## FOREWORD

The work reported herein was done at the request of the USAF School of Aerospace Medicine (SAM) (SMBEC), for the Aerospace Medical Division (AMRM), Air Force Systems Command (AFSC), under Program Element 62405154/7930.

The results of tests presented were obtained by ARO, Inc. (a subsidiary of Sverdrup & Parcel and Associates, Inc.), contract operator of the Arnold Engineering Development Center (AEDC), AFSC, Arnold Air Force Station, Tennessee, under Contract AF 40(600)-1200. The test was conducted under ARO Project No. TG0609 from March 14 through April 10, 1966. The manuscript was submitted for publication on January 9, 1967.

The author wishes to express appreciation to C. Baker, T. R. Hester, F. E. Hood, D. E. McCord, and J. I. Brown for assistance in analysis, sample preparation, and data assimilation associated with this test. The author takes this opportunity to thank also J. A. Baltz, formerly of ARO, Inc., for his aid and assistance in the early phases of the program.

Information in this report is embargoed under the Department of State International Traffic in Arms Regulations. This report may be released to foreign governments by departments or agencies of the U. S. Government subject to approval of School of Aerospace Medicine (SMBEC), or higher authority within the Department of the Air Force. Private individuals or firms require a Department of State export license.

This technical report has been reviewed and is approved.

**ABSTRACT**

Details of transferring and concentrating contaminants from 150-cc stainless steel cryogenic traps to small volume glass traps more suitable to trace analysis and gas chromatographic equipment used in analysis, along with analysis procedures used, are presented. The chromatographic instrumentation, calibrations, and data assimilation procedures are described. Basic test results and observations concerning the utility of procedures used, along with comparative discussions of various aspects of Phase II compared with Phase I, are noted.

## SECTION I INTRODUCTION

Beginning March 14, 1966, and continuing for 28 consecutive days, a sample set consisting of three 150-cc stainless steel sample bottles (Fig. 1, Appendix I) was used by SAM to cryogenically trap trace contaminants from the atmosphere of closed ecological systems. The bottles were connected in series and maintained respectively at 0, -78, and -175°C. After a trapping interval consisting of continuous circulation of the ecological atmosphere through them, the bottles were valved off, removed from the system, packed in dry ice, and shipped by air freight to AEDC for analysis.

The samples, aside from the trace contaminants which can generally be assumed to be hydrocarbon in nature, contained varying amounts of CO<sub>2</sub>, H<sub>2</sub>O, and other common gases, but only the trace contaminants and CO<sub>2</sub> were of interest. The primary purpose in analysis was to determine the total mass trapped for each constituent of interest. This need generated requirements for sample transfer equipment which would concentrate contaminants and facilitate the measurement of the total mass trapped by use of standard temperature and pressure (s.t.p.) volume measurements and also weight measurements, and from which samples could be removed for quantitative analysis by gas chromatography.

## SECTION II ANALYTICAL APPARATUS

Analysis during Phase I of this program was accomplished by flame ionization gas chromatography in conjunction with time-of-flight mass spectrometry; analysis by mass spectrometer was on a portion of the total sample at a slow scan rate. However, the relatively small amount of information gained by mass spectrometry, the rather large amount of sample required for mass spectrometer analysis, and the generally superior sensitivity of flame ionization chromatographic analysis over mass spectrometer analysis under these circumstances indicated a shift in emphasis in analytical techniques.\* Therefore, analysis during Phase II of this program was confined to gas chromatography.

## 2.1 SAMPLE PROCESSING APPARATUS

A schematic and photograph of the sample transfer apparatus as used in this test are shown in Fig. 2. Design of this system was a result of experience gained during Phase I of this program. It is essentially a system for measuring the total gas trapped at s.t.p. for individual samples, with provision for removal of trapped portions of the sample for chromatographic analysis via removable glass traps. The system was all glass except for metal portions on each side of the sample trap which connected the sample bottle and transducer to the system on the inlet side and the hypodermic needle to the system on the outlet side.

Sample transfer was accomplished by slowly evacuating gas trapped in the sample bottles through an LN<sub>2</sub> sample trap throttled at the outlet with a hypodermic needle. The bypass line to the sample trap was used only to aid in initial and final evacuation procedures. Sample traps (Fig. 3) themselves were approximately 6 in. long and constructed of 10-mm-ID Pyrex<sup>®</sup> tubing with attached rubber septum arms; indentations in the tubing near the outlet side acted as baffles against carryover of the sample. From just beyond the hypodermic needle to the 0 position of the constant-volume manometer, the entire system was composed of capillary tubing. This held the dead space of the system to a minimum and allowed maximum concentration of sample in the sample traps. However, in the case of samples with large amounts of CO<sub>2</sub> (Fig. 4), the mercury burets were used to keep the pressure of the system within the pressure range of the constant-volume manometer. During the evacuation procedure the pressure transducer was used to monitor the rate of evacuation. The entire transfer procedure depends upon all contaminants being removed from the gas stream flowing through the LN<sub>2</sub>-cooled sample trap. This, of course, from vapor pressure versus temperature considerations, is not strictly true, but the utility of the procedure, combined with the lack of interest in the permanent gases present in the sample other than CO<sub>2</sub>, the fact that trapping conditions in sample collecting by SAM had a lower limit of -175°C, and the absence of more sophisticated procedures, designated the process as a workable one.

After complete transfer of a sample to a sample trap, and following s.t.p. measurements (Fig. 5), the traps were removed from the system and weighed; liquid (Fig. 6) and gaseous portions of the samples were then removed from the traps via the septums with hypodermic syringes for gas chromatographic analysis.

## 2.2 CHROMATOGRAPHS AND ASSOCIATED EQUIPMENT

Chromatographic equipment used in this test included an F & M Scientific Corporation Model 720 dual column, programmed-temperature gas chromatograph equipped with a Model 1609 flame ionization detector and an F & M Model 810 Research Chromatograph with dual flame ionization detectors and automatic temperature programming recycler. Schematics and photographs of the Models 720 and 810 appear in Figs. 7 and 8, respectively. The chromatographs were in turn hooked up to an Infotronics Corporation Model CRS-11HSB digital readout system equipped with a serial-entry digital printer (Fig. 8b).

The F & M Model 810 served as the principal analytical tool and contained two 6-ft-long, 1/8-in.-OD stainless steel columns packed with 10 percent silicone gum rubber on Chromosorb W. Operating parameters for this instrument, as well as for all others used in this test, were experimentally determined by synthetic standards to be those which would yield best overall results in the analysis of SAM samples and are listed in Table I (Appendix II).

The F & M Model 720 was used in both the flame ionization and the thermal conductivity modes of operation. The flame ionization unit served as a complementary analytical tool to the Model 810 and contained a 24-ft-long, 1/4-in.-OD stainless steel column packed with 10 percent Carbowax 20 M on Chromosorb W. Whereas the silicone gum rubber column is more suitable for analysis of nonpolar materials, the Carbowax 20 M column is more suitable for polar materials and as such provided information which served to resolve insufficiencies in the Model 810 analysis, e.g., lack of resolution between certain pairs of compounds such as diethyl ether and isopropyl alcohol, acetaldehyde and methanol. One disadvantage and peculiarity of the Carbowax 20 M column was that gas samples could not always be run because of attendant instability of operation; therefore, in a number of cases liquid samples only were analyzed on this column. Independent analyses of SAM samples by two separate instruments was also useful as a crosscheck on the effectiveness and utility of analytical procedures on a day-to-day basis. Operating parameters of the 720 in the flame ionization mode are listed in Table II.

The thermal conductivity unit of the Model 720 was used to determine the CO<sub>2</sub> content of the samples. It contained a 12-in.-long, 1/4-in.-OD copper tube column packed with high activity silica gel. Operating parameters of the 720 in the thermal conductivity mode are listed in Table II.

The output of the Model 720 in both modes of operation and the Model 810 was fed to the digital readout system which provided automatic printing of peak integrals in numerical form along with elapsed time to peak crest retention times. Instrument settings of the readout system were selected for consistency with trace analysis requirements and are listed in Table III.

### SECTION III CHROMATOGRAPH CALIBRATIONS

The exact nature and number of hydrocarbon or other type of compounds to be expected in the cryogenic samples was not known exactly, but Phase I of this test - in which 30-odd compounds were found - served as a guide for the general types of structures to be expected; these included olefinic and aromatic hydrocarbons, cyclic, branched, and normal paraffins as well as alcohols, aldehydes, ketones, halogenated hydrocarbons, esters, ethers, and heterocyclic compounds. In all, 81 compounds were catalogued as to sensitivity and retention time on the 810 and 14 on the 720. These values are catalogued in Tables IV and V, respectively.

Standard mixes were prepared by making either a water solution of the compound of interest in 1-ℓ (volumetric) flasks or by injecting a known weight of pure liquid or known volume of pure gas into an evacuated 34-ℓ surplus oxygen tank (Fig. 9). Concentrations were 0.0001 mg/μℓ in the case of liquid mixes and 0.0002 mg/cc in the case of the gas mixes. As many as ten components were mixed in the gas phase and seven in the liquid phase. Gas mixes, after the desired components were injected into the evacuated tank, were brought to atmospheric pressure with helium and homogenized by running hot water over one end of the tank for 16 hr. Table VI contains typical quantitative data obtained from two calibration mixtures on the Model 810, and Figs. 10 and 11 show the chromatographic trace of these mixtures. Table VI and Fig. 12 show similar data from the Model 720.

### SECTION IV ANALYTICAL PROCEDURES

#### 4.1 SAMPLE TRANSFER

The analysis of each SAM sample started with the installation of the sample bottle on the transfer apparatus and

proceeded thereafter as follows:

1. System Evacuation - With stopcocks 1 and 3 open, stopcocks 2 and 4 closed, the mercury raised in all burets, and the mercury down in the constant-volume manometer, the system was evacuated using a mechanical pump system, flamed where necessary.
2. Leak Check - With all stopcocks closed, the system was checked for leaks by monitoring the readout of the pressure transducer.
3. Sample Transfer - With the transfer system evacuated and stopcocks 1, 2, 3, and 4 closed, the sample trap was cooled to LN<sub>2</sub> temperature, and the valve on the SAM sample bottle slowly cracked to permit transfer of the sample. The pressure transducer was used to monitor system pressure during transfer; pressure rise was limited to 10 or 20 mm/min.
4. Air Removal - After the system pressure had stopped rising - as indicated by the transducer - and with the valve on the SAM sample bottle open, air in the system was slowly pumped out by opening stopcock 3. At the same time, the sample bottle was heated gently and finally, after the system had reached a pressure of several millimeters, stopcock 1 was opened to aid in the final evacuation of air.
5. S.T.P. and Weight Measurements - After stopcocks 1 and 3 were closed, the mercury was raised in the constant-volume manometer and the sample trap isolated from the rest of the system except via the hypodermic needle by sealing off and separating with a torch the upper arms of the trap at marked points of constriction. The LN<sub>2</sub> dewar was then lowered away from the sample trap and the trap allowed to warm. The mercury in the constant-volume manometer was continually adjusted to compensate for pressure changes as the trap warmed. If the sample contained larger amounts of CO<sub>2</sub> than could be handled in the capillary portion of the system, the mercury in the calibrated burets was lowered to maintain between 800 and 900 mm of Hg. If the sample contained only a small amount of CO<sub>2</sub> and the resulting pressure on warming was below atmospheric, gaseous helium (GHe) was introduced through stopcock 4 to bring the pressure to between 800 and 900 mm in the system.

After all adjustments were final and the volumes and pressures noted, the trap was removed from the system

by pulling the rubber septum off the connecting hypodermic needle. The system was vented by closing stopcock 3 and slowly opening stopcock 2. The traps were then weighed and the mass of liquid (assumed to be H<sub>2</sub>O) was calculated by subtracting the empty weight of the trap, determined after analysis and adjusted for the difference in density between CO<sub>2</sub> or He and air as appropriate.

The system was then readied for another sample by sealing a new trap with a known volume in the system with the hypodermic needle inserted through the rubber septum on the side of the trap containing baffles.

#### 4.2 CHROMATOGRAPH ANALYSIS PROCEDURE

Portions of liquid, where present, and gas were removed via the rubber septums for analysis. Sample sizes were always 2  $\mu$ l of liquid and 1 cc of gas. Liquid samples were removed first to maintain equilibrium as much as possible. By using the calibration data in Tables IV and V and the determined weights and volumes for each sample, peak identification was made for resulting chromatograms.

### SECTION V TEST RESULTS AND TYPICAL CHROMATOGRAMS

In keeping with basic test requirements, the total mass trapped of each quantitatively identified compound in each SAM sample is reported in Table VII. Quantities are identified in both the liquid and vapor phases along with the totals for each set. For cases where identifiable peaks were too small to be integrated, the designation for quantity found is <0.00001 mg. Included under remarks are short statements concerning all peaks not identified for each set of samples.

Figures 13 through 15 show typical background effects of CO<sub>2</sub>, H<sub>2</sub>O, and temperature programming; these were taken into account in the analysis of chromatograms. Peaks are identified numerically according to retention data taken from Tables IV and V. Shown in Figs. 16 through 22 is a set of chromatograms taken on a typical set of SAM samples.

## SECTION VI CONCLUSIONS

Perhaps the most satisfactory procedure during Phase II of this program was that of transferring samples from SAM sample bottles to the glass traps used in analysis. This transfer procedure was eminently satisfactory in all cases and, aside from some questions such as uniform mixing of gases, provides a basic design which could be further improved and used in this or other similar types of analysis.

In Phase I of this program some 20-odd compounds were identified. With improved instrumentation and techniques, Phase II showed many more materials than this to be present, but with increasing complexity of sample composition positive identification of components using retention data alone becomes insufficient and identification leans more toward judgement-type data than is desirable. The use of two chromatographs utilizing different column materials helped to alleviate this problem, but it is felt that a split of sample as it leaves the chromatograph analyzing column with a portion of the material going to the flame detector and a portion to a direct-hookup, fast scanning, high resolution, high sensitivity, mass spectrometer would do much toward refining the analysis beyond empirical techniques.

One other detail of analysis which would remove or alleviate much struggle would be to transfer calibration data to a computer program and log sample results by any of a number of techniques for analysis by computer. Under the present technique this would not work because of the many judgements which must be made in analyzing a chromatographic trace of a sample, but if this could be used in conjunction with a successful mass spectrometer direct hookup as previously indicated, it shows much promise.

13 ABSTRACT Details of transferring and concentrating contaminants from 150-cc stainless steel cryogenic traps to small volume glass traps more suitable to trace analysis and gas chromatographic equipment used in analysis, along with analysis procedures used, are presented. The chromatographic instrumentation, calibrations, and data assimilation procedures are described. Basic test results and observations concerning the utility of procedures used, along with comparative discussions of various aspects of Phase II compared with Phase I, are noted.

INSTRUCTIONS

1. **ORIGINATING ACTIVITY:** Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (*corporate author*) issuing the report.
- 2a. **REPORT SECURITY CLASSIFICATION:** Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.
- 2b. **GROUP:** Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.
3. **REPORT TITLE:** Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.
4. **DESCRIPTIVE NOTES:** If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.
5. **AUTHOR(S):** Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.
6. **REPORT DATE:** Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.
- 7a. **TOTAL NUMBER OF PAGES:** The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.
- 7b. **NUMBER OF REFERENCES:** Enter the total number of references cited in the report.
- 8a. **CONTRACT OR GRANT NUMBER:** If appropriate, enter the applicable number of the contract or grant under which the report was written.
- 8b, 8c, & 8d. **PROJECT NUMBER:** Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.
- 9a. **ORIGINATOR'S REPORT NUMBER(S):** Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.
- 9b. **OTHER REPORT NUMBER(S):** If the report has been assigned any other report numbers (*either by the originator or by the sponsor*), also enter this number(s).
10. **AVAILABILITY/LIMITATION NOTICES:** Enter any limitations on further dissemination of the report, other than those

imposed by security classification, using standard statements such as:

- (1) "Qualified requesters may obtain copies of this report from DDC."
- (2) "Foreign announcement and dissemination of this report by DDC is not authorized."
- (3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through \_\_\_\_\_."
- (4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through \_\_\_\_\_."
- (5) "All distribution of this report is controlled. Qualified DDC users shall request through \_\_\_\_\_."

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. **SUPPLEMENTARY NOTES:** Use for additional explanatory notes.
12. **SPONSORING MILITARY ACTIVITY:** Enter the name of the departmental project office or laboratory sponsoring (*paying for*) the research and development. Include address.
13. **ABSTRACT.** Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. **KEY WORDS:** Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional.
