ABSTRACT

We present the Catalog of Cepheids from the LMC. The Catalog contains 1333 objects detected in the 4.5 square degree area of central parts of the LMC. About $3.4 \cdot 10^5$ *BVI* measurements of these stars were collected during the OGLE-II microlensing survey. The Catalog data include period, *BVI* photometry, astrometry, and R_{21} , ϕ_{21} parameters of the Fourier decomposition of *I*-band light curve.

The vast majority of objects from the Catalog are the classical Cepheids pulsating in the fundamental or first overtone mode. The remaining objects include Population II Cepheids and red giants with pulsation-like light curves.

Tests of completeness performed in overlapping parts of adjacent fields indicate that completeness of the Catalog is very high: > 96%. Statistics and distributions of basic parameters of Cepheids are also presented.

Finally, we show the light curves of three eclipsing systems containing Cepheid detected among objects of the Catalog.

All presented data, including individual *BVI* observations are available from the OGLE Internet archive.

Key words: *Cepheids – Magellanic Clouds – Catalogs*

1. Introduction

Cepheids were among the first variable stars discovered by astronomers – the prototype of the class, δ Cep, and η Aql were found to be varying in brightness by J. Goodricke and E. Pigott, respectively, in 1784. The great career of these objects

* Based on observations obtained with the 1.3 m Warsaw telescope at the Las Campanas Observatory of the Carnegie Institution of Washington.

begun at the beginning of 20th century when their famous Period–Luminosity relation was discovered in the Small Magellanic Cloud by Leavitt (1912). Cepheids became one of the most important standard candles used for distance determination in the Universe, although the calibration of the Period–Luminosity relation is still a topic of lively debate. Proper calibration is of great importance because Cepheids are now routinely discovered in galaxies to about 25 Mpc with the HST instruments. Thus, the Cepheid based distance scale is one of the most important steps in the distance scale ladder.

Cepheids are relatively well understood pulsating stars. Their role in the modern astrophysics is hard to be overestimated. Beside the Period–Luminosity relation these objects are the ideal laboratory for testing the stellar structure, theory of stellar evolution etc. Therefore it is crucial to have at hand a large sample of these stars with good quality observational data so the theoretical work could be verified.

Although many Cepheids were discovered in the Galaxy their observational data are very inhomogeneous, taken by different observers with different instruments. Two nearby galaxies – the Magellanic Clouds – are potentially much better hosts of these objects. Both Large and Small Magellanic Clouds are known to contain many Cepheids. Additional advantage of Cepheids from these galaxies is that they are located at approximately the same distance what makes analyses of their properties much simpler.

Unfortunately both Magellanic Clouds have been neglected photometrically for years – the vast majority of known Cepheids in the Magellanic Clouds were observed with old photographic or photoelectric techniques giving an order of magnitude worse quality than the modern CCD-based techniques. Situation has significantly changed in 1990s when large microlensing surveys began regular monitoring of the Magellanic Clouds for microlensing events. Photometry of millions stars in both Magellanic Clouds is a natural by-product of these surveys and for the first time good quality light curves of the Magellanic Cloud Cepheids could be obtained. Both MACHO and EROS microlensing surveys reported discovery of many Cepheids and presented observations of these stars in the LMC and/or SMC (Alcock *et al.* 1995, Alcock *et al.* 1999, Sasselov *et al.* 1997, Bauer *et al.* 1999). Unfortunately, all these data were taken with non-standard photometric bands.

The Magellanic Clouds were added to the list of objects observed by the Optical Gravitational Lensing Experiment (OGLE) at the beginning of the second phase of the survey in January 1997. Since then both Magellanic Clouds are monitored regularly, practically on every clear night. Observations are made through the *BVI* filters very closely reproducing the standard *BVI* system. After more than two years of observations the photometric databases are complete enough so the search for variable stars could be performed. Large samples of Cepheids were extracted from databases of both Magellanic Cloud fields.

In the previous papers of this series we presented analysis of double-mode Cepheids in the SMC (Udalski *et al.* 1999a), discovery of 13 Cepheids in the SMC –

candidates for objects pulsating in the second overtone mode (Udalski *et al.* 1999b) and analysis of the Period–Luminosity and Period–Luminosity–Color relations of huge samples of Cepheids from the LMC and SMC (Udalski *et al.* 1999c). In this paper we present first of two Catalogs of Cepheids from the Magellanic Clouds – the Catalog of Cepheids from the LMC. Similar Catalog of about 2300 Cepheids from the SMC will follow.

The Catalog of Cepheids from the LMC contains 1333 objects. They come from the 4.5 square degree area of central parts of the LMC. The vast majority of them are the classical Cepheids. Other stars include a sample of Population II Cepheids and a sample of red giant objects which variability resembles pulsation-like light curves. We do not include additional sample of about 70 double-mode Cepheids detected in the LMC – these objects will be described in a separate paper similar to double-mode Cepheids from the SMC (Udalski *et al.* 1999a).

We also present statistics and distributions of basic parameters of the LMC Cepheids like location in the LMC, periods, colors and parameters of the Fourier decomposition of light curve. Finally, we point attention to three Cepheids in the eclipsing systems which could potentially provide precise data on sizes and masses of their components.

The large and homogeneous sample of Cepheids presented in this paper with high quality photometry and high completeness can be used for many projects concerning these stars. Therefore we decided to make the data public – all data presented in this paper, including individual *BVI*-band observations and finding charts are available from the OGLE Internet archive.

2. Observations

All observations presented in this paper were carried out during the second phase of the OGLE experiment with the 1.3-m Warsaw telescope at the Las Campanas Observatory, Chile, which is operated by the Carnegie Institution of Washington. The telescope was equipped with the "first generation" camera with a SITe 2048×2048 CCD detector working in drift-scan mode. The pixel size was $24 \mu\text{m}$ giving the $0.417 \text{ arcsec/pixel}$ scale. Observations of the LMC were performed in the "slow" reading mode of CCD detector with the gain $3.8 \text{ e}^-/\text{ADU}$ and readout noise of about 5.4 e^- . Details of the instrumentation setup can be found in Udalski, Kubiak and Szymański (1997).

Observations of the LMC started on January 6, 1997. 11 driftscan fields covering 14.2×57 arcmins in the sky were observed during the first months of 1997. Additional 10 fields were added in October 1997 increasing the total observed area of the LMC to about 4.5 square degree. Because the microlensing search is planned to last for several years, observations of selected fields will be continued during the following seasons. In this paper we present data collected up to June 1999.

Observations were obtained in the standard *BVI*-bands with majority of measurements made in the *I*-band. The effective exposure time was 125, 174 and 237 seconds for the *I*, *V* and *B*-band, respectively. The instrumental system closely resembles the standard *BVI* one – the color coefficients of transformation ($a \cdot CI$; a – color coefficient, CI – color index: $B - V$ for *B* and $V - I$ for *VI* filters) are equal to -0.041 , $+0.004$ and $+0.032$ for the *B*, *V* and *I*-band, respectively.

Due to microlensing search observing strategy the vast majority of observations were done through the *I*-band filter (about 120–360 epochs depending on the field) while images on about 15–40 epochs were collected in the *BV*-bands. The *B*-band photometry is at the writing of this paper less complete than *VI* photometry – reductions of only 40% of fields were finished. For the remaining fields only *VI* photometry was available. *B*-band photometry of these fields will be completed after the next observing season.

Collected images were reduced with the standard OGLE data pipeline. Quality of data is similar to the photometric data of the SMC described in Udalski *et al.* (1998b). In particular, accuracy of absolute photometry zero points is about 0.01–0.02 in all *BVI*-bands. More details on the LMC photometric data will be presented with release of the photometric maps of the LMC in the near future.

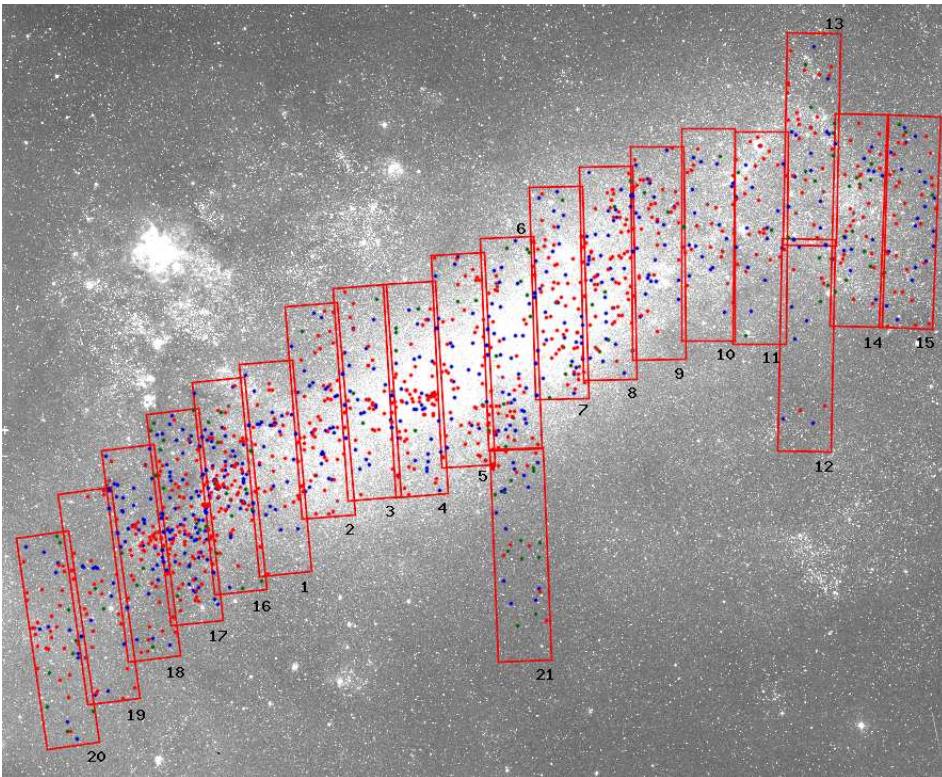

Fig. 1. OGLE-II fields in the LMC. Dots indicate positions of Cepheids from the Catalog. North is up and East to the left in the Digitized Sky Survey image of the LMC.

Table 1
Equatorial coordinates of the OGLE-II LMC fields

Field	RA (J2000)	DEC (J2000)
LMC_SC1	5 ^h 33 ^m 49 ^s	-70°06'10"

LMC_SC20	5 ^h 46 ^m 18 ^s	-70°44'50"
LMC_SC21	5 ^h 21 ^m 14 ^s	-70°33'20"

Table 1 lists equatorial coordinates of center of each field and its acronym. Fig. 1 shows the Digitized Sky Survey image of the LMC with contours of the observed fields.

3. Selection of Cepheids

The search for variable objects in the LMC fields was performed using observations in the *I*-band in which most observations were obtained. Typically about 120–360 epochs were available for each analyzed object with the lower limit set to 50. The mean *I*-band magnitude of analyzed objects was limited to $I < 19.5$ mag. Candidates for variable stars were selected based on comparison of the standard deviation of all individual measurements of a star with typical standard deviation for stars of similar brightness. Light curves of selected candidates were then searched for periodicity using the AoV algorithm (Schwarzenberg-Czerny 1989). The period search was limited to the range of 0.1–100 days. Accuracy of periods is about $7 \cdot 10^{-5} \cdot P$.

Candidates for Cepheids were selected from the entire sample of variable stars based on visual inspection of the light curves and location in the color-magnitude diagram (CMD) within the area limited by $I < 18.5$ mag and $0.25 < (V - I) < 1.3$ mag. Several objects located outside this region (*e.g.*, highly reddened Cepheids) and objects with no color information but with evident Cepheid-type light curves were also included to this sample. In total more than 1500 Cepheid candidates were found in the 4.5 square degree area of the LMC center.

Each of the analyzed LMC fields overlaps with neighboring fields for calibration purposes. Therefore several dozen Cepheids located in the overlapping regions were detected twice. We decided not to remove them from the final list of objects because their measurements are independent in both fields and can be used for testing quality of data, completeness of the sample etc. 105 such objects were detected and we provide cross-reference list to identify them.

4. Basic Parameters of Candidates

4.1. Intensity Mean Photometry

For each object which passed our selection criteria we derived the *BVI* intensity mean photometry by integrating the light curve converted to intensity units. It was approximated by the Fourier series of fifth order. Result was converted back to the magnitude scale. Accuracy of the mean *I*-band photometry is about 0.001 – 0.005 mag and somewhat worse (about 0.01 mag) for poorer sampled *BV*-bands.

Full *BVI* photometry is available only for eight fields: LMC_SC1–LMC_SC8. For the remaining fields the *B*-band databases are not complete enough for precise determination of the mean brightness. Photometry of these fields will be completed after the next observing season of the LMC.

For each object we also determined the extinction insensitive index W_I (called also Wesenheit index, Madore and Freedman 1991):

$$W_I = I - 1.55 \times (V - I). \quad (1)$$

The coefficient 1.55 in Eq. (1) corresponds to the coefficient resulting from standard interstellar extinction curve dependence of the *I*-band extinction on $E(V - I)$ reddening (*e.g.*, Schlegel, Finkbeiner and Davis 1998). It is easy to show that the values of W_I are the same when derived from observed or extinction free magnitudes, provided that extinction to the object is not too high so it can be approximated with a linear function of color.

4.2. Interstellar Reddening

Determination of the interstellar reddening to the LMC Cepheids has an important role in analyses of these objects, distance determination etc. It is well known that the reddening in the LMC is clumpy and variable (Harris, Zaritsky and

Thompson 1998), therefore applying the mean reddening value to all objects is generally not justified.

With large photometric databases of millions stars we are in position to determine the average reddening in many lines-of-sight within the LMC. Unfortunately, we do not have U -band photometry which would allow to derive the reddening from young, hot OB stars. Therefore we used for this purpose much older but much more numerous red clump stars. It should be noted, however, that Cepheid population can be distributed in the LMC somewhat differently than red clump stars and OB-stars determination could be more appropriate for Cepheids. On the other hand the differences should not be large for the LMC seen almost face-on.

We used red clump stars for mapping the fluctuations of mean reddening in our observed fields treating their mean I -band magnitude as the reference brightness. It was shown to be independent on age of these stars in the wide range of 2–10 Gyr, and it is only slightly dependent on metallicity (Udalski 1998a,b). The latter correction is not important in this case because of practically homogeneous environment of field stars in the LMC (Bica *et al.* 1998). Thus, the mean brightness of red clump stars can be a very good reference of brightness for monitoring extinction. Similar method was used by Stanek (1996) for determination of extinction map of Baade's Window in the Galactic bulge.

The reddening in the LMC was determined in 84 lines-of-sight. We divided each of our 21 2048×8192 pixel fields to four 2048×2048 pixel subfields (subfield 1: $0 < y < 2048$, etc.). In each of the subfields we determined the mean observed I -band magnitude of red clump stars with technique identical to that described in Udalski *et al.* (1998a). Differences of the observed I -band magnitudes were assumed as differences of the mean A_I extinction. We converted differences of A_I extinction to differences of $E(B - V)$ reddening assuming the standard extinction curve: $E(B - V) = A_I/1.96$ (Schlegel *et al.* 1998).

The zero points of our reddening map were derived based on previous determinations in three lines-of-sight, two of them using OB-stars. These determinations included determination of reddening around two LMC star clusters: NGC1850 ($E(B - V) = 0.15 \pm 0.05$ mag, based on UBV photometry, Lee 1995) and NGC1835 ($E(B - V) = 0.13 \pm 0.03$ mag, based on colors of RR Lyr stars, Walker 1993) and determination based on OB-stars in the field of the eclipsing variable star HV2274 (Udalski *et al.* 1998c). All these zero points were consistent with our map to within a few thousands of magnitude.

We also checked the absolute calibration of our map comparing the observed I -band magnitude of red clump stars with extinction free magnitude determined from a few star clusters in the halo of the LMC (Udalski 1998b). We additionally checked the value of extinction free magnitude of red clump stars in the LMC by its new determination from the field stars around the same clusters. Resulting value was consistent to within 0.01 mag with star cluster red clump determination. The calibration *via* extinction free magnitude of red clump stars gave somewhat larger

LMC_SC21	0.133	0.152	0.145	0.146

zero point of the $E(B - V)$ reddening – by about 0.02 mag which we adopt as the error of our map. The final $E(B - V)$ reddening in 84 lines-of-sight in the LMC is listed in Table 2. Interstellar extinction in the BVI bands was calculated using the standard extinction curve coefficients (*e.g.*, Schlegel *et al.* 1998):

$$\begin{aligned} A_B &= 4.32 \cdot E(B - V), \\ A_V &= 3.24 \cdot E(B - V), \\ A_I &= 1.96 \cdot E(B - V). \end{aligned}$$

4.3. Astrometry

Equatorial coordinates of all candidates were calculated based on transformation derived with the Digitized Sky Survey images. Details of procedure are described in Udalski *et al.* (1998b). About 2800–7400 stars common in OGLE and DSS images (depending on stellar density of the field) were used for transformation. Internal accuracy of the equatorial coordinates is about 0.15 arcsec with possible systematic errors of the DSS coordinate system up to 0.7 arcsec.

4.4. Fourier Parameters of Light Curve Decomposition

For each object we derived Fourier parameters $R_{21} = A_2/A_1$ and $\phi_{21} = \phi_2 - 2\phi_1$ of the Fourier series decomposition of I -band light curve. A_i and ϕ_i are the amplitudes and phases of $(i - 1)$ harmonic of the Fourier decomposition of light curve. Parameters R_{21} and ϕ_{21} are often used for analyses of pulsating variable stars and for discrimination between objects pulsating in different modes.

We fitted the fifth order Fourier series to the magnitude scale I -band light curve. In the case of objects with almost sinusoidal light curve for which the first harmonic amplitude and phase were not statistically significant, $R_{21} = 0$ and ϕ_{21} is not defined.

4.5. Classification

Based on the Period–Luminosity (P – L) diagram constructed for the extinction insensitive index W_I we divided all objects into four groups: classical Cepheids pulsating in the fundamental mode (FU), classical Cepheids pulsating in the first overtone mode (FO), objects brighter than FO mode Cepheids (BR) and objects

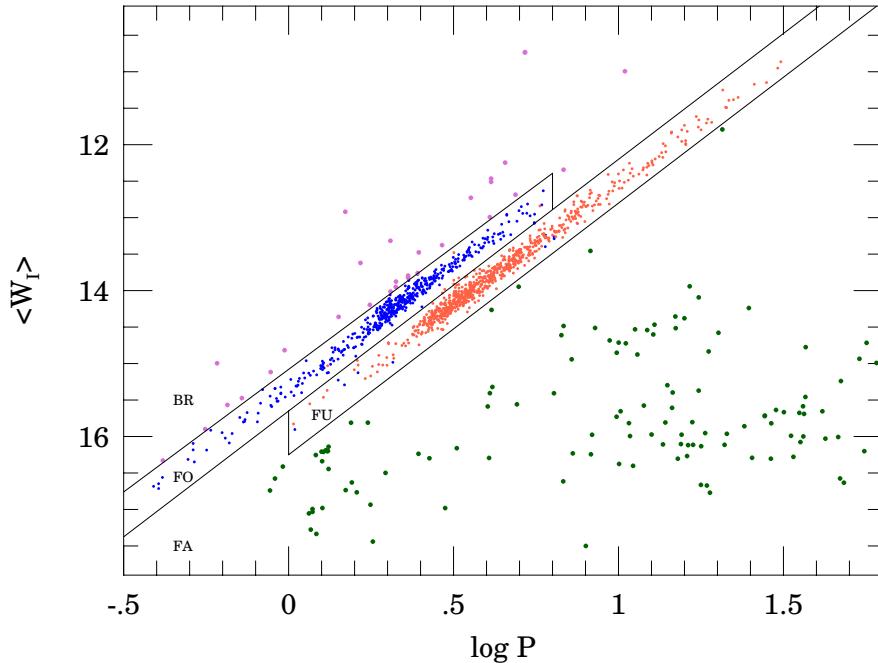

Fig. 2. Period–Luminosity relation for extinction insensitive index W_I . Contours divide the diagram into sections where fundamental (FU) and first overtone mode (FO) classical Cepheids are found. Section denoted by BR indicates region where objects were classified as brighter than FO Cepheids and by FA – as fainter than FU Cepheids. Small dots mark positions of objects finally classified as FU and FO classical Cepheids (light and dark dots, respectively). Larger dots – BR (light dots) and FA (dark dots) objects.

fainter than FU mode Cepheids (FA). Fig. 2 presents P – L diagram for the W_I index with boundaries of these four regions.

Due to very good accuracy of photometry and features of the W_I index, which removes simultaneously effects of extinction and color dependence of the Cepheid P – L relation, the separation between the FU and FO Cepheids is remarkable. Nevertheless, we also checked location of all selected FU and FO Cepheids in the R_{21} and ϕ_{21} vs. $\log P$ diagrams. It is well known that such diagrams allow to separate between the FU and FO mode pulsators (*cf.* Alcock *et al.* 1999, Udalski *et al.* 1999a). Sequences for FU and FO Cepheids in both diagrams, in particular R_{21} vs. $\log P$, are well separated and in most cases classification is straightforward. However, in a few period ranges the sequences almost overlap (for $0.6 < \log P < 0.8$ in the R_{21} vs. $\log P$ diagram and $0.2 < \log P < 0.4$ and $\log P \approx 0.75$ in the ϕ_{21} vs. $\log P$ diagram). Therefore we checked light curves of all objects located in these regions to confirm classification indicated by position in the P – L diagram. Also all objects located in opposite mode sequences than indicated from P – L position were inspected. In about 20 cases the classification was changed. In eight cases those were FU objects blended with other stars and therefore shifted to FO Cepheids in the P – L diagram. In eleven cases – FO mode stars shifted to FU objects in the P – L diagram of the W_I index because of high reddening, blends with blue stars etc. Fig. 3 presents the final R_{21} vs. $\log P$ and ϕ_{21} vs. $\log P$ diagrams for all objects classified as FU and FO mode classical Cepheids.

5. Catalog of Cepheids from the LMC

1402 objects passed our selection criteria described in Section 3. Among candidates for Cepheids in the LMC a subsample of double-mode classical Cepheids containing about 70 objects was extracted. These objects will be presented in a separate paper of this series. The remaining Cepheid candidates are listed in Table 3.

The first column of Table 3 is the star identification: *field_name star_number*. In the next columns the equatorial coordinates, RA and DEC (J2000), period in days and moment of the zero phase corresponding to maximum light are given. Then follow intensity mean IVB photometry supplemented by extinction insensitive index W_I and the mean interstellar reddening in object direction. In the next two columns Fourier parameters, R_{21} and ϕ_{21} , of the light curve decomposition are listed. Finally, in the last column classification of the object is provided.

Table 3 contains 1435 entries but only 1333 objects: 102 stars were detected twice – in overlapping parts of adjacent fields. Table 4 provides cross-identification of all such objects including for completeness three double-mode Cepheids not presented in this paper and not listed in Table 3.

The I -band light curves of all objects are presented in Appendices A–U. The ordinate is phase with 0.0 value corresponding to maximum light. Abscissa is the I -band magnitude. The light curve is repeated twice for clarity.

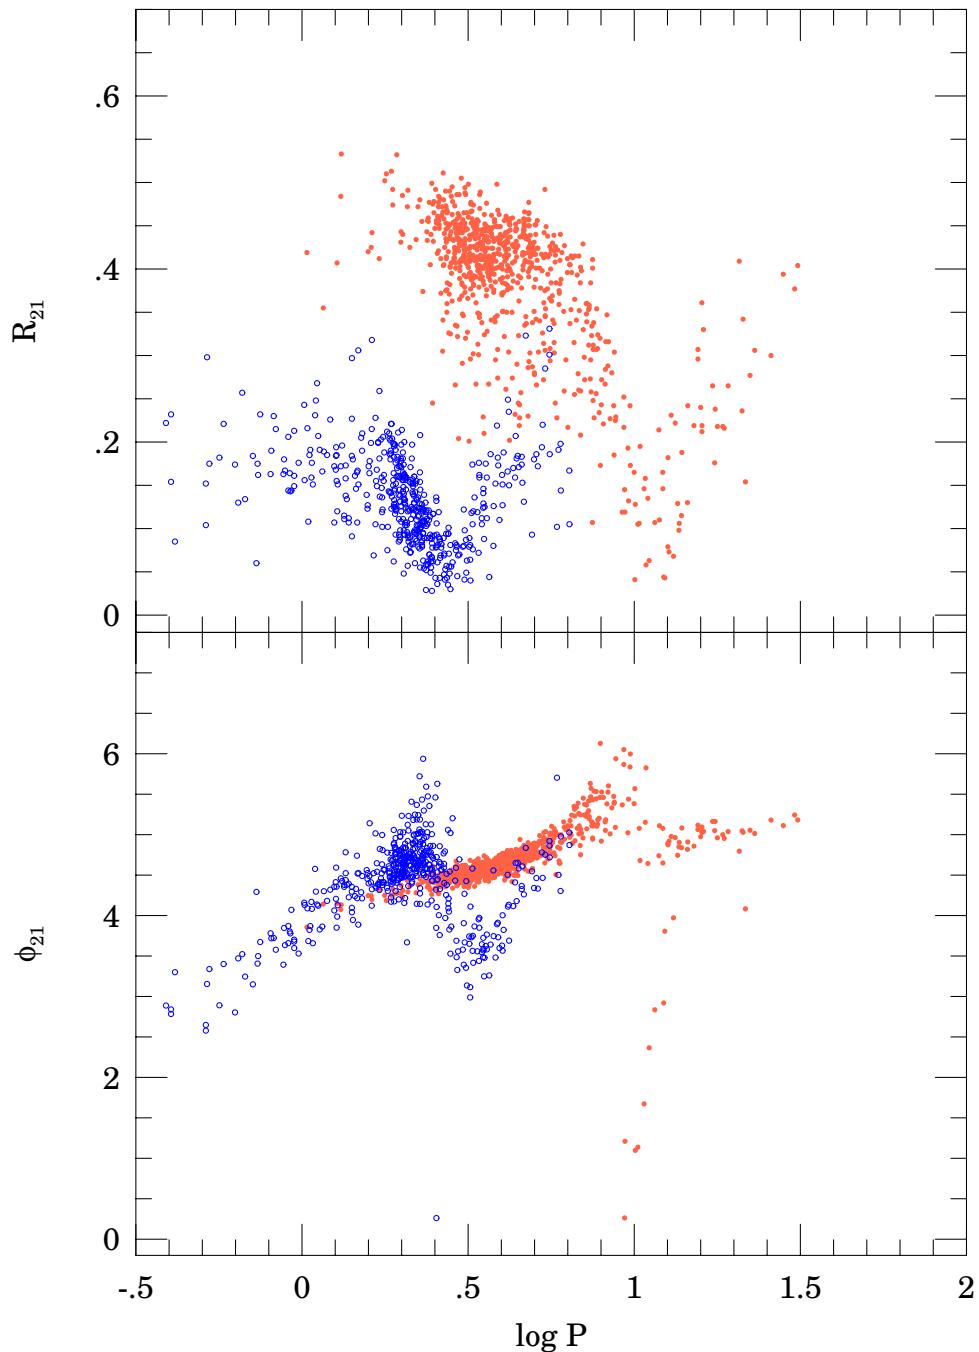

Fig. 3. R_{21} and ϕ_{21} vs. $\log P$ diagrams for single-mode classical Cepheids from the LMC. Dark open circles indicate positions of first overtone Cepheids while light dots positions of fundamental mode pulsators.
