1 Introduction

With more than 20 years of experience in the development of spatial light modulators (SLM) and the cooperation with our partners, HOLOEYE offers products that are used world-wide in many different types of industrial and R&D applications. We are constantly working on the enhancement of our technology and look for possibilities to enable or adapt to new applications where HOLOEYE products can play a significant role.

HOLOEYE SLMs are based on 2D reflective liquid crystal on silicon (LCoS) displays with standard video resolutions. The optical and electrical anisotropy of the used LC material allows for us to modulate the phase or polarization in space and time, depending on the incident polarization orientation and applied voltage across the LC cell. Those properties make the SLM a powerful tool for various applications in the field of adaptive optics.

In this document, we will focus on our reflective phase only SLM devices. The first part includes a short overview about the most relevant SLM parameters and how they are determined at HOLOEYE. The 2nd part will focus on applications.

Figure 1: HOLOEYE Spatial Light Modulator product range

2 Spatial Light Modulator Characterization

This chapter deals with the main parameters for a phase only SLM including: phase modulation depth, stability, wave front quality, diffraction efficiency and tolerance to high power/energy illumination. We will provide a short overview about measurement principles, setups, and calibration processes for the most efficient usage.

2.1 Phase Calibration

HOLOEYE SLM products are suitable for different wavelength ranges and applications. Differences are within anti reflection and dielectric mirror coatings, and LC cell thickness for adapted phase retardation depth as well as used LC materials. An exact knowledge of the phase modulation characteristics is essential to be able to generate phase calibration curves for defined modulation requirements.

To measure the phase modulation characteristics of our reflective phase only SLMs, we use a common path interferometer (Fig 1) in combination with a fast 1D camera that can detect sub frame phase modulation with a frequency of 20 kHz. This fast time resolved phase measurement is essential since all HOLOEYE devices use fast full digital addressing.

The digital addressing also assures high reliability and a compact driver unit as basically only two voltages need to be generated. Full digital addressing leads to slight phase flicker effects that need to be investigated in order to design an optimal LC cell architecture and driving sequences for a most stable phase response.

Figure 2: Optical interferometric setup for phase calibration and linearization of Spatial Light Modulators

Phase calibration and linearization of Liquid Crystal on Silicon Spatial Light Modulators is realized with interferometry setup presented in Figure 2.

The following figures show typical measurement results of the phase calibration process. On figure 2, typical phase modulation curves are presented including max phase depth (blue curve), adapted Voltage settings for $\sim 2\pi$ modulation (green curve) and the gamma corrected response for a linear 2π phase modulation curve, which is the recommended SLM setting for most applications.

Figures 4, and 5 show the related time resolved sub frame phase response with phase flicker values for the SLM settings in figure 3.

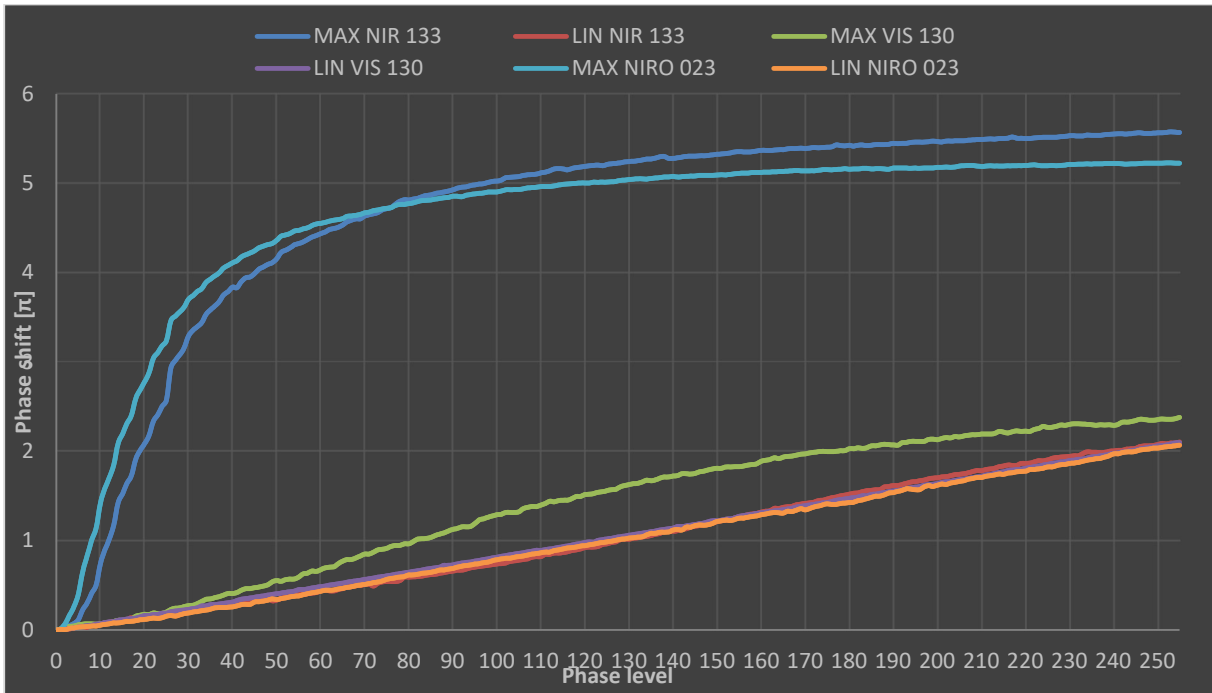

Figure 3. Phase shift calibration and final linearization measurements with PLUTO-2.1 for NIR 133, VIS 130 and NIRO 023 displays.

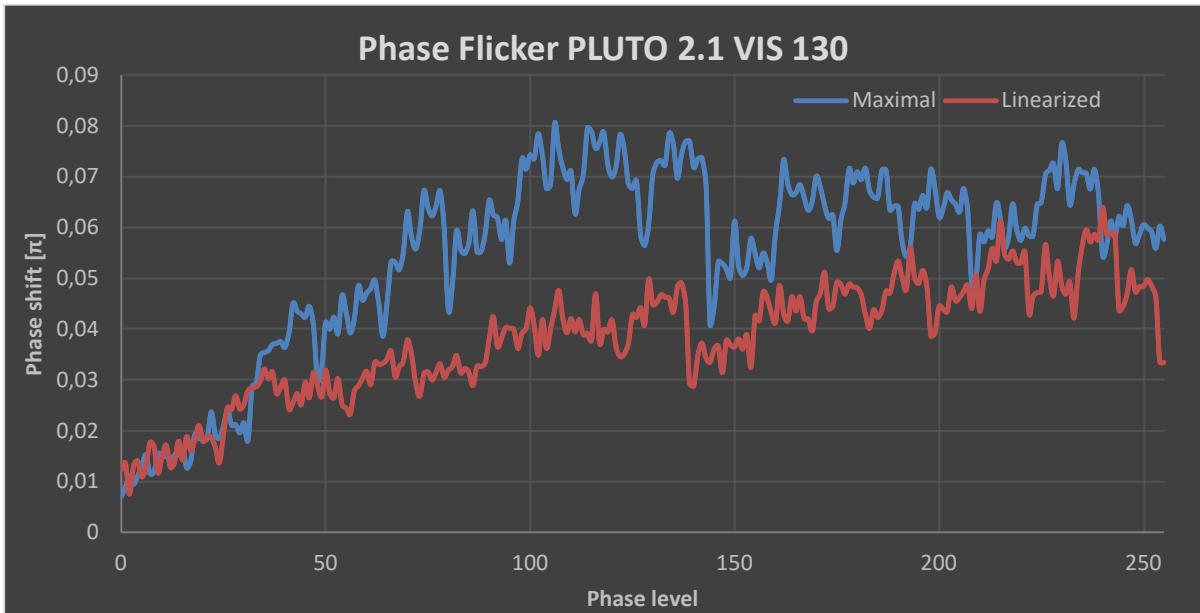

Figure 4. Phase flicker (peak to peak) calibration measurements for @520 nm with PLUTO 2.1 VIS 130

Figure 5. Phase flicker (peak to peak) calibration measurements for @1064 nm with PLUTO 2.1 NIRO 023

As one can see, the phase calibration process allows to adjust the SLM modulation characteristics for optimal performance. Linear response with desired phase shift reduces phase flicker to possible minimum values.

All presented measurements have been performed for an LCOS temperature of 30°C. Since LC viscosity is temperature dependent, temperature management provides a further degree of freedom for stabilizing the phase response. Chapter 4 includes information on an available HOLOEYE temperature management system (TMS).

2.2 Wavefront Compensation

Due to the fabrication process, the backplane of the Liquid Crystal on Silicon display is inherently not flat. This can introduce aberrations to a light beam and influence efficiency and wave front quality. Due to the nature of a 2D phase only SLM, the device is able to compensate its own flatness imperfection by addressing a compensation function. It is of great interest to characterize this wave front error and generate the corresponding compensation function.

The characterization process at HOLOEYE utilizes a Shack Hartman Sensor (SHS) and a customized Twyman-Green Interferometer (TGI). This allows for verification display deformation with two different methods, to compare data values. While the SHS setup is mainly used for a quick incoming inspection, the TGI setup is more accurate, applying a high resolution CMOS camera and a piezo steered moveable mirror for the phase shifting process.

Our TGI setup is used to generate wave front compensation functions to correct for the inherent LCoS backplane deformation as well as the ability to measure and compensate possible LC gap variations. A step-by-step description of the compensation process is presented below. Figure 6 shows the TGI setup and figure 7 shows a 3D example of reflected wave fronts before and after compensation. Figure 8 illustrates a 2D visualization (including some characterizing values) and resulting point spread functions (PSF) before and after correction.

Figure 6: Optical setup for wavefront calibration based on Twyman Green interferometer.

Figure 7. Measured wavefront before and after compensation for PLUTO 2.1 VIS 014. Peak Value improved from 680 nm to 103nm. RMS corrected from 108 nm to 12 nm.

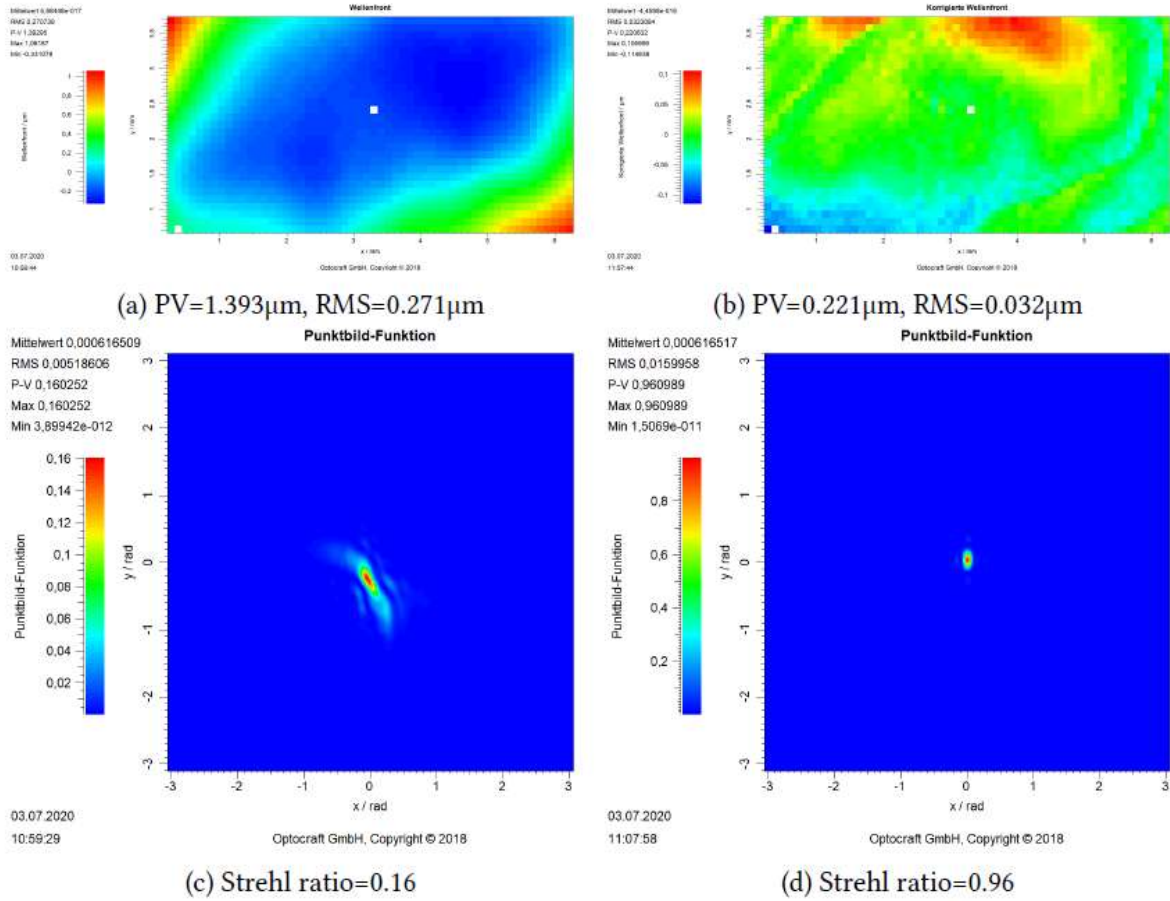

Figure 8: Wavefront and Point Spread Function measured with SHS before (a, c) and after (b, d) compensation Presented data for PLUTO 2.1 VIS 014.

An example for the impact of the compensation on the wavefront and Point Spread Function can be seen in Figure 8. Since the display has a rectangular shape, we observe an elliptical shape of the corresponding PSF. The reduction of the RMS value (from $\lambda/2$ to $\lambda/30$) and the improvement of the Strehl ratio (from 0.16 to 0.96) are considerable.

Within a production run it may occur that one of displays shows an exceptional strong deformation. But even those, strong deformations can be compensated successfully, as figure 9 demonstrates.

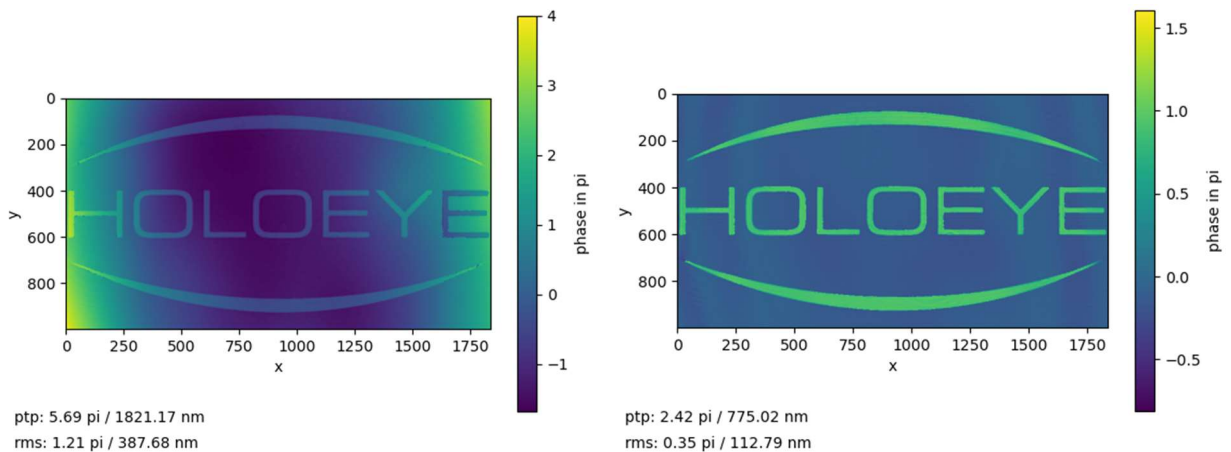

Figure 9: HOLOEYE Logo with 1π step height displayed on a spatial light modulator with strong deformation caused by production run before compensation (left) and after curvature only compensation (right).

2.3 Diffraction efficiency camera setup

2D Phase modulators can act as dynamic diffraction gratings which generates arbitrary light distributions. The simplest grating is an on-off binary (Ronchi) grating that diffracts the light in the optimal case, into a plus and a minus first diffraction order with similar intensities. The next complicated grating is a prism- or blazed grating that diffracts the light ideally in only one diffraction order. The diffraction angle depends upon the grating period and orientation, enabling a flexible beam deflection. Both simple grating versions can be used to characterize the quality of a phase only SLM and its calibration.

With an iterative Fourier algorithm, complex calculation gratings, also called computer generated holograms. (CGH) generate multiple diffraction orders which result in a 2D intensity pattern in the Fourier plane of a lens. This will be the central topic of chapter 1 in the Applications section. We will focus on the mentioned simple gratings. To measure the diffraction efficiency, we use the simple setup shown in Figure 10. The main part is a high level CCD camera with a high linearity over a wide dynamic range that is usually meant for astronomical investigations.

Results obtained with this CCD camera based setup can be a useful reference for our customers and help with quality control, the development process, and generation of optimal driving sequences and calibration data. A high degree of automation for this setup is reached by using customized software based on the HOLOEYE Software Development Kit (SDK) and provides the ability to compare different settings of our devices and optimize configurations for a wide range of wavelengths.

Figure 10: Diffraction efficiency setup based on a CCD camera.

Values presented in Figure 11 have been determined for 4, 8, 16 and 32 level blazed gratings at 450nm, 520nm, 637nm, 800nm, 1060nm, 1300nm and 1550nm with 9:5 sequence configuration and linearized phase response for PLUTO displays.

Data chosen for suitable HOLOEYE products depends upon the operating wavelength. Diffraction efficiency values in the figure below are seen at the 0th order of uniform phase as a reference (100%)

Figure 11: Measured diffraction efficiencies of the 1st order of blazed gratings with different spatial frequencies for defined wavelengths.

2.4 Spatial Light Modulators for high power applications

Nowadays more and more applications require high power light sources. For a manufacturer it is a challenge to develop and to investigate suitable LCoS phase only display versions that can handle various types of high power and high energy lasers.

HOLOEYE designs special versions for high power use, which are equipped with a dielectric mirror coating on top of the pixel electrodes. This reduces absorption in the inter-pixel gap and diffraction losses, what leads to higher light efficiency. Due to less absorption, these display versions could be used with higher incident laser power compared to the standard versions. High average power above a couple of $10\text{W}/\text{cm}^2$ can still lead to a heating of the LCoS display and coupled heat should be dissipated in order to assure long life time. HOLOEYE therefore offers Thermal Management Systems (TMS) that are designed for and tested with our devices in many laboratories around the world.

HOLOEYE SLMs designed for High Power applications are equipped with a dielectric mirror coating (DMC). The reflectivity for each display is optimized for the design wavelength range. Using a reflectance setup based on a white light source and a spectrometer we can provide precise data for a broadband spectrum. In Figure 12, one can see results for three phase only LCoS display versions with DMC optimized for high reflectivity and low absorption in different wavelength ranges

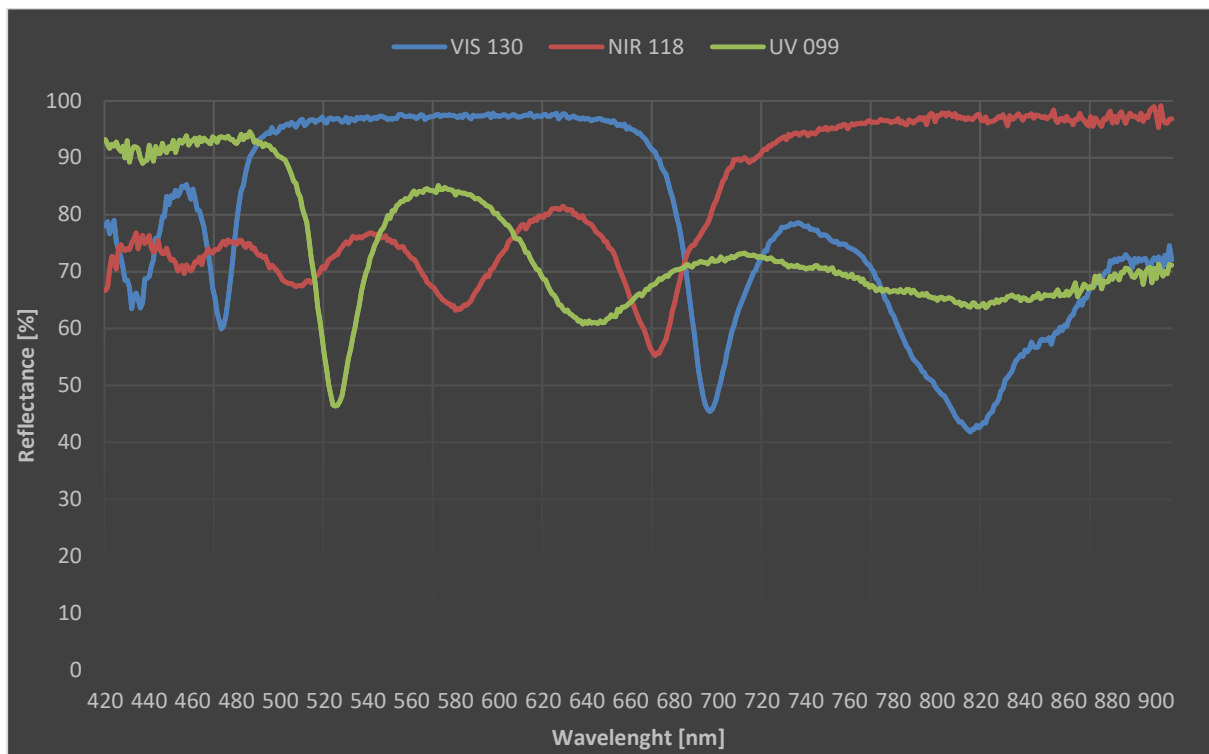

Figure 12: Wavelength dependence of the reflectance for three PLUTO-2.1 versions designed for specific wavelength ranges.

Besides reduced absorption it is of course essential to investigate the compatibility to high power and high energy light sources experimentally, what will be discussed in the following chapter.

Laser-induced damage (LID) is defined as any permanent laser radiation induced change in the characteristics of the surface/bulk of the specimen which can be observed by an inspection technique and at a sensitivity related to the intended operation of the product. Laser-induced damage threshold (LIDT) is defined as the highest quantity of laser radiation incident upon the optical component for which the extrapolated probability of damage is zero.

LID of the sample is investigated by performing a standardized S-on-1 test procedure. A LIDT value is determined by taking the average of the highest fluence value before no damage was observed and the lowest fluence value at which damage was first observed.

Those standard S-on-1 tests give a good indication of maximal power levels. However, those tests are usually done and useable for passive optical components and characteristic material damage can be determined. But absorption within the LC layer can lead to a change of characteristics before a visual physical damage occurs.

Such effects are usually also accumulative and irreversible damage can happen at lower powers after a certain time of irradiation. It is therefore of great importance to investigate the SLM characteristics while illuminating with high power / energy levels during operation to determine maximal power levels for long time exposure.

In this context it is important to us to check how our products perform under “real-life conditions”, by investigating the threshold upon which the functionality is still given. In the case of a LC-SLM we define the breakdown by a significant drop of diffraction efficiency (change of more than 10%).

Table 1 contains a collection of recent data for power handling capability, which was collected by our engineers and our customers during experiments done in high power laser laboratories.

Display	Wavelength (nm)	Pulse Width	Rep.rate (kHz)	Irradiation Time	Irradiance (W/cm ²)	Fluence (mJ/cm ²)	Comment
UV-099	355	15ps	250	20min/2min	6,7/10	0,027/0,04	No change / P<90%
UV-099	405	-	-	15h	8,0	-	No change
VIS-130	445	-	-	6h/2,5h	53/100	-	No change / P<90%
VIS-130	532	7,8ps	400	50min	302	0,75	P<90%
VIS-016	515	220fs	610	4h	7,00	0,012	P<90%
NIR-113	800	110fs	5	2h	15	3	P<90%
NIR-118	800	110fs	5	8h/15min	8/13,6	1,5/3	No change / P<90%
NIR-015	1030	220fs	100	60min	212/240	2,1/2,4	No change / P<90%
NIR-149	1030	10ps	50	8h	127	2,5	No change
NIR-149	1064	8,4ps	400	8h	565	1,41	No change

Table 1: Power handling capability collected with high power pulsed lasers.

HOLOEYEs Thermal Management System (TMS) improves power handling for DMC versions and for our standard panels without DMC. HOLOEYE offers two versions of Thermal Management Systems.

TMS01 is based on a Peltier element in combination with a passive heat sink.

TMS02 is prepared to work with higher laser power and is based on active water cooling. It can increase power handling of HOLOEYE devices to hundreds of Watts per cm² (cw) at around 1064 nm.

Figure 13: Display mounts compatible with Thermal Management Systems

HOLOEYE LCOS SLM displays have an integrated temperature sensor. This signal can be used for a feedback loop with the TMS through HOLOEYE configuration manager software in order to stabilize the temperature to defined values.

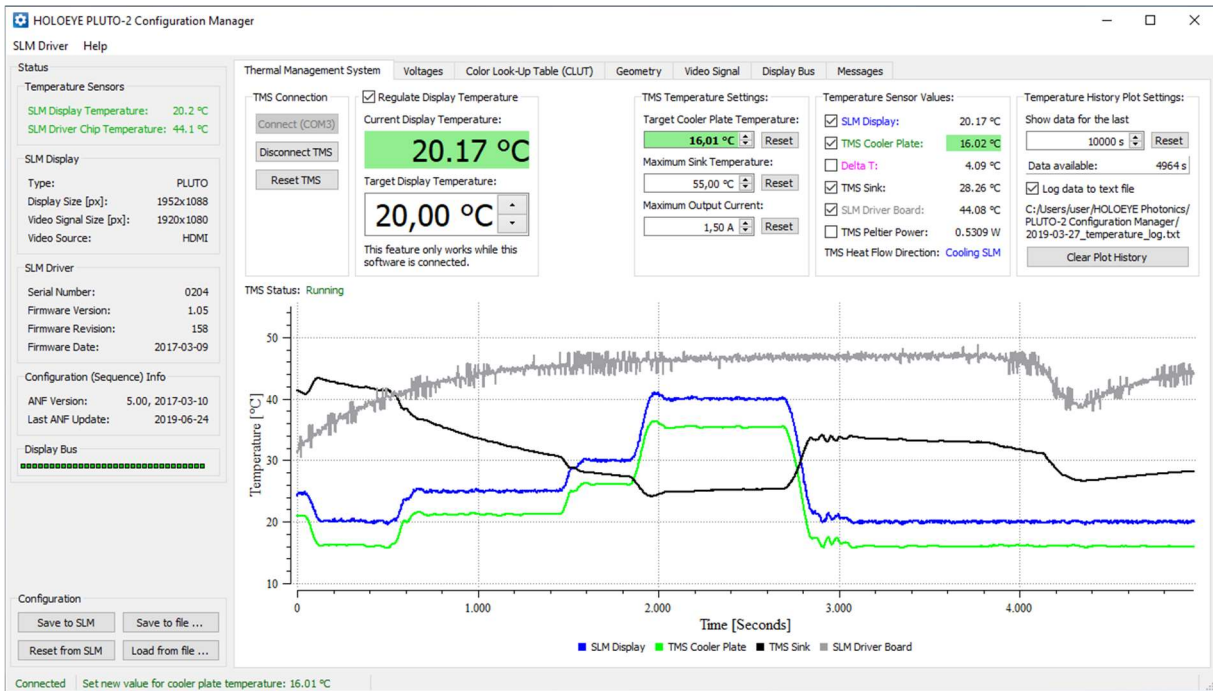

Figure 14: Screen shot of temperature stabilization using the HOLOEYE Configuration Manager software. The temperature is monitored for ~5000s and shown in a diagram. In this time the display temperature was set to multiple values (20°C, 25°C, 30°C, 40°C and back to 20°C).

3 Applications

Liquid Crystal based spatial light modulators can be used for a wide variety of different applications in the field of optics. At this document we concentrate on the most common applications.

At the end of the document, you will find an extended list of applications and HOLOEYE will be happy to send related information on request. Please also check our publication data base on our web page https://holoeye.com/category/spatial_light_modulators/

3.1 Digital Holography

Digital holography (DH) is the logical advancement of holography with respect to the availability of high resolution digital image sensors and fast signal transformations. It also permits a totally new approach for coherent optical metrology that can be described by the principle of direct numerical wavefront reconstruction. In contrast to all indirect methods that are based on the evaluation of intensity distributions, DH allows direct access to the phase of the wavefront.

Spatial light modulators give an opportunity to display digital holograms and optimize them digitally for optimal results. On presented examples you can find how SLMs were implemented into optical setups or prototypes. Experimental results underline the high quality in reconstruction and projection that could be achieved.

Industry applications: Augmented and virtual reality, metrology, quantum holography, Holographic- and Head-Up Displays.

4 Polarization entanglement-enabled quantum holography

Hugo Defienne, Bienvenu Ndagano, Ashley Lyons and Daniele Faccio.
Nature Physics (2021), <https://doi.org/10.1038/s41567-020-01156-1>

Figure 21: Experimental set-up for polarization entanglement-enabled quantum holography. Light emitted by a laser diode at 405 nm and polarized at 45° illuminates a pair of β -barium borate (BBO) crystals whose optical axes are perpendicular to each other to produce pairs of photons entangled in space and polarization by type I spontaneous parametric down-conversion. After the crystals, pump photons are filtered out by a combination of long-pass and band-pass filters. The momentum of red photons is mapped onto an SLM divided into two parts (Alice SLM and Bob SLM) by Fourier imaging with lens f_1 . Lenses f_2 - f_3 image the SLM plane onto two thin diffusers (inset) positioned on a motorized translation stage (MTS) and lenses f_4 - f_5 image it on an EMCCD camera split into two parts (Alice EMCCD and Bob EMCCD). That is, each photon of a pair experiences a phase disorder independent of that experienced by its twin. A polarizer at 45° is positioned between lenses f_4 and f_5 . Stray light is inserted by illuminating another dynamic diffuser with a laser (810nm) to produce a time-varying speckle pattern that is superimposed on top of quantum light using an unbalanced beam-splitter (BS 90T/10R). An adjustable aperture is positioned in the Fourier plane of the SLMs. For clarity, only two propagation paths of entangled photons at k and $-k$ are represented, although they have a higher-dimensional spatial structure. SLMs, EMCCD cameras and diffusers are represented by pairs, although they are in practice single devices spatially divided into two independent parts. The SLM is represented in transmission, although it operates in reflection.

6 Neural Holography with Camera-in-the-loop Training

Yifan Peng, Suyeon Choi, Nitish Padmanaban, Gordon Wetzstein
 ACM Transactions on Graphics, November 2020, Article No.: 185,
<https://doi.org/10.1145/3414685.3417802>

Figure 23: Above: Holographic display prototype. Our benchtop display uses a fiber-coupled RGB laser module, collimating optics, a liquid crystal on silicon (LCoS) spatial light modulator and a machine vision camera.

Bottom: Comparison of computer-generated holography (CGH) algorithms captured with a prototype holographic near-eye display. The classic Gerchberg-Saxton approach is intuitive but it suffers from speckle and other artifacts (left). Wirtinger Holography was recently introduced as an iterative CGH method that achieves better image quality (center left). We introduce camera-in-the-loop (CITL) optimization strategies that achieve unprecedented holographic image quality (center right). Moreover, we introduce a neural network architecture, HoloNet, that achieves a quality comparable to the best existing iterative approaches in real time for full-resolution 1080p images (right).

3.2 Microscopy

Within optical setups designed for microscopy, a Spatial Light Modulator can be applied in different functions. On the one hand as a dynamic diffractive optical element in the illumination path the SLM gives the flexibility to shape and steer the light e.g. for structured illumination or light sheet microscopy.

On the other hand placed into the detection path, a variety of contrast techniques can be implemented by introducing the corresponding phase masks. Furthermore, the SLM can correct for aberration introduced by the specimen and other optical elements, including SLM itself.

Industry applications: Two-photon microscopy, laser-scanning microscopy, absorption microscopy, light sheet microscopy, phase contrast imaging

3 Single shot, three-dimensional fluorescence microscopy with a spatially rotating point spread function

Zhaojun Wang, Yanan Cai, Yansheng Liang, Xing Zhou, Shaohui Yan, Dan Dan, Piero R. Bianco, Ming Lei, and Baoli Yao
Biomedical Optics Express Vol. 8, Issue 12, pp. 5493-5506 (2017),
<https://doi.org/10.1364/BOE.8.005493>

Figure 238: Schematic of the single shot, three-dimensional fluorescence microscope. The expanded and collimated beam is projected in parallel onto the specimen as an epi-illumination source. The wavefront of the fluorescence beam emitted from the specimen is modulated by the spatial light modulator, which is lastly focused onto CCD camera. The inset shows an example of the loaded CGH on the spatial light modulator. DM: long pass dichroic mirror ($\lambda=500$ nm). SLM: Spatial Light Modulator. M1-M8: mirrors.

4 Spatial Light Modulator Microscopy

Volodymyr Nikolenko, Darcy S. Peterka, Roberto Araya, Alan Woodruff, Rafael Yuste
Cold Spring Harbor Protocols – December 2013
 DOI: 10.1101/pdb.top079517

Figure 29: Optical diagram of the Spatial Light Modulator microscopy system used in laboratory.

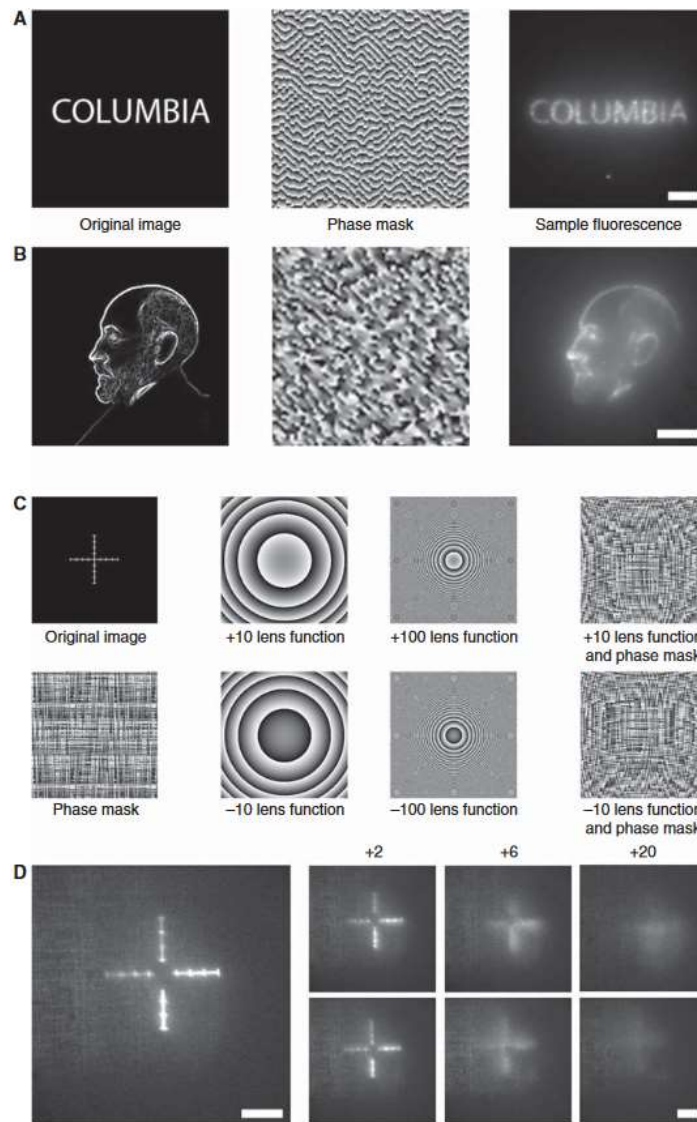

Figure 30: Spatial Light Modulator light patterning and depth focusing. Imaging samples from an agarose gel saturated with Alexa Fluor 488 fluorescence indicator to test the efficiency of two-photon excitation. Images were acquired using a 60x0.9 numerical aperture objective.

(A) A simple binary bitmap pattern was uploaded into SLM software, and the phase mask obtained is shown in the middle panel. Grayscale corresponds to a phase shift from 0 to 2π . The resulting two-photon fluorescence image of the sample acquired with the CCD is shown on the right panel. These data also show that liquid-crystal-based diffractive SLMs can withstand structured nonlinear illumination.

(B) Complex grayscale patterns can be used to program the SLM. A stylized picture of Santiago Ramon Cajal, based on a historical photograph, was used.

(C) Focusing with an SLM. The SLM software allows additional optical functions to be applied on top of the phase mask. In this example, a lens function was used to shift the focus of excitation in the axial dimension. The original image and its corresponding phase mask as well as the lens phase function alone added to the original phase mask are shown.

(D) Two-photon fluorescence image of the test pattern acquired with the CCD camera. The virtual focus plane is moved away in both directions from the camera's imaging plane using a lens function of corresponding strength

5 Light-sheet microscopy with length-adaptive Bessel beams

Tobias Meinert and Alexander Rohrbach

Biomedical Optics Express Vol. 10, Issue 2, pp. 670-681 (2019),
<https://doi.org/10.1364/BOE.10.000670>

Figure 31: Setup sketch for a light-sheet microscope using length-adaptive Bessel beams. Here, a SLM is used for beam formation. The scan mirror (SM) placed in a plane conjugated to the BFP of the illumination objective (IO) scans the phase shaped beam through the focal plane of the detection objective (DO). (a) In a pre-scan, the shape of the object is estimated by using constant, long Bessel beams and scattered laser light images to a camera. (b) Different amplitude modulations of the holograms on the SLM adapt the focal positions and the beam lengths to the shape of the object (depicted in red) varying at each scan position. The DO and a tube lens (not shown) image the fluorescent light onto the camera, equipped with a rolling shutter (slit) to enable line-confocal detection.

3.3 Wavefront correction and processing

One of features, which Spatial Light Modulators could provide is modifying optical fields in terms of amplitude, phase or both in the same time. Parameters like resolution and fill factor of each pixel are under investigation and improvement in newest laboratory experiments.

Thanks to phase modulation of light in the SLM plane, it is possible to correct aberrations present in optical setup. Most popular method to correct an incoming wavefront is to use a set of Zernike polynomials coefficients. With newest applications it is very important to adapt to actual conditions in real time. Thanks to SLMs features it is easily achievable.

Industry applications: Microscopy, Imaging

3.4 Holographic Optical Tweezer

Optical tweezers allow to trap a microscopic object of nano- or micrometer size by gradient forces and move it precisely. Many applications require the ability to control more than one object simultaneously.

Holographic optical tweezers (HOT) extend the basic principle of optical tweezers towards the optical control of a multitude of particles. Using SLMs one can modulate the phase-front of a laser light field spatially by means of computer generated holograms (CGH) in order to create several single tweezers in the microscopic sample at the same time.

Industry applications: Cell sorting, Drug development, micro rotator,

Figure 39: (a) The HOT setup is composed of a laser ($\lambda = 1070 \text{ nm}$), a polarizer (P), plano-convex lenses L_1 (focal length 150 mm), L_2 (120 mm), L_3 (400 mm), and L_4 (300 mm) with anti-reflection coating, an SLM, a microscope objective, and a camera. A halogen lamp, a condenser lens, and an IR blocking filter enable bright field imaging. (b) During characterization the SLM was locally addressed with binary gratings, the 0th order was blocked outside the microscope using a beam block (BB), bright field illumination was turned off, and the IR blocking filter was removed to allow detection of the laser light reflected off a cover glass or mirror. For $P_{\text{SLM}} \geq 0.5 \text{ W}$, a reflective ND filter was also inserted outside the microscope to decrease the power reaching the camera.

3.5 Beam shaping with structured light

Control of laser beam irradiance profile, particularly providing uniform distribution, is of great importance for various holography applications based on SLMs.

A specific demand of SLM illumination in these techniques is in strict requirements to flatness of phase front of a laser beam that should be conserved while any irradiance profile transformations, i.e. flatness of both phase front and irradiance distribution should be realized simultaneously.

Industry applications: 3D scanners, Imaging Technologies, Free Space Communication, Microscopy, Holographic Optical Tweezers, Material Processing

3.6 Higher Order Generation

Higher order mode generation is a standard application for phase only SLMs. Even though this finds also use for e.g. HOT and beam shaping that are discussed earlier we decided to treat it in a separate chapter due to its high interest for the optical community.

Examples for higher order modes are Laguerre Gaussian (LG) modes, airy beams and Bessel beams. LG modes that are circular symmetric can be generated by vortex functions and carry orbital angular momentum, what makes them suitable for optical trapping, STED microscopy and also multiplexing in free space communication applications.

Airy beams as propagation invariant wave propagates along a curved parabolic route and are also self-healing, meaning that they are resistant against disturbances in the optical beam path comparable to Bessel beams that is a non-diffracting beam, what means that it does not diffract while propagating and does not spread out quickly after being focused. These properties enable a wide variety of different applications for e.g. imaging and microscopy.

Industry applications: Microscopy, Optical trapping, Free Space Communication, Imaging

4 Direct measurement of a 27-dimensional orbital-angular-momentum state vector

Mehul Malik, Mohammad Mirhosseini, Martin Lavery, Jonathan Leach
Nature Communications 5(1):3115, DOI: 10.1038/ncomms4115

Figure 52: Experimental setup for direct measurement of a high-dimensional state vector.

State preparation: a quantum state in an arbitrary superposition of OAM modes is prepared by impressing phase information with SLM1 on spatially filtered (SMF) photons from an attenuated HeNe laser.

Weak measurement: a particular OAM mode is weakly projected by rotating its polarization. In order to do so, the OAM modes are first transformed into finite-sized momentum modes by two refractive optical elements made out of Poly methyl methacrylate (R1 and R2). Then, a Fourier transform lens (L1) and a fan-out hologram implemented on SLM2 are used to generate three adjacent copies of each momentum mode. The phase between these copies is corrected by SLM3. Another lens (L2) converts these larger momentum modes into well-separated position modes at its focus. Finally, a QWP0 used in double pass with SLM4 is used to rotate the polarization of the OAM mode to be weakly projected. Another QWP and HWP are used to remove any ellipticity introduced by transmission and reflection through the non-polarizing beam splitter.

Strong measurement: a strong measurement of angular position is performed by Fourier transforming with a lens (L3) and post-selecting state $\Theta = \Theta_0$ with a $10 \mu\text{m}$ slit.

Readout: the OAM weak value $\langle \pi_l \rangle$ is obtained by measuring the change in the photon polarization in the linear and circular polarization bases. QWP2, HWP1, a polarizing beam splitter (PBS) and two single-photon avalanche detectors (SPADs) are used for this purpose.

 SPIE Optical Engineering + Applications, 2016, DOI: 10.1117/12.2238416

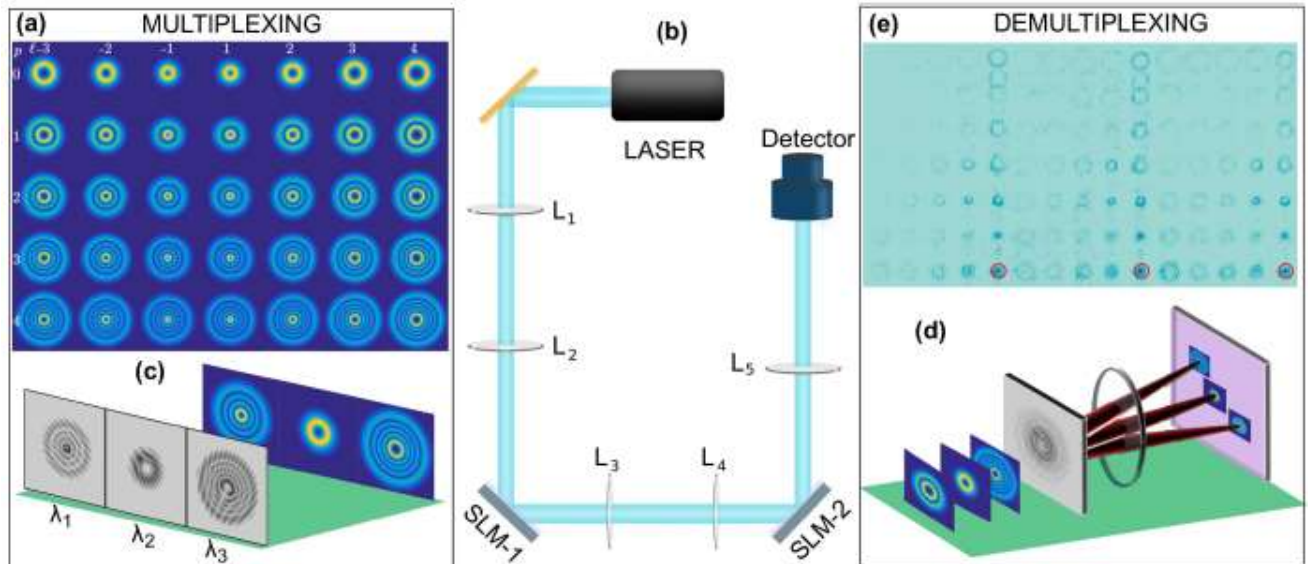

Figure 54: Schematic of Multiplexing and Demultiplexing setup.

- (a) Intensity profiles of LG_{pl} modes generated from combinations of $p = (0, 1, 2, 3, 4)$ and $l = (-3, -2, -1, 1, 2, 3, 4)$.
 (b) Experimental setup: Three components of a multiline Ion-Argon laser $\lambda_1 = 457 \text{ nm}$, $\lambda_2 = 488 \text{ nm}$, $\lambda_3 = 514 \text{ nm}$, are separated using a grating and sent to a Spatial Light Modulator (SLM-1)
 (c) The SLM is split into three independent screens, and addressed with holograms to produce the set of modes shown in (a). The information is propagated through free space and reconstructed in the second stage with a modal filter.
 (d) The modal filter consists of a superposition of all holograms encoded in SLM-2.
 (e) Each mode is identified in the far field using a CCD camera and a lens.

3.8 Wavelength Selective Switching and Telecommunication

In commercial telecommunication system the primary application of LCOS is inside WSS that enable reconfiguration and routing within optical networks by addressing different prism/blazed grating functions.

Advantage compared to conventional WSS is higher reliability and life time due to the absence of moving parts/gratings.

Industry applications: Telecommunication

3.9 Mask-less and holography lithography

Photomasks for new integrated circuits with next generation design rules are increasingly more complex and costly, especially for development, prototyping, and eventual low volume production.

Optical mask-less lithography is an alternative method in which the conventional photomask is replaced by a programmable SLM that is used as an amplitude mask that will be projected on e.g. a photosensitive film.

Industry applications: Photo semiconductor device development, Micro ID numbering, MEMS, Bio-Life science complex chemistry, optical communication, projection in automotive lighting.

The use of an LCD SLM for microstructure pattern projection on the sample, e.g. photoresist, allows not only the realization of binary level structures but also of multilevel structures in contrast to the Digital Mirror Devices.

Figure 65: Schematic of Zone-Plate-Array Lithography. An array of zone plates (diffractive micro-lenses) focuses normally incident light into an array of spots on the surface of the substrate. Light intensity in each spot is independently controlled by pixels on an upstream SLM. The substrate is scanned and patterns of arbitrary geometry are written in a "dot-matrix" fashion.

3.10 Polarization Generation

In recent years Spatial Light Modulators were used to produce spatially variant states of polarization controlled by computer. Different method can be used to create polarization pattern with Liquid Crystal on Silicon Spatial Light Modulator.

Due to the birefringent nature of LC based SLMs it is possible to generate any possible state of polarisation by retarding the orthogonal polarisation components against each other. Conventional LCoS displays for projection applications require a max polarisation rotation of 90° what equals a $\lambda/2$ phase retardation.

Using a 2π phase only SLM in combination with a quarter wave plate leads to a higher flexibility in polarisation generation to generate e.g. radially or azimuthal polarised light fields.

Industry applications: High-resolution imaging, confocal microscopy, two-photon microscopy, second-harmonic generation microscopy, dark field imaging, microellipsometry, optical communication

<https://doi.org/10.1364/OL.39.005274>

Figure 67: Experimental setup: Gaussian beam generated by a He-Ne laser passes through a HWP a Glan laser polarizer (GLP) to produce a horizontally polarized beam. Then the fundamental Gaussian beam is transformed into a vortex-bearing LG_0^1 mode by a spatial light modulator. The modified Mach-Zender interferometer comprising of two cascaded beam splitter and an odd number of reflections can convert the LG_0^1 into LG_0^{-1} mode. In addition, we add PP1 and PP2 (two cascaded GLPs of which the second one is fixed) in each arm of the interferometer to justify the intensity factors. HH (a pair of HWPs within which only the second one can be rotated) is added to modify the phase factors. QP consisting of QWP and GLP, is used to measure Stokes parameters. The intensity distribution of the field is detected by a CCD camera.
