45 °C of MHP or WLP, or control: no treatment for 20-min). Vascular reactions were measured using a Doppler ultrasound (4 MHz) at the posterior tibial artery (10 cm above the medial malleolus). Temperature probes (60 Hz) were attached on the skin of lateral foot (1 cm below from the lateral malleolus for skin and inner tissue—insulated by neoprene fabric. After baseline measurements, each treatment was randomly applied to the area just below from the right lateral malleolus. Each measurement was recorded at baseline and every 3-min thereafter until the end of the protocol (total time: 42-min). To test treatment effects over time, 3×16 mixed model ANOVAs and Tukey-Kramer post-hoc tests were performed ($p<0.05$). **RESULTS:** From the baseline values, WLP immediately increased volume (50%, $p<0.0001$) and velocity (46%, $p<0.0001$) of blood flow, and increased values were maintained during treatment ($F_{30,846}=3.6$, $p<0.0001$). After the removal of WLP, increased values were maintained for 13-min as compared to baseline ($p=0.02$). MHP did not produce any change in vascular reaction. Both MHP (2 °C, $p<0.0001$) and WLP (6 °C, $p<0.0001$) immediately increased skin temperature, and increased temperatures were maintained until the removal of both treatments ($F_{30,846}=47.6$, $p<0.0001$). Both MHP (4 °C, $p<0.0001$) and WLP (6 °C, $p<0.0001$) took 3-min to increase temperature in the inner tissue ($F_{30,846}=52.9$, $p<0.0001$). An increased temperature (2 °C from baseline) was maintained for 10-min (MHP) and 12-min (WLP) after the removal of each treatment. **CONCLUSIONS:** When treating tissues, especially located in 2.5 cm deep (e.g. ankle sprain), WLP may produce a similar effect as deep thermotherapy since it increases vascular response and inner tissue temperature. Application of MHP should be reconsidered as it does not affect vascular reaction at all.

(No relationships reported)

South Korea is fast approaching an aging society phase, as 9.5% the population was aged 65 and older in 2006, and is expected to be 14.3% in 2018 and 20.8% in 2026, entering the aging society and the ultra-aging society phases, respectively, based on the United Nation's standard.

PURPOSE: The purpose of this study was to analyze the effects of aquarobic exercise on senior fitness, prostaglandin I₂ (PGI₂), and thromboxane A₂ (TXA₂) in elderly Korean women. **METHODS:** Thirty two healthy elderly, women aged 74.11 ± 4.12 years, were randomly assigned to aquarobic exercise group (EX; n = 11) trained for 12-week or to a “non-exercise” control (Con; n = 11) group. The variables of senior health-related fitness, PGI₂, and TXA₂ were measured in all the participants before and after the 12-week study. This intervention trial was designed to compare pre- and post-exercise intervention variables. Changes from baseline to the end of the intervention were determined by a paired *t*-test and independent *t*-test.

RESULTS: The results of the present study were consistent with the findings of the previous studies, as the cardiorespiratory endurance (492.55±73.92 vs. 414.50±19.87 m), muscular strength (24.99±1.93 vs. 19.29±1.96 kg), muscular endurance (24.05±5.38 vs. 19.38±5.39 times/30sec), and flexibility (13.32±5.00 vs. 11.56±5.04 cm) increased significantly in the aquarobic exercise group ($p < 0.05$). The results of the present study show no changes in prostaglandin I₂ and thromboxane A₂ levels in any group; however, the program participation led to the balance between PGI₂ and TXA₂, which is consistent with the finding of previous research. This result likely reflects the positive effect of the sustained aquarobic exercise on senior physical fitness and functioning.

CONCLUSIONS: The findings of this study discussed so far indicate that aquarobic exercise has a positive effect on senior health-related fitness, highlighting the importance of aquarobic exercise for elderly women.

(No relationships reported)

PURPOSE: Resistance training is part of the physical activity recommendations for overweight and obese individuals, and the health- and fitness industry is a popular venue to perform resistance training. Group exercise sessions, like BodyPump, is a popular alternative with over 5 million participants weekly, as well as individual heavy load resistance training. BodyPump is a high-repetition low- to moderate load session, claimed to burn up to 540 calories each session. The purpose of this study was to estimate total exercise workload and energy expenditure during a one-hour session with BodyPump, and to compare these outcomes with a time-matched session of traditional individual heavy load resistance training. **METHODS:** Eighteen previously untrained, overweight women participated in the study (mean age 36.4 years ±10.1, BMI 29.8 kg/m²±4.6), ten exercising BodyPump and eight heavy resistance training (8 repetition maximum [RM] x 3 set). Exercise workloads were estimated by multiplying load (kg) x repetitions x sets, and energy expenditure was assessed with indirect calorimetry, during the sessions. RMR was estimated before and twice after the sessions (0-20 min and 120-140 min). **RESULTS:** The participants exercising BodyPump lifted significantly more loads than the heavy resistance training group (19485 kg ±2258 vs 15616 kg ±2976, $p=0.006$), while the energy expenditure was similar with 302 kcal ±67 in BodyPump and 289 kcal ±69 in the heavy resistance training group ($p=0.69$). With no group differences, RMR 0-20 min post-exercise increased by 31% after BodyPump, and 27% after heavy resistance training. **CONCLUSION:** One session of BodyPump resulted in a higher total workload compared to traditional heavy load resistance training. In contrast, the energy expenditure during exercise and changes in RMR were similar between the groups. With a modest energy expenditure of approximately 300 calories, the women did not reach the claimed energy costs during a BodyPump session.

2840 Board #360 June 2 11:00 AM - 12:30 PM

Can The Lamberts Submaximal Cycle Test Reflect Overreaching In Professional Female Cyclists?

Lieslot Decroix¹, Robert Patrick Lamberts², Romain Meeusen, FACSM¹.
¹Vrije Universiteit Brussel, Brussel, Belgium. ²University of Cape Town, Cape Town, Belgium.

Email: lieslot.decroix@yub.ac.be

(No relationships reported)

Purpose: The Lamberts and Lambert Submaximal Cycle Test (LSCT) consists of 3 stages during which cyclists cycle for 6 minutes at 60%, 6 minutes at 80% and 3 minutes at 90% of their maximal heart rate, followed by one minute recovery. It was the aim of this study to determine if the LSCT is able to reflect a state of functional overreaching in professional female cyclists during an 8 day training camp and the following recovery days.

Methods: Six professional female cyclists performed an LSCT on day 1, day 5 and day 8 of the training camp and 3 days after the training camp. During each stage of the LSCT, power output and rating of perceived exertion (RPE) were determined. Training diaries and profile of mood status (POMS) were also completed and results were analyzed by repeated measures ANOVA to verify differences between day 1, day 5, day 8 and day +3. To investigate differences in performance parameters (P60, P80, P90, RPE, HRR), a contemporary approach of data analysis using magnitude-based inferences was employed, where chances for meaningful changes (larger than normal day-to-day variability) were assessed as “likely” (> 75-95%), “very likely” (> 95-99%) and “most likely” (> 99%).

Results: Power output and RPE during the 2nd stage of the LSCT were “likely” higher on day 5 and “very likely” (power) and “most likely” (RPE) higher on day 8, compared to day 1. During the 3rd stage of the LSCT, power output and RPE were “likely” higher on day 5 and “very likely” (power) and “likely” (RPE) higher on day 8, compared to day 1. On day 8, increased power output and RPE during these stages were accompanied by the inability to reach 90% of their maximal heart rate. All athletes reported increased feelings of fatigue ($F(2,10)=17.43$; $p=.001$) and muscle soreness ($F(2,10)=6.5$; $p=.02$). No significant changes were found in any of the parameters of the POMS (anger, vigor, fatigue, depression), nor in the energy-balance (vigor-fatigue) during and after the training camp. After 3 days of recovery, all parameters of the LSCT returned to baseline, indicating a state of functional overreaching during the training camp.

Conclusion: The LSCT can be used to reflect a state of functional overreaching in elite professional female cyclists during an 8 day training camp and the following recovery days.

Acute Inflammatory and Blood Pressure Response to Episodic Resistance Exercise in Young, Healthy Females
 Katherine LeWine, Elizabeth Mullin, Brian Thompson, Samuel A.E Headley, FACSM. *Springfield College, Springfield, MA.*
 (Sponsor: Dr. Samuel Headley, FACSM)
 (No relationships reported)

Several chronic illnesses are characterized by low-grade chronic inflammation, resulting in increased levels of circulating pro-inflammatory cytokines. Exercise has been shown to reduce the levels of circulating cytokines, as well as create an anti-inflammatory environment through the release of interleukin-6 from skeletal muscle. **PURPOSE:** The current study was designed to investigate whether or not family history of hypertension affected levels of interleukin-6 (IL-6) and systolic blood pressure (SBP) in young, physically active females, in response to an acute bout of resistance exercise. **METHODS:** A total of 14 females (age = 23.14 ± 2.28 years) completed the study. Subjects were split into two groups of seven based on familiar pre-disposition of hypertension. Subjects completed a resistance protocol of three sets of 10 at 67% of 1 repetition maximal. Blood samples and SBP was taken pre-exercise, post-exercise, and 1-hr post exercise. **RESULTS:** No significant interaction ($p > .05$) was found for levels of IL-6 or SBP between both groups. No change in IL-6 was found from pre to post exercise ($p = .942$). A significant main effect ($p < .05$) was found for SBP across the time periods. Post-systolic blood pressure was higher immediately following exercise ($p = .000$, $M_{pre} = 110.28$, $M_{post} = 123.00$) and decreased to baseline or lower after 60-minutes of recovery ($p = .000$, $M_{pre} = 123.00$, $M_{60post} = 107.71$). **CONCLUSIONS:** The results of this study indicate that family history of hypertension does not affect the levels of IL-6 or SBP in young, healthy females following resistance exercise. However, systolic blood pressure can decrease following a 60-minute recovery, after an acute bout of resistance exercise to levels at baseline or below.

2842 Board #362 June 2 11:00 AM - 12:30 PM
Effect of Combined Exercise on Urinary Incontinence in Postmenopausal Women
 Sun Young Na¹, Nan Hee Lee², Chung Moo Lee¹, John D. Smith², Sukho Lee². ¹*Sookmyung Women's University, Seoul, Korea, Republic of.* ²*Texas A&M University San Antonio, San Antonio, TX.*
 (No relationships reported)

The risk factors of stress urinary incontinence (SUI) are obesity, diabetes, metabolic syndrome, and pelvic floor dysfunction in postmenopausal women. Combined exercise with aerobic and resistance training included core exercise would be effective intervention for the SUI. **PURPOSE:** To investigate the effect of combined exercise program (CEP) on SUI in postmenopausal women. **METHODS:** This study was conducted with stratified random sampling, random assignment and a pre-post test design. Forty-two postmenopausal women with SUI (58.95 ± 4.16 years old) were divided into an exercise group (EG) and control group (CG) and categorized for metabolic syndrome (MEG, N=7; MCG, N=7), obesity (OEG, N=7; OCG, N=7), and normal (NEG, N=7; NCG, N=7) conditions, respectively. The CEP consisted of 12 weeks aerobic (40-75 % of Heart Rate Reserve and 11-13 based on Rate of Received Exertion, 50-70 minutes, 3 times/week) and resistance training to strengthen the core muscles for total body training. Control groups maintained their normal daily lifestyle. Vaginal contraction, HOMA-IR, estradiol (E_2), and body composition were assessed. Repeated measures ANOVAs were used to determine differences between each condition. **RESULTS:** Duration of vaginal contraction ($F=15.410$, $p=.002$) and HOMA-IR ($F=5.729$, $p=.034$) in the MEG were significantly improved compared with MCG. Peak pressure of vaginal contraction ($F=14.706$, $p=.002$), average pressure of vaginal contraction ($F=20.839$, $p=.001$), and % fat ($F=134.440$, $p=.000$) in the OEG were significantly improved compared with OCG. **CONCLUSION:** The CEP has efficacy for SUI prevention and alleviation by increasing pelvic floor muscle contraction, specifically for postmenopausal women with metabolic syndrome and obesity, as improving insulin resistance and body fat.

2843 Board #363 June 2 11:00 AM - 12:30 PM
Effect of Etiologically Mediated Cardiorespiratory Dysfunction on Resistance to Fatigue in Women with Systemic Lupus Erythematosus (SLE)
 Liana C. Wooten, Monira I. Aldhahi, Randall E. Keyser, FACSM, FACSM. *George Mason University, Fairfax, VA.*
 (No relationships reported)

Impaired cardiorespiratory function can mediate reductions in resistance to fatigue during physical activity. Women with systemic lupus erythematosus (SLE) incur excessive levels of fatigue (SLE-fatigue) with previously reported evidence of cardiorespiratory limitations that are etiologically mediated. The potential cardiorespiratory endurance limitations have yet to be investigated in this population. **Purpose:** To characterize cardiorespiratory endurance in women with SLE using submaximal, sustained work rate exercise testing. **Methods:** 15 subjects, 7 women with SLE (39.7±7.5 years; 69.2±7.6 Kg) and 8 sedentary but otherwise healthy controls (40.1±2.9; 73.4±17.7 Kg) completed a 5-MET sustained work rate endurance test ending at volitional exhaustion or when 60 minutes of treadmill walking time had accrued. VO_2 kinetics transition constant (Kt) and amplitude (ΔVO_2) were measured. Data were analyzed using independent t-tests and statistical significance was set at $p < 0.05$. **Results:** There were no significant differences in cardiorespiratory function between groups at baseline. Total time duration on the treadmill (27.5±9.6 vs 57.4±7.0 min; $p > 0.01$), Kt (8.4±2.8 vs 13.4±4.4; $p = 0.02$), and ΔVO_2 (0.65±0.17 vs 0.85±0.17 Liters, $p = 0.04$) were decreased in the SLE group compared to controls. **Conclusion:** Previous studies have characterized relationships between overall patient-perceived fatigue severity, performance fatigability and etiologically mediated cardiorespiratory dysfunction in women with SLE. The current study expands on this evidence suggesting that decreased cardiorespiratory endurance may be mediated through delayed metabolic transition during physical activity in these women. The inability to sustain the energy requirements requisite for a 5-MET work rate accentuate the severity of functional limitations ultimately impacting health-related quality of life in this population. NIH/NICHD 1R03HD39775

Does the Cardiomyocyte Circadian Clock Influence Size of the Heart?

Graham R. McGinnis, John C. Chatham, Martin E. Young, *University of Alabama at Birmingham, Birmingham, AL.*

(No relationships reported)

Circadian clocks, driven by the transcription factors Clock (circadian locomotor output cycles kaput) and Bmal1 (brain and muscle arnt-like 1), are sophisticated mechanisms that regulate 24-hr rhythms in numerous physiological processes ranging from gene expression to behavior. The cardiomyocyte clock has been shown to regulate cardiac metabolism and function, and its disruption decreases lifespan. However, the role of the circadian clock in regulating cardiomyocyte growth remains unknown. **PURPOSE:** To determine the role of the cardiomyocyte circadian clock in regulating hypertrophic growth of the heart. **METHODS:** We used mice with genetically disrupted clocks specifically within the heart (Cardiomyocyte-specific Bmal1 Knockout; CBK) and littermate control mice (CON) to investigate the role of the cardiomyocyte circadian clock on cardiac growth/size. Signaling was assessed through Western blotting, while rates of protein synthesis were measured using radiolabeled tracers (both in vivo and ex vivo). Rapamycin feeding (14 ppm and 42 ppm, 10 days) was utilized to pharmacologically inhibit mTOR. **RESULTS:** We found that disruption of the cardiomyocyte circadian clock leads to increased activation of the Akt/mTOR/S6 signaling axis in the heart. Rates of protein synthesis displayed a diurnal rhythm in CON mice (highest at ZT0) in vivo, which was chronically elevated in CBK mice; the same genotype effect was seen in ex vivo perfused hearts. CBK hearts exhibited increased heart size (relative to CON hearts), which was normalized by rapamycin feeding. **CONCLUSION:** Genetic disruption of the cardiomyocyte circadian clock leads to chronic activation of the Akt/mTOR/S6 signaling axis in the heart, associated with increased protein synthesis and size.

Regulation of the Skeletal Muscle Circadian Transcriptome by the Master Myogenic Regulatory Factor, Myod1

Brian A. Hodge¹, Xiping Zhang², Karyn A. Esser, FACSM². ¹*Buck Institute for Research on Aging, Novato, CA.* ²*University of Florida, Gainesville, FL.*

(No relationships reported)

Molecular clocks are comprised of interlocking transcriptional:translational feedback loops that promote circadian rhythms in physiology through controlling downstream gene expression in a temporal and tissue-specific fashion. The mechanisms in which the core clock factors (ubiquitously expressed in all tissues) target skeletal muscle specific genes are poorly understood. **PURPOSE:** Here we investigate the role of the muscle specific factor MYOD1 in regulating skeletal muscle circadian gene expression. **METHODS:** Dual-luciferase assays and real-time bioluminescence (Lumicycle) were performed in C2C12 myotubes to determine transcriptional responses and rhythmic expression patterns of the muscle specific circadian gene, Titin-cap (Tcap), with over expression of the core-clock genes BMAL1:CLOCK with

MYOD1. To identify genome-wide binding sites for BMAL1:CLOCK and MYOD1 we performed chromatin immunoprecipitation and ultra-high throughput sequencing (ChIP-Seq) in wildtype C57BL/6 quadriceps and C2C12 myotubes. HOMER software was utilized for Next-Gen sequencing analysis. **RESULTS:** We utilized a bioinformatics approach to identify Tcap as a skeletal muscle specific, circadian gene. Interestingly, we found that MYOD1 transactivates Tcap in a synergistic fashion with BMAL1:CLOCK and enhances Tcap's circadian amplitude. Three e-box elements within the Tcap promoter are required for cooperativity between the clock factors and MYOD1. ChIP-Seq analysis in skeletal muscle indicated that MYOD1 targets a large subset of the skeletal muscle circadian transcriptome. **CONCLUSION:** These findings support the hypothesis that MYOD1 is a key regulator of circadian gene expression in skeletal muscle.

Habitual Physical Activity Mitigates the Adverse Effects of Metabolic Syndrome on Arterial Stiffness and Cerebral White Matter Integrity

Evan P. Pasha, Alex C. Birdsill, Stephanie Oleson, Andreana P. Haley, Hirofumi Tanaka, FACSM. *The University of Texas at Austin, Austin, TX.* (Sponsor: Hirofumi Tanaka, FACSM)

Email: evan.pasha@utexas.edu

(No relationships reported)

PURPOSE: Metabolic syndrome (MetS) adversely affects the vasculature and cerebral white matter integrity. Arterial stiffening has been associated with diminished cerebral white matter integrity. Habitual physical activity (PA) can ameliorate components of MetS and subsequently affect arterial stiffening and white matter integrity. Our aim was to determine the role of habitual PA on mitigating the adverse influence of MetS on arterial stiffness and cerebral white matter integrity. **METHODS:** Sixty-six middle-aged adults (40-62 years) composed of 27 healthy, 18 sedentary MetS (Sed MetS), and 21 physically active MetS individuals (Active MetS) were studied. Carotid artery stiffness was assessed via simultaneous ultrasound and tonometry. Cerebral white matter integrity was measured using diffusion tensor imaging through metrics of fractional anisotropy (FA) and mean diffusivity (MD). **RESULTS:** Carotid β -stiffness index in Active MetS was lower than Sed MetS but was not different from Healthy controls (6.6 ± 1.5 , 7.7 ± 2.1 , and 5.6 ± 1.6 au, $p=0.001$). The same group pattern was observed with white matter microstructural integrity in regions of interest (ROIs). Mean ROI FA was significantly greater in Active MetS compared with Sed MetS but was not different from Healthy controls (0.54 ± 0.03 , 0.51 ± 0.02 , and 0.53 ± 0.02 au, $p=0.012$). Mean ROI MD was significantly lower in Active MetS compared with Sed MetS but was not different from Healthy controls (0.85 ± 0.05 , 0.89 ± 0.05 , and 0.86 ± 0.05 mm²/s, $p=0.019$). **CONCLUSION:** Middle-aged individuals with MetS who habitually perform PA demonstrated lower arterial stiffness and more favorable cerebral white matter integrity than their sedentary peers, indicating that habitual exercise may be effective in mitigating the adverse effects of MetS on the vasculature and brain at midlife.

This work was supported by grants from the NIH, NINDS (to APH) and the NSF (to AB).

Changes in Brain Perfusion Following Weight Loss are Associated with Changes in Body Mass Index

Chelsea M. Stillman¹, Jennifer C. Watt², Renee J. Rogers³, John M. Jakicic, FACSM³, Kirk I. Erickson³. ¹University of Pittsburgh School of Medicine, Pittsburgh, PA. ²University of Pittsburgh, Pittsburgh, PA. ³University of Pittsburgh, Pittsburgh, PA.
 (Sponsor: John Jakicic, FACSM)
 (No relationships reported)

PURPOSE: Being overweight or obese, defined as having a body mass index (BMI) of 25 or greater, is associated with brain hypoperfusion. However, it is unknown to what extent obesity-related hypoperfusion can be reversed following weight loss. Further, the relative contributions of diet and physical activity (PA) on brain perfusion are poorly understood. The aim of the present study was to examine changes in brain perfusion following weight loss, and to relate changes in perfusion to changes in BMI. **METHODS:** 121 healthy adults (M±SD = 44.3±8.6 years old; 95 female) completed a 12-month randomized controlled trial involving an energy restricted diet (diet-only), a diet + 150 minutes of moderate intensity PA per week (Mod-PA), or diet and 250 minutes of moderate intensity PA per week (High-PA). Participants also completed MRI scans before and after the intervention, including a pseudocontinuous arterial labeling (pcASL) scan. Changes in brain perfusion were assessed with a voxelwise linear regression to examine regions where changes in brain perfusion covary with changes in BMI. Results were corrected for multiple comparisons at a threshold of $p < .05$, $k > 15$. **RESULTS:** There was a significant reduction in BMI following the intervention, suggesting that it was effective at facilitating weight loss, regardless of group ($M(SD) = 2.4 \pm 3.3$ kg/m², $p < .001$). Brain perfusion following the intervention increased across the brain, particularly in the medial temporal lobe and prefrontal cortex. Changes in BMI were correlated with baseline-to-post intervention increases in brain perfusion in two clusters in the right medial prefrontal cortex ($r(105) = .21$, $p = .03$, peak MNI xyz = 43, 98, 40, $k = 42$; $r(105) = .21$, $p = .03$, peak MNI = 42, 80, 27, $k = 37$). **CONCLUSIONS:** A 12-month intervention involving diet alone, or diet combined with PA effectively increased brain perfusion across the brain. Collapsing across intervention groups, the magnitude of weight loss (via changes in BMI) was positively correlated with changes in prefrontal brain perfusion. The regional specificity of this later finding is important as it suggests that weight-loss may have the greatest effects on brain health in regions that are particularly vulnerable to obesity. Future work will identify whether these effects are being driven by changes in PA, diet, or both.

 (No relationships reported)

Resistance exercise (RE) is recommended for men and women and is important for improving cardiovascular (CV) and metabolic disease risk factors. High-intensity RE acutely increases arterial stiffness and blood pressure (BP), coupled with reduced cerebral blood flow velocity (CBFv) and greater flow pulsatility in the cerebral circulation, which may be detrimental to cerebral microvasculature. Because females have different CV control mechanisms, it is important to assess potential sex differences in cerebral vascular responses to acute RE. **PURPOSE:** To examine the effect of sex on hemodynamics and cerebral vascular responses following acute RE in young recreationally active men and women. **METHODS:** Healthy men ($n = 11$, 28 yrs, BMI = 24.6) and women ($n = 9$, 25 yrs, BMI = 23.2) performed RE (3 sets of 10 repetitions of isokinetic concentric/concentric unilateral knee flexion/extension). Measurements were obtained at baseline and post-exercise (1, 5, 30 min). Beat-to-beat heart rate (HR), brachial BP (bSBP, bDBP, bMAP), cardiac output (CO), stroke volume (SV) and end-tidal CO₂ were collected. CBFv was measured by transcranial Doppler. Carotid BP (cSBP, cDBP, cMAP) measurements were obtained using applanation tonometry. Central pulse wave velocity (PWV) was measured by an automated ambulatory BP monitor. **RESULTS:** See table. Mean CBFv increased 1-min post-exercise and decreased below baseline 5-min post-exercise ($p < 0.01$) in both groups. CBFv pulsatility increased following RE and was elevated above baseline 5-min post-exercise ($p < 0.01$) in both groups. PWV increased 1-min post-exercise ($p < 0.01$) in both groups. Most variables returned to baseline at 30 min. **CONCLUSION:** RE increased central arterial stiffness, mean CBFv and CBFv pulsatility similarly for both sexes. Although CO increased at 5-min, CBFv dropped below baseline and pulsatility continued to rise above baseline. This temporary disruption in cerebral autoregulation may impact brain health in both sexes.

 (No relationships reported)

Hypohydration exceeding 2% body mass is known to impair endurance capacity. It is hypothesized that the central nervous system, specifically the brain, is negatively affected by hypohydration, leading to a decline in endurance capacity.

PURPOSE:

To investigate the effects of exercise-induced hypohydration on the brain.

METHODS:

Ten trained endurance males (mean±sd: age 23.3±1.1 years; body fat 10.5±2.4%; VO_{2peak} 65±5 ml kg⁻¹ min⁻¹) were dehydrated to -3% body mass by running on a treadmill at 65% VO_{2peak} in a 25°C environment, before drinking to replace 100% or 0% of fluid losses in two randomized, counterbalanced trials. Participants underwent MRI scans at baseline and post-fluid replacement to examine brain volume, functional activity and cerebral perfusion. Magnetic resonance spectroscopy was used to measure brain temperature (at primary motor cortex) before and during the dehydration run. Endurance capacity was assessed by running to exhaustion at 75% VO_{2peak}. Results were assessed using paired sample T-test with $p < 0.05$ considered significant.

RESULTS:

MRI results demonstrated a reduction in total brain volume in hypohydration (HH) as compared to euhydration (EU) trials (EU: 1.007, HH: 0.993; $p = 0.003$). BOLD (blood-oxygen-level dependent) activation in the primary motor (M1) and somatosensory cortex (S1) during a plantar flexion task were similar between conditions (M1: $p = 0.314$, S1: $p = 0.332$). Global and regional cerebral perfusion remained unchanged between conditions (Global: $p = 0.055$, M1: $p = 0.447$, S1: $p = 0.458$). Brain temperature measured at baseline was higher than core temperature (Brain: 37.7±0.5°C, Core: 36.7±0.3°C; $p < 0.0001$). However, both temperatures were similar during exercise (Brain: 38.2±0.4°C, Core: 38.6±0.3°C; $p = 0.110$). Endurance capacity was reduced with hypohydration (EU: 45.2±9.3 min, HH: 38.4±10.7 min; $p = 0.033$).

CONCLUSION:

Under hypohydration, the endurance capacity is impaired and total brain volume is reduced. Brain functional activity and cerebral perfusion are notably well-preserved. Brain temperature could be regulated within a narrower homeostatic range than the core temperature.

Cerebral Blood Flow during Dynamic Exercise Correlates with Blood Pressure in Autonomic Brain Regions

Mikio Hiura¹, Akitaka Muta², Muneyuki Sakata³, Satoshi Wagatsuma³, Tetsuro Tago³, Jun Toyohara³, Kenji Ishibashi³, Kenji Ishii², Tadashi Nariai². ¹Hosei University, Tokyo, Japan. ²Tokyo Medical and Dental University, Tokyo, Japan. ³Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan.

 (No relationships reported)

PURPOSE: During dynamic exercise changes in cerebral blood flow (CBF) has been demonstrated. While global CBF remains stable in the prolonged exercise via cerebral autoregulation, alterations in BP would be associated with fluctuation of regional CBF (rCBF). However, association between rCBF and BP during exercise has not been elucidated. The aim of the present study is to examine changes in rCBF evoked by dynamic exercise using positron emission tomography (PET) and to identify brain regions where rCBF correlates with BP. **METHODS:** Twelve healthy young males performed 20 min cycling exercise and rCBF were measured using oxygen-15-labeled water and PET (Discovery PET/CT, GE) at the baseline (Rest), during and after exercise. Heart rate (HR) and mean blood pressure (MBP) were monitored. With the accumulated image and the measured arterial input function, rCBF was calculated using the autoradiographic method. For an anatomical reference, individual brain MRI scans were acquired and the image data were analyzed using SPM software and the quantitative analysis of rCBF was performed using Dr. View software. **RESULTS:** During exercise HR and MBP increased to 119 ± 8 bpm and 107 ± 13 mmHg, respectively, at the endpoint of exercise. At 20 min after exercise, MBP significantly decreased compared to Rest, from 91 ± 8 to 86 ± 10 mmHg ($P < 0.05$). rCBF increased in the sensorimotor cortex and cerebellar vermis during exercise ($P < 0.001$, uncorrected). Following exercise rCBF decreased in the frontal lobe in the

($P < 0.005$, uncorrected). rCBF increased by 35 % during exercise and decreased by 12 % at 20 min after exercise compared with Rest. Regression analysis revealed that rCBF in the midbrain, left hippocampus and right anterior cingulate gyrus over the course of exercise ($P < 0.05$, corrected).

CONCLUSIONS: The present study suggest that dynamic exercise induced fluctuation in rCBF as well as BP. The regression analysis implies that brain regions including brainstem hippocampus and cingulate gyrus might be susceptible to changes in BP. As light- to moderate-intensity exercise evoked post exercise hypotension, these findings are associated with brain center of autonomic function which is regulated via connection between brainstem regions and cardiovascular structures, the central baroreflex network.

 (No relationships reported)

Cardiorespiratory fitness (CRF) and physical activity (PA) are positively associated with cognition and may mitigate pathological changes that occur with age and Alzheimer's disease (AD). However, there is limited information on the interaction between CRF and PA in predicting brain health in older adults. Throughout aging and the AD cascade, patterns of decreased cerebral blood flow (CBF) are apparent and vascular health abnormalities have been postulated as a precursor to downstream pathologies such as amyloid-beta accumulation and neuronal dysfunction. Limited research suggests that CRF is positively associated with CBF. However, no study to date has examined CRF and PA concomitantly with CBF. **Purpose:** To determine the unique contributions of CRF and moderate-vigorous physical activity (MVPA) when predicting CBF in an older adult population at-risk for AD. **Methods:** 159 cognitively healthy (MMSE ≥ 24) adults (mean age = 63.8, SD = 5.4) from the Wisconsin Registry for Alzheimer's Prevention participated in this study. Participants performed a graded maximal exercise test to measure CRF (VO_{2peak} , ml/kg/min) and wore a triaxial accelerometer on their hip for seven consecutive days to quantify their PA behaviors. Participants also underwent MRI scanning where CBF was measured using pseudocontinuous ASL. CBF was sampled from 5 brain regions implicated in AD using the Alzheimer's Disease Neuroimaging Initiative FDG Meta-ROI suite. **Statistical analyses:** Pearson correlation was used to examine the association between CRF and MVPA. Multiple linear regression was used to determine whether CRF and/or MVPA were significant and independent predictors of CBF. **Results:** CRF and MVPA were moderately correlated ($r = .37$; $p < .05$), suggesting these two constructs may provide unique contributions to CBF. Regression analysis revealed CRF was significantly and positively associated with CBF while accounting for minutes of MVPA, accelerometer wear time, age, gender, and global cerebral blood flow ($p < .05$). **Conclusions:** Results suggest fitness level, independent of physical activity, is associated with greater CBF in regions that decline with aging and AD. Cardiorespiratory fitness appears to be an important physiological component of brain health in older adulthood that is not explained by physical activity behaviors.

 (No relationships reported)

Apolipoprotein E (APOE) $\epsilon 4$ allele carriers (carriers) are at high risk for Alzheimer's Disease (AD). Evidence suggests that carriers have altered resting-state brain connectivity (rs-conn), which may be a precursor to cognitive decline and pathological changes. Exercise, however, has been shown to be beneficial for cognitive function and is capable of changing rs-conn. **Purpose:** Our purpose was to assess differences in rs-conn between carriers and non-carriers before and after an exercise intervention. **Methods:** Participants completed resting-state fMRI scans at the beginning (pre) and end (post) of a 3 day/week, 8-month, moderate-intensity exercise program ($n=12$; 8 carriers & 4 non-carriers; mean age = 59.5 yrs). Independent samples t tests with a false discovery rate correction for multiple comparisons were used to determine differences in rs-conn between carriers and non-carriers (contrast=carriers > non-carriers) at pre and post with alpha set a priori at $\alpha=.05$. **Results:** Before

intervention, the carriers exhibited significantly more rs-conn as compared to non-carriers between cerebellum 10 (left (L)) and the middle frontal gyrus (L) ($t(10)=7.88$, $p=.002$), planum temporale (L) ($t(10)=5.82$, $p=.01$), anterior cingulate ($t(10)=4.99$, $p=.02$), and cerebellum 4/5 (L) ($t(10)=4.8$, $p=.02$). There was also significantly more rs-conn for the carriers as compared to non-carriers between the anterior parahippocampal gyrus (right (R)) and the frontal orbital cortex (L) and between the occipital pole (L) and cerebellum 10 (R) (p 's $< .05$). In contrast, carriers had less rs-conn compared to the non-carriers in the paracingulate gyrus (L) and the occipital fusiform gyrus (R) ($t(10)=-5.97$, $p=.02$). Following treatment, however, there were no group differences in rs-conn in the aforementioned regions ($p > .05$). **CONCLUSION:** We found significantly more rs-conn in various motor and attention regions before the exercise intervention in the APOE $\epsilon 4$ carriers suggesting a compensatory mechanism. These differences were no longer evident after an 8-month exercise intervention suggesting that exercise may reorganize carriers' neural connectivity towards that of non-carriers. Since alterations in rs-conn have been suggested as a precursor to AD, exercise interventions may be especially beneficial for APOE $\epsilon 4$ carriers.

 (No relationships reported)

Cerebrovasculature responsiveness (CVR) to alterations in arterial carbon dioxide (PCO_2) content is a common test to assess brain health. Traditionally, higher CVR is associated with higher aerobic fitness, while natural aging and brain-related diseases are associated with lower CVR. However, recent findings challenge some of these relations, but may be related to inconsistent neuroimaging methodologies. **PURPOSE:** 1) to examine fitness effects on CVR between active and sedentary individuals using functional magnetic resonance imaging (fMRI) and transcranial Doppler (TCD), and 2) compare different stimulus concentrations for CVR measures between fMRI and TCD. **METHODS:** Fourteen volunteers participated (26 ± 7 yrs; 8 active, 6 sedentary), with 10 pair-matched for age and sex to examine fitness effects (5 active, 5 sedentary). Following medical screening, participants completed an aerobic fitness test (VO_2 max) and the CVR protocol familiarisation. Participants then completed two experimental sessions on separate days (randomized and counter-balanced). For both sessions, CVR was assessed using two concentrations of CO_2 via the same Douglas bag open circuit (4-min cycles of room air, 5% CO_2 , room air, 7% CO_2). CVR was measured using fMRI (EPI-based sequence allowing simultaneous acquisition of blood-oxygen level dependent and perfusion responses) and TCD (middle cerebral artery flow velocity). CVR measures were correlated (Pearson's) with fitness and differences between stimulus concentration within and between approaches compared. **RESULTS:** 1) Higher VO_2 max was associated with higher CVR derived from 5% and 7% CO_2 stimuli, but were higher for fMRI (5%: $r=.640$, $p=.06$; 7%: $r=.690$, $p=.04$) than TCD (5%: $r=.209$, $p=.30$; $r=.365$, $p=.17$). 2) When comparing CVR between fMRI and TCD, values obtained from the 5% stimulus correlated ($r=.626$, $p < .05$); while there was no correlation between values obtained from the 7% stimulus ($r=.252$, $p=.46$). Paired t -tests comparing CO_2 concentration (5% vs 7% CO_2) revealed no difference for fMRI-derived CVRs ($p=.93$), but a trend between TCD-derived CVRs ($p=.10$). **CONCLUSION:** Both fMRI and TCD-CVR approaches differentiated active and sedentary groups. The CVR measure between and within neuroimaging approaches was differentially influenced by CO_2 concentration.

Are Vascular Conductance and Muscle Blood Flow During Exercise Affected by Hypoxia and Arterial Perfusion Pressure?

Rodrigo Villar¹, Richard L. Hughson². ¹Franklin Pierce University, Rindge, NH. ²University of Waterloo, Waterloo, ON, Canada.

(No relationships reported)

PURPOSE: To investigate the combined effect of hypoxia and altered arterial perfusion pressure on vascular conductance (VC), muscle blood flow (MBF), and O₂ delivery (DO_{2ext}) during exercise. **METHODS:** Ten healthy volunteers repeated plantar flexion contractions at 20% (low power output = LPO) and 30% (higher power output = HPO) of their maximal voluntary contraction in 35° head-down-tilt (HDT) and 45° head-up-tilt (HUT) to modify muscle perfusion pressure (MPP) while breathing normoxic and then hypoxic air. Popliteal diameter and muscle blood flow velocity were measured by ultrasound to determine MBF. VC was estimated by dividing MBF by MPP, and DO_{2ext} was estimated from MBF and saturation. **RESULTS:** From normoxia to hypoxia in LPOHUT, there were no changes in VC (0.9 ± 0.4 mL.min⁻¹.mmHg⁻¹ and 0.8 ± 0.4 mL.min⁻¹.mmHg⁻¹) and MBF (127.2 ± 58.8 mL.min⁻¹ and 119.5 ± 53.2 mL.min⁻¹), resulting in reduced DO_{2ext} (123.9 ± 57.2 mL.O₂.min⁻¹ and 109.6 ± 48.5 mL.O₂.min⁻¹, p < 0.05). In LPOHDT, there was an increase in VC from 2.9 ± 0.8 mL.min⁻¹.mmHg⁻¹ in normoxia to 3.3 ± 0.8 mL.min⁻¹.mmHg⁻¹ in hypoxia (p < 0.05) and MBF from 146.3 ± 34.2 mL.min⁻¹ in normoxia to 167.3 ± 38.1 mL.min⁻¹ in hypoxia (p < 0.05), maintaining DO_{2ext} (142.2 ± 33.2 mL.O₂.min⁻¹ and 152.6 ± 34.3 mL.O₂.min⁻¹). From normoxia to hypoxia during HPOHUT, there were no changes in VC (1.4 ± 0.5 mL.min⁻¹.mmHg⁻¹ and 1.4 ± 0.6 mL.min⁻¹.mmHg⁻¹), MBF (203.3 ± 74.3 mL.min⁻¹ and 210.3 ± 84.2 mL.min⁻¹), and DO_{2ext} (197.0 ± 72.4 mL.O₂.min⁻¹ and 190.8 ± 75.0 mL.O₂.min⁻¹). During HPOHDT, there was an increase in VC from 3.6 ± 1.0 mL.min⁻¹.mmHg⁻¹ in normoxia to 4.1 ± 1.2 mL.min⁻¹.mmHg⁻¹ in hypoxia (p < 0.05), MBF from 186.8 ± 55.4 mL.min⁻¹ in normoxia to 221.6 ± 68.7 mL.min⁻¹ in hypoxia (p < 0.05), and DO_{2ext} (180.9 ± 53.3 mL.O₂.min⁻¹ and 201.0 ± 60.8 mL.O₂.min⁻¹, p < 0.05). In hypoxia, VC reached its upper functional limit and the consequence was revealed by increased muscle activation. **CONCLUSION:** During HPOHDT in hypoxia, a functional limitation for the recruitment of VC constrained MBF and DO_{2ext}, which contribute to a greater metabolic stress and advance of muscle fatigue. During LPOHDT, LPOHUT and HPOHUT in hypoxia, changes in VC compensated for the alterations in O₂ availability and MPP with no apparent functional limitation in the VC recruitment, which would allow further rises in MBF to maintain DO_{2ext}.

Blood Flow Regulation and Oxygen Uptake during High Intensity Forearm Exercise

Eivind Wang¹, Stian K. Nyberg¹, Ole K. Berg², Jan Helgerud¹. ¹Norwegian University of Science and Technology, Trondheim, Norway. ²Molde University College, Molde, Norway.

Email: eivind.wang@ntnu.no

(No relationships reported)

The vascular strain is very high during heavy handgrip exercise, but the intensity and kinetics to reach peak blood flow, and peak oxygen uptake, are uncertain. **PURPOSE:** We included 9 young (25±2yr) healthy males to evaluate blood flow and oxygen uptake responses during continuous dynamic handgrip exercise with increasing intensity. **METHODS:** Blood flow was measured using Doppler-ultrasound and venous blood was drawn from a deep forearm vein to determine arteriovenous oxygen difference (a-vO_{2diff}) during 6-minutes bouts of 60, 80 and 100% of maximal work rate (WR_{max}), respectively. **RESULTS:** Blood flow and oxygen uptake increased (p<0.05) from 60%WR_{max} (557±177(SD) mL.min⁻¹; 56.0±21.6 mL.min⁻¹) to 80%WR_{max} (679±190 mL.min⁻¹; 70.6±24.8 mL.min⁻¹), but no change was seen from 80%WR_{max} to 100%WR_{max}. Blood velocity (49.5±11.5 cm.sec⁻¹ to 58.1±11.6 cm.sec⁻¹) and brachial diameter (0.49±0.05cm to 0.50±0.06 cm) showed concomitant increases (p<0.05) with blood flow from 60% to 80%WR_{max}, while no differences were observed in a-vO_{2diff}. Shear rate also increased (p<0.05) from 60% (822±196 s⁻¹) to 80% (951±234 s⁻¹) of WR_{max}. The mean response time (MRT) was slower (p<0.05) for blood flow (60%WR_{max}:50±22s; 80%WR_{max}:51±20s; 100%WR_{max}:51±23s) than a-vO_{2diff} (60%WR_{max}:29±9s; 80%WR_{max}:28±5s; 100%WR_{max}:20±5s), but not different

from oxygen uptake (60%WR_{max}:44±25s; 80%WR_{max}:43±14s; 100%WR_{max}:41±32s). No differences were observed in MRT for blood flow or oxygen uptake with increased exercise intensity. **CONCLUSION:** When approaching maximal intensity, oxygen uptake appeared to reach a critical level at ~80% of WR_{max} and be regulated by blood flow. This implies that high, but not maximal, exercise intensity may be an optimal stimulus for shear stress-induced small muscle mass training adaptations.

(No relationships reported)

Numerous studies have investigated cerebral blood flow (CBF) responses during orthostatic stress, primarily using middle cerebral artery (MCA) blood velocity. Due to methodological limitations associated with this measurement, there has been a recent transition towards measuring blood flow in vertebral (VA), internal carotid (ICA) and external carotid arteries (ECA) using duplex Doppler ultrasound. Limited studies have simultaneously characterized the response of all these cerebral vessels to simulated orthostatic stress. Likewise, previous studies examining the influence of the sympathetic nervous system on the cerebral vasculature have also relied mainly on MCA velocity measures, primarily performed during infusion of α-adrenergic receptor agonists or antagonists. **PURPOSE:** To investigate regional CBF responses to a moderate and high level of reflex-mediated sympathetic activation via lower body negative pressure (LBNP) at -10 and -40 Torr, respectively. **METHODS:** In 8 young men, beat-to-beat arterial pressure (finger photoplethysmography), heart rate (ECG), VA, ICA, ECA and brachial artery blood flow (duplex Doppler ultrasound) and MCA blood velocity (transcranial Doppler) were measured at rest and during 5 min of -10 and -40 Torr LBNP performed in random order. Conductance was calculated as blood flow of the respective artery/mean arterial pressure. **RESULTS:** In both LBNP trials, there was a significant decrease in brachial artery blood flow and conductance (-10 Torr: -26.0±10.6 % baseline; -40 Torr: -42.3±4.4 % baseline, p=0.006). In contrast, VA, ICA and ECA blood flow and conductance were unaffected (e.g., VA conductance, -10 Torr: -5.8±4.6 % baseline; -40 Torr: -0.03±2.5 % baseline, p=0.654). MCA blood velocity was also unchanged by LBNP (p=0.648). **CONCLUSION:** Despite the large sympathetically-mediated reductions in brachial artery conductance, cerebral vascular conductance, assessed in multiple arteries, was unaffected by graded sympathetic activation with LBNP. These preliminary data suggest minimal direct effect of reflex-mediated elevations in sympathetic nerve activity on CBF. Supported by NIH grant 1 RO1 HL 127071.

Muscle Blood Flow Responses to Dynamic Handgrip Exercise in Young Obese Adults

Kanokwan Bunsawat, Georgios Grigoriadis, Garrett Griffith, Sang Ouk Wee, Elizabeth Schroeder, Bo Fernhall, FACSM, Tracy Baynard, FACSM. *University of Illinois at Chicago, Chicago, IL.* (Sponsor: Tracy Baynard, FACSM)

Email: bunsawa2@uic.edu

(No relationships reported)

INTRODUCTION: Exercise intolerance is a hallmark characteristic of obesity, which may be related to an impaired ability to appropriately increase blood flow to the contracting muscles. Limited evidence suggests that steady-state vasodilator responses to dynamic forearm exercise are preserved or even increased in young obese humans compared with lean peers, but this topic still remains poorly understood. **PURPOSE:** To evaluate exercise-induced changes in hemodynamics in young obese adults compared with lean adults. **METHODS:** Thirteen lean (female=6; 26±1 yrs; 22.4±0.5 kg/m²) and 14 obese adults (female=7; 27±1 yrs; 32.6±0.6 kg/m²) performed 2-min of dynamic forearm exercise at 15 and 30% of maximal voluntary contraction (1-s contraction; 2-s relaxation). Ultrasonography [brachial diameter, forearm blood flow (FBF), forearm vascular conductance (FVC)], and beat-to-beat hemodynamics [mean arterial pressure (MAP), heart rate (HR), stroke index (SI), systemic vascular resistance index (SVRI), cardiac index (CI), systemic arterial compliance index (SACI)] were collected. FBF and FVC were normalized to lean forearm mass, and hemodynamics were indexed to body surface area. **RESULTS:** There were no group differences in any variable at baseline. Brachial artery diameter, FBF, FVC, and HR increased from baseline at 15% and 30% of MVC similarly in both groups (P<0.05). There was an interaction for SVRI (P<0.05), where SVRI decreased from baseline at 15% and 30% MVC only in the lean group (P<0.05). **CONCLUSION:** Although young obese adults did not exhibit an impairment in exercise-induced increases in

blood flow, systemic vascular resistance did not decrease with exercise in obese adults. Future studies in an older population may reveal more consistent obesity-related impairments, whereas our current cohort is young and lack comorbidities.

Reduced Skeletal Muscle Blood Flow In Persons With Multiple Sclerosis Exhibiting Autonomic Nervous System Dysfunction

Nathaniel B. Ketelhut, Christopher M. Hearon, Frank A. Dinunno, Thorsten Rudroff, FACSM. *Colorado State University, Fort Collins, CO.* (Sponsor: Thorsten Rudroff, FACSM)
Email: nathan.ketelhut@colostate.edu

(No relationships reported)

Multiple Sclerosis (MS) is a demyelinating disease of the central nervous system characterized by a variety of symptoms including fatigue, reduced exercise capacity, and autonomic nervous system (ANS) dysfunction. **PURPOSE:** The purpose of this study was to determine whether persons with MS (PwMS) demonstrate reduced skeletal muscle blood flow during exercise compared to age matched controls.

METHODS: The first analysis included 7 PwMS (age: 52.0 ± 9.8, 6 women) and 6 controls (age: 49.2 ± 9.8, 4 women). ANS function was assessed in both groups using the 31 item Composite Autonomic Symptom Score (COMPASS-31) questionnaire. A subset of 3 women with MS exhibiting ANS dysfunction (age: 55.3 ± 7.0, Patient Determined Disease Steps: 1-3) were then age, sex, and workload matched with controls (age: 51.3 ± 9.5) for the second analysis. Mean blood velocity was measured (Doppler Ultrasound) and femoral blood flow (FBF) and conductance (FVC) were calculated during submaximal single leg knee extension with a modified cycle ergometer on the right leg at 20% and 40% of work-rate max (WRmax). FBF and FVC were normalized per 100g of thigh fat free mass. Comparisons for analysis 1 were made with unpaired 1-tailed T-Tests and comparisons for analysis 2 with paired 1-tailed T-Tests.

RESULTS: Analysis 1: FVC tended to be lower in the MS group at 20% WRmax ($P = 0.13$) and 40% WRmax ($P = 0.13$). However, there was no difference in FVC when absolute workloads were matched (MS 40% WRmax vs. Con 20% WRmax: MS: 6.3 ± 1.0 watts, Con: 5.0 ± 0.8 watts) between groups ($P = 0.41$). Analysis 2: Absolute and relative workloads were matched for each group (20% WRmax, MS: 4.2 ± 0.8 watts, Con: 4.0 ± 1.0 watts; 40% WRmax, MS: 8.3 ± 1.7 watts, Con 8.0 ± 2.0 watts). FBF was lower at 40% WRmax ($P = 0.05$), while FBF at 20% WRmax ($P = 0.13$) and FVC at both workloads tended to be lower in MS (20% WRmax, $P = 0.13$, 40% WRmax, $P = 0.14$).

CONCLUSIONS: These results suggest that PwMS exhibiting ANS dysfunction may have reduced blood flow during exercise at similar relative and absolute workloads compared to age/sex matched controls. These findings warrant further investigation into the regulation of skeletal muscle blood flow in PwMS to determine whether impaired blood flow contributes to common symptoms of MS such as reduced exercise capacity and fatigue.

Oxygen Extraction Reserve Immediately After Ramp Incremental Maximal Exercise: Beyond the Deoxy-hemoglobin Breaking Point

E. Calaine Inglis, Danilo Iannetta, Juan M. Murias. *University of Calgary, Calgary, AB, Canada.* (Sponsor: Donald H Paterson, FACSM)

Towards the end of a ramp incremental (RI) test to exhaustion, the near-infrared spectroscopy (NIRS)-derive deoxygenated hemoglobin ([HHb]) signal plateaus, suggesting an upper limit in oxygen (O_2) extraction. However, it is unknown whether this plateau is the highest level of O_2 extraction, or if a "reserve" in O_2 extraction exists, such that the plateau in the [HHb] in the presence of a still raising O_2 utilization (VO_2) towards the end of a RI test is indicative of a local increase in blood flow.

PURPOSE: To assess the existence of a "reserve" in O_2 extraction immediately at the end of a RI cycling test to exhaustion.

METHODS: Nine male participants (27 ± 4.6 yrs; 79.9 ± 8.6 kg) performed a RI (30W·min⁻¹) test to exhaustion on a cycle ergometer (Velotron Dynafit Pro, Seattle, WA, USA) to determine the VO_2 (Quark CPET, Cosmed, Rome, Italy) and the [HHb] (Oxiplex TS, ISS, Champaign, USA) responses. The [HHb] signal was measured on the Vastus Lateralis (VL) muscle. An automatic rapid inflation cuff was used to occlude blood flow to the leg (300 mmHg), at the upper portion of the thigh, for two minutes immediately at test failure. A paired samples t-test was used to compare the VO_2 (onset of the plateau in the [HHb] signal and end-exercise) and the normalized (0-100% of the response during RI test) [HHb] signal (plateau and peak value obtained during occlusion).

RESULTS: The end-exercise VO_2 (VO_{2max} ; 4.35 ± 0.57 L·min⁻¹) was larger than that observed at the onset of the plateau in the [HHb] response (3.77 ± 0.52 L·min⁻¹; $p < 0.05$). Post-exercise peak [HHb] (following occlusion) was higher compared to its plateau value ($p < 0.05$), with a mean difference of 38.1 ± 18.9 %.

CONCLUSIONS: This study demonstrated the existence of a "reserve" in O_2 extraction, despite a continuous increase in the VO_2 response towards the end of a RI cycling test. These data suggest that the observed plateau in the [HHb] response is not related to O_2 extraction reaching its upper limit, but likely due to increased local blood flow.

The Exercise Pressor Reflex in Hyper- and Hypo-Responsive Humans

Nathan M. Garvin, Jin-Kwang Kim, David N. Proctor, FACSM, James A. Pawelczyk, FACSM. *The Pennsylvania State University, University Park, PA.* (Sponsor: James Pawelczyk, FACSM)

The exercise pressor reflex has been hypothesized to help preserve muscle perfusion (i.e., a flow-maintaining reflex rather than a pressure-raising reflex). Therefore, people with a hyper-responsive exercise pressor reflex should be better able to sustain exercise when blood flow is compromised. **PURPOSE:** To compare exercise tolerance in people with exaggerated and blunted exercise pressor reflexes. **METHODS:** From a large cohort of college age men and women we recruited groups of subjects identified as high (>75th percentile) and low (<25th percentile) blood pressure responders to static exercise (30% maximal voluntary contraction for 3 min). The groups were matched for body size, grip strength, and resting blood pressure. Subjects initiated rhythmic handgrip exercise (30 contractions/minute) at 10% MVC for 3 min and continued exercising while blood flow was progressively restricted with a cuff gradually inflated on the upper arm (3 mmHg/15 sec). Blood pressure (Finometer), heart rate (ECG) and blood flow (Doppler ultrasound) were measured continuously. Exercise ended when a rating of perceived exertion (Borg scale) of 19-20 was reached, or when blood flow was less than 10% of the steady-state exercise flow. **RESULTS:** Each group stopped exercising at a similar RPE and with similar blood flow. As expected, the high responder group had approximately double the increase in mean arterial pressure at the end of exercise and during post-exercise circulatory arrest when compared to the low responder group (31±12 vs. 15±7 and 29±13 vs. 12±6 mmHg respectively, $P<0.02$). The high responder group was able to exercise for 14±1 min, but exercise duration was significantly less for the low responder group (12±1 min, $P<0.05$). **CONCLUSIONS:** Inter-individual variation in the exercise pressor reflex has functional effects. People with an exaggerated exercise pressor reflex may be able to better maintain perfusion and exercise intensity.
